Recombinant pAdEasy-1: a recombinant plasmid containing human adenovirus type 5 sequences except for the E1A sequence. When transfected into a suitable producer cell line providing the E1 function in trans (eg HEK 293 cells), recombinant infectious viral particles are produced although these are not replication competent. There is a low but finite probability of recombination between the vector and the endogenous E1a sequences. In such circumstances the insert sequences would be lost from the resulting a devirus genome to produce a recombinant infectious "wild-type" human Type Adenovirus (an ACDP Hazard Category 2 pathogen).

pCDNA: Non-mobilisable vector unless a derivative modified in these respects Amp r and either Neo r, Hyg r, or Zeocin R. As the pCDNA series of vectors have both CMV and T7 promoters, it may be used for cloning in non-expressing strains such as HB101, DH5 alpha which do not express T7 RNA polymerase and also for expression in a host strains which constitutively expresses T7 RNA polymerase. Contains SV40ori sequence as well as bacterial origin of replication permitting replication in mammalian cells expressing SV40T.

pShuttle: identical to pAdTrack-CMV except it does not contain a CMV promoter or the GFP element.

pShuttle-CMV: identical to pShuttle but containing an CMV promoter and an SV40 polyadenylation signal flanking the multiple cloning site.

pBMN-CIP-Sin: SIN derivative of retroviral vector pBMBNZ with an EMCV IRES-puro fusion for selection of infected cells with puromycin. Latter has MMLV pol and eng
genes replaced with a multicloning site, allowing the insertion of heterologous DNA fragments. The retroviral packaging sequence ( ) is retained which allows incorporation of the vector into retroviral particles when co-transfected with suitable helper vectors or when used with suitable packaging cell lines stably expressing helper functions. The full-length Moloney LTRs are retained. The "SIN" designation indicates a self-inactivating vector. During integration of the provirus the 5’ LTR is inactivated (as well as the 3’LTR), which minimises the possibility of activating adjacent cellular genes. Mobilisation-defective in E. coli.

pRevTet-On. Mobilisation-defective 7.6 kb retroviral vector expressing the rtTA protein from a CMV promoter. The vector is derived from pLNCX, a Moloney murine leukemia virus (MoMuLV)-based vector. The 5’ viral LTR controls expression of the transcript that contains the viral packaging signal and the neoR gene for selection in mammalian cells. pRevTet-On also includes the ampR gene.

pCineo-GALV: Non-mobilisable pCI-neo based vector (pGEM non-mobilisable backbone). Plasmid contains a strong CMV IE enhancer driving expression of the full length GALV gene, an optimised chimeric intron composed of the donor site from the first intron of the human beta-globin gene and acceptor site from an immunoglobulin gene intron which increases expression from some cDNAs. Also includes SV40 laste polyadenylation signal. These three elements combine to yield strong, constitutive expression of the GALV gene in mammalian cells.

pVPACK vectors: Mobilisation-defective CMV-based vectors constructed to express retroviral structural components (gag, pol and env) in mammalian cells. The vectors include a gag-pol-expressing vector that is cotransfected with the retroviral expression vector together with one of four envelope (env)-expressing vectors. Because all of the cis and trans elements required to produce infectious virus are separated onto three plasmids, with minimal or no sequence overlap between the plasmids and most MMLV retroviral vectors, the probability of generating replication-competent retrovirus (RCR) by homologous recombination is greatly reduced. The retroviral elements have been cloned into the MCS in the following cassette: CMV-IE promoter-MCS-IRES-Puro-bGH plyA. The pVPACK vectors also contain the amp resistance gene and CoIE1 origin of replication from pBR322.

* pVPACK-gp: 10.7 kbp vector encoding MMLV gag-pol protein.
* pVPACK-VSV-G: 6.4 kbp vector encoding VSV-G protein. VSV-G recognises a phospholipid that is present on all cell types, which theoretically allows any mitotic cell to be efficiently infected. Additionally, VSV-G confers stability on the resulting viral particles which are potentially more robust than traditional eumphotropic retroviral vectors.
* pVPACK-ampho: 6.4 kbp vector encoding amphe env protein.
* pVPACK-10A1: 6.4 kbp vector encoding 10A1 env protein which allows the same cell-surface receptor to be recognised as the amphotropic env plus a second receptor; it can essentially infect any cell that an amphotropic virus can infect and, in some cases, with a higher efficiency.

Origin & function

Human sense or anti-sense cDNA or genomic libraries for screening using functional cloning studies with transfected mammalian cells. The latter will be recombinants of the following types:

* reporter constructs (eg genes encoding marker proteins such as fluorescent proteins, linked to specific promoters eg associated with various cell signalling pathways).
* library constructs eliciting biological effects, such as responses to specific hormones or other signalling molecules, which will be monitored after transfection.

Defined wild-type and altered human genes to investigate mechanism of action of the gene products by monitoring the effects of specific alterations on the predicted biological effect(s).

Defined human genes of suspected but uncertain function to investigate the nature of potential substrates (eg where protein substrates are suspected, by studying incorporation of labelled precursors into those molecules in control and transfected cells).

Human genes encoding transcription factors which may have a role in differentiation to monitor recombinants for subsequent development of specific differentiation markers.

Human genes modified to encode tags (eg FLAG, HIS-6; c-myc) human proteins to investigate protein-protein interactions by immunoprecipitation and identification of
Evaluation of foreseeable effects

Reporter constructs (e.g., genes encoding marker proteins such as fluorescent proteins, linked to specific promoters e.g., associated with various cell signalling pathways) are unlikely to lead to a harmful outcome since there are many reports of expression of such proteins in vitro and in vivo without obvious harmful effects.

For inserts encoding proteins predicted to elicit biological effects, such as responses to specific hormones or other signalling molecules, expression of these following accidental exposure is likely to lead to effects similar to those predicted for cells which have been experimentally transfected. Where accidentally exposed cells already express the products, the effects are anticipated to be minimal unless the level of expression associated with the vectors is significantly higher than that occurring naturally. In the case of anti-sense constructs, or where mutations are introduced which are anticipated or known to reduce or abolish specified activities of the associated products, then reduction of the activity of the corresponding naturally occurring gene products is anticipated, although this is likely to be transient and of variable degree.

Where inserts encode human transcription factors which may have a role in differentiation it is possible that accidental transfection could, depending on the susceptibility of cells exposed, lead to re-differentiation of those cells to the corresponding phenotype.

Where expression of products is regulated using specific inducible expression systems (e.g., tetracycline-responsive), then expression is the case of accidental exposure is likely to be very limited in the absence of the inducers. In most systems, significant levels of expression are not anticipated unless there is coincident exposure to inducers (e.g., individuals receiving tetracycline therapy in the case of the tetracycline-responsive system).

It is possible that where the function of the inserts is unknown or only partly known, that effects on proliferation including potential oncogenic effects, could be associated with some of these sequences. However, oncogenesis appears in general to involve more than one contributing change from the normal condition and it is unlikely that exposure would lead to this outcome although this cannot be excluded completely. The likelihood of accidental exposure leading to harm is judged to be negligible with the adoption of risk class 2 measures including the use of safety cabinets for work where aerosols may be generated.

Containment and control measures for GMOs that are not microorganisms (e.g., GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

An autoclave for inactivation of waste is not present in every building where the relevant laboratories are located. However, all relevant waste is contained in double autoclave bags which are collected from the laboratories in sturdy wheeled containers provided with lids. These are transported to a centrally-located on-site autoclave for inactivation. No special measures will be used to control rodents or insects. Adequate control is judged to be in place with the existing standard facilities, particularly having regard to the nature of the recombinant organisms and vectors and the negligible risk of these being disseminated in the environment.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid wastes (other than sharps): are placed in an autoclave bag and when sufficiently full, the neck is twisted closed and the bag placed in a second autoclave bag which is sealed with autoclave tape. The bag is then placed in a specified location in the laboratory, pending collection. The closed bags are collected daily by Shift Technicians who transport them in robust wheeled and lidded containers to an on-site autoclave for inactivation in an autoclave located in a specialised facility on site. This procedure has been validated using a 12-point thermocouple procedure in which probes are placed in a representative load. Annual independent thermocouple testing of the autoclave cycle is carried out by a specialist contractor. After autoclaving, waste is collected by a contractor for final disposal by off-site incineration. Sharps are placed in suitable purpose-designed robust containers with a lid and when full are placed for collection and final disposal by incineration by our waste contractor.

Liquid waste associated with mammalian cell culture and viral vectors is treated with 1% Virkon (final concentration) for at least 30 minutes. This treated liquid mixture is...
then flushed to drain using copious amounts of water. Liquid waste associated with recombinant bacteria is treated with 1% Virkon or 2.5% Chloros (hypochlorite; - 25000 ppm available Cl final concentration.

In a validation test with GFP serving as a marker, treatment of GFP expressing retroviral particles for 5 minutes at room temperature at Virkon concentrations as low as 0.2% reduces CFU to levels comparable to background fluorescence. A 1% solution (ie 50x) is routinely used to treat waste overnight at room temperature and provides for safe, effective destruction of retroviral particles. The kill rate is effectively 100%.

The following outlines an investigation into the use of Virkon for treatment of adenoviral waste products:

B-gas adenovirus stock = 4x10(9)/ml in DMEM + 10% foetal bovine serum.

The following treatments and controls were produced:

(a) 25 ul stock (1x10 8 virus) + 25ul 4% Virkon
(b) 25 ul stock (1x10 8 virus) + 25ul 2% Virkon
(c) 25 ul stock (1x10 8 virus) + 25ul 1% Virkon
(d) 25 ul stock (1x10 8 virus) + 25ul PBS (positive control)
(e) 25 ul DMEM(10%FBS) + 25ul 4% Virkon
(f) 25 ul DMEM(10%FBS) + 25ul 2% Virkon
(g) 25 ul DMEM(10%FBS) + 25ul 1% Virkon
(h) 25 ul DMEM(10%FBS) + 25ul PBS

After 5 minutes at room temperature, 2.5 ul (equivalent to 5x10(6) virus) aliquots were added to 1x10(6) HEK 293 cells in 5 ml DMEM + 10% FBS. These cells allow adenovirus to replicate so should amplify any infective particles. Final Virkon concentration in test culture was 0.0005%. Cells were stained for B-gal expression after 48 hrs incubation at 37 degrees C.

Results
(a) No blue cells
(b) No blue cells
(c) No blue cells
(d) 100% blue cells (cytopathic effect of adenovirus replication also noted as anticipated in HEK 293 cells)
(e) No blue cells
(f) No blue cells
(g) No blue cells
(h) No blue cells

The sensitivity with viral titre used allows conclusion that at least a 4 log reduction is achieved but the actual value is likely to approach 100% kill.

This data confirms for recombinant viral systems, the claims from the manufacturer for the efficacy of Virkon in respect of the corresponding wild-type viruses.

The mammalian cells used in this programme are highly dependent on the availability of appropriate nutrients and environmental factors. They will not survive even brief periods in water much less in the disinfectant solutions used for this work.

Is an emergency plan required according to regulation 20?

Project Ref 108/09.1

Date Ackn'd: 16/04/2009

CU2 Project Title: Knockdown of a number of receptors using lentiviral transduction particles in a variety of mammalian cell types

Class: Class 2

CultureVol: < 1 Litre

Non-GMM: Consent Granted

Project notified under transitional arrangements: N

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

Project Additional Information
Purposes of the contained use
To knockdown the protein of interest and determine effects on phenotype of cells.

Recipient or parental organism
A variety of mammalian cell lines

Host/vector system
Commercially available lentiviral particles. These Self-inactivating replication incompetent viral particles are produced in HEK293T packaging cells by co-transfection with packaging plasmids. The method consists of three plasmid system consisting of: A packaging vector which contains the minimal set of lentiviral genes required to generate the virion structural proteins and packaging functions. The vesicular stomatitis virus G-protein envelope vector, which provides the heterologous envelope for pseudotyping, and the transfer vector, which contains the sequence of interest as well as the cis acting sequences necessary for RNA production and packaging. The multi-plasmid approach results in no single plasmid containing all the genes necessary to produce packaged lentivirus. Resulting particles are replication-incompetent and deletion in the U3 portion of the 3' LTR eliminates the promoter-enhancer region, further negating the possibility of viral replication. The system has also removed virulence genes which are not necessary for packaging. Transduction particles encoding sequences for the knockdown of the protein of interest, as well as positive and negative controls will be ordered.

Origin & function
Lentiviral particles are commercially available. Particles are to be used to knockdown the receptor at the mRNA level and assess any phenotypic effects.

Evaluation of foreseeable effects
Lentiviral particles are commercially available. Particles are to be used to knockdown the receptor at the mRNA level and assess any phenotypic effects. The protein of interest is a receptor whose function is executed via the binding of ligand. Activation of this receptor family induces signalling cascades that result in multiple biological responses, including cell proliferation, angiogenesis, differentiation, migration, and survival. It is unclear which of these phenotypic effects will be affected by knockdown of the protein of interest. Phenotypic effects are likely to be cell type specific. Low potential hazard should be associated with the expression of the knockdown product in cell lines. Cell lines may show effects on phenotypes mentioned above. But there are no reported effects on wound healing in the literature from knockout studies. Null mice show abnormalities in the lung but no aerosol producing activity is going to be used here, risk of lung toxicity is low. Mice also exhibit liver abnormalities, of cholesterol and bile acid synthesis, but it is very unlikely that the lentivirus would be exposed to a hepatocyte as no sharps are being used. There are no abnormalities of the immune system in null mice, hence if accidental ingestion of the lentivirus did occur and infect immune cells, immune system would not be compromised and cells would be cleared from the system. It is anticipated that the product will be correctly folded and active. The genes of interest are not a known oncogenes. Expression of the insert in the recombinant organisms is unlikely to affect the pathogenicity of the expression hosts. Contact of the replication deficient lentivirus will be avoided using appropriate containment measures as transduction of the cells of the worker could result in an unknown effect. In the worst case scenario, a replication competent lentivirus capable of knocking down the kinase is produced and then infects an individual via body fluid contact (e.g. sharps contact) or ingestion/inhalation. The individual would then be infected with a potentially damaging lentivirus with unknown effects. The virus would be transmissible by body fluid contact. The likelihood of this is negligible due to the system using 3 plasmids for production of the virus, i.e. no single vector contains all the genes necessary to produce packaged lentivirus. The particles are made using features of 2nd and 3rd generation lentiviral packaging systems. Genes for replication and structural proteins are absent in the packaged viral genome since these genes are supplied by other plasmids in the packaging cells. The viral genome contains only the region between the 5’ and 3’ LTRs of the promoter, hairpin sequence, puromycin resistance gene. In addition, the lentiviral vector contains a self-inactivating 3’ LTR that renders it unable to produce infectious virus once it integrates into the host chromosome. There are no known incidents of third generation systems producing replication competent virus - cell lines transfected with these particles can be monitored for replication competency using commercial p24 titer assays. A more likely scenario is that a worker contaminates themselves with a replication deficient lentivirus. The likelihood of harm to human health due to this is low because the lentiviral particles will elicit an immune response, hence will be rapidly removed by the immune system. Workers will also be using appropriate containment methods i.e. class 2 cabinet for pipetting all virus-containing supernatants. When pipetting virus-containing supernatants and transferring plates or flasks to and from the laminar flow hood, the production of aerosols will be avoided. All plasticware used to handle liquid containing virus particles will be disinfected with virkon solution. Media and other liquids which may contain infectious vector will also be inactivated before disposal. Although not required, all work with lentiviral particles will be done in a restricted access lab. The use of sharps with this work is also prohibited, reducing the risk of accidental exposure.
To body fluids and gloves will be worn throughout. All work is small scale.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

All measures required at CL2 will be applied except for the presence of an autoclave in the building. At Alderley Park autoclaves are not present in all buildings where risk class 2 work takes place. In some buildings, autoclaves are present but are only available for media and glassware sterilisation. The waste management facility has a central autoclave facility and a collection and transport process, which we judge to provide an equivalent level of protection.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid GMM contaminated waste will be triple bagged in biohazard waste bags, suitably labelled and autoclaved. This solid waste will be comprised mainly of plastic ware used in the culturing of the organisms and contaminated tissues used in the decontamination process. As a result there will be no viable GMMs remaining in the solid waste. All liquid waste will be disinfected with 1% virkon. Solutions will be left soaking for 2 hours before disposal via the drain with copious amounts of water. Procedures and relevant training and safety inspections are in place to ensure that all workers deal with waste correctly as specified above.

Project Additional Information

Purposes of the contained use

The transduced cells will be used to identify inhibitors of the enzymes. Cells are lysed post compound dosing and a signal is detected using a FRET assay.

Recipient or parental organism

Human osteosarcoma cell line (ATCC HTB-96). No adventitious agents believed present. Note that Class 2 containment recommended by ACDP/UKCCCR but this can be considered a purely COSHH issue unless any modification is anticipated to increase any hazard. J. Ponten and E. Saksela derived this line (originally 2T) in 1964 from a moderately differentiated sarcoma of the tibia of a 15 year old girl. Viruses were not detected during co-cultivation with WI-38 cells or in CF tests against SV40, RSV or adenoviruses. Mycoplasma contamination was detected and eliminated in 1972.

Host/vector system

Non-mobilisable vector from Life Technologies based on pFastBac (see also Condreay et al, PNAS 96, 127-132, 1999). The AcNPV polyhedrin promoter has been replaced by the CMV IE enhancer/promoter. The mini-Tn7 element, which is transposed from pFASTBAC-1 into the bMON14272 vector in E coli DH10Bac cells, also contains a gentamycinR gene, multiple cloning site and SV40 poly A signal inserted between the left and right arms of Tn7. In addition the plasmid contains an ampicillinR gene and a pUC-based non-mobilisable vector backbone. The generation of the recombinant "Bacmid" requires the presence of a helper plasmid (pMON7124) encoding a transposase which functions in trans. The recombinant "Bacmid" can be used to transfect insect cells to produce recombinant polyhedrin- Baculovirus particles.

Origin & function

There are 2 substrate genes of interest to be expressed as a fusion protein with GFP. In addition there are both wild type and cysteine mutant (reduced/no activity) versions of the target enzymes. GFP is Green fluorescent protein that is widely used as a fusion protein, and whose only known function is fluorescence.

The two substrate genes are involved in cell growth, proliferation and apoptosis. Enhanced levels of both are upregulated in many tumours.

Evaluation of foreseeable effects

Potential hazards could come from the use of Baculovirus particles and the expressed enzymes/substrates, where the operator accidentally inhales, injects or digests the GMO and where it could come to the potential expression of the proteins as a gene product in the worker's cell or gut flora. Bacmam virus particles are only actively replicating in insect cells, although they are known to transduce mammalian cells and cause expression of the transduced genes in mammalian cells. Expression of some
of these enzymes in mammalian cells is expected to increase the levels or activity of their substrate proteins, which could result in increased tumourigenicity. Overexpression of the two substrates may lead to increased proliferation in certain cells. Due to the combination of the overexpression genes increasing proliferation, the lack of clarity around the required virus dose to cause a transformation in lung epithelium and lack of evidence how well complement can clear Bacmam virus from lung epithelium, the work flows will be enclosed in class II cabinets.

The overall risk of this work can be considered to be low as recombinant baculo virus particles have the potential to transduce mammalian cells, but the risk around the virus remains negligible, since the baculovirus is incapable of replicating in mammalian cells, as they do not contain the necessary transcription factor for viral replication. The efficacy of transfection in vivo appears to be limited primarily by complement depending inactivation of the baculo particles and is therefore much less efficient than in vitro. In respect to accidental uptake of the cells, the immune system is expected to inactivate and remove any foreign cell from the body. Nevertheless, due to the combination of the overexpression of a gene increasing proliferation, the lack of clarity around the required virus dose to cause a transformation in lung epithelium and lack of evidence how well complement can clear Bacmam virus from lung epithelium, the final GMO is classified as class 2

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

All measures required at CL2 will be applied except for the presence of an autoclave in the building. At Alderley Park autoclaves are not present in all buildings where risk class 2 work takes place. In some buildings, autoclaves are present but are only available for media and glassware sterilisation. The waste management facility has a central autoclave facility and a collection and transport process, which we judge to provide an equivalent level of protection.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All solid GMM contaminated waste will be triple bagged in biohazard waste bags, suitably labelled and autoclaved. This solid waste will be comprised mainly of plastic ware used in the culturing of the organisms and contaminated tissues used in the decontamination process. As a result there will be no viable GMMs remaining in the solid waste. All liquid waste will be disinfected with 1% virkon. Solutions will be left soaking for 16 hours before disposal via the drain with copious amounts of water. Procedures and relevant training and safety inspections are in place to ensure that all workers deal with waste correctly as specified above.

### Project Additional Information

**Purposes of the contained use**

This proposed work aims to validate Lentiviral delivery as a means of rapidly generating stable mammalian cell lines for screening applications. Two established receptor assays will be transferred into the Lentiviral system.

**Recipient or parental organism**

HEK-293: Human embryonic kidney cells stably expressing the transforming gene of human Type 5 Adenovirus. DNA from nucleotides 1 to 4344 [Louis N et al Virology 1997 Jul 7;233(2):423-9] is integrated into chromosomes 19. When used as a helper cell line for production of recombinant adenoviral particles, production of wild-type virus (an ACDP Hazard Group 2 pathogen) can occur albeit at a low frequency. Two specific non-homologous recombination events would be required to generate replication-competent virus. In a supernatant rescue assay performed on the virus stock to check for replication competent adenovirus (ref: Dion et al J. of Virol Methods 1996 vol56 p99-107 no replication competent virus was detected in 1x10e9 infectious particles, If virus stocks are repeatedly passaged in HEK293 cells replication-competent virus can appear after 9 passages. Methods to produce virus using pAdEasy-1 only require a maximum of three passages in HEK293 cells. Given this data, the risk of generating wild-type adenovirus is considered to be negligible using these procedures. HEK293 cells have an unexpected relationship to neurons [Shaw, G et al; FASEB J. 2002 Jun;16(8):869-71], a finding that may require reinterpretation of many previous studies in which it was assumed that HEK293 cells resembled more typical kidney epithelial cells. The HEK cell line supplied by ATCC is stated to be tumorigenic in nude mice and to require minimum containment at Biosafety Level 2. Collectively, this information indicates a requirement for CL2. When making a risk assessment and classification for the purposes of the GMO.
The CHO-K1 cell line (ATCC CCL-61) was derived as a subclone from the parental CHO cell line initiated from a biopsy of an ovary of an adult Chinese hamster by T.T. Puck in 1957. The cells require proline in the medium for growth because they cannot convert glutamic acid to glutamic gamma-semialdehyde, leading to proline deficiency.

If well authenticated, these cells pose negligible risk and can be safely handled at CL1.

### Host/vector system

Lentiviruses belong to the HIV group of retroviruses. These are naturally occurring RNA viruses packaged into a capsid and a membranous envelope. Upon infection of the target cell the RNA is reversed transcribed and integrates randomly into the host genome. Lentiviruses contain none genes: three structural genes, gag (encodes virus core: capsid, matrix, nucleocapsid), pol (encodes enzymes: reverse transcriptase, integrase, protease, RNaseH) and env (encodes virus envelope); two regulatory genes, tat (upregulates viral transcription, binds TAR-responsive RNA element TAR) and rev (regulates viral RNA transport and splicing, binds rev responsive element RRE); and four accessory genes, (vif,vpr,vpu and nef) which are critical for in vivo replication and pathogenesis. Both pTZV and pTRIPZ lentiviral particles are designed to infect mammalian cells so there is a potential risk for human transduction. However, the virus is being provided by Open Biosystems in a ready-to-use format and will not be propagated on site. Furthermore, work will be carried out in a class II laminar flow hood due to the usage of tumour cell lines and no needles will be used. The lentiviral vectors from Open Biosystems have been designed to maximise their biosafety features. The envelope of HIV-1 has been completely removed from the vector and replaced with the VSV-G gene from Vesicular Stomatitis Virus to pseudotype (envelope) the virus particles. To minimise the threat of producing recombinant and new replication-competent virus, the genes are separated onto five different plasmids and contain no significant areas of homology. The expression vector contains a deletion in the 3' LTR that results in self-inactivation of the virus after transduction of the target cell. Additionally, the four packaging plasmids may allow expression in trans of the proteins required to produce virus but none of the plasmids contain LTRs or the packaging sequence. This means that none of the HIV-1 structural genes are present in the packaged DNA.

### Origin & function

FGFR4: Fibroblast growth factor receptors of (FGFRs) are a family of 4-transmembrane receptor tyrosine kinases with functions executed through interactions with the FGF family of ligands. FGFR activation induces signalling cascades that result in multiple biological responses, including cell proliferation, angiogenesis, differentiation, migration and survival. FGFR4 is the weakest activator of the MAPK cascade and appears to have roles in cell motility, proliferation and tissue remodelling. (Sahadevan et al, J. Pathology (2007) 213, p82-90; Wang et al, Clinical cancer research, (2004) Vol 10, p6169-6178). PPARdelta: Human nuclear hormone receptors consist of a ligand-binding domain and DNA binding domain. Upon ligand binding, receptors are activated by either moving from the cytoplasm to the nucleus where they bind specific DNA sequences or through the induction of a conformational change that results in activation of the receptor already bound to its target sequence. PPAR agonists bind selectively to PPARα, causing it to activate specific DNA response elements and modulate gene transcription. The hybrid GAL4-PPARδ protein can be activated by PPAR ligands to modulate gene transcription from promoters that interact with the GAL4 DNA binding domain. Outcomes of PPARδ activation include induction of angiogenesis in endothelial cells, proliferation of hepatic stellate cells, increasing oxidative metabolism and promotion of adipocyte differentiation. The construct to be expressed in this proposal is a truncated form of PPARδ fused with a GAL4 DNA binding domain. This modification ensures that only genes linked to GAL4 responsive promoters will be induced by GAL4-PPARδ. Luciferases, derived from Renilla reniformis, Photinus pyralis or Pyrophorus piargophthalmalaries, catalyse the production of light using the substrates luciferin and ATP. In the absence of luciferin Luciferase has no known adverse effect.

### Evaluation of foreseeable effects

The final GMO cell lines could colonise the operators airways or colon if inhaled or ingested. FGFR4 is a 4-transmembrane receptor tyrosine kinase with functions executed through interactions with the FGF family of ligands. FGFR4 is the weakest activator of the MAPK cascade. It appears to have roles in cell motility, proliferation and tissue remodelling, and as such should be viewed as an oncogene. PPARδ is a nuclear hormone receptor that mediates activation and or repression of various downstream target genes. Known outcomes of PPARδ activation include induction of angiogenesis in endothelial cells, proliferation of hepatic stellate cells, increasing oxidative metabolism and promotion of adipocyte differentiation. If transferred to the cells of an operator this could lead to aberrant gene activation. However, the particular construct to be expressed is a truncated form of PPARδ fused with a GAL4 DNA binding domain. This modification ensures that only genes linked to GAL4 responsive promoters will be induced by GAL4-PPARδ overexpression or by activation of GAL4-PPARδ ligands. There is some literature evidence to suggest that GAL4 can activate transcription from a minimal TATA promoter in HeLa cells so it cannot be ruled out that it could activate endogenous promoters in mammalian cells. The construct will be
co-expressed with a UAS Luciferase reporter gene, leading to expression of Luciferase. Luciferases will cause the production of light using the substrate luciferin and ATP and in the absence of luciferin will have no known effect. Fluorescent protein expression will cause cells to emit a coloured light. EGFP is not known to cause any adverse effects in cells, it is unlikely that inhalation or ingestion of the final call line by a worker could result in delivery of any of the constructs to an appropriate site of action to realise any of these potential effects.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

All measures required at CL2 will be applied except for the presence of an autoclave in the building. At Alderley Park autoclaves are not present in all buildings where risk class 2 work takes place. In some buildings, autoclaves are present but are only available for media and glassware sterilisation. The waste management facility has a central autoclave facility and a collection and transport process, which we judge to provide an equivalent level of protection

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid GMM contaminated waste will be triple bagged in biohazard waste bags, suitably labelled and autoclaved. This solid waste will be compromised mainly of plastic ware used in the culturing of the organisms and contaminated tissues used in the decontamination process. As a result there will be no viable GMMs remaining in the solid waste. All liquid waste will be disinfected with 1% virkon. Solutions will be left soaking for 2 hours before disposal via the drain with copious amounts of water. Procedures and relevant training and safety inspections are in place to ensure that all workers deal with waste correctly as specified above.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

CU2 Project Title Validation of new targets in a Pol Beta mutated cell line

Class 2 CultureVolClass2 < 1 Litre

CEased

Non-GMM Consent Granted

Project notified under transitional arrangements

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

Project Additional Information

Purposes of the contained use

To identify potential new targets that would combine well with a base excision repair deficiency in DNA polymerase β (POLβ). Specifically to test the hypothesis that homologous recombination proteins are synthetic lethal with a dominant negative truncated version of Polβ, which mimics a tumour associated variant of Polβ.

Recipient or parental organism

A549 human lung carcinoma cancer cell line (ATCC#CCL-185)

Host/vector system

Mammalian Cell Expression Vector:
LZRS-MS-IRES-GRP. Non-mobilisable Episomal retroviral expression vector containing a IRES element and gene encoding neo resistance. The vector also contains full sequence 5’ and 3’ LTR regions. (refs: based on original plasmid described in Human gene therapy 7 1405-1413 1996 and Experimental cell res. Vol 312 no 17 p3336 2006). Mammalian Cell Expression host:
A549 (lung) cell line

Origin & function

All details of construction are within the following paper: Vens et al., Nuc. Acid Res, 2002 vol 30, no. 13, 2995-3004. Briefly, a cDNA encoding a 14-kDa truncated N-terminal sequence of POLB was generated by PCR of the pKSPOLB plasmid and cloned into LZRS-MS-GFP retroviral expression vector. Green fluorescent protein (GFP) is also expressed from the LZRS-MS vector.

DNA Polymerase Beta us a 39kDa single polypeptide protein that has been extensively characterised. Pol Beta catalyses the extension of DNA strands by the addition of
nucleotide triphosphates. Pol Beta is a distributive enzyme with no intrinsic proof-reading exonuclease activity. Pol Beta is required in the Base Excision Repair (BER) pathway of DNA repair and is responsible for replacing a single or a few nucleotides after removal of damaged bases by other elements of the bER machinery. Specifically, Pol Beta contributes to the repair of DNA damage occurring by alkylating agents Pol Beta also contains an N-terminal dRP lyase domain that catalyses the release of 5'-terminal deoxyribose phosphate residues from incised abasic sites which are intermediates in the BER process. Pol beta has DNA binding activity. The 14 kDa truncated version of Polβ is expressed from the LZRS-MS-GFP vector (please note that matched cells are stably transected with empty LZRS-MS-GFP vector) in stably transduced A549 lung cells, with the intention of recapitulating a tumour associated mutation. Truncated Polβ retains its' DNA binding activity, but is polymerase inactive and so behaves in a dominant negative (DN) fashion, preventing completion of BER.

Evaluation of foreseeable effects

Potentially Harmful effects associated with
(i) the recipient micro-organism(s) No  
(ii) the vector(s) Yes  
- Contains retroviral elements, notably intact 5' and 3' LTR regions  
(iii) the donor micro-organism(s) N/A  
(iv) the resulting genetically modified micro-organism(s) No

The 14kDa DN-PolB is a tumour associated variant of PolB and is thought to contribute to tumour progression through facilitating the accumulation of mutations and preventing correct repair via base excision repair pathway. However this form has also been described in 'normal' tissue, and it is suggested that DN-PolB may play a regulatory role at moderate expression levels (Ref: Starcevic et al., 2004 vol 3, no. 8, 998-1001). Hence overexpression may result in increased cellular proliferation of the final GMO and consequently could increase the chances of colonisation of lung epithelia if exposed. Due to the nature of the work, which uses small culture columns (maximum size T175 flask), in tissue culture hoods, the chance of contact with cells is minimal. Furhtermore, in a non-immunocompromised individual any foreign agents are expected to be cleared efficiently.

Animal Units   Large Scale Activities   Human Clinical Applications
The use of Human umbilical cord vein endothelial cells (HUVECs) stably expressing either GFP or a form of a target human gene that is resistant to siRNA to the target gene can be confirmed that the phenotypic effects seen with the siRNAs are specific and not as a result of off target effects.

The aim of the current experimental programme is to rescue gene expression using endothelial cells that are stably expressing an siRNA resistant to the gene. By doing this it can be confirmed that the phenotypic effects seen with the siRNAs are specific and not as a result of off target effects.

The target protein functions to inhibit caspase activation, thereby leading to negative regulation of apoptosis or programmed cell death. This has been shown by disruption of the target protein induction pathways which leads to changes in apoptosis and tumour growth. The target protein is expressed highly in most human tumours and fetal tissue, but is completely absent in terminally differentiated cells. This fact therefore makes this protein an ideal target for cancer therapy as cancer cells are targeted while normal cells are left alone.

Within this programme 2 GMOs should be considered as being a potential hazard. The first is the cell line generated that over expresses the target gene.
poses are that it may be ingested or inhaled and result in colonization within the lungs or other epithelial cells and result in growth of the transduced cells. The second GMO is the virus particle which has the potential to enter the body of the operator through the skin, via ingestion or through inhalation and the consequences of this could be transduction and proliferation of the transduced operator cells. The target protein is an anti-apoptotic protein highly expressed during fetal development and cancer cell malignancy. The target protein controls the G2/M phase of the cell cycle by inhibiting apoptosis and promoting cell division. The target protein is known to be expressed across most tumour cell types and is at the same time absent in normal non-malignant cells. The target protein can be regarded as an oncogene as it is aberrant over expression in most cancer cells contributes to the phenotype of the cancer cells being more resistant to apoptotic stimuli and chemotherapeutic therapies and, thus, allowing for continued proliferation and survival. The potential hazard of over expressing the target protein would therefore be to enhance cell survival through increased cell division and decreased apoptosis resulting in the possibility of the cells acquiring a cancer cell phenotype.

The objective of this work is to generate a stable mammalian cell line that over expresses CYP17 in a cell line that is null for CYP17 expression. The cell line once established will be used for selection studies against cell lines that express the Androgen Receptor.

LnCAP cells LNCaP clone FGC [LNCaP.FGC] Available from ATCC. References date from at least 1980. Tissue: human carcinoma; prostate; from metastatic site: left supraclavicular lymph node. Tumorigenic in nude mice. Products: human prostatic acid phosphatase; prostate specific antigen. Receptors Expressed: androgen; estrogen. Morphology: epithelial. These cells are responsive to 5-alpha-dihydrotestosterone (growth modulation and acid phosphatase production). The cells do not produce a uniform monolayer, but grow in clusters which should be broken apart by repeated pipetting when subcultures are prepared. They attach only lightly to the substrate, do not become confluent and rapidly acidify the medium. Growth is very slow.

Lovo ATCC CCL-229. Human colonic adenocarcinoma derived in 1971 from a metastatic left supraclavicular region colorectal tumour. The line is positive for expression of c-myc, K-ras, H-ras, N-ras, Myb, sis and fos oncogenes. Tumor specific nuclear matrix proteins CC-3 and CC-4 are also expressed.

Retroviral transduction system based on the Moloney Murine Leukemia Virus (MMULV) this consist of expression construct, a construct to provide the packaging and envelope proteins which require the transfection of HEK 293 cells for the generation of virus that can then be used to transduce the host cells.

pBMN CIP SIN Non-mobilisable vector is based upon the pBMNZ backbone, and contains an MMLV 5' LTR, packaging sequence (Psi), powerful CMV promoter, a multi-cloning site, EMCV IRES-puro fusion for selection of infected cells with puromycin, and the MMLV 3'LTR. All viral structural genes have either been removed or
rendered inactive by the introduction of stop codons with the open reading frames. There is minimal or no sequence overlap between "insert" vector and the others used for virus production (gag/pol, and envelope). This makes this transient system much safer than the majority of stable producer cell lines or vector-based systems for which there is a large degree of homology between the packaging vector(s) and the retroviral expression vector. In these latter systems there is a relatively high probability of production of replication-competent retrovirus (RCR) due to homologous recombination between the vectors. In addition, pBMN-CIP-SIN is also a self-inactivating (SIN) retroviral vector. This is generated by a deletion in the 5'LTR rendering the 5'LTR and 3'LTR retroviral promoters inactive in infected cells. In addition to reducing the chances of insertion activation of endogenous genes, this feature also reduces further the chances of generating replication competent virus.

pVPACK GAG POL Mobilisation defective pVPACK-gp from Stragene is a 10.7 kbp pUC18 based vector which contains a nic sequence. Expression of the retroviral gag-pol protein is driven by a CMV promoter. Downstream lies an IRES-hisD sequence for selection if required and a bGH polyA signal. Used with other plasmids in packaging cells to generate retroviral vectors.

pVPACK VSVG Mobilisation defective pVPACK-VSV-G from Stragene is a 6.4 kbp pUC18 based vector. Expression of VSV-G protein is driven by a CMV promoter. Downstream lies an IRES-puro sequence for selection if required and a bGH polyA signal. Such particles are anticipated to have a wide tropism in terms of host and tissue tropism and to be more stable than conventional vectors with other types of glycoprotein.

Origin & function

Lung alveoli contains two epithelial cell types, type 1 and type2 pneumocytes (PTI and PTII). PTII serve as stem cells to produce more PTI cells. During development the Androgen receptor has been demonstrated to effect PTII branching morphogenesis and lung maturation. The adenocarcinoma lung cell line A-549 (transformed PTII cells) cells have the potential to synthesize and secrete testosteone in culture with foetal calf serum. (Endocrinology 141: 2786–2794, 2000) and have demonstrated changes of gene expression upon the administration of androgen Mikkonen et al (Molecular and Cellular Endocrinology 317 (2010) 14–24). Mikkonen et al have also demonstrated that mice treated with androgen altered murine lung gene expression profiles; for example, by up-regulating transcripts involved in oxygen transport and down-regulating those in DNA repair and DNA recombination. Several of these genes might be important in the establishment of a malignant phenotype such as such as oxygen utilization and apoptosis. The gene TMPRSS2 was also up regulated upon androgen exposure in mice and a direct target in A549 cells, this gene is also an Androgen receptor target in prostate cells (Wang et al., 2007 Mol. Cell 27,380–392). Lung carcinoma tumours and normal adjacent tissue showed AR immunoreactivity. Reports also indicate the Estrogens pathway is important in lung cancer development (Marquez-Garban et al., 2007 Steroids 72, 135–143. Androgen-dependent up-regulation in murine lung of Angpt14 was also demonstrated and this has been implicated in lung cancer progression and metastatic potential (Padua et al., 2008 Cell 133, 66–77). The potential over expression of CYP17A in lung cells may result in DHEA production. DHEA stimulates the production of estrogens, testosterone, progesterone, cortisone, and other steroid hormones which may result in an androgen response in the lung.

Evaluation of foreseeable effects

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

02/03/2022
To understand the mechanisms by which signalling pathway synergy is observed, preliminary data has shown differential regulation of the FOXO proteins following intra-pathway combinations in vitro. To determine whether this regulation of FOXO is pertinent to the observed phenotype, there is a need to effectively knockdown the FOXO proteins in mammalian cells prior to signalling pathway inhibition. As stable and efficacious knockdown is required, a lentiviral shRNA approach would be desirable. Ready to use VSV-G pseudotyped lentiviral particles will be purchased from Sigma. It is not planned to generate viral particles in house under this proposal.

Recipient or parental organism

Human breast and prostate cancer tumour cell lines. HCC70, MOA-M8-468, PC3

Host/vector system

pLKO.1 lentiviral system purchased from Sigma. MISSION TRC viral particles are produced using a 3 plasmid system. Features of the pLKO.1-puro vector allow for transient or stable transfection of the shRNA as well as production of lentiviral particles. Stable gene silencing is selected using the puromycin selectable marker while self-inactivating replication incompetent viral particles can be produced in packaging cells (HEK 293T) by co-transfection with compatible packaging plasmids. pLKO.1-puro Vector Description and Features; cplCTE - Central polypurine tract / constitutive transport element hPGK - Human phosphoglycerate kinase eukaryotic promoter puroR - Puromycin resistance gene for mammalian selection SINLTR 3' - self inactivating long terminal repeat f1 ori f1 - origin of replication ampr - Ampicillin in resistance gene for bacterial selection pUC ori - pUC origin of replication 5' LTR - S'lon9 term inal repeat Psi - RNA packaging signal RRE - Rev response element

Origin & function

Mission TRC lentiviral particles contain short-hairpin RNA (shRNA), an RNA molecule of sense and antisense sequences connected by a short spacer of nucleotides that enables the molecule to form a loop structure. When expressed, it is transported from the nucleus into the cytoplasm, where it's processed by the Oieer enzyme into 21-23 nucleotide siRNA duplexes. The shRNA is able to enter the RNAi pathway and result in gene silencing by blocking translation. The shRNA sequence is designed to be selective towards the gene that is to be targeted, through binding to the complementary sequence of mRNA, reducing the number of off-target effects. Targeting of FOXO mRNA using shRNA will result in the loss of FOXO protein expression. Transduction particles encoding sequences for FOXO shRNA knockdown, as well as non-targeting shRNA negative control and green fluorescent protein (GFP) expressing positive control will be ordered. The GFP positive control is a plasmid that contains GFP cDNA that upon integration in the target genome, GFP mRNA will be transcribed which will result in the expression of GFP protein in the cell. GFP is a fluorescent protein which is naturally found in jelly fish and has been expressed in a wide variety of organisms with no toxic effects. The Forkhead box (FOXO) proteins (FOX01, FOX03 and FOX04) are transcription factors that play an important role in response to activation of the PI3K signalling pathway. AKT, a key node in the PI3K signalling axis directly phosphorylates and inactivates the FOXO proteins through sequestration of FOXO in the cytoplasm. In the absence of PI3K signalling or through targeted inhibition of the PI3K pathway, the FOXO proteins are dephosphorylated and translocate to the nucleus with they are able to bind to and regulate their target genes. Studies
have demonstrated that regulating the activity of the FOXO proteins is critical for a complete PI3K signalling response.
GFP is a protein composed of 238 amino acid residues that exhibits bright green fluorescence when exposed to light in the blue 10 ultraviolet range. GFP is considered to be an inert, non-toxic protein and is frequently used as a reporter protein to monitor gene expression levels.

Evaluation of foreseeable effects

There are 2 GMOs to consider. The first is the VSV-G pseudotyped lentiviral particles that present the potential risk of transducing the operator own cells. If infected with the virus, there is a risk that the FOXO shRNA can target operators mRNA to knockdown FOXO protein. It is unclear what effect that FOXO KO would have on the operators cells. The second GMO for consideration are the modified cell lines. FOXO KO has the potential to alter the growth properties/transforming ability of the cancer cell lines. This could potentially be manifested in an increased ability to survive.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

No animals or plants are proposed to be used

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

All measures required at CL2 will be applied except for the presence of an autoclave in the building. At Alderley Park autoclaves are not present in all buildings where risk class 2 work takes place. In some buildings, autoclaves are present but are only available for media and glassware sterilisation. The waste management facility has a central autoclave facility and a collection and transport process, which we judge to provide an equivalent level of protection.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid GMM contaminated waste will be triple bagged in biohazard waste bags, suitably labelled and autoclaved. This solid waste will be comprised mainly of plasticware used in the culturing of the organisms and contaminated tissues used in the decontamination process. As a result there will be no viable GMMs remaining in the solid waste. All liquid waste will be disinfected with 2% virkon. Solutions will be left soaking for 2 hours before disposal via the drain with copious amounts of water. Procedures and relevant training and safety inspections are in place to ensure that all workers deal with waste correctly as specified above.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N

**Project Additional Information**

**Purposes of the contained use**

The aim of this programme of work is to use CRISPR-Cas9 mediated genome wide screening to find and validate potential therapeutic targets. Libraries of CRISPR gRNA against any and all coding and non-coding regions of the human genome targets will be screened against a number of cell based assays in the presence of the protein Cas9. The CRISPR gRNAs and the Cas9 protein will be delivered to cells using a lentiviral delivery system. The CRISPR gRNA vector contains a puromycin resistance gene under control of the EF-1a promoter to allow selection. CRISPR gRNA lentiviral particles can be provided in single shot, 96 or 384well micro plate format. The ready to use lentiviral particles that make up the library are produced using the third generation lentiviral packaging system that has been
designed to produce replication incompetent virions and provide biological containment. Application of CRISPR/Cas9
gRNA targeting could have the following effects on gene transcription; deletion, repression or upregulation. It is not
planned to generate viral particles in house under this proposal.

Recipient or parental organism

Mammalian cell lines, including human tumour cell lines and induced pluripotent stem (iPS) cell derived cell lines, that
may or may not be expressing reporter constructs, e.g. beta lactamase and luciferase. When appropriate, tumour cell
lines will be handled at Biosafety Level 2 to comply with appropriate COSHH Risk Assessment (UKCCCR Guidelines
for the Use of Cell Lines in Cancer Research, British Journal of Cancer (2000) 82(9),1495-1509). The iPS cell lines
are derived from adult somatic tissue and generated using non viral reprogramming methods.

Host/vector system

The CRISPR gRNA and Cas9 lentiviral particles used in this proposal are each produced using the pLenti-CRISPR
transfer vector and three separate packaging plasmids, pLP1, pLP2 and pLP/vSVG. The transfer vector contains
sgRNA scaffold under the control of a U6 promoter and puromycin resistance gene driven by an EFS promoter. The
vector also contains a WPRE insert at approximately 500bp in size with a deleted X Protein locus. Ready to use VSV
G pseudotyped lentiviral particles for the CRISPR-Cas9 system are provided at high titer in the format of separate
Cas9 (-10^7 pfu/mL) and gRNA (-10^6 pfu/mL) expression vectors. The lentivector Cas9 construct expresses
human-codon optimised Cas9 Wild-type nuclease, while the lentivector gRNA expression constructs contain
specifically designed gRNAs driven by U6 Pol III promoters for robust expression. The gRNA sequences have been
designed using bioinformatic algorithms to confer specificity of Cas9 to a specific locus.

Origin & function

The pre-packaged ready to use pseudoviral particles for expression of Cas9 wild-type nuclease along with viral
particles for expression of the gRNA library can be co-infected into the target cells for specific gene knock out,
repression or regulation. The expression of gRNA targeting sequence introduces double strand breaks via the Cas9
endonuclease system that result in homologous and/or non-homologous end joining often resulting in small insertions
and/or deletions which can disrupt or knockout the gene.

The control CRISPR particles used to optimise the transduction and selection conditions will express emGFP. emGFP
is a derivative of the fluorescent protein GFP from the jellyfish Aequorea victoria. The fluorescent protein is widely
expressed in mammalian cells and is unknown to have any harmful or toxic effects. The CRISPR negative control
particles used in this work express EmGFP linked to puromycin resistance through a self-cleavage P2A peptide and
scrambled gRNA expression driven by a human U6 promoter. The scrambled gRNA is designed not to cause gene
modification when combined with the Cas9 nuclease. The CRISPR positive control particles used express EmGFP
linked to puromycin resistance through a self-cleavage P2A peptide and express gRNA targeting human
hypoxanthine-guanine phosphoribosyltransferase 1 (HPRT1). When combined with the Cas9 nuclease gRNA
targeting HPRT1 will result in modification of this gene and loss of HPRT1 protein expression in the cell.

The delivery system uses a separate lentiviral vector to express Cas9 within the cell. The Cas9 lentivector expresses
human-codon optimised Cas9 wild-type nuclease. Cas9 is a nuclease; an enzyme specialised for cutting DNA, with
two active cutting sites, one for each strand of the double helix. The gRNA interacts with Cas9, directs the nuclease to
the specific complimentary DNA sequence. Arrayed libraries of CRISPR gRNAs contain multiple copies of gRNAs
against a specific target in the genome in each well. Pooled libraries contain gRNAs against multiple different
genome targets in the same well.

The lentiviral library is designed to deliver distinct gRNA constructs targeted to maximise gene perturbation and
minimise off target effects. gRNA expression is driven by U6 promoter and the insert also contains a puromycin resistance selection motif.

Evaluation of foreseeable effects

There are 2 GMOs to consider. The first is the VSV-G pseudotyped lentiviral particles that present the potential risk of transducing the operator own cells. Application of gRNA and Cas9 lentiviral vectors has the potential to cause DNA damage via double strand breaks and initiate cellular homologous or non-homologous end joining repair resulting in insertions and/or deletions that could disrupt or knock-out the targeted gene. Application of CRISPRiCas9 gRNA targeting could have the following effects on gene transcription; deletion, repression or upregulation. This is difficult to predict but could potentially alter the cell phenotype, for instance increasing the ability to survive or proliferate. There is the potential of off-target DNA double strand breaks following transduction with the CRISPR gRNA particles however the reported incidence of this is low when compared to other modification technologies. The second GMO for consideration are the modified cells created following transduction. Potential gene disruption could alter the growth properties/transforming ability of the cells. This could potentially be manifested in an increased ability to survive.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

No animals or plants are proposed to be used.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Alderley Park, Macclesfield (address no. 1):
Autoclave is not present in the building where this class 2 work will take place.
In some buildings of Alderley R&D, autoclaves are present but are only available for media and glassware sterilisation.
The on-site waste management facility has a central autoclave facility. There is a collection and transport process, which we judge to provide an equivalent level of protection, as described in answer to question 12. Class 2 solid waste will be deactivated within the confines of the laboratory, prior to disposal.
Building 310, Cambridge (address no.2):
No derogation required. All containment requirements are satisfied. Unlike Alderley Park, Building 310 has an autoclave present within the building.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Alderley Park, Macclesfield (address no. 1):
Class 2 solid waste will be chemically deactivated before leaving the laboratory, which is a restricted access room. The solid waste will be comprised mainly of plasticware and contaminated tissues used in the decontamination process. To deactivate, 2% virkon strength for a minimum contact time of two hours will be implemented. As a result, there will be no viable GMMs remaining in the solid waste.
All solid GMM contaminated waste will then be at least double bagged into biohazard autoclave waste bags, and secured with autoclave tape. Should there be any chance of liquid drip escape, absorbent pads are used within the bag. The bags are labelled and a trained waste technician will transfer the bags using medibins and a specifically designed wheeled clinical waste carrier. A bespoke 1.5 tonne lorry is used to take the carrier the short distance to an on-site and enclosed waste facility where the waste is transferred into the building and into the autoclave for 100% sterilisation.
All liquid waste will be disinfected with 2% virkon. Solutions will be left soaking for 2 hours before disposal via the
Procedures, relevant training, supervision and safety inspections are in place to ensure that all staff comply with waste protocols correctly as specified above.

Building 310, Cambridge (address no.2):

All liquid waste will be disinfected with 2% virkon. Solutions will be left soaking for 2 hours before disposal via the drain with copious amounts of water.
Use of lentiviral CRISPR Cas9 gene editing systems for in vitro cell line studies to support drug discovery programmes

The aim of this programme of work is to use CRISPR Cas9 gene editing to find and validate potential therapeutic targets for drug discovery purposes. The intention is to modulate the activity of a variety of different human genes by single or multiple modifications in a range of cell lines maintained under tissue culture conditions. There are no plans to modify whole organisms. CRISPR gRNA targeted to specific coding and noncoding regions of the human genome will be screened in a number of cell based assays in the presence of the protein Cas9. The CRISPR gRNAs and the Cas9 protein will be delivered to cells using lentiviral delivery systems. The vectors will contain an antibiotic resistance gene such as puromycin and/or a standard fluorescent marker driven by an established mammalian promoter to allow for selection. The lentiviral particles will be supplied ready to use by an external commercial suppliers using packaging plasmids to produce VSV-G pseudotyped replication incompetent virions with suitable biosafety features. Application of CRISPR/Cas9 gRNA targeting could have the following effects on gene transcription in the final GMOs: deletion, repression, or upregulation. It is not planned to generate viral particles in house under this proposal. The CRISPR gRNA and Cas9 lentiviral particles used in this proposal are each produced using 3rd generation transfer vectors and packaged with either 2nd generation or 3rd generation packaging systems. The transfer vectors used are all commercially available and include 2 approaches: a two vector system where the Cas9 and gRNA are on separate vectors and a single vector system where both are contained on one vector. For the former, transfer vectors such as pLenti-CRISPR, pLKO.1 and pTRIPZ will be used to express either Cas9 from a conventional mammalian promoter or sgRNA scaffold under the control of a U6 promoter, along with a selectable resistance gene driven by a similar promoter. Vectors also contain a WPRE insert either with or without the x protein promoter. For the single vector system both Cas9 and gRNA are expressed from one transfer vector using one of a range of conventional mammalian promoters and U6 RNA promoter respectively. Ready to use VSV-G pseudotyped lentiviral particles for the CRISPR-Cas9 system are provided at high titre in the format of separate Cas9 expression vectors. The gRNA sequences will be designed using bioinformatic algorithms to confer specificity of Cas9 to a specific locus. This proposal covers the use of commercial reagents: there is no intention to generate viral particles.

Recipient or parental organism

Mammalian cell lines, including human tumour cell lines and induced pluripotent stem (iPS) cell derived cell lines, that may or may not be expressing reporter constructs, e.g. beta lactamase and luciferase. When appropriate, tumour cell lines will be handled at Biosafety Level 2 to comply with appropriate COSHH Risk Assessment (UKCCCR Guidelines for the Use of Cell Lines in Cancer Research, British Journal of Cancer (2000) 82(9), 1495-1509). The iPS cell lines are derived from adult somatic tissue and generated using non viral reprogramming methods.
The CRISPR gRNA and Cas9 lentiviral particles used in this proposal are each produced using 3rd generation transfer vectors, all of which are commercially available and include 2 approaches: a two vector system where the Cas9 and gRNA are on separate vectors and a single vector system where both are contained on one vector. For the former, transfer vectors such as pLenti-CRISPR, pLKO.1, pLV-CE and pTRIPZ will be used to express either Cas9 from a conventional mammalian promoter or sgRNA scaffold under the control of a U6 promoter, along with a selectable resistance gene driven by a similar promoter. For the single vector system the transfer vector will be pLV-U6g-EPGC where both Cas9 and gRNA are expressed from one transfer vector using one of a range of conventional mammalian promoters and U6 RNA promoter respectively. Transfer vectors will contain all or some of the following elements: Chimeric 5’ LTR, U3 truncated 3’ LTR, cPPT/CTS (central polyuridine tract/central termination sequence), Ψ (packaging signal), RRE (Rev-response element), IRES (encephalomyocarditis virus internal ribosome entry site), mammlian promoter (CMV, CAG, RSV) and WPRE insert either with or without the WHV x protein promoter. All transfer vectors will be packaged in HEK293T cells by the supplier using a range of commercially available 2nd and 3rd generation packaging plasmids with minimal viral components and include pVPackg, pVPackVSVG, pMDLg/pRRE, pMD2.G and pTLA1 series. Particles will be packaged with VSV-G pseudotyped envelopes. Ready to use lentiviral particles for the CRISPR-Cas9 system are provided at high titre (10^7-10^8 pfu/ml). The gRNA sequences will be designed using bioinformatic algorithms to confer specificity of Cas9 to a specific locus. This proposal covers the use of commercial reagents: there is no intention to generate viral particles within the scope of this notification.

**Origin & function**

Cas9 is a bacterial nuclease specialized for cutting DNA, with two active cutting sites, one for each strand of the double helix. The gRNA interacts with Cas9 and directs the nuclease to the specific complimentary DNA sequence. The intention is to utilise different forms of Cas9 in the target cells. These include, S. pyogenes (sp) Cas9 (traditional most well known Cas9) (UniProt: Q99ZW2 (CAS9_STRP1)), S. pyogenes (sp) Cas9 D10A (Ran et al 2013, Cell 154:1380-1389), spCas9-HF-1 (Same functions of sp.Cas9 but more specific repaired in the cell by homology directed repair (HDR), using the intact strand as the template. HDR has high fidelity and rarely results in errors. Two adjacent, opposite strand nicks can cause a double strand break (DSB) and trigger error-prone non-homologous end joining (NHEJ) repair; however, in the presence of a repair template, the double nicks can be repaired by HDR. Double nicking greatly reduces unwanted off-target effects. The gRNA interacts with Cas9, leads the nuclease to the specific complimentary DNA sequence to cause a single or double stranded cut in the DNA. In the absence of the gRNA the Cas9 should not cut the DNA. The gRNAs will be expressed as RNA and are designed to optimise specificity using proprietary supplier controls to target Cas9 to specific genes. Dependent on precise gene function, perturbation by Cas9/gRNA could result in altered function within the final GMO cell line.

rtTA3 expression will be utilised for inducible expression in the TRIPZ vector and is derived from tTA, a Tet-off regulatory protein comprising a fusion of 1-207aa of the Tet repressor protein and the C terminal 127aa of Herpes Simplex VP16 activation domain. rtTA3 is mutated at 4aa in the TetR domain reversing the functionality of the repressor such that binding of Tetracycline is required for operator binding [Gossen et al 1994 Curr. Opin. Biotechnol 5:516-520]. In the presence of tetracycline, rtTA3 will bind the TRE elements in the Tet Operator and increase expression of genes under the regulation of this control region.

Fluorescent reporter proteins GFP, eGFP, RFP, CFP, AsRed and YFP will be expressed as markers for downstream analysis. GFP is a fluorescent protein from the jellyfish Aequorea victoria. eGFP, CFP and YFP have been generated by GFP mutations to improve or alter spectral characteristics. RFP is a synthetic variant of fluorescent protein originally isolated from Discosoma coral. AsRed2 is a fluorescent protein from the Anemonia sulcata red fluorescent protein. These fluorescent proteins have been widely expressed in mammalian cells and are not known to have any harmful or toxic effects.

Puromycin, kanamycin, blasticidin and neomycin resistance gene products are classified as antibiotic resistance genes. These have been widely expressed in mammalian cells and are not known to have any harmful or toxic effects.

**Evaluation of foreseeable effects**

There are 2 GMO hazard sources to consider: the virus and the final cell line GMO.

Firstly, although all viral particles will be replication defective, the presence of the WHV x protein promoter in the WPRE fragment of some transfer vectors has been associated with a transforming phenotype (Themis et al, Molecular Therapy 12(4):763-71, 2005). Whilst it is anticipated that this hazard will only require Containment Level 2 control measures, systems devoid of these potential viral hazards will be the preferred choice where possible. Studies in mice have shown that while some vectors such as those based on MuLV vectors are genotoxic (due to insertional mutagenesis), however lentiviral vectors are not known to be associated with genotoxicity (Montini, et.)
al., Nature Biotechnology, 2006). Furthermore, all of the viral vectors proposed for use have a number of safety features which include a deletion in the enhancer of the U3 region of 3'LTR ensuring self-inactivation; chimeric 5'LTR containing mammalian promoter to decrease the risk of viral LTR activity and necessity of Tat expression; absence of accessory genes (vif,vpr,vpu,nef); the vector and helper constructs contain no significant areas of homology, minimizing their chance for recombination; HIV-1 structural genes (gag, pol, rev) will not be present in the transduced cells. All lentiviral particles are hence replication-incompetent. Exposure to gRNA and Cas9 lentiviral vectors has the potential to cause DNA damage via double strand breaks and initiate cellular nonhomologous end joining repair resulting in insertions and/or deletions that could disrupt or knockout the targeted gene. The resulting modifications could have the effect of deletion, repression or upregulation on the target gene. This could potentially alter the cell phenotype, for instance increasing the ability to survive or proliferate. There is also the potential of off-target DNA double strand breaks following transduction with the CRISPR gRNA particles, however the reported incidence of this is extremely low. Hence exposure of the operator to any virus particle by inhalation or direct inoculation into the circulation could potentially pose a risk. Consequently appropriate containment level 2 control measures will be used to minimise exposure: Class II Microbiological Safety Cabinet, double gloves, suitable and sufficient warning signs, proper waste deactivation and disposal, minimised aerosol production and in a restricted access laboratory. All staff will be trained in safety procedures and use of lab equipment. Volumes of high titre virus-containing liquids (up to 10^8 pfu/ml) will be no greater than 50ul in any one experiment. Plasticware/media/other liquids will be inactivated with a validated procedure or placed in a dedicated waste container for on site autoclaving and then disposed under COSHH regulations. For the final cell lines these will be monitored using a commercial p24 ELISA assay and demonstrated devoid of viral particles prior to moving to BCL1 containment. Plates handled outside of a Class II Microbiological Safety Cabinet will be lidded and effectively double sealed to minimise spillage risk. Cell cultures are considered to be disabled hosts as they will not survive outside of a laboratory and are not able to colonise the operators

The second consideration is the modified cells created following transduction. Potential gene disruption could alter the growth properties or transforming ability of the cells. This could potentially be manifested in an increased ability to survive. Consequently exposure by inhalation, ingestion or in the circulation could potentially lead to an increased risk of colonisation. However cell cultures are considered to be disabled hosts as they will not survive outside of culture conditions and any exposure will result in clearance by the operators immune system. As a consequence final GMO cell lines are very unlikely to colonise an immune competent operator.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

No animals or plants are proposed to be used.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation required

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

For both addresses:
Class 2 solid waste will be chemically deactivated before leaving the laboratory. Access to the laboratory is restricted. The solid waste will be comprised mainly of plasticware and contaminated tissues used in the decontamination process. To deactivate, 2% virkon strength for a minimum contact time of two hours will be implemented. As a result, there will be no viable GMMs remaining in the solid waste. All solid GMM contaminated waste will then be at least double bagged into biohazard autoclave waste bags, and secured with autoclave tape. Should there be any chance of liquid drip escape, absorbent pads are used within the bag. The bags are labelled and a trained waste technician will transfer the bags using medibins and a specifically designed wheeled clinical waste carrier to the autoclave within the building for 100% sterilisation. All liquid waste will be disinfected with 2% virkon. Solutions will be left soaking for 2 hours before disposal via the drain with copious amounts of water

Procedures, relevant training, supervision and safety inspections are in place to ensure that all staff comply with waste protocols correctly as specified above.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y
This proposal was approved by the AstraZeneca GMSC on 29th June 2016 as Risk Class 2

### Project Ref 108/16.2

**Date Ackn’d:** 25/11/2016  
**CU2 Project Title:** Cell engineering for purification and molecular cargo loading of extracellular vesicles with CRISPR/Cas9 components for in vitro genome editing  
**Class:** Class 2  
**Culture Vol:** 1-50 Litres

### Project Additional Information

**Purposes of the contained use:**  
The aim of this programme is to engineer cell lines for production of Extracellular Vesicles (EVs), including exosomes, loaded with different molecular cargo of interest. Initially the cell lines will be...
engineered to load Cas9 and CRISPR gRNA, separately or in combination, into EVs as well as modifying EV-associated proteins to facilitate affinity purification. Loading of functional Cas9 and CRISPR gRNA against various human genome targets will be assessed with various cell based assays in the presence of the produced EVs. The generation of cell lines for CRISPR/Cas9 modification is covered in 'Generic GMO number 6: 20160321101713, and we will be using many of the same Cas9 variants, cell lines and vectors detailed in that proposal.

Recipient or parental organism

Mammalian tumour and non tumour cell lines Mammalian cell lines, including human tumour cell lines and induced pluripotent stem (iPS) cell derived cell lines. When appropriate, tumour cell lines will be handled at Biosafety Level 2 to comply with appropriate COSHH Risk Assessment (UKCCCR Guidelines for the Use of Cell Lines in Cancer Research, British Journal of Cancer (2000) 82(9),1495-1509). These cell lines are generated in house [or by an external contractor] using standard cloning vectors and expression vectors and hosts. It is anticipated that the insertion and expression of the target will not increase the inherent risk posed by the parental cell line used. All details will be recorded in the Generic GMO spreadsheet and assessed by a competent scientist.

Host/vector system

pCDNA3 series 5-6kb mobilisation-defective vectors containing pBR322 nic sequence. CMV promoter and T7 promoter allows cloning without expression in E coli not containing T7 polymerase and also constitutive expression in mammalian cells. Contains SV40 ori allowing replication in cells expressing SV40T. Other features include ampicillin resistance gene and hygro, neo or zeo resistance genes; SV40 poly and ColE1 origin.
pTOIC This is an in-house generated episomal vector based on pBluescript backbone with pUC origin of replication for bacterial propagation. Non mobilisable. Contains PGK promoter driving a neomycin resistance gene. Contains a TRE3G inducible promoter driving expression of Cas9 (s.pyrogenes) and EmGFP with an intervening T2A peptide element and BGH polyadenylation signal. Contains Tetracycline transactivator (Tet-ON-3G) gene driven by a CAGG promoter with an SV40 polyadenylation site. Incapable of replication in mammalian cells. For growth in E.Coli, it contains a pMB1 origin of replication and ampicillin resistance. azPGE Series PL-16-0157 azPGE- pEF1_Cas9_T2A_PuroR. This is an inhouse generated episomal vector based on pBluescript backbone with pUC origin of replication for bacterial propagation. Non mobilisable. These are the promoters that can by driving Ca9 expression: CMV, EF1a, SV40, PGK, TRE, TRE3G (Clonetech) promoter driving expression of Sp Cas9 (UniProt: Q99ZW2 (CAS9_STRP1)), Sa Cas9 (UniProt: J7RUA5 (J7RUA5_STAAU)) and SpCas9-HF1 (Addgene: Plasmid #72247). It may contain the following: Antibiotic resistance genes: neomycin, puromycin, kanamycin and blasticidin. Fluorescent proteins: AsRed2, eCyFP or eCFP, eGFP and GFP. ZFN and
obligate sites that recognize ZFNs to enable integration of DNA into AAVS1 by ZFN. T2A peptide elements can be used to allow post translational cleavage of two proteins transcribed from the same promoter and a BGH polyadenylation signal. It may also contain a U6 promoter for eukaryotic expression of gRNA. Incapable of replication in mammalian cells. For growth in E.Coli, it contains a pMB1 origin of replication.

pMLu Vector for RNA expression driven by U6 promoter.

Origin & function

All insert sequences will be generated by routine gene synthesis using external providers. Where appropriate, protein sequences for inserts will be obtained from Uniprot. Inserts include FKBP, FRB, CIB1, CRY2, PHYB, PIF3, PIF6, HO1, PoyA, VVD, MS7, PP7, CAS9, CRE, GYRB, CD9, CD63, RAB5, and RAB1. CRISPR gRNA and protein insert sequences will be cloned into standard mammalian expression vectors e.g. pcDNA3.1 or pMLu.

Evaluation of foreseeable effects

There are 2 GMO hazard sources to consider; the final EV producing cell line GMO and the Cas9 and/or gRNA loaded EVs. Although it is not anticipated, modified cells for EV production could possess an increased survival ability and improved proliferation rate and hence may present additional hazards to operators if ingested, introduced into the circulation or inhaled as an aerosol. Exposure to Cas9 and gRNA loaded EVs has the potential to cause DNA damage via double strand breaks and initiate cellular non-homologous end joining repair resulting in insertions and/or deletions that could disrupt or knock-out the targeted gene. There is also the potential of off-target DNA double strand breaks following exposure with the Cas9 and gRNA loaded EVs.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

No animals or plants are proposed to be used

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Project Ref 108/16.3

Date Ackn'd: 25/11/2016
CU2 Project Title: Use of the BacMam/multiBacMam as a delivery system for genomes editing applications

Class 2, Culture Volume Class 2, Consent Granted

Date Project 02/03/2022

Page 3238 of 15326
This proposal covers the engineering of the BacMam system (commercially available Thermofisher Scientific) or MultiBacMam system (Sari et al. 2016, AZ external collaboration -Imre Berger-Bristol University) for precise genome editing by including CRISPR/Cas9 and its derivatives, Cpf1 and Zinc Finger Nucleases that can be used to insert sequences into and/or modify the genome in cell lines. Moreover, transiently expressing catalytically dead Cas9 molecules fused to epigenetic transcriptional regulator can be used (CRISPRi/CRISPRa, Thakore et al. 2016). The aims of this GMO are: Firstly that base vectors listed in this GMO that already have Cas9 +/- gRNA and a fluorophore, can be used for subcloning of the gene editing system into the transfer vector of the BacMam system or MultiBacMam system for later assembly and production of Baculovirus particles in insect cells. Secondly, the engineered Baculoviruses will be used to transduce cell lines. If a gene is targeted either from the start before the work is carried out, this should be individually risk assessed, discussing the risks of targeting that specific locus. The BacMam Baculoviral particles will be produced in house in UK and supplied ready to use replication incompetent virions able to transduce mammalian cells via the vesicular stomatitis virus G envelope glycoprotein (VSV-G pseudotype). Baculoviral particles derived from MultiBacMam system will be produced by Imre Berger research laboratory in Bristol and supplied ready to use as pseudotyped (with envelope glycoproteins to increase transduction efficiency in mammalian cells; e.g. VSV-G, gp64, gp120/gp41) non-pseudotyped replication incompetent virions. MTA is already in place. Strep-tag will be fused to the baculoviral protein gp64 for large scale virus purification by affinity chromatography. Application of CRISPR/Cas9 gRNA targeting could have the following effects on gene transcription in the final GMOs: deletion, repression, or upregulation. Viral particles used in this proposal are produced using commercial and non-commercial transfer vectors. In both the BacMam and MultiBacMam systems the CRISPR gRNA and gene editing nuclease are present in a single vector set-up, pCMV-DEST (BacMam) or in house modified AzPGE series (MultiBacMam). Both types of transfer vectors include Tn7 sites for transposition of the CRISPR modules into the Baculovirus genome (Bacmid) which is then used to produce viral particle in insect cells. Both Cas9 and gRNA are expressed using a range of conventional mammalian promoters and U6 RNA promoter respectively. pCMV-DEST vector also contain a WPRE insert. Ready to use pseudotyped/non-pseudotyped baculoviral particles for the precise genome editing can be provided at high titre or as diluted supernatant ready to use. The gRNA sequences will be designed using
bioinfomatic algorithms to confer specificity of Cas9 to a specific locus. This proposal cover the use of commercial and non-commercial reagents. Baculoviral particles will be used to make CRISPR/ZNF modifications for in vitro assays in mammalian cell lines.

Recipient or parental organism

S. frugiperda (Sf9/Sf21/expresSF+) Includes both Sf9 and Sf21 cell lines. Cells derived from Spodoptera frugiperda (the Fall Armyworm). The larvae of this moth are an economic pest of cotton every year in extreme southern areas of the USA. Insect cell cultures can be regarded as especially disabled hosts as they represent no intrinsic hazard to human health or the environment unless they are contaminated with adventitious agents. Sf9 was cloned by G.E. Smith and C.L. Cherry in 1983 from the parent line, IPLB-SF 21 AE, which was derived from pupal ovarian tissue of the fall armyworm, Spodoptera frugiperda, by Vaughn, et al., in 1977. “expresSF+” cells are a serum-free cell-line derived from Sf9 by Protein Sciences Corporation using a series of stringent selection steps in serum-free medium supplemented with insulin.

Mammalian Cell Lines Mammalian cell lines, including human tumour cell lines and induced pluripotent stem (iPS) cell derived cell lines, that may or may not be expressing reporter constructs, e.g. beta lactamase and luciferase. When appropriate, tumour cell lines will be handled at Biosafety Level 2 to comply with appropriate COSHH Risk Assessment (UKCCCR Guidelines for the Use of Cell Lines in Cancer Research, British Journal of Cancer (2000) 82(9),1495-1509). The iPS cell lines are derived from adult somatic tissue and generated using non viral reprogramming methods.

Host/vector system

BACMAM pCMV-Dest pCMV-Dest Vector contains a CMV promoter to drive constitutive expression of the target gene. It also contains VSV-G elements, which enable baculovirus to have high transduction efficiency, and a WPRE element, which elongates transient expression in mammalian systems. This WPRE sequence also contains a 3’ fragment corresponding to the promoter and 5’ coding region from the WHV X protein. The X protein promoter is associated with tumourogenesis in certain settings. To facilitate successful cloning, AmpR and gentamicin have been incorporated for positive selection, as well as Cm(R) (chloramphenicol resistance gene) for negative selection.

pFL/ pKL multiBacMam series These are plasmids generated by Imre Berger laboratory (Bristol University). There can be promoters that can be driving Ca9 expression: CMV, EF1a, SV40, PGK, TRE, TRE3G (Clonetech) promoter driving expression of Sp Cas9 (UniProt: Q99ZW2 (CAS9_STRP1)), Sa Cas9 (UniProt: J7RUA5 (J7RUA5_STAAU)) and SpCas9-HF1 (Addgene: Plasmid #72247), sp.Cas9 D10A Nickase (Ran et al 2013, Cell 154:1380-1389), Cpf1 (Zetsche et al.; 2015), Cas9 fusion to cytidine deaminase (Komor et al. 2016), Cas9 fusions to epigenetic/gene regulation domain (CRISPRi/CRISPRa). It may contain the following: Antibiotic resistance
genes: neomycin, puromycin, gentamicin, chloramphenicol, spectinomycin, zeocin, kanamycin and blasticidin. Fluorescent proteins: AsRed2, TurboRFP, eCyFP or eCFP, eGFP and GFP. ZFN and obligare sites that recognise ZFNs to enable integration of DNA into AAVS1 by ZFN. T2A peptide elements can be used to allow post translational cleavage of two proteins transcribes from the same promoter and a BGH polyadenylation signal. They may also contain a U6 promoter for eukaryotic expression of gRNA. Incapable of replication in mammalian cells. For growth in E.Coli, it contains a ColE1 origin of replication. They may have Tn7 transposon for direct integration into the MultiBac bacmid by Tn7 transposition. They may have a loxP imperfect inverted repeat suitable for fusion via loxP to the pSPL/pUCDM multiBacMam plasmid series.

The PGE constructs used for subcloning into the BacMam system or multiBacMam system are made and sequenced within AZ. These vectors can be modified to use alternative versions of Cas9 that have the same function with equal or reduced on and off-target activity including: 1) S. pyogenes (sp) Cas9 (traditional most well known Cas9) (UniProt: Q99ZW2 (CAS9_STRP1)) 2) S. pyogenes (sp) Cas9 D10A (Ran et al 2013, Cell 154:1380-1389) 3) spCas9-HF-1 (Same functions of sp.Cas9 but more specific version with less off target effects caused by mutations in (N497A/R661A/Q695A/Q926A). (Addgene: Plasmid #72247). 4) Staphylococcus aureus (sa) Cas9 (Cas9 from a different strain, has very similar function but smaller). 5) Cpf1 from Acidaminococcus and Lachnospiraceae, Cpf1 is a single RNA-guided endonuclease lacking tracrRNA, and it utilizes a T-rich protospacer-adjacent motif. Moreover, Cpf1 cleaves DNA via a staggered DNA double-stranded break (Zetsche at al, 2015). 6) catalytically dead mutant of the Cas9 protein fused to transcriptional/epigenetic regulators (CRISPRi/CRISPRa, e.g. p300, vp64, dnmt3a Thakore et al. 2016) 7) catalytically dead mutant of the Cas9 protein fused to cytidine deaminase (AID, APOBEC3G, APOBEC1, CDA1) to mediate the direct conversion of cytidine to uridine, thereby effecting a C to T (or G to A) substitution (Komor et al. 2016), Cas9 fusions to epigenetic/gene regulation domain (CRISPRi/CRISPRa). These vectors can also be modified to include the following if desired a fluorescent proteins: AsRed2, TurboRFP, eCyFP or eCFP, eGFP and GFP. The vectors that contain a gRNA sequence will also be modified to change the 20 bp targeting sequence depending on the project. The vectors may contain tetracycline regulated expression of genes from tetracycline responsive promoters. The Strep-tag is a synthetic peptide consisting of eight amino acids (Trp-Ser-His-Pro-Gln-Phe-Glu-Lys). This peptide sequence exhibits intrinsic affinity towards Strep-Tactin, a specifically engineered streptavidin
There are 2 GMO hazard sources to consider: the virus and the final cell line GMO. Bacmam is designed not to integrate into the host genome, but there is at least one report of stable modification with earlier versions of this vector and hence the potential for integration (Condreay et al. 1999 Proc. Natl. Acad. Sci. USA Vol. 96, pp. 127-132). pBacmam also contains a WPRE gene which also encodes the Sprime end of the WHV X protein and includes the upstream promoter, associated with a transforming phenotype (Themis et al 2005 Molecular Therapy Vol. 12, No. 4, pp763-771), carrying a low but perceivable risk of a transforming operators cells. Whilst it is anticipated that this hazard will not require any control measures above that for CL2, systems devoid of these potential viral hazards will be the preferred choice where possible. Fluorescent proteins listed in this GMO have been stably expressed in a range of cell types with no hazardous effects observed. Strep-tag fusion proteins have been stably expressed in a range of cell types with no hazardous effects observed. Addition of the Strep-tag to the baculoviral protein gp64 is not predicted to alter infectivity of the baculoviruses in insect cells or transduction efficiency in mammalian cells. However, Strep-tag might slightly diminish the virus titre obtained from insect cells. Application of gRNA and Cas9 (or other gene editing nucleases) or ZNF baculoviral vectors has the potential to cause DNA damage via double strand breaks and initiate cellular nonhomologous end joining repair resulting in insertions and/or deletions that could disrupt or knockout the targeted gene. There is an intention to use a range of targets that could potentially affect the operator when exposed to the BacMam virus. The main hazards that should be considered is anything that may increase the risk of the cell surviving if it were accidently exposed to someone such as modification of tumour suppressor or promoting genes or insertion of viral components. Deletion, disruption or up-regulation of genes that may cause oncogenic transformations such as tumour suppression or increased cytotoxicity in the cell can be potentially harmful if exposed to operator, or the environment. Consequently exposure to viral particle by inhalation, ingestion, or in the circulation could lead to an increased risk of colonisation. It is anticipated that the risk to the operator and the environment is low due to the contained use of the resultant GMOs within a designated Class 2 laboratory and by trained personnel. There is the potential of off-target DNA double strand breaks following transduction with the CRISPR gRNA particles, however the reported incidence of this is low when compared to other modification technologies. Cas9 should only be active when the full gRNA is present therefore it should not cut in the absence of gRNA or with the target specific sequence cut out. Thus, potential inoculation with a cell line where a functional gRNA has not been used does not result in a greater risk than the parental cell line. In CRISPRi/CRISPRa off-target gene activation/repression is negligible even in the presence of gRNA. In base editing PGE, there is a potential risk of off-target mutations near the double strand break
(Yamanaka et al. 1996, Robbiani & Nussenzweig 2013, Lawrence et al. 2013, Alexandrov et al. 2013). In Cas9 fusion proteins Cas9 guided targeting is not affected. The antibiotic resistance proteins listed in this GMO have been stably expressed in a range of cell types with no hazardous effects observed.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

No animals or plants are proposed to be used

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Class 2 solid waste will be chemically deactivated before leaving the laboratory, which is a restricted access room. The solid waste will be comprised mainly of plasticware and contaminated tissues used in the decontamination process. To deactivate, 2% virkon strength for a minimum contact time of two hours will be implemented. As a result, there will be no viable GMMs remaining in the solid waste. All solid GMM contaminated waste will then be at least double bagged into biohazard autoclave waste bags, and secured with autoclave tape. Should there be any chance of liquid drip escape, absorbent pads are used within the bag. The bags are labelled and a trained waste technician will transfer the bags using medibins and a specifically designed wheeled clinical waste carrier to the autoclave within the building for 100% sterilisation. All liquid waste will be disinfected with 2% virkon. Solutions will be left soaking for 2 hours before disposal via the drain with copious amounts of water. Procedures, relevant training, supervision and safety inspections are in place to ensure that all staff comply with waste protocols correctly as specified above.

Purposes of the contained use

This risk assessment addresses the generation and use of genetically modified lentiviral, retroviral and Bacmam particles encompassing GM risk class 2 activities assigned by the AstraZeneca UK GMSC to be within scope of this ‘Connected Programme of Work’. The aim here is to use 2nd and 3rd generation lentiviral and retroviral delivery systems or current Bacmam systems, to achieve single or multiple genetic mutations by utilising shRNA, CRISPR/Cas9 (and derivatives thereof) or overexpression techniques, in a range of mammalian cell lines in order to facilitate drug discovery projects. The extent of the planned work is limited to in vitro studies. For retroviral and lentiviral systems approaches include both transfection of plasmid vectors into eukaryotic packaging cell lines such as HEK-293T to generate replication-defective viral particles and, use of such replication-defective viral particles (generated at AstraZeneca or elsewhere) to transduce mammalian cell lines. Bacmam studies will adopt the similar approaches but will utilise packaging in an insect cell line and also may require an additional initial step of Bacmid generation in a disabled E.coli strain. Target cell
lines may comprise established and primary mammalian cell lines not known or suspected to contain pathogens at Hazard Group 3 or above. This could include human, rodent and primate sources.

Recipient or parental organism

Lentiviral and retroviral particles (or vectors) based on a range of human virus (HIV) or animal virus (MMLV, MMTV and MSCV). All vector systems will be split to minimise possibility of replication and where packaging cell lines are to be used these will be consistent with 2nd generation or later systems. Hence these viral vectors are extremely unlikely to be able to replicate in human cells or in the wider environment and are unable to present the pathogenesis associated with the originating pathogen. Viral particles may be pseudotyped to effect different tropisms by the use of ecotropic and amphotropic envelope proteins, including VSV-G. Other viral sequences may be present to improve efficiency of these molecular tools such as wild-type or mutated forms of the Woodchuck Hepatitis Virus Post-transcriptional Response Element (WPRE) which enhance transgene RNA stability. Bacmam vectors are modified forms of baculovirus vector series in which the AcNPV polyhedrin promoter has been replaced by the CMV IE enhancer/promoter and along with a WPRE element represents the only mammalian elements present.

Target cell lines for transduction may comprise established and primary mammalian cell lines not known or suspected to contain pathogens at Hazard Group 3 or above. This could include human, rodent and primate sources.

Host/vector system

For lentiviral and retroviral systems, viral particles will be generated by introducing plasmids containing elements of the virus genome into established packaging cell lines, eg. human embryonic kidney (HEK293) cells. There may be instances where the essential viral packaging genes will be expressed stably by the packaging cell, with a single plasmid carrying the vector backbone and transgene being introduced by transfection, and in other cases the viral functions and the vector backbone/transgene will be encoded on separate plasmids which will be transfected together. For Bacmam systems, since bacmids are non-infectious, this aspect of vector production is not subject to scrutiny for CL2 control measures. Packaging which will be achieved by transfection of isolated bacmid constructs of insect cells and the subsequent use of bacmam particles will be covered by this notification.

Such viral vectors will then be used to transduce a range of human and animal cell lines. Target cell lines for transduction may comprise established and primary mammalian cell lines not known or suspected to contain pathogens at Hazard Group 3 or above. This could include human, rodent and primate sources.

Origin & function

As this is a connected programme of work, the genetic material to be introduced will be from a range of origins and have a variety of functions. This will include putative and known oncogenes and tumour-suppressor genes, cytoskeletal proteins, short hairpin RNA (shRNA) molecules intended to inhibit the expression of a range of genes including those known or suspected to be involved in pathways of oncogenesis, and genes intended to induce immortalisation and the extension of the proliferative lifespan of cells. CRISPR/Cas9 systems may be expressed which are intended to cause double-stranded breaks in DNA, leading to mutation by non-homologous end-joining or insertion of specific mutations or tags with homology-directed repair constructs. Variants of the CRISPR/Cas9 system include, S. pyogenes (sp) Cas9, spCas9-HF-1, saCas9, catalytically dead mutants of Cas9 fused to effectors such as cytidine deaminase or transcriptional/epigenetic regulators (CRISPRi/CRISPRa) and non Cas9 modifiers such as Cpf1. This connected programme does not include the use of viral vectors expressing toxin genes or major pathogenesis factors.

Evaluation of foreseeable effects

For retroviral and lentiviral vectors, use of second generation (or later) viral vector systems in which all accessory genes have been deleted, and where gag, pol, env and rev genes are provided in trans (either on additional accessory plasmids or integrated into the genome of packaging cell lines), means that the risk of production of replication-competent or infectious virus is extremely low. In addition the use of self-inactivating (SIN) viral vector systems in which promoter and enhancer elements have been removed from the long terminal repeats (eg U3 deleted 3'LTR for lentiviral transfer vectors), reduces the risk of transcriptional activation of genes proximal to the insertion site, but there remains the possibility gene activation by constitutive promoter/enhancer sequences within the inserted genetic material. Insertion of the viral genome could also result in disruption of genes involved in cellular regulation (e.g. tumour-suppressor genes). WPRE sequences used to increase the levels of expressed mRNA will be present in many vector systems. Although some versions of these elements also express a promoter fragment of the Woodchuck Hepatitis Virus X protein for which there is published evidence for its association with oncogenic activity (Höhne et al., EMBO 9, 1137-1145.1990; Schuster et al., Oncogene 19, 1173-1180. 2000), it is anticipated that this would not result in a need for a higher containment level (>CL2). Nevertheless to improve safety considerations, the preference will be for vectors...
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

For address 1:
Class 2 solid waste will be chemically deactivated before leaving the laboratory. Access to the laboratory is restricted. The solid waste will be comprised mainly of plasticware and contaminated tissues used in the decontamination process. To deactivate, 2% virkon strength for a minimum contact time of 2 hours will be implemented. As a result, there will be no viable GMMs remaining in the solid waste. All solid GMM contaminated waste will then be at least double bagged into biohazard waste bags, and secured with tape. Should there be any chance of liquid drip escape, absorbent pads are used within the bag. The bags are labelled and a trained waste technician will transfer the bags using medibins and a specifically designed wheeled clinical waste carrier for offsite disposal. All liquid waste will be disinfected with 2% virkon for a minimum contact time of 2 hours before disposal. Procedures, relevant training, supervision and safety inspections are in place to ensure that all staff comply with waste protocols correctly as specified above.

For address 3:
Class 2 solid waste will be chemically deactivated before leaving the laboratory. Access to the laboratory will be restricted. The solid waste will be comprised mainly of plasticware and contaminated tissues used in the decontamination process. To deactivate, 2% virkon strength for a minimum contact time of 2 hours will be implemented. As a result, there will be no viable GMMs remaining in the solid waste. All solid GMM contaminated waste will then be at least double bagged into biohazard autoclave waste bags, and secured with autoclave tape. Should there be any chance of liquid drip escape, absorbent pads are used within the bag. The bags are labelled and a trained waste technician will transfer the bags using medibins and a specifically designed wheeled clinical waste carrier. A bespoke 1.5 tonne lorry is used to take the carrier the short distance to an on-site and enclosed waste facility where the waste is transferred into the building and into the autoclave for 100% sterilisation. All liquid waste will be disinfected with 2% virkon. Solutions will be left soaking for 2 hours before disposal via the drain with copious amounts of water. Procedures, relevant training, supervision and safety inspections are in place to ensure that all staff comply with waste protocols correctly as specified above.

For addresses 2 and 4:
The majority of Class 2 solid waste will be inactivated using onsite autoclave facilities. Some Class 2 solid waste may be chemically deactivated before leaving the laboratory. Access to the laboratory is restricted. The solid waste will be comprised mainly of plasticware and contaminated tissues used in the decontamination process. Where chemical deactivation is adopted, 2% virkon strength for a minimum contact time of 2 hours will be implemented. As a result, there will be no viable GMMs remaining in the solid waste. All solid GMM contaminated waste will then be at least double bagged into biohazard autoclave waste bags, and secured with autoclave tape. Should there be any chance of liquid drip escape, absorbent pads are used within the bag. The bags are labelled and a trained waste technician will transfer the bags using medibins and a specifically designed wheeled clinical waste carrier to the autoclave within the building for 100% sterilisation. All liquid waste will be disinfected with 2% virkon. Solutions will be left soaking for 2 hours before disposal. Procedures, relevant training, supervision and safety inspections are in place to ensure that all staff comply with waste protocols correctly as specified above.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]
Our work consists of the use of genetically engineering, attenuated (or weakened) vaccine strains of vaccinia virus (VACV) to express protein “payloads.” The goal of this work is for the virus to target and specifically replicate within tumour cells while expressing these protein payloads. We will use in vitro cell assays and in vivo mouse (via intravenous injections) model to study the ability/efficacy of these payloads and delivery vehicles (VACV) for impairing tumour growth.

In vitro cell lines infected will include human and mouse immortalized and primary non cancer and cancer cell lines. ADCP categories will vary depending on the cell type.
and can be known or unknown. Potential contaminants pathogens might be human pathogens. For example, human cervical cancer cell lines and human head and neck
tumour cell lines harbour HPV (human papillomavirus) genomic material. Primary human samples are generally screened for the presence of the high risk human
pathogens hepatitis virus and HIV by the supplier. Samples containing such pathogens should not be used. Note: Medium hazard cells and Activity Class 2 cells present a
greater risk than low hazard cells, usually due to their potential to harbour human pathogens.

Standard laboratory mouse strains including C57/BL6J, BALB/c, NSG, nude/SCID are all purchased from approved vendors with appropriate health screen information.

**Host/vector system**

The host/vector system is a double-deleted Copenhagen strain of vacinia virus (VACV). The “double-deleted” refers to the targeted deletion/disruption of the viral I4L and
J2R gene products which encode for the viral ribonucleotide reductase and viral thymidine kinase genes, respectively. Together these two modifications render this strain
highly attenuated and restrict virus replication to metabolically active tumour cells (Foloppe et al. PMID 31011628). VACV has no known animal reservoir but can infect
humans and other mammals. A large number of virus strains exist and have been used (including the wildtype Copenhagen strain) as human vaccines for the eradication
of smallpox disease. The engineered Copenhagen strain used in these studies are highly attenuated and virus replication is restricted to human tumour cells.

**Evaluation of foreseeable effects**

While the host reservoir in nature is unknown, vaccinia virus is a human pathogen but is categorized on the HSE’s approved list of biological agents as “buffalopox”
vaccinia virus” and is considered a hazard group 2 agent by ACDP classification. The specific recombinant VACV strain of Copenhagen origin does not replicate in mice
unless a human tumour is present. Vaccinia virus (VACV) infections in humans are typically mild and asymptomatic. Wild-type and engineered VACV have generally
shown only mild toxicity in trials where they have been evaluated as oncolytics. Side effects of VACV infection can include mild skin reactions (including the formation of
lesions with the potential for virus shedding through infected cells lysis), transient fever, and malaise. VACV has the longest and most extensive history of use in humans.
Accidental exposure to VACV may occur through ingestion, parenteral inoculation, and droplet or aerosol exposure of mucous membranes or broken skin with infectious
particles. When working with wildtype, non-attenuated vaccinia strains ocular exposure is of particular concern due to the immune-privileged status of the eye. Many
different strains of vaccinia virus has been used as smallpox vaccines and administered by local routes of administration in hundreds of millions of humans in the 19th and
20th centuries, giving unprecedented information on VACV behaviour in humans, with the identification of populations which are at risk for rare but serious adverse events
and the measures to respond to these (Cono et al. PMID 12617510; Kretzschmar et al. PMID 16933957). Following injection into the skin, the subcutaneous infection by
the virus is brief and limited. As VACV contains antigens that stimulate an immune response that are cross-reactive with smallpox antigens, the vaccine thereby confers
protection from the human smallpox disease.

1. Viral vector: The genetic modifications described above will not increase or enhance the pathogenicity/ virulence / survivability of the parental double-deleted
Copenhagen strain of VACV nor will it permit these recombinant viruses to outcompete with wildtype vaccinia virus in nature. These vaccinia viruses remain attenuated
with the genetic modifications as outlined above. These specific vaccinia viruses are restricted to replication in only human tumour cells.

2. Engrafted animals: there is a theoretical risk of transmission through biting but the risk as assessed is negligible

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Animals treated with vaccinia constructs will be housed in IsoCage red line indivdually Ventilated Cages red line cages and all handling of animals for husbandry or
experimental tasks (dosing, measuring, sampling) will be carried out in biological safety cabinets with the user wearing suitable PPE, including gown, gloves, surgical mask,
and safety glasses. Routine cleaning of cages post usage. Dirty cages must be broken down within the Biosafety cabinet and placed into paper autoclave bags, sealed with
contents including enrichment and bedding included and sent for heat treated sterilisation (autoclave) prior to the cleaning and washing processes. The cages are not left
for an extended time period, e.g. overnight, but autoclaved as soon as possible on leaving the room. All animal carcasses will be placed in a double containment in a Class
2 microbiology safety cabinet, the outside containment will be treated with 1% Virkon solution before either being sent directly for incineration or stored for a short time (less
than 24hrs) at -20, before subsequent incineration. Animals harbouring human tumours that are infected with these vaccinia constructs can theoretically transmit virus to
cage mates who also harbour human tumours but again this risk is negligible and any infected animals will be housed in separate caging, appropriate to mitigate such
Transmission. Local Emergency procedures with regards to a spill, escape of an animal, needlestick injury including Occupational Health assessment and medical treatment are already in place, available to staff and rehearsed regularly.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste will be inactivated prior to disposal as Non-Infectious Healthcare Waste (EWC 18 01 04) or where inactivation is not possible as Infectious Healthcare Waste (EWC 18 01 03). Inactivation should be by autoclaving or by chemical treatment with 1% final Virkon for at least 30 minutes (or other validated method).
- Liquid waste inactivated in 1% final Virkon for >30minutes
- Solid waste inactivated in 1% final Virkon for >30minutes

Routine cleaning of cages post usage. Dirty cages must be broken down within the Biosafety cabinet and placed into paper autoclave bags, sealed with contents including enrichment and bedding included and sent for heat treated sterilisation (autoclave) prior to cleaning and washing processes. The cages are not left for an extended time period, e.g. overnight, but autoclaved as soon as possible on leaving the room. All animal carcasses will be placed in a double containment in a Class 2 microbiology safety cabinet, the outside containment will be treated with 1% Virkon solution before either being sent directly for incineration or stored for a short time (less than 24hrs) at -20, before subsequent incineration.

BJ5183 Especially disabled E. coli K-12 derivative with partial recombination capability to allow the recombination of pAdEasy-1 and pAdTrack-CMV. It is ampicillin and kanamycin sensitive.

Virus Producer Cell Line: HEK293
HEK 293 is a human embryonic kidney cell line of widespread use. It has the adenovirus E1A region integrated into its genome stably expressing the transforming gene of human Type 5 Adenovirus, and thus provides complementation to E1A deficient adenovirus constructs allowing their replication - this is used as the packaging cell line. DNA from both the right and left ends of the viral genome is present. When used as a helper cell line production of recombinant adenoviral particles, production of wild-type virus (an ACDP Hazard Group 2 pathogen) can occur albeit at a low frequency. Two specific non-homologous recombination events would be required to generate replication-competent virus. In a supernatant rescue assay performed on the virus stock to check for replication competent adenovirus (ref. Dion et al J. of Virol Methods 1996 vol56 p99-107) no replication competent virus was detected in 1x10e9 infectious particles. If virus stocks are repeatedly passaged in HEK293 cells replication-competent virus can appear after 9 passages. Methods to produce virus using pAdEasy-1 only require a maximum of three passages in HEK293 cells. Given this data, the risk of generating wild-type adenovirus is considered to be negligible using these procedures.

Expression Host Cells: HEK293, MCF, T47D
HEK-293: see description above.
MCF-7: The MCF7 line is derived from a human mammary gland adenocarcinoma and retains several characteristics of differentiated mammary epithelium contains the Tx-4 oncogene. CL2 following UKCCR guidelines.

T47D cells: ECACC Ref No: 85102201 Established from the pleural effusion of a ductal carcinoma of the breast of a 54-year old female. The cells carry receptors for a variety of steroids. ATCC refer in an entry for a mouse myeloma cell line (HB-8630) to human mammary tumor virus particles isolated from the T47D clone-10 mammary cancer cell line. CL2 following UKCCR guidelines. No reason to suspect that the modification will have any effect on the hazard posed by any such endogenous virus.

Host/vector system

Cloning Vectors (used with DH5alpha; DH10B and BJ5183 bacterial hosts): pShuttle: This is identical to pAdTRack-CMV except it does not contain a CMV promoter or the GFP element. It is used in conjunction with pAdEasy, to generate recombinant adenoviral plasmids in E. coli. The resulting recombinant plasmid can be used to generate infective but replication-defective adenoviral particles following transfection into suitable mammalian host cells (e.g HEK 293 cells) able to provide the E1a sequence in trans. PadTrack-CMV is a 9.2 kbp vector obtained from Bert Vogelstein (He et al PNAS 1998 vol 95 p2509-2514) and is used in conjunction with pAdEasy-1 to generate recombinant adenoviral plasmids in E. coli. The resulting recombinant plasmid can be used to produce infective but replication-defective adenoviral particles following transfection of suitable mammalian host cells (e.g. HEK293) above to provide the E1a sequence in trans.
pAdEASY-1: A33.4 kbp vector obtained from Bert Vogelstein (He et al PNAS 1998 vol 95 p2509-2514) which contains all the adenovirus type 5 sequences except nucleotides 1-3533 (encompassing the E1 genes) and 28, 130-30, 820 (encompassing E3 region). The vector also contains an ampicillinR gene and an origin of replication from pBR322, hence the plasmid is mobilisation defective (Bom+ Tra- Mob-) The vector is used in conjunction with pAdTrack vectors to generate recombinant adenoviral plasmids in E. coli (eg when co-transformed into a bacterial host with the pAdTrack-CMV shuttle vector containing an insert sequence, recombination in the host leads to production of a recombinant pAdEasy-1 containing insert sequences. That plasmid can be used to transfact appropriate mammalian cells (eg. HEK293) to generate recombinant E1a-deleted adenoviral particles.

Additional information for Recombinant Viral Vectors

"Insert" Vector(s): recombinant pAdEASY-1 used with packaging cell line (HEK) and resulting viral particles used to transfact mammalian expression host cells MCF-7 and T47D.

Origin & function

This is an artificial construct containing: a nuclear localisation signal - NLS (derived from SV40 large T), hER1.0/1.1ZFP DNA binding domain (synthetic), either a KRAB transscriptional repression domain (derived from Drosophila Kruppel) or a VP16 transscriptional activation domain (derived from a fragment of Herpes Simplex Virus) and a FLAG domain (synthetic) in pcDNA3. This artificial construct is under the control of the Tet Repression system (Tet Off). This comprises two cassettes which have been PCRd from commercially available vectors: Cassette 1 consists of a Tet repressor under the control of a CMV IE promoter linked to VP16 followed by an IRES-EGFP element and Bovine growth hormone Poly A. Cassette 2 comprises a 7 x Tet Operon with a CMV IE minimal promoter, followed by a multiple cloning site (into which the above ZFP constructs will be inserted) and an SV40 Poly A. The two cassettes are inserted back to back into the pSHUTTLE expression plasmid. (See Vogelstein et al. PNAS., Vol 99, pp. 2509-2514, March 1998)
The two proteins to be expressed are artificial constructs. Each consists of zinc fingers which are expected to bind specifically to an 18-bp sequence in the hERa promoter. In the presence of tetracycline their presence will be switched off. However, in the absence of tetracycline they are expected to be highly expressed. The proteins will contain a Nuclear Localisation Signal and will therefore be targeted largely to the nucleus of hER2.0/1.1 NKF/NVF expressing cells, where the KRAB transcriptional repressor domain and VP16 transscriptional activator domain will assert their effects on hERa transcription within 1kb of the hERa Sp1 binding site. The expressed proteins are expected to be biologically active but are designed to exert their effects only in cells expressing endogenous hERa. Since ERa is a transcription factor, over-expression will have no effect unless the cells are exposed to estrogens, in which case the consequence will be to activate expression of estrogen responsive genes.

Evaluation of foreseeable effects

Taking a very precautionary approach, the likelihood of potentially harmful effects being realised as a consequence of exposure of the operator or environment to the viral vectors was judged to be low. Risks associated with other GMOs are judged to be negligible.

### Project Additional Information

**Purposes of the contained use**

Growth of a non pathogenic vibrio species up to 1L shake-flask volume expressing the non toxic B subunit of E.coli enterotoxin and recovery of the expressed protein from the cell culture supernatant.

**Recipient or parental organism**

Marine vibrio strain (considered non pathogenic to humans)

**Host/vector system**

An IPTG induced expression vector carrying the gene for the non-toxic B subunit of E.coli enterotoxin.

**Origin & function**

E.coli Enterotoxin B subunit expressed in a vibrio species.

Therapeutic uses,
- Allergy eg Allergic Rhinitis
- Autoimmune Disease eg Rheumatoid Arthritis
- Vaccine Adjuvant

**Evaluation of foreseeable effects**

No hazards have been identified.

The introduction of the B subunit genes of the E.coli enterotoxin into the vibrio organism is unlikely to alter any existing pathogenic traits.

The host cell line is considered non pathogenic to humans.

The B subunit of E. coli enterotoxin has been extensively evaluated in pre-clinical pharmacology studies without any adverse effects. As all vibrio species are assigned as biological hazard class 2 organisms by ACDP all project work (cell culture, primary recovery and purification) with the organism will be carried out in microbiology laboratories working to containment level 2.

All potentially contaminated waste will be autoclaved prior to disposal.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Following fermentation and primary recovery the culture supernatant will be 0.22 um filtered. No viable GMO will be present following this stage but samples will be tested for viable counts.

It is unlikely that the vibrio organism would survive in the environment and as the organism is already present in the wider marine environment the consequence of release of the organism into the environment is negligible.

All potentially contaminated waste will be autoclaved prior to disposal and uplifted from the site by an approved contractor.

Is an emergency plan required according to regulation 20? N

Project Additional Information

Purposes of the contained use

Quality control testing - the GMO is provided as a component within a commercial bioassay kit. The bioassay kit is used to determine the binding of affinity of IgGl mAbs to the CD32B Fc receptor stably expressed on HEK293 cells.

Recipient or parental organism

HEK293 cells from the American Type Culture Collection (ATCC. CRL-1573).
The parent HEK293 cell line contains adenovirus, which is deemed ACDP Hazard Group 2.
Where a cell line is deliberately infected with a biological agent or where it is likely that the cell line is contaminated with a particular agent, the containment level used must be appropriate for work with that agent - SACGM recommended baseline containment measures for work with cell cultures. Adenoviruses main route of transmission is via infected aerosol particles therefore all operations involving the cell line will be performed inside a Class II MSC thereby mitigating this risk. Adenoviruses can cause mild to severe illness, though serious illness is less common.
People with weakened immune systems, or existing respiratory or cardiac disease, are at higher risk of developing severe illness from an adenovirus infection. no such individuals will handle these cells.

Host/vector system

Initially amplified in the intermediate host E.coli DH5Alpha, the plasmid p-SNAP FcgRIIB containing the CD32B transgene was transfected into HEK293 cells using lipofectamine transfection reagent by Cisbio (commercial supplier). The plasmid DNA (CD32B transgene) is non mobilisable and there is no mechanism for independent replication following transfection. Consequently, existing pathogenic traits are not deemed to be altered from the transfection process. with the GMO considered a BSL-2 agent.

Origin & function

The physiological function of CD32B is to regulate the activation state of the expressing cell through interaction with other cell surface receptors. The CD32B gene incorporated into the HEK293 cell line is not deemed to have an impact on existing pathogenic traits; the transformation carried out to generate the recombinant DNA is assessed by Cisbio (cell line supplier) as containment level 1, with CD32B non-infectious for human health. Furthermore, “The SACGM Compendium of guidance Part 2: Risk assessment of genetically modified microorganisms” (p64) provides guidance on hazards posed by genetic insertion. The compendium demonstrates that if the gene is already present in nature (e.g. mammalian cells), the impact of transfer will be diminished. Considering that CD32B is a naturally occurring immune checkpoint Fc receptor, present in B cells of the human immune system, the risk to human health from
CD32B expression can be effectively judged as zero (i.e. it is non-toxic).
The GMO will be used at small scale for the performance of Quality Control bioassay analysis. The cells will be
utilised as "thaw-to-plate" cells; the cells are provided in single use aliquots by Cisbio, with the aliquot of cells thawed
and immediately applied in the bioassay. Consequently, there will be no propagation of the cell line at FUJIFILM
Diosynth Biotechnologies UK Ltd.

**Evaluation of foreseeable effects**

The parent HEK293 cell line is classified by ATCC as Biosafety Level-2 (BSL-2) (ACDP Hazard Group 2) as it
contains adenovirus genetic material. The adenovirus infection has not been altered during the lipofectamine
transfection process performed by Cisbio, with the GMO assigned BSL-2 status by the supplier. The plasmid DNA
(CD32B transgene) is non mobilisable and there is no mechanism for independent replication following transfection.
Consequently, existing pathogenic traits are not deemed to be altered from the transfection process, with the GMO
considered a BSL-2 agent.

The cells will be utilised as "thaw-to-plate" cells; the cells are provided in single use aliquots by Cisbio, with the aliquot
of cells thawed and immediately applied in the bioassay. Adenovirus' main route of transmission is via infected
aerosol particles however all operations involving the cell line will be performed inside a Class II MSC thereby
mitigating this risk, the cells will be chemically inactivated and discharged into yellow biohazard waste containers for
incineration, on completion of the testing. Furthermore, all materials and equipment exposed to the biological agent
(e.g. the Class II MSC) will be disinfected with chemical cleaning agents, designed to destroy viral particles. In
consideration of these practices, the risk of wider environmental containment being breached, can be effectively
judged as low risk. Additionally, the cell line will be handled in accordance with Biosafety Level-2 (BSL-2) guidelines
and as per laboratory practices for FUJIFILM Diosynth Biotechnologies UK Ltd BSL-2 Bioassay Laboratory.

The CD32B gene incorporated into the HEK293 cell line is not deemed to have an impact on existing pathogenic
traits; the transformation carried out to generate the recombinant DNA is assessed by Cisbio as containment level 1,
with CD32B non-infectious for human health. Furthermore, "The SACGM Compendium of guidance Part 2: Risk
assessment of genetically modified microorganisms" (p64) provides guidance on hazards posed by genetic insertion.
The compendium demonstrates that if the gene is already present in nature (e.g. mammalian cells), the impact of
transfer will be diminished. Considering that CD32B is a naturally occurring immune checkpoint Fc receptor, present
in B cells of the human immune system, the risk to human health from CD32B expression can be effectively judged as
zero (i.e. it is non-toxic).

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

NA

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

NA

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

The BSL 2 laboratory has a dedicated procedure for cleaning of the cell assay laboratory in addition to a cleaning
procedure for contamination in the laboratory.

The cell line is extremely unlikely to survive outside of assay media due to sensitivity to temperature, pH and culture
conditions, nonetheless the cells and disposable assay materials (e.g. assay plates and laboratory consumables) will
be chemically inactivated using Chemgene (anti viral disinfectant that denatures DNA & RNA) and discharged into
yellow biohazard waste containers for incineration on completion of the testing. These biohazard bins are locked and
disposed of by a licenced contractor (https://www.stericycle.co.uk) maintaining the cradle to grave containment

02/03/2022
approach. (assumed degree of kill of 100%). Furthermore, all materials and equipment exposed to the biological agent (e.g. the Class II MSC) will be disinfected with chemical cleaning agents, designed to destroy viral particles (chemgene).

Following testing by the department of Biochemistry at Cambridge University, HLD4 formulation was proven to precipitate I denature double stranded DNNRNA. Adenovirus genome is double stranded DNA.

02/03/2022
Project Additional Information

**Purposes of the contained use**

The laboratories are to be used for the growth and expansion of mammalian cell lines (primarily HEK293) and the production, purification and viral testing of Adeno Associated Virus. The cell culture may be perfomed using either adherent or suspension culture methods. The viral vectors will be produced by transient transfection or infection (from a viral stock) and once produced the vectors will be purified using chromatography, tangential flow filtration (TFF) and filtration (both depth and sterile filtration). The purified vectors will be analysed to determine the amount of virus and the quality of the vector produced using a number of biochemical and chemical techniques.

**Recipient or parental organism**

The parental organism is a Human Embryonic Kidney cell line (HEK293) that has been procured from OXgene and is a clonal suspension HEK cell line that has been optimised for the production of adeno associated viral vectors by triple transfection. The cells have not undergone additional genetic modification beyond the addition of some adeno viral sequences which were used to create the original HEK293 cell line in 1977. These cell have been used extensively in the production of viral vectors for many years.

**Host/vector system**

The adeno associated viral vector production utilises a plasmid triple transfection system. This vector system has been designed to ensure that the vectors that are produced are not able to replicate. In triple transfection a three plasmid system is used, in which one plasmid (rep/cap plasmid) codes for the structural components of the vector, the second plasmid (Helper plasmid) codes for the sequences from an adenovirus that are required for generation and assemblay of the vector, and the third plasmid (GOI or transgene plasmid) codes for the genetic information that will be encapsulated in the viral vector. The product coded by the transgene plasmid and the rep/cap plasmid will vary depending on the intended cellular target and disease that is being treated.

**Origin & function**

All the genetic material involved will be generated from a recombinant source; all the plasmids used for producing the viral vectors will initially be made by gene synthesis and then subsequently produced at a larger scale via fermentation in E.coli and subsequent purification at either Fujifilm Diosynth Biotechnologies or supplied by a customer. All materials used are well characterised and undergo safety testing prior to use or receipt at FDB.

The function of the plasmids used is to allow the production of AAV particles that contain a specific gene sequence.
Evaluation of foreseeable effects

The HEK293 cell line is a well-characterised and tested cell line that has been used in clinical research and production of therapeutics since the 1970s, and is therefore of low risk to human health. The primary concern comes from the presence of Adenoviral DNA within the cells. Adenoviruses are infectious to humans and cause human disease, however the HEK293 cell line doesn’t contain the full adenoviral sequence and cannot produce adenoviruses in the absence of an adenoviral infection. The cells are an immortalised cell line that has been shown to be oncogenic in mice at a high passage number. Whilst this may be a potential risk to human health, the cells will not be taken to a high number of passages from thaw and is therefore very unlikely to pose an oncogenic risk.

The AAV construct is specifically designed to be non-replication competent. The construct is produced by triple transfection of three plasmids to produce AAV vectors which is structurally the same as a wild type AAV but only contains an expression cassette that codes for the GOI and none of the Rep Cap or helper sequences that would be required for viral replication. Whilst these AAV vectors are not able to replicate, they can transduce specific cell lines, depending on the serotype. Therefore there is a risk that should an exposure event occur, an exposed individual could transiently make the product coded for by the GOI. Whilst in some cases the GOI product will be harmless, when a different GOI is used an assessment will be made to assess the potential risk. Where the GOI poses a risk to individuals, additional controls (if deemed necessary by the risk assessment) will be put in place to ensure the safety of the users and subsequent HSE notification will be made if the work is deemed higher than GM activity class 2.

The cell line is extremely unlikely to survive outside of culture media due to sensitivity to temperature, pH and culture conditions, therefore it is unlikely to be a risk to the environment. AAV is a relatively hardy virus; non-enveloped DNA virus and therefore relatively stable and resistant to dehydration. It is therefore possible that it could survive for extended periods in the environment. However, due to the design of the vector and the lack of modification to the structure of the viral capsid, it is not able to replicate and is not known to be able to cause disease or replicate in animal hosts. Therefore they are unlikely to pose any significant risk to the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste products that have potential to contain GMM will be treated with either Chemgene at a 10% v/v concentration or 10% v/v Sodium Hypochlorite, for up to 1hr. Chemgene has demonstrated virucidal activity against Parvoviruses (<4 log), Adenoviruses (3.68 log), and Lentiviruses (4.5 log), making it suitable for use as a disinfectant on all the viruses that could be made in the labs. They will then be autoclaved or placed into biohazard bins for incineration. These biohazard bins are locked and disposed of by a licenced contractor (https://www.stericycle.co.uk) maintaining the cradle to grave containment approach. (assumed degree of kill of 100%). Furthermore, all materials and equipment exposed to the biological agent (e.g. the Class II MSC) will be disinfected with chemical cleaning agents, designed to destroy viral particles (chemgene). Following testing by the department of Biochemistry at Cambridge University, HLD4 formulation was proven to precipitate / denature double stranded DNA/RNA.
Please enter comments on the GM safety committee on the risk assessment

Assessment circulated to GMSC on Jul 30th 2021.
1. Please see my comments on the attached document. I think the containment classes stated make sense to me. This looks like class 2 containment will be required.
   I'll be honest, I think I might need some graphics to explain the molecular biology content in more simple terms as there seems to be a lot here. I would need it more if I was to be convinced to lower it to class 1 containment. I would like to see what other members of the committee think.
2. I agree, I think there is a reasonable amount of evidence that the HEK's are probably class I but since PHE and FDBT handle them as class II it makes sense to follow that precedent.
3. In terms of the GMO RA, I've added a couple of comments. There is a bit of jargon that either needs explaining or rephrasing and a potentially superfluous/confusing passage which doesn't seem to add anything.
4. I agree with keeping it as a Class II. I also agree with the use of graphic and simplistic explanations.
5. Hi All, I agree as well! Class 2 based on the current information.
6. I agree with class II on current understanding especially if PHE use that classification.
7. I support this assessment. You need to add your details to section 8 - ‘assessment prepared by:’

Project Ref  109/21.3

Date Ackn'd 02/03/2022
Cloning and expression of a recombinant protein in CHO cell lines

The laboratories are to be used for the transfection, growth and expansion of CHO cells to enable stable cell lines expressing the recombinant proteins to be generated. The cell culture will be performed with suspension cell culture methods. Stable cell lines will be generated using plasmid DNA which will be transfected into cells using electroporation methods and then selected using a DHFR selectable marker. These recombinant cell lines will be used to generate recombinant proteins (using shake flasks) which will be purified and analysed.

The parental organism is an immortalised mammalian cell line, specifically a Chinese hamster ovary (CHO) cell line (CHO-DG44). The cells have not undergone any additional genetic modification and have been used for the production of recombinant proteins for many years. The CHO cell line comes from a GMP cell bank that has been tested for the presence of adventitious agents. It is a well characterised cell line with a low risk of endogenous infection with a biological agent presenting no apparent harm to laboratory workers (CL1).

The inserted DNA sequence covered by the risk assessment is an immunomodulatory protein, specifically the expression of the gene expressing a xxxxxxxx. The xxxxxxxxx has been engineered to bind human leukocyte antigen. The DNA for the xxxxxxxx to be expressed will be synthesised by commercial gene synthesis and then cloned into expression vectors. All materials used are well characterised and undergo safety testing prior to use or receipt at FDB. The function of the plasmids is to allow expression of the gene encoding the xxxxxxxxx product. The product plasmid is not designed to replicate in mammalian cells. The stable cell line will have linearised plasmid DNA.
integrated into the host cell genome. However, there are no mechanisms within the plasmid to enable transposition to other sites or replicons within the host i.e. the plasmid is non mobilisable.

**Evaluation of foreseeable effects**

The CHO DG44 cell line is well characterised and tested cell line that has been used in the production of therapeutics since the 1970s and is therefore of low risk to human health. The cell line is extremely unlikely to survive outside of the culture media due to sensitivity to temperature, pH and culture conditions, therefore it is unlikely to be a risk to the environment.

The primary concern comes from the GOI which may cause a risk to human health. The antibody being expressed is biologically active at low doses. This means that the acceptable daily exposure (ADE) limits for this molecule is low and the secretion of active molecule from the GMM could make the recombinant cell line a risk to workers via internalisation (principally via inhalation). Cell lines will be handled in accordance with containment level-2 guidelines and all staff working with these cell lines will follow site safety procedures.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Liquid waste containing the GMM will be treated using > 1% v/v chemgene for > 2 hours (internal study has shown this achieves 100% cell death). This will then be either disposed of via the drain to the public sewer or placed into biohazard bins for incineration.

Solid waste that has been exposed to the GMM will be placed into biohazard bags before being put into biohazard bins for incineration. The biohazard bins are locked and disposed of by a licenced contractor (https://www.stericycle.co.uk) maintaining the cradle to the grave containment approach. Assumed degree of kill of 100%.

Furthermore, any equipment and materials exposed to the GMM (e.g class II biological safety cabinet) will be disinfected with chemical cleaning agents as described above.

An autoclave is present in the building where the work will take place. The autoclave is on a service contract and is inspected annually where the autoclave is tested and verified and a calibration is performed. Autoclave tape is used as a visual aid to show whether run has been successful and records of each run are kept in a logbook.

**Is an emergency plan required according to regulation 20?**

Purposes of the contained use

The laboratories are to be used for the growth and expansion of CHO cells to enable stable cell lines expressing the GOI under test to be generated. The cell culture will be performed with suspension cell culture methods. Stable cell lines will be generated using plasmid DNA which will be transfected into cells using electroporation methods and then
selected using a DHFR selectable marker. These recombinant cell lines will be used to generate protein (using shake flasks or bioreactors) which will purified and analysed. The notification has been submitted as a connected programme of work (more than one contained use at a single notified premises) at FDBK (Billingham & Wilton) as the scientific goals align i.e Mammalian cells are genetically modified to express recombinant proteins which will be purified and analysed as biotherapeutics. The cell line and vectors used will not change for this programme, the only variable is the gene of interest (GOI) product. A risk assessment for each GOI will be undertaken and reviewed by FUJIFILM Diosynth Biotechnologies GMSC to ensure the risk does not exceed GM activity class 2. If the risk exceeds the original classification or if additional controls are required, a new contained use notification will be made.

Recipient or parental organism

The parental organism is an Immortalized mammalian cell line, specifically a Chinese hamster ovary (CHO) cell line (CHO-DG44). The cells have not undergone any additional genetic modification and have been used for the production of recombinant proteins for many years. The CHO cell line comes from a GMP cell bank that has been tested for the presence of adventitious agents. It is a well characterised cell line with a low risk of endogenous infection with a biological agent presenting no apparent harm to laboratory workers (CL1).

Host/vector system

CHO-DG44 DHFR selection system The plasmid backbones are non-mobilisable. Introduction of plasmids into cells will be accomplished by DNA-mediated transfection.

Origin & function

The inserted genes will be immunomodulatory proteins such as high potency fusion proteins, bispecific and trispecific proteins which are biologically active at low doses. There are no plans to work with active toxins, allergens, Oncogenes or hormones. It is possible that work may be performed to express cytokines and growth factors. Examples of such proteins are (but not limited to):
- Vibecotamab (XmAb®14045), a tumor-targeted bispecific antibody (BiAb) that contains both a CD123 binding domain and a cytotoxic T-cell binding domain (CD3).
- Aflibercept is a recombinant fusion protein that acts as a soluble decoy receptor and binds to vascular endothelial growth factors A and B (VEGF-A, VEGF-B) and placental growth factor (PIGF). Aflibercept inhibits the activation of VEGF receptors and the proliferation of endothelial cells, thereby inhibiting the growth of new vessels that supply tumours with oxygen and nutrients.
- Rilonacept is a dimeric fusion protein consisting of the ligand-binding domains of the extracellular portions of the human interleukin-1 receptor component (IL-1R1) and IL-1 receptor accessory protein (IL-1RAcP) linked in-line to the fragment-crystallizable portion (Fc region) of human IgG1 that binds and neutralizes IL-1.
- Eloctate is a recombinant Antihemophilic Factor, Fc Fusion Protein, it is a recombinant DNA derived, antihemophilic factor indicated in adults and children with Hemophilia A (congenital Factor VIII deficiency).
- Glofitamab is a bivalent CD20-Targeting T-Cell–Engaging Bispecific Antibody

The most potent of these being vibecotamab which has been assessed in the risk assessment. Each molecule will be assessed in the same level of detail outlined in this Risk assessment prior to experimental work. The vectors used are designed to allow the expression of the gene of interest. The DNA for proteins to be expressed will be synthesised by commercial gene synthesis and then cloned into expression vectors. All materials used are well characterised and undergo safety testing prior to use or receipt at FDB.
The function of the plasmids is to allow expression of the GOI. The product plasmid is not designed to replicate in mammalian cells. The stable cell line will have linearised plasmid DNA integrated into the host cell genome. However, there are no mechanisms within the plasmid to enable transposition to other sites or replicons within the host i.e. the plasmid is non mobilisable. CPW boundaries will be implemented to exclude any higher risk activities-A risk assessment for each GOI will be undertaken and reviewed by FDB's GMSC to ensure the risk does not exceed GM activity class 2. If it is deemed to increase the activity above Class 2 then the activity will not be permitted.

Evaluation of foreseeable effects

The CHO DG44 cell line is well characterised and tested cell line that has been used in the production of therapeutics since the 1970s and is therefore of low risk to human health. The cell line is extremely unlikely to survive outside of the culture media due to sensitivity to temperature, pH and culture conditions, therefore it is unlikely to be a risk to the environment.

The primary concern comes from the GOI which may cause a risk to human health. Examples of the proteins being expressed are bispecific and trispecific molecules which are biologically active at low doses. There are no plans to work with active toxins, allergens, Oncogenes or hormones. It is possible that work may be performed to express cytokines and growth factors. Each new molecule will be assessed with respect to their potency prior to the initiation of any experimental work in the FDBK laboratories which has the potential to expose the operator to the substance, via any route. The assessment is performed by the Contamination Control Group, who will generate both a provisional Acceptable Daily Exposure limit (ADE) and a provisional Operator Exposure Limit (OEL). The assessment will be approved by the EHS manager prior to issue. The potency as indicated by the OEL will determine the control measures that are required to constrain operator exposure to below safe health based limits. Using this molecule information, any potentially harmful effects associated with the GOI, in which the transgene does encode a cytokine or growth factor (or other potentially harmful insert) will be taken into account in the GMO risk assessment. If the risk assessment (taking into account the nature of the work) determines the expressed product/API is harmful to human health and safety at any point in the process then it will be carefully considered when assigning an appropriate level of containment, FDBK would not work with anything above GM activity class 2.

Cell lines will be handled in accordance with containment level-2 guidelines and all staff working with these cell lines will follow site safety procedures.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste containing the GMM can be autoclaved or treated using > 1% v/v chemgene for > 2 hours (internal study has shown this achieves 100% cell death). This will then be either disposed of via the drain to the public sewer or placed into biohazard bins for incineration.

Solid waste that has been exposed to the GMM will be placed into biohazard bags before being put into biohazard bins for incineration. The biohazard bins are locked and disposed of by a licenced contractor ([https://www.stericycle.co.uk ] maintaining the cradle to the grave containment approach. Assumed degree of kill of 100%.

Furthermore, any equipment and materials exposed to the GMM (e.g class II biological safety cabinet) will be
disinfected with chemical cleaning agents as described above. An autoclave is present in the building where the work will take place. The autoclave is on a service contract and is inspected annually where the autoclave is tested and verified and a calibration is performed. Autoclave tape is used as a visual aid to show whether run has been successful and records of each run are kept in a logbook.

CRS by inhalation appears to be a real risk and CRS looks unpredictable in severity depending on the individual. Xx Not sure if this is helpful but the NIH have shared a paper from the UK which recommends class 2 minimum for what they call Cytotoxic Agent Research Laboratories (CARL): https://www.ncbi.nlm.nih.gov/pmc/articles/PMC7720356/

From everything I have read in the attached documents, HSE guidance and online info on CRS I would be recommending containment level 2 controls even though the cell line is well characterised and level 1.

I agree with xx that it should be Containment Level 2 due to the nature of the API.

xx, xx, xx, xx, xx xx: I support this assessment.

xx. I agree with earlier comments from xx. I think there are useful suggestions in the paper which if not already included in the SHESOP should be included in the RA for this project and rolled into future SHESOP updates.

The committee agreed there was scope for a CPW submission.

Project Ref 109/22.1

Date Ackn’d: 24/02/2022  Use of a genetically modified HEK293 cell line from InvivoGen (commercial supplier)

Class: Class 2  CultureVolClass2: < 1 Litre  CultureVolumeClass3-4: 

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
Purposes of the contained use

Quality control testing - the GMO is provided as a component within a commercial bioassay kit. The bioassay kit is used to determine the in vitro biological potency of IFNa/b through the SEAP reporter gene stably expressed on HEK293 cells.

Recipient or parental organism

The parent HEK293 cell line is classified by ATCC as Biosafety Level-2 (BSL-2) as it contains Adenovirus 5 (ATCC, Cat# CRL-1573), however only left end sequences of the viral genome are present. The Ad5 insert was cloned and sequenced, and it was determined that a colinear segment from nts 1 to 4344 is integrated into the chromosome.

Host/vector system

The HEK-293 cell line has been genetically modified by InvivoGen to express a secreted embryonic alkaline phosphatase (SEAP) reporter gene under the control of the type I interferon pathway. The receptors are added by simple transfection of plasmids using a cationic lipidic transfection agent (the plasmids are not linearized before transfection). There is no mechanism within the plasmid (SEAP transgene) for independent replication following transfection. Consequently, existing pathogenic traits are not deemed to be altered from the transfection process, with the GMO considered a BSL-2 agent.

Origin & function

SEAP removes phosphates from a variety of molecules. It is a common tool in biology and although is classified as an irritant, the concentration in the culture shall be low and highly unlikely to cause irritation to process operators. The SEAP gene incorporated into the HEK293 cell line is not deemed to have an impact on existing pathogenic traits; Furthermore, “The SACGM Compendium of guidance Part 2: Risk assessment of genetically modified microorganisms” (p64) provides guidance on hazards posed by genetic insertion. The compendium demonstrates that if the gene is already present in nature, the impact of transfer will be diminished.
The parent HEK293 cell line is classified by ATCC as Biosafety Level-2 (BSL-2) (ACDP Hazard Group 2) as it contains adenovirus genetic material. Despite the GMO containing Adenovirus 5 viral DNA, the risk of Adenovirus 5 (Ad5) infection to process operators is deemed to be low as the GMO is unlikely to produce active (replicating) or infectious Adenovirus 5.

Adenovirus’ main route of transmission is via infected aerosol particles however all operations involving the cell line will be performed inside a Class II MSC thereby mitigating this risk, the cells will be chemically inactivated and discharged into yellow biohazard waste containers for incineration, on completion of the testing. Furthermore, all materials and equipment exposed to the biological agent (e.g. the Class II MSC) will be disinfected with chemical cleaning agents, designed to destroy viral particles. In consideration of these practices, the risk of wider environmental containment being breached, can be effectively judged as low risk. Additionally, the cell line will be handled in accordance with Biosafety Level-2 (BSL-2) guidelines and as per laboratory practices for FUJIFILM Diosynth Biotechnologies UK Ltd BSL-2 Bioassay Laboratory.

The SEAP gene incorporated into the HEK293 cell line is not deemed to have an impact on existing pathogenic traits; the cell line was transfected using cationic lipid agents for delivery of the plasmid DNA, with stable clones maintained under selection pressure. Additionally, the HEK-Blue™ IFN-α/β cell line has demonstrated a high degree of stability (up to 20 passages post thaw) from the vendor (InvivoGen). No mechanisms exist within the host organism to enable transposition to other sites or replicons within the host. Consequently, the transformation carried out to generate the recombinant DNA is extremely unlikely to have affected pathogenicity, with the GMO incapable of replicating or producing infectious Adenovirus 5. Furthermore, ‘The SACGM Compendium of guidance Part 2: Risk assessment of genetically modified microorganisms’ (p64) provides guidance on hazards posed by genetic insertion. The compendium demonstrates that if the gene is already present in nature (e.g. Human placenta), the impact of transfer will be diminished.

Evaluation of foreseeable effects

Not applicable.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The BSL 2 laboratory has a dedicated procedure for cleaning of the cell assay laboratory in addition to a cleaning procedure for contamination in the laboratory. The cell line is extremely unlikely to survive outside of assay media due to sensitivity to temperature, pH and culture conditions, nonetheless the cells and disposable assay materials (e.g. assay plates and laboratory consumables) will be chemically inactivated using Chemgene (anti viral disinfectant that denatures DNA & RNA) and discharged into yellow biohazard waste containers for incineration on completion of the testing. These biohazard bins are locked and disposed of by a licenced contractor (https://www.stericycle.co.uk) maintaining the cradle to grave containment approach. (assumed degree of kill of 100%).

Furthermore, all materials and equipment exposed to the biological agent (e.g. the Class II MSC) will be disinfected with chemical cleaning agents, designed to destroy viral particles (chemgene). Following testing by the department of Biochemistry at Cambridge University, HLD4 formulation was proven to precipitate / denature double stranded DNA/RNA. Adenovirus genome is double stranded DNA, (https://www.scientificlabs.co.uk/handlers/libraryFiles.ashx?filename=Technical_Data_Sheets_C_CLE3360_A.pdf)
Autoclaves are accessible in both buildings where the contained use will be carried out i.e both Billingham and Wilton.

The biosafety committee had no comments on the risk assessment and supported the approach and assignment of GM activity class 2 /containment level 2. The risk assessment was signed off on the 24th Jan 2022.

Historical Significant Changes
The purpose of the contained use in this project is to create isogenic mutants of C. difficile by removing (deleting) phage sequences from bacterial host genomes, enabling comparison of growth, virulence, phage susceptibility and gene expression between deletion mutants and wild type strains in vitro.

E. coli and C. difficile will be recipients of genetic modification. E. coli strains derived from disabled K12 (e.g. DH5alpha and TOP10) will be used for the construction and propagation of recombinant plasmids, and CA434 (i.e. E. coli HB101, which is derived from disabled K12 and carrying the IncPbeta conjugative plasmid, R702) will be used for the transfer of recombinant plasmids to C. difficile through conjugation [1].

C. difficile is an anaerobic spore forming bacterium in hazard group 2; toxigenic strains can cause C. difficile infection in humans and neonatal piglets under certain conditions while non-toxigenic strains are largely known not to cause disease, with evidence of protection against toxigenic strain infection in animal models and piglets [2-4]. Almost all toxigenic and non-toxigenic strains, either with known genome sequences or not, contain phage sequences/phages. The significance of phages is not well-established, although there is some evidence of phage-mediate toxin-regulation [5] and antibiotic gene transfer [6], hence the purpose of this project.

References
Host/vector system

pMTL8000 series and its derivatives, such as pMTL-SC7315 and pMTL-SC7215 are widely used for cloning and genetic manipulation of genes in C. difficile [1, 2]. The vector encodes a traJ gene for conjugation between E. coli and C. difficile, a CoIE1 for replication in E. coli, different replicons for replication in C. difficile strains, and either catP, ermB, or tetA encoding chloramphenicol resistance, erythromycin resistance, or tetracycline resistance, respectively for selection of C. difficile transconjugants [1].

Plasmids in this series can integrate into the chromosome by homologous recombination via a designed sequencespecific cassette. However for the purpose of this project, double crossover mutants will be selected for where the plasmid will be lost. Such mutants will be selected for using either codA for counter selection of C. difficile transconjugants on 5-fluorocytosine [2], or a CRISPR-based system selection, which is lethal to cells that do not undergo homologous recombination [3, 4]. Either codA, or a cassette containing sgRNA and either Cas9 or Cas12a gene will be cloned into the vector backbone as previously described [2, 3] [4].

References

Origin & function

The genetic material involved are of bacterial and phage origin. The pMTL8000 plasmids and antibiotic resistance gene markers are derived from C. difficile plasmids and transposons. The allele exchange cassette or sgRNA sequence will be derived from phage. The intended functions are to enable replication of plasmids within C. difficile, selection of transconjugants, and deletion of phage genomes by gene editing or allelic replacement.

Deletion of prophage genomes can be achieved either through a one-stage process if using a CRISPR-Cas approach, or a two-stage process if using counter-selection methods. The CRISPR-Cas approach involves selecting for viable transconjugants which have the intended deletion in the genome. The Cas9 or Cas12a gene sequences are derived either from E. coli or Streptococcus pyogenes [1, 2]. Counter selection method involves first selecting for singlecrossover integration followed by isolation of double-crossover excision events using replicative-defective plasmid that carry a counterselection marker, codA, derived from E. coli. CodA confers sensitivity to 5-fluorocytosine (FC), so that double-crossover recombinant clones which have lost the recombinant plasmid will be resistant to FC [3].

References

The E. coli strains are equivalent to hazard group 1. GM E. coli strains will not be pathogenic, and recombinant plasmids they harbour will not encode any virulence genes. Hence it is not expected to cause harm to other organisms. There should not be any hazard associated with E. coli transfer of the plasmid to other C. difficile or bacteria, as the allelic exchange cassette for deletion is sequence specific to the targeted phage genome. The plasmid is transferred at very low frequencies and is unstable in the intended host (C. difficile) [1, 2].

The strains used in this project will be toxigenic (e.g. CD630, R20291, LiBA-5763, CD843) and non-toxigenic (e.g. CD062, CD80, CD37) strains which contain phage sequences [3-6]. There should not be any foreseeable effects that are significantly different from wild-type C. difficile infection arising from the deletion of prophage genomes from C. difficile genomes. Prophage genomes do not have pathogenic traits, and they are not integrated into virulence genes so that prophage deletion will not result in a functional virulent gene. Prophage deletion is expected to result in reduced virulence, transmission abilities, and horizontal gene transfer, based on current literature and hypotheses. Disease transmission is by exposure to C. difficile spores, hence environmental contamination can only occur if spores were not inactivated before leaving the containment facility. This would be prevented by waste management procedures outlined in the section below.

References

Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not applicable

For only GMMS - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All solid waste generated from the laboratory will be sealed in plastic bags and decontaminated by autoclave for 30 minutes at 124°C for 100% kill prior to disposal off-site by University approved procedures. The types of solid waste include: agar cultures, disposable pipette tips and serological pipettes, disposable plastic tubes and bottles, paper towels used to wipe down benches with 10% hypochlorite or 1 % Anigene. All liquid waste generated from the laboratory will be decontaminated by autoclave as described above. Autoclaved liquid waste will then be poured down a laboratory sink and flushed with water. The types of liquid waste include liquid cultures, small volumes (<1 mL) of bacterial resuspensions in water used for boiling prior to PCR, small volumes (<1mL) of chemically lysed bacterial cells used for genomic DNA extractions. Autoclaving is the most effective method of sterilisation and is expected to kill 100% of C. difficile spores. This was
validated by spiking 10 mL and 100 mL of brain heart infusion broth (BHIB) with 10^{18} cfu/mL and 10^{17} cfu/mL, respectively, of C. difficile spores (ribotype 078 strain). Viable counts of both cultures were done on pre-reduced Brazier's agar. The liquid cultures were decontaminated by autoclaving at 124 degrees C for 30 mins. Viable counts of both cultures were carried out again, and no colony growth was detected after incubation for 72h. Decontaminated cultures were also inoculated in 1 mL volumes to 9 mL of fresh (pre-reduced) BHIB and incubated for 72h. No growth was observed, as determined by 00600 readings.

1. The latest version of the University's Biosafety management document (version 6) should be referred to.
2. GM cultures should be stored in a locked fridge and freezer to further restrict access to users directly involved in this work. Archived bacterial stocks should be stored in a locked deep freezer to reduce access to people not involved in this project. Hence a lockable fridge/freezer will be purchased to be housed in 2J013, and glycerol stocks will be stored in a lockable deep freezer in 1J006.
3. A training record should be kept with training details and date.
4. The method of transporting GMO between labs should be outlined.
5. It should be made clear that students who are at risk of C. difficile infection (COI) will not be allowed to work with the pathogen, even though the groups at risk of COI (e.g. hospitalised patients, the elderly above 65 years old, immunocompromised and on antibiotic therapy) are unlikely to undertake research.

The risk assessment has been amended taking into account the committee's comments

Purposes of the contained use

The research is concerned with the study of dormancy/persistence in M. tuberculosis, the causative agent of tuberculosis. Anarabiosis, host fatty acid metabolism, cell wall thickening, synthesis of a 16-kDa-crystallin protein and associated transcriptional regulators/signalling pathways have all been postulated to play a role in the ability of M. tuberculosis to persist in the host for long periods of time and cause reactivation disease.

To study the role these genes may play in persistence, deletion mutants in the related vaccine strain, M. bovis BCG, will be made where the gene of interest will be replaced with an antibiotic resistance gene. This will help determine the effect of knocking out specific genes on the ability of the mutant strains to grow anaerobically, survive in macrophages in vitro, generate a thickened cell wall, etc. This should help elucidate a particular gene's contribution to the phenomenon of mycobacterial persistence.

Recipient or parental organism

Host: M. bovis BCG is an ACDP class 2 organism and can be worked with on the open bench. The organism is an attenuated strain of the pathogenic species M bovis and since the 50s has been given in a live form intradermally as a vaccine to protect against tuberculosis. It has a history of safe use.

Recipient or parental organism

The vector is a suicide plasmid pXii82C15 which is identical to the non-mobilisable pGEM3Z(+) f vector except that it contains a minimal (750bp) pAL500 mycobacterial origin of replication to enable the vector to replicate once in the host following transformation. The single round of replication provides time for the homologous sequences carried on the vector and on the wild type chromosome to recombine. As with pGEM3Z(+)f, the suicidevector carries an ampicillin resistance coding region. The vector has also been modified to carry two counter selectable marker genes. These are the E. coli lacZ which encodes B-galactosidase to determine blue/white colour selection of mutants and the B. subtilis sacB which encodes levansucrase which converts sucrose to levans which is harmful to bacteria and leads to the death of transformed bacteria when they are plated onto agar containing 10% sucrose. Thus sucrose sensitivity acts as a second counterselectable marker for positive selection of allelic exchange events.

Host/vector system

Donor nucleic acid sequences will be obtained from M. bovis BCG which is an attenuated strain of M. bovis. Since the 1950s it has been used as a vaccine against tuberculosis. The genetic basis for its attenuation is now known. It has three deletions (RD1-RD3) relative to its progenitor M bovis, and 10 deletions (RD1-RD10) relative to the human pathogen M. tuberculosis. Among the known products encoded by the loci which are deleted in M bovis BCG and contribute to its attenuation are an invasin, several phospholipases, glycine-rich polymorphic proteins, the ESAT-6 secreted proteins and an epoxide hydrolase. The DNA sequence encoding resistance to the antibiotic hygromycin, which is not used therapeutically, will be obtained from the non-pathogenic soil actinomycete, Streptomyces hygroscopicus.

The aim of the work is to knock out/delete the function of the gene pertinent to the study of mycobacterial persistence by replacing it with the hygromycin resistance gene. The insert present on the vector to be transformed will comprise the hygromycin resistance gene with several kilobases of genomic M bovis BCG DNA flanking the gene on either side. This is needed to enable the homologous sequences present on the wild type chromosome and the GMM to recombine homologously and replace the gene of interest with the hygromycin resistance gene following transformation into the M bovis BCG host. Genes of interest to be replaced will include those postulated to play a role in mycobacterial resistance such as the hspX gene encoding the 16-kDa-crystallin protein, genes encoding the biochemical components of the thickened cell wall, and genes encoding transcriptional regulators and components of signalling pathways involved in sensing low oxygen conditions and the presence of nitric oxide.

Evaluation of foreseeable effects

There should be no effect on human health. M bovis BCG is administered to humans in the form of a live vaccine and knocking out/deleting genes involved in mycobacterial persistence should, if anything, lead to attenuation of the mutant strains and lessen the organism's ability to survive/persist in human tissue. It is highly unlikely that the GMO would be able to colonise or infect humans, but if it did, an infection caused by the GMO could be treated readily with the antimycobacterial drugs rifampicin and isoniazid. The drug target for these agents would still be intact in the GMOs as they are not involved in persistence and would therefore not be targeted for
deletion studies. There is negligible risk of accidental release and negligible risk to the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

no derogation

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All cultures are to be autoclaved prior to disposal. Degree of kill - effectively 100%
Laboratory consumables such as tips and loops will be soaked in 2% stericol overnight, drained and placed in sharps box for disposal by incineration. Phenolic compounds such as Stericol are effective against tubercle bacilli at concentrations of between 0.2-3% within 20-30 minutes contact time (Vesley and Lauer in Laboratory Safety - Principles and Practices, 2nd Edition 1995, eds Fleming, Richardson, Tulis and Vesley, ASM Press, Washington DC).

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The local GMSC has approved this activity.

Project Ref 116/01.11

Date Ackn'd 11/05/2001

CU2 Project Title OVEREXPRESSION OF AKT, TIE 1 & 2, ANGIOPOIETIN, VEGFS,

Class 2

CultureVolClass2 < 1 litre

CultureVolumeClass3-4
To investigate the role of vascular endothelial cell growth factor family (VEGF-A-D and placenta growth factor/PIGF) and their cognate receptors (Flt-1, Flt-4 and KDR) and the Tie receptor tyrosine kinases (Tie-1 and Tie-2) and their ligands the angiopoietins (Ang 1-4), in both physiological and pathological angiogenesis. Replication defective adenovirus will be generated to express wild type or dominant negative mutants of these growth factors and receptors to investigate their activity in vitro. Endothelial, trophoblast and other cell lines will be transfected with adenovirus and their activity examined in various assays, eg proliferation, migration and tube formation. In order to delineate the signalling pathways activated by these receptors we will use replication defective adenovirus expressing wild type or dominant negative mutants of signalling molecules (Akt/PKB, HO-1 and PKC family) that lie downstream of these receptors.

Recipient or parental organism

Host: Embryonic kidney 293 cells which complement the replication deficiency; these cells have adenovirus tumour genes that complement the replication deficiency in the adenovirus.

Host/vector system

Vector: Adenovirus Type 5, E1 and E3 deleted. The site of insertion is the E1 site of an adenovirus Type 5 E1 replacement vector, eg pACCMVpLpA. The plasmid contains the CMV promoter for efficient expression of the effector genes. Recombinant (Replication defective) virus will be produced following transfection of the resultant plasmids into human embryonic kidney 293 Cells, together with a plasmid clone of E3-deletion partial adenovirus genome, which allows recovery of the virus by homologous recombination. Recombinant adenoviruses will also be produced by homologous recombination in a bacterial system (E.coli strain BJ5183) as described by Chartier et al (J. Virol 70:4805 - 4810, 1996). The adenoviral DNA and "shuttle" plasmid (pAD.CMV-Link.1) with the effector gene are recombined in the above mentioned bacterial cells. Linearised DNA (encoding the replication defective adenovirus and effector gene) will transfected into HEK 293 cells and the virus recovered by purification. The shuttle plasmid has a gene cassette that replaces the E1 adenoviral sequences with a CMV promoter, multiple cloning site and SV40 polyadenylation signal. This cassette is flanked by human adenovirus type 5 sequences consisting of 0-1 map units for the left arm and 9-16 map units for the right arm.

Origin & function

Donor: Mouse and/or human cDNA cloned by PCR.

The genetic material includes AKT, VEGFs, HO-1, Tie 1 and Tie 2 angiopoietin, PKC family.

To investigate the role of vascular endothelial cell growth factor family (VEGF-A-D and placenta growth factor/PIGF) and their cognate receptors (Flt-1, Flt-4 and KDR) and the Tie receptor tyrosine kinases (Tie-1 and Tie-2) and their ligands the angiopoietins (Ang 1-4), in both physiological and pathological angiogenesis. Replication defective adenovirus will be generated to express wild type or dominant negative mutants of these growth factors and receptors to investigate their activity in vitro. Endothelial, trophoblast and other cell lines will be transfected with adenovirus and their activity examined in various assays, eg proliferation, migration and tube formation. In order to delineate the signalling pathways activated by these receptors we will use replication defective adenovirus expressing wild type or dominant negative mutants of signalling molecules (Akt/PKB, HO-1 and PKC family) that lie downstream of these receptors.

Recipient or parental organism

Host: Embryonic kidney 293 cells which complement the replication deficiency; these cells have adenovirus tumour genes that complement the replication deficiency in the adenovirus.

Host/vector system

Vector: Adenovirus Type 5, E1 and E3 deleted. The site of insertion is the E1 site of an adenovirus Type 5 E1 replacement vector, eg pACCMVpLpA. The plasmid contains the CMV promoter for efficient expression of the effector genes. Recombinant (Replication defective) virus will be produced following transfection of the resultant plasmids into human embryonic kidney 293 Cells, together with a plasmid clone of E3-deletion partial adenovirus genome, which allows recovery of the virus by homologous recombination. Recombinant adenoviruses will also be produced by homologous recombination in a bacterial system (E.coli strain BJ5183) as described by Chartier et al (J. Virol 70:4805 - 4810, 1996). The adenoviral DNA and "shuttle" plasmid (pAD.CMV-Link.1) with the effector gene are recombined in the above mentioned bacterial cells. Linearised DNA (encoding the replication defective adenovirus and effector gene) will transfected into HEK 293 cells and the virus recovered by purification. The shuttle plasmid has a gene cassette that replaces the E1 adenoviral sequences with a CMV promoter, multiple cloning site and SV40 polyadenylation signal. This cassette is flanked by human adenovirus type 5 sequences consisting of 0-1 map units for the left arm and 9-16 map units for the right arm.

Origin & function

Donor: Mouse and/or human cDNA cloned by PCR.

The genetic material includes AKT, VEGFs, HO-1, Tie 1 and Tie 2 angiopoietin, PKC family.
Ad5 infects humans and is classified as an ACDP level 2 pathogen. In adults it does not normally cause disease as most adults will have been exposed to one of the common subgroup C viruses (which includes Ad5) by adolescence. Ad5 primarily infects the respiratory tract, although it is shed via the gut and can probably replicate therein. The vectors used in the present study will be replication defective (by virtue of the E1 deletion) and are therefore regarded as safer than the wild type virus. The possibility that replication competent virus may arise by recombination with the permissive cell line is recognised, although this does not occur with high frequency.

The presence of replication competent virus can be detected by infecting a cell line that does not complement the E1 deficiency, such as HeLa cells, than harvesting after 5-7 days and testing the lysates for plaquing or CPE on HeLa or A549 cells. We will test for replication competent virus on the initial batch of adenovirus prepared from a seed stock. If any contamination is found in this batch of adenovirus prepared from the seed stock, both adenovirus and seed stock will be discarded.

The recombinant virus will not be capable of autonomous spread in the event of accidental operator infection. In the unlikely event that an operator received and infective dose of virus via the respiratory tract, it would only cause a productive infection if the operator had a pre-existing infection with wild type virus and the same cells took up the recombinant virus. Sub group C serotypes are known to persist in adenoids and tonsils following primary infection, but the mechanism by which the virus is maintained is not clearly understood. The number of virus containing cells is low, and most virus remains cell associated and can only be detected after prolonged incubation of the tissue in vitro. Thus the risk of double infection with recombinant and wild type virus is considered to be very low. The possibility of co-infection in the gut should be considered. While it is known that, in some instances, there is prolonged shedding of sub group C viruses via the alimentary canal, there is no evidence to suggest that there is long term persistence of the virus so the opportunity for coinfection of a single cell with both wild type and recombinant virus is considered remote.

The effect of the insert should also be considered: the virus will be capable of expressing the protein in human cells infected, but will not be capable of autonomous spread as the virus is replication defective, localising the effect. With good laboratory practice the risk will be minimised. The most likely source of accidental exposure will be from aerosolisation. The virus will be handled in a Class II safety cabinet, thus minimising the risk.

Any exposure to the incoming virus would be likely to elicit an immune response. The major capsid protein is the major neutralising antigen; there would be a primarily type 5 response. Most individuals have a pre-existing immunity to Ad5 and a secondary immune response to the recombinant virus would be expected.

Environmental considerations: The recombinant adenovirus is replication defective and will not have an extended host range, therefore the potential hazard to the environment is negligible. Accidental release is unlikely from the containment conditions.

Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste will be collected in an autoclave bag for transfer to autoclave in a robust container. The waste will then follow the clinical waste route, being taken away by an approved contractor for ultimate disposal by incineration. Degree of kill - effectively 100%.

Contaminated liquid waste will be collected in screw capped pots containing 1% Virkon. Contaminated glassware, plastic tips will be submerged in 1% Virkon for at least 30 minutes. Following submersion in Virkon plastic tips will be disposed of in a sharps bin to be sent for incineration.

1% Virkon will be used for disinfection. Exposure to a 1% solution of Virkon for 15 minutes has been shown to inactivate adenovirus infected cell pellet by >4 log scale. A 1% solution also inactivates adenovirus seed stock by >6 log scale (Institute of Cancer Studies, University of Birmingham).
Please enter comments on the GM safety committee on the risk assessment

Query: The proposers do not seem to be aware that 293 cells contain adenovirus tumour genes, or at least it is not explicit that they are.

Response: Assessment amended to make this clear.

Query: Original assessment stated that Virkon, hypochlorite and SDS would be used for disinfection - the efficacy of these was questioned by a number of GMSC members.

Response: Virkon chosen as disinfectant. Has been tested against adenovirus by Institute of Cancer Studies.

Query: Are applicants going to monitor batches of virus for presence of wild type virus?

Response: Presence of wild type virus to be monitored per seed stock prepared for fresh batch of virus. To be done using a non-complementing cell line and checking for the lytic cycle.

Query: What harm would the inserts do if the recombinant got into a person and were expressed.

Response: There is a small risk of the insert expressing in the case of accidental operator exposure although the effect will be localised as the viruses are not replication competent.

Query: How are Class II cabinets vented? Into lab through double HEPA filter?

Response: Yes, through two HEPA filters into lab.

The genes encoding the \(\alpha\) and \(\beta\) peptide chains of the HLA-DQ6 molecule (DQA1*0102 and DQB1*0602 respectively) have been cloned into the pALTERMAX vector (Promega) and subjected to site-directed mutagenesis to create 10 mutant alleles (previously approved work). We now plan to use these mutant alleles to create a range of artificial antigen-presenting cells expressing variant forms of the DQ6 molecule. The alleles will be subcloned into the pClneo plasmid expression vector (Promega) and the suitable pairs of cloned alleles will be introduced into the HLA class II deficient B lymphocyte cell line, BLS-1, by electroporation. The antigen-presenting cells will then be used in functional studies, investigating the ability of the mutant molecules to a) bind to peptides derived from antigens relevant to the pathogenesis of Type 1 diabetes and b) activate DQ6-restricted T cell clones. This assessment relates to the gene transfer into the BLS-1 line.

**Recipient or parental organism**

Host: Initial host - E. coli strain DH5x - disabled, non-colonising laboratory adapted host. Non-pathogenic to humans. Final host - EBV transformed B lymphoblastoid cell line, BLS-1. This is derived from a human with a bare lymphocyte syndrome, a genetic disorder which precludes the expression of HLA class II molecules on the cell surface. The cell line is unable to colonise the workers as it will provoke a host - versus - graft immune response (BLS-1 is HLA class I incompatible with both staff members who will be working with it). The cell line is considered to pose a potential risk of infection with EBV.

**Host/vector system**

Vector: pClneo plasmid expression vector (Promega). Contains SV40 enhancer and early promoter regions including SV40 origin of replication, f1 origin of replication, CMV immediate early enhancer/promoter region for constitutive expression of cloned gene in mammalian cells, ampicillin resistance gene and neomycin phosphotransferase gene. pClneo is based on the pUC series of vectors and is therefore non-mobilisable.
Donor: Wild type inserts were cloned by RT-PCR from EBV transformed human B lymphoblastoid cell line. MGAR (from European Collection of Cell Cultures, Porton Down) MGAR cells were initially derived from a healthy human donor.

Genetic Material: Full length cDNAs (DQA1*0102 and DQB*0602) encoding the x and B peptide chains respectively of the DQ6 molecule, plus ten full length cDNAs containing single point mutations created by site-directed mutagenesis ("DQA1*0102 mutants and 8 DQB1*0602 mutants). Individual peptide chains have no biological function but combine to form functional DQ heterodimer. DQ molecule involved in binding antigenic peptides and activation of antigen specific and allo-specific CD4+ T cells. All cDNAs encode signal peptide for cell surface expression of heterodimer.

Evaluation of foreseeable effects

In DH5x - the DQA1 and DQB1 genes will be inserted separately into these host cells. The individual genes are incapable of generating functional protein. Furthermore, these cells lack the accessory molecules necessary for the correct assembly and folding of the peptide chains. We do not know whether any peptide will be secreted, but it will be non-functional.

In BLS-1 - intact functional DQ heterodimers will be expressed under the control of the CMV immediate-early promoter/enhancer. Previous studies using this cell line have shown the expression levels of DQ to be similar to those observed in normal B cell lines. CDNAs carry signal peptides for cell surface expression of the x and B peptide chains - no protein should be secreted from the cells.

Risk to human health - Cloning work: The host bacterial strain is non-pathogenic to humans. Genetic modification will not pose any risk to health as no functional protein will be expressed and the pathogenicity of the host will not be altered (except conferring resistance to ampicillin).

Expression work: The only risk to human health will be related to the EBV transformation of the BLS-1 cell line, which poses an additional risk of EBV infection. Genetic modification will not pose any additional risk - the manipulation of BLS-1 will create a cell line which expresses a combination of HLA class I and class II molecules which does not occur naturally. Thus it will not be possible for any worker (present or future) to be HLA compatible with the GMOs at all class I and class II loci. Any mis-match will result in a host-versus-graft rejection response which will have no adverse effects on the exposed individual. We have a record of the HLA profile of staff in the department and all new workers are routinely HLA typed. We will therefore be able to identify any subjects who are class I compatible with the unmodified BLS-1 cells and may therefore be at risk of colonisation.

Risk to Environment: B lymphocyte lines will die outside correct culture environment. No potential hazards associated with GM bacterial cells. Potential hazard to environment is low. Likelihood of release is also low.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All contaminated liquid waste to be collected in screw capped waste pots containing 1% Virkon and autoclaved. Contaminated Disposable plasticware to be placed in autoclave bags and placed in a robust container for transport to autoclave. Contaminated plasticware such as pipettes and tips will be submerged in 1% Virkon overnight prior to disposal in autoclave bags (pipettes) or sharps bins (tips). All autoclaved/treated solid waste is bagged and ultimately taken away for incineration by a contractor (Eurocare, Birmingham).

Contaminated glassware to be soaked overnight in 1% Virkon.

Autoclaving - effectively 100% kill. Please see attached data on in-house tests on Virkon.
The assessment was circulated to the Medical School GMSC and approved without adverse comment. One query was received on the efficacy of SDS as a disinfectant, which had been included in the original assessment. The investigator amended the assessment to exclude use of SDS and to only use Virkon instead.

**Purposes of the contained use**

The ability to mount T-cell mediated responses to viruses and other pathogens requires establishment of a pool of functionally competent peripheral T-cells. For this to occur haemopoietic stem cells must be recruited to the thymus where, under the influence of the thymic microenvironment, with a particular importance of thymic epithelium, they undergo a programme of differentiation and selection. Disfunctional epithelium can stop further thymocyte development, resulting in the lack of mature T-cells in the periphery and consequently causing severe immune deficiency. The aim of this work is to gain a better understanding of the role of epithelium in T-cell development, which knowledge will be useful in devising strategies to boost or restore thymic T-cell output where this has been compromised by disease, ageing or toxic therapies. Since epithelial cells are not or very poorly dividing, the use of adenoviral vector systems is necessary. Commercially available kits from Q-Biogene and Takara will be employed to create recombinant virus vectors able to express genes regulating thymocyte differentiation and development. The recombinant adenoviruses will lack the E1 gene which makes them incapable to propagate in ordinary cells. MHC class II epithelial cells will be selected from the thymi of Balb/c mice and incubated with the viral supernatant overnight, then GFP expression will be detected by FACS and positive cells will be selected and reaggregated with thymocytes and fibroblasts. Our aim is to increase the expression of adenovirally-transduced genes in mouse thymic epithelium and assess the role of the genes in question (B7.1, Fox and Akt/PKB) in the regulation of thymocytes development.

**Recipient or parental organism**

**Hosts:**
1) Standard E.coli strains eg. DH5a. Disabled host with a non-mobilisable vector. Inserts are under control of eukaryotic promoters, therefore expression is negligible. Containment level requirements are already in place within the laboratory.
2) Packaging cells to produce virions Ad-5-transformed human embryo kidney line 293 supply E1 functions in trans from chromosomally integrated genes.
3) Target cells: primary mouse (Balb/c, C57) epithelial cells will be MHC class II purified and reaggregated in vitro.

**Host/vector system**

**Vector:**
The vector will be an adenoviral shuttle vector in which an expression cassette can be inserted. Upon homologous recombination in bacteria with a plasmid containing the E1- E3 Ad5 genome, a new plasmid is generated in which the expression cassette is inserted into the original E1 region of the adenovirus genom.

**Origin & function**

**Donor:** Healthy, mouse embryonic (15 day) thymus cDNA, genes are involved in normal development of mouse thymocytes and epithelium.
Genetic material: Fox, B7.1: wild type mouse proteins involved in the regulation of Tcell development and maturation Akt/PKB: wild type signalling molecule involved in the regulation of cellular survival.
GFP: fluorescent protein which has not been shown to have pathogenic properties.

**Evaluation of foreseeable effects**

Human Health considerations: The plasmid constructs in E.coli have no significant implications for health & safety. Expression of Fox, B7.1 and Akt/PKB in cells in vitro presents no greater hazard than the unmodified cells. Non of the expressed proteins are known to have any toxicity or transforming activity or cause allergy. The genetically modified adenoviral vectors are designed to result in efficient expression of the above proteins in the epithelium and in turn in vitro reaggregated with various subpopulations of primary mouse thymocytes and their effect on epithelial cell maturation. Adenoviruses are relatively stable at room temperature and are naturally infectious to the respiratory tract as aerosols. If accidental inoculation occurred, it might cause flu like symptoms, and the viral DNA would be introduced into a number of cells giving transient, high level expression of the transgene over a period of a few days to weeks. However, since the virus will be unable to replicate and any expression of the mouse genes regulating thymocyte development would be eventually lost from the infected cells (the process fastest in dividing cells) and further spread would not occur. In small proportion of infected cells chromosomal integration of the vector might
give the potential for long-term maintenance and expression. However, chromosomal integration of adenoviral sequences is a rare event, in the region of one integration in 10 (to the power of 4) exponentially growing infected cells. Although the number of cells undergoing replication in the respiratory tract at any one time is not precisely known, it is generally accepted that the majority of cells in the epithelium are post-mitotic, on the differentiation pathway. It is our opinion that a considerable intake of virus would have to occur to produce an integration event in vivo, much greater than the minimal in vitro transforming dose of 1 x 10 (to the power of 5) pfu.

The majority of people undergo primary infection with AD5 in childhood, and both humoral and cellular combined to prevent further productive infection in the adult. Such immunity will reduce viral entry into cells and hasten the immune destruction of infected cells in the event of accidental infection with the recombinant virus. The recombinant virus will not be capable of autonomous spread in the event of accidental operator infection. In the unlikely event that an operator were to receive an "infectious dose" of recombinant virus and the same cells would concurrently be infected with wild type virus could lead to replication of the virus. The risk of double infection of the same cells with recombinant and wild type adenovirus at the same time is considered to be very low.

The possibility that replication competent adenivirus might arise (at low frequency) by recombination within the permissive cell line is recognised. Protocols have been published for monitoring this phenomenon, and virus stocks are routinely screened on non-permissive cells to assess their status, indeed, the presence of significant levels of RCA would become obvious in the experimental use of the virus. The transgenes will be inserted in the E1 region of the virus, and so become obvious in the experimental use of the virus. The transgenes will be inserted in the E1 region of the virus, and so in the event of homologous recombination to restore E1 functions, the B7.1, Fox and Akt/PKB gene will be lost from the viral genome.

Environmental considerations: Gene transfer to both humans and mice is a possibility. The hazard is low as the non-replicative adenoviral particles are relatively stable at room temperature but it would require high exposure for infection. Even high level exposure could only cause temporary, mild flu-like symptoms. Supernatants will be contained within a Class II microbiological safety cabinet, and live animals will not gain access to the work area. Workers will wear protective clothing and will handle the virus in the safety cabinet in a containment level 2 lab, thus preventing the virus escaping into the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All tissue culture plastics and liquid waste generated during the production of adenoviral supernatants will be autoclaved before disposal. Solid waste is then removed by a contractor for ultimate disposal by incineration. Autoclaving achieves effectively 100% kill of all GMMs. Pipette tips will be treated with Virkon then autoclaved before being removed as clinical waste and incinerated. 1% Virkon is effective against adenovirus according to manufacturer's information: This indicated efficacy of Virkon against a variety of adenoviruses at 1% concentration, and also against a number of strains of E. coli at dilutions ranging from 1% to 0.125%. It has been demonstrated that 15 minutes exposure to 1% Virkon achieves >4log kill for adenovirus infected cell pellets, and >6log kill of adenovirus seed stocks.

Is an emergency plan required according to regulation 20?  

N

If yes, tick to confirm that it is attached to this form

N

Tick to confirm that you have attached a risk assessment to this form

Y

Tick if you are claiming exemption from disclosure for section of the risk assessment

N
GMSC raised issue of monitoring for recombination. This has been addressed in the assessment. Also, request for provision of validation information on Virkon - this has now been added. GMSC requested that consideration be given to the procedure for dealing with a 10ml spill of virus stock in the open lab. This has been addressed in the Emergency Action section. The GMSC has approved the assessment.

**Project Additional Information**

**Purposes of the contained use**

To investigate the use of fibroblast growth factor-2, expressed, e.g. in target neuronal cells, to provide neurotrophic signals to CNS neurons and thus facilitate the survival and regeneration after nerve tract lesion. In some experiments, FGF2 will also be used in combination with other neurotrophic molecules, e.g. neurotrophin (NT-3), brain derived neurotrophic factor (BDNF), nerve growth factor (NGF) or cytokines, e.g. transforming growth factor-beta (TGF-b) or cytokine antagonists (e.g. decorin).
Vectors will initially be constructed as plasmids in E. coli. These may be transfected into mammalian cells, leading to expression of the FGF-2 (but without any generation of virus). However, in order to facilitate into mammalian cells, leading to expression of the FGF-2 (but without any generation of virus). However, in order to facilitate gene transfer to a number of cell lines, and to model possible therapeutic use, a replication defective adenovirus expressing FGF-2 will also be generated.

**Recipient or parental organism**

**Host:** Plasmids grown in standard disabled laboratory strains of E. coli. Mammalian cells used for viron production will be Ad-5 transformed human embryo kidney line 293, or similar lines, e.g. 293T cells (a derivative which also expresses SV40 T antigen), HER AdS E1a; 911 (another HER/human embryo retinal line); PER.C6; all supply E1 functions in trans from chromosomally integrated genes. Eventual target cells for the GM virus will be established neuronal and glial cell lines and primary neural material. The route to construction of the adenoviral vector plasmids carrying FGF2 etc, involved intermediate plasmids which are suitable for DNA transfection into mammalian cells (e.g. carrying the neomycin G418 s selectable marker), so this will also be done in order to select derived mammalian cell lines which stably express the constructions. Such cells will not be capable of producing the GM virus.

**Host/vector system**

**Vector:** Initial assembly of the constructs will be in standard plasmid vectors, based on pUC19 and pBR322. The virus to be produced from the plasmid constructs in helper mammalian cells will be replication dwefective, GM human adenovirus type 5 (E1 deleted). Our vectors in current use are also E3 deleted, thus removing adenoviral genes which play various roles in evasion of the host immune response.

**Origin & function**

**Donor:** Human FGF2 open reading frame PCR amplified from a human brain library. GFP from jellyfish, although we intend to use EGFP, a modified version with modified spectral characteristics and optimised for expression in mammalian cells. Genetic material: Fibroblast growth factor-2 is a heparin binding growth factor which occurs in several isoforms resulting from alternative initiations of translation: an 18kD cytoplasmic isoform and four larger molecular weight nuclear isoforms (22, 22.5, 24 and 34kD). FGF-2 has pleiotropic roles in many different cell types and tissues; it is a motogenic, angiogenic and survival factor which is involved in cell migration, cell differentiation and a variety of development processes. Although devoid of signal peptide, it could be secreted. It acts mainly through a paracrine/autocrine mechanism involving high affinity transmembrane receptors and heparin surfate proteoglycan low affinity receptors, but also through a still unknown intracrine process(es) on intracellular targets. FGF-2 has many biological functions which are probably isoform specific. FGF2 is expressed at very low levels and sequestered by many mesenchymal cells, and at high levels by glia and some neuronal populations in the CNS. In the CNS FGF2 is transiently up-regulated after injury and its limited availability is thought to limit the potential for neuron survival and axon regeneration after nerve tract injury. Its receptor FGFR1 is also expressed by responsive cells after injury, and the interaction of FGF2 with FGFR1 is thought to stimulate gliosis, neuron survival and the abortive axon regeneration. Despite its potential pleiotropic activities, FGF2 is not reported to be oncogenic, and seldom acts alone to initiate cellular responses, requiring co-factors for full activity.

**Evaluation of foreseeable effects**

**Human Health Considerations:** The plasmid constructs in E. coli have no significant implications for health and safety. Expression of FGF2 in cells in vitro presents no greater hazard than the unmodified cells, (cells derived from the operator will not be used, thus there is no likelihood of colonisation). Adenoviral vectors carrying the FGF2 gene will be able to infect a broad range of human and other mammalian cells, including cells in the operator in the event of accidental contamination, leading to expression of the transgene. The expression of FGF2 is not expected to have any direct consequences for the expressing cell, i.e. it is not known to be toxic or have any signalling functions within the expressing cell. FGFR1, the receptor for FGF2, is reported to be expressed on some mesenchymal cells, allowing stimulatory signals to be provided by this route, facilitating the subsequent activation and proliferation of the antigen-stimulated cells. At the extreme it is possible that this might promote limited motosis. However, this is considered unlikely, as it would depend on the prior presence of receptor bearing cells primed to replicate. Also, under normal physiology, the ligand has a high affinity for heparan sulphate proteoglycans (a component of the extracellular matrix of all tissues) which acts to mop up soluble FGF2, sequestering it and blocking its signalling ability through its receptor. This ligand sequestration is a natural regulatory phenomenon for this class of ligands, and to be biologically active the ligand needs local activation by specific proteases. It is unlikely that this would occur to any significant degree.
Adenoviruses are relatively stable at room temperature and are naturally infectious to the respiratory tract as aerosols. Although it is envisaged that most of our experiments will use adenovirus entrapped in a solid matrix, thereby minimising the aerosol risk, if accidental inoculation were to occur, the viral DNA would be introduced into a number of cells giving transient, high level expression of the transgene over a period of a few days to weeks. However, the GM virus will be replication defective and following an accidental inoculation, further spread would not occur. With time the genome would be lost from the vast majority of infected cells, or the infected cells may be eliminated by immune responses against adenoviral antigens. In a small proportion of infected cells chromosomal integration of the vector might give the potential for long term maintenance and expression. However, chromosomal integration of adenoviral sequences is a rare event. Although the number of cells undergoing replication in the respiratory tract at any one time is not precisely known, it is generally accepted that the majority of cells in the epithelium are post-mitotic, on the differentiation pathway. It is our opinion that a considerable intake of virus would have to occur to produce an integration event in vivo.

The majority of individuals appear to undergo primary infection with Ad5 in childhood, and both humoral and cell-mediated immunity combine to prevent further productive infection in the adult. Such immunity will reduce viral entry into cells and hasten the immune destruction of infected cells, in the event of accidental human contamination with the recombinant virus. The recombinant virus will not be capable of autonomous spread in the event of accidental operator infection. In the unlikely event that an operator were to receive an infectious dose of virus via the respiratory tract, it would only lead to replication of the GM virus if they had a concurrent infection with wild type virus, and the same cells took up both wild type and recombinant viruses. Sub-group C serotypes (including Ad5) can persist in the adenoids and tonsils following primary infection, but the mechanism by which the virus is maintained is not known. However, the number of virus-containing cells is very low, and most virus remains cell-associated, and can only be detected after prolonged incubation of the tissue in vitro. Thus the risk of double infection with recombinant and wild types virus is considered to be very low.

Environmental considerations: Human adenoviruses are not known to infect other species in the wild. Experimental administration of Ad5 wt virus to cotton rats can cause pneumonia when administered at high doses, given intranasally; but cotton rats are not indigenous to the UK. Mice can only be killed by high virus doses delivered intravenously or intraperitoneally; the virus goes to the liver and causes primarily toxic damage. The recombinant virus is replication defective and will not have an extended host range. Apparent level of potential hazard to the environment is negligible. Potential hazard to species in the environment from E coli containing the plasmids associated with this work also appears negligible, due to minimal intrinsic hazard and poor ability of the strains to survive in the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste is treated by autoclaving at 130C for 60 minutes before disposal to drains. Disposable solid waste which may be contaminated with GMMs is also autoclaved before removal as "clinical waste" by specialist contractors with final disposal by incineration. Exceptions to the above are: "Sharps", including scalpel blades, needles, and disposable plastic tips for micropipettors, may be decontaminated by drawing up Virkon disinfectant and soaking in Virkon for 15 minutes. Disposable plastic pipettes may also be decontaminated with Virkon in this way. Autoclaving achieves effectively 100% kill of GMMs. Manufacturer's information indicates efficacy of Virkon against adenoviruses at 1% concentration, and also against a large number of E coli strains at dilutions ranging from 1% to 0.125%. We have demonstrated that 15 minutes exposure to 1% Virkon achieves >410^10 kill for adenovirus infected cell pellets and >610^10 kill of adenovirus seed stocks.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y
Please enter comments on the GM safety committee on the risk assessment

One comment from the GMSC: "Does the transgene always go into the Ad E1 region?" The response from the investigator was yes, it does.
The GMSC have approved this assessment.

Purposes of the contained use

We wish to submit a series of assessments that form a connected programme of work that includes several laboratories, several pathogens and several activities.
work focuses on the characterisation of proven or potential virulence, stress-induced and antibiotic-resistance determinants from human bacterial pathogens that fall into ACDP category 2. These include:

- Salmonella enterica (non-typhoidal serovars and the attenuated vaccine strain Ty21a)
- Echerichia coli (non-vero-toxin-producing)
- Campylobacter jejuni
- Corynebacterium diphteriae
- Staphylococcus aureus and coagulase-negative staphylococci
- Bacteroides fragilis, Clostridium difficile
- Mycoplasma pneumoniae, Shewanella putrefaciens
- Mycobacterium bovis BCG
- Streptococcus pyogenes, S. pneumoniae, S. agalactiae and viridans group streptococci (eg. S. mitis, S. oralis)
- Pseudomonas aeruginosa, Pasteurella multocida, Actinobacillus actinomycetemcomitans, Yersinia pseudotuberculosis Enterococcus faecalis and E. faecium, Neisseria gonorrhoeae.

Specific activities include:

1. Cloning of DNA fragments from pathogenic bacteria in non-mobilisable vectors in laboratory strains of E. coli with a view to sequencing or mutating the fragments. No attempt will be made to express the foreign DNA.
2. Creation of mutants in wild type strains by random transposon mutagenesis using eg. mud-lac and resulting in insertional inactivation, linked in some cases with the creation of transcriptional fusions to reporter genes.
3. Creation of mutants of pathogens by allele replacement using a suicide vector (or insertion duplication vector in streptococci).
4. Allele replacement using a gene that expresses a marker protein which is highly unlikely to have any biological effect (such as beta-galactosidase, luciferase, green-fluorescent protein) into a pathogen to monitor gene expression under different environmental conditions.
5. Expression of proteins at a high level in a disabled host bacterium to enable further chemical/biochemical characterisation of the protein.
6. Expression in the strain of its origin of a gene from a pathogenic bacterium running off its own promoter on a shuttle vector, so as to complement a mutant phenotype.
7. Expression of antibiotic resistance determinants in a disabled host bacterium to enable further characterisation of the resistance mechanism.

**Recipient or parental organism**

| Activity 1 | Disabled laboratory strains of E. coli including or similar to those listed in Part 2a, Annex II of the ACGM Compendium of Guidance |
| Activity 2 | Wild type pathogenic bacteria as described above |
| Activity 3 | Pathogenic bacteria as described above |
| Activity 4 | Pathogenic bacteria as described above |
| Activity 5 | Disabled lab strains of E. coli |
| Activity 6 | Lab strains of E. coli then pathogenic bacteria as described above |
| Activity 7 | Disabled lab strains of E. coli |

**Host/vector system**

| Activity 1 | Any non-mobilisable or mobilisation-defective vector including or similar to those listed in Part 2a, Annex II of the ACGM Compendium of Guidance |
| Activity 2 | N/A |
| Activity 3 | Non-mobilisable or mobilisation defective vectors that: can be propagated in crippled E. coli strains but not in the target species, eg pUC replicates in crippled E. coli but not in C. jejuni; show temperature sensitive replication in E. coli eg pNIL and pGOAL series; recombine with the target gene on the chromosome to cause insertional duplication of the plasmid in S. pneumoniae, eg p326(cat)pDL278(spc),pCR2(erm) |
| Activity 4 | A suicide vector |
| Activity 5 | Non mobilisable vectors, eg pGEX4T3, the pET and pCAL vectors, that express the protein, either from strong promoters or from the gene's native promoter in |
Its native form or as part of a his-tagged, calmodulin-binding peptide-tagged or similar fusion to an innocuous protein.

Activity 6 - Non-mobilisable or mobilisation defective shuttle vectors which carry origins of replication that work in both E. coli and a given other pathogen (eg C.diptheriae).

Activity 7 - Non-mobilisable or mobilisation defective vectors including or similar to those listed in ACGM Compendium of Guidance.

### Origin & function

Donors of material for activities 1-7 as listed above.

Activity 1 - Pathogenic bacteria as described above.

Activity 2 - Well characterised transposable elements, eg for Salmonella - Mud-lac; For pseudomonas - mini-Tn5 and its derivatives mini-Tn5-luxCDABE, mini-Tn5-gfp, mini-Tn5-lac; For Streptococci and Enterococci Tn916, Tn917, ISS1 and derivatives.

Activity 3 - Pathogenic bacteria as described above

Activity 4 - Depends on marker (eg. E. coli for beta-galactosidase, firefly or luminesent vibrios for luciferase, jellyfish for GFP.

Activity 5 - Pathogenic bacteria as described above.

Activity 6 - Pathogenic bacteria as described above.

Activity 7 - Pathogenic bacteria as described above.

Genetic material used in activities 1-7 listed above.

Activity 1 - DNA fragments encoding various genes. Examples include Salmonella DNA fragments amplified from next to transposon insertions or long PCR fragments that differ between different strains of pathogenic bacteria.

Activity 2 - N/A - chromosomal material will be disrupted.

Activity 3 - DNA fragments encoding various genes.

Activity 4 - A gene that expresses a marker protein which is highly unlikely to have any biological effect (eg beta-galactosidase, GFP, luciferase).

Activity 5 - DNA fragments encoding various genes. The worst case scenario is expression of genes encoding subunits of known or potential toxins from Group 3 pathogens, eg the catalytic subunit of the Shiga like toxin from E. coli 0157, the catalytic subunit of the recently described typhi toxin.

Activity 6 - DNA fragments encoding various genes.

Activity 7 - Antibiotic resistance genes expressed from their native promoters.

### Evaluation of foreseeable effects

#### Human Health considerations:

Activity 1 - No risk to human health, this part of the work falls into containment level 1.

Activity 2 - The disruption of putative virulence genes and their fusion to reporter genes will produce a GMO which will be no more hazardous than the wild type and which can therefore be handled at the ACDP category relevant to the wild type - ie level 2.

Activity 3 - The disruption of putative virulence genes and their fusion to reporter genes will produce a GMO which will be no more hazardous than the wild type and which can therefore be handled at the ACDP category relevant to the wild type - ie level 2.

Activity 4 - The introduction of the gene for the marker protein and disruption of the resident gene will produce a GMO which will be no more hazardous than wild type and which can therefore be handled at the ACDP category relevant to the wild type - ie level 2.

Activity 5 - Using the Brenner scheme the damage is set at 10 (-3) in line with discussion on ricin in Part 2A annex 1 of the ACGM Guidance. Exactly similar considerations apply to bacterial toxins, ie the catalytic subunit of any toxin cannot exert any effect unless delivered in soluble active form to the appropriate compartment of the appropriate cells within the human body.

This cannot happen here as the necessary delivery mechanisms (eg a secretion system for getting out of the cell, a binding domain for attaching to cells and mediating entry) will be absent from the cloning host, so we feel justified in assigning a value of 10 (-3). We will never express the binding and toxic domains in the same cell. A possible exception is the class of virulence determinants known as "autotransporters", under study by Ian Henderson. Here the determinants necessary for export from the bacterial cell are contained within the same protein as the toxic moiety. However, even the most toxic of these, the enterogaegregative E. coli plasmid-encoded toxin PET, is unable to damage host cells or organ transplants when expressed at low levels in disabled hosts so we feel justified in assigning a damage value of 10 (-3), and probably more appropriately 10 (-6) even though these proteins can be exported from the bacterial cell.

Activity 6 - The shuttle vector simply re-introduces a characteristic that was already present in the wild type and had then been removed by mutagenesis. The procedure will
Environmental considerations:

Activity 1 - All waste is autoclaved before leaving the building so it is very unlikely that GMOs or constructs will escape into the environment. If by some chance they did escape the disabled host would not be able to survive and the non-mobilisable vector would not be able to leave the host. Any DNA released into the environment would be similar to that which occurs during the usual processes of decay. The environmental impact would therefore be negligible.

Activity 2 - All waste is autoclaved before leaving the building so it is very unlikely that GMOs or constructs will escape into the environment. Transposon mutagenesis is a naturally occurring process and all the species we are interested in harbour transposable elements. Any disruption or alteration of gene function as a result of transposon insertion is therefore already likely to have occurred in the natural environment. We anticipate that insertional mutagenesis will result in a less fit phenotype which will be outcompeted by the wild type if it happened to escape into the environment. Transciptional fusions will be made only to reporter genes with no conceivable environmental effect. Although the transposons will carry antibiotic resistance genes as selectable markers, these will not, in the unlikely event of escape, present an increased risk to the environment because the genes used do not encode resistance to drugs used therapeutically against the host species; these resistance determinants are already abundant in naturally occurring isolates of the host species; in the case of mud-lac, the element carrying them is no longer transposable.

Activity 3 - As all waste is autoclaved before leaving the building it is highly unlikely that any GMOs or constructs will escape into the environment. Our allele replacement will be done using non-mobilisable vectors that

- can be propagated in crippled E. coli strains, but not in the target species, e.g. pUC18 replicates in E. coli but not in Campylobacter jejuni (Biotechniques 1999 Jan; 25(6):50-2, 54, 56 Karlyshev et al)
- show temperature-sensitive replication in E. coli (e.g. pK03 used in E. coli and Salmonella: http://arep.med.harvard.edu/labgc.pko3.html).

In such cases, as the construction of a disrupted gene occurs in a non-mobilisable vector in a disabled host, the resultant GMO would not be able to survive in the external environment and the non-mobilisable vector would not be able to leave the disabled host. Therefore the environmental effects would be negligible. Once the allele replacement is complete, the resulting GMO, carrying a disrupted gene, is likely to be less fit than the wild type and so will be out-competed by it, were it to escape into the environment (see arguments about natural mutations above). Allele replacement requires the introduction of antibiotic resistance genes into the target strain, both during the interim stage when the plasmid is integrated in the chromosome, and in the final stage when the disrupted allele has replaced the wild type allele. In this situation, similar constraints apply as in transposon mutagenesis - these antibiotic resistance genes will not, in the unlikely event that they escape, present an increased risk to the environment because:

- We will use only those genes that DO NOT encode resistance to drugs used therapeutically against the host species (e.g. ampicillin is not used to treat campylobacteriosis)
- These resistance determinants are already abundant in naturally occurring isolates of the host species (e.g. chloramphenicol resistance in Salmonella typhimurium DT109: Arcangioli et al. J Med Microbiol. 2000 Jan;49(1):103-10.)
- They are not lodged on a transposable or mobilisable element.

Activity 4 - As all waste is autoclaved before leaving the building it is highly unlikely that any GMOs or constructs will escape into the environment. Transcriptional fusions will be made only to reporter genes with no conceivable environmental effect (genes for beta-galactosidase, luciferase, or green-fluorescent protein). However, as an interim step, antibiotic-encoding suicide vectors may be used (see discussion above).

Activity 5 - As all waste is autoclaved before leaving the building it is highly unlikely that any GMOs or constructs will escape into the environment. The vectors that are used are non-mobilisable and will be propagated only in disabled lab strains of E. coli. If by some slim chance they were to escape, the disabled host would not be able to survive in the external environment and the non-mobilisable vector would not be able to leave the disabled host. The environmental impact would therefore be negligible.

Activity 6 - As all waste is autoclaved before leaving the building it is highly unlikely that any GMOs or constructs will escape into the environment. Our complementation work will be done using non-mobilisable or mobilisation-defective vectors that are initially propagated in crippled E. coli strains. This initial propagation of a non-mobilisable or mobilisation-defective vector in a disabled host means that the resultant GMO will not be able to survive in the external environment. The environmental effects of such a GMO escaping will thus be negligible. Also as the non-mobilisable vector will not be able to leave the disabled host, gene release into the environment could occur only in a way that parallels natural decay processes.

Once the shuttle vector is inside a pathogenic strain there is a possibility that it could create a GMO capable of surviving in the external environment. However, this GMO
will be no more fit than the wild type if the complementation of the mutant phenotype works and will probably be less fit if it does not. In the extremely unlikely event that it might escape from the laboratory, it will therefore present no increased environmental risk over and above that presented by the wild type pathogen. Also as the non-mobilisable vector will not be able to leave the disabled host, gene release into the environment could occur only in a way that parallels natural decay processes. The shuttle vector might be construed as providing a novel means of gene transfer between the pathogen and E. coli. However, any genes transferred in this way are unlikely to be expressed in a new organism, as there are considerable barriers to the expression of heterologous genes in most bacteria (eg. many Campylobacter genes are not expressed off their own promoters in E. coli: Wosten et al J Bacteriol 1998 Feb; 180(3):594-9). Furthermore, as the shuttle vectors that we will use are non-mobilisable or mobilisation-defective, they will not be able to escape easily from their hosts, should these by some unlikely eventuality find their way into the environment.

Activity 7 - As all waste is autoclaved before leaving the building it is highly unlikely that any GMOs or constructs will escape into the environment. The vectors that are used are non-mobilisable and will be propagated only in disabled lab strains of E. coli. If by some slim chance they were to escape, the disabled host would not be able to survive in the external environment and the non-mobilisable vector would not be able to leave the disabled host. In addition, in the absence of selective pressure the antibiotic resistance genes will not confer any increase in fitness. The environmental impact would therefore be negligible.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste (aside from disinfected fluids) will be autoclaved - Kill rate effectively 100%

Two general purpose chemical disinfectants are used: Chlorine based disinfectants (Haztabs and Chloros) and Microsol. Chlorine based disinfectants should be used at 25000ppm available chlorine and material should be left to soak overnight before disposal. Disinfected liquids may then be disposed of to drains and solids to the appropriate waste bin. Alternatively, 10% Microsol may be used.

Validation data for Microsol.

Data has not been included for all the organisms listed, as not all of these organisms will be used in the first instance. However, data for these other organisms will be obtained and added when they are used.

2% Stericol or Hycolin can be used for Mycobacteria. These phenolic compounds have been shown to be effective against tubercle bacilli at concentrations between 0.2-3% with a 10-30 mins contact time (Vesley and Lauer in Laboratory Safety - Principles and Practices 2nd Edition 1995, eds Fleming, Richardson, Tulis and Vesley).
GMSC was primarily concerned with the generic nature of the programme and needed reassurance that any future changes to the work would continue to be brought to the Committee for discussion and approval. The GMSC has approved this application.

**Purposes of the contained use**

EPEC/VTEC adhere to, and colonise the human intestinal mucosa, resulting in a diarrhoeal disease syndrome. Acquired virulence properties are necessary to promote a range of pathogenesis events; initial attachment, subversion of host cell signalling and ultrastructural changes to the epithelial surface resulting in the formation of histopathic lesions, termed attaching and effacing lesions. In this study, using established adhesion assay models the bacterial/host cell interaction phenotype is studied using a variety of EPEC strains and transformed human carcinoma cell lines.

**Recipient or parental organism**

commercially available cell lines

**Host/vector system**

multiple plasmids. List available attached to risk assessment Some examples are pCVD438, pMSD2, pCVD462...

**Origin & function**
over 100 mutants of wildtype enteropathogenic E.coli with deletion mutations

**Evaluation of foreseeable effects**

Wild type EPEC/VTEC pose key virulence factors which are expressed as either proteins on the surface of the bacteria or soluble proteins secreted from the bacteria and translocated into the host cell via attachment fimbriae. EPEC/VTEC deletion mutants are lacking one or more virulence factors, via the knockout of relevant genes. Plasmid transformants have the gene inserted back into the deletion mutant restoring the strain to the original genetic capability. Hep-2, T84, Caco-2 cell lines are commercially available transformed lines from nasal pharyngeal (Hep-2) and intestinal epithelium (T84 Caco-2) cancers.

Wild type EPEC are able to cause diarrhoea in humans; however, in this laboratory under the small scale risk criteria a low level of risk is associated. Deletion mutants with the removal of one or more virulence genes possess a level of risk far lower than wild type. The phenotype of the transformant is often attenuated and is not fully expressed to the same level of wild type strains. No deletion mutant/transformant possess virulence levels or present an infective risk higher than that of the wild type strain. The majority of laboratory activities in this case fall into containment level 1, with some in level 2. Containment level 2 is applied to ensure that there are sufficient control measures in place for any event that may occur in the laboratory environment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

n/a

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

No derogation - Full level 2 applied.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All GM waste is autoclaved at 121 degrees C for 50 minutes. Degree of kill - effectively 100%
Decontaminated glassware then undergoes usual wash-up procedures. Disposable plastic waste is placed into yellow incineration bags which are placed in designated areas for collection and disposal.

### Project Additional Information

#### Purposes of the contained use

Retroviral vectors (pBABE) containing human HIF2 a cDNA that have been produced elsewhere will be used to produce retroviral particles via transfection of a phoenix producer cell line. A number of human cell lines will be infected with these retroviruses and the effect on the expression of possible target genes will be analysed at the transcriptional and translational level. A number of other retroviral vectors containing cDNAs involved in these pathways (e.g., VHL, HIF1 a) may also be produced by subcloning pre-existing cDNAs available in the laboratory.

#### Recipient or parental organism

**Hosts:**

1. Disabled E. coli strains such as DH5a, JM109. Inserts are under the control of eukaryotic promoters, therefore expression is negligible.
2. Packaging cell Phoenix line (based on human embryonic kidney cell line 293 transformed with adenovirus E1 gene carrying a temperature sensitive T antigen co-selected with neomycin). Phoenix is a second-generation retrovirus producer line for the generation of helper free retroviruses. Different promoters for gag-pol and envelope were used to minimise their inter-recombination potential. Gag-pol was introduced with hygromycin as the co-selectable marker and the envelope proteins were introduced with diphtheria toxin 1 resistance as the co-selectable marker. The production of replicative virus through recombination has not been observed. The inserts should not affect that. The cell line has been tested for helper virus production and has been established as being helper virus free. The vector will be transfected in the Phoenix line and the medium containing the retroviral virions will be harvested 24 and 48 hours later, aliquoted and stored at -80 degrees C.
3) Cell lines derived from human kidney, colon, lung and breast.

**Host/vector system**

**Vector:**
The vector will be a retroviral shuttle vector, pBABE (Mo MuLV based vector, containing LTR, gag, cloning sites BamHI, EcoRI and selection by puromycin or neomycin transcribed from a SV40 promoter) are based on standard cloning plasmids, but have also the information for the encoded sequences to be packaged into viral particles when introduced into special packaging cell lines. The vectors themselves do not possess the genes required for the production of infectious virus. The vectors contain drug resistance markers for both pro and eukaryotic selection.

**Origin & function**

**Inserts:** Hypoxia inducing factor 1 and 2 alpha; succinate dehydrogenase subunit B; VHL; Ras Association domain Factor Isoform A (RASSF1); BLU, SLIT2 - genes involved in regulation of tumorigenecity.
**Donor:** Human cDNA from healthy tissue, originally gifts, therefore unsure of origin.

**Evaluation of foreseeable effects**

**Effects on human health:** The shuttle vector or the produced retrovirus with insert poses a negligible risk for infection. The retroviral virions, produced in the Phoenix line, can only infect dividing cells, therefore infection requires special conditions and is highly unlikely to happen in the event of an accident. No sharps will be used and the work will be carried out in a Class II safety cabinet to reduce the risk of accidental infection.

The shuttle vectors which have the non-mobilisable insert under the control of eukaryotic promoters do not possess the genes required for the production of infectious viruses. The retroviral virions, produced in the Phoenix line, can only infect dividing cells, therefore infection requires special conditions. This is unlikely to happen when the appropriate safety measures are taken.

Furthermore, in the unlikely event of infection the retroviral virions are proliferation defective. The insert coding the expression proteins HIF1a and HIF2a are putative oncogenes, having a role in angiogenesis, although they will have negligible toxicity or transforming activity. All other stated inserts are recognised or putative wild-type tumour suppressor genes and have no known tumour promoting properties.

**Environmental hazards:** The potential hazard is considered to be negligible as the retrovirus particles are very unstable and the virus is non-replicative. Retoviral supernatants will be contained within the tissue culture area. Live animals will not gain access to the work area.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation - full level 2 containment applied.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Tissue culture plastics will be autoclaved before disposal. Pipettes are to be soaked in Virkon before autoclaving. Small volumes of liquid containing viral particles will be used immediately or treated with Virkon. Virkon will be used at 1% concentration although 0.5% Virkon is effective against retroviridae (Ref given in risk assessment).

*Sacrificial* viral supernatants will be put through disposal protocols and tested for viability by reinfection of cell lines.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N
The GMSC requested more information on the inserts and the potential risk to human health. Some of the comments included: What are BLU and SLIT2?

Even though the recombinant retroviruses may not be able to replicate in non-helper cells, they can still enter and express inserts. Since the inserts are putative oncogenes, has the effect of this been considered?

Cloning in retrovirus does not address the potential risk of virus transferring a potentially hazardous gene in the event of an accident. The applicants assume that the failure of the virus to replicate means that the construct is not hazardous.

Page 1 title section: The function or putative function of the genes identified needs to be described to allow an assessment of risk to be made.

The assessment was amended to take account of these comments. This assessment has now been approved by the GMSC.

Project Ref 116/03.1

Date Ackn'd: 11/06/2003
CU2 Project Title: INVESTIGATION INTO THE LIVER REPOPULATING CAPACITY OF HUMAN LIVER STEM LIKE CELLS.

Date Project Ceased: 19/11/2004

Class: Class 2
Culture Class: < 1 litre
Consent Granted: not applicable

Withdrawn: N
Project notified under transitional arrangements: N
Project Additional Information

Purposes of the contained use

The study will focus on the potential of human liver stem cells as alternative sources of functional human hepatocytes and biliary epithelial cells. Isolated human liver stem cells will be stably transduced with a recombinant lentivirus expressing the gene for Green Fluorescent Protein. The potential of these marked cells to repopulate acutely injured livers will be assessed by cell transplantation experiments in NOD/SCID mice (but not here in the UK).

Recipient or parental organism

Hosts. Standard disabled lab strains of E. coli as DH5a and JM109 will be used for growth of plasmids. Manipulation of large plasmids may involve homologous recombination in strain BJ5183. Human cell line 293T will be used for both initial rescue of virus from transfected DNA, and for virus, propagation. Primary human liver stem cells (which are non-permissive for production of replication deficient lentivirus), will be transduced with recombinant lentivirus expressing GFP.

Host/vector system

Vectors: Plasmids; Third generation lentiviral vector (replication defective). Please see assessment for details.

Origin & function

Sequence encoding Green Fluorescent Protein which functions as a reporter molecule that fluoresces upon exposure to uv light.

Evaluation of foreseeable effects

Risks to human health: The lentiviral vectors used in this study are third generation lentiviral vectors. In these third generation vectors all six regulatory/accessory proteins (Rev, Tat, Vif, Vpr, Vpu and Nef) are removed, except Rev. Rev acts as the post-transcriptional level and is necessary for HIV gag/pol messenger. As an extra safety responsive element [RRE]) and facilitates the cytoplasmic export of gag/pol messenger. As an extra safety measurement Rev is placed on a separate vector (RSV-Rev) beside transfer vector. Only 700 bp of the HIV envelope protein are present in the transfer vector, plus RRE and the packaging signal. The packaging construct contains the minimal RRE of 375 bp and the gag/pol genes. Through deletions in both LTRs and the absence of 5 of the 6 accessory proteins, including the replication essential Tat it is highly unlikely that replication competent virus is produced. In published studies and from our own experience with these vectors replication competent virus has never been detected. The HIV-envelope protein is replaced by non-retrovirally envelope protein (VSV-G). It is highly unlikely that this will be incorporated in a new hybrid replicative virus. It is impossible that wild-type HIV will be formed, because of the omission of 5 accessory proteins with HIV-env.

Environmental considerations: Proteins will not be expressed in bacteria used for plasmid propagation. Bacteria used for propagation are attenuated strains that will not survive in the environment. The recombinant virus is replication defective and will not have an extended host range, the GFP transgene is innocuous, so there is negligible potential hazard to the environment. Containment conditions specified should prevent environmental release of virus or E. coli carrying the associated plasmids; and the virus is replication defective.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation applied for.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste is treated by autoclaving at 130 degrees centigrade for 60 mins before disposal to drain. Disposable solid waste which is or may be contaminated with GMMs is also inactivated by autoclaving at 130 degrees centigrade for 30 mins, before removal as clinical waste by specialist contractors, with final disposal by incineration. Autoclaving achieves 100% kill. Warning lights, and chart recorder, indicate whether or not the autoclave run has achieved the appropriate temperature for the required time. The autoclave is run by trained staff, who are instructed to treat waste as still contaminated if the autoclave run was not to specifications. Under such circumstances the waste would be autoclaved again, after rectifying any reason for the malfunction.

The autoclave is inspected and serviced on a regular basis. Autoclave is regularly tested with Brown's tubes.

Sharps, including scalpel blades, needles and disposable plastic tips, may be decontaminated by drawing up Virkon disinfectant, and by soaking in Virkon for a minimum of 15 minutes. Disposable plastic pipettes may also be decontaminated by immersion in Virkon as above. Manufacturer's information indicates efficacy of Virkon against strains of E. coli at dilutions ranging from 1% to 0.125%. The manufactureres of Virkon (Antec International Ltd) have also commissioned studies on the virucidal effect of Virkon on Human Immunodeficiency virus and found that a 0.5% solution of Virkon inactivated 10^66 infectious doses (ID50) of HIV-1 per ml within 10 minutes at room temperature.

Is an emergency plan required according to regulation 20?  

N

If yes, tick to confirm that it is attached to this form

N

Tick to confirm that you have attached a risk assessment to this form

Y

Tick if you are claiming exemption from disclosure for section of the risk assessment

N
1. I am not sure that the statement that pMDLg/pRRE expresses no gag/pol has ever been convincingly demonstrated. Perhaps it is better to say that only very low or undetectable levels will be anticipated.
2. The applicant states that he has never detected replication competent virus. How has he looked for it? Has it ever been detected?
3. Is there validation data for Virkon against lentiviruses?
4. Is the KI discus test carried out annually rather than six monthly?
5. The autoclave should be additionally tested with Brown's tubes on a regular basis.

All of the above have been addressed in the assessment. The GMSC have approved this assessment.

02/03/2022
### Purposes of the contained use

The study will investigate the promoter activities of a range of HLA-DQA1 and -DGB1 alleles associated with susceptibility to, and protection from, autoimmune type 1 diabetes.

### Recipient or parental organism

**Hosts:** Initial host - E. coli JM109, a disabled lab adapted host, non pathogenic.

Final host - EBV transformed lymphoblastoid cells lines, MGAR, COX, BSM, EMJ and HHK. These cell lines are derived from healthy human subjects with different HLA-DG genotypes. They are commercially available and are not derived from workers in the department of Medicine. The cell will be unable to colonise workers as they are incompatible at the HLA class 1 and class II loci and will therefore provoke a host-versus-graft immune response. There is a potential infection risk from the EBV but the proposed GM is not expected to alter this pathogenicity. The DG promoters are very weak eukaryotic promoters and will not be integrated into the genome of the host cells.

### Host/vector system

**Vectors:** pCAT3 Basic reporter vector contains f1 origin of replication, ampicillin resistance gene and chloramphenicol acetyltransferase gene. pCAT3 control vector also contains SV40 promoter and SV40 enhancer sequences.

pSVB-Gal contains SV40 promoter/enhancer. E. coli gpt promoter located upstream of the lac Z gene and ampicillin resistance gene. All vectors are derived from the pUC series and are non-mobilisable.

### Origin & function

**Source:** Five EBV transformed human B lymphoblastoid cell lines, homozygous for different DG types (MGAR, COX, BSM, HHK, EMJ). All cell lines are from the European Collection of Cell Cultures, Porton Down, and are all initially derived from healthy human donors.

**Genetic sequences:** 600bp fragments of the proximal promoter region of the following HLA-DQ alleles - DGA1*0102, DGA1*0103, DGA1*0301, DGA1*0501, DGB1*0201, DGB1*0302, DGB1*0602, DGB1*0603, DGB10604 - cloned upstream of the reporter gene encoding chloramphenicol acetyltransferase. All wild type sequences.

### Evaluation of foreseeable effects

**Human Health:** The host bacterial strain is non-pathogenic to humans. Genetic modification will not pose any risk to health as no expressed protein will be secreted from the cells and the pathogenicity of the host will not be altered (except conferring resistance to ampicillin).

Expression in human lymphocytes - the primary risk to health will be related to the EBV transformation of the host cell lines, which poses an additional risk of EBV infection. Genetic modification of these cells will not pose any additional risk as no protein products will be secreted and the GMOs created will be transient (they will be lysed for analysis 48 hours after transfection). The cell lines are HLA incompatible with the workers and will therefore provoke a host-versus-graft immune rejection response, preventing colonisation. A record is kept of the HLA profile of staff working in the department of Medicine and all new workers are routinely HLA typed. New subjects at risk of colonisation by the cell lines can therefore be identified and prevented from working with the cells.

Immunocompromised individuals and pregnant women will not be permitted to work with the transformed lymphocyte lines due to the risk of EBV infection.

**Environmental considerations:** B lymphocyte lines will die outside correct culture environment. No potential hazards associated with GM bacterial cells - disabled, non-colonising, laboratory adapted host.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**N/A**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

No application for derogation

02/02/2022
Liquid waste contaminated with GMMs will be decanted into waste pots containing Vernagel to solidify the waste. This waste will then be inactivated by autoclaving (100% kill). Solid waste (excluding serological pipettes) autoclaved prior to disposal via clinical waste route - ultimately incinerated. Serological pipettes to be soaked overnight in 1% Virkon, drained and sealed in bags for autoclaving. Autoclave regularly tested. Brown's tubes used every week to check autoclave performance.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

1. Who are the donors of the healthy B-cell lines mentioned in the section “Name and Characteristics of the Host”? The cells from other workers within the Dept. of Medicine should not be cultured.

2. 70% ethanol should not be used to decontaminate the safety cabinet due to the fire/explosion risk. Trigene would be safer.

3. Putting Virkon treated waste through the autoclave may corrode the machine.

4. Has 0.5% SDS been validated as a disinfectant?

The above points have been addressed. SDS is no longer to be used as a disinfectant. The GMSC has approved this assessment.

Project Ref 116/04.2

Date Ackn'd CU2 Project Title Class CultureVolClass2 CultureVolumeClass3-4

02/03/2022
In order to investigate the signalling properties of the largely endothelial-restricted vascular endothelial cell growth factor (VEGF) receptors (VEGFR-1/Flt-1, VEGFR-2/KDR, VEGFR-3/Flt-4 and neuropilins) and Tie receptor tyrosine kinases (Tie-1 and Tie-2) we will produce recombinant replication-deficient retroviruses encoding chimaeric receptors and wildtype/inactive mutants of downstream signalling intermediates.

Recipient or parental organism

Host - The two retrovirus systems will be packaged in (I) HEK293T cells or (ii) GP+E86 or gp envE86 packaging cells Plasmids will be amplified in E.coli (e.g. DH5)

Host/vector system

Replication-defective retroviruses derived largely from Maloney murine leukaemia virus (MuLV). These will be generated using two systems: (I) The MFG retrovirus vector uses a series of 3 plasmids pMD.MLV (gag-pol), pMD.G(env) encoding the cDNAs of proteins required for viral packaging, and pMMP into which sequences of interest are inserted. (ii) LNCX plasmid contains a cytomegalovirus (CMV) immediate early promoter which drives the expression of the inserted gene, and lacks gag, pol, and env genes which are provided by packaging cells.

Origin & function

Human and mouse
EGFR-1, c-fms, VEGFR-1-3, Tie-1/-2(Tek), neuropilin, RhoA-N19, h*ARK1, dn-p85, Rac-N17, Phospholipase D (PLD), LacZ and enhanced-GFP. These include chimaeric receptors and proteins which alter cell signalling. See assessment for greater detail.

Evaluation of foreseeable effects

The chimaeric receptor inserts harness the EGF and c-fms receptor extracellular domains and the intracellular portions of VEGF, neuropilin and Tie receptors. The wild-type VEGFRs, neuropilins and Tie receptors are not associated with cell transformation. However, they may promote malignant progression indirectly. Although it is unlikely that these viruses would pose an oncogenic risk, differences in the abundance and distribution of the EGF and CSF-1 activating ligands compared with the natural ligands and their uncharacterised activity in cell types that would not normally express them should be taken into consideration. The mutant/inactive signalling proteins are well established (e.g. RhoA-N19, Rac-N17) inhibitors of cell signalling pathways some of which are associated with cell transformation and some have been shown to inhibit
cell transformation and malignant progression. Although it is unlikely that these inhibitors would present a risk of cell transformation they could disrupt normal cell function. Retroviruses expressing LacZ and E-GFP are not associated with toxicity or cell transformation. Amphotropic retroviral vectors facilitate efficient gene transfer into replicating human cells and following infection the viral genome is incorporated into the target cell chromosomes. There is a potential risk of insertional mutagenesis or enhancement of host cell expression of genes adjacent to the integration site associated with retroviral infection. There is also a potential risk that virus stock may become contaminated with replication-competent retroviruses. These viruses would be considered to pose a greater risk of malignant transformation given their potential to replicate and spread. However, it is unlikely that replication-competent retrovirus would be generated. Amphotropic retroviruses have a broad host range and are therefore capable of infecting animals in the wild. However, the risk is extremely low as retroviruses are readily inactivated and will not survive for long in the environment. The potential for an environmental hazard would be dependant upon the unlikely generation of recombinant replication competent retrovirus. Outside the tissue culture environment the retrovirus packaging cell lines and infected target cells will not be viable. The plasmids encoding the retroviral genes and inserts are mobilisation-defective in their E.coli hosts. The plasmids do not contain bacterial promoter sequences and so the inserts will not be expressed. The disabled host bacteria will not survive long in the environment.

containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

TriGene will be used to disinfect contaminated plastics, liquid waste and working areas. TriGene will be used at 1:50 dilution which is more than sufficient to inactivate retroviruses based upon the manufacturer's information even under heavy soil conditions (see below). Contaminated plastics will be immersed for at least one hour in TriGene solution and then autoclaved at 130°C for 60 mins before disposal. Solid waste will then be removed as "clinical waste" and incinerated by specialist contractors and liquid waste washed down the drain.

Expected degree of kill:

Autoclaving will effectively kill 100% of all GMMs

According to the manufacturer's information (MediChem Int.) TriGene inactivates HIV, FIV and the Feline Leukaemia virus (FeLV) at 1:200 (EN 1650) and 1:400 (EN 1276) dilution and therefore should inactivate similar retroviruses.

Please enter comments on the GM safety committee on the risk assessment

Because of the 2 classes of GMM created in this work the GMSC expressed concern at "mixed" working and highlighted this as an issue to be monitored. The GMSC has approved this assessment.

Project Additional Information

Purposes of the contained use
Genesis of lentiviral HCV pseudotypes: To investigate how HCV infects liver cells and the role of the humoral immune response plays in controlling HCV replication. This assessment covers the generation of lentiviral pseudotypes using a disabled lentiviral vector by transient expression of HCV gpl from an independent promoter. Genesis of HCV DNA and RNA: This seeks to generate synthetic HCV strain JFH RNA for subsequent recovery at CL3.

Recipient or parental organism
Genesis of lentiviral HCV pseudotypes: Hosts include E. coli (Top 10 strains, Invitrogen); 293T embryonal kidney cell line; Human hepatoma cell lines (HepG2, Huh-7, HepH, HH29); Primary hepatocytes.

Genesis of HCV DNA and RNA: E. coli (JM 109 derivative strain, Top10, Invitrogen).

Host/vector system
Genesis of lentiviral HCV pseudotypes: Vectors - pCDNA3 and pNL4.3R-E-lentiviral vector (based on a lab strain of HIV-1 from which the vpr and envelope genes have been deleted).

Genesis of HCV DNA and RNA: Vector - pUC19 (Stratagene).

Origin & function

Genesis of lentiviral HCV pseudotypes: Insert - HCV envelope gps - The E1E2 gps mediate viral attachment and fusion of the viral and host cell membranes necessary for infection of a target cell. The E1E2 region will be PCR amplified from clinical material and synthetic start and stop codons added to enable expression. Donor - Human (plasma samples and liver biopsies).

Genesis of HCV DNA and RNA: Insert - HCV DNA encoding the full length genomic sequence is not infectious for chimpanzees. However, synthetic RNA derived from plasmid DNA can lead to infection and seroconversion if delivered directly into the liver of a chimpanzee. The JFH strain of HCV will be used at this time. Donor - Human (plasma samples and liver biopsies).

Evaluation of foreseeable effects

Genesis of lentiviral HCV pseudotypes: 1) Transfected ‘producer’ 293T - Transfection of the pE1E2 expression constructs into 293T cells will result in the expression of HCV gps, which pose minimal risk to human health. Co-transfection of 293T cells with the lentiviral pNL4.3R-E- and vectors encoding the viral gps (HCV, VSV and MLV) will lead to expression of the reporter gene luciferase and the HIV proteins (gag, pol) which will drive assembly of pseudotypic particles. None of these viral proteins or luciferase have been associated with toxicity. 2) Lentiviral pseudotype infected target cells - The pseudotypes can only undergo a single cycle of infection and so the ‘infected’ target cells do not release new rounds of progeny virus. These cells do express lentiviral proteins and luciferase, which have no reported toxicity for humans. Accidental exposure by injection of these antigen expressing cells could lead to an immune response to the viral expressed genes. Whilst not harmful the detection of these immune responses is used in diagnosis of HIV infection, and so could lead to a false positive. Risks will be contained by handling materials at CL2. Environmental risks - The E. coli hosts used are disabled and require a supplemented media for growth. The 293T and hepatoma cell lines are only viable within tissue culture media and in the presence of CO2. The pseudotyped viral particles are not desiccation resistant and are incapable of replication. No risk to the environment.

Genesis of HCV DNA and RNA: HCV JFH plasmids bearing E1E2 sequences will constitute new GMOs. The E1E2 ORF(s) will be derived from naturally occurring sequences present within infected patients and will be unlikely to possess biolocal properties not already present within nature. DNA encoding HCV genomic length sequences are not infectious for chimpanzees and constitute minimal risk to human health. Synthetic HCV genomic RNA transcripts can be infectious for the chimpanzee if delivered intrahepatically. Other routes of delivery have not led to infection. Consequently the risk to human health at generating the RNA is minimal and can be contained at CL2. All experiments involving the delivery of the RNA into mammalian cells will take place at CL3 (to be submitted in due course). Environmental risk - The E. coli strains are disabled and are transfected using non-mobilisable vectors. The naked DNA generated by in vitro transcription will be unprotected from environmental RNAases and will degrade rapidly if released.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation applied for.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Surfaces to be wiped with 10% Trigene which has been shown to be an effective agent for inactivation of a wide range of enveloped viruses. Disposable plasticware will be rinsed in 10% Trigene, autoclaved and disposed of as clinical waste by incineration. Disposable gloves, paper towels etc will be deposited in autoclave bags and autoclaved before disposal.
Centrifuges and other equipment will be disinfected by wiping with 10% Trigene. If necessary the buckets can be totally immersed in this disinfectant. Autoclaving of waste achieves 100% kill.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

Originally the assessments were circulated in a different format with different titles, but the GMSC felt that those assessments were repetative and lacking in clarity. Comments were passed back to the PIs and meetings were held to discuss the comments in detail. The assessments were revised and recirculated for final approval. The GMSC has now approved the work.

CU2 Project Title  

Cell culture propagation of Hepatitis C virus:
**Project Additional Information**

**Purposes of the contained use**
This proposal seeks to deliver HCV strain JFH RNA into human liver derived cells and to characterise the resulting particles. This follows on from the recently notified Class 2 proposals. "Genesis of HCV virus DNA and RNA" & "Genesis of lentivirus pseudotype particles bearing HCV glycoproteins". This proposal includes expression of HCV strain JFH in human liver cells. Translation of viral RNA will lead to expression of HCV proteins, particle assembly and release.

**Recipient or parental organism**
As section below.

**Host/vector system**
Host: Primary and transformed human liver cells: screened and found to be negative for known human pathogens (HIV, HBV etc). After RNA transfection, the cells will be monitored for HCV infection for up to 14 days before being discarded.
Vector: The JFH strain of HCV is the only known HCV sequence capable of autonomous replication in hepatoma cell lines without adaptive mutation. Recent experiments suggest that the JFh strain can assemble and release viral particles at low titre in cell culture, which can be passaged in human cells. It is not known if these particles are infectious for humans.

**Origin & function**
Donor: HCV within clinical material from infected patients.
Genetic material: The investigators plan to transfect synthetic HCV RNA generated by run off transcription into liver cells to generate virus particles. Construction of these HCV genomes has been described in previously notified proposals. Plasmid DNA encoding the full length HCV genomic sequence is not infectious for chimpanzees. However, synthetic RNA derived from this DNA can lead to infection and seroconversion if delivered directly into the liver of a chimpanzee (Kolykhalov 1997).

**Evaluation of foreseeable effects**
Hazards to human health: Transfection and delivery of HCV RNA transcripts into human liver cells will lead to the expression of viral proteins which will result in the assembly of viral particles. Plasmid DNA encoding HCV JFH with heterologous E1E2 sequences will constitute new GMOs. The E1E2 ORF(s) will be derived from naturally occurring sequences present within infected patients and will be unlikely to possess biological properties not already present in nature. Synthetic HCV genomic RNA transcripts can be infectious for the chimpanzee if high doses are delivered intra-hepatically. Other routes of HCV RNA delivery have not led to infection. All experiments involving the delivery of genomic RNA into mammalian cells will take place under CL3 containment.
Environmental Hazards: The GMOs generated by this work pose no threat to the environment. The eukaryotic cells and cell lines used will be unable to survive in the external environment. The naked DNA used in electroporation will be unprotected from environmental RNAases and would be degraded rapidly if released into the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Project Ref 116/05.3

Date Ackn’d 08/07/2005

CU2 Project Title Cellular transduction in vitro and in vivo with engineered second generation……

Class CultureVolClass2 CultureVolumeClass3-4

Class 2 ≤ 1 Litre
**Project Additional Information**

**Purposes of the contained use**

The laboratory is dedicated to researching potential therapeutic targets for central nervous system (CNS) repair and the use of gene therapy in the CNS. The aim of this project is to analyse the efficiency of gene delivery to neurons using a lentiviral vector based on HIV-1.

**Recipient or parental organism**

Host - Virus will be produced in 293T cells (do not contain any complementing genome). Infectivity of the virus will be tested on 911/HeLa cell lines (viral titering). The engineered viruses will be tested for infectivity and transgene expression initially in vitro in established cell lines including PC-12 and C6 glioma cells and rat and mouse dorsal root ganglia (DRG) and retinal ganglion primary neuronal cell cultures. These will be used to transduce neurons in vivo in rat and mouse CNS injury models by injection into a number of sites, or delivery within a fibrocellular matrix (gene activated matrix) implanted into these sites.

**Host/vector system**

Vector - GM Lentivirus based on HIV-1 backbone with the ability to integrate the vector provirus into the host genome. This virus is multiply attenuated (deletions of vpu, vif, vpr and nef virulence genes and the env gene) and incapable of replication in the host. A 400bp deletion in the U3 region of the 3'LTR renders the virus self-inactivating (Zufferey et al.1998, j.Virol.72 (12) p 9873). The vector is pseudotyped with the vesicular stomatitis virus glycoprotein G (VSV-G) coat replacing the wild-type env encoded coat, to produce an amphotropic virus or with Rabies G protein to produce a predominantly neuronal tropic virus.

**Origin & function**

Genetic material - Aequorea Victoria Jellyfish; Green Flourescent Protein (GFP) - reporter gene. Human; Nerve Growth Factor, Neurotrophin 3, Brain Derived Neurotrophic Factor, Ciliary Neurotrophic Factor, Fibroblast Growth Factor type 2 - to stimulate neurite outgrowth from transduced neurons. Woodchuck Hepatitis Virus; Post-transcriptional Regulatory Element - WPRE (with a deletion in the X-protein encoding region - for increased mRNA handling and robust expression. shRNA sequences (based on rodent mRNA) homologous to components of axonal growth cone, inhibitory pathway components including: low affinity neurotrophin receptor p75NTR, TNF, Related receptor TROY, LINGO-1, RhoA small GTPase, Rho activated kinase (ROCK) - to give knockdown by RNA interference, disrupting the cascade and preventing inhibition of neurite outgrowth by myelin. Caspase 3 shRNA - to knockdown caspase 3 and impede neuronal apoptosis. shRNA sequences will be chemically synthesised.

**Evaluation of foreseeable effects**

Vector: Insertional mutagenesis: The insertion of HIV-1 provirus into the host is widespread, can be multiple and can involve activation of transcription in adjacent host
genes (due to strong LTR promoters), resulting in insertional mutagenesis and potential activation of oncogenes depending on the site of insertion. Despite the latter possibility, lentiviruses are not usually oncogenic. The risk of insertional mutagenesis has been addressed by using a SIN vector but there is the potential ability of the internal promoter used (of which CMV and Sffv are strong promoters) to read-through the inserted genome and activate transcription of adjacent genes. Germline integration should not occur.

Recombination and formation of replication competent retrovirus (RCR): Recombination resulting in wild-type HIV-1 cannot occur. Vector design uses 3 plasmids to reduce the occurrence of recombination of a functional genome during production. Production of a replication competent GM virus is highly unlikely. Testing of the system for RCR has previously shown absence of detectable helper virus. Importantly, in the absence of RCR the virus will not disseminate. Immunogenicity: Lentiviral vectors used so far have shown minimal immune response to their introduction, VSV-G toxicity has not been reported and Rabies G vectors in the CNS have shown minimal immune response, nontoxicity, plus unaltered physiological profiles.

Inserts: SIN vectors should prevent expression of anything external to the transgene cassette in all cells. Risks due to the GFP insert are minimal. The risks of neurotrophin and FGF-2 inserts are deemed to be low, these genes have not been shown to be tumorigenic in previous studies despite their cellular effects, the risks remains but is reduced by the restriction of dissemination of the virus and the reduction (to minimal) of exposure when working within safe guidelines. All shRNA sequences except RhoA, ROCK and Caspase3 should pose effectively zero hazard if accidental inoculation occurred. The former 3 do pose a risk of tumorigenic effects especially inhibition of caspase 3, the risk is reduced by the sequence specific homology required for siRNA action to occur. We have acknowledged GTAC/SACGM advice given following the report of liver tumours in mice treated with lentiviral vectors. Appropriate measures will be taken in our animal experimentation work and in this vector system WPRE is represent with a large deletion in the coding region for Xprotein (to address it's potential oncogenic effect), it should not be necessary to suggest a containment level above 2.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Freshly mixed 1% Virkon. Followed by 70% Ethanol will be used for regular decontamination of all surfaces, transport and storage containers, incubator shelves and for the decontamination of titanium centrifuge buckets (suitable for this rotor).

1% Virkon has been proven active against HIV-1, Rabies and parent Rhabdoviridea (VSV).

All disposable pipettes, pipette tips, flasks, tubes and culture dishes that have been in contact with viral media will be transferred to a fresh 1% Virkon solution after use where they will be left to immerse for a least 20 minutes before transferring to a sharps container for incineration (tips only) or 2 (doubled up) autoclave bags for autoclaving (130oC for 30 minutes) and removal as "clinical waste" by specialist contractors, with final disposal by incineration. Protective clothing will be immediately transferred to autoclave bags after use.

Media used will be removed by a vacuum pump in the biological safety cabinet, which will then be used to aspirate 1% Virkon for disinfection. Media from the vacuum pump tank will be autoclaved at 130oC for 60 mins prior to disposal into allocated drains. Any media spills will be cleaned up immediately by use of Virkon powder to absorb the spill followed by wiping the surface with 1% Virkon and 70% Ethanol.

Surgical instruments and micropipette injection tips will be transferred to 1% Virkon immediately after use and packaged appropriately for incineration (sharps container for tips) or in the case of instruments for decontamination by autoclaving in BMSU.

The operating room will be decontaminated using 1% Virkon.
The GMSC felt the assessment was extremely thorough and approved it without adverse comment.

**Project Additional Information**

**Purposes of the contained use**

The researchers wish to submit a series of assessments that form a connected programme of work that includes several pathogens and several activities. The work focuses on the characterisation of proven or potential antibiotic-resistance determinants from human and animal bacterial pathogens that fall into ACDP category 2. These include:

- Salmonella enterica (non-typhoidal serovars)
- Escherichia coli (non-vero-toxin-producing)
- Campylobacter jejuni
- Staphylococcus aureus and coagulase-negative staphylococci
- Bacteroides fragilis
- Mycobacterium bovis BCG
- Streptococcus pyogenes, S. pneumoniae, S. agalactiae and viridans group streptococci (eg S. mitis, S. oralis)
- Pseudomonas aeruginosa

**Recipient or parental organism**

Host organisms: Non-pathogenic laboratory strains of E. coli (eg K12), and pathogenic bacteria as described below.

Enterobacteriaceae (salmonella, E. coli, Campylobacter spp) are capable of causing diarrhoeal disease which is usually self-limiting within a few days, symptoms can include; diarrhoea, vomiting and abdominal cramps. Rarely these species can cause systemic disease and bacteraemia.

Staphylococcus aureus is capable of causing skin and wound infections which can be self limiting or may be prolonged. S. aureus is capable of causing severe systemic infections if it enters the bloodstream. Symptoms of skin infections include rashes, abscess and spot formation.

Bacteroides fragilis is an obligately anaerobic pathogen capable of causing deep wound infections.

Streptococci are capable of causing respiratory tract infections which may be self limiting within a couple of weeks or may become chronic and require antibiotic treatment to resolve them. Symptoms include coughing, shortness of breath and chest pain.

Pseudomonas aeruginosa is a versatile pathogen capable of causing a range of infections, particularly of the respiratory tract. P. aeruginosa can also cause systemic infection. Symptoms of the respiratory infections include coughing, shortness of breath and chest pain.

Mycobacterium bovis can rarely cause tuberculosis, symptoms are prolonged and can include fever, chills, weight loss, abdominal pain, diarrhoea or constipation.

**Host/vector system**

Vectors: Non-mobilisable or mobilisation defective vectors including, or similar to those in Part 2A, Annex II of ACGM Compendium of Guidance.

Non-mobilisable or mobilisation defective vectors that 1) can be propagated in crippled E. coli strains, but not in target species, eg pUC18 replicates in E. coli but not Campylobacter jejuni; 2) show temperature sensitive replication in E. coli, eg pK03 used in E. coli and Salmonella.

Non mobilisable vectors (eg pGEX4T3, the pET and pCAL vectors) that express the protein, either from promoters (eg tac) or from the gene's native promoter in its native form or as part of a his-tagged, calmodulin-binding peptide-tagged or similar fusion to an innocuous protein.

Non-mobilisable or mobilisation defective shuttle vectors which carry origins of replication that work in E. coli and a given other pathogen.
**Origin & function**

Source - Pathogenic bacteria as described above in Host section.
Genetic Material - DNA fragments encoding antibiotic resistance genes.

Source - E. coli, Firefly or luminescent vibrios, jellyfish
Genetic material - Genes that express marker proteins, which are highly unlikely to have any biological effect - Beta galactosidase, luciferase, Green Fluorescent Protein.

**Evaluation of foreseeable effects**

Human Health - Where host strains are non-pathogenic, expression of antibiotic resistance genes in these hosts will not increase pathogenicity. Elsewhere the risks are those associated with the wild type host - the genetic manipulations proposed should not increase the virulence of the resulting GMMs. In some areas of the work the GMMs created will become less susceptible to some antibiotics, although pathogenicity is likely to remain unaltered.

Environment - Each activity has its own environmental risk assessment within the assessment. In all cases the risk to the environment is very low or negligible. Please see assessment for discussion on each activity.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All bacterial cultures and contaminated solutions will be autoclaved. Autoclave runs are monitored. 100% kill rate. Waste from the autoclaving process is taken away from incineration as hazardous waste by approved contractor.

Please enter comments on the GM safety committee on the risk assessment

Specific comments from one reviewer are attached. These have been addressed within the assessment by the PI. Other concerns raised by the GMSC included the broad nature of the proposal, and how to successfully monitor the work. It is anticipated that this proposal will catch all previously notified work, and that the Principal Investigator will submit any additional activities to the GMSC for approval in future.

02/03/2022 Page 3347 of 15326
**Project Ref** 116/05.5

**Project Additional Information**

**Purposes of the contained use**

Human endothelial cells of various origins will be immortalised using a dual vector system that is controlled by temperature. Use will be made of a system that has already been optimised and established in other laboratories for this cell type. The vectors are Babe hygro-hTERT, an amphotropic murine leukemia virus containing the human telomerase gene (cell survival gene) and U19tA58LT virus containing the SV40T antigen (immortalising gene construct).

**Recipient or parental organism**

HOST - Primary human endothelial cells from a variety of sources. Commercially available from donors screened for infectious agents and unrelated to operators.

**Host/vector system**

VECTOR - pBabe hygro=mammalian expression, retroviral, resistant to ampicillin, high copy. The pBabe retroviral vector constructs transmit inserted genes at high titres and express them from the Mo MuLV Long Terminal Repeat (LTR). pBabe- hygro-hTERT was constructed by inserting the EcoRI-to-Sall fragment containing the full length hTERT cDNA from pCI-Neo hTERT into the EcoRI-Sall sites of pBabe-hygro.

Packing cell line for babe hygro hTERT is TEFLY-A derived from human rhabdomyosarcoma TE61 cells containing CeB and AF plasmids containing vector core and...
envelope proteins respectively. The U19tsA58LT vector was constructed by using the pZipNeoSV(X)1 backbone and encodes a full length LT cDNA (SV40 T antigen) from U19tsA58 and confers resistance to G418. Expression conditional on temperature as inactive at 37°C. Amphotropic packing cell line is PA317, a mouse fibroblast with herpes TK gene. Both vectors will be obtained from an external source already constructed and therefore no further manipulation will be required. Retrovirus is replication deficient.

Origin & function

OTGIN - Full length hTERT cDNA is the human telomerase gene. Telomerase is an enzyme which replicates the terminal sequence of eukaryotic chromosomes, namely the telomeras. Cells which have an unlimited replicative capacity such as male germ cells and the majority of human cancers have high levels of telomerase activity. SV40 is derived from the Polyomaviruses Simian Vacuolating Virus 40. The SV40 large T antigen is an early protein that interacts with the p53 and Rb tumour suppressor proteins.

Genetic material - U19tsA58L is a combination of 2 mutants, U19 which encodes a LT (Large T antigen) that does not bind specifically to SV40-origin DNA sequences, and tsA58 which encodes a thermolabile LT antigen that is wild type at 33.5°C, but inactive at 37°C.

Evaluation of foreseeable effects

Human Health - Constructs will be obtained pre-made and therefore no manipulations will be required other than infection of host cells. Minimal risk from ingestion as U19tsA58 thermolabile and inactive at 37°C some risk by skin contact where body temperature lower. Human telomerase activity can only be reconstituted by both the essential RNA subunit, hTERC, along with the catalytic protein component coded for by the hTERT gene, which are controlled at the transcriptional level. Retrovirus is replication deficient and so can not form viable progeny. Cells expressing hTERT and SV40 T antigen are only tumourigenic when contain oncogenic Ras (Neoplasia 2002 Nov-Dec;4(6):493-500) so this significantly lowers risk. Self inoculation with a significant dose of retrovirus could result in tumour formation but would probably require a large number of cells to be infected. Retrovirus is unable to infect non-dividing cells so this lowers likelihood of reversion to generate replication competent virus - minimised in FLY packaging cells as the gag-pol is separated from the env on different plasmids and use heterologous promoters rather than viral LTR promoters. Little or no evidence of generation of replication competent retrovirus. PA317 cells are able to generate replication competent virus but if are handled at level 2 this should provide sufficient operator protection. Cells to be transformed will not be derived from the operator or any members of staff affiliated to the laboratory. Therefore if inoculation due to sharp injury were to occur they would be susceptible to a strong allogenic immune response and so be rapidly eliminated.

Environment - Retrovirus is replication deficient and therefore unable to produce viable progeny, additionly retroviruses have a short half-life. The system is thermolabile and inactivated at 37°C. The host cells to be used are primary cultures of human cells which are unable to survive outside of controlled cell culture conditions. Therefore it is considered that release of any of the components will not harm the environment. Negligible risk. If accidental release were to occur it would be in very small quantities and the ramifications would be negligible.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be put into capped pots and autoclaved. Plastic waste, paper waste and pipette tips in Diposafe jars will be autoclaved. Waste is then removed by clinical
waste contractor for incineration.

When the proposal was originally circulated to the GMSC it lacked considerable detail. The attached comments reflect the requests for additional information. The assessment was expanded to address the issues raised and then recirculated to the GMSC. A few more suggestions came in from the committee in response, and the enclosed assessment is the final version.

### Purposes of the contained use

The work investigates the basic molecular biology (e.g. gene sequences, regulation of gene expression etc) and molecular microbiology of E.coli K12 and E.coli O157 (Sakai). ONLY these strains will be used in this project. Aims and objectives include: 1) To generate reproducible expression and metabolic data on acid stress response in E.coli. 2) Construction of mathematical models representing E.coli K12 and E.coli Sakai response to acid. 3) Experimental verification of the models generated. 4) Refinement of the initial computational models.

### Host/vector system

**Host:** Host strains for recombinant DNA work will be standard laboratory-adapted E.coli K-12 and the E.coli O157 Sakai. For expression of e.g. known virulence factors at high levels, highly disabled strains such as recA-hosts will be used, whereby risk of mobilisation of sequences is minimised. For mutagenesis experiments, either E.coli K12 or Sakai will be used and genes of interest replaced by modified alleles which will inactivate the gene in question. Strains of E.coli used will normally be those for which whole-genome DNA sequences are available.

**Vector:** Vectors will generally be pUC, pBluescript and related non-mobilisable ColE1-based standard vectors, or lambda phage-based cloning vectors, or standard low copy number vectors such as pACYC or pSC101 and derivatives. They may include high level expression systems such as in the Novagen pET system in which expression is tightly controlled via T7 RNA polymerase.

### Origin & function

**Source of genetic material:** Sources are either whole genomic DNA or PCR-amplified known sequences, from Escherichia coli K12 and Sakai. In general source DNA will be taken from an organism for which a whole genome sequence is known. No organisms requiring containment level greater than 2 will be used.

**Function of genetic material:** Sequences used may be any gene or sequence including gens of known or unknown function, including virulence factors. Genes may be partial or complete and may include expression signals. Libraries may be constructed for limited purposes e.g. two-hybrid screening. Genes identified as putative factors associated to response to acid stress will be transferred between the two strains. Such experiments would not result in an increased containment level.

For mutagenesis work, sources include widely used and well characterised antibiotic resistance marker cassettes of known sequence, e.g. carrying resistance markers for kanamycin or chloramphenicol which are not used clinically or are or minor clinical significance only. These marker sequences are very widely used for such mutagenesis.
experiments and may be capable of full expression under control of their own or vector or host-derived expression signals. Where practicable, antibiotic resistance markers will be deleted after creation of mutagenised alleles, to leave an unmarked lesion in a strain of wild type antibiotic susceptibility. In general kanamycin resistance genes will be used in preference to chloramphenicol in view of the limited clinical usefulness of the latter antibiotic. In E.coli mutagenesis, the method of Datsenko and Warner (PNAS 97, 6640-6645, 2000) will be the method of choice and after excision leaves no permanent resistance marker.

Evaluation of foreseeable effects

Risks to Human Health: The level 3 containment requirement, and indeed the HSE definition for EHEC strains of E.coli and other bacteria such as Shigella spp expressing the toxin, is determined solely by the presence and expression of the stx genes (stx 1 and/or stx 2) encoding Shiga-like STX or Verocytotoxin VT. The toxin-deleted strains which are the subject of this assessment are thus by definition not EHEC and fall within containment level 2. They are nevertheless potentially capable of causing enteric or other infections or colonising the human body whether as members of the mucosal or enteric microflora. However, the diseases caused are rarely life threatening to those in normal health, are self limiting or readily treatable. E.coli K12 is a non-pathogenic strain which does not pose a safety threat. The parental pathogens concerned in the work generally express virulence factors involved in some or all of the above effects on health. GMMs based on E. coli hosts may acquire a limited number of such characteristics which in theory might enhance their pathogenic properties, but these are unlikely to comprise more than one or a small number of virulence attributes in any one instance and are not therefore likely to create new virulence phenotypes more pathogenic than the parent organism from which the cloned sequences originated (full virulence of pathogens is known generally to be the sum of expression of a number of virulence related genes).

Site-directed mutagenesis of parental pathogenic organisms by allelic replacement with disabled genes, based on engineered insertional inactivation with or without simultaneous partial or complete deletion of the wild type gene will utilise antibiotic resistance markers of no or limited clinical value such as kanamycin or chloramphenicol. Such constructs will be less virulant than wild type due to deletion of known or probably virulence determinants, and hence will be of reduced impact as pathogens and not likely to pose clinical problems in the unlikely event of an accidental infection of humans.

Environmental risk: The GMMs cannot be considered likely to express virulence or other factors that would be potentially harmful to the environment. No harmful effects are foreseen.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Inactivation will be by autoclaving of all wastes (including any small quantities of disinfectant - treated residues e.g. paper towels used for wiping up small spills) contaminated by GMMs, at a minimum of 121°C for 15 mins, validated by monitoring of internal chamber temperature and automatic printout of every autoclave run. Validation will be carried out using Bacillus subtilis spore strips and autoclave tape used on every sample being autoclaved. This method is widely acknowledged to guarantee complete killing of all known bacteria. Wastes from autoclaving will be disposed of to the drains (liquids) or to clinical waste incineration.

Is an emergency plan required according to regulation 20?  

N

If yes, tick to confirm that it is attached to this form 

N

Tick to confirm that you have attached a risk assessment to this form  

Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  

N
The original assessment was broader than the attached version and was felt to be too broad by the GMSC. The investigators decided to use only K12 and sakai strains of E.coli for this work as a result of the GMSC's comments:

* The objectives of this project need to be more clearly spelt out, and the host organisms need to be defined. The committee feels the organisms in use should be specified, rather than suggesting that "level 2 organisms may be the host".

There was also a concern at the number of facilities listed for use in the project and the GMSC needed reassurance that the project was going to be well managed and closely supervised.

**Project Ref 116/06.2**

**CU2 Project Title**
Molecular studies of the genes and gene products of Kaposi's sarcoma-associated herpesvirus (KSHV), the virus also known as human herpesvirus (HHV)-8.

**Class**
Class 2

**CultureVol**
1-50 Litres

**Non-GMM Consent Granted**
Not Applicable

**Project notified under transitional arrangements**
No
**Project Additional Information**

**Purposes of the contained use**

To understand the molecular mechanisms governing KSHV gene expression and the processes by which KSHV gene products regulate host cell functions, such as cell cycle and immunological activities.

**Recipient or parental organism**

Three types of KSHV strain will be studied: (i) Wild type (WT) virus produced from naturally infected primary effusion lymphoma cells or other natural sources. (ii) Virus specifying either green fluorescent protein (strain rKSHV.152) or enhanced-GFP (E-GFP) and Ds red fluorescent protein (strain rKSHV.219) or other innocuous reporter and antibiotic resistance genes. (iii) Virus derived by bacterial artificial chromosome technology, either wild type (strain BAC36) or deleted for specific KSHV open reading frames to assess their contribution to KSHV pathogenesis. Additionally, recombinant replication-defective adenovirus and retrovirus constructs expressing KSHV genes will be used to investigate the function of specific genes and plasmids carrying KSHV genes will be grown in E.coli and transfected into mammalian cells in tissue culture.

**Host/vector system**

Disabled E.coli for plasmid construction. Eukaryotic cells such as 293 and other cell types, human and non-human, to generate infectious particles of WT and genetically modified KSHV and to study infection processes. Primary effusion lymphoma (PEL) cell lines for production of KSHV. Target cells: human cell lines, primary cells of endothelial, epithelial and lymphoid origin (liver, gut, stomach, thymus, B-and T-lymphocytes, monocytes). E1-deleted, replication-defective adenovirus vectors will be produced in cells such as 293 cells that complement the E1-deficiency of the vector; transgenes will be inserted at the site of E1 deletion of the vector. For generation of retrovirus vectors, packaging cell lines in which the gag-pol and env genes are separated will be used, to minimise the possibility of recombination leading to replication-competent virus.

**Origin & function**

Genetic material will be derived from KSHV.
Recombinant vectors will be used for projects including:
(i) Generating restriction fragments for use as DNA & RNA probes.
(ii) Studies of KSHV promoter regulation.
(iii) Functional studies of KSHV proteins purified from bacterial cells.
(iv) Transient and stable expression of wild type and mutant KSHV proteins in eukaryotic cells in studies of their function.
(v) Functional studies of KSHV proteins purified from stable eukaryotic cells.
(vi) Recombinant adenovirus vector expression of wild type and mutant KSHV proteins in eukaryotic cells in studies of their function.
(vii) Recombinant retrovirus vector expression of wild type and mutant KSHV proteins in eukaryotic cells in studies of their function.
(viii) Recombinant KSHV virion production and purification for infection studies.
(ix) Recombinant KSHV virion production and purification for functional studies of virus and virus-infected cells.

**Evaluation of foreseeable effects**

KSHV is a human gammaherpesvirus. The incidence of KSHV is 3.5% in the general population of the U.S. and the United Kingdom. However, in those geographical areas where Kaposi’s sarcoma (KS) is endemic, the incidence is much higher, e.g. - 11.5% in western Sicily and 29% in south Africa. KSHV cannot survive outside the only known host, human beings; transmission between individuals requires direct contact and probably occurs via saliva. Overwhelming serological and molecular data implicate KSHV in the aetiology of KS, but infection with the virus alone is not sufficient for the development of KS, and additional factors are required, including immune suppression and perhaps host genotype.

Current opinion in the KSHV field is that the virus is either not transforming, or is poorly transforming. In this regard, Kaposi’s sarcoma, the tumour with which KSHV is most confidently identified as the aetiologic agent, is also not considered a true monoclonal neoplasm, but rather a hyperplasia in which KSHV and environmental cofactors such as inflammatory cytokines, promote cell proliferation. Late stage KS tumours may eventually develop into true sarcomas, since there is then often some evidence of
Several published reports claim that experimental KSHV infection of endothelial cells results in extended lifespan allowing their prolonged passage in vitro. In vivo, KSHV replication in tumour cells is in predominantly latent, suggesting that the proteins encoded by the latency genes may be involved in pathogenesis. The present studies encompass these KSHV genes and the proteins they encode. Present information on these transforming proteins can be summarised as follows:

LANA: this protein is expressed in KSHV-associated tumours. It functions to maintain the KSHV episome and might also serve as a transcription activator. LANA interacts with p45 and represses its transcriptional activity and can modulate the E2F-pRB pathway. It may have cell-transforming activity.

v-cyc is expressed in Kaposi's sarcoma lesions and in body cavity lymphomas. It activates the G1/S and G2/M cell cycle transitions by interacting with the cellular cyclin-dependent kinase 6 (cdk6) resulting in inactivation of Rb by phosphorylation. As a result, the E2F transactivator is released from Rb. V-cyc is resistant to the cell cycle inhibitors p16, p21 and p27. This facilitates transition from G1 to S and G2 to M. Transfection of v-cyc in quiescent fibroblasts leads to G1/S transition.

K1: has transforming functions in conventional rodent transformation assays. It recruits the Syk, vav, ans PI3 kinases to the cell membrane. Expression in vivo has not been demonstrated so far. Modulates B cell receptor expression.

Kaposin: stabilises certain cytokine transcripts.

V-GCR: encodes a chemokine receptor homolog. It includes the expression of the angiogenic factor VEGF and can transform cells.

V-IRF-1: inhibits interferon-induced signaling and transforms rat fibroblasts. No expression of this protein in the majority of KSHV-associated tumours in vivo.

The rKSHV.152 and rKSHV.219 strains replicate to similar, low levels as wild type virus and are not expected to present any greater hazard. The genes encoded by the BAC 36 are not expressed in the bacterial host. Hence, there is no potential to increase the pathogenicity of the host. Ther BAC 36-derived virus mutants are expected to have a decreased ability to infect and replicate in target cells compared to wild type KSHV. Mutated recombinant KSHV strains are expected to be less harmful than their wild type counterparts. The reporter genes are not expected to affect KSHV pathogenesis.

None of the KSHV genes, or the proteins they encode, presents a higher risk to workers particularly given that KSHV is, in the worst case scenario, only poorly transforming (see above). Nevertheless, cell transformation has been observed in studies with certain individual KSHV proteins, e.g. - K1, vGCR and vIFR-1 and level 2 containment should be used to minimise the chance of accidental contamination of workers with adenovirus or retrovirus constructs expressing KSHV genes. Should a worker be exposed to one of the proteins, an immune response would be anticipated, but is unlikely to confound diagnostic assays, since KSHV infection is not screened for routinely. Retroviral vectors allow efficient gene transfer, resulting in chromosomal integration, in the target cells. Infection is dependent on proliferation of the target cells, and has somw associated risk of insertional mutagenesis. Note that such insertional mutagenesis has resulted in oncogenic activation and leukemia in some patients in a gene therapy trial for X-SCID, however this was in the context of deliberate administration of very high doses of virus expressing the cytokine receptor gamma chain to haematopoietic stem cells. The lack of such adverse effects in most other gene therapy trials using retroviruses indicates that the chromosomal insertion of replication-defective retroviruses is generally unlikely to cause overt harm. Any accidental inoculation would result in many orders of magnitude fewer insertional events than in gene therapy clinical trials, and the level of risk is therefore much lower. Also, due to the (very slight) possibility of replication competent retrovirus, non-producer cells that have been infected with the virus should continue to be handled under conditions that prevent human contamination, at least until it has been proven that they are not producing (replication-competent) virus.

Expression of KSHV genes in mammalian cells is not expected to confer additional biological hazards. With the exception of ORF K9, encoding vIRF and ORF 74, encoding vGCR encoding a G protein coupled receptor (GPCR), none of the KSHV genes are active in a conventional rodent cell transformation assays. Expression of vGCR protein can purportedly lead to transformation of primary endothelial cells, but the risks of such cells becoming accidently inoculated into a worker is low, as is the risk of malignant transformation occurring in such individuals. None of the primary cell or cell lines used in these studies will be derived from the worker. Therefore, regardless of either the presence or absence of an expressed KSHV protein, their inoculation into the worker will induce a strong allogenic immune response, which will protect the individual. Therefore, handling of cells expressing either individual or few KSHV proteins poses no greater threat than that of culturing tumour-derived cell lines. However, this work is also classified as level 2 since in some experiments there will be a theoretical possibility that the transfected constructs could recombine with KSHV in the cell to generate GM KSHV, the potential hazards of which are discussed above.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation. Full CL2 applied.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

1% Virkon solution is validated for disinfection of most herpes viruses, including Herpes Simplex virus (HSV) and Cytomegalovirus (CMV). KSHV titres are several orders of magnitude lower than HSV titres, so that complete inactivation of this virus is expected.

All liquid waste is treated by autoclaving at 130°C for 60 mins, before disposal to drains.

Disposable solid waste which or may be contaminated with GMMs is also inactivated by autoclaving at 130°C for 30 mins, before removal as "clinical waste" by contractors, with final disposal by incineration.

The exceptions to autoclaving are:

"Sharps", including scalpel blades, needles (with or without attached syringes), and disposable plastic tips for micropipettes, may be decontaminated by drawing up Virkon disinfectant, and soaking in Virkon for a minimum of 10 minutes.

Disposable plastic pipettes may also be decontaminated by immersion in Virkon as above.

Expected degree of kill:

Autoclaving achieves effectively 100% kill of all GMMs.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The main issue raised by GMSC members concerned the potential transforming ability of KSHV. One reviewer noted that Fields Virology spoke of "KSHV-induced cell transformation", and stated that "direct infection and transformation of primary bone marrow endothelial cells has also been reported". The assessment clearly identifies the association with Kaposi's sarcoma, but emphasises the current opinion of experts in the field that the virus is, at worst weakly transforming. Nevertheless, a precautionary approach has been accepted that the virus, or certain genes from it, may be able to contribute to malignancy. The risk assessments have been amended to the satisfaction of the GMSC, and the work has been given approval.

### Project Additional Information

**Purposes of the contained use**

Mutants will be created in the human pathogens, *S. agalactiae*, and these will be assessed in a variety of phenotypic assays to identify those mutants that have reduced virulence. The genetic basis of the reduced virulence will be determined and this information used in downstream research to develop novel inhibitors and create attenuated vaccine strains.

**Recipient or parental organism**

Host- Disabled laboratory strains of *E. coli*, w/t *Streptococcus agalactiae*

**Host/vector system**

Vectors - *E. coli*-S. agalactiae shuttle vectors: Suicide vectors/pWV01 derivatives for introducing gene deletion constructs into the chromosome of *S agalactiae*. 
pJRS233, pVE6007, pAT28, pHY304, pG+host5, pCAM45

**Origin & function**
Donor- Strepococcus agalactiae

Genetic material - The inserts are kanamycin [Kan R], chloramphenicol [CmR], erythromycin [EmR] and spectinamycin [SpcR] resistance genes:

S.agalactiae infections are prevented by the administration of Intrapartum Antibiotic Prophylaxis (IAP) - penicillin, or clindamycin in penicillin allergic people. No strain has ever been reported to be resistant to penicillin, however strains are commonly found to be penicillin tolerant. This finding has not changed the UK or US recommendations to use penicillin alone for prophylaxis.

S.agalactiae infections are treated with either penicillin or a third generation cephalosporin, such as cefotaxime. Some wild-type strains are resistant to erythromycin and kanamycin through the acquisition of wild-type transposons, such as Tn916 and Tn917. Thus, these antibiotics are not routinely used or recommended for treatment. Chloramphenicol is not routinely used for the treatment of bacterial infections in babies because of adverse side effects. Infection recurrence has been reported in some babies infected with penicillin tolerant S.agalactiae. In such instances, a combination of penicillin and gentamicin are used for treatment. We therefore will not create penicillin or gentamicin resistant GMO strains.

Human Health risks: Wild-type S. agalactiae is highly adapted to colonising mammalian hosts. 10-30% of people at any one time are colonised with wild-type S.agalactiae. Invasive disease by the wild-type organism in healthy immune competent adults and children is a rare event. Where disease does arise, it predominantly occurs in newborn babies (~1:2,000 newborn babies have proven infection in the UK). In the majority of pregnant mothers vaginal colonisation is a benign event, however in a small minority vaginal colonisation is followed by bacterial invasion of the amniotic cavium and the fetus becomes secondarily infected initially with pneumonia, and secondarily with septicaemia. Laboratory staff who work with S.agalactiae will be educated/counseled about colonisation in pregnancy, and will be in an informed position to arrange Screening and IAP through their Midwife/Obstetrician.

Genetically modified S.agalactiae strains, with disruptions of genes known to encode virulence determinants or virulence regulators, are likely to be less fit at colonising and causing disease in man. For instance, wild-type S.agalactiae expresses a polysaccharide capsule containing sialic acid, surface proteins involved in adhesion to host cells, surface immune evasion molecules such as IgA protease, and it secretes toxins known to injure host cells. The expression of these proteins and structures is regulated by a network of interacting regulators. We aim to disrupt the regulators that we predict to be involved in expression of these virulence determinants. The actual genes we will disrupt have been chosen because homologues in the closely-related pathogen Streptococcus pyogenes are known to enhance the expression of virulence determinants, and regulatory mutants of this bacterial species have reduced virulence. Thus, we would expect that the mutants that we intend to create will have a reduced capacity to cause disease. The main risk to laboratory staff would therefore come from handling the wild-type strain. There is a tiny theoretical risk that a GMO could be created that has an enhanced ability to cause human disease. However, we will not create GMO strains that are resistant to the antibiotics commonly used for treatment. It is extremely unlikely that mutations of the virulence regulators would create a Class 3 GMO. Such mutations must arise naturally in the wild-type organism, and yet we have not seen the natural emergence of a category 3 strain.

See additional sheet for Environmental risk section.

Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Inactivation will be by autoclaving of all wastes (including any small quantities of disinfectant - treated residues e.g. paper towels used for wiping up small spills) contamination by GMOs, at a minimum of 121°C for 15 mins, validated by monitoring of internal chamber temperature and automatic printout of every autoclave run. This method is widely acknowledged to guarantee complete killing of all known bacteria. Wastes from autoclaving will be disposed of to the drains (liquids) or to clinical waste incineration.

**Kill = 100%**

Comments from GMSC included:

No large spills procedure defined or detailed.

Should pregnant women avoid doing these experiments? If so it needs to be stated.

Is it safe for people who are allergic to penicillin to be exposed to these bugs? (it leaves only 1 possible type of antibiotic for treatment, according to this?).

More detail requested throughout, e.g. what is the likelihood/consequences/symptoms of a virulent infection and what are the modifications being made to the virulence genes.

If a more virulent GMM were generated, what additional procedures would be in place to contain it - would it be a cat 3 organism?

All of these queries have been addressed and the assessment has been approved by the GMSC.

Project Ref 116/07.1
The study of signalling pathways in platelets has provided important information on the events that underlie their role in haemostasis and thrombosis. Megakaryocytes can be used to analyse signalling pathways in platelets but such studies are limited by the inability to transfected megakaryocytes with exogenous DNA constructs. It is proposed that the lentiviral system is used to drive infection as an alternative to transfection. This approach will be used to express mutant proteins of interest & knock down the function of specific gene products using RNA interference.

Recipient or parental organism

Host - Virus to be produced in human 293T cell line; Mouse primary megakaryocytes and the immortalised mouse megakaryocyte cell line HPC-7 (non-permissive for the production of replication deficient lentiviruses)

Host/vector system

Vectors - pWP1; pLVTHM; pMDLg/pRRE-rev; pMD2.g; pCMV-GIN-ZEO third generation lentiviral vector. Details given in assessment.

Origin & function

Source - Aequora victoria (jellyfish); Mouse

Genetic material - Green Fluorescent Protein; Mouse forms of I) wild type and mutant forms of immunoglobulin, lectin and tetraspanin transmembrane proteins and named signalling proteins; ii) short hairpin oligonucleotides against membrane receptors and signalling proteins named under (I) The Ig receptors are PECAM-1, G6b-B, G6F and CPV1; the lectin receptor is CLEC-2; the tetraspanins are CD9, CD63, CD151, TSSC6. The signalling proteins are Grb2, SHP-1, SHP-2; OPAL1, HS-1, cortacin, Arp2, Scar-1, Scar-2.

Future genes of interest, not named here, but with that function in similar signalling pathways, will be added to a list at the end of this assessment for periodical review by the local GMSC.
A) Risk of regenerating replication competent virus or the parental virus (HIV). In the third generation lentiviral vectors all six regulatory/accessory proteins (Rev, Tat, Vif, Vpu and Nef) are removed, except Rev. Rev acts at the post-transcriptional level is necessary for HIV gag/pol expression. Rev binds to a RNA motif (Rev responsive element [RRE] and facilitates the cytoplasmic export of gag/pol messenger. As an extra safety measurement Rev is placed on a separate vector, plus RRE and the packaging signal. The packaging construct contains the minimal RRE of 374bp and the gag/pol genes. Through deletions in both LTR's and the absence of 5 of the 6 accessory proteins, including the replication essential Tat, it is highly unlikely that replication competent virus is produced. In published studies and from Professor Alastair Strain's (Birmingham Biosciences) experience with these vectors, replication competent virus has never been detected. The HIV-envelope protein is replaced by non-retroviral envelope protein (VSV-G). It is highly unlikely that this will be incorporated in a new hybrid replicative virus. It is impossible that wild-type HIV will be formed, because of the omission of 5 accessory proteins and HIV-env.

The lentiviral vectors to be used in this study are third generation lentiviral vectors kindly provided by Dr Didier Trono or purchased from Open Biosystems.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation - full containment level 2 applied.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste is treated by autoclaving at 135°C for 15 min, before disposal to drains. This procedure has been approved at the University of Birmingham for Professor Alistair Strain's laboratory previously.

Disposal solid waste, including sharps in the appropriate biohazard sharps bins, which is or may be contaminated with GMMs, is also inactivated by autoclaving at 135°C for 15 min, before removal as "clinical waste" by specialist contractors, with final disposal by incineration. The autoclave is also tested with Brown's tubes on a regular basis.

Expected degree of Kill:

Autoclaving achieves effectively 100% kill of all GMMs

The manufactures of Virkon (Antec International Ltd) have commissioned studies on the virucidal effect of Virkon on Human Immunodeficiency virus and found that a 0.5% solution of Virkon inactivated 106 infectious doses (ID50) of HIV-1 per ml within 10 minutes at room temperature. Since we are only using stocks of up to 105, Virkon should be effective.

**Purposes of the contained use**

The Proline Rich Homeodomain (PRH) protein is also known as Hex, plays a variety of roles in the development and differentiation of mammalian cells, including haematopoieses. It is a transcription factor that can regulate translation and cell proliferation. Loss of PRH activities or expression is associated with myeloid leukaemias suggesting that PRH is a tumour suppressor protein in myeloid lineages. The work focuses on understanding the mechanism of action of PRH as a transcription factor.
Hosts - Bacterial work: E. coli K-12, JM101, XL1 and E. coli BL21. Yeast work: S. cerevisiae, strains MAV203; Mammalian cell lines for transient transfection: Human K562 blasts, HL60, avian human Jurkat cells, human HeLa avian BM2 cells, Simian Cos-7 cells, Murine HPC-7 and BM-HPC-5 haematopoietic stem cell lines, HUVEC cells - Primary human cell line Adenoviral infection of Cos-7 cells and human and mouse haematopoietic cell lines with Ad-PRH.

Host/vector system

Vectors - Bacterial expression vectors: pKK233-3, pGex, pTrcHis Yeast expression vectors pACT-1, pAS2-1, pGAD, pGB Mammalian expression vectors, pMUG1, pcDNA3, pCMV, pEGFPc1

Origin & function

Source of genetic material - PRH/Hex (human, mouse or chicken) cDNA cDNAs corresponding to PRH-interacting proteins including TLE corepressor protein, Casein kinase 2, POG 1 (Proliferation of Germ cell 1) HC8 (proteasome subunit), ZnF127 (zinc finger protein), p32

Function - PRH is a homeodomain protein that is involved in the regulation of transcription, translation and cell proliferation. The insert is either the cDNA for the full length protein, or the coding sequence corresponding to subdomains of the PRH protein, or the coding sequence for mutant PRH proteins. Additionally proteins that interact with PRH (see above) are used as inserts for expression in bacterial, yeast and mammalian cells. The cDNAs for these proteins derive from a two hybrid screen for PRH interacting proteins.

Evaluation of foreseeable effects

Human health risk - Bacteria and Yeast - Disabled strains of E. coli and non-pathogenic yeast expressing PRH are unlikely to be a hazard because they are unlikely to colonise humans. Some homeodomain proteins are known to be capable of intracellular transfer. It is not known whether PRH has this property but to prevent this outcome purified recombinant PRH proteins are always handled whilst using gloves. Even if PRH protein were to enter human cells it is unlikely that this would be sufficient to cause cancer. PRH proteins have only been shown to have an oncogenic effect in one study when they were retrovirally expressed, stably and at high levels. However a number of studies have also shown that high level expression of PRH leads to haematopoietic cell death and would therefore not lead to leukaemia. Transient transfection studies in cell lines - As mentioned above these studies are unlikely to cause cancer because PRH protein in these cells is not expressed stably. Transfected cells also present a low risk, since (if people are not working with their own cells), colonisation of the operator would probably be prevented by an allogenic immune response. Adenoviral-PRH infection of cell lines - The adenovirus can infect many human cells efficiently and it is possible that Ad-PRH that is inhaled or taken into the bloodstream or epidermal tissues by needles or injury could infect cells. I would expect the encoded protein to be expressed locally at the site of delivery, which may have effects on cell function/growth control. Effects will depend on cell type, and infection would be transient; however in view of the biological activities of the protein, particularly the risk of oncogenicity, this probably does warrant level 2 containment during work with the virus. Environmental Risks - The bacterial strains used are disabled and cannot exist for long in the external environment. Similarly the adenovirus is replication defective and can only survive with the specific host cell. Therefore, neither the bacteria nor the virus pose a threat to the environment and so environmental hazard is negligible. The following are PRH partner proteins as identified by a yeast two hybrid screen. They are not expected to result in any significant human harm when expressed in bacteria, yeast or transiently transfected into mammalian cell lines. Casein kinase 2 beta subunit is the regulatory subunit of CK2 and a PRH interacting partner protein. CK2 overexpression can be oncogenic in mammalian cells but over-expression of the regulatory subunit in isolation is as far as I am aware not known to have this effect. Bacterial, yeast or transient transfection studies in mammalian studies with the regulatory CK2 subunit are unlikely to have deleterious effects on human health. POG1 (Proliferation of Germ cell 1), FanCD2. The loss of this protein is related to loss of proliferation by germ cells. Also mutation of this ubiquitin ligase contributes to Fanconi's anaemia. HC8 (proteasome subunit) is a component of the 20S proteasome subunit and interacts directly with PRH in cells and in vitro. The function of this interaction is not known.
ZnF127/Makorin 3 Imprinted/Ring Finger protein associated with Prader-Willi syndrome.
P32 multifunctional protein, transcriptional corepressor protein and repressor of splicing.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

| N/A |

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

| No derogation - full CL2 applied |

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All tissue culture plastics (135°C, 15 min) and liquid waste (121°C, 20 min) generated during the production of adenoviral supernatants will be autoclaved before disposal. Autoclaving achieves effectively 100% kill of akk GMMs. Small volumes of liquid containing the viral particles will be used immediately. Pipette tips will also be treated with 1% Virkon then autoclaved before removed as clinical waste and incinerated. 1% Virkon is effective against adenoviruses according to the manufacturers information.

*Expected degree of kill:*
The manufacturers' information indicates efficacy of Virkon against a variety of adenoviruses at 1% concentration, and also against a number of strains of E. coli at dilutions ranging from 1% to 0.125%. It has been demonstrated that 15 minutes exposure to Virkon achieves >4log10 kill for adenovirus-infected cell pellets, and >6log kill of adenovirus seed stocks.

| Is an emergency plan required according to regulation 20? Y |
| If yes, tick to confirm that it is attached to this form N |
| Tick to confirm that you have attached a risk assessment to this form Y |
| Tick if you are claiming exemption from disclosure for section of the risk assessment N |

**Please enter comments on the GM safety committee on the risk assessment**

The section on human health effects was inadequately completed when the assessment was first submitted. The assessment was returned and additional information requested. In some circumstances PRH appears to function as an oncogene, and therefore the possibility that work could cause cancer was an issue requiring further elaboration.

Other proteins were mentioned in the original assessment and information on the activities of these was also requested (included on the additional sheet with this CU2 form).

The revised version of the assessment was submitted and approved without further comment by the GMSC.

Project Additional Information

Purposes of the contained use

1) Stable introduction of constructs to express short hairpin (sh) RNAs in cells, to target a variety of cellular or viral RNAs for degradation by RNA interference.

2) Stable introduction of constructs into cells to express genes of interest.

Recipient or parental organism

Human or other mammalian cell lines, including tumopur cell lines; primary human or rodent cells.

Host/vector system

Retrovirus vectors will be deleted for gag, pol and env genes, and produced in "split" packaging systems (e.g. FLY-A13 or FLY-RD18; Pheonix), in which the gag-pol and env genes are expressed from separate constructs, reducing the risk for regeneration of replication-competent recombinants to an extremely low level. Some vectors are also "self-inactivating" (SIN), with a deletion within the 3' U3 region which allows the vector to go through only a single round of infection after packaging. The envelope proteins used will allow infection of human cells, e.g. murine amphptropic, feline RD114, VSV-G.
Lentivirus vectors will be at least 3rd generation as described in the HSE/SACGM Guidance, i.e. the vectors being deleted for all viral genes, and separated onto at least 2 or 3 plasmids. The HIV envelope protein will not be used, all currently planned work will use the VSV-G envelope glycoprotein. Alternative systems may be used, such as the Invitrogen or Trono lab systems. All lentivirus vectors used will be self inactivating (SIN).

Origin & function

Genes of initial interest include human telomerase, T-cell receptors, and EBV latent genes, and this list will increase.

Evaluation of foreseeable effects

The effects of downregulating expression of a targeted gene will depend upon the particular gene, and could range from no discernable effect to marked phenotypic changes. Similarly, the effects of expressing a transferred gene could range from negligible to profound. In both situations, we consider the "worst case scenario" would be to bring about changes that could contribute to transforming a normal cell into a malignant cancer cell. For example, either shRNA-mediated downregulation of a tumour suppressor gene, or expression of either an oncogene or a gene associated with cellular immortalisation such as telomerase, could have such an effect. Although conversion of a cell from a normal to a cancerous state is believed to depend upon the accumulation of multiple changes affecting growth control and cellular checkpoints, making it unlikely that accidental worker inoculation and infection of a modest number of the cells with the viruses would lead to cancer, the seriousness of this potential consequence warrants the control measures afforded by level 2 containment to minimise the potential for accidents.

Since retroviruses and lentivirus vectors insert their genomes into the chromosomal DNA of infected cells, there is an associated risk of insertional mutagenesis. There have been examples of leukaemias apparently resulting from insertional activation of an oncogene in human gene therapy clinical trials; however these have only arisen in a minority of patients receiving such vectors, and involving doses many orders of magnitude greater than would occur in any foreseeable accident. Also, liver tumours have been reported following systematic injection of certain lentivirus vectors in foetal or neonatal mice. It is unclear whether these were caused as a result of insertional mutagenesis/oncogene activation, or whether the WPRE present in some of the vectors may have contributed an oncogenic protein fragment. Although standard retrovirus vectors can only affect replicating cells, lentiviruses can also infect non-dividing cells, and thus would be expected to result in a greater level of cell transduction following accidental worker exposure. Use of certain envelope proteins, such a VSV-G to pseudotype the viruses, can also increase the stability of the viruses to some extent, and is done precisely because it can result in more efficient infection of human cells.

Although this in principle increases the risk to workers, in practice it may be balanced by the fact that lower levels of virus are needed for the experiments that would otherwise be the case. Thus, although it must be recognised that accidental worker inoculation, either to mucosa or via percutaneous exposure could lead to stable gene transfer to cells in the body on balance it appears unlikely that a foreseeable accident could result in a level of worker exposure that would likely to result in tumourigenesis. Use of level 2 containment is considered appropriate to control the risks.

The possibility of generating replication-competent retroviruses or lentiviruses should also be considered. Replication competent retroviruses in their natural host species are associated with tumourigenesis, via insertional activation of oncogenes. The split packaging cells to be used for retrovirus generation and "3rd generation" systems for lentivirus production make it very unlikely that replication-competent viruses could be produced, and such systems have a history of safe use. Use of SIN vectors adds a further level of safety, since this effectively limits the vector to a single infectious cycle.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid and liquid waste normally inactivated by autoclaving. Surface decontamination using 1% Virkon.
Autoclaving gives 100% kill.

The GMSC agreed with the classification of the work. Some comments were made, e.g. further information requested on the characteristics of the vectors. This information was added and the proposals have been approved by the committee.

**Purposes of the contained use**

The principle aim of our work is to identify novel genes that are involved in blood vessel formation. Such genes have great potential as targets with which to either enhance or disrupt vessel formation. As an example, the disruption of new vessel formation has led to the discovery of new and more effective cancer drugs such as Avastin. The endothelium is a rich source of novel genes and aim is to provide new targets to enable the development of better treatment.

**Recipient or parental organism**

The hosts are cells in culture. The primary cells are either human or murine endothelial cells. After infection they will be studied up to week in a variety of different assays pertinent to new vessel formation in vivo. These include proliferation, migration and tube forming assays.

**Host/vector system**

The vectors are genetically modified viruses (adenovirus and lentivirus) that contain the exogenous gene of interest. The virus is replication incompetent.

**Origin & function**

The gene material will either be cloned out of endothelial cells or obtained from a gene bank such as an image clone. The aim of the experiments is to determine the function of the genes by introduction via virus into appropriate reporter systems. Examples of endothelial genes are LYL1, SOX7, SCM8, RhoJ, Robo4, Sphki, KCTD1 5, LRRRC6C, PCDHI2, Cl2orfll, ECSM2, GBP4, IKBKE, MED28. In view of the fact that our aim is to identify novel genes involved in angiogenesis there will be a continuous stream of new ones.

**Evaluation of foreseeable effects**

There are two aspects that should be considered with respects to effects of these experiments on human health and these are the firstly the potential for virus produced to infect the user and the consequence of this and secondly the potential for the virus to replicate after infecting the target cells.

Adenoviral vectors -

Adenovirus is able to infect all human cells and is naturally infectious to the respiratory tract. Cells infected with the genetically modified virus would express high levels of the insert gene/transgene. However this expression would be transient, lasting a few days or in some cases possibly a month and infected cells would be targeted by the individual's immune system, which may already have been primed via exposure to wild type adenovirus found in the environment. The integration of adenoviral DNA into human chromosomes is a very rare event and so it is very unlikely this would occur in an infected individual. We propose to look at the function of a variety of genes that are expressed by endothelial cells and which we hypothesise may play a role in angiogenesis, and in some cases specifically tumour angiogenesis. Some genes express proteins are more well characterised than others, see above and so in some cases it is not possible to anticipate how expression of the gene would affect the biology of an infected cells. Induction of angiogenesis can be harmful to health, for example inducing angiogenesis in the eye may contribute to blindness, and angiogenesis induced in an unvascularised incipient tumour may promote its tumorigenesis. Due the transient nature of transgene expression after infection with the genetically modified adenovirus and the very low probability of integration of the transgene into the host genome, we believe the long term consequences of accidental infection with these genetically modified adenoviruses to be minimal. It is however of the utmost importance to use strict precautionary measures to prevent this from occurring and to stringently decontaminate all areas in contact with the virus to protect all individuals from infection with adenovirus produced.
Adenoviral vectors cont.
The genetically modified adenovirus is replication deficient (it is lacking the El region). Thus infected cells would not be able to produce more virus carrying the transgene. The only way that it could become replication competent would be via recombination with a wild type virus. This may occur if there is concurrent infection of the genetically modified virus with infection with wild type virus or in there is infection of cells which are persistently infected with wild type virus. The latter is rare but has been seen in the adenoids. The genetically modified virus is constructed with the transgene being placed in the El region such that were recombination to occur to produce a replication competent virus then this would necessarily result in the elimination of the transgene and its promoter. The genetically modified virus also has the E3 region removed which contains genes which encode proteins involved in immune evasion, thus the genetically modified virus should elicit a stronger immune response against it than its wild type equivalent.

Lentiviral vectors -
Since lentivirus is able to infect all human cells the virus produced would potentially be able to infect the user if inhaled, swallowed or introduced into the blood stream. This could result in the integration of transgenes described above into the genome and could result in lifelong existence with in the genome and expression of this transgenic DNA. While we cannot be certain what would result from this, given the role of many of our genes of interest in cell signalling and angiogenesis they may promote angiogenesis in situations that may be harmful to human health. For example inducing angiogenesis in the eye may contribute to blindness, and angiogenesis induced in a unvascularised incipient tumour may promote its tumorigenesis. It is theoretically possible that insertion of the lentiviral DNA close to an oncogene may result in its constitutive activation leading to a transformation event. The use of self-inactivating (SIN) lentivirus vectors appears to reduce this risk relative to that of using the MoMuLV-type retroviruses. It is therefore of the utmost importance to use stringent precautionary measures to prevent this from occurring and to stringently decontaminate all areas in contact with the virus to protect all individuals from infection with lentivirus produced.

A number of strategies have been used by the third generation lentiviral vector system to severely minimise the chance that infected cells could themselves produce infective particles. These safeguards include the removal of 5 out of the six ieyulaLulu'ajuuesuly piciteirs rev, i at, vir, vpr, vpu anu (NeT), only rnv remains as ins is requirea ror me expression gag/pol and as a safety measure, it is encoded on a separate plasmid from both gag/pol and the transgene. Only 700 bp of the HIV envelope protein are present in the transfer vector, plus Rev responsive element [RRE] and the packaging signal. The packaging construct contains the minimal RRE of 374 bp and the gag/pol genes. Through deletions in both LTR's and the absence of 5 of the 6 accessory proteins, including the replication essential Tat it is highly unlikely that replication competent virus is produced. In published studies and from Birmingham Biosciences experience with these vectors replication competent virus has never been detected. The HIV-envelope protein is replaced by non-retroviral envelope protein (VSV-G). It is highly unlikely this will be incorporated in a new hybrid replicative virus. It is impossible that wild-type HIV will be formed, because of the omission of 5 accessory proteins and HIV-env.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

no derogation

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste is treated with Trigene at 1/1 00, then autoclaved and incinerated. Liquid waste is disinfected with Trigene at 1/100 dilution prior to autoclaving. Mouse carcasses will be incinerated. Trigene is effective against adenovirus according to the manufacturers information.

Liquid waste is treated with Trigene at to give a final dilution of 1/100 followed by autoclaving at 135°C for 15 mm, before disposal to drains. Disposable solid waste, including pipette tips which are stored in sealed plastic jars are inactivated by autoclaving at 135°C for 15 mm, before removal as “clinical waste” by specialist contractors, with final disposal by incineration Sharps, including needles will be soaked in trigene at 1/100 prior to disposal in appropriate sharps bins. The autoclave is also tested with Brown s tubes on a regular basis, Expected degree of kill: . Autoclaving achieves effectively 100% kill of all GMMs. Trigene at 1/100 kills 100% human adenovirus type 5 according to the manufacturer’s instructions.
Lentivirus assessment - some comments/suggestions from GMSC

In the box "effects on human health" (p6) it would be worth mentioning that there is the small but finite risk that the lentivirus insertion could result in activation of cellular genes (eg Oncogenes) close to the insertion site although use of SIN lentivirus vectors appears to reduce this risk relative to that of using MoMuLV-type retroviruses. You list a number of genes at least one is an oncogene, others may promote neovascularisation. Will these viruses always be used singly, or is it possible that several could be use for co-infection? Potentially, this could deliver the many different events required for full tumourigenesis in one needlestick injury. Please either exclude this, or draw attention to the potentially greater hazard of such multiple use.

In the box "interim containment level" on P8, I think the statement "we do not consider the GFP, endothelial expressed transgenes or the short oligonucleotides to significantly increase the potential hazard, thus we classify the replication-defective lentivirus vector with this transgene as class 2" to be incorrect. Introducing an oncogene, etc does pose a greater risk than an empty SIN-lentivirus vector. I would say something more along the following lines: although the expression of some of these transgenes (eg Xyz is an oncogene) increases the potential hazard, the risks can still be controlled by use of containment level 2 measures; the additional features of containment level 3 are not required to reduce the risk to an acceptable level.

Is this risk assessment also intended to cover the initial preparation of the plasmids in E.coli? If so, it requires modification to make this clear, although the level of hazard from these is lower, and so containment level 1 is likely to be sufficient for the bacterial stages of the work.

Project Ref 116/09.1

Date Ackn'd: 02/03/2022
Using lentiviral vectors to achieve the need for efficient gene transfer in many cell types, including lymphocytes; the need for stable expression of introduced genes, or knock-down of endogenous gene expression via shRNA and inhibitory RNA mechanisms. This has a wide application in studies of the immune response, e.g. Recombinant lentivirus vectors with T cell receptors, B cell receptors, cytokines, MHC class I and II, HDAC, MPO and PR3 proteins to allow stable production of proteins for clinical laboratory analysis and antigen processing and presentation of cell receptors.

Recipient or parental organism

Hosts - Disabled laboratory strains of E. coli (including Stbl3, DB3.1, DH5α,HB101, Top10, and XL10-gold).

293HT cells for lentivirus production.

Target: Human cell lines (e.g. 293T cells, Jurkat T cells and other established human cell lines) and Chinese Hamster Ovary cell line, primary human T and B cell lines. Primary and established human tumour cell lines will also be transduced.

Host/vector system

Lentiviral vectors - pLVX-IRES-Puro vectors (Clontech), pJZ189/pTRIP vector, pH′SIN vector, or other comparable vectors. Replication defective - but are infectious lentivirus vectors, with the potential to infect human cells, e.g. in the event of accidental exposure of the operator. This potential hazard arises in part from the fact that lentivirus vectors insert into the host cell genome, which is potentially mutagenic; and in part from the fact that this could result in long-term expression of the gene inserts.

Although the lentivirus vectors are derived from HIV, the vector systems to be used are all 3rd generation systems which divide the helper functions onto multiple plasmids designed to minimise the possibility of generating a replication-competent virus through recombination, and do not use the HIV envelope protein. Additionally, all the vectors adopt the „self inactivating“ (SIN) design, which restricts the viruses made from the packaging cells to a single cycle of infection.

Origin & function

The following genes are to be included at this stage, but this list may grow, to include other inserts of similar or lower hazard.
 recognised a bound peptide antigen in association with MHC molecules on the surface of all nucleated cells and can signal to initiate an immune response.

**B cell Receptor** – Recognises and binds to antigens to begin the process of mounting a humoral immune response.

**Immunoglobulins** – Recombinant immunoglobulin constructs (e.g., IgG) closely related to B cell receptors.

**Cytokines** – Represent a large group of immunological mediators controlling cellular communication. These are a diverse group of proteins including Interferons, Interleukins, and Chemokines. These have a broad range of biological activity including inducing cell proliferation, activation, differentiation, and cell death. Those of immediate interest include IL1, IL6, IFN gamma, TNF alpha, and related proteins involved in inflammatory processes; IL2, IL4, IL7, IL15 and IL21 (lymphocyte stimulating cytokines); GM-CSF, IL4, IL1 (roles in activating antigen-presenting cells).

**Neutrophil Granule components** – Myeloperoxidase (MPO) and Proteinase 3 (PR3) are enzymes found in phagocytes and a disease biomarker for microscopic polyangiitis.

**Antigen Processing Molecules** – Regulates the processing of antigens by antigen-presenting cells. These include MHC molecules listed below, TAP, Tapasin, ERp57, ERAAp, Proteasome, Cathepsin, Invariant Chain, HLA-DM and HLA-DN

**MHC Class I** – Found on all nucleated cells, presents self or foreign peptides to CD8 T cells. In humans there are 6 genes (HLA-A, HLA-B, HLA-Cw, HLA-E, HLA-G and HLA-F). This family of molecules are extremely polymorphic with a large number (>1,000) of alleles. We will focus on a number of common alleles such has HLA-A*0201, HLA-B*0702 and HLA-A*0101.

**MHC Class II** – Found on professional antigen-presenting cells, presents self or foreign peptides to CD4 T cells. There are 3 genes in this family (HLA-DR, HLA-DP and HLA-DQ) which, like MHC Class-I molecules, are very polymorphic.

**Reporter Molecules:** Fluorescent Proteins reporter genes (e.g., Green Fluorescent Protein, Red Fluorescent Proteins), bioluminescent proteins (Luciferase) and antibiotic resistance genes (Puromycin Resistance, Hygromycin Resistance, Zeocin Resistance) are widely used in basic and clinical research to label, select and characterise cells of interest. None of these genes have been shown to have pathogenic properties.

**HDACs:** (Histone Deacetylase) HDAC1-HDAC11 are a family of transcriptional regulators which are particularly active in controlling immune cells activation and differentiation.

**siRNA and shRNA** – These constructs will be used to reduce the expression of genes listed above, to determine the function of these genes.

In the future, the work may expand to include other leucocyte surface antigens (e.g., CD4, CD8, CD27, etc)

---

**Evaluation of foreseeable effects**

The plasmid constructs in E. coli have no significant implications for health & safety.

The major potential hazards are associated with the production of infectious lentivirus vectors, with the potential to infect human cells, e.g. in the event of accidental exposure of the operator. This potential hazard arises in part from the fact that lentivirus vectors insert into the host cell genome, which is potentially mutagenic; and in part from the fact that this could result in long-term expression of the gene inserts.

Although the lentivirus vectors are derived from HIV, the vector systems to be used are all 3rd generation systems which divide the helper functions onto multiple plasmids designed to minimise the possibility of generating a replication-competent virus through recombination, and do not use the HIV envelope protein. Additionally, all the vectors adopt the “self inactivating” (SIN) design, which restricts the viruses made from the packaging cells to a single cycle of infection. See assessment for further details.

Potential hazards may also arise from the nature of the genes inserted into the vectors.

If cells in the body were to express introduced allogeneic MHC genes, following accidental exposure to the lentivirus vector, these cells would be rapidly eliminated by both the adaptive and innate arms of the immune response. Over-expression, or knock-down of the genes involved in antigen processing could modulate the immunogenicity of the cells, most likely to make the cells subject to attack by the adaptive or innate effector arms of the immune response.

It is highly unlikely that expression of the TCR, BCR or Ig constructs in a small number of cells would result in immunological activity that would be harmful. Expression of cytokines from infected cells following an accidental exposure could in principle induce local inflammation and immune activation. The worst case scenario is that infection of a T cell with lentiviruses expressing growth-promoting cytokines could lead to autocrine stimulation, which could contribute to lymphoproliferative disease, although we consider this a very remote possibility, considering the likely scale of accidental exposure.

PR3 and MPO are normally present in serum, and it appears unlikely that their expression within a small number of accidentally infected cells following operator exposure would be clinically significant.
HDAC expression has potential to alter post-translational modifications and the pattern of gene expression in cells. It is difficult to predict the consequences of this; however, the HDAC activity would be predicted to remain under control of normal signalling pathways in the cells.

In conclusion, in addition to the potential risks related to insertion mutagenesis/gene activation by the viruses, there appears a low level of risk from some of the gene inserts of contribution to inflammatory or lymphoproliferative disease. It is therefore appropriate to adopt precautions to minimise the likelihood of exposure, including avoidance of sharps, use of protective gloves, working with virus within class 2 cabinets, and ensuring an appropriate level of training.

Environmental risk - Gene transfer to other species is a possibility, however the in-built safety features, in particular lack of replication, potentially limit any environmental concern. The hazard is low: the non-replicative lentiviral particles are stable at room temperature for a couple of hours but it would require high exposure, and often simultaneous exposure to other factors (for example growth factors) for infection. The virus will be handled in a CL2 facility, and a safety cabinet will be used, so the likelihood of release to the environment is negligible.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation - full CL2 applied.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All tissue culture plastics and liquid waste (135 oC, 15 min) generated during the production of lentiviral supernatants will be autoclaved before disposal. Autoclaving achieves effectively 100% kill of all GMMs. Small volumes of liquid containing the viral particles will be used immediately or Bleach treated or Microsol treated. Pipette tips will also be treated with 10% Microsol then autoclaved before removed as clinical waste and incinerated.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment Y

Please enter comments on the GM safety committee on the risk assessment

Further information was requested on the potential hazard of the inserted genes, as the assessment dwelt heavily on the hazards of the vector. This has now been addressed and the GMSC has approved this proposal.

The aim is to understand the functional organisation and dynamics of neuronal networks in the mammalian brain. Quantification and characterisation of the synaptic partners of individual neurons is crucial for the development of realistic models of neuronal networks and a quantitative understanding of the functional operation of those networks. Changes in synaptic connectivity in chronic experimental models of neurological disease play a major role in determining the mechanisms of the abnormal neuronal dynamics of diseases such as epilepsy.

Quantifying the connectivity within neuronal networks requires the ability to label a single neuron, and for that label to be transported across synapses in one direction in a manner that prevents onward propagation to other neurons in the network. The labelled tissue can then be studied histologically and/or electrophysiologically. Viruses are the only tracing tools that have the properties that allow labelling across synapses without weakening of the signal, and control production to prevent onward propagation across multiple synapses in series. A review of the literature shows that this has only been demonstrated in rabies virus and in Bartha virus, an attenuated strain of the Aujeszky disease or pseudorabies virus (PRV). Both rabies and Bartha only propagate in a retrograde direction, unlike other viruses used for tracing neuronal pathways, such as herpes simplex and lentivirus, which propagate in both directions. Rabies virus is highly restricted DEFRA group 4 Specified Animal Pathogen and most definitely is not considered here. Despite the similar names, PRV and rabies are completely unrelated: PRV is a DNA virus of the α-herpesvirus subfamily and rabies is an RNA virus. Wild type PRV is SAPO Group 2, suitable for work in conventional laboratories; attenuated strains pose a smaller risk. The proposed work uses a TK-deficient version of a vaccine strain of attenuated PRV.

The TK-deficient Bartha virus will be grown in PK-15 (pig kidney) cells in culture. These cells produce the thymidine kinase required by the virus to replicate. They are an established cell culture line that has been used extensively without reported complications.
The highly disabled virus and TK construct will be injected into brain. Replication of the virus will be in the single neuron loaded with the TK construct and a limited number of glia close to the injection site. As soon as it is possible to perform these experiments the extent of the distribution of the virus in glia following intracerebral injections will be determined and it will be reported back to the appropriate committees if the virus appears in glia further than 1 mm from the injection site. Vaccine strains of PRV with gE and TK deletions have been shown to cause minimal local pathology at injection sites and are not shed. Injection of GFP expressing tk-Bartha virus into the brain show the virus is restricted to the injection site and to anatomically connected neuronal pathways. The TK genes from HSV and PRV lack sufficient sequence homology to allow recombination of TK from the construct into the TK-deficient Bartha virus. Even in the unlikely event of recombination of TK into TK-deleted PRV-Bartha, the resulting virus would effectively be the vaccine strain of PRV-Bartha.

Host/vector system

Vector: TK deficient Bartha virus, with or without fluorescent protein expression cassette or Ca2+ indicator and/or "timer" sequence; Expression cassettes for pgk-HSV-TK and amplicon-fluorescent proteins delivered by injection.

- PRV/Bartha virus. The normal host of the wild-type pseudorabies virus is the pig, but it can also infect rodents, dogs and cows, but not humans or other higher primates. Bartha is a vaccine strain with: a deletion in the unique short (US) regions including the glycoprotein (g)I, gE, US9 and US3 genes, and point mutations in the gC, gM, UL21 and US3 genes; there is no evidence of restoration of virulence despite widespread use of the vaccine in agriculture in mainland Europe and elsewhere, which has been attributed to the dispersion of the mutations across the genome.
- Recombinant Bartha-fluorophore virus was generated by co-transfection of linearised targeting plasmids with the full-length DNA of the parental virus by electroporation of actively growing PK-15 cells. Fluorophore expressing plaques were selected for production. Recombination was performed in Hungary, and is not proposed under this application. Ca2+ indicator and timing signal were inserted as described in Boldogkoi et al 2009.
- TK/fluorophore cassette. PGK promoter driven TK
- Amplicon ampiclon consists of pUC18 vector into which has been cloned a 1.9 kbp Bam HI-Sac I fragment of PRV containing its origin of replication (oris), and a 1.5 kpb Nar I fragment (from circularized PRV) containing the pac1 and pac2 packaging signals (from the two ends of the linear PRV genome) in head-to-tail arrangement, as in rolling-circle replicating form of PRV.mem Cheery or memGFP is inserted into the genome.
- Neuron and glia. The amplicon and virus will co-infect a single neuron in the brain. The amplicon replicates by the rolling circle mechanism of the virus, and concatamers are packaged into virus particles which allow transfer to the presynaptic neurons. The several glia that take up the TK-deleted Bartha virus will allow replication as a result of the host cells' TK expression, but the viruses do not transfer between cells.

Origin & function

The following genes are to be used initially, but other reporter genes for other aspects of neuronal function may be used in future. These will be of similar or lower hazard than those included here. Any additional genes will be considered by the local GMSC and will be notified if it is considered that they constitute a significant change to the proposal:

- Green Fluorescent Protein: fluorescent protein gene.
- mem-Cherry: membrane bound fluorescent protein gene.
- mRFP: fluorescent protein gene.
- Herpes simplex virus TK gene: produces thymidine kinase, in construct with eukaryotic regulatory sequences (PGK promoter, SV40 polyadenylation sequences).
- TN-L15: truncated chicken skeletal muscle troponin C in which the N-terminal amino acid residues 1-14 are deleted
- VAMP-GFP: Vesicle associated membrane proteins fused with GFP
- MARCKS-EGFP: a cytosolic protein kinase C substrate fused with EGFP

- Original donor for Green Fluorescent Protein was the jellyfish Aequorea victoria.
- Original donor for DsRed was Discosoma species (disc or mushroom anemones found in coral reefs); mRFP and mCherry are derivatives of DsRed with improved fluorescence characteristics.
- Original donor for TK was Herpes simplex.
- Original donors for TN-L15 were chicken skeletal muscle, human cardiac muscle.
The Bartha virus strain is an attenuated form of PRV which is used for vaccination of pigs in many parts of the world. Unattenuated PRV causes Aujeszky Disease in pigs, and is a notifiable animal pathogen in the UK, rated as SAPO 2 by DEFRA. Unattenuated PRV also infects other species, including rodents, dogs and cows. The most obvious symptoms are severe pruritus leading to self-mutilation. PRV does not cause disease in humans and other higher primates, but can cause local itch after needle stick injury. The risk from the disabled vaccine strain is minimal.

The Bartha strain has several recognized mutations, including a deletion in the unique short (US) region encompassing the glycoprotein (g)I, gE, US9, and US2 genes and point mutations in the gC, gM, UL21, and US3 genes.5,6,7,8 These mutations explain (a) its reduced virulence and (b) crucially for the present use, the loss of its propagation from presynaptic to postsynaptic neurons, with preservation of propagation from postsynaptic to presynaptic neurons. Vaccine strains with gE and TK deletions produce “slight lesions … in target tissues of vaccinated animals” and were not shed. Bartha virus has been used extensively for vaccination against Aujeszky’s disease in many parts of the world, with no evidence of restoration of virulence, which has been attributed to the large size of the deletions and their distribution across the genome. This leads us to conclude that the Bartha strain has few, if any, pathological effects on pigs, and minimal risk of reversion to virulence, which argues that restrictions of staff contact with farms are not necessary to protect animal health. However, we will adopt such restrictions to avoid the miniscule risk of causing pigs to become seropositive which would trigger slaughter given the absence of any UK policy on genotyping that would identify the vaccine strain.

Bartha virus can cause CNS disease in mice, with no peripheral nervous system symptoms. These studies used 10^6 PFU of virus applied to the skin, leading to symptoms by 220 hours for the Bartha strain (c.f. 7 hours for unattenuated PRV). The LD50 for the Bartha strain applied to the skin was 7.4 x 10^5 PFU.

The strain of Bartha virus used here has been further attenuated by deletion of the thymidine kinase (TK) gene. We know that this virus differs from Bartha in failing to replicate in non-mitotic cells, including neurons. The virus does replicate in glia in the immediate vicinity of the injection site, but there is no propagation between glia or between glia and neurons. The restoration of full PRV virulence would require the acquisition of four specific genes, which is a vanishingly small risk. However, on the precautionary principle, we will contain the virus and infected materials, and will decontaminate all materials produced during these experiments. The risk to the environment is therefore low. The virus is not shed and is limited to the injection site and synaptically connected neurons after injection. However the pathology caused by TK-positive Bartha virus after peripheral injection is limited to the brain, and will not apply in the TK-deficient Bartha used here because it cannot replicate in neurons and it has minimal, if any, propagation between glia.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form Y

02/03/2022

Page 3376 of 15326
This application has been subject to intense scrutiny by the local GM Committee and the University's Biological Hazards Committee. The Committees requested additional proof of the attenuation of the PRV, and asked for a more detailed explanation of how the virus replicated in the neuron using the TK construct. As this proposal is also being submitted to Defra as a SAPO licence application the committees requested additional information on the control measures applied.

Project Additional Information

02/03/2022 Page 3377 of 15326
Embryonic stem (ES) cells have the potential to differentiate into all cells within the body. Whilst this property of ES cells holds great promise for regenerative therapy, where they can be differentiated into any cell-type and transplanted into recipients, it is also a safety issue because these cells will form teratomas when transplanted into recipients. Our current research focuses on the differentiation and transplantation of ES-derived hepatocyte-like cells (ES-HLCs). We intend to use "3rd generation" lentiviruses expressing genes which we believe will affect engraftment of ES-HLCs, or improve their safety. The other arm of this research is aimed at identifying molecules which may improve the efficiency of the transplantation of human and murine hepatocytes and ES-derived hepatocyte-like cells. It is our intention to express genes which encode cell surface receptors and adhesion molecules to assess the impact of these proteins on these cells migration and adhesion, respectively.

Recipient or parental organism
Human and mouse cells (eg ES cells, primary hepatocytes and hepatocarcinoma cell lines, primary non-parenchymal cells)

Host/vector system
Retroviral/Lentiviral vectors - for this piece of work 3rd generation lentivirus vectors, e.g. pLenti6 from Invitrogen.

Origin & function
Genes involved in adhesion (ieCD44 and integrins) and migration (ie chemokine receptors). Additional specific genes are to include tmpk, eGFP, osteopontin and gaussian luciferase (gLUC). The addition of new genes will be considered by the local GMSC and changes notified to HSE if it is felt likely they fall outside the scope of the connected programme.

This particular project involves TMPK with F105Y mutation, green fluorescent protein (GFP), CXCR3, CD44 integrin α1, CD47, Gaussian luciferase (Gluc)

Evaluation of foreseeable effects
The plasmid construct in E.coli have no significant implications for health and safety.

Integrins, CD44 and OPN have been implicated in accelerated tumorigenic processes. CD47 has been found to be highly expressed on cancer cells and has been demonstrated to allow cells to evade scavenging by macrophages.

It is very unlikely that naked DNA incorporating genes with oncogenic potential could be directly introduced through the skin, but operators are advised to wear gloves when handling large amounts of such DNA, or when there may be a significant risk of skin contact; and to take particular care in the rare instances when sharps might be used.

Infection to the respiratory tract is relatively poor as a result of aerosol dispersal, however this cannot be entirely ruled out with high viral titre. If accidental inoculation occurred, the viral DNA would be introduced into a number of cells where chromosomal integration might give potential for long-term high expression of the transgene.

The main hazard is associated with the lentiviruses that will be generated in packaging cells. The viruses will be capable of infecting human cells, with the consequent insertion of the vector genome into chromosomal DNA. This raises the possibility of oncogene activation at the site of integration. Consideration of the experiences from human gene therapy clinical trials suggest this risk is low, as any accidental exposure would involve many logs fewer virus particles, nevertheless precautions to avoid exposure are appropriate.

There is also the prospect of the generation of replication competent virus. However, we will be using 3rd generation lentivirus systems which are self-inactivating and replication defective which will greatly reduce the chance of generating replication competent virus.

The final cell lines stably transduced with the lentivirus vectors should not pose a significantly greater hazard than that of the untransduced cells, as both would be subject to alloreactive immune responses.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

No derogation. Full CL2 applied.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste is treated by autoclaving at 130°C for 60 mins. before disposal to drains.
Disposible solid waste which is or may be contaminated with GMMs is also inactivated by autoclaving at 135°C for 15 mins, before removal as "clinical waste" by specialist contractors, with final disposal by incineration.
The exceptions to the above are:
"Sharps", including disposable plastic tips or micropipetteors, may be decontaminated by drawing up Virkon disinfectant, and soaking in Virkon for a minimum of 10 minutes. Disposable plastic pipette may also be decontaminated by immersion in Virkon as above.

Expected degree of kill:
Autoclaving achieves effectively 100% kill of all GMMs.
The manufacturer's information indicates efficacy of Virkon against HIV (at dilutions from 1:100 - 1:1400)

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form N

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Comments were fairly minor and merely requested clarification in most instances. For example, further information was requested on the use of needles - weather this involved infectious virus, or stably transduced cells. Also, a request for information on the volumes involved in the project. Reportin arrangements for accidents were also amended.

Purposes of the contained use

The generation of patient-specific pluripotent stem cells through reprogramming of adult somatic cells has become a major goal in stem cell science. Reprogramming, that is, taking a cell that has a determined function in the adult and artificially altering its pattern of expressed genes so that the earliest stages of development are recapitulated, can be achieved by introducing three or four transcription factors that are known to be associated with the maintenance of pluripotency in embryonic stem (ES) cells. As a result of the enforced alteration in gene expression, a small proportion of the somatic cells adopt a phenotype that is highly similar to that of ES cells, and as such these cells have been termed induced pluripotent stem (iPS) cells. Reprogramming of mouse or human cells into iPS cells has been achieved by the introduction of four transcription factors, Oct4, Klf4, Sox2 and c-Myc and it is widely accepted that the cells generated share many of the characteristics of ES cells. iPS cells have already been generated from patients with a number of inherited conditions, and in some cases these have been differentiated into the cells thought to underlie the effect of the genetic defect.

Introduction of the reprogramming transcription factors requires the use of lentiviral vectors, which have to be packaged in viral coat proteins so that they can infect either mouse or human cells. The GMM involved consists of a highly inactivated HIV-derived vector that is packaged into infectious viral particles by co-transfection into cells together with separate vectors expressing the viral core and envelope proteins (a "5-component" system). There is no risk of viral spread. Lentivirus encoding reprogramming transcription factors will be used to infect primary mouse or human fibroblasts. A second round of infection with a lentivirus encoding Cre recombinase will be used to delete the reprogramming lentivirus from the resultant iPS cells.

Recipient or parental organism

Hosts: Plasmids grown in standard disabled laboratory strains of E. coli
293T cells for lentivirus generation
Mouse fibroblasts (tail tip derived or embryonic day 14) and human fibroblasts (foreskin or adult skin biopsy derived)
Vector: Five component system (HIV-derived), transfected into 293T cells to allow assembly and packaging:
- Lentiviral vector (STEMCCA or integrase-negative Cre vector)
- HIV gag/pol expressing plasmid
- VSV-G envelope protein expressing plasmid
- Rev expressing plasmid
- Tat protein expressing plasmid

The requirement for transfection of five plasmid vectors into the packaging cells makes accidental transfer to other cells essentially impossible. Since the lentiviral vectors incorporate deletion of enhancer/promoter elements from the 3’ LTR they are self-inactivating (SIN), essentially eliminating any possibility of secondary spread, even if helper functions were present. Note that other HIV accessory proteins, and HIV envelope protein, not used so no possibility to generate HIV.

Donor: Mouse and human cDNAs cloned by RT-PCR from mRNA derived from various tissues and Cre sequences derived from E.coli bacterial genomic DNA

Transcription factor genes (mouse/human Oct4, Sox2, Klf4, c-Myc and B-Myb): involved in maintenance of the pluripotent stem cell state. These have specific roles in pluripotent stem cells as well as activities in a range of other cell types:
- Oct4: pluripotency factor expressed in ES cells and during early embryonic development
- Sox2: pluripotency factor expressed in ES cells and during early embryonic development
- Klf4: pluripotency factor expressed in ES cells and during early embryonic development
- c-Myc: pluripotency factor, also involved in proliferation control in a wide range of cell types
- B-Myb: possibly a pluripotency factor, but known to be associated with proliferation in a wide range of cell types

Bacterial Cre recombinase: acts on target sequences to limit bacteriophage infection. As used here it will promote excision of the targeted genes that are flanked by loxP sites.

Evaluation of foreseeable effects

Negligible risk from the plasmid vectors in E. coli, where the genes should not be expressed, and no generation of the lentivirus will be possible.

The greatest potential hazards are associated with the infectious lentivirus vectors. The vector system is designed to minimise the chance of recombining helper functions into the virus, so that the potential for generating replication-competent lentivirus is essentially zero. Furthermore, the vector is SIN, which would prevent the possibility for further mobilisation.

There is a potential hazard from insertional mutagenesis/oncogene activation, in the event of accidental human contamination/infection. This hazard may be lower than for retroviruses due to different insertion site preference, nevertheless a theoretical possibility. The risk is low if only a small number of insertion events are involved.

There is a potential hazard arising from insertion of the genes into human cells, most significantly in the case of the oncogene c-myc. It is unlikely that infection of a small number of cells would cause cancer, since oncogenesis would be a multistep process. In addition, the immune system would be likely to eliminate cells acquiring aberrant gene expression.

Lentivirus infection of human cells could occur through mucosal contamination or percutaneous injury, hence there is a requirement to minimise these risks. Aerosol route of infection may be possible at very high titres, although this not considered to be a common route of retrovirus/lentivirus transfer.

In contrast to the potential hazards presented by the infectious virus, there should be minimal risk from stably transduced target cells, since if there has been sufficient time and medium changes so that no original virus remains then the chance of replication-competent virus being present is virtually zero. Mouse cells are not a risk to humans; the human target cells WILL NOT BE DERIVED FROM THE OPERATOR OR ANYONE WITH ACCESS TO THE CELLS. Hence in the event of accidental human inoculation with the transduced cells, they should be rapidly eliminated by an allogeneic immune response.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation - full CL2 applied
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Disinfected liquid waste will be autoclaved (134 degrees/15 mins.). Similarly treated solid waste will be put into biohazard bags for incineration

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  Y

The GMSC felt that the assignment to class 2 was appropriate, given the use of a lentivirus vector capable of infecting humans and the nature of the transgenes, especially considering the oncogenic potential of myc. There were some minor comments, requesting further information on some points

Project notified under transitional arrangements N
### Project Additional Information

#### Purposes of the contained use

The focus of the group is the role of chemokines and chemokine receptors in immune regulation. Chemokines and their receptors govern the chemotaxis of cells and influence central biological processes including organ-organization and immune responses. Part of the work concerns the role of chemokines and chemokine receptors in the regulation of the host immune responses to tumour growth. The expression of these molecules both on the tumour cells and on the immune cells can influence the development of a protective immune response. The use of retroviral vectors enables the transfer of genes to cells that are difficult to transfect by conventional methods and will be an essential tool for the work.

#### Recipient or parental organism

- **Hists** Stbl3, DB3.1, DH5ca, Top10, and XL10-gold competent cells
- **293FT**, Phoenix amphi and Phoenix ecco 293 cells
- **Target**: Primary cells and immortalized cell lines. Human and mouse

#### Host/vector system

- **pLNCX2**, pLEGFP-C1/N1, pRetroX-IRES-ZsGreen1, pRetroX-IRES-DsRedExpress (Clontech recombinant retroviral vector system). Replication defective.
- MigRI and MigRII retroviral vectors developed in the lab of W.S. P, Department of Pathology and Laboratory Medicine, University of Pennsylvania, PA. Origene HuSH-29 shRNA Vectors or equivalent. Replication defective.
- Other virus vectors may be used in future, e.g. lentivirus, adenovirus, and these will be assessed by the GMSC. If it is considered that the nature of the hazard or the risk level is altered in any way, further notifications will follow.

#### Origin & function

Initially the work will involve the following inserts, though others of a similar nature may be used. Any changes to the assessment, through the addition of inserts, will be assessed by the GMSC and where appropriate, notified to HSE.

- **CCR1-CCR11**: chemokine receptors expressed on a wide variety of cells. Influences chemotaxis.
- **CXCR1-CXCR7**: chemokine receptors expressed on a wide variety of cells. Influences chemotaxis.
- **CCL1-CCL28**: ligands for CC-receptors. Influences chemotaxis.
- **CXCL1-CXCL16**: ligands for CXC-receptors. Influences chemotaxis.
- **DARC, D6 and CCR2**: chemokine receptors. Regulate chemotaxis.
GFP Zs-Green1 and EGFP and DsRed Express etc.: selection of fluorescent proteins which have not been shown to have pathogenic properties. They are used to allow gene expression detection.

Firefly luciferase: gene from which allows luminescence detection. No pathogenic properties.

ShRNA sequences: the shRNA expression cassettes consist of a 29 bp target gene specific sequence, a 7 bp loop, and another 29 bp reverse complementary sequence, all under human U6 Promoter. A termination sequence (TTTTTT) is located immediately downstream of the second 29 bp reverse complementary sequence to terminate the transcription by RNA Pol III. The gene-specific shRNA cassettes are sequence-verified to ensure its match to the target gene.

Evaluation of foreseeable effects

Human Health: E. coli - Disabled host with a non-mobilisable vector, requiring CL1. Inserts are under control of prokaryotic promoters, therefore expression is negligible. Neither the vectors with insert nor the produced retrovirus with insert poses a risk for infection. The retroviral virions, produced in the Phoenix line, can only infect dividing cells, therefore effective infection requires special conditions and therefore highly unlikely to happen wearing protective clothing. Furthermore, at the unlikely event of an infection, the retroviral virions are proliferation defective and the insert, coding that the expressed proteins might affect immune responses in a localised area, but they are not oncogenes and are not known to have any toxicity or transforming activity.

Environmental risk: Potential hazard is NEGLIGIBLE, since the retrovirus particles are very unstable and even accidental exposure would not cause pathogenesis. Also, the virus is non-replicative. Retroviral supernatants will be contained within the tissue culture hood and incubator and live animals will not gain access to the work area.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation - Class 2 applied

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All tissue culture plastics and liquid waste generated during the production of retroviral supernatants will be autoclaved before disposal. Autoclaving achieves effectively 100% kill of all GMMs. Small volumes of liquid containing the viral particles will be used immediately or Microsol/Trigene treated.

Pipette tips will also be treated with 10% Microsol then autoclaved before removed as clinical waste and incinerated.

Is an emergency plan required according to regulation 20?

N

If yes, tick to confirm that it is attached to this form

N

Tick to confirm that you have attached a risk assessment to this form

Y

Tick if you are claiming exemption from disclosure for section of the risk assessment

N

Please enter comments on the GM safety committee on the risk assessment

The project was initially classified as Class 1, but the use of gloved when handling the viruses was considered a sensible precaution, likewise use of a safety cabinet and some access restrictions. It was therefore regraded to Class 2.
Project Additional Information

Purposes of the contained use

Our two groups are interested in internalisation and trafficking processes within mammalian cells. Specifically, we have major programmes of research on phagocytosis and the internalisation and trafficking of manufactured nanoparticles, in particular metal oxides such as CeO2 or ZnO. Thus, we will be employing in-vitro models of lung epithelium and blood brain barrier, as well as primary and cell line phagocytic cells (monocytes, neutrophils, macrophages and dendritic cells) to study these cellular processes. In order to exploit these models, we need to express exogenous transgenes (non of which are oncogenic or otherwise toxic), such as tagged and mutant proteins, in primary cells. However, as primary cells are generally resistant to conventional transfection methods we will need to employ lentiviral transduction in these studies.

Recipient or parental organism

Virus will be produced in the human embryonic kidney HEK293T cell line. Functional virus will be used to transfect either primary (peripheral blood monocyte derived) human macrophages, or macrophage-like cell lines including THP1 (human) or RAW/J774.A1 (mouse) as well as epithelial cells (e.g. HUVECs)

Host/vector system
Third generation lentiviral vectors (replication defective) pWPI, pLVTHM and/or pLVX-EF1α-IRES-Puro; packaging vector pMDLg/pRRE; pRSV-Rev expressing the HIV-rev gene; and envelope vector pMD2.G

**Origin & Function**

Origins: Human and mouse cDNA

Commercially available fluorescent tags such as GFP, mCherry, Cerulean etc.

Genetic material: GFP, mCherry, Cerulean.

WASH actin associated protein, WASP actin associated protein, Exo70 marker of exocytosis, Rab5 GTPase, Rab7 GTPase, Rab11 GTPase, Atg9 autophagosome marker, Lysosomal associated membrane protein (LAMP), CD63, Cathepsin D, and vacuolar STPase, as well as markers and inhibitors for endocytosis pathways (e.g. clathrin, eps 15 (EH29), caveolin 1, caveolin 1 (Y14F), dynamin (WT), dynamin (K44A)). Both mouse and human homologues of such genes will be utilised. Any additional genes of future interest, which function in similar signalling pathways, will be added to a list at the end of this assessment for periodical review by the GMSC - theses additional genes will be low-risk genes only, i.e. they will not include, for example, active human oncogenes or microbial toxins.

**Evaluation of foreseeable effects**

The sequences we propose to study have no known role in tumorigenesis, toxicity or other processes deleterious to the host and thus present low risk in their own right. However, it is theoretically possible that insertion of the lentiviral DNA close to an endogenous oncogene may result in its constitutive activation leading to a transformation event, although the self-inactivating (SIN) lentivirus vectors that we will use appear to reduce this risk relative to that of using the MoMuLV-type retroviruses. It is therefore critical to use strict precautions to prevent user exposure to these lentiviral constructs from occurring and to stringently decontaminate all areas in contact with the virus.

With regard to the possibility of lentiviral replication after target cell infection, a number of strategies have been used by these so-called 'third generation' lentiviral vector system to minimise the chance of infective particles being produced by infected cells. These safeguards include the removal of five out of the six regulatory/accessory proteins; Tat, Vif, Vpr, Vpu and Nef. The sixth, Rev, is retained since it is essential for the expression of gag/pol, but is encoded on a separate plasmid from both gag/pol and the transgene as an additional safety measure. Only 700 bp of the HIV envelope protein are present in the transfer vector, plus Rev responsive element [RRE] and the packaging signal. The packaging construct contains the minimal RRE of 374 bp and the gag/pol genes. Through deletions in both LTRs and the absence of five of the six accessory protein, including the replication essential Tat, it is highly unlikely that replication competent virus would be produced. Such vectors have now been used globally for many years, but to the best of our knowledge no users have ever detected replication competent virus.

**Risks to Environment:** The recombinant virus is replication defective and does not have an extended host range so would be unlikely to spread to a large number of organisms if it were potentially released. The fluorescent proteins are not considered to present any potential threat. Transgenes encoded by the lentivirus may be able to modify the behaviour of any cells they infect, but this would only occur if the virus came in direct contact with mammalian cells, which would be an unlikely scenario. Should this occur, the replication defective nature of the virus would ensure that this is a self-limiting process.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

| N/A |

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

No derogation - CL2 applied

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Liquid waste is treated with 1% Virkon, followed by autoclaving at 121°C for 15 min, before disposal to drains. The autoclave is serviced and calibrated on a regular basis. Disposable solid waste, which is or may be contaminated with GMMs, is also inactivated by autoclaving at 121°C for 15 min, before removal as "clinical waste" by specialist contractors, with final disposal by incineration.
Expected degree of kill:
Autoclaving is expected to achieve a 100% kill of all GMMs.

Is an emergency plan required according to regulation 20?  N
If yes, tick to confirm that it is attached to this form  N
Tick to confirm that you have attached a risk assessment to this form  Y
Tick if you are claiming exemption from disclosure for section of the risk assessment  N

Please enter comments on the GM safety committee on the risk assessment
Aside from some minor clarifications on waste treatment, the other main issue raised related to the handling of breakages in the centrifuge so an additional emergency protocol has been added under this section in the risk assessment. There were no other concerns raised

Purposes of the contained use

This work focuses on bacterial pathogenesis, physiology and genomics, with particular interests in gene regulation and chromosome organisation. The group primarily work with non-pathogenic and pathogenic (HG2) Escherichia coli strains. They may also investigate other category 2 pathogens, including strains of Vibrio cholerae, or Yersinia spp but will never genetically alter these organisms. Thus, they will only genetically modify E. coli (both harmless and pathogenic strains). These modifications will involve general cloning, expression and characterisation of selected genetic determinants.

All organisms that the group will handle fall within ACDP category 1 or 2. However, on occasion they may also handle ONLY DNA from strains within taxonomic groups that fall within category 3, such as Yersinia pestis. They never work with these organisms directly and have no intention to work with genes encoding toxins or other potentially harmful proteins. DNA from these category 3 organisms will only be cloned into hosts that are handled at level 1 (e.g. E. coli). They stress that they DO NOT handle any category 3 organisms, nor will they ever make any genetic modifications to such organisms.

Activity 1: Cloning of bacterial DNA in disabled E. coli strains;
Activity 2: Allele replacement;
Activity 3: Gene expression in disabled E. coli strains;
Activity 4: Gene expression in wild type ACDP 1 and 2 organisms or mutant organisms created under Activity 2.

Recipient or parental organism

Commonly used well-characterised disabled laboratory strains of E. coli from commercial or academic sources (e.g. DH5alpha, JM109, Top10, MG1655).

Also ACDP HG2 strains of E. coli.

Host/vector system

They wish to include within this assessment any well-characterised commercially or academically available non-mobilisable or mobilisation defective
derivatives of the vectors listed in the Compendium Of Guidance. In addition, for transposon mutagenesis, they may rely on transduction with well-characterised lambdoid phages to introduce the transposon.

**Origin & function**

Activity 1 in assessment: E. coli, V. cholera, Y. enterocolitica - DNA fragments, typically non-coding promoter regions, but also genes encoding non-harmful proteins.

Activity 2: ACDP HG 1 and 2 strains of E. coli - PCR products incorporating genes from these bacteria, with or without antibiotic resistance genes or marker genes. In the case of transposon mutagenesis, well-characterised transposable elements that carry reporter genes.

Activity 3: ACDP HG1 and 2 strains of E. coli - DNA fragments encoding different genes (none associated with toxin production).

Activity 4: ACDP HG1 and 2 strains of E. coli - DNA fragments encoding various genes (never encoding toxin production or harmful products).

**Evaluation of foreseeable effects**

Activity 1: Transformed E. coli are disabled and non-pathogenic, so should not carry any risks. Transgene plasmids will confer antibiotic resistance but not to any clinically relevant antibiotics. As all waste is autoclaved before leaving the building it is highly unlikely that any GMOs or constructs will escape into the environment.

If by some slim chance they were to escape, the disabled host would not be able to survive in the external environment and the non-mobilisable vector would not be able to leave the disabled host. Any release of DNA into the environment would be similar to that which occurs during the usual processes of decay. The environmental impact would therefore be negligible.

Activity 2: Transformed E. coli are disabled and non-pathogenic, so should not carry any risks. Transgene plasmids will confer antibiotic resistance but not to any clinically relevant antibiotics. As all waste is autoclaved before leaving the building it is highly unlikely that any GMOs or constructs will escape into the environment. Allele replacement requires the propagation of antibiotic resistance genes, during the interim stage when plasmids are introduced into the target strain and in some cases in the final stage, when the disrupted allele has replaced the wild type allele. In either situation, these antibiotic resistance genes will not, in the unlikely event that they escape, present an increased risk to the environment because:

- as noted above, they will use genes that do not encode resistance to drugs used therapeutically against the host species (e.g. ampicillin is not used to treat E. coli enteritis)
- These resistance determinants are already abundant in naturally occurring isolates of the host species.

Once the allele replacement is complete, the resulting GMO, carrying a
disrupted gene, is likely to be less fit than the wild type and so will be outcompeted by natural isolates, were it to escape into the environment. As noted above, any marker genes used with have no environmental effects.

Activity 3: Transformed E. coli are disabled and non-pathogenic, so should not carry any risks. Transgene plasmids will confer antibiotic resistance but not to any clinically relevant antibiotics. The expression of the proteins of interest in bacteria is very unlikely to increase their pathogenicity. As all waste is autoclaved before leaving the building it is highly unlikely that any GMOs or constructs will escape into the environment. The vectors that are used are non-mobilisable and will be propagated only in disabled lab strains of E. coli. If by some slim chance they were to escape, the disabled host would not be able to survive in the external environment and the nonmobilisable vector would not be able to leave the disabled host. The environmental impact would therefore be negligible.

Activity 4: Among diarrhoeagenic E. coli strains, only those carrying the verotoxin are classified as category 3 pathogens. The group DO NOT use these strains in their laboratory. The distinction between these strains and other related ADCP strains is made on the grounds that these strains have the potential to cause illness that is life-threatening and can be difficult to treat. In contrast, the ADCP 2 pathogens they use in the laboratory (principally E. coli strains) elicit only self-limiting local pathology and are responsive to antibiotics. Thus, altering the expression levels or copy number of any genes from these category 2 strains and/or expressing them within category 2 strains other than those from which they originate, cannot conceivably enhance the pathogenic potential of the host strain sufficient to warrant reclassification as category 3 pathogens. Furthermore, even if, in the very worst case, some enhancement of virulence were seen, the strain would remain treatable with antibiotics. Thus, they conclude that this work can be carried at containment level 2. As all waste is autoclaved before leaving the building it is highly unlikely that any GMOs or constructs will escape into the environment. Their complementation work will be done using non-mobilisable or mobilisation-defective vectors that are initially propagated in crippled E. coli strains. This initial propagation of a non-mobilisable or mobilisation-defective vector in a disabled host means that the resultant GMO will not be able to survive in the external environment. The environmental effects of such a GMO escaping will thus be negligible. Also as the non-mobilisable vector will not be able to leave the disabled host, gene release into the environment could occur only in a way that parallels natural decay processes. SEE ASSESSMENT FOR FURTHER DISCUSSION

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None
Inactivation will be by autoclaving of all wastes (including any small quantities of disinfectant–treated residues e.g. paper towels used for wiping up small spills) contaminated by GMMs, at a minimum of 121°C for 15 mins, validated by monitoring of internal chamber temperature and automatic printout of every autoclave run. This method is widely acknowledged to guarantee complete killing of all known bacteria and they regularly check the killing efficiency of the autoclave by attempting to grow autoclaved bacterial cells. Wastes from autoclaving will be disposed of to the drains (liquids) or to clinical waste incineration.

The aims of the study are to investigate the mechanisms of replication of RNA viruses and how they subvert the cellular machinery to achieve this goal. Recombinant viruses will allow us to analyse this process in greater detail and is fundamental to this research strategy and its aims. The long term aims are the improvement of fundamental knowledge in the area of RNA virus replication and the future development of vaccines and antivirals.

The GMOs are viruses derived from DNA plasmid copies of RNA viruses, specifically non-segmented RNA viruses from the Mononegavirales order such as Measles virus. The target viruses are all classed as ACDP2 or lower and will not include ACDP3+ or SAPO restricted pathogens from this Order. The GMOs will also include pseudotyped replication defective lentiviruses that are capable of transducing mammalian cells to overexpress viral or host genes e.g. to over-express genes relevant in studying pathogenesis. The recipient hosts for these GMOs are mammalian cells (primary derived or immortalised cell lines) and/or mice (lab-strains or transgenic derivatives). Bacteria (commercial non-pathogenic strains) will also be used to replicate the DNA clones prior to manipulation.

The vector system for these studies is based on the use of full length DNA clones of RNA virus genomes. The non-segmented RNA virus genomes of ACDP2 (and lower) pathogens are cloned downstream of promoters that can drive transcription of a genome like RNA. This RNA, in the correct context, and with the correct support, is capable of producing infectious virus. The plasmid backbones used for this system are based on standard commercially available versions. The lentiviral system for over-expression of chosen genes is based on the commercially available ViraPower based system. A replication defective and truncated HIV1 genome is used as a vector to generate pseudotyped particles capable of infecting (non-productively) target cells. Integration and selection is anti-biotic mediated however, no nascent virus can be produced.

The genetic material (viral or cellular) will be sourced from biological isolates of these RNA viruses (Mononegavirales of ACDP2 and lower classification only), from mammalian cell-lines, from primary cell cultures or through in vitro commercial genetic synthesis. All ethical approval for the receipt of the relevant clinically associated samples will be in place prior to the commencement of work. Importantly, the genetic material will be used to generate recombinant RNA viruses with equivalent or reduced pathogenesis relative to the parental strain. Also, the pseudotyped lentiviruses are incapable of producing productive progeny virus. Recombinant tagged/mutant viruses will
be used to determine the molecular basis for pathogenesis both in vitro and in vivo (in mice only).

**Evaluation of foreseeable effects**

Recombinant viruses: Only ACDP2 class 1 and 2 pathogens from the Mononegavirales order will be ‘rescued’. Work with ACDP3+ and SAPO restricted pathogens will not be carried out. The viruses rescued will be designed in such a way as to not increase pathogenesis, relative to the parental strain. This will obviously be confirmed using in vitro tests under ACDP2 conditions in the lab. The foreseeable effects to the organism of such mutations and/or addition of tags (fluorescent etc) are therefore to either maintain its virulence or attenuate it. The risks to the environment and public are therefore effectively zero. This bears true for the recombinant lentiviruses as well as these are replication competent and incapable of producing nascent virus after the primary infection step.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Transgenic mice will be used for some of the proposed work, where virus is used to infect mice or transgenic mice. These will be held in a secure Animal facility, with the use of isolators to house the infected mice. Agreed procedures will be in place for the removal of carcasses.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

No derogation - full CL2 applied

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

GM MeV in waste will be inactivated with 1% Distel (formerly Trigene) or 1% Virkon, which has been shown to be an effective agent for inactivation of a wide range of enveloped viruses including Measles. Measles is also susceptible to 70% Ethanol.

All biological waste generated in the IBR is then autoclaved at 135°C for 15 mins under pressure before removal as clinical waste by licensed contractors. Nothing is released to the environment. All autoclave runs are monitored and recorded by trained staff - any failed runs are treated as infectious and re run.

02/03/2022
This work will investigate the physiology, gene regulation and behaviour of class 2 ACGM microorganisms that are relevant to the process engineering industries. Example industries include but are not limited to the manufacture of fast-moving consumer goods, pharmaceuticals, medical devices and food. Microorganisms play roles in these industries in terms of both positive and negative impact. Positive impacts from organisms would include processes that utilise microorganisms to generate specific products. Negative aspects usually involve microorganisms contaminating process plant or products, either during manufacture or use. In both cases, understanding the microorganisms can aid improving the processes and products. The genetic modifications will fall under one of the following categories:

a) Whole-cell tagging with GFP or a functionally similar fluorescent protein in order to visualise the organisms using e.g. microscopy for flow cytometry;

b) Use of promoter-fluorescent protein reporter fusions to allow measurement of gene expression using e.g. microscopy for flow cytometry;

c) Gene knockouts, to determine the effects on bacterial physiology, viability, behaviour etc.;
d) Complementation of gene knockouts; and
e) Expression of heterologous genes from organisms of similar or lower ACDP hazard level, to determine effects on bacterial physiology and behaviour.

Recipient or parental organism

A variety of bacterial species at ACDP class 2, initially including:
Pseudomonas aeruginosa
Escherichia coli ACDP class 2 strains (eg UPEC, EHEC - non-toxigenic strains only).
Additional bacterial species at ACDP class 2 will be used as the project progresses. Each new species will be assessed.
Species that are ACDP HG2 but pose an elevated risk from aerosolisation (e.g. respiratory pathogens that infect healthy individuals, such as Neisseria meningitidis) will NOT be used.

Host/vector system

Examples of vectors will include:
For Pseudomonas: pME6032 - shuttle vector, pVS1 (For Pseudomonas) and p15A (for E. coli) ori, tetracyclin resistance. No mob gene.
pVS1/p15A-based GFP promoter probe vectors such as pPROBE-KT.
pBBR-based GFP promoter probe vectors such as pPROBE-TT. (pBBR is mobilizable; doi: 10.1094/MPMI.2000.13.11.1243)
For E. coli: standard cloning vectors with colE1, pMB1, p15A, pRW origins of replication, antibiotic resistances such as AmpR, TetR, KanR, ChlR.
The use of broad host range vectors is unfortunately needed due to the range of species covered in this assessment.
Non-mobilisable plasmids will be used where possible, limiting potential spread.

Promoter-reporter gene fusions may also be chromosomally integrated

Origin & function

Donor:
Health and Safety Executive
(a & b) Fluorescent proteins: The jellyfish Aequorea victoria for green fluorescent protein (GFP); The coral Discosoma sp. for red fluorescent proteins; The plant Arabidopsis thaliana for the flavin-based Fluorescent protein (FbFP) iLOV; The freshwater algae Chlamydomonas reinhardtii for the FbFP CreiLOV.
(c) Antibiotic resistance genes would be sourced from a variety of organisms / plasmids.
(d) Complementation would involve resupplying the knocked out gene on a plasmid and so the donor would be the same species as the host.
(e) Heterologous genes would be taken from ACDP class 2 bacteria.

Inserts:
(a & b) Aequorea victoria gfp and mutated derivatives (eg eGFP, YFP); Discosoma sp. OsRed and derivatives (eg mRFP, mCherry); Arabidopsis thaliana FbFP iLOV and Chlamydomonas reinhardtii CreiLOV.
(c) Antibiotic resistance genes would be used to confirm chromosomal mutations, eg AmpR, KanR.
(d) Complementation of knocked out genes - various genes.
Various heterologous genes, but none that are known virulence factors or could be expected to increase virulence.

**Evaluation of foreseeable effects**

Human health: The GMMs generated in this study are not expected to pose any greater risk to healthy humans than their non-GMM parent strains. Experiments will be designed to minimise risk.

(a & b) Expression of GFP or functionally similar molecules is not likely to increase virulence; increased metabolic burden will likely decrease overall fitness and thus decrease virulence.

(c) Knockout of genes will not be likely to increase virulence. No genes known to be negative regulators of virulence functions will be knocked out.

(d) During complementation experiments no virulence factors will be overexpressed from plasmids. Host proteins may be expressed at slightly higher levels from plasmids than from the host chromosome, but assessment will be made in each case to ensure that no genes known to give rise to increased virulence are overexpressed.

(e) No modifications will be made that are likely to increase virulence.

As such, no genetic modifications likely to increase virulence or increase toxicity will be made.

Consideration of increasing biofilm colonization ability: Biofilm formation is a complex process involving many genes; genetic modification will be used to change biofilm structure and function in this work. However, each modification will be carefully assessed beforehand in terms of risk of increased colonisation / infection ability; modifications will not be made that are deemed to result in a hypercolonizing phenotype. All GMMs will be studied at a small scale (< 100 mL) initially; any found to have a hypercolonizing phenotype will not be grown at larger scales. All GMMs will be studied at a small scale (<100mL) initially; any found to have a hypercolonising phenotype will not be grown at larger scales.

Before growth in CDC bioreactors all GMMs will be characterised at smaller scales.

Generation of Random mutants: Generation of random gene knockout mutants using a method such as TRADIS might be used in the project. In this case, TRADIS libraries would be grown at small scale and clones of interest assessed before growth at larger scale.

Environment: Organisms: All species to be used are ubiquitous in the environment. The GMMs would typically be less fit than the wild type organisms, and therefore less able to survive in the environment.

Recombinant DNA: use of mobilisable and broad host range plasmids increases risk of transfer of recombinant genetic material, but as no virulence genes are being cloned, transfer of recombinant DNA would result in: a) transfer of fluorescence genes, which would have little effect on environmental recipients; b) transfer of antibiotic resistance genes, which would be unlikely to confer resistance to clinically useful antibiotics to organisms that would be likely to cause infection; or c) transfer of other genes encoding proteins with no virulence function, which would not be likely to result in environmental harm.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

No derogation requested

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Virkon is regularly used at the manufacturers’ recommended concentration (1%). Virkon is validated for use with P. aeruginosa and E. coli (> 5 log kill).

1 % Virkon will be used as the primary disinfectant for laboratory benches; squeeze bottles containing 1 % Virkon will be provided to treat small spillages.

Efficacy against other organisms to be used in the project in future will be checked via biological risk assessments.
Spill control for CDC bioreactors: as stated above CDC bioreactors and carboys are run on drip trays. The drip trays will contain any spills. Spills will therefore be disinfected using Virkon powder to gave 1 % concentration. Disinfected spill material will be absorbed into spill kits or paper towels and these will be placed in yellow bags and sent for clinical disposal- they will not be autoclaved.

Liquid wastes are inactivated in waste autoclaves in the Biochemical Engineering building (127 °C, 15 psi, 35 minutes). Waste inactivation is checked by the use of indicator tape. Glassware is then washed, plasticware disposed of through clinical waste route.

Degree of kill = 100%.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

Please enter comments on the GM safety committee on the risk assessment

It was generally felt that this was a well written assessment. The GMSC asked for some additional info, as follows:

Would it be possible to give a couple of examples of the genes that will be targeted in the KO strains and an idea of how many might be generated during the overall project. Will all the mutants be generated by recombinational insertion of a drug selection cassette or will random mutagenesis be used at some point?

It is sensible that experiments will be started on a small scale in the first instance. However what is the reason for using 60 L reactors? Perhaps this could be justified in a couple of sentences.

What action would be taken if there was a spillage from the large scale reactor?

All of the above, as well as minor queries around waste treatment, were addressed within the risk assessment.

Project Ref 116/19.1

Date Ackn'd CU2 Project Title Class CultureVolClass2 CultureVolumeClass3-4
Identification of fungal effector recognition determinants in plants, and contribution to non-host resistance (NHR) against fungal pathogens and plant induced resistance in *Solanum lycopersicum* against pathogens using fluorescent proteins (FPs) to monitor disease.

Project Additional Information

**Purposes of the contained use**

Project 1. The aim of this work is to identify the determinants of fungal effector recognition in different plant species, and assess their contribution towards NHR. The pathogen used will be the ascomycete fungus *Zymoseptoria tritici*. A virus-induced gene silencing (VIGS) system based on Tobacco Rattle Virus (TRV) will be used to test ability of different plants to recognise pathogen effectors and resist pathogen infection.

Project 2. The aim of this project is to test induced resistance in different plants against GM isolates of the oomycete pathogen *Phytophthora infestans* (88069). In order to monitor in planta colonisation by the pathogen, the isolate of transgenic *P. infestans* expressing Red fluorescent proteins (RFP) will be used for these experiments.

**Recipient or parental organism**

Project 1. The recipient/parental organisms will be either wild-type (IP0323) or previously modified (IP0323~ku70, ST16(pGPD-GFP)) strains of the fungus *Z. tritici*. The IP0323~ku70 strain contains the Nptll gene conferring geneticin (G418) resistance in place of the native Ku70 gene. ST16(pGPD-GFP) contains the Hph gene for hygromycin resistance and the GFP gene for fluorophore expression. In VIGS experiments, the pTV vector system (based on RNA2 of TRV) is maintained in the Agrobacterium tumefaciens strain GV3101. For full viral infection to be initiated, TRV RNA1 must be provided by A. tumefaciens strain C58C1 carrying the vector pBINTRA6. Both A. tumefaciens strains are disarmed, non-oncogenic strains with natural resistance to the antibiotic rifampicin. Both the pTVand pBINTRA6 vectors carry the Nptll gene for resistance to kanamycin.

Project 2. The *P. infestans* isolate was originally transformed with RFP from Discosoma sp (mushroom coral).

**Host/vector system**

Project 1. The modified *Z. tritici* strains were originally produced as described above. For pTV, both pTV (TRV RNA2) and pBINTRA6 (TRV RNA1) encode the Nptll gene for resistance to kanamycin.

Project 2. The *P. infestans* isolate was originally transformed with the pTOR transformation vector which contains the NPTII gene for selection of transformants for G418 (geneticin) resistance. No hazards have been associated with the
vector.

Origin & function

Project 1. No further modification of Z. tritici strains IP0323, IP0323~ku70 or ST16 (pGPD-GFP) will be performed. For pTV VIGS experiments, short (200-400bp) segments of the plant gene to be silenced will be identified and cloned from cDNA sourced from the same plant species. Fragments will be inserted into the polylinker site of the pTV vector, and silencing initiated by Agrobacterium-mediated expression of both pTV (TRV RNA2) and pBINTRA6 (TRV RNA1) in plant tissues.

Project 2. Tandem dimer (td)Tomato Red Fluorescent Protein. Genes encoding fluorescent proteins are used in order to monitor in planta colonisation. They have a long history of safe laboratory use and no risks have been reported.

Evaluation of foreseeable effects

Project 1. None of the Z. tritici strains or pTV vectors described here are human or animal pathogens. It is highly unlikely that any further modifications (of the type described here) will produce strains that pose a hazard to humans or animals. Therefore the risk to human and animal health is considered low.

Modified Z. tritici could persist in the local environment if it were to encounter susceptible wheat plants. However, the strains used here were isolated from plants several decades ago and are therefore less-well adapted to modern field conditions than highly-virulent field isolates. The strains described here will be less virulent on modern wheat cultivars which often harbour suites of Stb resistance genes for protection against Z. tritici. Furthermore, the strains described here are fully susceptible to control by the 001 and SOH I classes of fungicides. The risk to the environment is therefore considered low.

The pTV vector system will only produce reconstituted virus when viral RNA1 and RNA2 are combined in planta. It is not anticipated that insertion of plant gene fragments into pTV will enhance virulence. TRV has a broad host range amongst dicot plants and the principal method of transmission is by nematode vectors of the genera Trichodorus and Paratrichodorus. In addition, the virus can be transmitted by seed, grafting of infected material and mechanical inoculation. The pTV vector lacks the Orf2b and Orf2c genes which are required to permit the virus to be transmitted by nematode vectors. Plants used for VIGS experiments are typically 2-8 weeks old. These plants are discarded before flowering and seed set. Infected plant materials from glasshouse experiments could theoretically initiate further infections if they were disposed of incorrectly, and put in close and prolonged physical contact to potential host plants to allow mechanical inoculation. However the inability of modified virus to spread via nematodes make it highly unlikely that accidental release would lead to persistent infection of plants outside the laboratory. The risk to the environment is therefore considered low.

Project 2. The transgene-carrying host organism is Phytophthora infestans 88069, a Dutch isolate. P. infestans is distributed worldwide, including major Solanum growing regions in Europe, North America, and South America. P. infestans primary hosts are potato (Solanum tuberosum) and tomato (Solanum lycopersicum). Stable inserts of fluorescent proteins such as tdtomato or NPTII genes do not enhance virulence, host range or survival of P. infestans.

Transgenic isolates already exist and the transgenes encoding the fluorescent proteins are stably inserted into chromosomal DNA of the host organism. Therefore, GMM transference is negligible. Transfer of via oospores is highly unlikely as only asexual phase of the pathogen will be used during experiments.

No P. infestans strain has ever been recorded as pathogenic to humans or animals, or produce toxins or allergens to mammals.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Glasshouses used in this work will comply with CL2: Access restricted to authorised personnel; Negative pressure
with filtration; Control of run-off water; Dedicated PPE; All waste autoclaved before being incinerated.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation - CL2 applied

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Project 1. All infected plant material and contaminated plasticware will be placed in biohazard bags and autoclaved at 127°C for 35 minutes prior to disposal. This treatment will destroy all microorganisms and plant cells. All contaminated glassware will be soaked overnight in 1% Distel.

Project 2. Infections will be performed by the detached-leaf/fruit inoculation method. All infected material (leaves or fruit) and laboratory material (tips, tubes, Petri dishes, etc) will be placed in biohazard bags, sealed and autoclaved before disposal. Transgenic material is autoclaved at 127°C for 35 minutes. This cycle kills all plant materials and microorganism.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Most comments related to the assessment of the Tobravirus-based vector system. The comments were generally relatively minor and requested clarification on the following points amongst others:

The use and properties of Agrobacterium;
Clarification of the specific genes in Nicotiana/Oak that are going to be silenced and what will the effect be (in addition to the vectors' genes);
Confirmation that there were no homologues of these genes present on the chromosome (eg as relics of previous infections) that could restore function by homologous recombination;
The risk of aerosolisation from syringes and pipetting;
The procedures for spills in glasshouses.
All points were addressed in the assessment.

Animal Units | Large Scale Activities | Human Clinical Applications

02/03/2022
Use of genetically modified microorganisms in laboratory animal infection models

**Purposes of the contained use**

This contained use notification covers the use of genetically modified CL 1 and CL2 microorganisms in murine and zebrafish animal infection models. Modifications to be studied are likely to include, but not be limited to, the expression of fluorescent tags or the disruption of putative virulence factors by approaches such as homologous recombination. Modified microbes will be introduced to wildtype or transgenic mice or zebrafish and then altered patterns of disease studied according to protocols previously approved in line with Home Office regulations.

**Recipient or parental organism**

A range of fungal and bacterial pathogenic species, including but not limited to Gram-negative bacteria (Salmonella, E. coli, Citrobacter, etc), Gram-positive bacteria (Staphylococcus, Streptococcus, etc), Mycobacteria and fungal pathogens (Cryptococcus, Candida, etc). All organisms are CL2 or below and genetic modifications to be studied are anticipated to either be neutral (e.g. expression of GFP or similar markers) or deleterious (e.g. loss of virulence factors) to the pathogen.

**Host/vector system**

A range of vector systems will be used, depending on the microorganism to be studied, but typically these are either plasmid-based expression systems (e.g. for fluorophore expression) or homologous recombination strategies (for gene 'knockout'). Vector systems to be used are typically not re-mobilisable once introduced into the host and
consequently the risk of horizontal gene transfer to endogenous microbes within the mouse/zebrafish is minimal.

Origin & function

Diverse. Genes to be studied will depend on the specific organism and project, but typically fall into the following groups:

a) 'marker' genes, such as GFP, mCherry or so forth - designed to express visible or biochemical markers that can be followed within the host organism

b) 'knockout' cassettes, designed to eliminate the expression of an endogenous gene within the microbe, such as a virulence factor

c) 'gene switch' experiments, in which, for instance, a gene from one strain of E. coli is introduced into a different strain of the same species to test its function in a different host. Such experiments are carefully considered prior to local approval being granted, in order to minimise the risk of inadvertent 'gain of function' events in which pathogenicity is increased.

Evaluation of foreseeable effects

The foreseeable consequences of each experiment are those which the experiment is designed to address - for instance, reduced disease symptoms in a mouse infection model, following infection with a 'knockout' bacterium. Inadvertent foreseeable consequences are minimal, since all of the work proposed here will be conducted within contained animal facilities. Animals are monitored carefully to ensure high standards of welfare and thus any unexpected effects of the GMO will be rapidly detected. All waste, import/export of animals and entry/exit of staff is carefully regulated from the facility and hence the likelihood of an inadvertent release of a GMO to the environment is negligible.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

This notification concerns the use of GMMs within animal models. This includes lab scale work with zebrafish larvae, for example, but will also include work in animal facilities (mouse work). These facilities are designed to prevent escape. The animal work will carried out within a dedicated containment suite within the animal facility. A quarantine procedure is in place to prevent researchers entering any other part of the building (containing 'clean' animals) for 48 hours after being in the containment suite. Dedicated PPE (full suit, hair net and mask) is provided and must be worn. Shedding from the animal is possible, particularly with oral gavage. Bedding will be autoclaved and sent for disposal via the clinical waste stream for incineration.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation - CL2 applied

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste will be autoclaved, bagged and sent for incineration via the University’s clinical waste contractor. Liquid waste is also autoclaved and disposed of to drain. Autoclaving achieves 100% kill. 1 % Virkon is used for disinfection within the laboratory and may also be used to treat liquid waste at 1 %.

All animal bedding and associated animal waste is autoclaved before disposal via the clinical waste stream for incineration. 100% kill.
A number of risk assessments are associated with this notification - two have already been submitted as examples to cover the bacterial and fungal aspects of the work. Most of the comments were in relation to the laboratory work, rather than the extension of the work into animal models, although more information on controls specific to the animal facility were requested.

## Project Additional Information

### Purposes of the contained use

1. Stable introduction of constructs to express short hairpin (shRNA) in cells, to target a variety of cellular or viral RNAs for degradation by RNA interference.
2. Stable introduction of constructs into cells to modify genes of interest (e.g. by CRISPR)
3. Stable introduction of constructs to express wild-type or mutant proteins to examine function, or markers (e.g. fluorescent proteins)

### Recipient or parental organism

Human or other mammalian cell lines, including tumour cell lines; primary human or rodent cell lines. Cell lines may be injected into relevant animal models, such as murine models.

Vectors expressing shRNA, CAS9 and/or guide RNA sequences for CRISPR approaches, or modified genes of interest may be inoculated into relevant animal models as above.

### Host/vector system

Retrovirus vectors will be deleted for gag, pol and env genes, and produced in split packaging systems (e.g. FLY:A13 or FLY-RD18; Phoenix), in which the gag-pol and env genes are expressed from separate constructs, reducing the risk for generation of replication competent recombinants to an extremely low level. Some vectors are also "self-inactivating", with a deletion within the 3' U3 region which allows the vector to go through only a single round of infection after packaging.

The envelope proteins used will allow infection of human cells, e.g. murine amphotropic, feline RD114, VSV-G Lentivirus vectors will preferably be 3rd generation (although 2nd generation may also be used), i.e. the vectors being deleted for all viral genes, and separated onto at least 2 or 3 plasmids. The HIV envelope protein will not be used, all currently planned work will use the VSV-G envelope glycoprotein. Alternative systems may be used, such as the Invitrogen or Trono lab systems. Wherever possible, allentivirus vectors used will be self-inactivating (SIN).

### Origin & function

The shRNA constructs will be designed to inhibit expression of a variety of cellular genes through the process of RNA
interference (but may include "control" constructs, designed not to match any cellular gene). A wide variety of cellular genes will be targeted in different constructs, including tumour suppressor genes; other constructs will be designed to downregulate genes of certain viruses associated with particular human cancers, e.g. Epstein-Barr virus. CRISPR approaches may similarly be used to modify similar target genes to prevent their expression or modify their function. In addition they may be used to introduce a marker (e.g. fluorescent tag) that allows the expressed modified protein to be detected.

Retrovirus or lentivirus vectors will be constructed that express a variety of genes, either from human (or other mammalian species), or from viruses such as EBV, that are of interest for their association with certain human cancers. Genes of initial interest include human telomerase, T-cell receptors and EBV latent genes and this list will continue to increase.

(In the accompanying assessment the genes of interest include inserts currently derived from: PRMT1, PRMT5, RUVBL1, USP7, USP11, MEP50, luciferase, FOXP1, BCLAF1, THRAP3, FXR1, FMRP, SPIN1 and corresponding shRNA sequences. Vectors also contain Cre recombinase for induction of LoxP mediated recombination of floxed alleles in mice.)

Evaluation of foreseeable effects

The effects of regulating expression of a targeted gene will depend upon the particular gene, and could range from no discernible effect to marked phenotypic changes. Similarly, the effects of expressing a transferred gene could range from negligible to profound. In both situations we consider the "worst case scenario" would be to bring about changes that could contribute to transforming a normal cell into a malignant cancer cell. For example, either shRNA-mediated downregulation of a tumour suppressor gene, or expression of either an oncogene or a gene associated with cellular immortalisation such as telomerase, could have such an effect. Although conversion of a cell from a normal to a cancerous state is believed to depend upon the accumulation of multiple such changes affecting growth control and cellular checkpoints, making it unlikely that accidental worker inoculation and infection of a modest number of the cells with the virus would lead to cancer, the seriousness of this potential consequence warrants the use of control measures afforded by Containment Level 2 to minimise the potential for such accidents.

Since retroviruses and lentivirus vectors insert their genomes into the chromosomal DNA of infected cells, there is an associated risk of insertional mutagenesis. There have been examples of leukaemias apparently resulting from insertional activation of an oncogene in human gene therapy clinical trials; however, these have only arisen in a minority of patients receiving such vectors, and involved doses many orders of magnitude greater than could occur in any foreseeable accident. Also, liver tumours have been reported following systemic injection of certain lentivirus vectors in foetal or neonatal mice. It is unclear whether these were caused as a result of insertional mutagenesis/oncogene activation, or whether WPRE present in some of the vectors may have contributed an oncogenic protein fragment. Although standard retrovirus vectors can only infect replicating cells, lentiviruses can also infect non-replicating cells, and thus would be expected to result in a greater level of cellular transduction following accidental worker exposure. Use of certain envelope proteins, such as VSV-G to pseudotype the viruses, can also increase stability of of the viruses to some extent, and is done precisely because it can result in more efficient infection of human cells.

Although this in principle increases the risk to workers, in practice it may be balanced by the fact that lower levels of virus are needed for the experiments than would otherwise be the case. Thus, although it must be recognised that accidental worker inoculation, either to mucosa or via percutaneous exposure could lead to stable gene transfer to cells in the body, on balance it appears unlikely that a foreseeable accident could result in a level of worker exposure that would be likely to result in tumorigenesis. Use of CL2 is considered appropriate to control the risks.

The possibility of generating replication-competent retrovirus or lentiviruses should also be considered. Replication competent retroviruses in their natural host species are associated with tumourgenesis, via insertional activation of oncogenes. The split packaging cells to be used for retrovirus generation and use of "2nd or 3rd generation" systems...
for lentivirus production make it very unlikely that replication competent viruses could be produced, and such systems
have a history of safe use. Use of SIN vectors adds a further level of safety, since this effectively limits the vector to a
single infectious cycle.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

No notifiable Large GMOs are involved in this work, although work in animal models will be carried out (e.g. murine
models).

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid and liquid waste normally inactivated by autoclaving. Surface decontamination using 1% Virkon (unless
corrosion is likely, in which case Chemgene (1:100 - 1:200 dilution may be used for these applications). Autoclaving
achieves 100% kill.

Within animal facilities, bedding and associated waste is autoclaved and sent for incineration. There is no shedding
from animal. Any spills will be treated with Virkon, mopped up, placed in double yellow bags and removed for
autoclaving

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The GMSC has approved the accompanying assessment. Further information was requested on the vectors and the
inserts and it was felt that the assessment was quite complex, given the number of genes and vectors. The
assessment was rewritten to clarify these points.

We wish to submit a series of assessments that form a programme of work that includes several laboratories, several pathogens and several activities to study the role of mobile genetic elements (plasmids and integrative conjugative elements) in the transfer of antibiotic resistance genes. This work focuses on the characterisation of mobile genetic elements carrying antibiotic resistance genes from human commensals and human pathogens that fall into ACDP category 2. Prior to GMO work, all mobile genetic elements will be sequenced to completion and excluded when genes encoding toxins are present.

The bacteria to be used include:
- Escherichia coli (non-vero-toxin producing)
- Klebsiella pneumoniae, and closely related species (K. variicola, K. quasipneumoniae) and Klebsiella aerogenes
- Salmonella enterica (non-typhoidal serovars)
- Staphylococcus aureus and coagulase-negative staphylococci
- Streptococcus pyogenes, S. pneumoniae, S. agalactiae, and viridans group streptococci (e.g. S. mitis and S. oralis)
- Enterococcus faecalis, E. faecium and other Enterococcus species
- Bacteroides fragilis and other Bacteroides species
- Clostridoides (Clostridium) difficile and other Clostridia, with the exception of Clostridium botulinum and other neurotoxin producing Clostridia
- Pseudomonas aeruginosa

Specific activities include:
1. cloning of DNA fragments (using site specific recombination) harbouring reporter constructs (genes encoding...
fluorescent proteins, including GFP, YFP, RFP and mCherry) and an antibiotic resistance marker (including erythromycin, tetracycline, ampicillin, spectinomycin, kanamycin) into mobile genetic elements that have originated from wild-type strains, including strains isolated from patients, hospitals, or the environment. Some of these elements have been extensively characterised (e.g. pKpQIL, pCT, pNDM), while others have not yet been characterised beyond their sequence.

2. conjugation, transformation or alternative methods of DNA transfer of the plasmids harbouring reporter constructs to strains of the same and different species in ACDP category 2.

3. These genetically modified mobile genetic elements within microorganisms will be used in murine and zebrafish infection models. The transfer of the modified mobile genetic elements into new bacterial hosts will be monitored using the fluorescent tags. All in vivo experiments will be performed according to protocols previously approved and in line with Home Office regulations.

### Recipient or parental organism

Hosts for activities 1-2 as listed above
Activity 1: Wild-type bacteria as described above
Activity 2 & 3: Wild-type bacteria as described above, bacteria as described above with selectable markers/genes encoding fluorescent proteins integrated on the chromosome, and other bacteria that are present in human-associated microbial ecosystems which fall into ACDP category 1 or 2.

### Host/vector system

Vectors for activities 1-3 as listed above:
Health and Safety Executive
Activity 1: Mobile genetic elements isolated from wild-type strains including hospital, patient, and environmental isolates.
Activity 2: Mobile genetic elements isolated from wild-type strains including hospital, patient, and environmental isolates.
Activity 3: Mobile genetic elements isolated from wild-type strains including hospital, patient, and environmental isolates.

### Origin & function

Donors of material for activities 1-3 as listed above
Activity 1 - Non-mobilisable vectors carrying antibiotic resistance genes and fluorescent reporter genes
Activity 2 & 3 - Conjugative plasmids developed in Activity 1 which carry antibiotic resistance gene markers and fluorescent reporter genes

### Evaluation of foreseeable effects

Human Health considerations
Health and Safety Executive
Activity 1: The integration of reporter constructs and antibiotic resistance markers in wild-type conjugative plasmids will result in a slightly increased risk to human health as the conjugative plasmid will carry an additional antibiotic resistance gene. Containment level 2 is appropriate.
Activity 2 & 3: The transfer of conjugative plasmids with a reporter construct and an antibiotic resistance marker will result in a slightly increased risk to human health as the new host strains will carry an additional antibiotic
resistance gene. Containment level 2 is appropriate.

Environmental considerations:

Activity 1: All waste is autoclaved before leaving the building so it is very unlikely that GMOs or constructs will escape into the environment. If by some chance they did escape the mobilisable plasmids will have a fitness defect, due to the cost of carrying the fluorescent reporter construct, that minimises the chance of the plasmid spreading successfully in the environment. The environmental impact of this activity is therefore negligible.

Activity 2: All waste is autoclaved before leaving the building so it is very unlikely that GMOs or constructs will escape into the environment.

Activity 3: All of the proposed work will be conducted within contained animal facilities. Animals are monitored carefully to ensure high standards of welfare and thus any unexpected effects of the GMO will be rapidly detected. Import/export of animals and entry/exit of staff is carefully regulated from the facility and hence the likelihood of an inadvertent release of a GMO to the environment is negligible. Furthermore, a quarantine procedure is in place to prevent researchers entering any other part of the building (containing 'clean' animals) for 48 hours after being in the containment suite. Dedicated PPE (Full suit, hair net and mask) is provided and must be worn. Shedding from the animal is possible, particularly with oral gavage. Bedding and all animal waste will be autoclaved and sent for disposal via the clinical waste stream for incineration, hence the likelihood of an inadvertent release of a GMO to the environment is negligible.

No notifiable Large GMOs are involved in this work. Animal model work would involve zebrafish and murine models.

Work in animal models will be carried out in the animal facility’s containment suite:

- The containment suite has a "Sanirack" system, which is HEPA-filtered for the animal and on the exhaust. Cages are sealed and, on removal from the rack, both cage and rack are sealed from the room. Cadavers and bedding are autoclaved before disposal and are then sent for incineration via the clinical waste route. Cages are also autoclaved before being processed for cleaning.
- Work can be carried out in a Class 2 safety cabinet.
- PPE includes gowns, gloves and FFP3 face masks.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

All GMMs will be fully contained. No derogation requested.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

After use, solid media and plastic/glassware that have come into contact with GMMs will be autoclaved (50 mins, 127 degrees) and disposed of. Effectiveness of waste autoclave is regularly monitored and all runs are validated with internal temperature monitoring and reporter tape.

Two general purpose chemical disinfectants are used: Virkon (peracetic acid; CAS:79-20-0) and Chemgene, which combines a variety of active ingredients including: alcohols (CAS:68439-45-2), quaternary ammonium compounds (CAS: 68424-85-1), chlorhexidine (CAS:18472-51-0), Didecyltrimethylammonium chloride (CAS: 7173-51-5), and Bis(3-aminopropyl) Dodecylamine (CAS: 2372-82-9). It has activity against bacteria (including mycobacteria, and spore forming bacteria), fungi, and viruses.

Liquid waste containing GMMs will be inactivated with Virkon (exposed to 1 % Virkon for a minimum of 30 minutes) or Chemgene (exposed to 10% Chemgene solution for a minimum of 60 minutes). This will result in 100% kill of bacterial cells, including spores. All waste (aside from disinfected fluids) will be autoclaved as described above.
All animal bedding and associated animal waste is autoclaved before disposal via the clinical waste stream for incineration (100% kill).

It is not clear whether the resistance plasmids will still carry the "naturally occurring" resistance genes and whether these are genes for resistance against clinical drugs and whether you will therefore generate pathogenic strains with resistance against clinical compounds. It seems to me that putting these markers into the resistance plasmids should not create a danger. However, the researcher does not seem to specify how the insertion of these marks into the plasmids will be done and whether they will be inserted at a specific location and what location will be if known. Knowing how insertion is being done will indicate whether it will occur at a specific location or is random. It is conceivable that insertion at specific location could derepress certain genes which might have harmful phenotypic consequences that could be assessed with a knowledge of the plasmid.

Clarification was also requested on how this assessment linked into others within the department. Copies of these (approved and, where appropriate, notified) assessments were supplied.

Please enter comments on the GM safety committee on the risk assessment

Project Ref 116/20.2

Date Ackn'd 17/04/2020  
CU2 Project Title Cell Biology of Poxvirus Infection  
Class 2  
Culture Class CultureVol  
< 1 Litre
The laboratory focuses on determining the mechanisms by which Vaccinia virus subjugates host cells proteins and cellular functions. This work relies heavily on the use of recombinant viruses for cell, molecular, biochemical and virology based experimentation.

(**The following viruses will serve primarily as controls and these stocks will be stored and not used without further risk assessments being written, which will then be considered by the GMSC and be added to this connected programme of work if appropriate. They are all HG2 pathogens. They all fall under the experimental procedures outlined for vaccinia. In all cases the volumes worked with will be far below that outlined for vaccinia GMM protocols. In all cases the GM viruses are equivalent to or attenuated when compared to the respective WT virus. Those viruses are:

- Human Cytomegalovirus (HCMV): Strains: WT (AD169) IE2GFP (Viable Human Cytomegalovirus Recombinant Virus with an Internal Deletion of the IE2 86 Gene Affects Late Stages of Viral Replication) UL32GFP (Viable Human Cytomegalovirus Recombinant Virus harboring a EGFP-tagged version of UL32 in place of the endogenous copy)
- Influenza A Virus: Strains: WSN (WT H1 N1) rVII1 (Amantadine sensitive) PR8/NS1-GFP (lab strain H1 N1 with nonstructural protein 1 tagged with GFP) X31 (WT H3N2) Semliki Forest Virus: Strains: SFV-4 (WT) SFV-4-ZsG (WT that expresses ZsGreen fluorescent protein replacing non-structural protein 3) Respiratory Syncytial Virus Strains: RSVA2 (WT) RSV-RFP (WT that expresses RFP) RSV-GFP (WT that expresses GFP Simian virus 40 Strains: WT) Wild type and recombinant vaccinia viruses [strains western reserve (WR) and International health department strain J (IHDJ)] expressing EGFP, mCherry or containing viral structural proteins modified by EGFP, mCherry, HA, FLAG sequences, or a combination thereof.

Recipient or parental organism

Wild type and recombinant vaccinia viruses [strains western reserve (WR) and International health department strain J (IHDJ)] expressing EGFP, mCherry or containing viral structural proteins modified by EGFP, mCherry, HA, FLAG sequences, or a combination thereof.

Host/vector system

The function of the inserted material is to provide means of visualization, purification, and detection of virus particles or their structural constituents. The plasmids used for recombination (pJS4 and pUC19) pose no risk of direct or indirect effects, are not replication competent in mammalian cells and pose no possibility of gene transfer to host cells as they do not contain human sequences. Both pUC19 and pJS4 are mob-minus plasmids. The aforementioned tags
GFP, mCherry, HA and FLAG have been incorporated individually or in combination into individual recombinant viruses of each virus strain (WR, IHD-J and Copenhagen)

Origin & function

The GFP sequence was originally derived from Aequoraea victoria, and modified to produce mCherry. HA is derived from influenza virus and FLAG is an artificially derived sequence. All VACV genes that have been tagged are left intact. The vast majority of recombinants (-200) are in the WR background, with only a subset of recombinants made in IHD-J (-10) and Copenhagen (-20). In all cases, the recombinant viruses are attenuated or of equal replicative capacity as their WT variants as assessed by gene expression profiles, 24-h yield and virus spread (plaque assay).

Evaluation of foreseeable effects

Human Health: The wild type viruses are the most virulent. The recombinant viruses will either express fluorescent proteins to mark stages of gene expression or package fluorescent structural proteins for visualization of virus particles. All of these insertions either have no impact on virus pathogenicity or limit the pathogenicity of the virus. Vaccinia virus is used as a live vaccine against smallpox Virus, thus it is routinely used in humans. The likelihood of laboratory exposure is very limited. Exposure requires sub-cutaneous injection and does not occur via aerosol or direct contact with intact skin. To further lower the chance of exposure, only workers trained in good laboratory practice (as specified in local Codes of Practice for laboratory workers) will handle infectious material.

Environmental: Vaccinia virus poses no risk to the environment. It cannot replicate independently, is not a plant pathogen, and displays low stability under environmental conditions. In addition, vaccinia has little capacity to spread from human to human. It can be isolated in the wild from cows and buffalo yet no spread among herds or crossspecies has been reported. No vaccinia outbreak, either natural or accidental (laboratory) has been reported. Although capable of rapid spread among rodents in proximal contact (within individual cages in animal housing facilities, but not cage-to-cage) the rapid disease progression and high mortality rates limit spread within populations. (Espisito, J., Fenner, F. 2001. Poxviruses. In Fields Virology, 4th ed., Vol. 2. Lippincott-Raven, Phila. 2887-2916.)

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation - full CL2 applied

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

5% Virkon which results in a degree of killing of 100% of Vaccinia virus on contact (Butcher and Uleato 2005, Contact inactivation of orthopoxviruses by household disinfectants), Distel (Trigene): ATS labs study 'Virucidal efficacy of a disinfectant for use on inanimate environmental surfaces' March 2007. EC50 of 1 % Distel in vaccinia stock solutions containing 1 x1 OE9 units of infectious virus/milliliter which is equivalent to 99.9% killing.

All solid material (plastic dishes) potentially containing virus will be collected in autoClave bags contained within metal housing containers and autoclaved. Smaller plastic objects (tips used to handle virus or virus containing liquid) will be inactivated by autoclaving. The vast majority of work is carried out in flasks with caps. As VACV is only delivered through wounding, round dishes in autoclave bags pose no foreseeable threat. There has never been a reported instance of VACV infection via petri dish. In addition, the fewest number of handling steps involving liquid when...
dealing with infectious material is preferred. Liquid waste will be collected in aspiration bottles containing Distel Advanced Virucidal solution (1% for at least 24h) prior to disposal. For routine infection work disposable polystyrene aspirating pipets will be utilized for aspirating virus containing media into proper disposal containers. All aspiration will be followed by disinfection of disposable polystyrene aspirating pipets through aspiration of 5% Virkon which results in a degree of killing of 100% on contact (Butcher and Uleato 2005, Contact inactivation of orthopoxviruses by household disinfectants). Autoclaving achieves 100% kill.

The GMSC was happy with the classification of the work and merely requested clarification of some points, particularly around disinfection. As described earlier, other viruses, which may be used as controls, are mentioned within this assessment, but individual assessments will be written for these viruses, should they ever be needed.

**Date Project Ceased** 02/03/2022
Toxoplasma gondii (Toxoplasma) is an obligate intracellular eukaryotic parasite that has a broad host range including humans. Latent Toxoplasma infection is widespread among the human population (approximately 30% of the world’s population is seropositive for Toxoplasma), while life threatening infection generally only occurs in individuals with weakened immune systems or neonates. Toxoplasma is able to invade any nucleated cell from warm blooded animals, inside the cell it resides within a parasitophorous vacuole (PV) – a membrane enclosed compartment derived from the host cell membrane into which the parasite inserts its own virulence associated proteins.

The long-term aim is to identify novel pathways and mechanisms which host cells use to recognise and restrict the growth of Toxoplasma within the PV. Host cell defences are able to restrict parasite replication especially if the cells are activated by the cytokine IFN-gamma.

Genetically modified Toxoplasma will help to experimentally test different aspects of the pathogen’s pathogenicity. The genetically modified Toxoplasma used will fall into two categories – fluorescently tagged Toxoplasma for microscope imaging (e.g. constitutively expressed GFP, mCherry) and Toxoplasma which have had a specific virulence associated gene deleted.

In order to probe the immune response both in vitro in tissue culture cells, we will employ the fact that Toxoplasma is amenable to genetic modification. By using parasites either knocked-out for genes that potentially influence immune recognition or infectivity, as well as parasites that transgenically express tagged versions of Toxoplasma effector genes, we will be able to pinpoint the molecular mechanisms of this recognition.

Host: Toxoplasma gondii - no genetic modification will be undertaken in the lab, but GM strains will be used.

Recipient or parental organism

N/A

Host/vector system

N/A

Origin & function

No modification carried out by this lab - strains obtained from elsewhere. Previous modifications made by other labs and now used as standard community strains routinely include fluorescent and bioluminescent proteins expressed under a constitutively active promoter for imaging applications (see below).

Toxoplasma strains genetically deleted for effector proteins or expressing transgenic effector proteins were constructed using the antibiotic pyrimethamine by other laboratories. Some of the genetically modified Toxoplasma strains will be more virulent in mice or alter the nature of the observed response in tissue culture cells as compared to their parent strains. We will not use murine experimental systems. None of the genetically modified Toxoplasma strains will ever be more virulent than any other wild-type strain available. In other words, virulence factors from one strain of Toxoplasma are expressed in another strain in order to test if these virulence factors are the specific mediators of the immune response.
Fluorescent proteins – e.g. GFP, mCherry, tdTomato. These proteins emit light at a specific wavelength when stimulated with a different lower wavelength of light. They are commonly used in Biological sciences in conjunction with fluorescent microscopy / fluorescent spectrometry to localise and quantify proteins within an organism or cell.

Bioluminescent proteins – e.g. Firefly luciferase (from Photinus sp.). Luciferase is an enzyme that produces light as a by-product of the enzymatic degradation of a substrate – for biological sciences this substrate is usually luciferin. Bioluminescence is often used as an alternative to fluorescent proteins due to its increased stability in organisms and the requirement for no excitation light.

None of the genetically modified Toxoplasma strains are expected to present an increase in hazard to humans compared to the initial parent strains used to derive the genetically modified form from. The inserted gene products are all derived from different Toxoplasma strains or encode non-infectious, non-hazardous proteins (e.g. green fluorescent protein). No Toxoplasma strains will be used that express genes toxic to human health. Toxoplasma strains knocked out for virulence factors will only ever render the modified strain as virulent as another wild-type Toxoplasma strain.

Evidence of foreseeable effects

Evaluation of foreseeable effects

None of the genetically modified Toxoplasma strains are expected to present an increase in hazard to humans compared to the initial parent strains used to derive the genetically modified form from. The inserted gene products are all derived from different Toxoplasma strains or encode non-infectious, non-hazardous proteins (e.g. green fluorescent protein). No Toxoplasma strains will be used that express genes toxic to human health. Toxoplasma strains knocked out for virulence factors will only ever render the modified strain as virulent as another wild-type Toxoplasma strain.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation, full CL2 applied.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All materials that have come into contact with live Toxoplasma parasites will be first disinfected with Presept solution (one 2.5g tablet in 500ml water) for at least two hours. After this time Toxoplasma is no longer viable so liquid waste can be disposed of down the sink while solid waste can be placed into the autoclave waste stream.

Is an emergency plan required according to regulation 20? Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Tick to confirm that you have attached a risk assessment to this form N

Additional information on the strains was requested and this has been supplied in the form of an Excel spreadsheet. Further information was requested on the disinfectants/concentration used and this was added. The GMSC also asked how the lab would be managed to ensure the risks associated with the agent would be communicated to all lab users. The PI has set out an action plan for this.

#### Project Additional Information

**Purposes of the contained use**

This notification relates to new research to study both pathogenic and beneficial bacteria and fungi associated with plants in relation to specific disease and pest systems. For the purpose of providing clarity on the experimental approaches to be adopted, the research is broken down into two main areas (projects): Project 1: The aim of this project is to identify pathogenicity factors in fungal plant pathogens. The roles of these genes in pathogenicity will be characterised by inactivating the targeted gene via targeted double-homologous gene disruption via Polyethylene Glycol (PEG)-mediated protoplast or Agrobacterium tumefaciens-mediated transformation (AGTM). The fungal strain harbouring the inactive gene is then examined for its ability to cause disease on their corresponding plant hosts. Complementation of knock-out strains will also be performed to verify the pathogenicity gene’s role in virulence. In some instances, fungal strains will also be altered to express fluorescent proteins so that their growth can be monitored in planta infections. Project 2: This project will aim to identify the mechanisms used by the bacteria to colonise plants and insects. Gene systems within these bacteria will be identified by genetic screens. These systems will be analysed further to ascertain what function each system plays and to examine the role in bacterial fitness. Comparative analysis of other plant- and soil-associated bacteria will be done to examine the evolution of these bacteria in the plant and insect environment. This project will also include an investigation of the genetic basis of host specificity and will define factors contributing to host range of plant pathogenic bacteria. It will be examined whether epiphytic populations of the bacteria contain virulence factors that regulate their ability to persist on cultivated and wild cherry, ash, and oak as well as herbaceous model plants Arabidopsis, bean and tomato. Knock-out, or deletion, of gene candidates possibly involved in host specificity, virulence and fitness will be produced to further determine...
function. We will also explore the genetic basis of bacterial interactions with bacteriophage. This will identify the mechanisms used by the bacteria to resist infection by bacteriophage.

In future there may be toxicity studies with biocontrol strains for controlling insect pests. This would involve using aphids such as Myzus persicae and larvae of Galleria mellonella.

Recipient or parental organism

Project 1: Recipient or parental strains will be the fungal wheat/barley pathogens, from the Dothideomycetes Class. Typical examples are Zymoseptoria tritici, Bipolaris sorokianae, Pyrenophora tritici-repentis, Parastagonospora nodorum. From comparative genomics projects some sister species of these fungi may also be used for comparative purposes, such as Parastagonospora avenaria and Pyrenophora teres-teres.

Project 2: Recipient or parental strains will be the wildtype strains of plant pathogens Pseudomonas syringae from the pathovars tomato, phaseolicola, aesculi, morsprunorum and syringae (can be epiphytic and endophytic, causing leaf spot (tomato), bleeding canker (horse chestnut), halo blight (bean) and canker (Prunus species like cherry), respectively; wildtype strains of Pseudomonas savastanoi pv. fraxini, causing bacterial canker on ash, and Brenneria goodwinii, Gibbisella quercicancans, and Rahnella Victoriana, causing Acute Oak Decline (the latter three are considered opportunistic pathogens), P. avellanae: 011, 48, 51, 592, 593, 595, 596, 598 (causing bacterial canker on hazelnut); P. viridiflava: 2848 (causing leaf blight on tomato); P. cichorii 9437, 907; P. marginalis 247, 667, 949 (causing bacterial canker on lettuce, celery and chrysanthemum); P. corrugata 2445 (causing pith necrosis on tomatoes); P. agaricis 2289 and 2472 (causing drippy gill on mushrooms); P. tolaasii 2192T (causing bacterial blotch on mushrooms); P. entomophila L48 (ubiquitous in soil, aquatic, and rhizosphere, insect pathogen); Xanthomonas sp. e.g. X. campestris 8004, 8397 (causing black rot on crucifers); Erwinia sp. e.g. E. amylovora CFBP430 (causing fire blight on apples and pears); Pectobacterium sp. e.g. P. atroseptica SCRI1143 (causing blackleg of potatoes); Dickeya sp. e.g. D. capitata (causing soft rot diseases on many crops); plus other strains of the bacterial genera/species listed here would likely be isolated from the environment.

Non-pathogenic or insect-targeting environmental bacteria will include Pseudomonas sp. including fluorescens SBW25, PFO-1, PFO2, WCS365, ATCC17400, F113, P667, P702, protegens (Pf-5), chlororaphis, poae (PpR24); P. putida KT2440, PAW340; P. jessenii; P. rhizospherae; Rhizobium sp. e.g. R. leguminosarum J1300 (symbiont of legumes); Arthrobacter sp. JS443; Pantoea sp. e.g. P. agglomerans (strains carrying biocontrol marker and not clinical isolates); P. stewartii; Paenibacillus and Bacillus sp. (non-pathogenic to humans, thus NOT B. anthracis or B. cereus); naturally isolated Citrobacter sp. (not C. rodentium).

These strains are from our own (or collaborators) collections, collected from environmental samples. The bacteria listed above are classified as ACDP level 1.

Host/vector system

Project 1: For vector construction the host/vector systems are standard cloning organisms, including non-pathogenic E. coli, S. cerevisiae and A. tumefaciens. Standard non-pathogenic E. coli strains (i.e. DH5α and Top10) will be transformed with the pPAN7-1 (hygromycin, ampicilin, GFP), pPAN8-1 (bleomycin, ampicilin), ppk2 (hygromycin, kanamycin resistances, GFP) or pYAE (hygromycin, kanamycin, GFP) vectors. pYAE contains a yeast origin of replication and can be grown in S. cerevisiae strain BJ5464 (cloning intermediate). A. tumefaciens strain LBA1126, contains helper plasmid pAL1100spec (used for fungal transformation), this strain also contains resistance to rifamicin. Ppk2 and pYAE vectors can both be cloned into and replicated within A. tumefaciens. A. tumefaciens is used to transform the plant pathogenic fungi listed above.

Project 2: Standard non-pathogenic strains of Escherichia coli (principally DH5α and S17-1 or S17-1λpir and Top10) will be used as hosts for vectors and used for conjugation of the vector into recipient bacterial strains. All vectors function to carry genes (Broad or Narrow host range) or to mobilise plasmids (helpers).

Broad host range vectors: pML122; pDSK600; pJJ3200; pGfpgus; pBBR1MCS-based vectors (#1-5); pME6010, pME6030 and pME6031; pRK415; pLAFR3.

Narrow host range vectors: pULIC3; pLVETD; pUT.

Helper plasmids: pRK201; pRK2073.

Cloning vector: pCR2.1 and TOPO derivative.

Transposons: IS-Omegon-Km/hah.

pK18mobascB will be used for knock out by homologous recombination.

Origin & function

Project 1: Details of the resistance or fluorescent markers found in the plasmids are as follows: NptII encodes the neomycin phosphotransferase II enzyme which permits metabolism of the antibiotic geneticin (G418). Hph encodes the Hygromycin B phosphotransferase enzyme which permits metabolism of the antibiotic hygromycin. GFP
The patient pathogenic fungi covered under this project have never been known to infect humans or animals, therefore the risks that they pose to human/animal health are considered very low. Furthermore, the resistance genes and GFP marker that will be used to select for GM strains, have been used routinely in molecular biology for many years. GM plant pathogenic fungi that carry these markers have never been reported to harmful to human or animal health. The genetic modifications proposed are primarily knock-outs of suspected plant virulence-related genes, thus we expect that GM fungi will be less virulent than their respective WTs. Some ectopic transformants will have similar virulence levels to the WT strains. Therefore, should an accidental release of a GM strain occur it is very likely that these strains would be equal or less fit than the natural populations of fungi and would be outcompeted by natural strains. The Dothideomycete pathogens covered are pathogenic on wheat and barley and pose little to no threat to other plant species. Only splashed dispersed asexual spores will be generated for experiments in this project. These spores are not capable of being aerially dispersed over longer distances. The location of the GM work is in the CAT2 containment facilities at the School of Biosciences, which is in the centre of Birmingham city and several kilometres away from any open wheat/barley fields. Therefore, in the unlikely event of accidental environmental release the likelihood of a GM strain finding a suitable host near the Biosciences building is also deemed to be extremely low.

Project 2: The plant pathogens being used in this project are ubiquitously present in the environment (on plants/water/soil). There is no evidence that environmental Pseudomonas species (not including P. aeruginosa), or other bacterial species mentioned above are harmful or pathogenic to humans. Several strains can be toxic to some insects, but genetic modification is unlikely to increase their infectivity to insects and will not cause them to become pathogenic to humans. The E. coli strains used for cloning are non-pathogenic to humans and do not colonise the human gut. The vectors and inserts do not pose a hazard to human health and safety. None of the strains listed have any known virulence or toxic effects on animals and humans. In the highly unlikely event of accidental release, the mutants of plant pathogens or insect-toxic strains will likely have attenuated virulence and pathogenicity on plants or insects (probably be unable to propagate to the same population levels as the wildtype), while other mutants may be neutral (have no changes in their pathogenicity). Much more rarely, strains may have increased virulence, due to overexpression of a virulence factor giving more severe symptoms, but in doing so this is highly likely to incur an overall fitness cost on the bacterium and thus likely making the alteration subject to compensatory mutations that reduce virulence while increasing fitness. Therefore, control measures and maintenance of good laboratory practice within the class 2 laboratories will be in place to prevent and eliminate any dispersal of the strains.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation – CL2 applied

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Project 1 and 2: All infected plant material and disposable laboratory consumables will be placed in autoclave bags and autoclaved before disposal. Transgenic material is autoclaved at 127°C for 35 minutes. This cycle kills all plant cells and microorganisms. The temperature is monitored and recorded by a probe placed in the centre of one of the bags being autoclaved. The autoclave is regularly checked and serviced by the manufacturer. Autoclave conditions are automatically recorded and archived.
The GMSC requested further information on strains used, along with their characteristics – e.g. whether they were pathogenic, their host range, etc, and in the case of existing strains, whether these were taken from a commercial source or an existing strain collection.

They also raised questions around the likelihood that more virulent strains may be generated - for example, by knockout of a transcription factor that represses expression of a virulence factor, or whether, when inserted into E. coli, any of these genes would introduce novel functionality e.g. attachment, invasion, toxin generation.

Because the work involves targeting toxins and secretion systems, both classes of gene that committee members thought were virulence factors (certainly in human pathogens), clarification was requested on whether these were virulence factors in plant pathogens.

The committee also asked that the risk posed by transfer of broad host range plasmids to other environmental species be considered in more detail, and also requested reassurance that there was no risk to human health from any of the modifications.

There were also requests for more information on the controls used, particularly around waste treatment.

All of these points were clarified in the assessments and final versions are supplied with this notification.

We propose to generate insertional mutants of the fungi Crytociccis neoformans and Cryptococcus gattii by means of T-DNA integration. Transgenic Cryptococcus strains will then be screened for altered virulence in the model host Caenorhabditis elegans and in the macrophage cell line J774.

Recipient or parental organism

Agrobacterium tumefaciens (primary), Cryptococcus neoformans and Cryptococcus gattii (secondary). E.coli DH5a will be used for routine cloning manipulations.

Host/vector system

Vectors – pBlN19 contains Streptomyces faecalis-derived kanamycin-resistance gene (kan R) with a prokaryotic promoter allowing selections of E.coli and Agrobacterium cells bearing the plasmid an Escherichia coli origin of replication (ori), and the two boundary sequences from the T-DNA region of the Ti plasmid. These two boundary sequences recombine with plant chromosomal DNA, inserting the segment of DNA between them into the host (Cryptococcus) DNA. Broad host range (most plant species, some fungi).

Origin & function

Nourseothricin acetyltransferase (NAT) gene controlled by C.neoformans ACT1 promoter Neomycin resistance gene controlled by C.neoformans ACT promoter. Derivates of the green fluorescent (GFP derivaties, BFP derivates, YFP) and derivates of the red fluorescent protein as well as other commonly used reporter genes.

Evaluation of foreseeable effects

Human health effects: having considered the nature of the modified organisms, the nature of the transgenes added and the nature of culturing and testing the yeast, we cannot identify and enhanced risk to human health above that normally associated with the culture of C.neoformans of C.gattii, both ACDP II organisms. The bacterial selection genes are widely used and the structural comparisons of the anti-fungal substances nourseothricin and gentamycin do not show any similarity to commonly medically used fungicides. We do not therefore anticipate additional risks to human or animal healthy from these selectable markers. The second stage of this protocol, to attempt homologous gene disruption, is intended to disable host genes. As such, transgenic strains are likely to be reduced, rather than increased, in virulence.

Environmental effects – Cryptococcus neoformans is already widespread in the UK environment (especially in soil). Accidental release would distribute Cryptococcus strains carrying a fungicide resistance gene that is used for selection of transgenic yeast or the GFP gene. As the commonly medically used antifungals show no structural similarity to these fungicides, we do not expect any complications in patients' treatment. It is unlikely that the release of GFP carrying Cryptococcus in the wild would have
any effect on the environment. Mating between cryptococcal strains is thought to be extremely rare in the wild, hence it is unlikely that these transgenes would enter the indigenous Cryptococcus population. Further insertion mutants (opposed to targeted mutants) could show increased or decreased virulence, but no spores (the infective agent) are produced in routine cultures. Spores are produced during sexual reproduction of two opposite mating types or pseudohyphal growth. Mating and Fruiting as well as pseudohyphal growth needs to be stimulated by certain environmental factors such as starvation, desiccation or pheromones. As none of these requirements are fulfilled under applied culture conditions, no spores will be produced in the lab. Bacterial and yeast cultures are to be autoclaved after use. Cryptococcus will be handled in a safety cabinet. Glycerol cultures of the GMO will be stored in a lockable freezer and access will be restricted to authorised personnel.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation - Full CL3 applied.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Disposable plasticware will be rinsed in 10% Trigene, autoclaved within the CL3 laboratory and disposed of via the clinical waste system, ultimately being incinerated. Disposable gloves, paper towels etc will be deposited in autoclave bags and autoclaved within the facility before disposal through the aferementioned clinical waste route. Autoclave within CL3 lab - run of 30 mins at 135C, all runs recorded.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The GMSC and local Advisory Group for the Control of Biological Hazards have scrutinised the assessment (along with the preceding Class 2 assessments) very thoroughly. Committee members met with the Principal Investigators to discuss the work on a number of occasions. Comments on this particular assessment are attached. The final assessment has taken these points into consideration.

Emergency procedures are laid out in the accompanying risk assessment. It was felt that an Emergency plan was not necessary because of the nature of the GMO in this case, but laboratory procedures are in place to deal with any accidental releases or exposures in the laboratory.

**Project Additional Information**
Purposes of the contained use

The objectives of the programme of work are to construct and characterise mutants of Corynebacterium glutamicum and Mycobacterium bovis BCG. These mutants will be used to analyse well-defined, non-toxic, mycobacterial cell wall components and genes that contribute to the basic physiology of corynebacteria and mycobacteria.

Recipient or parental organism

Disabled laboratory strains of E. coli including or similar to those listed in Part 2A, Annex II of the ACGM Compendium of Guidance.

C. glutamicum and M. bovis BCG. M. bovis BCG is one of the oldest and most widely used live vaccines; about 3 billion doses of this attenuated M. bovis strain have been used to immunise individuals against tuberculosis worldwide. Whole genome comparisons of M. tuberculosis H37Rv and M. bovis BCG (Pasteur) have now been undertaken to determine the genetic determinants of attenuation. These reveal several (14) large deletions in the M. bovis BCG (Pasteur) genome which encompass 119 open reading frames (Behr et al., 1999 Science 28: 1520-3).

The ACDP categorisation of pathogens according to hazard and categories of containment (fourth edition, 1995), classifies M. bovis BCG as hazard group 2. However, appendix 17 (page 108) states "The BCG strains of M. bovis and the so-called 'vole bacillus' M. microti have both been used in vaccines, but if mishandled, can give rise to abscess formation. The BCG strains are included in Hazard Group 2 because of this and the extremely remote possibility of reversion to virulence although when used under clinical conditions for immunisation, laboratory Containment Level 2 is not necessary". Staff working on the programme have previously been immunised with BCG.

C. glutamicum is known for its ability to massively excrete L-glutamate. The capacity of C. glutamicum to excrete glutamate has been used for more than 40 years to produce this amino acid on an industrial scale in ever increasing quantities, around 106 tonnes/year (Hodgson, 1994, Bio/Technology 12: 152-155). The ACDP categorisation of pathogens, according to hazard and categories of containment (fourth edition, 1995), classifies Corynebacteria spp. as hazard group 2. Although, C. glutamicum has been defined as having "biological limitations" which mean that it is unlikely to survive in the gut, lung and elsewhere. This description is also generally considered to cover laboratory adapted strains (particularly multiply auxotrophic or recombination deficient mutants) as well as other non-pathogenic hosts with a negligible capacity to persist in humans and a history of safe use.

Host/vector system

Any non-mobilisable or mobilisation defective including or similar to those listed in Part 2a Annex II of the ACGM Compendium of Guidance.

The pNIL, pGOAL and pYUB854 series of vectors for constructing suicide vectors to generate marked and unmarked mutants in M. bovis BCG.

The pK18mob suicide vector will be used to generate marked mutants in C. glutamicum.

Non-mobilisable shuttle vectors that can replicate in E. coli and mycobacteria (eg pJEM15, pMV261, pVV16, pPR27 and their derivatives). These vectors contain an E. coli origin of replication (from the pUC series of cloning vectors), a mycobacterial origin of replication from plasmid pAL5000 and antibiotic resistance markers (eg Kanamycin and hygromycin).

Origin & function

Source: C. glutamicum, M. bovis BCG and M. tuberculosis H37Rv

Genetic material: DNA fragments encoding various well defined genes involved in cell wall metabolism, eg glycosyltransferases, fatty acid biosynthesis, polyketide biosynthesis, siderophore biosynthesis, p450 enzymes and peptidoglycan biosynthesis.

Evaluation of foreseeable effects

PLEASE SEE ASSESSMENT FOR DETAILS

The risk assessment deals with the risks to human health and the environment under each specific activity. Most of the work will make use of crippled lab strains and non-mobilisable vectors, although wild type strains will be used to study the effects of defined chromosomal mutations on mycobacterial cell wall physiology and other
phenotypes. The risks to human health are therefore associated with the wild type host. Environmental risks are dealt with under each activity in the assessment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full level 2 applied

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All potentially infected material is autoclaved prior to disposal and incineration. 100% kill of GMMs. Disinfectants such as hycolin (2% v/v) and Chloros are available for spills.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Some members of the GMSC pointed out that the original assessment contained a reference to antibiotic resistance markers, but did not then list them or discuss them further. These were added.

The GMSC asked what were the 'well defined genes involved in cell wall metabolism and cellular physiology'? Examples were added to illustrate this, as a full list would have been extremely long.

Tje assess,ent jas neem approved by the GMSC.

Project Ref 125/03.1
**Project Additional Information**

**Purposes of the contained use**

The work is concerned with understanding how bacterial gene expression is regulated using *E. coli* K12 as a model. The strategy is to use genetics to identify regulatory components at particular loci and then to use genetics and biochemistry to understand the interaction between these components. This involves many genetically manipulated constructs in which altered regulatory elements and regulatory components are tested. Additionally genes encoding regulatory factors are manipulated to facilitate overexpression and purification of the corresponding protein.

**Recipient or parental organism**

Hosts: Standard disabled hosts such as *E. coli* K12 strains. For mutagenesis the hosts will be standard, well characterised strains of the wild type organism.

**Host/vector system**

Vector: Vectors will generally be pUC, pBluescript and related non-mobilisable CoIE1-based standard vectors, or mabda phage-based cloning vectors, or standard low copy number vectors such as pACYC or pSC101 and derivatives.

**Origin & function**

Inserts: Sequences used may be any gene or sequence including genes of unknown function, including virulence factors. Genes may be partial or complete and may include expression signals, eg segments from the *E. coli* lac, gal, mal, ara, mel nir, and nrf operons, the fnr, crp, rpoA, rpoBC, rpoD, rpoS, fis, ihfA, ihfC hupA, hupB and hns genes. Various 'anonymous' but completely sequenced regulatory genes from K12 or the Sakai 0157 strain. Non coli genes include *B. pertussis* cyaA, *V. fischeri* lux, plus various commercially available genes that are used as tools. Libraries may be constructed for limited purposes, eg two hybrid screening.

Donor. Sources are either whole genomic DNA or PCR-amplified known sequences, from *E. coli*. In general source DNA will be taken from an organism for which a whole genome sequence is known. No organisms requiring greater than containment level 2 will be used. In some experiments the starting material will be clones from other laboratories, eg encoding lac, gfp, lux, cya or other 'tools' for molecular biology.
Effects on human health: None of the constructs cause harm beyond that of the starting host and no risk additional to that of the parental wild type organisms is envisaged.

Environmental hazards: The potential hazard is negligible as the GMMs cannot be considered likely to express virulence or other factors that would be potentially harmful to other species or the environment. Accidental release is highly unlikely.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation - full level 2 containment applied.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste will be autoclaved - a process that is validated by monitoring of the internal chamber. An automatic printout of every run is produced. Achieves 100% kill. Wastes from autoclaving will be disposed of to drain or to clinical waste incineration.

The standard disinfectant used is Virkon, 1% w/v solution. This will only be used to sterilise lightly contaminated surfaces, and is not used for treatment of substantial culture volumes, or for rendering safe contaminated matter such as absorbent towels - these will be autoclaved. Studies have shown the efficacy of 1% solutions to achieve typically at least 10 (to the power of 5) reduction in counts under appropriate conditions.

**Project Ref 125/03.2**

**Date Ackn'd** 04/04/2006

**CU2 Project Title** CYTOSKELETAL GENE ANALYSIS IN ENTAMOEBA AND DICTYOSTELIUM

**Class** Class 2

**CultureVolClass** 1-50 Litres

**Date Project Ceased** 03/08/2006

**Consent Granted** Not Applicable

**Project notified under transitional arrangements** N

**Withdrawn** N

**Historical Significant Changes** TRANSFERRED FROM GM CENTRE 125 - 4/4/06. TRANSFERRED TO

**Origin of genetic material:** Dictyostelium strain AX3 - a free living non-pathogenic soil amoeba which grows at 22 degrees centigrade and is harmless to crops and agriculture.

Antamoeba histolytica strain HM-1:IMSS -- standard laboratory strain. Cysts are the only infectious stage of this parasite and these can not develop or form in standard lab cultures, hence the parasite is not transmissible to humans in this setting. The cultured form, ie the trophozoite, is very fragile and susceptible to desiccation and detergents. As they are unable to persist in the environment the chance of environmental damage is remote.

Genetic material: Full length cDNAs encoding Entamoeba Arp2 and Arp3 - major skeletal proteins involved in movement and cell shape. Selectable markers conferring

**Recipient or parental organism**

**Host/vector system**

**Origin & function**

**Recipient or parental organism**

Hosts. E. coli XL1-blue - disabled and slow growing;

DH5 -as XL-blue.

**Vector**. pUC18 - standard molecular biological plasmid vector.

**Purposes of the contained use**

To express cDNAs encoding Entamoeba cytoskeletal and signalling proteins in both Entamoeba and Dictyostelium cells.
G418 resistance.

**Evaluation of foreseeable effects**

**Effects on human health:**

Dictyostelium - None. It is a non-pathogenic soil amoeba, unable to grow at human body temperature and is harmless to crops and agriculture.

Antamoeba histolytica - No likely risks. It is a parasitic enteric protozoan that is responsible for amoebiasis in humans. The disease is characterised by diarrhoea/dystentery, intestinal tissue invasion and potential liver abscess formation. Epidemiology, the organism is ubiquitous and has a worldwide distribution, although prevalence is much higher in developing, disadvantaged countries and tropical regions. In contrast, rates of infection are low in the developed world, with the majority of these infections being found in specific groups (e.g. travellers from developing or high incidence areas). Symptomatic invasive amoebiasis only develops in 10% of individuals harbouring the parasite. The organism can exist as both cysts and trophozoites. Transmission is feco-oral and results from ingestion of viable cysts in contaminated food or water. Cysts can remain viable for a long time depending on environmental conditions but are extremely sensitive to desiccation. Trophozoites on the other hand are more fragile and degenerate rapidly in the external environment as well as being easily destroyed by acidic pH (e.g. stomach acid).

As the only infectious stage of the parasite, the cyst, does not form in standard laboratory cultures the parasite is not transmissible to humans in this setting. Accidental infections have never been reported, but effective drug treatments are available should this happen.

Environmental hazards: Dictyostelium - negligible hazard. The strains used are very weak due to multiple mutations and would not compete with local Dictyostelium species.

Entamoeba - The organisms are very sensitive to desiccation and detergents and are not free-living. As they are unable to persist in the environment the chances of environmental damage are remote.

The work will be carried out at CL2 and the likelihood of accidental release is very low.

E. coli XL-blue/DH5 - non-colonising, disabled lab strains, no risk to human health or the environment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

No derogation applied for CL2 applied. The laboratory set aside for this work is a relatively new facility and is currently being fitted with a hand wash basin.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Dictyostelium - to kill spent cultures: 1% chlorine bleach.

Entamoeba - Tubes containing liquid cultures and contaminated disposables will be placed in autoclave bags and autoclaved at 121 degrees for 50 minutes and discarded as "clinical waste" (incineration).

Agar plates, loops, tips etc will all be autoclaved. 100% kill.

All methods are more than sufficient to kill Dictyostelium which are fragile, as well as Entamoeba which are sensitive to desiccation and detergents and are not free-living.

Bacterial cultures will be killed with Virkon at the recommended dilution (1:100)
I feel information on human health should be transferred to the relevant section; the nature of the "normal laboratory clothing and protective equipment" should be defined; the autoclave used for disposal of cat 2 waste should be monitored (it is anyway, why not say so for completion?); and the disinfection regimen should be defined, i.e. is 1% chlorine bleach 1% available chlorine, and what is the actual dilution of Virkon used?

POINTS ADDRESSED IN ASSESSMENT
* There is no mention of any possible alteration in phenotype resulting from the introduction of cytoskeleton and signalling proteins in Entamoeba and Dictyostelium. I assume they will not become (more) pathogenic but perhaps this could be addressed.

* No increase in virulence/pathogenic capacity is expected. As mentioned in the application, Dictyostelium are free-living non-pathogenic soil amoebae which grow at 22 degrees and therefore do not pose a threat to humans. Likewise Entamoeba does not pose a risk to humans in this/our setting because the cyst, which is the only infectious stage of the parasite, can does not develop or form in standard laboratory cultures, hence the parasite is not transmissible to humans.

The GMSC also asked whether the Class 1 and Class 2 work should be split into two separate proposals. The investigator felt this was not necessary and not desirable because the work is one experiment, in which cDNAs encoding Entamoeba cytoskeletal and signalling proteins will be expressed in both Entamoeba and Dictyostelium cells.

The GMSC has approved this assessment.

Project Ref 125/05.1
Investigation into the role of downstream components of the FGFR cell signalling pathway in primary human cells.

The technique of RNA interference (RNAi) will be used to knockdown FRS2 (a component of the fibroblast growth factor receptor signalling pathway) in primary human cells. Use of a replication incompetent bicistronic HIV1 based lentivirus will be applied to deliver the SiRNA into cells.

Host: Host bacteria for growth of plasmids are standard disabled lab strains of E. coli such as DB3.1 and Stbl3. DB3.1 is an E. coli strain that is resistant to CcdB effects and can support the propagation of plasmids containing the ccdB gene. One shot Stbl3 chemically competent E. coli from Invitrogen are well suited for use in cloning unstable DNA such as lentiviral DNA containing direct repeats. Human cell line HEK 293T will be transfected with the pLenti4/V5-DEST and the packaging vectors and lentivirus harvested from the supernatant. Primary human cells that are non-permissive for production of replication defective lentivirus will be transduced with recombinant lentivirus expressing GFP and RNAi gene of interest. Further work may use mouse embryo fibroblasts.

Recipient or parental organism

Source: Green Fluorescent Protein from jellyfish. Sequence encoding a small part of FRS2 (approx 21 bases) from human and hairpin sequence needed for RNAi to work effectively.

Genetic material: The sequence encoding GFP which functions as a reporter molecule that fluoresces upon exposure to uv light. Also, a partial sequence encoding a small section of the FSR2 protein and a hairpin sequence needed for the short hairpin RNAs to be produced and work effectively. FSR2 is an adaptor protein that acts downstream of FGFR.
**Evaluation of foreseeable effects**

| Human health: In third generation lentiviral vectors all six regulatory/accessory proteins (Rev, Tat, Vif, Vpr, Vpu and Nef) are removed, except Rev. Rev acts at the post-transcriptional level and is necessary for HIV gag/pol expression. Rev binds to an RNA motif (Rev Responsive Element RRE) and facilitates the cytoplasmic export of gag/pol messenger. As an extra safety requirement Rev is placed on a separate vector (pLP2) to the transfer vector. Only 700bp of the HIV envelope protein are present in the transfer vector, plus RRE and the packaging signal. The packaging construct contains the minimal RRE of 374bp and the gag/pol genes. Through deletions in both LTRs and the absence of 5 of the 6 accessory proteins, including the replication essential Tat, the biosafety of the vector is increased. In published studies replication competent virus has never been detected. The HIV envelope protein is replaced by non-retrovirally envelope protein (VSV-G). It is highly unlikely that this will be incorporated in a new hybrid replicative virus. It is impossible that wild type HIV will be formed because of the omission of 5 accessory proteins and the HIV-env. No protein is expected to be expressed in bacterial strains used for plasmid propagation. |
| Environmental Considerations: Proteins will not be expressed in bacteria used for plasmid propagation. Bacteria used for propagation are attenuated strains that will not survive in the environment. The recombinant virus is replication defective and will not have an extended host range, the transgenes are innocuous, so there is negligible potential hazard to the environment. Potential hazard to species in the environment either from the viruses, or the E. coli containing the plasmids, therefore appears negligible. Containment conditions specified should prevent environmental release of virus, or of E. coli carrying associated plasmids. |

| Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants) |
| N/A |

| For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification) |
| No derogation. |

| Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate) |
| Liquid waste will be aspirated into, and exposed to, 1% Virkon for a minimum of 30 minutes, or collected into autoclavable pots and autoclaved before disposal to drain. Disposable solid waste will be inactivated by autoclaving with final disposal by incineration. Exceptions to this are: Contaminated micropipettor tips will be soaked in 1% Virkon for a minimum of 30 minutes before being rinsed and disposed of in Sharps containers, which will be sent for incineration. Disposable plastic pipettes also treated with Virkon prior to rinsing and disposal as above. Exposure to Virkon for a minimum of 30 minutes, or autoclaving effectively kills 100% of GMMs. |

Construction of gene detection mutants or gene replacement mutants. Analysis of phenotype of altered mutants in invitro and in vivo (animal) systems.

**Recipient or parental organism**

- Streptococcus pneumoniae
- Neisseria meningitidis
- Staphylococcus aureus

**Host/vector system**

- Introduction of linear DNA generated by polymerase chain reaction (PCR)
- Transposon Tn917 for gene inactivation
- Plasmid pMTL23 for gene inactivation in Neisseria

**Origin & function**
Modified genes from the pathogens including virulence factors such as toxins, surface proteins and signalling molecules.

**Evaluation of foreseeable effects**

All the organisms used are carried as commensals in the normal human population. All genetic alterations involve the removal of genes or protein function such that the GMO will be no more harmful to people or the environment than the parental organism. In most cases the risk will decrease in the GMO due to the genetic modification partially disabling the organism. Antibiotic resistance markers will only be used if they are associated with the normally occurring population.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

none

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

none

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

GMO Liquid cultures (volume up to 100ml) will be autoclaved. Following autoclaving cultures will be sterile. Other material (equipment etc) will be sterilized by disinfection. Animals infected with GMOs are incinerated. No GMO will be released into the environment.

**Project Ref** 553/09.6
**Project Additional Information**

**Purposes of the contained use**

The use of replication defective Lentiviral vectors to modulate expression of candidate genes to assess their role in tumourigenesis

**Recipient or parental organism**

E.coli K12 or B derivatives

Mammalian cell cultures - especially disabled hosts which should be recognised as foreign by the human immune system. Due to the presence of adventitious agents certain cell lines will be handled at Containment level 2.

**Host/vector system**

Standard Lentiviral vector systems, which produce replication defective virions. The system to be used is a third generation one. The expression vectors have a deletion in the 3' LTR which results in self inactivation. The number of HIV genes have been reduced to gag, pol, rev, tat and vpr. The envelope protein is VSV-G which allows amphotrophic infection. The genes are split onto four different plasmids. No replication competent virus can be produced.

**Origin & function**

Mammalian genes thought to be involved in Hereditary Leiomyomatosis renal cell cancer (HLRCC) such as Fumerate Hydratase, succinate dehydrogenase and G-protein coupled receptors.

Fumerate Hydratase is a nuclear-encoded protein that catalyses a step of the Krebs cycle, converting fumerate to malate. It is also thought to be a tumour suppressor as inactivated protein is seen in tumours from patients suffering from Hereditary Leiomyomatosis renal cell cancer.
Succinate dehydrogenase is an enzyme also involved in the Krebs cycle catalysing the oxidation of succinate to fumarate.

G-protein coupled receptors are transmembrane signalling receptors, which pass signals across cellular membranes to activate internal pathways.

Other genes identified during the course of the project may also be expressed/knocked down.

shRNA constructs to knock down expression of the above genes.

Standard reporter genes and antibiotic resistance genes

**Evaluation of foreseeable effects**

E. coli K12 or B derivatives are disabled hosts which cannot colonise the human gut and have a history of safe use. Genes are not expected to be expressed in these systems due to the lack of bacterial promoter.

Mammalian cell cultures are especially disabled hosts which should be recognised as foreign by the human immune system. Due to the presence of adventitious agents certain cell lines will be handled at Containment Level 2. As lentivirus integrates into the host DNA and lacks essential genes for replication, mammalian cells, which have been infected pose minimal risk.

293 cells (and various derivatives) are used to produce viral particles which are capable of one round of infection. These cells will be handled at Containment Level 2 with the use of sharps minimised.

Lentiviral particles are infectious but replication defective however they are capable of integrating into the host genome where they may cause insertional mutagenesis. Control measures are in place to minimise the likelihood of exposure however needles are required for inoculations.

Inoculations using transduced cells pose minimal risk to the worker as the lentivirus will be integrated into the host genome and replication defective. The cells should be recognised as foreign by the human immune system.

Inoculations using lentivirus capable of one round of infection poses the greatest risk due to the use of needles. Workers are trained in these procedures including the policy of not re-sheathing needles and disposing of intact needle-syringe assembly into sharps bins immediately after use.

Accidental exposure to a single gene is considered to be low risk.

Inoculations using lentivirus capable of one round of infection poses the greatest risk due to the use of needles. Workers are trained in these procedures including the policy of not re-sheathing needles and disposing of intact needle-syringe assembly into sharps bins immediately after use.

The genes themselves are involved in individual steps of the Krebs cycle and cellular signalling. Although the loss of fumarate hydratase is seen in HLRCC patients it is likely that other gene mutations are required for the progression of the disease.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste steam for landfill.

02/03/2022
Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycles as specified in BS2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), or inactivate by chemical means (following manufacturers guidelines), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration.

Animal bedding - EITHER autoclave using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), dispose via the industrial (black bag) waste stream for landfill OR dispose via clinical waste stream for incineration.

Animal carcasses - dispose via clinical waste stream for incineration.

Degree of kill:
Autoclaving, effectively 100% kill (annul validation)
Incineration, effectively 100% (licensed incinerator)
Chemical, effectively 100% kill (following manufacturers guidelines)

Project Additional Information

Purposes of the contained use

To infect human or murine cells with retro- or lenti-viral gene delivery systems. As the result, cells will permanently harbour genes encoding (1) transcription factors, epigenetic regulatory molecules, cell cycle regulators or oncogenes, (2) small hairpin RNA, (3) RNA aptamers or (4) genes encoding peptide aptamers without any replications. These genes are continuously expressed or can be induced by addition of chemicals such as 17β-estradiol, Tamoxifen, or Tetracycline. Transduced cells will be used for DNA and RNA analysis, cultured in vitro or transplanted into immuno-compromised mice.

Recipient or parental organism

MMLV (Moloney murine leukaemia virus) or MSCV (murine stem cell virus) based replication defective, non-mobilisable retroviral vectors e.g. pBabe. These are well-established and widely used retrovirus based expression vectors with a history of safe use.

The third generation of lentiviral vectors, e.g. pHIV7, HR’CS-G and their derivatives, Drug inducible expression vectors, pLVX-Tight-Puro (Clontech) co-transfected with the regulator pLVX-Tet-On Advanced or pLVX-Tet-Off Advanced. Virus particles in this system are produced by the Lenti-X HT Packaging Mix which utilises a trans-lenti viral vector system.

Lentiviral vector systems in which shRNA constructs can be directly cloned, e.g. pKLO.1.

MSCV-PM-miR30, pPRIME-CMV-GFP-FF3, pPRIME-CMV-dsRed-FF3 or pPRIME-TET will be provided by Dr Stephen Elledge (Department of Genetics and Genomics Harvard Medical School).

MSCV-MigR1 will be provided by Dr. Warren Pear (Abramson Family Cancer Research Institute University of Pennsylvania).

MSCV-Ires-hCD2t will be provided by professor Meinrad Bussligner (IMP, Vienna).

pLVTHM and pLVET-ITR-KRAB will be provided by Dr. Didier Trono and Dr. Patrick Aebischer respectively (Ecole Polytechnique Federale de Lausanne).

pHIV7-GFP will be provided by professor John J. Rossi (Beckman Institute, CA, USA).

pLL3.7 will be provided by Tyler Jacks (MIT).
Other vectors are commercially available pBABE-puro and pSico (Addgene deposit), pMSCVneo, pMSCVhygro, pMSCVpuro and pLVX-Tight-Puro (Clontech), pKLO.1 (Sigma, Open Biosystems), pSLIK (ATCC).

A full list of components (inserts, vectors and eukaryotic cell lines) can be found as a separate attached document (Manipulation of the regulatory state of haematopoietic cells COMPONENTS.doc).

**Host/vector system**

Human and mouse cell lines including haematopoietic, fibroblastic, hepatic cells. Mouse primary cells including embryonic stem cells, haematopoietic cells and embryonic fibroblasts from wild type transgenic or knock out animals. These are categorised as belonging to biological hazard group 1.

Primary human cells such as CD34+ cells, leukaemic blast cells, myeloid cells and lymphoid cells from normal donors and patients. These are biological hazard group 2 due to the potential risk of infection from endogenous pathogens.

**Origin & function**

Generation, propagation and use of these retro- or lenti-viral expression vectors aim to introduce the coding sequence of transcription factors, oncoproteins, inhibitory RNA molecules or peptide aptamers into murine or human primary cells or established cell lines. The objective is to over-express or knock down the expression of targeted molecules or to interfere with their function into cells, and analyse alterations in the expression and structure of the target genes and cellular phenotypes.

**Evaluation of foreseeable effects**

The E.coli bacteria used are not pathogenic to humans or animals and are not expected to survive in the environment, they therefore belong to hazard group 1.

The cells which will be transduced in the project are either established cell lines, mouse primary cells or human haematopoietic cells. They are highly unlikely to be able to survive outside the culture vessel and are non-transplantable due to immuno-incompatibility. The use of Class 1 containment with good laboratory practice will be sufficient to limit hazards to human health and the environment from these cell lines. Primary cell lines are categorised as requiring containment level 2 due to the potential for adventitious agents to be present.

Packaging cells for retroviral production are either HEK 293T or NIH-3T3 derivatives and HEK 293T for lentiviruses. Prior to the induction of viral vectors or packaging vectors, they do not produce any viral products and are considered in the same way as an established cell line. Once virus vectors and packaging vectors are transfected into packaging cells, these cells are capable of producing viral particle which can infect human cells and have to be used at containment level 2. Once transduced, viral sequences are integrated into the host genome, and occasionally integrate in a position adjacent to oncogenes which thereby leads to a constitutive increase in the level of expression of these oncogenes due to the promoter/enhancer in the Long Terminal Repeat (LTR). Depending on the position, virus integration can cause the aberrant silencing or disruption of the endogenous genes. Lentiviral systems described in this assessment have a self-inactivating (SIN) mutation which abolishes LTR promoter activity so as to prevent the aberrant activation of endogenous genes. With third generation retrovirus systems, the retroviral structural genes are encoded on two different plasmids and contain additional mutations, and at least 3 non-homologous recombination events are necessary to generate replication competent virus. Consequently, they are highly unlikely to acquire a replicative ability in cells. Lenti-vector particles are generated by co-expressing the virion packaging elements and the vector genome in a细胞 as a producer. In the case of HIV-1-based vectors, the core and enzymatic components of the virus come from HIV-1, while the envelope is derived from a heterologous virus. To decrease the probability of generating replication competent recombinant (RCR) virus a second generation vector was created which has deletions in its crucial virulence factors. In order to further improve their safety a third generation of lentiviral vectors was developed in which the transgene vector contains a deletion in the 3' LTR U3 region making it self-inactivating in target cells and the packaging vector is a split genome construct with the tat gene deleted and the rev gene expressed by a separate non-overlapping construct. This vector achieves transduction of target cells as well as that observed with the previous generation. To date, neither second nor third generation lentiviral vectors have been found to generate RC virus.

Some of the inserts described in the risk assessment have been shown to have transforming activities when overexpressed. The major risk of generating viral vectors expressing normal transcriptional regulatory proteins therefore comes from either introducing abnormally high levels of a normal or mutated factor into normal cells or from the downregulation of endogenous proteins by RNAi. In some cases, this could lead to aberrant cell differentiation, proliferation, apoptosis or in rare cases, oncogenic transformation. However, the expression of these proteins is highly unlikely to change the natural immunogenic characteristics of the cells they are expressed in, which are therefore very unlikely to colonize humans due to immuno-incompatibility. Consequently, the transfection of these cells and expression of the transfected genes will not
significantly alter the capacity of these cells to persist in the environment or cause harm to either humans, animals or other aspects of the environment.

The work will be undertaken in accordance with containment level 2. This includes culture of primary cells, retroviral infection protocols and subsequent culture of any cell-lines produced that have not been screened for the presence of retrovirus. Screening of the cell-lines will be by assay of reverse transcriptase activity. The assay will be carried out within the laboratory designated for Class 2 work until cell culture-derived material has been dissociated using lysis buffer (50mM Tris, 80mM KCl, 2.5mM DTT, 0.75mM EDTA, 0.5% Triton-x-100), after which time it can be continued outside of the facility providing the principles of Good Laboratory Practice are followed. Cell-lines in which no retroviral activity has been found can be de-rated to Class 1. Access to cell culture facilities such as incubators or safety cabinets in which Class 2 work is being performed will be restricted to users registered for Class 2 work. The University Occupational Health Department will be given a list of names of all workers with access to the facility and will give these workers appropriate health surveillance.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not Applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All plastic ware that has come into direct contact with viral supernatants or cell material that has been transfected or infected, e.g. pipettes, tubes etc., will be decontaminated either by immersing in 1% Virkon or trigeine prior to autoclaving, or be taken directly for autoclaving in a sealed, watertight container. All other consumables will be autoclaved.

Tips and tubes will be placed in a plastic, sealable disposable jar in the hood that will be sealed immediately after use. The outside will be sprayed with a disinfectant, put into an autoclave bag, closed, then removed from safety cabinet, put into another autoclave bag and subsequently autoclaved. The tips/tubes will not be soaked in virkon or trigeine as the disposable jar provides an extra layer within the autoclave bag separating workers from the potentially hazardous material.

Serological pipettes will be rinsed with disinfectant by aspirating the solution a few times before disposal into a two-layered autoclave bags. Immediately after the procedure, the autoclave bag will be sealed and subsequently autoclaved.

Used culture flasks, plates, and dishes will be put into an autoclave bag, closed, the outside of the autoclave bag will be sprayed with a disinfectant, then put in another autoclave bag and subsequently autoclaved. The final route for all solid material that has been contaminated is incineration.

Liquid waste will be rendered biologically inactive by adding virkon or trigeine to give a final concentration of 1% and leaving overnight before discarding down the sink. It can either be emptied aspirated in a beaker of concentrated virkon or trigeine in the hood or by using a vacuum aspirator directly into a reservoir of concentrated virkon or trigeine. Should the latter option be employed, the vacuum pump system must be fitted with the appropriate filters (changed once a month) and the nozzle and hose will be rinsed with 1% virkon or trigeine at the end of each day.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment N
The application for this connected program of work was considered by the LIMM Local GM Safety Committee at its 6 monthly meeting on the 14th July 2008. Copies of the risk assessment had been sent to the members of the Committee approximately 10 days in advance of the meeting. The Committee felt that the project had been well set out with a clear description of the (second and third) generation retro and lentiviral vector and host systems presented, along with a description of the potential risks associated with their proposed use. Furthermore, there was a very detailed description of the inserts proposed to be investigated.

Discussion mainly centered on where the work would be undertaken and the routes of waste disposal. The bulk of the work would be undertaken in the tissue culture room on Level 6 Wellcome Trust Brenner building. However, viral stocks would sometimes require centrifugation in an ultracentrifuge based in a different ancillary room. It was felt that so long as the centrifuge tubes containing the viral cultures were both sealed and opened in the tissue culture hoods then there was not a problem with this procedure. However, emergency decontamination provision must be put in place in the event of a tube failure. The main topic of conversation regarding waste disposal related to tip disposal. It was decided that the safest route of disposal of the tips would be via collection in DispoSAFE P.E.T. jars (Microbiological Supply Company) that would then be (double) bagged in autoclave bags by workers registered at Class 2 and then transported to Level 3 WTBB for autoclaving. After autoclaving this waste is sent for incineration as a matter of course.

The consensus of the Committee was that the work described was a Class 2 project and that the group of individual projects merited the title ‘a connected program of work’. They felt that the project could now be submitted to HSE for approval.

Project Additional Information

Purposes of the contained use
Laboratory - based, preclinical studies developing gene therapy for cancer

Recipient or parental organism
Adenovirus; cell lines and primary tumour material

Host/vector system
E1-deleted, replication-defective adenovirus vectors; probably E3-deleted. The wild-type fibre gene will be substituted with genetically modified derivatives intended to permit binding to integrins (e.g. by insertion of peptide motifs into the HI loop). Binding to the normal receptor (CAR) will initially not be modified, but may be ablated in later vectors. The viruses will be generated from transfected plasmid DNA constructs, and grown, in cells that compliment the E1 deficiency, e.g. HEK293 cells.

Origin & function

Page 3470 of 15326
The vector sequences are derived via plasmid cloning from adenovirus type 5; integrin-binding motifs designed based on known binding motifs. Some cancers, e.g. chronic lymphocytic leukaemia (CLL) have only low levels of the coxsackie and adenovirus receptor CAR, and so adenoviral gene transfer to these is very inefficient. Retargeting the virus by insertion of integrin-binding peptide motifs into the capsid fibre protein is expected to allow more efficient delivery of therapeutic genes to the cancer cells and, if the natural CAR-binding ability is simultaneously removed, may confer some selectivity of gene delivery to the cancer cells. A range of transgenes may be inserted into the E1 region of the viral vectors; the initial risk assessment covers reporter genes (e.g. green fluorescent protein); and the potentially therapeutic genes CD80, 4-1BB ligand, CD40 ligand, and GM-CSF (secreted or membrane-anchored).

Other potentially therapeutic genes may also be inserted under this connected programme of work including e.g. other immunomodulatory genes; prodrug activating enzymes; tumor-suppressor genes; we understand these would not require further notification to HSE if the GMSC agrees on the basis of risk assessments that there is no significant increase in the potential hazard.

Evaluation of foreseeable effects

No significant biological effects expected from expression of reporter genes. The immunomodulatory genes may have potential to induce local inflammatory responses in the event of contamination, and would be expected to enhance immune responses against the infected cells. Systemic or long term adverse effects are unlikely. The retargeting of the vectors is expected to alter the relative efficiency for entering different cell types. There is a theoretical possibility for recombination e.g. with wild type virus, which could generate a replication-competent virus carrying the modified fibre. Containment conditions and working practices will minimise this risk. Such recombination would lead to concomitant deletion of the exogenous transgenes inserted in the E1 region.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid virus containing waste is bagged and placed in a designated metal container which is removed to the autoclave. Liquid virus waste is discarded to bottles which are placed in a designated metal container for autoclaving. All liquid waste is treated by autoclaving before disposal to drain. Disposable solid waste is also autoclaved before removal as "clinical waste" by specialist contractors, with final disposal by incineration. The exceptions are:-

Sharps and pipettes are soaked in 1% Virkon for a minimum of 15 minutes before disposal in an approved sharps box. The disinfectant is discarded down the sink. Glassware used in this virus room is soaked overnight in 1% Virkon before removal for normal tissue culture wash up processing. Disposable plastic pipettes may also be decontaminated by immersion in Virkon as above.

Autoclaving achieves effectively 100% kill of GMMs. Manufacturer’s data indicates efficacy of Virkon against a variety of adenoviruses at 15 concentration, and also against a number of strains of E.coli at dilutions ranging from 0.125% - 1%. We have demonstrated that 15 minutes exposure to 1% Virkon achieves >4log kill for adenoviral infected cell pellets and >6log kill of adenovirus seed stocks.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
The risk assessments were circulated to the committee and discussed with the applicant at a specially convened meeting on 8/5/2001. The committee noted that the potential for homologous recombination with wild type E1 sequences to result in the inadvertent generation of replication-competent, retargeted virus, and the potential hazard of such a virus was discussed. It was noted that the HSE/ACGM Guidance contained an example of a risk assessment for a retargeted, replication competent adenovirus (RCA), which indicated level 3 containment. Following discussion, the GMSC agreed that such recombination was a rare event in complimenting cell lines, and the committee was assured that the safest practicable complimenting cells would be used. Stocks would be monitored for RCA, and any found to be contaminated would be safely inactivated. Working practices to prevent cross-contamination were described. The committee agreed that the work could be safely conducted at containment level 2 and was therefore class 2. Any unexpected results from the work that might affect the assessment of safety, and any accidents involving the viruses will be reported to the committee. Other points of detail were clarified, and the final risk assessments modified in line with these discussions. The work has therefore now been approved by the GMSC.

**Project Additional Information**
### Purposes of the contained use
Studying the roles and regulation of cell signalling proteins.

### Recipient or parental organism
Mammalian cell cultures.

### Host/vector system
E1-deleted, replication-defective adenovirus vectors. The viruses will be generated from transfected plasmid DNA constructs, and grown, in cells that complement the E1 deficiency, e.g. HEK293 cells.

### Origin & function
The cell signalling proteins to be expressed will be derived from human or other mammalian species. In addition to the wild type forms, constitutively active or dominant negative mutants may be generated. They will have various roles (which are under investigation) in cell signalling pathways. The risk assessments included with this notification relate to Rho family proteins, and phosphoinositol-3 kinase (P13 kinase); as detailed in the risk assessments these are regulators of cell movement and proliferation.

(Risk assessments for other cell signalling proteins expressed in similar adenovirus vectors have been approved by the GMSC as class 1; these include phospholipase D, Arf family (GTPases, PIP kinases). Similar adenovirus vectors encoding other cellular signalling proteins may also be generated and used in this connected programme of work; it is our understanding that these would not require further notification to HSE if the GMSC agrees on the basis of risk assessments that there is no significant increase in the potential hazard.

### Evaluation of foreseeable effects
The cell signalling proteins that are to be expressed will have a variety of roles in the regulation of various cellular responses, eg inflammation, cell survival, control of apoptosis, proliferation, migration. For proteins of negligible apparent hazard, the viruses are classified as class 1. Viruses categorised as class 2 will express cell signalling proteins that have some association with harmful processes, eg. some may have been associated with a role in oncogenic transformation; however a role in cancer would only be in conjunction with many other oncogenic events, and so the degree of hazard from their transient expression in an E1-deleted adenovirus is only modest.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

No derogation applied for

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Utoclaving is preferred means of decontamination (effectively 100% kill). Liquid waste is autoclaved and disposed to drains. Disposable solid waste is also autoclaved before being removed as clinical waste, with final disposal by incineration.

The exceptions to the above are:
"Sharps", including scalpel blades, needles and disposable tips for micropipettors may be decontaminated by drawing up 1% Virkon disinfectant and soaking in Virkon for a minimum of 120 minutes. Disposable plastic pipettes may also be decontaminated by immersion in Virkon as above. Virkon has effectively 100% kill rate.
here was discussion regarding the boundary between class 1 and 2 risk assessments, reaching agreement with that shown on the risk assessments. Points of detail have been clarified, and the final risk assessments modified in line with these discussions.

Historical Significant Changes

TRANSFERRED FROM GM 67 - 4/4/06.
### Purposes of the contained use

Identification of human tumour antigens; characterisation of immune response to tumour antigens; possible future investigation of role in cell signalling pathways.

### Recipient or parental organism

Virus vectors are used in order to achieve efficient gene transfer and expression of the tumour antigens in target cells in vitro for immunological assays. In the first instance, replication-deficient adenoviruses (E1-deleted) will be used. Future work may involve other well-established virus vectors, such as vaccinia virus (particularly for immunological assays) or replication-defective retroviruses (signalling studies).

### Host/vector system

E1-deleted, replication deficient adenovirus. Virus production in cells that complement E1 deficiency, eg HEK293 cells. Target cells for immune responses include human dendritic cells, fibroblasts, lymphocytes, epithelial cells.

Future work is likely to involve other virus vectors, particularly vaccinia or replication-defective retroviruses.

### Origin & function

The polycomb proteins BM1-1 and EZH2 were identified using the SEREX screening technique, using the sera of patients with hepatocellular carcinoma, and their potential utility as tumour-associated antigens will be further investigated in this project. This family of proteins are transcriptional regulators of haematopoiesis, and have been implicated in growth transformation of cells, hence may play a direct, contributory role in tumour development.

This work is leading to the investigation of other members of the polycomb family, and other tumour-associated antigens, some of which may also be involved in growth-regulatory pathways.

The main interest in this project is recognition of these antigens by the immune system and their potential as targets for cancer immunotherapy. Future work may also investigate their role in cell signalling pathways. Their potential contribution to the multistep process of oncogenesis warrants containment of these viruses at containment level 2.

### Evaluation of foreseeable effects

Stable incorporation of these genes into cells, and subsequent high level or ectopic expression of these proteins may contribute to cellular transformation processes. However the adenoviruses carrying these constructs do not result in stable, long term expression in infected cells; they are also replication-defective and so unable to spread.

Vaccinia viruses also only result in a short period of expression of the transferred genes, before the infected cells are lysed.

Use of retrovirus vectors would result in integration of the construct into genomic DNA of successfully infected cells. However this only occurs in replicating cells; the viruses are labile and low titre, not readily transmissible other than by direct inoculation, and readily contained at level 2.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No application for derogation.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All liquid waste is treated by autoclaving typically at 130 degrees C for 60 mins, before disposal to drains. Disposable solid waste which is or may be contaminated with GMMs is also inactivated by autoclaving at 130 degrees C for 30 mins, before removal as "clinical waste" by specialist contractors, with final disposal by incineration.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

Please enter comments on the GM safety committee on the risk assessment

The GMSC had no adverse comments on this assessment.

Historical Significant Changes  TRANSFERRED FROM GM CENTRE 67 - 4/4/06.
This project involves use of recombinant CMV viruses to stimulate T lymphocytes in vitro, from blood of virus carriers. In addition to the current batch of recombinant CMV viruses we may in future seek to undertake work with recombinant CMVs that are deficient for other novel immune evasion genes and/or different combinations of the above described immune evasion genes. Also we may wish to acquire/construct a CMV virus incorporating a non-harmful reporter gene such as green fluorescent protein (GFP).

We do not expect the hazards associated with such viruses to be any greater than the ones we currently plan to work with. Prior to embarking on such new studies we would submit a new or modified risk assessment to the GMSC.

**Recipient or parental organism**

Host: MRC5 fibroblasts, U373 cells (Astracytoma cell line that is permissive to CMV), endothelial cells, human fibroblasts.

**Host/vector system**

Vector: Human CMV

**Origin & function**

Genetic material: 1: Cytomegalovirus genes.

CMV is a lymphotropic/epitheliotropic beta-herpesvirus that is carried as an asymptomatic life-long infection by the majority of individuals in all communities. Control of CMV infection is thought to be due to the potent cellular immune response that is detected in healthy immunocompetent virus carriers. Laboratory strains of CMV such as AD169 and Towne are highly restricted in host cell range, namely fibroblasts. This is believed to be attributed to the loss of genes over passage time in vitro (Bolovan-Fritts C, Wiedeman JA. 2001. Human cytomegalovirus strain Toledo lacks a virus-encoded tropism factor required for infection of aortic endothelial cells. J Infect Dis. 184:1252-61. Sinzger C, Schmidt K, Knapp J, Kahl M, Beck R, Waldman J, Hebart H, Einsele H, Jahn G 1999. Modification of human cytomegalovirus tropism through propagation in vitro is associated with changes in the viral genome. J Gen Virol. 80:2867-77.)

It is a general consensus that recombinant CMVs made from such parental strains will not acquire the potential to replicate in other cell types (Thomas Jones - personal communication).
The following genes are deleted in the recombinant viruses.
 RV798 (all of US2 to US11),
 RV35 (US6 to US11)
 and
 RV47 (US2 to US3 only)

The functions of each gene product are described

US2: The US2 gene product is expressed in the early phase of the viral replication cycle. This protein induces rapid degradation of newly synthesized MHC class 1 molecules, reducing the half life from over 6 hours to less than 2 minutes. It appears that US2 proteins bind to MHC class 1 molecules causing the transport of these complexes to the cytoplasm (Jones et al. 1997). After deglycosylation, both US2 proteins and MHC class 1 molecules are degraded. CMV also interferes with MHC class II expression in several ways as described elsewhere (Miller et al. 1998; Phillips et al. 1998; Tomazin et al. 1999).

US3 &US11 : The US3 and US11 genes are expressed in the immediate early phase and encode for products that physically associates with MHC class 1-B2m complexes. Whereas the US3 protein causes the retention of MHC class 1 molecules in the ER (Jones et al. 1996), US11 binds to MHC class 1 molecules and directs their translocation to the cytoplasm (Wiertz et al. 1996).

US6: The US6 gene is expressed much later in the delayed or late phase and subsequently remains expressed throughout the virus life cycle. US6 interferes with peptide loading of MHC class 1 molecules in the ER (Ahn et al. 1997). This is achieved by US6 proteins transiently associating with the complex containing TAP, MHC class 1-B2m (and other proteins such as Tapasin and calreticulin). This interaction results in the inhibition of peptide translocation across the ER membrane and efficiently blocks assembly of the trimeric MHC class 1-B2m-peptide complex.

US8: Human cytomegalovirus US8 is a type 1 membrane protein that partially colocalizes with cellular endosomal and lysosomal proteins. Although US8 does not have discernible effects on the processing and cell surface distribution of major histocompatibility complex (MHC) class 1 products, it is demonstrated that US8 binds to MHC class 1 heavy chains in the endoplasmic reticulum (Tirabassi & Pleogh, J Virol 2002 Jul;76(13):6832-5).

The other genes replaced (US4, US7, US9, US10) are not fully characterized with regards to function. They appear to be cytoplasmic proteins and may have some function in immune subversion also (Huber et al. J Virol. 2002 Jun;76(11):5748-58).

The pp65 gene is deleted in the RVAd65 virus

pp65: is a structural protein located in the viral tegument. Pp65 is expressed during the late phase of viral replicative cycle. Pp65 has been demonstrated to have kinase activity and co-immunoprecipitates with a cellular kinase (Plk-1) but is dispensable for virus growth in vitro. Although it has been reported to have immune evasive properties, pp65 itself is the target of a massive immune response (both cellular and antibody mediated). It is believed that parent CMV (strain AD169) preparations contain non-infectious viral particles known as dense bodies which contain a large excess of this protein. This is thought to bias towards stimulation of T cells specific for pp65. Therefore the absence of this gene may allow for other peptides to be presented by MHC class 1 molecules and the T cell reactivities to be detected.

Evaluation of foreseeable effects

The genes that have been deleted are involved in either immune subversion or part of the virion structure. The consensus view of prominent CMV virologists is that their absence does not appear to alter the pathogenic capacity of CMV. In fact it is more likely that these viruses will be more immunogenic and provoke a more vigorous response than parent CMV due to the less hindered presentation of a variety of antigens. The absence of pp65 is expected to allow for the presentation of other immunodominant CMV antigens such as IE-1, pp150 and pp50. One possibility to be considered is that an enhanced immune response may also result in greater inflammation at the site of infection. It is envisaged that this will be self-limiting and restricted to the site of infection.
The presence of prokaryotic gene sequences in these recombinant viruses are not believed to increase the pathogenicity or host range of these viruses.

CMV does not immortalise human cells in vivo or in vitro - the removal of immune-subversive genes should render the virus more immunogenic, and not confer transforming properties.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste to be treated by autoclaving at 130 degrees C for 60 mins before disposal to drain. Disposable solid waste which is or may be contaminated with GMMs is also inactivated by autoclaving at 130 degrees C for 30 mins, before removal by a specialist company for incineration. Disposable plastic pipettes may also be decontaminated by immersion in Virkon.

HGMP follows site regulations on the disposal of GM material. All disposal and waste treatment eg. autoclaving, is carried out by the Sanger Centre. Autoclaved waste is collected and sent in specialised containers to the Addenbrooke's hospital site for incineration. Some waste eg. CIN bins are sent directly for incineration.

Specific details of waste disposal:

- **Culture media:** This is all containment level 1 waste. The maximum culture volume disposed of at any one time is 11. Each research group inactivates their own media waste by treating with either Tegodyne, Virkon or Proceine 40 according to manufacturers instructions and biocide screening data supplied with the disinfectants. The waste is then disposed of down the sink, flushed with copious amounts of water.

- **Culture dishes:** These are put into lined plastic tubs which are then autoclaved, prior to incineration.

- **Plastic ware (eg. Pipette tips, eppendorf tubes etc):** These are put into 51 plastic containers with lids which are then autoclaved, prior to incineration.

- **Gloves, paper towels etc. which have potentially been in contact with GM material are disposed of in yellow bags which are then sent for incineration.**

- **Sharps which have potentially been in contact with GM material are disposed of in "CIN bins" which are then sent for incineration.**

The new site will follow rules implemented by the babraham site. All GM waste will be autoclaved in a specially designed "dirty" autoclave, before being added to yellow bags and put into specialised containers, organised by the site management. This waste is then sent to The Cambridge Pet Crematorium, Thriplow Heath, Cambridge.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Tick if notifying a connected programme of work N
Cells grown in biofilms behave and respond differently to cells grown in liquid media suspensions. Understanding how these changes affect the phenotype of a biofilm-grown cell is critical to our ability to control and manipulate bacterial biofilms, which play a major role in beneficial applications like water purification and detrimental scenarios like infections from implanted devices and bio-fouling of air-conditioning systems and water distribution networks. Members of the oral bacterial flora have been extensively studied and cultured in mono- and mixed-species culture, and thus lend themselves to more sophisticated studies involving the up-regulation and down-regulation of factors that direct their adaptation to the biofilm lifestyle. In the main, the biofilm-adaptive factors identified in different bacterial strains have been associated with stress responses as well as activation of mobile genetic elements, but the regulatory factors are still not well understood, nor have all the biofilm adaptive factors been identified. The goals of the work covered by this application are to examine in detail these biofilm adaptive responses in members of a well characterised mixed oral bacterial consortium both in single and mixed culture conditions.

Recipient or parental organism

Recipient organism: K12 laboratory strains of Escherichia coli will be used for all cloning work. K12 strains are considered to be non-colonising.

Host/vector system
E. coli strains MC1061 or DH5 - a will be used to propagate shuttle and suicide vectors. E. coli strain S17 will be used to mobilise the mobilisable (but not conjugative) shuttle vectors. Various shuttle vectors proposed for use are pVA838, pDL278 and pFX3 which are nonmobilisable Streptococcal/E. coli shuttle vectors; pT-COW a mobilisable but nonconjugative E. coli/Prevotella-Porphyromonas shuttle vector; and pBR322 a non mobilisable E. coli plasmid. His-tag vectors like the pQE derivatives from Clontech for specific use in E. coli.

Origin & function
Various biofilm adaptive factors from these oral strains will be cloned and identified. Not overt attempt to express these elements will be made until they have been suitably characterised by sequencing. Identified factors that have been determined not to be toxins may be cloned into vectors for the express purposes of recombinant protein purification or expression for future studies on their role in biofilm adaptation.
Evaluation of foreseeable effects

In all cases the aim of this work is to identify factors present in ACDP cat2 organisms that are activated under biofilm growth. No overt attempts will be made to express any of these factors in E.coli until they have been identified. Although increased toxin production has been associated with other biofilm-forming organisms like Pseudomonas aeruginosa, the purpose of these studies will not be to study toxin expression, so if toxins are identified as being biofilm adaptive factors in these oral organisms they will not be targets for future study. Instead, this proposed work involves identifying other genetic elements that are strictly involved in the cells ability to adapt to the biofilm environment (i.e. global regulatory factors, mobile genetic elements, stress response facors novel membrane proteins, and other elements not directly capable of conferring virulence factors to the ACDP category 1 E.coli K12 species beyond that of the original ACDP category 2 oral organism. Therefore handling recombinant E.coli at containment level 2 conditions obviates any foreseeable effects. In the case where vectors are introduced into the oral bacteria this will be done either to mark them with an antibiotic resistance marker found on vectors suitable to those organisms or to reintroduce regulatory sequences for reporter gene analysis. In either case, the virulence of the oral bacteria will not be enhanced so work done under containment level 2 conditions, again, obviates any foreseeable effects.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N.A.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation requested.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All biological waste will be handled according to the School's strictest guidelines. All waste, with the exception of glass pipettes will be bagged or boxed in metal tin cans and be subjected to autoclaving according to the British Laboratory Standards for biological waste. These autoclaves are regularly serviced and tested by the School. This will result in a 100% kill with all non-glass waste ultimately subjected to incineration and glass waste being washed (post autoclaving) with recirculation into the general glassware pool. Glass pipettes will be neutralised in fresh bleach-based disinfectant before being washed and autoclaved as is the standard practice within the School.

Is an emergency plan required according to regulation 20? N

Animal Units | Large Scale Activities | Human Clinical Applications

02/03/2022
The objective is to develop our understanding of key regulatory and signalling systems such as those influencing nitrogen metabolism and the regulatory response to ambient pH in A. fumigatus. This will utilise approaches that will have successful employed with A. nidulans. In response to comparative genomic analysis as well as proteomic and transcriptomic data, molecular genetic analysis will be undertaken to investigate the function of key regulons and the putative regulatory and signalling components. An initial step will be to construct strains disrupted for specific genes identified by the upstream analysis. This will be achieved by homologous integration of deletion constructs bearing selectable markers such as Neurospora crassa pyr-4 (encoding pyrophosphorylase orotidine MP decarboxylase). Additionally we will construct epitope tagged versions of key genes to identify interacting proteins. This work involves standard cloning procedures in laboratory strains of E. coli, followed by transformation into A. fumigatus. Assessment of the effect of mutations will be through plate tests, northern and proteomic analyses of wild-type and mutant strains. The identity of transformed A. fumigatus strains will be confirmed by PCR, sequencing and Southern’s, as appropriate.

A. fumigatus is humanely to normal healthy people, but it is listed in ACDP hazard group 2. It can cause postoperative infections, aspergilloma (particularly in patients with cystic fibrosis, post-TB, asthmatics), sinusitis in normal people and eye infections. Immunosuppressed individuals are the most at risk of developing pneumonia, disseminating to other organs and serious illness. Conidia (spores can cause an allergic response in sensitive individuals. It is usually transmitted by inhalation of airborne conidia which are widely distributed in nature. Conidia can be readily isolated from most environments including air, human homes, offices, work-places and soil.

A. fumigatus is sensitive to amphotericin B, itracomazole and voriconazole. It is also susceptible to 1% sodium hypochlorite and 70% ethanol.
Standard cloning procedures will be carried out in laboratory strains of E.coli to produce deletion constructs and epitope tagged versions of regulatory genes. Standard pUC based vectors will be used for this work. These constructs or PCR amplified and gene disruption in A.fumigatus utilises cosmids (e.g. from pWe15 cosmid libraries) bearing the sequence of the gene of interest will be prepared for transformation into A.fumigatus in E.coli strains (e.g. KS272) expressing the phage Reda and Redb recombination functions. This will involve replacement of a region of the gene of interest with the sequence of a marker gene to facilitate selection of recombinants in both E.coli and A.fumigatus. Purified cosmid DNS will be transformed into A.fumigatus.

**Origin & function**

The genetic material will originate from A.fumigatus and will have a role in regulation or signalling in nitrogen metabolism or in response to pH.

**Evaluation of foreseeable effects**

Virulence is multifactorial, and so far discrete virulence determinants in A.fumigatus have not been identified. However, nitrogen and pH regulatory mechanisms have been implicated in the pathogenicity of other pathogenic fungi. Strains deleted are AfareA which have been tested for pathogenicity have reduced pathogenicity compared with the parental strain. One study has reported that a revertant from AfareA deletion, where an uncharacterised mutation led to increased expression of specific nitrogen regulated genes, had increased pathogenicity. We do not intend to create revertants in this project, and we anticipate that this project will therefore produce strains with reduced pathogenicity. The regulatory genes and signalling genes produce regulatory proteins or enzymes, which are unlikely to have a harmful biological activity alone. Experiments using isolated DNA, RNA or protein should therefore involve little risk. Cloning within laboratory strains of E.coli will not involve expression, and should also be low risk. Vectors will be capable of expression in A.fumigatus and Anidulans, but not in E.coli.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Conidia: Measures to control the spread of conidia by handling plate cultures in a Class 2 cabinet. The cabinet to be sprayed with 70% ethanol before and after use, and between strains. Plates to be taped closed and exterior decontaminated (70% ethanol) for transport between cabinet and incubator in case of dropping a plate. Use scatter plates before/after work to test that conidia are contained by these measures. Mycelium: Mycelium to be ground to a powder in cabinet. Waste mycelium will be autoclaved to ensure that it is inactivated if not previously killed by extraction procedures. Any contamination incidents decontaminated with 1% sodium hypochlorite for 30 min. Spent growth medium: Spent medium, and washes from liquid cultures to be incubated with bleach prior to discard down drain. Inform Occupational Health so they can record work with this allergenic sensitiser (if deemed appropriate).

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

**Project Additional Information**

**Purposes of the contained use**

Contained use is required to prevent dissemination of genetically altered commensal bacteria that have the capacity to cause disease.

**Recipient or parental organism**

The parental strains of the two organisms that will be used are for Staphylococcus aureus strains SH1000 (8325/4) and Newman and for Enterococcus faecalis strains OG1RF and JH2-2. These are opportunist pathogenic bacteria. These are not attenuated strains but are the commonly used strains for genetic manipulation. Staphylococcus aureus SH1000 (8325/4), Newman in conjunction with the following plasmids: pAZ106, pLTV1, pMUTIN4, pCL84, (all integrative) pCU1, pSB2035 (both replicative).
Enterococcus faecalis OG1RF, JH2-2 with/without the following plasmids: pAZ106, pLTV1, pMUTIN4, (all integrative), pSB2035, pCU1, pTCVlac, pAT28 (replicative).

Escherichia coli BL21 (DE3) in conjunction with pETderivative vectors (T7 promoter)

Host/vector system

S.aureus and E.faecalis genes will be amplified and cloned into the vectors listed in section 7 using E. coli. The plasmids produced and containing the correct inserts will be purified and used to transform E. faecalis and S. aureus. The plasmids used are for two separate types: 1) replicative and maintained extrachromosomally for functions such as gene reporters and gene complementation; 2) integrative for generating insertional replacement mutations and maintained due to recombination with chromosome.

Overexpression of proteins will only be done in E.coli BL21 (DE3) using the pET system. No overexpression of proteins will be done with either S.aureus or E.faecalis as host.

Origin & function

The S.aureus and E.faecalis strains that will be used for the proposed study are laboratory isolates that have been obtained from laboratories that are currently researching the area of host/pathogen biology. Originally, these were isolated from humans.

The intended functions are to study the role and regulation of surface and secreted proteins of these two commensal bacteria to investigate their potential roles during opportunistic infection. This will mainly be done by in vitro analysis of gene and protein expression and this will be done in coordination with a diversity of characterised mutant strains of these organisms to determine the heirarchy of gene expression for virulence and secreted protein production. Murine abscess models of infection will be used for study of staphylococcal mutants that are predicted by virtue of in vitro observations to have a role in virulence. These models of infection will be studied outwith the University of Liverpool in collaboration with others. E.faecalis mutants will be tested in invertebrate models of infection at Liverpool using the worm Caenorhabditis elegans, a well established model of infection.

Evaluation of foreseeable effects

S.aureus is a category 2 microorganism and the mutations that will be made are likely to reduce virulence of the organism compared to the parent strain. This drop in virulence may even reduce the S.aureus strain to category 1, however, due to the ability of S.aureus to colonise humans all of the work will be done in category 2 condition.

E.faecalis is a category 2 microorganism and the mutations that will be made are likely to reduce virulence of the organism compared to the parent strain. This drop in virulence may even reduce the E. faecalis strain to category 1, however, due to the ability of E. faecalis to colonise the digestive tract of human of the work will be done in category 2 conditions.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste will be placed in labelled, capped glass bottles and autoclaved, which results in total kill. Any spillages will be cleaned up with 2% w/v stericol and waste will be autoclaved, again resulting in a total kill. Lab coats will be worn at all times and after work is completed hands will be vigorously washed prior to exiting the category 2 laboratory.
General laboratory plastic waste (tips, plastic containers) will be placed in the hazard bags and collected for incineration.

Caenorhabditis elegans infected with E. faecalis will be completely contained in agar plates in sealed boxes during the infection model. The plates will be autoclaved after the experiment resulting in total kill. Spillages will be cleaned up with 2% stericol, resulting in death of bacteria and invertebrates, and wiped up with absorbant tissue that will be autoclaved. The invertebrate model experiments will be performed in a designated Class 2 pathogen handling facility to protect workers.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Relatively small volumes (maximum 100-500 ml - very rarely 2 litres) produced in each experiment.

Surplus, used and waste culture medium treated with ActiCHLOR disinfectant tablets and/or autoclaved before disposal as clinical waste as per UWCM/Trust policy. Cell remnants treated in the same manner. All contaminated plastic ware is autoclaved.

Autoclaves operated in accordance with departmental SOP. Autoclaves regularly serviced and tested by Trust Works dept. personnel. Autoclaves subject to independent annual inspection and testing.

Historical Significant Changes

Project Transferred to GM130 on 26/04/2005.
To elucidate the normal and pathogenic roles of the huntingtin protein, which leads to Huntington's disease when bearing a glutamine tract in excess of 36 residues.

Huntington's disease (HD) is an autosomal dominant neurodegeneration associated with an expanded trinucleotide repeat which gives rise to a glutamine tract in the N-terminus of the protein, huntingtin. The expanded glutamine tract is selectively toxic and kills particular neuronal populations, initially the medium spiny neurons of the striatum but later other neuronal populations are affected. We wish to express both full-length and truncated huntingtin with various repeat lengths in mammalian cell cultures, along with other proteins known to interact with huntingtin. This will allow us to carry out a number of experiments to answer the following questions:

1. Do huntingtin and the interacting protein co-localise in the cells? Which sections of the transfected proteins are important to that co-localisation? Is this cell-type dependent?
2. Does the presence of the interacting protein ameliorate or enhance any observed effect of huntingtin, eg as measured by apoptosis, electrical activity or other appropriate functional assay?
3. Do variations in the interacting proteins affect the interaction with huntingtin?

The recipient or parental organisms for the standard cloning are disabled non-pathogenic E coli strains. The recipient cell lines for expression of the proteins are standard cell culture lines which cannot survive out of culture and which are kept free from any adventitious agents as far as can be determined by our routine assays for contaminating agents which are problematic in tissue culture, eg mycoplasma.

All cell transfections will be transient.

Host/vector system

Cell lines: Cos7, HeLa, HEK293, N2a, PC12, IMR32, SK-N-SH and variants of this line such as SK-N-5Y.

Vectors include pRcCMV, pcDNA3.19+/- and variants, eg pc3.1DNA HisMax and HisMyc pUni/V5-His-TOPO Echo cloning system (Invitrogen), Clontech living colour vectors (CMV promoter, GFP tags).
Evaluation of foreseeable effects

Huntingtin with an expanded polyglutamine tract is known to be toxic, particularly when expressed in truncated fragments. However, expression will be restricted to transient experiments only. The vectors used for expression in the mammalian cells will not be capable of replication in such cells and should they integrate into the host genome at low levels all the cells will be destroyed at the end of the experiment anyway. Huntingtin is ubiquitously expressed but only particular cell-types are damaged by its expression. These cells are in the brain and thus access of the vectors to the cells susceptible to damage is extremely unlikely. Should the vectors actually be transported to the appropriate cells they would be unlikely to integrate with the host genome in the absence of selection pressure and in order to manifest a problem substantial numbers of cells would need to be so affected. This is extremely unlikely. However the object of these experiments is to overexpress the proteins so promoters which give good expression levels in mammalian cells will be used, thus if the construct could integrate into the host genome of an appropriate cell then the cell would undoubtedly be compromised. HD is a late onset disease, but high repeat numbers (>50) as would be used in this experiment, give early onset disease (<20 years) and expression levels are also thought to be important in downstream cellular effects.

The toxicity of huntingtin and its truncated fragments are the reason for classifying this project as Class 2. The interacting proteins currently under study are the nuclear receptor co-repressor and endophilin 3, neither of which are known to be toxic to mammalian cells when overexpressed. Other interacting proteins may also be used but should any of these be intrinsically as toxic or more toxic than huntingtin itself, then a fresh application to work at the appropriate containment level will be made. Similarly, if the interaction observed in cells causes substantially increased toxicity of huntingtin (eg >10-fold increase in cell death at a given time-point) then shorter repeat units will be used experimentally to decrease the toxicity or again, a further application will be made to continue the work at appropriate containment levels.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Cell cultures are kept entirely within our tissue culture suite until disposed of by sterilisation and autoclaving. They would not survive outside the specialist conditions of tissue culture (37°C, 5%CO2).

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Committee were concerned about the ability of the gene to cause harm if it were accidentally injected, but satisfied now that Containment Level 2 conditions and practices are sufficient. Risk Assessment now suitable and sufficient.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All cultures, mammalian cell and microorganism, will be autoclaved in an approved and regularly tested autoclave room 2.05 Institute of Medical Genetics. In addition all disposables which come into contact with cell cultures will sterilised in freshly made solutions of Actichlor at a minimum concentration of 20,000ppm for a period of at least 2h. The tissue culture hoods used will also be disinfected with the above solution plus a 70% ethanol spray. The above procedures are already standard operating procedures in the Tissue Culture Suite in IMG.

Recyclable culture glassware is collected in lidded autoclavable discard drums. Drums are autoclaved for 30 mins at 121°C. Any autoclaved spent media and culture is run to drain and glassware is washed and reused.

Bioreactors with culture and spent media are autoclaved or sterilised by steam in situ according to volume at 121°C. Contents are cooled and sent to drain. With large capacity bioreactors (>20 litres) biomass is removed by centrifugation and incinerated because of environmental considerations.

Disposable contaminated plastics are collected in autoclave bags, in lidded autoclave drums and autoclaved at 121°C for 30 minutes. Bags are then put in clinical waste bags categorised and sent for incineration.

Any sharps are collected in sharps bins and sent for incineration. (This is being reviewed to include treatment before incineration).

Disinfectants are used for the cleaning of surfaces in accordance with Good Microbiological practice.

Action for spills: Absorbents are recommended to be used with disinfectants for spillages and these should be bagged and autoclaved.

Recommended disinfectants to be used according to biological material: 1% Virkon, Hibitane 1 in 200, Chloros, SBS 0.5%, Data sheets available

Validation of autoclaves and all these disinfectants is under review.

**Historical Significant Changes:** 116/03.1 TRANSFERRED FROM GM116.
### Project Additional Information

#### Purposes of the contained use

The study will focus on the potential of human liver stem cells as alternative sources of functional human hepatocytes and biliary epithelial cells. Isolated human liver stem cells will be stably transduced with a recombinant lentivirus expressing the gene for Green Fluorescent Protein. The potential of these marked cells to repopulate acutely injured livers will be assessed by cell transplantation experiments in NOD/SCID mice (but not here in the UK).

#### Recipient or parental organism

**Hosts.** Standard disabled lab strains of E. coli as DH5a and JM109 will be used for growth of plasmids. Manipulation of large plasmids may involve homologous recombination in strain BJ5183. Human cell line 293T will be used for both initial rescue of virus from transfected DNA, and for virus, propagation. Primary human liver stem cells (which are non-permissive for production of replication deficient lentivirus), will be transduced with recombinant lentivirus expressing GFP.

#### Host/vector system

**Vectors:** Plasmids; Third generation lentiviral vector (replication defective). Please see assessment for details.

#### Origin & function

**Sequence encoding Green Fluorescent Protein which functions as a reporter molecule that fluoresces upon exposure to uv light.**

#### Evaluation of foreseeable effects

**Risks to human health:** The lentiviral vectors used in this study are third generation lentiviral vectors. In these third generation vectors all six regulatory/accessory proteins (Rev, Tat, Vif, Vpr, Vpu and Nef) are removed, except Rev. Rev acts as the post-transcriptional level and is necessary for HIV gag/pol messenger. As an extra safety responsive element [RRE]) and facilitates the cytoplasmic export of gag/pol messenger. As an extra safety measurement Rev is placed on a separate vector (RSV-Rev) beside transfer vector. Only 700 bp of the HIV envelope protein are present in the transfer vector, plus RRE and the packaging signal. The packaging construct contains the minimal RRE of 375 bp and the gag/pol genes. Through deletions in both LTRs and the absence of 5 of the 6 accessory proteins, including the replication essential Tat it is highly unlikely that replication competent virus is produced. In published studies and from our own experience with these vectors replication competent virus has never been detected. The HIV-envelope protein is replaced by non-retrovirally envelope protein (VSV-G). It is highly unlikely that this will be incorporated in a new hybrid replicative virus. It is impossible that wild-type HIV will be formed, because of the omission of 5 accessory proteins with HIV-env.

**Environmental considerations:** Proteins will not be expressed in bacteria used for plasmid propagation. Bacteria used for propagation are attenuated strains that will not survive in the environment. The recombinant virus is replication defective and will not have an extended host range, the GFP transgene is innocuous, so there is negligible potential hazard to the environment. Containment conditions specified should prevent environmental release of virus or E. coli carrying the associated plasmids; and the virus is replication defective.
### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation applied for.

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste is treated by autoclaving at 130 degrees centigrade for 60 mins before disposal to drain. Disposable solid waste which is or may be contaminated with GMMs is also inactivated by autoclaving at 130 degrees centigrade for 30 mins, before removal as clinical waste by specialist contractors, with final disposal by incineration. Autoclaving achieves 100% kill. Warning lights, and chart recorder, indicate whether or not the autoclave run has achieved the appropriate temperature for the required time. The autoclave is run by trained staff, who are instructed to treat waste as still contaminated if the autoclave run was not to specifications. Under such circumstances the waste would be autoclaved again, after rectifying any reason for the malfunction.

The autoclave is inspected and serviced on a regular basis. Autoclave is regularly tested with Brown's tubes.

Sharps, including scalpel blades, needles and disposable plastic tips, may be decontaminated by drawing up Virkon disinfectant, and by soaking in Virkon for a minimum of 15 minutes. Disposable plastic pipettes may also be decontaminated by immersion in Virkon as above. Manufacturer's information indicates efficacy of Virkon against strains of E. coli at dilutions ranging from 1% to 0.125%. The manufactureres of Virkon (Antec International Ltd) have also commissioned studies on the virucidal effect of Virkon on Human Immunodeficiency virus and found that a 0.5% solution of Virkon inactivated 10^6 infectious doses (ID50) of HIV-1 per ml within 10 minutes at room temperature.

### Is an emergency plan required according to regulation 20?

N

### If yes, tick to confirm that it is attached to this form

N

### Tick to confirm that you have attached a risk assessment to this form

Y

### Tick if you are claiming exemption from disclosure for section of the risk assessment

N

### Please enter comments on the GM safety committee on the risk assessment

1. I am not sure that the statement that pMDLg/pRRE expresses no gag/pol has ever been convincingly demonstrated. Perhaps it is better to say that only very low or undetectable levels will be anticipated.
2. The applicant states that he has never detected replication competent virus. How has he looked for it? Has it ever been detected?
3. Is there validation data for Virkon against lentiviruses?
4. Is the KI discus test carried out annually rather than six monthly?
5. The autoclave should be additionally tested with Brown's tubes on a regular basis.

All of the above have been addressed in the assessment. The GMSC have approved this assessment.

Historical Significant Changes
TRANSFERRED TO GM CENTRE 116 - 4/4/06.
**Project Additional Information**

**Purposes of the contained use**

The objectives of the programme of work are to construct and characterise mutants of Corynebacterium glutamicum and Mycobacterium bovis BCG. These mutants will be used to analyse well-defined, non-toxic, mycobacterial cell wall components and genes that contribute to the basic physiology of corynebacteria and mycobacteria.

The programme of work on M. bovis is illustrative rather than exhaustive so that similar work can begin on other mycobacterial ACDP category 2 organisms without the need to submit a fresh application each time. Changes to the project will, however, be risk assessed and passed to the local GMSC for approval.

A previous risk assessment titled "The use of recombinant Mycobacterium smegmatis for the biochemical/physiological analysis of cell wall products "covers our work studying the function of mycobacterial genes (from M. tuberculosis H37Rv and M. bovis BCG) using Escherichia coli K12 and M. smegmatis as hosts prior to our move from the University of Newcastle upon Tyne. This assessment was approved by the University of Newcastle upon Tyne ACGM committee in 1999 as Hazard Group 1 and was reassessed as Activity class 1 in January 2000, in revising assessments under the New Contained Use Regulations 2000. Work in the laboratory using E. coli K12 and M. smegmatis as hosts for mycobacterial sequences, including work linked with the current project, will continue to be covered by this original risk assessment and has been approved by the local GMSC at the University of Birmingham. In addition, whilst at the University of Newcastle upon Tyne approval was granted by the Microbiological Hazards and Genetic Modification Safety Advisory Committee for the project "The use of recombinant Mycobacterium bovis BCG to examine gene function" (October 2001) and assessed as containment level 2, class 2. The project was subsequently notified to the HSE and approval was granted in November 2001 at Newcastle (REF: GM540). The present assessment aims to extend cover to the use of C. glutamicum and the vaccine strain M. bovis BCG (Pasteur) as hosts (M. bovis BCG as originally proposed at Newcastle prior to our move to the School of Biosciences at The University of Birmingham.

The individual activities with this connected programme are as follow:

1. Cloning of DNA fragments from C. glutamicum, M. bovis BCG and M tuberculosis H37Rv in non-mobilisable vectors in lab strains of E. coli with a view to sequencing or mutating the fragments.
2. Creation of mutants in wild type strains of C. glutamicum and M. bovis BCG by random transposon mutagenesis resulting in insertional inactivation, linked in some cases with the creation of transcriptional fusions to reporter genes.
4. Allele replacement using a gene that expresses a marker protein which is highly unlikely to have any biological effect (such as B-galactosidase, luciferase, GFP) into a pathogen to monitor gene expression under different environmental conditions.
5. Expression of proteins at a high level in a disabled host bacterium to enable further chemical/biochemical characterisation of the protein.
6. Expression in C. glutamicum and M. bovis BCG of well defined genes from C. glutamicum, M. Bovis BCG and M tuberculosis H37Rv running off its own promoter on a shuttle vector, also to complement well-defined mutant phenotypes.
7. Expression of antibiotic resistance determinants in a disabled host bacterium to enable further characterisation of the resistance mechanism.

**Recipient or parental organism**

Disabled laboratory strains of E. coli including or similar to those listed in Part 2A, Annex II of the ACGM Compendium of Guidance.

C. glutamicum and M. bovis BCG.

M. bovis BCG is one of the oldest and most widely used live vaccines; about 3 billion doses of this attenuated M. bovis strain have been used to immunise individuals against tuberculosis worldwide. Whole genome comparisons of M. tuberculosis H37Rv and M. bovis BCG (Pasteur) have now been undertaken to determine the genetic determinants of attenuation. These reveal several (14) large deletions in the M. bovis BCG (Pasteur) genome which encompass 119 open reading frames (Behr et al., 1999 Science 28: 1520-3).

The ACDP categorisation of pathogens according to hazard and categories of containment (fourth edition, 1995), classifies M. bovis BCG as hazard group 2. However, appendix 17 (page 108) states "The BCG strains of M. bovis and the so-called 'vole bacillus' M. microti have both been used in vaccines, but if mishandled, can give rise to abscess formation. The BCG strains are included in Hazard Group 2 because of this and the extremely remote possibility of reversion to virulence although when used..."
under clinical conditions for immunisation, laboratory Containment Level 2 is not necessary”. Staff working on the programme have previously been immunised with BCG. C. glutamicum is known for its ability to massively excrete L-glutamate. The capacity of C. glutamicum to excrete glutamate has been used for more than 40 years to produce this amino acid on an industrial scale in ever increasing quantities, around 106 tonnes/year (Hodgson, 1994, Bio/Technology 12: 152-155). The ACDP categorisation of pathogens, according to hazard and categories of containment (fourth edition, 1995), classifies Corynebacteria spp. as hazard group 2. Although, C. glutamicum has been defined as having "biological limitations" which mean that it is unlikely to survive in the gut, lung and elsewhere. This description is also generally considered to cover laboratory adapted strains (particularly multiply auxotrophic or recombination deficient mutants) as well as other non-pathogenic hosts with a negligible capacity to persist in humans and a history of safe use.

Host/vector system

Any non-mobilisable or mobilisation defective including or similar to those listed in Part 2a Annex II of the ACGM Compendium of Guidance.

The pNIL, pGOAL and pYUB854 series of vectors for constructing suicide vectors to generate marked and unmarked mutants in M. bovis BCG.

The pK18mob suicide vector will be used to generate marked mutants in C. glutamicum.

Non-mobilisable shuttle vectors that can replicate in E. coli and mycobacteria (eg pJEM15, pMV261, pVV16, pPR27 and their derivatives). These vectors contain an E. coli origin of replication (from the pUC series of cloning vectors), a mycobacterial origin of replication from plasmid pAL5000 and antibiotic resistance markers (eg Kanamycin and hygromycin).

Origin & function

Source: C. glutamicum, M. bovis BCG and M. tuberculosis H37Rv

Genetic material: DNA fragments encoding various well defined genes involved in cell wall metabolism, eg glycosyltransferases, fatty acid biosynthesis, polyketide biosynthesis, siderophore biosynthesis, p450 enzymes and peptidoglycan biosynthesis.

Source: Depending on marker -E. coli for B-galactosidase, luminescent vibrios for luciferase, jellyfish for GFP.

Genetic material - A gene that expresses a marker protein which is highly unlikely to have any biological effect, eg GFP, luciferase, B-galactosidase.

Antibiotic resistance genes expressed from their native promoters.

Evaluation of foreseeable effects

PLEASE SEE ASSESSMENT FOR DETAILS

The risk assessment deals with the risks to human health and the environment under each specific activity. Most of the work will make use of crippled lab strains and non-mobilisable vectors, although wild type strains will be used to study the effects of defined chromosomal mutations on mycobacterial cell wall physiology and other phenotypes. The risks to human health are therefore associated with the wild type host. Environmental risks are dealt with under each activity in the assessment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full level 2 applied

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All potentially infected material is autoclaved prior to disposal and incineration. 100% kill of GMMs. Disinfectants such as hycolin (2% v/v) and Chloros are available for spills.
Some members of the GMSC pointed out that the original assessment contained a reference to antibiotic resistance markers, but did not then list them or discuss them further. These were added.

The GMSC asked what were the ‘well defined genes involved in cell wall metabolism and cellular physiology’? Examples were added to illustrate this, as a full list would have been extremely long.

The assessment was approved by the GMSC.

Project Additional Information

**Purposes of the contained use**

The work is concerned with understanding how bacterial gene expression is regulated using E. coli K12 as a model. The strategy is to use genetics to identify regulatory components at particular loci and then to use genetics and biochemistry to understand the interaction between these components. This involves many genetically manipulated constructs in which altered regulatory elements and regulatory components are tested. Additionally genes encoding regulatory factors are manipulated to facilitate overexpression and purification of the corresponding protein.

**Recipient or parental organism**

**Hosts:** Standard disabled hosts such as E. coli K12 strains. For mutagenesis the hosts will be standard, well characterised strains of the wild type organism.

**Host/vector system**

**Vector:** Vectors will generally be pUC, pBluescript and related non-mobilisable CoIE1-based standard vectors, or mabda phage-based cloning vectors, or standard low copy number vectors such as pACYC or pSC101 and derivatives.

**Origin & function**

**Inserts:** Sequences used may be any gene or sequence including genes of unknown function, including virulence factors. Genes may be partial or complete and may include expression signals, eg segments from the E. coli lac, gal, mal, ara, mel nir, and nrf operons, the fnr, crp, rpoA, rpoBC, rpoD, rpoS, fis, ihfA, ihfC hupA, hupB and hns genes. Various 'anonymous' but completely sequenced regulatory genes from K12 or the Sakai 0157 strain. Non coli genes include B. pertussis cyaA, V. fiscerii lux, plus various commercially available genes that are used as tools. Libraries may be constructed for limited purposes, eg two hybrid screening.

**Donor.** Sources are either whole genomic DNA or PCR-amplified known sequences, from E. coli. In general source DNA will be taken from an organism for which a whole genome sequence is known. No organisms requiring greater than containment level 2 will be used. In some experiments the starting material will be clones from other laboratories, eg encoding lac, gfp, lux, cya or other 'tools' for molecular biology.

**Evaluation of foreseeable effects**

**Effects on human health:** None of the constructs cause harm beyond that of the starting host and no risk additional to that of the parental wild type organisms is envisaged.

**Environmental hazards:** The potential hazard is negligible as the GMMs cannot be considered likely to express virulence or other factors that would be potentially harmful to other species or the environment. Accidental release is highly unlikely.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation - full level 2 containment applied.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste will be autoclaved - a process that is validated by monitoring of the internal chamber. An automatic printout of every run is produced. Achieves 100% kill. Wastes from autoclaving will be disposed of to drain or to clinical waste incineration.

The standard disinfectant used is Virkon, 1% w/v solution. This will only be used to sterilise lightly contaminated surfaces, and is not used for treatment of substantial culture volumes, or for rendering safe contaminated matter such as absorbent towels - these will be autoclaved. Studies have shown the efficacy of 1% solutions to achieve typically at least 10 (to the power of 5) reduction in counts under appropriate conditions.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

</tbody>
</table>
**Project Additional Information**

**Purposes of the contained use**
To express cDNAs encoding Entamoeba cytoskeletal and signalling proteins in both Entamoeba and Dictyostelium cells.

**Recipient or parental organism**

**Hosts.** E. coli XL1-blue - disabled and slow growing; DH5 - as XL-blue.

Dictyostelium strains AX2 and AX3 - free living, non-pathogenic soil amoeba. Grow more slowly than wild type under non-laboratory conditions. No pathogenicity or harm to humans or livestock. Potential harm to environment is negligible. Entamoeba histolytica strain HM-1:IMSS - standard laboratory strain. Cysts are the only infectious stage of this parasite and these can not develop or form in standard lab cultures, hence the parasite is not transmissible to humans in this setting. The cultured form, ie the trophozoite, is very fragile and susceptible to desiccation and detergents. As they are unable to persist in the environment the chance of environmental damage is remote.

**Host/vector system**
Vector. pUC18 - standard molecular biological plasmid vector.

**Origin & function**

Origin of genetic material: Dictyostelium strain AX3 - a free living non-pathogenic soil amoeba which grows at 22 degrees centigrade and is harmless to crops and agriculture.

*Antamoeba histolytica strain HM-1:IMSS* -- standard laboratory strain. Cysts are the only infectious stage of this parasite and these can not develop or form in standard lab cultures, hence the parasite is not transmissible to humans in this setting. The cultured form, ie the trophozoite, is very fragile and susceptible to desiccation and detergents. As they are unable to persist in the environment the chance of environmental damage is remote.

Genetic material: Full length cDNAs encoding Entamoeba Arp2 and Arp3 - major skeletal proteins involved in movement and cell shape. Selectable markers conferring G418 resistance.
### Evaluation of foreseeable effects

**Effects on human health:**

**Dictyostelium** - None. It is a non-pathogenic soil amoeba, unable to grow at human body temperature and is harmless to crops and agriculture.

**Entamoeba histolytica** - No likely risks. It is a parasitic enteric protozoan that is responsible for amoebiasis in humans. The disease is characterised by diarrhoea/dystentery, intestinal tissue invasion and potential liver abscess formation. Epidemiology, the organism is ubiquitous and has a worldwide distribution, although prevalence is much higher in developing, disadvantaged countries and tropical regions. In contrast, rates of infection are low in the developed world, with the majority of these infections being found in specific groups (e.g., travellers from developing or high incidence areas). Symptomatic invasive amoebiasis only develops in 10% of individuals harbouring the parasite. The organism can exist as both cysts and trophozoites. Transmission is faeco-oral and results from ingestion of viable cysts in contaminated food or water. Cysts can remain viable for a long time depending on environmental conditions but are extremely sensitive to desiccation. Trophozoites on the other hand are more fragile and degenerate rapidly in the external environment as well as being easily destroyed by acidic pH (e.g., stomach acid).

As the only infectious stage of the parasite, the cyst, does not form in standard laboratory cultures the parasite is not transmissible to humans in this setting. Accidental infections have never been reported, but effective drug treatments are available should this happen.

**Environmental hazards:** Dictyostelium - negligible hazard. The strains used are very weak due to multiple mutations and would not compete with local Dictyostelium species.

Entamoeba - The organisms are very sensitive to desiccation and detergents and are not free-living. As they are unable to persist in the environment the chances of environmental damage are remote.

The work will be carried out at CL2 and the likelihood of accidental release is very low.

**E. coli XL-blue/DH5** - non-colonising, disabled lab strains, no risk to human health or the environment.

### Containment and control measures for GMOs that are not microorganisms (e.g., GM animals & plants)

N/A

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation applied for CL2 applied. The laboratory set aside for this work is a relatively new facility and is currently being fitted with a hand wash basin.

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

**Dictyostelium** - to kill spent cultures: 1% chlorine bleach.

**Entamoeba** - Tubes containing liquid cultures and contaminated disposables will be placed in autoclave bags and autoclaved at 121 degrees for 50 minutes and discarded as "clinical waste" (incineration).

Agar plates, loops, tips etc will all be autoclaved. 100% kill.

All methods are more than sufficient to kill Dictyostelium which are fragile, as well as Entamoeba which are sensitive to desiccation and detergents and are not free-living.

**Bacterial cultures** will be killed with Virkon at the recommended dilution (1:100)

**Is an emergency plan required according to regulation 20?** N

If yes, tick to confirm that it is attached to this form N
**Please enter comments on the GM safety committee on the risk assessment**

* I feel information on human health should be transferred to the relevant section; the nature of the "normal laboratory clothing and protective equipment" should be defined; the autoclave used for disposal of cat 2 waste should be monitored (it is anyway, why not say so for completion?); and the disinfection regimen should be defined, ie is 1% chlorine bleach 1% available chlorine, and what is the actual dilution of Virkon used?

**POINTS ADDRESSED IN ASSESSMENT**

* There is no mention of any possible alteration in phenotype resulting from the introduction of cytoskeleton and signalling proteins in Entamoeba and Dictyostelium. I assume they will not become (more) pathogenic but perhaps this could be addressed.

* No increase in virulence/pathogenic capacity is expected. As mentioned in the application, Dictyostelium are free-living non-pathogenic soil amoebae which grow at 22 degrees and therefore do not pose a threat to humans. Likewise Entamoeba does not pose a risk to humans in this/our setting because the cyst, which is the only infectious stage of the parasite, can/do not develop or form in standard laboratory cultures, hence the parasite is not transmissible to humans.

The GMSC also asked whether the Class 1 and Class 2 work should be split into two separate proposals. The investigator felt this was not necessary and not desirable because the work is one experiment, in which cDNAs encoding Entamoeba cytoskeletal and signalling proteins will be expressed in both Entamoeba and Dictyostelium cells.

The GMSC has approved this assessment.

**Project Ref** 125/05.1

**Date Ackn’d** 07/04/2005

**CU2 Project Title** Investigation into the role of downstream components of the FGFR cell signalling

**Class** Class 2

**CultureVolClass2** < 1 Litre
The technique of RNA interference (RNAi) will be used to knockdown FRS2 (a component of the fibroblast growth factor receptor signalling pathway) in primary human cells. Use of a replication incompetent bicistronic HIV1 based lentivirus will be applied to deliver the SiRNA into cells.

**Recipient or parental organism**

Host: Host bacteria for growth of plasmids are standard disabled lab strains of E. coli such as DB3.1 and Stbl3. DB3.1 is an E. coli strain that is resistant to CcdB effects and can support the propagation of plasmids containing the ccdB gene. One shot Stbl3 chemically competent E. coli from Invitrogen are well suited for use in cloning unstable DNA such as lentiviral DNA containing direct repeats. Human cell line HEK 293T will be transfected with the pLenti4/V5-DEST and the packaging vectors and lentivirus harvested from the supernatant. Primary human cells that are non-permissive for production of replication defective lentivirus will be transduced with recombinant lentivirus expressing GFP and RNAi gene of interest. Further work may use mouse embryo fibroblasts.

**Vector(s):** The viraPower Lentiviral Expression System (Invitrogen) used allows creation of a replication incompetent HIV-1 based lentivirus which can then be used to deliver and express our gene of interest in either dividing or non-dividing cells. Four vectors are involved; one viral transfer vector and three packaging vectors (see assessment for details). The method used to clone our gene of interest into the lentivirus vector is gateway cloning and for this another vector will be used, known as pDONR.

**Origin & function**

Source: Green Fluorescent Protein from jellyfish. Sequence encoding a small part of FRS2 (approx 21 bases) from human and hairpin sequence needed for RNAi to work effectively.

Genetic material: The sequence encoding GFP which functions as a reporter molecule that fluoresces upon exposure to uv light. Also, a partial sequence encoding a small section of the FSR2 protein and a hairpin sequence needed for the short hairpin RNAs to be produced and work effectively. FSR2 is an adaptor protein that acts downstream of FGFR.
Human health: In third generation lentiviral vectors all six regulatory/accessory proteins (Rev, Tat, Vif, Vpr, Vpu and Nef) are removed, except Rev. Rev acts at the post-transcriptional level and is necessary for HIV gag/pol expression. Rev binds to an RNA motif (Rev Responsive Element RRE) and facilitates the cytoplasmic export of gag/pol messenger. As an extra safety requirement Rev is placed on a separate vector (pLP2) to the transfer vector. Only 700bp of the HIV envelope protein are present in the transfer vector, plus RRE and the packaging signal. The packaging construct contains the minimal RRE of 374bp and the gag/pol genes. Through deletions in both LTRs and the absence of 5 of the 6 accessory proteins, including the replication essential Tat, the biosafety of the vector is increased. In published studies replication competent virus has never been detected. The HIV envelope protein is replaced by non-retrovirally envelope protein (VSV-G). It is highly unlikely that this will be incorporated in a new hybrid replicative virus. It is impossible that wild type HIV will be formed because of the omission of 5 accessory proteins and the HIV-env. No protein is expected to be expressed in bacterial strains used for plasmid propagation.

Environmental Considerations: Proteins will not be expressed in bacteria used for plasmid propagation. Bacteria used for propagation are attenuated strains that will not survive in the environment. The recombinant virus is replication defective and will not have an extended host range, the transgenes are innocuous, so there is negligible potential hazard to the environment. Potential hazard to species in the environment either from the viruses, or the E. coli containing the plasmids, therefore appears negligible. Containment conditions specified should prevent environmental release of virus, or of E. coli carrying associated plasmids.

Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be aspirated into, and exposed to, 1% Virkon for a minimum of 30 minutes, or collected into autoclavable pots and autoclaved before disposal to drain.

Disposable solid waste will be inactivated by autoclaving with final disposal by incineration.

Exceptions to this are: Contaminated micropipettor tips will be soaked in 1% Virkon for a minimum of 30 minutes before being rinsed and disposed of in Sharps containers, which will be sent for incineration. Disposable plastic pipettes also treated with Virkon prior to rinsing and disposal as above.

Exposure to Virkon for a minimum of 30 minutes, or autoclaving effectively kills 100% of GMMs.

The maximum culture volume that could be released at any one time is 2 litres. GM waste: Liquid waste is deactivated using Domestos bleach at recommended concentrations (Domestos containers are date-stamped on receipt and bottles with dates older than 6 months not issued for lab use); Solid waste is double-bagged and disposed of by autoclaving (120 degrees /20 min) by trained staff (a signed record is kept of all autoclave runs). Monthly validation of autoclaves is made by the inclusion of Browne's tubes.

PROJECT TRANSFERRED TO GM 37 (26/10/07)

Purposes of the contained use

P. falciparum is a serious human pathogen classified by ACDP as Group III* (derogation applies such that they can be handled in category II facilities, with no requirement for positive pressure of HEPA filtration, since there is no risk of airborne contamination.).

No significant additional hazards have been identified above and so it is appropriate to assign the same containment level as that required for the non-GM organism. This is categorised by ACDP as Class III, but derogation is permitted to allow work to proceed under containment level 2. A COSHH form pertaining to P. falciparum cultures has been signed by all relevant personnel.

Recipient or parental organism

The function of the inserted parasite gene product will frequently be unknown, or can only be implied through homology with other organisms. Gene knockout experiments targeting genes linked to invasion should result in parasites with lowered invasion potential. Knockouts of potential drug targets (e.g., protein kinases) are aimed at reducing the fitness of the knockout parasites, preferably to produce non-viable or severely functionally-impaired parasites. Allelic replacement of protein kinase genes with those exhibiting hypersensitivity to inhibitors should result in parasites with increased sensitivity to these inhibitors. Growth rates are not expected to be affected, other than negatively, in any of these experiments.

Host/vector system

Growth of Plasmodium falciparum in human red blood cells.

Origin & function

Stable transfection systems for the human malaria parasites have only recently become available, and provide a means to investigate gene function using gene modification or ablation ("knockout"). Transfection is achieved through electroporation of either red blood cells prior to infection by the parasite, or ring-stage parasites (asexual development cycle in the blood), using in vitro cultured parasites grown in human erythrocytes, with specific plasmid vectors such as pHRPCAT. These vectors contain a drug-selectable marker, usually the dihydrofolate resistance gene (DHFR) from pyrimethamine-resistant strains of either P. falciparum or Toxoplasma gondii, for selection with pyrimethamine, or the human DHFR for selection with the antifolate drug WR99210. We will also use plasmids based on the pHHT-TK vector 4, which allows negative selection using gancyclovir.
Transient transfection (without permanent modification of the parasite’s genome) will be performed using plasmids encoding reporter genes such as GFP, luciferase or CAT. The mRNA levels of specific genes will be targeted by RNAi.

Plasmodium genes considered for possible GM work:

* Protein kinases (a preliminary examination of the PlasmoDB database indicated the presence of approximately 60 genes of this family in the parasite’s genome, any of which can be of interest in the context of our work).
* Cyclins (pfcyc-1, -2, -3, -4)
* Apical complex proteins (esp. pFRH1, -2A, -2B, -3, and -4)

Evaluation of foreseeable effects

Any environmental risk is more likely due to the organism itself rather than the genetic modification. Because we will not be using mosquitoes, the release of the parasite into the environment is exceedingly unlikely.

The function of the inserted parasite gene product will frequently be unknown, or can only be implied through homology with other organisms. Gene knockout experiments targeting genes linked to invasion should result in parasites with lowered invasion potential. Knockouts of potential drug targets (e.g., protein kinases) are aimed at reducing the fitness of the knockout parasites, preferably to produce non-viable or severely functionally-impaired parasites. Allelic replacement of protein kinase genes with those exhibiting hypersensitivity to inhibitors should result in parasites with increased sensitivity to these inhibitors. Growth rates are not expected to be affected, other than negatively, in any of these experiments. For all new transgenic strains, growth rates will be checked as part of phenotypic characterisation.

Containment and control measures for GMOs that are not microorganisms (e.g., GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Similar containment requirements are for unmodified P. falciparum. As for unmodified P. falciparum, derogation from various aspects of Level 3 containment is appropriate. The reasons for derogation relate to the fact that infection by aerosol or ingestion does not occur, and spread of the disease requires the appropriate vector species of mosquitoes, which are absent in the area where the work will occur.

We request derogation from standard level three containment on the three points detailed below. Plasmodium cannot be transmitted by aerosol. The normal route of transmission is by mosquito bite. In laboratory conditions, the only means of infection is by an accidental puncture wound, for example with a contaminated syringe needle. Also, plasmodium is exceptionally fragile. To survive outside its host species (humans and mosquitoes), it must be kept in complex media. Plasmodium dies instantly if placed in water and is also killed by drying.

1. Negative pressure relative to the pressure of immediate surrounds. Derogation requested. Plasmodium transmission by aerosol does not occur.
2. Extract and input air from the laboratory should be HEPA filtered. Derogation requested. Plasmodium transmission by aerosol does not occur.
3. Protective footwear. Derogation requested for footwear. The risk of live/infectious parasites escaping to the environment in this way is nil as they cannot survive outside the host in the environment - not necessary as this requirement is only where and to the extent the risk assessment shows it to be required.
4. Autoclave required in the laboratory suite.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid and liquid waste is inactivated using Hibitane prior to disposal. Solid waste for autoclaving will be double-bagged and transported to the autoclave room in a plastic drum. The culture room is kept locked and access is restricted to trained personnel. Written training and culture records are maintained. The sensitivity of new transgenic strains to killing by hibitane will be tested.
We feel this is a good and well thought out risk assessment. From an original discussion of the proposal, the committee raised a variety of questions, all of which have been answered to our satisfaction, by the principle investigators. In particular, we feel that the areas of derogation from level 3 are appropriate because of the extremely low risk of spread of plasmodium into the wider community and environment. We believe the only significant risk is to the actual individuals involved in the project where infection as a result of a puncture wound could theoretically occur. The risk of a puncture wound occurring is minimised by avoiding the use of sharps in handling transgenic plasmodium.

Project Ref 121/01.1
EXPRESSION AND OVER EXPRESSION OF FULL LENGTH AND PARTIAL FRAGMENTS OF HUNTINGTIN AND ITS INTERACTING PROTEINS

Purposes of the contained use

To elucidate the normal and pathogenic roles of the huntingtin protein, which leads to Huntington's disease when bearing a glutamine tract in excess of 36 residues.

Huntington's disease (HD) is an autosomal dominant neurodegeneration associated with an expanded trinucleotide repeat which gives rise to a glutamine tract in the N-terminus of the protein, huntingtin. The expanded glutamine tract is selectively toxic and kills particular neuronal populations, initially the medium spiny neurons of the striatum but later other neuronal populations are affected. We wish to express both full-length and truncated huntingtin with various repeat lengths in mammalian cell cultures, along with other proteins known to interact with huntingtin. This will allow us to carry out a number of experiments to answer the following questions:-

1. Do huntingtin and the interacting protein co-localise in the cells? Which sections of the transfected proteins are important to that co-localisation? Is this cell-type dependent?

2. Does the presence of the interacting protein ameliorate or enhance any observed effect of huntingtin, eg as measured by apoptosis, electrical activity or other appropriate functional assay?

3. Do variations in the interacting proteins affect the interaction with huntingtin?

Recipient or parental organism

The recipient or parental organisms for the standard cloning are disabled non-pathogenic E coli strains. The recipient cell lines for expression of the proteins are standard cell culture lines which cannot survive out of culture and which are kept free from any adventitious agents as far as can be determined by our routine assays for contaminating agents which are problematic in tissue culture, eg mycoplasma.

All cell transfections will be transient.

Host/vector system
Hosts

Cell lines: Cos7, HeLa, HEK293, N2a, PC12, IMR32, SK-N-SH and variants of this line such as SK-N-5Y.

Origin & function

Full length and truncated huntingtin constructs in plasmids obtained from collaborators or generated in house. Repeat lengths of 2-150CAG (or CAA/CAG). Full-length or truncated fragments of interacting proteins, provided they do not themselves have exceptional hazards associated with them such as potential oncogenic activity, in which case a further application in the appropriate Class will be made.

Vectors include pRcCMV, pcDNA3.19+/- and variants, e.g. pc3.1DNA HisMax and HisMyc pUni/V5-His-TOPO Echo cloning system (Invitrogen), Clontech living colour vectors (CMV promoter, GFP tags).

Evaluation of foreseeable effects

Huntingtin with an expanded polyglutamine tract is known to be toxic, particularly when expressed in truncated fragments. However, expression will be restricted to transient experiments only. The vectors used for expression in the mammalian cells will not be capable of replication in such cells and should they integrate into the host genome at low levels all the cells will be destroyed at the end of the experiment anyway. Huntingtin is ubiquitously expressed but only particular cell-types are damaged by its expression. These cells are in the brain and thus access of the vectors to the cells susceptible to damage is extremely unlikely. Should the vectors actually be transported to the appropriate cells they would be unlikely to integrate with the host genome in the absence of selection pressure and in order to manifest a problem substantial numbers of cells would need to be so affected. This is extremely unlikely. However the object of these experiments is to overexpress the proteins so promoters which give good expression levels in mammalian cells will be used, thus if the construct could integrate into the host genome of an appropriate cell then the cell would undoubtedly be compromised. HD is a late onset disease, but high repeat numbers (>50) as would be used in this experiment, give early onset disease (<20 years) and expression levels are also thought to be important in downstream cellular effects.

The toxicity of huntingtin and its truncated fragments are the reason for classifying this project as Class 2. The interacting proteins currently under study are the nuclear receptor co-repressor and endophilin 3, neither of which are known to be toxic to mammalian cells when overexpressed. Other interacting proteins may also be used but should any of these be intrinsically as toxic or more toxic than huntingtin itself, then a fresh application to work at the appropriate containment level will be made. Similarly, if the interaction observed in cells causes substantially increased toxicity of huntingtin (e.g., >10-fold increase in cell death at a given time-point) then shorter repeat units will be used experimentally to decrease the toxicity or again, a further application will be made to continue the work at appropriate containment levels.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Cell cultures are kept entirely within our tissue culture suite until disposed of by sterilisation and autoclaving. They would not survive outside the specialist conditions of tissue culture (37°C, 5%CO2).

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Committee were concerned about the ability of the gene to cause harm if it were accidentally injected, but satisfied now that Containment Level 2 conditions and practices are sufficient. Risk Assessment now suitable and sufficient.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All cultures, mammalian cell and microorganism, will be autoclaved in an approved and regularly tested autoclave room 2.05 Institute of Medical Genetics. In addition all disposables which come into contact with cell cultures will sterlised in freshly made solutions of Actichlor at a minimum concentration of 20,000ppm for a period of at least 2h. The tissue culture hoods used will also be disinfected with the above solution plus a 70% ethanol spray. The above procedures are already standard operating procedures in the Tissue Culture Suite in IMG.
Please enter comments on the GM safety committee on the risk assessment

None.

**Purposes of the contained use**

analysis of gene regulation during viral infection of human cell lines with cytomegalovirus. Attenuated virus, with or without the addition of a GFP reporter gene, will be used to infect human cell cultures. The expression of endogenous viral and cellular genes and their protein products will be monitored using techniques such as reporter assays, protein analysis techniques and differential mRNA expression.

**Recipient or parental organism**

The GMO in question is a pBabe-SOD3 retroviral vector and the pBabe-puro (empty mock) retroviral vector control. The pBabe-SOD3 retroviral vector will not be constructed at Cardiff University, but will be a gift from Professor Thomas von Zglinicki (Institute of Ageing & Health, Newcastle University).

The pBabe-SOD3 retroviral vector and pBabe-puro (empty mock) retroviral vector are based on the pBabe series of vectors, encoding a puromycin resistance gene, transcribed from the 3'-long terminal repeat of the viral vector (Morgenstern and Land, Nucleic Acids Res. 1990; 18: 3587-3596). The pBabe retroviral vectors are based on the Moloney murine leukaemia virus (Mo MuLV), expressing the inserted genes from the Mo MuV 3'-long Terminal Repeat. The characterised, full length SOD3 cDNA obtained from Professor Stefan Marklund (University of Umeå, Sweden), has been sub-cloned into the "defective" retroviral vector plasmid, pBabe.

This vector does not contain any viral proteins and so is not replication competent. The SOD3 retroviral vector plasmid will be transfected into a "packaging" (ΨCRIP) cell line, which will thereafter secrete retroviral virosomes, capable of infecting our chronic wound and normal skin fibroblasts, without further cycles of replication. Such cell lines have been developed to reduce the risk of wild type Mo MuV generation via homologous recombination events.

**Host/vector system**

cDNA sub-cloning was previously performed using a pUC18 plasmid and E.coli HB 101 as the host strain. The SOD3 cDNA has been sub-cloned into a "defective" retroviral pBabe-SOD3 retroviral vector plasmid.

The pBabe-SOD3 retroviral vector will be transfected into a "packaging" cell line (ΨCRIP), permanently transfected with "helper virus", which provides the necessary viral components for creating infection competent virus, which will thereafter secrete retroviral virosomes, capable of coding for the inserted sequence. Such cell lines have been developed to reduce the risk of wild type Mo MuV generation via homologous recombination events. These will be able to infect our chronic wound and normal skin fibroblasts, without further replication cycles.

**Origin & function**

cDNA for the antioxidant enzyme superoxide dismutase 3 (SOD3) has previously been isolated and characterized from a human placenta cDNA library (Hjalmarsson et al, Proc. Natl. Acad. Sci. USA 1987;84: 6340-6344). cDNA sub-cloning was performed using a pUC18 plasmid and E.coli HB101 as the host strain.

Retroviral virions, capable of coding for the inserted sequence, will be used to infect our chronic wound and normal skin fibroblasts with SOD3, without further replication cycles.

**Evaluation of foreseeable effects**

Project Ref 130/01.2

Date Ackn'd 01/02/2001

CU2 Project Title INTRODUCTION OF NEUROTRANSMITTER RECEPTORS AND CELL SIGNALLING MOLECULES INTO THE MAMMALIAN BRAIN USING REPPLICATION-DEFICIENT ADENOVIRAL VECTORS WITH ENHANCED GREEN FLUORESCENT PROTEIN TAGS.

Class 2

Consent Granted not applicable

Project notified under transitional arrangements Y

Tick if notifying a connected programme of work N
Certain neurotransmitter receptors, including the N-methyl-d-aspartate (NMDA) - type glutamate receptor, are important for learning, memory and interneuronal communication within the brain. While NMDA receptors may initiate these processes, they also require intracellular signalling molecules, including protein kinases, proteases, and adapter proteins. While the role of many of these have been investigated using either traditional pharmacological techniques or genome modification, these lack both temporal and spatial specificity. The use of viral vectors will allow us to express these molecules more selectively in targeted brain regions and at specific developmental stages.

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

Project Additional Information

Purposes of the contained use

ig-h3 is the gene encoding keratoepithelin, which is associated with a number of corneal dystrophies. The role of this protein is not clear. Therefore ig-h3 has been incorporated in recombinant adenovirus in order to overexpress the protein in corneal organ and cell culture and determine the effects of the protein.

Recipient or parental organism

Replication deficient adenovirus type 5

Host/vector system
Host: 293, HeLa, CRL 11516 cell lines, corneal primary epithelial cell culture, corneal organ culture.

Vector: Recombinant replication deficient adenovirus carrying wild type and mutant (R555W, R555Q) ig-h3 cDNA and -galactosidase gene.

Origin & function

ig-h3 cDNA was extracted from fibroblast cells and cloned into p E1-cl, which produced the recombinant adenovirus by co-transfection with pJM17 in cultured 293 cells. Plasmids as well as 293 cells were obtained from Microbox Biosystems Inc (Graham FL 1984 EMBO J 3:2917-22)

Evaluation of foreseeable effects

The produced recombinant adenovirus had deleted E1 and E3 viral gene, and therefore is replication deficient. This means that it is able to infect cultured cells/corneas in vitro (ie. transfer its genetic material, including transgene, to the nucleus of the cells) but unable to produce any progeny virus. Thus there are no harmful foreseeable effects.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Only disposable plasticware will be used for the activities that involve contact with the adenoviruses. Waste will be immersed in 3% virkon solution. According to manufacturer's instructions 1% Virkon is sufficient for complete inactivation of adenovirus. Following virkon disinfection, waste will be autoclaved at 121 degrees C for 20 minutes, conditions which result in 100% effective kill, and subsequently will be incinerated.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The GMBA Safety Committee has assessed the proposed project and has approved it at Class 2. The control measures to be used and the location for the project have also been approved as being suitable and sufficient.

02/03/2022
VIRULENCE AND ANTIMICROBIAL RESISTANCE OF PSEUDOMONAS
AERUGINOSA, BURKHOLDERIA CEPA CIA AND PROTEUS MIRABILIS

Purposes of the contained use

Genetic manipulation of Pseudomonas aeruginosa, Burkholderia cepacia and Proteus mirabilis will be used to identify virulence factors and the basis for antimicrobial resistance in these human opportunistic pathogens. The research will lead to the development of strategies to prevent and treat infection with these bacterial opportunistic pathogens.

Recipient or parental organism

Three Gram negative bacterial species will be genetically manipulated: Burkholderia cepacia, Pseudomonas aeruginosa and Proteus mirabilis. All these species are classified as ACDP as Hazard Group II biological agents. They can all cause opportunistic infections in patients which are compromised, but do not normally cause infection in healthy individuals. In addition, Escherichia coli K12 general purpose cloning strains will be the primary recipient of recombinant DNA. These E. coli strains carry multiple mutations and have not been associated with any health or environmental risk.

Three genetic modifications methods will be used to study virulence and resistance in these bacteria:
(i) Mutagenesis. This forms the primary genetic strategy which will be employed. Mutagenesis will be carried out using bacterial transposons based on the Transposon Tn5 and by site-directed means aimed at specific gene targets involved in resistance or virulence. The resulting mutants will have an attenuated phenotype as compared to their parental strains and hence this procedure does not carry an associated genetic modification hazard.
(ii) DNA cloning and sequence analysis. In order to analyse the genomic DNA of B. cepacia, P. aeruginosa and P. mirabilis it will be subcloned. The host species used for this analysis will be standard E. coli K12 cloning strains which are safe and have been extensively used in this type of research. Narrow-host range plasmid vectors (e.g. pUC18) and phagemid vectors (e.g. M13) will be used to subclone DNA. Use of E. coli K12 as a general cloning host has proven to be a very safe means of studying the genetics of both B. cepacia and P. aeruginosa.

(iii) Genetic complementation. B. cepacia, P. aeruginosa and P. mirabilis DNA will also be incorporated into broad-host range plasmid vectors capable of replication in a wide range of Gram negative bacteria (e.g. pUCP vectors and pSCOSBC1/PA1 vectors). After construction of genetic libraries in E. coli K12, these recombinant vectors will then be used for self-cloning procedures such as the re-introduction of wild-type DNA into a corresponding B. cepacia or P. aeruginosa mutant. Self-cloning will also be used to examine expression of the cloned DNA. The broad host range vectors used for this procedure can only be introduced by electroporation and are not self-mobilizable between bacterial species. Only self-cloning of DNA will be carried out (i.e. B. cepacia DNA to B. cepacia host strains, P. aeruginosa DNA to P. aeruginosa host strains or P. mirabilis DNA to P. mirabilis host strains). Hence, the latter restrictions of the method will greatly reduce the potential risk associated with the genetic manipulation strategy.

The foreseeable effects of the genetic manipulation procedures outlined above will not lead to the creation of GMOs which possess a risk greater than that of the ACDP Hazard Group 2 parental strains.

---

**Host/vector system**

**Host organisms:**
- Escherichia coli K12 cloning strains; ACDP Group 1 microorganism; E. coli will be used as the general purpose cloning host for the majority of genetic manipulation.
- Pseudomas aeruginosa; ACDP Hazard Group 2 microorganism; P. aeruginosa strains will be one of the sources of genetic material and will also act as recipient host for DNA from other P. aeruginosa strains (self-cloning only).
- Burkholderia cepacia; ACDP Hazard Group 2 microorganisms; B. cepacia strains will be one of the sources of genetic material and will also act as recipient host for DNA from other B. cepacia strains (self-cloning only).
- Proteus mirabilis, ACDP Hazard Group 2 microorganism; P. mirabilis strains will be one of the sources of genetic material and will also act as recipient host for DNA from other P. mirabilis strains (self-cloning only).

**Vector systems**
- Transposon donor plasmids - plasmids pUTMini-Tn5 derivatives, pOT182 and plasposon derivatives of pTnModOTc. All these vectors carry the transposon Tn5 on suicide donor plasmids incapable of replication outside of E. coli hosts, but capable of transient transfer of plasmids by conjugal mating procedures. They will be used to create transposon mutants of the host organisms listed above.
- pUC18 and M13 DNA sequencing vectors - narrow host range plasmid vectors (incapable of self-transfer). These vectors and their commercially available derivatives will be used for most general purpose genetic manipulation.
- pUCP derivative, pSCOSBC1 and pSCOSPA1 - broad-host plasmid vectors that require electroporation for introduction into bacteria, incapable of self-transfer. The plasmids will be used to carry DNA between p. aeruginosa strains or between B. cepacia strains.
- pEX18Tc - broad-host range suicide plasmid vectors. This vector will be used to create site-directed gene knockouts in the P. aeruginosa and B. cepacia strains. It possesses sucrose counter-selection and has been designed to facilitate gene knockouts.

**Origin & function**

DNA will derive from Pseudomonas aeruginosa, Burkholderia cepacia and Proteus mirabilis. Genetic modification will be carried out to determine the function of genes.
involved in virulence and antimicrobial resistance of these bacteria. Marked transposons will be mobilised from E. coli into P. aeruginosa, B. cepacia and P. mirabilis. Mutants which demonstrate either susceptibility to various agents or a diminished capacity for virulence will be selected using laboratory models of disease. The genes which have been disrupted by these transposon insertions will then be identified by genetic analysis. To determine if these disrupted genes play a role in the actual observed phenotype, the wild-type gene will be cloned back into the mutants; restoration of the parental phenotype will then be examined. In addition, the genes may also be mutated by site-directed mutagenesis to create unmarked, non-polar mutations, in order to clarify their role in virulence and resistance. This gene knockout and complementation approach will be used to elucidate the genetic basis for virulence, pathogenesis and overall environmental fitness in P. aeruginosa, B. cepacia and P. mirabilis.

Evaluation of foreseeable effects

The foreseeable effects of the genetic manipulation procedures outlined above will not lead to the creation of GMOs which possess a risk greater than that of the ADCP Hazard Group 2 parental strains, P. aeruginosa, B. cepacia and P. mirabilis. The GMO strains will either carry gene mutations which render themselves less fit that their parental strains. Or they will be mutants which have been complemented with wild-type DNA in order to test its true function; hence they will not be carrying "foreign DNA." E. coli K12 general cloning strains will be the host receiving DNA from other species eg. P aeruginosa, B. cepacia and P. mirabilis. Genetic manipulation of these non-pathogenic E. coli K12 cloning strains has proven very safe and has no foreseeable effects or risks.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste will be inactivated by autoclaving with a predicted 100% degree of kill. Liquid culture waste will be collected in sealed vessels. All other waste (tips, tubes, petri dishes) will be placed in autoclavable boxes or discard tins with lids. The waste will then be sterilised by autoclaving. Autoclave cycles will be monitored for efficacy of kill and the sterility of the waste checked at regular intervals by culture. Laboratory cleaning and small-spill disinfection will be carried out with the broad-spectrum biocidal agent, Virkon, following the manufacturer's recommended procedures and specifications.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The G MBA safety committee has assessed the proposed project and approved it as Class 2. The control measures and the location for the project have also been assessed and approved as being suitable and sufficient.

Project Containment

Laboratory Activities Glass Houses Growth Rooms
**Project Ref** 130/02.2

**Date Ackn’d** 26/11/2002

**CU2 Project Title** IMPROVED INSECTICIDAL BACTERIA

**Class** Class 2

**Culture Vol Class 2** < 1 litre

**Consent Granted** not applicable

**Non-GMM**

**Project notified under transitional arrangements**

**Withdrawn**

Tick if notifying a connected programme of work

---

**Project Additional Information**

**Purposes of the contained use**

The proposed activity involves the modification of bacteria that are insecticidal and, although their target range is highly limited and there are no significant effects on eg. vertebrates, according to legislation, these organisms are "animal pathogens". As a result, level 2 containment is indicated. Since these bacteria are not human pathogens, the purpose of containment is to protect the environment from the release of the modified organisms and not to protect the human operator from the organisms with which he/she is working. Hence, derogations are sought under section 11 of this form.

**Recipient or parental organism**

Bacillus sphaericus  
Bacillus thuringiensis  
Brevibacillus laterosporus (formerly known as Bacillus laterosporus)  
Auxotrophic Bacillus subtilis strains may be used for some aspects of the work

**Host/vector system**
### Hosts:
Bacillus sphaericus, Bacillus thuringiensis and other gram positive microorganisms

### Vectors:
E. coli/Bacillus thuringiensis shuttle vectors. Standard gram-positive vectors such as pUB110 and their derivatives.

### Origin & function
For the purpose of understanding the nature of insecticidal toxicity of the parental strains and to enhance this activity, the project envisages the use of the genes of the following origins and functions:

**Origin of material:**
Bacillus sphaericus, Bacillus thuringiensis, Brevibacillus laterosporus

**Function:**
- Insecticidal toxin gene coding regions and control regions.
- Genes with potential effect on the insecticidal virulence of host bacteria (eg possible peptide antibiotic genes).
- Genes affecting gram positive phenotype in relation to toxin synthesis (eg germination genes).
- Promoter sequences.
- Repressor proteins and control sequences.
- Origins of replication from stably-maintained plasmids from the above species.

### Evaluation of foreseeable effects
No potential hazard to human health. The source bacteria and their toxins are not human pathogens. The manipulations envisaged are intended to increase the insecticidal potency of the resulting strains by the addition of new toxin genes to complement the pre-existing armoury of these bacteria. All the genes already exist in the environment. The parental bacteria are already used extensively in public health programmes for the control of human disease vector insects.

Environmental risks: As above, no toxicity is envisaged outside the range of insects that are targets for the parental bacteria. Therefore, although there is a limited risk from the environment that the modified bacteria could survive if released, there is no perceived hazard associated. Toxins are highly specific to a very narrow range of insect species with no effects on non-target organisms. They are naturally present in the environment worldwide.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not applicable.

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Since the organisms involved are not human pathogens, it is not necessary to protect the operator from the organisms. Therefore, the following derogations are sought:

- Negative pressure relative to immediate surroundings - not necessary
- Microbiological safety cabinet/enclosure - not necessary
- Use of gloves - not necessary
- Observation window or alternative so that lab occupants can be seen - not necessary

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Waste procedures:
* All GMO contaminated waste (tips, tubes, glassware, plasticware spent media etc) to be treated before disposal
Tips, eppendorfs, inoculating loops, small o/n cultures etc: Place in double thickness OPEN autoclavable bag, bearing autoclave tape strip, for later autoclaving.

- Transfer items to the designated disposal autoclave without spillage in secure outer containers
- Place autoclave bags inside autoclavable containers to collect any leakage
- Include a Thermolog S autoclave test strip in each disposal run to ensure proper function: INSIDE the container whenever possible (it is not sufficient to place the strip on top of the waste bag)
- Sterilisation is only successful if the dark bar on the indicator enters the "safe zone"
- Record the use of the test strip in the log book
- Autoclave at 15 psi for at least the following times:

Project Ref 130/03.1
The project aims to determine the role of protein kinase C (PKC) in breast cancer cell growth and acquisition of tamoxifen resistance. Although PKC pharmacological inhibitors exist, there are no good isoform selective ones, so their value is limited. We have previously found that adenovirus is an efficient way of delivering dominant negative forms of PKC to cells. Here we wish to use this method to "knock-out" PKC expression in these cells and determine the effect of that on the cells ability to proliferate, invade and apoptose.

Various long-term cultures of breast cancer cell lines. These cells do not contain other viruses, so there is no risk of recombination events. Transfection with virus will only be transient and the biological hazard therefore negligible. All work with these cells is routinely carried out at Class II and this will of course be continued, and all media will be autoclaved and all lab ware treated with 5% Virkon prior to disposal.

The vector systems to be used are commercially available and well characterised. Type 5 adenovirus vectors will be used which have been rendered replication deficient due to deletion of the E1 gene region, which is a recognised safety feature. The virus will be further disabled by partial deletion of the non-essential E3 gene region. As such it is unable to replicate in the host cells. Adenovirus has no mechanism for cytolysis so in culture most viral particles remain cell associated, although they can spread to neighbouring cells, leading to plaque formation. Expression using the adenovirus vector is only transient.

Adenovirus vectors are extremely efficient in vivo delivery systems (hence the wish to use them for these experiments) and can be spread by aerosols. This potential hazard will be contained by restricting manipulations with the virus to biological safety cabinets.

The wild-type and dominant negative kinase defective protein kinase C sequences to be used were recommended by Dr Ohba, Institute of Mol Oncology, Showa University, Tokyo. The adenovirus containing these sequences were provided by Dr D Murphy of Bristol University and grown on in association with Dr Gavin Wilkinson, Dept of
Wild type PKC alpha cDNA (-4~ +2647) will be used. Kinase defective PKC-alpha dominant negatives contain a single base pair mutation at position 368 (K→R).

Wild type PKC delta cDNA (-12~ +2525) and kinase defective, dominant negative PKC delta containing a 4 bp mutation at position 376 (K→A) will be used.

These sequences will be used to infect the breast cancer cells to determine the effect of over or non-expression of these signalling molecules on cell proliferation and Tamoxifen resistance. Only the infection part of the project will be carried out under the current project.

Evaluation of foreseeable effects

There is obviously a potential hazard associated with using adenovirus recombinants to express transgenes that are overtly transforming or have a strong capacity to promote host cell proliferation. Protein kinase C is a signal transduction molecule associated with cell proliferation in a number of cellular systems. Although not thought to be the driving force behind cell replication, it does appear to act as a rheostat, enhancing proliferation/apoptotic and invasive responses. The inserted gene product could therefore potentially be harmful, however due to the transient nature of the infection, this risk is thought to be minimal. Dominant negative mutants of PKC have previously been widely used in other laboratories and by the co-applicant Dr J Assender at Bristol University. As the adenovirus is replication-deficient due to E1 and E3 deletions, they can not replicate in host cells unless E1 sequences are provided in trans (which will not be the case in this study). It is considered highly unlikely that this could happen spontaneously. Even if it did, evidence suggests that recombination would be associated with spontaneous loss of the transgene. Furthermore efficient delivery of large number of viral particles will be required to infect target cells, which is unlikely to happen, in vivo. Since the adenovirus is replication deficient, no persistent long term effects are likely.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The tissue culture cabinet and any potentially contaminated areas will be disinfected with 1% Virkon according to an approved protocol. Access to the laboratory will be restricted. Areas in which the virus is stored will be clearly labelled and kept locked when not in use. The laboratory door will be kept shut, a designated lab coat worn and designated pipettes used. Hands will be washed before personnel leave the room. Virus in solution (tissue culture media and buffers such as PBS) will be destroyed by autoclaving. Plastic ware, such as pipette tips and culture dishes will be fully immersed in 5% Virkon for at least 4 h. Pipette tips will then be disposed of in sharpsafe bins. Other solid wastes, such as soaked culture dishes and paper towels will be placed in unsealed autoclavable bags and autoclaved for 1 h at 129 degrees C before putting in yellow bags. The high concentration of Virkon used for soaking tips will ensure that the high organic content of the media is overcome and 100% killings should be achieved.

### Project Ref 130/03.2

- **Date Ackn'd**: 08/07/2003
- **CU2 Project Title**: TRACKING THE DEVELOPMENT OF ARTICULAR CARTILAGE USING PANTROPIC REPLICATION DEFICIENT PSEUDOTYPED RETROVIRUSES.
- **Date Project Ceased**: 02/12/2015
- **Class**: Class 2
- **Culture Volume**: ≤ 1 litre
- **Non-GMM Consent Granted**: not applicable
- **Project notified under transitional arrangements**: N

### Project Additional Information

The aim of the project is to use a pantropic replication-deficient pseudotyped retrovirus to follow both the development of articular cartilage in mouse, monodelphis and chick. The project is funded by the ARC and will make use of the Clonetech Pantropic retroviral expression system (K1063-1) to stably introduce a marker gene (lac z/GFP) into a chondroprogenitor cell population at the articular surface of developing joints. The virus will be introduced into the surface zone cells of neonate joints by...
microinjection and the fate of the cells followed by histology. Additionally, cultured bovine chondroprogenitors will be infected with marker genes and the fate of infected cells traced after microinjection into developing chick wing buds.

### Recipient or parental organism

Transient transfection of GP293 cells and chondrocytes. These cells do not contain other viruses, so there is no risk of recombination events. Transfection with virus will only be transient and the biological hazard therefore negligible. All work with these cells is routinely carried out at Class II and this will of course be continued, and all media will be autoclaved and all lab ware treated with 5% Virkon prior to disposal.

### Host/vector system

**Host organism**
The 293 GP cell line derived from human Ad5 transformed embryonal kidney cell line 293, stably expressing the gag and pol proteins for Moloney Murine Leukaemia Virus (MoMLV). Retroviral vectors generated from such cells are non-infectious since the virions contain none of the envelope proteins required for cell entry.

**Vector system**
Clonetech Pantropic Retroviral Expression System (K1063-1)

### Origin & function

A commercially available kit (see above) will be used to produce replication-deficient viruses carrying innocuous markers (lac z and GFP) to follow articular cartilage development and plasticity in vivo.

### Evaluation of foreseeable effects

The kit we will use is commercially available and since the virus is incapable of making the envelope proteins outside the packaging cell line, it is replication deficient and therefore poses a limited threat. However once the virus has been co transfected in the packaging cell line with the envelope glycoprotein, the virions produced are replication deficient, but highly infective. All work will therefore be performed in class II biological safety cabinet.

**Date of Significant Change**

**Project Additional Information**
### Purposes of the contained use

The aim of this project is to transfect full length and truncated (producing a functionally inactive protein) DNA encoding src kinase into endocrine-sensitive and endocrine-resistant mammalian cancer cells in order to investigate the role that src kinase plays in mediating the phenotype of endocrine resistance.

### Recipient or parental organism

Human breast cancer cells will be the recipient of the src cDNA-containing vector. These cells are in wide use and have been extensively characterised in this and other departments in terms of their protein expression and in vitro behaviour (low in vitro metastatic ability).

A possible consequence of the over-expression of active src kinase in these cells may be an increased growth rate over their parental cells. However, since these src mediated effects may require the presence of other growth factors receptors not normally present/expressed in low abundance on these cells, a phenotypic change may be absent.

### Host/vector system

src cDNA pre-cloned into a mammalian expression vector will be sourced from a reputable molecular biology company. We will choose a company that can provide src in a suitable vector with its expression under the control of the CMV promoter.

### Origin & function

Src cDNA will be supplied by a reputable company where their products have undergone rigorous testing prior to marketing. The intended function of the src DNA is for it to be expressed in breast cancer cells in order to determine its effects on celluar behaviour (such as growth). Conversely, expression of functionally inactive src (dominant negative) in these cells will aid in the identification of cellular processes in which src plays a key role.

### Evaluation of foreseeable effects

Any alterations in the growth rate of the transfectants will be determined by an in vitro growth assay. This will involve growing cells (stable transfectants) in 96-well microtitre plates for a suitable period of time (5-7 days) following which they are incubated with a growth indicator prior to lysing. Once lysed, the plates may be read on a microtitre plate reader.

The motility of src-overexpressing cells will be analysed by plating the cells on a fibronectin-coated surface and allowing migration to occur over a period of 24 hours. Following fixation of cells, migrating cells are stained and then counted using a microscope.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be disposed of by the addition of a chlorine-based disinfectant (5% w/v Virkon) for 24 hours prior to removal. Use of this chlorine-based disinfectant will also be employed for inactivation of GMMs in discarded containers and in cases of liquid spillage. This will result in 100% GMM death.

Solid waste will be treated with 1% Virkon for 24 hours to ensure 100% cell death.

In the absence of the principal investigator, maintenance and waste management of transfected cells will be performed by a qualified member of staff with the tissue culture department, appropriately trained in the handling of GMMs.
The GMBA Safety Committee has assessed the proposed project and has approved it at Class 2. The control measures to be used and the location for the project have also been approved as being suitable and sufficient.

**Evaluation of foreseeable effects**

Possible novel-harmful properties of the mc007 transgene: MCV mc007 like Human Papilloma Virus protein E7 binds Rb protein. The strength of this interaction in comparison to HPV E7 and the question if this binding leads to enhanced cell cycle progression and cellular transformation is the subject of this work. The potential hazard of inserting possible oncogenes, like mc007, into replication-deficient adenoviruses is the risk of recombination events between the recombinant and wildtype viruses, to generate a replication-competent recombinant adenovirus. Increased virulence or change tissue tropism are not to be expected from the insertion. However, mc007 might have other hazardous biological properties, as yet unknown. As a safety measure, the MCV transgene will be under the control of a tetracycline promotor. It is recognised, however, that very low level of transgene expression might occur in the absence of the tetracycline inducer.

Possible novel-harmful properties of other viral transgenes: MCV genes mc162, mc002L, mc161R, and mc026R have at most an indirect effect on cell proliferation, via interference with endosomal sorting mechanisms and protein ubiquitylation. Pleiotropic effects would be probably be mediated through the EGF receptor signalling.
cascade. For mc162 preliminary experiments indicate that it induces endosomal vesicle anomalies, resulting in cytotoxicity and cell death (apoptosis). Again, these viral proteins might have as yet unknown hazardous biological properties.

As a safety measure and to avoid cytotoxicity and apoptosis, all viral transgenes will be expressed under the control of tetracycline inducible promoter.

Cellular protein to be expressed in the replication deficient AdenoX adenoviral vector system are the human proteins of the ESCRT pathway and associated E3 ubiquitin protein ligases. These include Aip4, Nedd4, Hrs, Stam, Stam2, PI3P, SNX, and SNAP25. There is no evidence that overexpression of these human cellular genes will cause increased virulence of change of tissue tropism of the recombinant adenoviruses. To the contrary, overexpression will cause endosomal vesicle anomalies most likely resulting in cytotoxicity and apoptosis.

As a safety measure and to avoid cytotoxicity and apoptosis, all cellular transgenes will be under the control of a tetracycline inducible promoter.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Us eof recombinant adenoviruses will be restricted to class II safety cabinets. Infectious waste will be disinfected, autoclaved and then incinerated. Disinfection of liquid waste occurs in at least equal volumes of 3000ppm sodium dichloroisocyanurate. Small amounts of liquid disinfected waste will be autoclaved. Large amounts of liquid inactivated waste can be discarded to main drainage after 4 hours. Inactivation of adenoviruses in the disinfection procedure will be confirmed by a cell culture assay, where appropriately diluted and pH neutralized liquid inactivated waste is inoculated into 293 cells, before discarding into mains drainage. Pipettes or pipette tips are immersed in 3000ppm sodium dichloroisocyanurate (minimum final concentration), then autoclaved and incinerated. Spillage procedures are outlined in the Level 2 containment regulations.

Previously described adenovirus susceptibility to disinfectants: susceptible to 1% sodium hypochlorite, 2% glutaraldehyde and 0.3% sodium dichloroisocyanurate. Recommended: frsh solution of any disinfectant for 4 hours.

Previously described adenovirus susceptibility to physical inactivation: sensitive to heat; 1 hour at 56 oC is sufficient to inactivate virus.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The committee fully agreed with assignment to Containment Level 2 and Activity Class 2. Small alterations to the original risk assessment were requested regarding control of disinfection procedure and the likelihood of recombination between MCV and adenoviruses. The alterations and additional explanation were made and are part of the attached final RA for this project, which was accepted by the committee.

Project Containment
The aim of the project is to investigate the signalling pathways downstream of activated Ras in primary human thyroid follicular cells. We wish to use a commercial lentiviral system, Virapower from Invitrogen. This is a 3rd generation system that has been modified for enhanced safety features. We will introduce various Ras mutants into thyroid cells and dissect signalling pathways involved in proliferation. Other genes used are B-RAF, Ret/PTC and p21 and eGFP.
Origin & function

The following are in pBABE neo H-Ras V12 cDNA (activated H-Ras oncogene), H-Ras V12/G37 (point mutant activating Raf/GEF pathway alone), H-Ras V12/S35 (point mutant activating Raf/GEF pathway alone), H-Ras V12/C40 (point mutant activating P13K pathway alone).

Evaluation of foreseeable effects

The viral particles produced in this system are replication incompetent and only carry the gene(s) of interest. No other viral species are produced. This also means that none of the structural HIV genes (necessary for production of viral progeny) are present in the packaged viral genome. Gag, pol, rev and envelope genes are not present in the viral genome and are therefore never expressed in the target cell, so no new virus can be produced.

The stable cell lines that are made with the lentiviral system would not contain any of the packaging proteins. These proteins are only used to package the viral particles from the 293T cells. They are provided in trans, so they are not part of the viral particle themselves, and therefore not present when the target cell is transduced and the gene of interest stably integrated.

All four plasmids have been engineered to not contain any regions of homology with each other to prevent rare, but unwanted, recombination events that could lead to the generation of a replication competent virus. The expression of the gag-pol sequence is rev-dependent, thus preventing the expression of gag-pol in the absence of rev.

The gene transfer vector pLenti6/V5 has been modified to be "self-inactivating". A deletion has been made in the 3' LTR (called "delta U3") that has no effect on the generation of viral genome for packaging in the producer cell. However once the produced virus transduced a target cell, the mechanisms of reverse transcription use the 3'LTR as a template to create the 5'LTR. The end result is an integrated viral genome that is defective in both its 5' and 3' LTRs. Thus, there is no transcription of the viral sequences in the target cell and no packagable viral genome is produced. This self-inactivation also allows long-term expression from adjacent heterologous promoters.

This means that transduction with these lentiviral vectors ends with the gene of interest integrated into the host cell genome with no production of viral particles. Tat has been completely removed from the lentivirus system. The HIV LTR (in the pLenti6 vectors) has been modified and is now a hybrid fusion between the RSV promoter and the 5' LTR, and this modification makes it a stronger promoter and removes its dependence on tat for virus production. Tat is not required in any downstream events.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All lentiviral work will take place in a dedicated Class II facility. All liquid waste is sterilised at point of use by sodium dichloroisocyanurate. All solid waste is sterilised in an adjacent autoclaving facility. Use of glass and needles will be avoided to reduce the risk of sharps injury.

Autoclave thermocouple tested annually. Also daily monitoring of efficacy of autoclave. Discussed determining efficacy of disinfectants with HSE inspector on recent visit. Relying on manufacturer's quality control and the very unstable nature of GMOs involved.

**Significant Change ID**

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

The purpose of the planned GM work is to test a new therapeutic poxviral HCV vaccine in vitro and in a small animal model. We want to clone the full length HCV polyprotein of HCV type 1 strains and HCV type 4 strains into vaccinia virus MVA. We want permission to use a recombinant vaccinia virus WR containing a HCV type 1 polyprotein (vNM-HCVpp-923711; from pCVH77C-Yanagin et al., 1997) that has previously been constructed at the University of Heidelberg. The recombinant viruses are
to be tested in a transgenic mouse model of chronic HCV infection.

Recipient or parental organism

The GM organisms we want to notify the HSE about are
1. vNM-HCVpp-92311: vaccinia virus WR containing HCV typ 1 a polyprotein without regulatory sequences from pCVH77C; made at the University of Heidelberg as L (S) 2 organism
2. Vaccinia virus MVA containing polyproteins from HCV type 1 and 4 strains without regulatory sequences; planned.

Host/vector system

1. Vaccinia virus WR (Western Reserve; obtained from B. Moss 1996, contact bmoss@nih.gov).
2. Vaccinia virus MVA (obtained from ATCC in 2002 while in Heidelberg, transferred to Cardiff 2003)

Origin & function

We ask for permission to further characterise the completed vaccinia WR construct and proceed with the construction of the planned MVA constructs (particle morphology/immune EN; hostrange and induction of antiviral and anti inflammatory cytokines in eucarvotic cell lines, vaccination and challenge of Balb/c and HCV transgenic mice).

Origin of the recombinant vaccinia virus vNM-HCVpp-923711: Receptor virus: vRB12; Donor plasmid: pRB21 (Blasco and Moss, Gene 158: 157pp, 1995). Insert derived from pCVH77C (Yanagin et al., 1997): HCV-polypeptide (HCVpp); Cloning: HCV-ORG without regulatory signals (pRB-HCV-clone 9-2) Nadja Melquiot, Christoph Springfeld, J Encke, Joachim J. Bugert (2001-2002 unpublished results); Isolation of recombinant VV: 28.9.2002 by Nadja Melquiot and Joachim J Bugert (2002, unpublished results); Resulting in: vHCV-92-3 (primary isolate), vHCV-923-78, vHCV-923-7-1, vHCV-923-71-1; Final virus: vNM-HCVpp-923-711 (triple plaque purified on CV-1 (ATCC: CCL-70)-8.10.2002. This virus will be assessed regarding its hostrange and induction of an innate immune response in a number of mammalian cell lines (eg. HUH7, HepG2, CV-1, RK13, HeLa, A549). The WR recombinant HCV vaccinia virus will be used as a challenge virus will be used as a challenge virus in the mouse model to assess the efficacy of prior vaccination with cDNA and recomabt adenoviruses (separate project within the connected programme of work).

Recombinant vaccinia virus MVA will be prepared using the pLW44 donor plasmid and MVA obtained from the ATCC in chicken embryo fibroblasts made from embryonated chicken eggs. HCV typ 1 a and type 4 partial and if possible genomes will be isolated from patient material (serum) genotyped in Heidelberg University clinical centre and in the Cardiff NPHS virology lab.

HCV connected program of work: Molecular Virology of Hepatitis C virus

HCV 2.1 Maintenance of HCV full length open reading frame and subfragments in bacterial plasmid cloning vectors and donor plasmids in E. coli. HCV 2.2 Investigation of a pRB binding motif located in HCV E2: expression of full length and truncated HCV E2 protein in E. coli as a GST fusion protein. HCV 2.3 Expression of HCV full length open reading frame and selected HCV subproteins in mammalian cells using replication incompetent adenoviral expression vectors. HCV 2.4 Expression of HCV full length open reading frame and selected HCV full length open reading frame and selected HCV subproteins in mammalian cells using vaccinia virus expression vectors. HCV 2.5 Expression of subgenomic HCV replicons in mammalian cells. HCV 2.6 HCV transgenic mouse lines.

Evaluation of foreseeable effects

The most hazardous construct is likely the one with the HCV open reading frame without regulatory signals from pCVH77C cloned into replication competent vaccinia virus WR: recombinant Vaccinia Virus vNM-HCVpp-923711.

Properties of VV WR: VVWR has a broad cellular host range and infects humans and a variety of other mammals. However, VV WR has been one of the three vaccinia strains used by the WHO in the smallpox eradication campaign. The construct vNM-HCVpp-923-711 qualifies as a recombinant HCV vaccine in its own right, specifically because it excludes the HCV 5' and 3' NTR regulatory signals-making the production of infectious HCV particles containing replication competent HCV genomes impossible. To be expected are HCV - VLPs (virus like particles) or recombant vaccinia showing HCV antigen on their virion particles.

Properties of the HCV ORF insert: 1. HCV infection leads to hepatocarcinoma but the Hepatitis C virus genome does not encode known oncogenic proteins. 2. Hepatitis
C virus has a reduced susceptibility to tissue interferon action in vitro, which has been offered as an explanation for the chronic nature of the infection. 

Re 1: In contrast to natural (chronic) HCV infection, vaccinia recombinants will express potentially oncogenic proteins only for a very short period of time, because of their lytic nature. This reduces the likelihood of oncogenesis in the accidental human host to a negligible level.

Re 2: In the case of vaccinia recombinants HCV ORF, a reduced tissue interferon response triggered by HCV proteins are not relevant, because vaccinia virus encodes interferon reducing activities through at least 3 different pathways. This has no effect on the immediate eradication of the virus by the human immune system and the generation of a lasting neutralising immune response.

Properties of VV MVA: Modified vaccinia virus Ankara (MVA) has been adapted to chicken cells during 573 passages in and chicken embryo fibroblasts. MVA is effectively disabled in human cells and consequently in the human host, because the viral DNA cannot be packaged into virus particles (Krijnse-Locker et al., 2000).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Balb/c mice and transgenic HCV mice will be infected with recombinant vaccinia viruses. These experiments will take place in the Cardiff University-Biomedical services Unit and the animals will be kept in Scantainers.

For animal infection experiments, vaccinia viruses will be transported to the animal facility (in the same building, one floor up). Viruses will be in plastic vials, packed into sealable plastic bags, lined with absorbent paper towels, inside sealable plastic containers (L3 standard) with carrying handles and attached biohazard stickers. Virus suspension volumes carried in this way will not exceed 1ml. In the event of spillage, GM spillage procedures will be followed. Infection of laboratory animals will be carried out in the animal facility in class II microbiological safety cabinets (max dose 10^7 pfu).

Animals infected with replication competent VV WR will be housed in negative pressure bubble isolators for the duration of the experiments (usually 14 days).

Infection will be carried out using sharps (needles) via the footpad and the intraperitoneal (ip) route. Personnel carrying out these experiments are trained to a high level to avoid needle injuries, and are aware of all the risks involved with working with vaccinia virus.

All animal technicians taking care of the animals will be made aware of the symptoms of vaccinia infection. All care-taking procedures outside of negative pressure bubble isolators will be carried out using gloves and respiratory protection. All waste products, including water not drunk, will be autoclaved. Isolators will be disinfected with Virkon after use. Animal carcasses will be bagged inside the negative pressure bubble isolators in case of a sick animal or inside a class II safety cabinet at the humane endpoint (day 14), then frozen at -20 degrees C and later disposed by autoclaving.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Enclosed to this application are:
1. The assessment of the German Central Commission for Biological Security (Zentrale Kommission fuer Biologische Sicherheit-ZKBS) in the German language, which finds biosafety level 2 containment adequate for experiments with the recombinant vaccinia virus WR containing HCV polyprotein lacking regulatory sequences: Permission for a S2 project with the number AZ:57-8/8817.40-020/UNI.HD..52.02-13 to the construct in Germany.

2. Letter of the Heidelberg University BSA, describing the details of the project permission for Heidelberg, including the translation of the statement of the German HSE equivalent (Zentrale Kommission fur die Biologische Sicherheit at the Robert Koch Institut in Berlin) is attached to this GM proposal.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All laboratory work involving recombinant vaccinia viruses will be carried out in L2 containment level labs. All personnel will be trained in recognising vaccinia virus infections, awareness of human-to-human-transmission, and the increased risk for individuals suffering from eczema or other immune disorders (eg atopic dermatitis, severe acne, impetigo, contact dermatitis, psoriasis, chickenpox, steroid medication, pregnancy, infection from skin pathogens). The exposure route via the conjunctiva will be particularly stressed and the use of adequate protective gear enforced in the lab. All personnel will be monitored by the Occupational Health Service at the School of Medicine.

Laboratory work will be carried out in class II safety cabinets, with personal wearing gloves. Disposable plastic pipettes and pipette tips will be used. Recombinant viruses
will be used under conditions avoiding the generation of aerosols. Flasks containing virus will be kept sealed outside of the safety cabinets. Centrifugation will be carried out in sealed buckets, that will only be opened in safety cabinets. All waste materials will be collected in plastic bags in the safety cabinets, the bags will be sealed inside and then autoclaved. No sharps will be used except when inoculating animals (see point 8).

Removable equipment and interior surfaces of the safety caninets will be sprayed with Incidin PLUS (Ecolab, Swindon, UK) containing the patented active substance Glucoprotamine with wide effect spectrum against bacteria (also MRSA and TBC), fungi, papova-, adeno-, herpes-, rota- and hepatitis-B-viruses (HBV) in MADT and antigen test, as well as AIDS agent (HIV)-certified by the German Society for Hygiene and Microbiology (DGHM). Spillage of GM material will be treated with hypochloride. For the quality assurance of the disinfection and autoclaving procedures, vaccinia virus contaminated Incidin disinfected and bleached plasticware, as well as autoclaved waste material will be rinsed with a small volume of PBS and tested for rest-infectivity on CV-1 cells in a standard plaque assay.

The main concern of the Cardiff University GM committee was, what would be the effect of the insert on the wild type organism. The committee accepted the Pis interpretation on what would be the most hazardous GMO and also the letter from the University of Heidelberg BSA. The conclusion of the committee was to write to the HSE for advice.

The HSE Inspector was then involved in the safety assessment of this project. His main concern was, whether there was a possibility of a replicating HCV being produced from HCV-vaccinia recombinants (WR).

The Principal Investigator replied to the query confirming that there was no possibility for replicating HCV coming out of HCV-vaccinia infected eucaryotic cells. He explained that the part of the HCV genome to be used in this project is lacking all HCV untranslated 5' and 3' regulatory sequences, without which a packaged particle cannot replicate. Accidental infection with a particle packaging such a replication-incompetent genome would lead to immunisation. He pointed out that this was the essential point why German authorities allowed the project to be conducted under level 2 safety containment (see enclosed letter).

The BSA of Cardiff University, received no more adverse comments from the Cardiff University GM committee when she circulated the risk assessment after the principal investigators comments to the HSE Inspector's question. The GM committee recommended to submit a notification as Class 2.

Project Ref 130/06.2

Biofilm formation by GFP-tagged Pseudomonas aeruginosa.

Class 2

Consent Granted

Not Applicable

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

Project Additional Information

The purpose of our experiments is to utilise the GMM Pseudomonas aeruginosa strains to assess the proportion and spatial distribution of the organisms in in vitro biofilms comprising of mixed bacterial species. Using this approach it will be possible to enhance our knowledge on the interaction of different bacterial groups with biofilms that may develop within clinical settings.

Pseudomonas aeruginosa is a pathogen listed within ACDP hazard group 2. The organism is a Gram negative bacillus, aerobic, non-sporulating and is motile by polar flagella. As a pathogen Ps. Aeruginosa greatest risk of causing disease is in the immunocompromised where it colonises individuals in their respiratory tracts or urinary tracts. This colonisation can lead to pneumonia and bacteremia; chronic respiratory infections among cystic fibrosis patients; eye infections in contact lens wearers; nosocomial infections in immunocompetent patients. Mode of transmission is by direct contact with contaminated water, aerosols or aspirations. Survival of the organism for several months in water with minimal nutrients is possible. The organisms is susceptible to many disinfectants including 1% sodium hypochlorite, 70% ethanol, and 2% glutaraldehyde. It is also sensitive to extended spectrum penicillins, aminoglycosides, cephalosporins, polymixins, fluoroquinolones. The first line antibiotic treatment is an aminoglycoside with a B-lactam pencillin. The bacterium is inactivated by moist heat (121 C for 15 min).

In terms of laboratory hazards, no acquired infections with Ps. Aeruginosa have been reported to date, there are no special hazards and the primary hazard is by accidental parenteral inoculation; direct contact of mucous membranes with infected material; inhalation of infectious aerosols and ingestion.

Recipient or parental organism

Host/vector system

27/02/2006
No vectors are utilised by the researchers as the GFP strains will be gifted from our collaborators in Denmark.

**Origin & function**

The DNA sequences inserted are those from a mini-Tn7 transposon system. The GFP expressing strain has received a pUC19 derived plasmid carrying a GFPmut3.1 variant of the Aequorea victoria GFP. In addition, this plasmid vector also contains antibiotic resistance markers (ampicillin) and a mob region. Once the mini-Tn7 transposon has been inserted, the plasmids are lost from the bacterial strains. The inserted GFP2 gene is constitutively expressed and controlled by a modified lac promoter PA1/04/03. For cfp and yfp expressing strain, the mini-Tn7 transposon system contained 740 bp PCR amplicons from commercial templates (pECFP and pEYFP; Contech).

**Evaluation of foreseeable effects**

No work in the construction of the GMO will be undertaken at Cardiff University.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Biosafety level 2 practices will be used throughout. The organisms will be cultured within an enclosed fermenter. Protective clothing in the form of Howie style laboratory coats will be worn for all experiments. All cultures will be stored in sealed containers that are appropriately labelled. Laboratory spills will be treated by gently covering with paper towels and application of a 1% sodium hypochlorite solution. Contact time of at least 30 min before clean up and disposal.

All waste material will be autoclaved within using the autoclave housed within the laboratory. A kill rate of 100% is expected from the autoclaving procedure. All autoclave waste is subsequently disposed of by incineration.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

### Project Additional Information

**Purposes of the contained use**

The aims of the project are to determine whether the transfection of human chronic wound fibroblasts to over-express the antioxidant enzyme, superoxide dismutase 3 (SOD3), can reverse the chronic wound fibroblast phenotype and protect these cells from oxidative stress-induced ageing, allowing normal wound healing functions (proliferative life-span, cell migration, extracellular matrix turnover, etc) to be maintained. We intend to SOD3-transfect the human chronic wound and normal skin fibroblasts via retroviral infection, using the retroviral vector pBabe-puro, based on established protocols (Serra et al. J. Biol. Chem. 2003; 278: 6824-6830).

**Recipient or parental organism**

The GMO in question is a pBabe-SOD3 retroviral vector and the pBabe-puro (empty mock) retroviral vector control. The pBabe-SOD3 retroviral vector will not be constructed at Cardiff University, but will be a gift from Professor Thomas von Zglinicki (Institute of Ageing & Health, Newcastle University).

The pBabe-SOD3 retroviral vector and pBabe-puro (empty mock) retroviral vector are based on the pBabe series of vectors, encoding a puromycin resistance gene, transcribed from the 3'long terminal repeat of the viral vector (Morgenstern and Land, Nucleic Acids Res. 1990; 18: 3587-3596). The pBabe retroviral vectors are based on the Moloney murine leukaemia virus (Mo MuLV), expressing the inserted genes from the Mo MuLV 3'-long Terminal Repeat. The characterised, full length SOD3 cDNA, obtained from Professor Stefan Marklund (University of Umea, Sweden), has been sub-cloned into the "defective" retroviral vector plasmid, pBabe.
This vector does not contain any viral proteins and so is not replication competent. The SOD3 retroviral vector plasmid will be transfected into a "packaging" (ΨCRIP) cell line, which will thereafter secrete retroviral virions, capable of infecting our chronic wound and normal skin fibroblasts, without further cycles of replication. Such cell lines have been developed to reduce the risk of wild type Mo MulV generation via homologous recombination events.

Host/vector system

cDNA sub-cloning was previously performed using a pUC18 plasmid and E.coli HB101 as the host strain. The SOD3 cDNA has been sub-cloned into a "defective" retroviral pBabe-SOD3 retroviral plasmid.

The pBabe-SOD3 retroviral vector will be transfected into a "packaging" cell line (ΨCRIP), permanently transfected with "helper virus", which provides the necessary viral components for creating infection competent virus, which will thereafter secrete retroviral virions, capable of coding for the inserted sequence. Such cell lines have been developed to reduce the risk of wild type Mo MulV generation via homologous recombination events. These will be able to infect our chronic wound and normal skin fibroblasts, without further replication cycles.

Origin & function

cDNA for the antioxidant enzyme superoxide dismutase 3 (SOD3) has previously been isolated and characterized from a human placenta cDNA library (Hjalmarsson et al, Proc.Natl.Acad.Sci.USA 1987; 84: 6340-6344). cDNA sub-cloning was performed using a pUC18 plasmid and E.coli HB101 as the host strain.

Retroviral virions, capable of coding for the inserted sequence, will be used to infect our chronic wound and normal skin fibroblasts with SOD3, without further replication cycles. Transfected cells will be selected using puromycin, as this vector has been constructed to induce puromycin-resistance in cells. On transfection, puromycin-resistant clones will be selected and used in future in vitro wound healing-related experiments. The human chronic wound and patient-matched, normal skin fibroblast cell strains involved, have previously been derived from biopsies, collected with full Local Research Ethical Committee approval and informed consent from individuals (N=3), attending the Wound Healing Research Unit UHW.

Evaluation of foreseeable effects

For these experiments using retroviral gene transfer of SOD3, as SOD3 is a recognized enzymic antioxidant, we already know that the expression of SOD3 can lead to an increase in cellular proliferative lifespan and reduce oxidative stress. The present project wishes to determine whether the over-expression of SOD3 can reverse the chronic wound fibroblast phenotype and protect these cells from oxidative stress-induced ageing, allowing normal wound healing functions (proliferative life-span, cell migration, extracellular matrix turnover, etc) to be maintained. This will be undertaken using experimental techniques routinely used within the Department.

The pBabe-SOD3 retroviral vector has previously been extensively characterized by Professor Thomas Von Zglinicki's Group (Institute of Ageing & Health, Newcastle University), who constructed the retroviral plasmid (Serra et al. J Biol. Chem.2003; 278: 6824-6830). The vector is replication incompetent because it lacks the genes required to make viral capsid, and only carries the gene of interest. The vector is "packaged" in a "packaging" cell line (ΨCRIP), which produces virus capable of infecting the targets cell of interest; but without further replication cycles. Such cell lines have been developed to reduce the risk of wild type Mo MulV generation via homologous recombination events. Therefore, it is highly unlikely that homologous recombination events or transfer of genetic material between the GMO and other organisms would occur.

A potential hazard is obviously the exposure of humans to the retroviral particles. However, this will be minimized by performing all manipulations in a Class 2 Biological Safety Cabinet, in a designated laboratory facility. Access will be limited to Staff trained in ACGM level 2 procedures. These Staff will also have access to laboratory coats and disposable purple nitrile gloves (guaranteed to prevent viral particle penetration). All disposable material that has had contact with the viral particles will be chemically disinfected and autoclaved, prior to disposal. The use of sharps will be avoided to prevent accidental injury-related risks. Consequently, any risks of exposure of humans or the environment are very low.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable
None. All the measures specified as requirements for Level 2 containment will be implemented.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Virus will be held in a Class 2 containment facility with available autoclave and disinfectant. The Class II cabinet will be cleaned before and after use. Before use, the cabinet will be cleaned with sodium hypochlorite (Effervescent Chlorine Tablets, 1 tablet/litre water, 600 ppm concentration), followed by spraying with 70% ethanol. Chlorine tablets have been previously demonstrated by the Manufacturers' to be effective against all viruses at a recommended final concentration of 250ppm.

Anything used as part of the experimental procedure will be soaked in 600ppm sodium hypochlorite overnight, prior to removal from the cabinet. These will then be autoclaved before disposal.

After use, the cabinet will be sprayed with 70% ethanol and cleaned with sodium hypochlorite, before removing any contents (including stripettes, tips, flasks, medium, etc) from the cabinet. Anything used as part of the experimental procedure will be soaked in 600ppm sodium hypochlorite overnight, prior to removal from the cabinet. These will then be autoclaved before disposal. After use, the cabinet will be sprayed with 70% ethanol and cleaned with sodium hypochlorite, before removing any contents (including stripettes, tips, flasks, medium, etc) from the cabinet.

Is an emergency plan required according to regulation 20? N

Project Ref 130/06.4

02/03/2022
Project Additional Information

**Purpose of the contained use**

The project involves the growth of fibroblasts from the human progeroid syndrome Werner. These fibroblasts grow more slowly and have a much-reduced replicative life span than normal fibroblasts. The kinase inhibitor SB203580 rescues this reduced growth. The drug is believed to inhibit the MAP kinase p38 (MAPK14). The GM involves the introduction of an SB203580-resistant form of p38 into Werner syndrome fibroblasts using retroviral transfer and testing the effects of SB203580 on the resultant cells. A wild type p38 will be used as a control. To this end mutant and non-mutant forms of p38 will be cloned into a series of retroviral vectors. If we have problems cloning MAPK14 into retroviral vectors we will use pre-existing adenoviral vectors which already contain the mutant and non-mutant forms of p38. These plasmids will be co-transfected with pJM17 into 293 cells which supply an E1 helper function. Recombinant virus stocks will be plaque purified through reinfected 293 cells.

**Recipient or parental organism**

Host organisms are primary human cells, in particular fibroblasts. These cells may also have been infected with retroviruses expressing human telomerase (hTERT).

**Host/vector system**

All genes will be introduced into a series of plasmid backbones of the pBABE series of vectors. In the appropriate producer lines these produce ecotropic and amphotropic retroviruses where gene expression is driven by the MMLV LTR’s. All retroviruses are replication defective as many helper functions are supplied by the producer cell lines psiCRIP and Omega E. Cells that have stably integrated the retroviral expression cassette will be selected on the basis of drug resistance to G418 or puromycin. After infection no infectious viral particles can be produced.

The adenoviral vectors are replication incompetent due to absence of the E1 helper function. None of the genes intended for use contain or complement the E1 function. In addition, these are not capable of integrating into the host's DNA and are thus subject to rapid dilution with cell division. Homologous recombination with a wild-type adenovirus present in the host would generate competent virus, however, this recombination would result in the deletion of the inserted gene.

**Origin & function**

The project involves the growth of fibroblasts from the human progeroid syndrome Werner. These fibroblasts grow more slowly and have a much-reduced replicative life span than normal fibroblasts. The kinase inhibitor SB203580 rescues this reduced growth. The drug is believed to inhibit the MAP kinase p38 (MAPK14). The GM involves the introduction of an SB203580-resistant form of p38 into Werner syndrome fibroblasts using retroviral transfer and testing the effects of SB203580 on the resultant cells. A wild type p38 will be used as a control. To this end mutant and non-mutant forms of p38 will be cloned into a series of retroviral vectors. If we have problems cloning MAPK14 into retroviral vectors we will use pre-existing adenoviral vectors which already contain the mutant and non-mutant forms of p38. These plasmids will be co-transfected with pJM17 into 293 cells which supply an E1 helper function. Recombinant virus stocks will be plaque purified through reinfected 293 cells.

Host organisms are primary human cells, in particular fibroblasts. These cells may also have been infected with retroviruses expressing human telomerase (hTERT).

All genes will be introduced into a series of plasmid backbones of the pBABE series of vectors. In the appropriate producer lines these produce ecotropic and amphotropic retroviruses where gene expression is driven by the MMLV LTR’s. All retroviruses are replication defective as many helper functions are supplied by the producer cell lines psiCRIP and Omega E. Cells that have stably integrated the retroviral expression cassette will be selected on the basis of drug resistance to G418 or puromycin. After infection no infectious viral particles can be produced.

The adenoviral vectors are replication incompetent due to absence of the E1 helper function. None of the genes intended for use contain or complement the E1 function. In addition, these are not capable of integrating into the host's DNA and are thus subject to rapid dilution with cell division. Homologous recombination with a wild-type adenovirus present in the host would generate competent virus, however, this recombination would result in the deletion of the inserted gene.
Stress signalling kinases:

Human MAPK14 (p38)
Mutant MAPK14 (resistant to the inhibitor SB203580)

Evaluation of foreseeable effects

With regard to the hazards associated with the host/recipient the following have been considered including the pathogenicity of the host strain, virulence, infectivity and toxin production. In this case the recipients and hosts are non pathogenic.

With regard to the hazards rising directly from the inserted gene: These are non oncogenic and are downstream members of signalling pathways. In addition, the inserted MAPK14 is inactive unless activated by an intracellular signal. Activation of this pathway will affect the inserted gene in a similar fashion to the endogenous copy. With regard to the mutant form of MAPK14, the only effect will be resistance of this kinase to an exogenously applied kinase inhibitor. The function of the MAPK14 is essentially unaltered.

With regard to the hazards arising from the alteration of existing pathogenic traits: There is no increase in infectivity of pathogenicity and no disabling mutation within the recipient can be overcome due to the insertion of the foreign gene. Foreign genes do not encode pathogenicity determinants from a related organism.

Considering whether an inserted sequence that does not give rise to harmful phenotype in the recipient micro-organism could give harm as a result of natural gene transfer to another possibly related organism: This is extremely unlikely to have a harmful effect.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable to this application.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable to this application.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All retroviral and adenoviral work will take place in a dedicated Class II facility. All liquid waste is sterilised at point of use by sodium hypochlorite. All solid waste is sterilised in an adjacent autoclaving facility. Use of glass and needles will be avoided to reduce the risk of sharps injury.

Autoclave thermocouple tested annually. Also daily monitoring of efficacy of autoclave. Discussed determining the efficacy of disinfectants with HSE inspector on site. Relying on manufacturers quality control and the very unstable nature of GMO’s used.

Project Title
Introduction of interfering RNAs into mammalian cells for lowering gene expression.

Purposes of the contained use
The purpose of the project is to use retroviral, lentiviral and adenoviral vector expression of interfering RNAs in order to obtain significant reduction in the expression of specific genes (human, mouse or CMV in origin).

Recipient or parental organism
Retroviruses are viruses found throughout the animal kingdom and may be associated with oncogenesis. 
Lentiviruses are complex retroviruses that cause the transmissible immunodeficiency syndomes. 
Adenoviruses are primarily associated with mild, self limiting respiratory tract infections (common cold).

Origin & function
Deletion of the enhancer region of the 3'U3 of LTR. This results in a transcriptionally inactive vector that cannot be converted into a full length RNA. The deletion also reduces the risk of tumourigenesis via promoter insertion. 
In addition to loss of the regulatory/accessory genes (tat, vpr, vpu, vif and nef), pLKO.1 is also deficient for the gag, pol, rev and env genes of HIV-1, which must be
provided on three non-homologous plasmids expressed in a packaging cell-line.

Retrovirus: The origin of the retroviral vectors (as typified by pSUPER.RETRO and pSIREN-RetroQ-ZsGreen) requested in this application is the Murine Stem Cell Virus. The retroviral vectors are lacking the gag, pol and env genes required for viral replication. These genes are provided in trans either as stable transfectants or on separate plasmids. All packaging signals on the viral genes have been removed, preventing their packaging into recombinant virus, and retroviral genes are under control of non-homologous promoters reducing the possibility of recombination with packaging vector. These highly attenuated lentivirus and retrovirus vectors have shown sufficient biosafety for their inclusion in ongoing human clinical trials as therapeutic vectors.

Adenovirus: The recombinant adenovirus vectors are based on commercial. Replication-deficient adenovirus type 5 vectors that have been widely used worldwide in research and gene therapy protocols. All vectors will carry deletions in the adenoviral E3 region.

Evaluation of foreseeable effects

The generation of replication competent virus has to be viewed as a potential major safety issue. However, the probability of the lentiviral, retroviral or adenoviral vectors reverting to wild-type is extremely low (see risk assessments). Recombinant adenoviruses generated in these studies will be replication-deficient due to deletion in the E1 and E3 gene sequences. For replication deficient adenoviruses there is a potential risk of recombination with wild type viruses to generate replication competent virus. However, laboratory containment of replication deficient adenoviruses makes the likelihood of exposure to wild type viruses extremely remote. In summary, although the viral vectors can potentially infect a wide-range of cell types there is minimal risk of viral replication in infected cells.

Replication-deficient adenoviruses are not associated with oncogenesis due to loss of E1A and B gene products and the fact that the virus does not integrate. However, insertion mutagenesis is a potential concern for retroviral-based vectors. Retroviral integration can lead to oncogenesis but appears restricted to stem cells whereas integration of lentiviruses into the human genome is not known to result in oncogenesis.

In the context of insertional mutagenesis, an additional risk factor may influence the probability of an adverse event as the nature of the specific shRNA to be expressed from the retroviral/lentiviral vectors. The shRNAs of most concern would be those capable of achieving down-regulation of expression of known tumour suppressors. However, as tumourigenesis is recognised to require multiple events the likelihood of cellular transformation is nevertheless minimal.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Recombinant viruses will at all times be maintained in an environment designed to prevent aerosol spread. All flasks containing the virus shall be kept closed except when decanting and pipetting which will be conducted in tested class II safety cabinets. Centrifugation steps shall be performed in sealed buckets that will be opened only in safety cabinets.

Liquid waste will be disinfected with Activchlor (2500 ppm sodium dichloroisocyanurate), a chlorine-based disinfectant. The expected degree of kill will be 100%. The activity of the disinfectant will be checked using starch iodide test papers. Solid waste will be autoclaved.

Contaminated pipettes will be immersed in Actichlor for a minimum of 4hr prior to transferring to a container for autoclaving. The tissue culture cabinet and any potentially contaminated area will be disinfected with chlorine-based disinfectant according to an approved protocol. Access to laboratories employed for virus work will be restricted.

Project Additional Information

Purposes of the contained use
The purpose of the project is to use retroviral and lentiviral vector expression of leukocyte cell surface proteins in order to determine the functional characteristics of modified versions of these molecules including TCR's, MHC's, CD8 and CD4 coreceptors.

Recipient or parental organism
Retroviruses are viruses found throughout animal kingdom and may be associated with oncogenesis. Lentiviruses are complex retroviruses that cause the transmissible immunodeficiency syndromes.

Host/vector system
Mammalian cells/Retrovirus vectors (including pBABEpuro and pSIREN-RetroQ-Zs Green)
Mammalian cells/Lentivirus vectors (including pLKO.1 puro)

Origin & function
Retrovirus: The origin of the retroviral vector pSIREN-RetroQ-Zs Green is the Murine Stem Cell Virus. pBABEpuro is derived from the Mouse Leukaemia Virus. The retroviral vectors are lacking the gag, pol and env genes required for viral replication. These genes are provided in trans either as stable transfectants or on separate plasmids. All packaging signals on the viral genes have been removed, preventing their packaging into recombinant virus, and retroviral genes are under control of non-homologous promoters reducing the possibility of recombination with packaging vector.

Lentivirus: The origin of the lentiviral vector requested in this application is HIV-1. pLKO.1puro is a representative third-generation self-inactivating lentivirus vector (Dull et al, 1998, Zufferey et al, 1998, Stewart et al, 2003). The mechanism of attenuation includes: Deletion of the enhancer region of the 3' U3 of LTR. This results in a transcriptionally inactive vector that cannot be converted into a full length RNA. The deletion also reduces the risk of tumourigenesis via promoter insertion. In addition to loss of the regulatory/accessory genes( tat, vpr, vpu, vif and nef), pLKO.1 is also deficient for the gag, pol, rev, and env genes of HIV-1, which must be provided on three non-homologous plasmids expressed in a packaging cell-line.

These highly attenuated lentiviral and retroviral vectors have shown sufficient biosafety for their insertion in ongoing human clinical trials as therapeutic vectors.

Evaluation of foreseeable effects
The generation of replication competent virus has to be viewed as a potential major safety issue. However, the probability of the lentiviral or retroviral vectors reverting to wild-type is extremely low (see risk assessment). Therefore, although these viral vectors can potentially infect a wide range of cell types there is a minimal risk of viral replication in infected cells.

The only potential safety concern for retroviral-based vectors is insertional mutagenesis of essential genes. Retroviral integration can lead to oncogenesis but appears restricted to stem cells whereas integration of lentiviruses into the human genome is not known to result in oncogenesis. Although the leukocyte cell surface proteins themselves do not cause a major risk due to their natural presence on mammalian cells, their modification may in the worst case scenario induce autoimmune disease.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Tick if you are claiming exemption from disclosure for section of the risk assessment N
**Purposes of the contained use**

The outer skin layer provides a barrier to gene delivery. In this study, we will use microchannel creating devices, e.g., microneedles, to penetrate the outer barrier layer of skin to allow pathways for the delivery of genes into viable skin regions. Viral vectors will be used to drive gene expression in the viable skin. Potential therapeutic applications include cutaneous gene therapy and DNA vaccination.

**Recipient or parental organism**

- Continuous cell lines, HaCaT and A549 cells.
- Primary cell cultures of keratinocytes.
- When using explanted human skin tissue (ethical approval and informed consent in place) we will target cells in the epidermal/dermal region including keratinocytes, Langerhans cells and dermal dendritic cells.

**Host/vector system**

- Lentiviral vectors based on human immunodeficiency virus-i (HIV-i) will be generated from the pHR'SIN parental construct. There is no HIV viral protein expression from the vectors and they are multi-attenuated; all the HIV-i genes with accessory and potentially pathogenic functions have been deleted. The vectors are unable to replicate. The spleen focus forming virus (SFFV) long terminal repeat (LTR) will be used to drive expression. Vectors are self-inactivating due to a deletion in the 3' HIV-i LTR, providing another layer of safety. We use integration-deficient vectors which contain a mutated integrase that is functionally disabled.

**Origin & function**

- The transgenes expressed by the vectors are non-pathogenic and are not hazardous to human health or the environment.
- To test gene expression in skin: Reporter genes enhanced Green Fluorescent Protein (GFP) from Acquoria Victoria and beta-galactosidase.
- To test functional gene expression: cDNAs encoding Hepatitis B surface antigen will also be used as a representative therapeutic gene. As all workers are immunised against hepatitis B, this is a safe and appropriate option.

**Evaluation of foreseeable effects**

- The effluent non-integrating vectors will be able to undergo reverse transcription and nuclear entry but be defective specifically for the integration stage of the viral life cycle. This is due to mutation of the HIV integrase in order to disable its function. The maximum culture volumes used in preparation are 30mL. The vectors are inactivated by treatment with proline and autoclaving.
- The lentiviral vectors to be used in this project are based on human immunodeficiency virus-i (1-IIV-i) and will be generated from the pHR'SIN parental construct. There is
no HIV viral protein expression from this plasmid. The spleen focus forming virus (SFFV) long terminal repeat (LTR) will be used to drive expression of a reporter protein (e.g., eGFP, β-galactosidase) transgene. Furthermore, the vectors are self-inactivating due to a deletion in the 3' HIV-1 LTR, so that only the internal promoter will be active in transduced cells. Vectors will be generated with envelope from the G glycoprotein of vesicular stomatitis virus (VSV-G).

Reversion of a non-replicating lentiviral vector into a replicating form by recombination with wildtype has never been shown to occur and the multiple disabling mutations described mean that the risk of this occurring is very low.

Percutaneous or mucosal are routes of infection that will be prevented by standard category 2 procedures, such as wearing gloves, lab coat and use in category 2 cell culture hood. Even in the event of a laboratory accident, exposure has negligible chance of causing harm since the virus is unable to replicate and the transgenes used in these studies have no pathologic potential. In the event of an accident the immune system will not be compromised.

The overall likelihood that, in the event of exposure, the GM virus could cause harm to human health is effectively zero.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Excised human skin will be collected and experiments contained within a designated containment 2 laboratory.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Experimental procedures will not generate aerosols. A safety cabinet will be used. Sharps use minimised and sharps disposed of in dedicated sharps containers. Sharps primarily used for skin preparation before the use of any vector.

Work to be conducted within a dedicated category 2 laboratory. Skin handling, preparation and transfection to be conducted in a category 2 laboratory. Standard decontamination of work areas including wiping with 70% ethanol, Barcidal, Presept and 1% Virkon.

Lab coats specific for use in GMM room within which they remain. Spillage and disinfection procedures in place with notifications posted in laboratory. Spillage (small volume <50mL) to be wiped immediately with WIPEX infection control cloths and area swabbed with 1% Virkon. Contaminated cloths/tissue/coats etc. to be autoclaved as usual.

Spillage (large volume >50mL) on floor. All personnel to leave room for 30 min to allow aerosol to settle. Lab coats/clothing contaminated with spillage autoclaved for disposal. Broken glass collected with autoclavable forceps and decontaminated before placing in SharpsSafe containers. Inform Safety Officer of incident.

Solid and liquid waste will be autoclaved.

Contaminated waste, including paper towels and plasticware is placed in autoclave bags and transported in designated metal bins to autoclave for 1 hr at 130°C before placing in yellow biohazard bags.

Contaminated glassware and plastic disposable pipettes soaked in Presept 2500 ppm (2 x 2.5g tablets in litre water) for more than 30 min Pipettes can then be disposed in SharpsSafe containers.

All cytocidal agents have widespread activity used at recommended manufacturer’s concentrations are validated for 100% cell kill.

### Project Additional Information

**Purposes of the contained use**

The aim of this project is to enable production of recombinant retrovirus vectors for the transduction of non-human cells. This protocol is predominantly for the production of rodent cells that express receptors or other molecules in molecular pathways of the immune system. Typical application of this involves for example introduction of an immune receptor into a cell for study of its role in immune recognition and cell biology.

**Recipient or parental organism**

The eukaryotic cells that will be infected with the retroviral particles include non-human cell-lines and non-human primary cells. The majority of these cell lines will be rodent cells.
The retroviral vectors are replication deficient derivatives (e.g., MMLV and MSCV). The vectors consist of plasmid backbones containing a pair of viral long terminal repeats (LTRs), which must be transfected into packing cell lines that provide the structural proteins for packaging of infectious but replication incompetent retroviral particles. The packaging cell line determines the range of target cells that may be infected with the virus particles and ecotropic packaging cells are used to prevent infection of human cells.

**Origin & function**

The recombinant genetic material will be mostly mammalian derived (predominantly rodent). It will include material encoding molecules of immune pathways (e.g., cell surface immune receptors and molecules involved in their signalling pathways) and regulators of cell division and fate (e.g., homeobox genes). This material will be used for the analysis of the function of specific immune pathways or for generating novel cell lines from primary cells, respectively. Human material for the study of immune molecules and signalling pathways will also be used.

The recombinant viral vectors will be introduced into an ecotropic packaging cell line by transient transfection. The ecotropic packaging cell line contains the viral gag-pol and env sequences necessary for the packaging of infectious replication incompetent retroviral particles that cannot infect human cells. The viral particle containing culture medium is harvested and used to infect rodent cell lines or primary cells, usually by centrifugal infection. The murine cell lines are then selected in the appropriate manner (e.g., antibiotic containing media) to allow survival of those containing integrated retroviral vector and expressing the recombinant genetic material. This protocol will generate altered non-human cells for the study of immunological process as well as growth and differentiation altered rodent primary cells.

**Evaluation of foreseeable effects**

The viral vectors are disabled:

The viral vectors are replication deficient derivatives and packaging cell lines are required for the production of virus. They lack the viral gag-pol and env sequences required for production of infective virus. Plasmid backbones containing a pair of viral long terminal repeats (LTRs), which must be transfected into packing cell lines that provide the structural proteins for packaging of infectious but replication incompetent retroviral particles. The use of ecotropic packaging cell lines ensures that human cells are not infected.

The retroviral vector cannot revert to wildtype:

The retroviral vector is free from unnecessary retroviral sequence and the viral proteins (gag-pol and env sequences) required for packaging of infectious viral particles are contained on different selectable cassettes within the packaging cell line.

Hazard to human health (e.g., infectivity and the effect of additional material on tropism or biological function):

Theoretically, virus could be delivered to humans by mucous membranes, cut skin, or via trauma (e.g., needle stick injury). However, the virus is only packaged in ecotropic packaging cells and so is not able to infect human cells. Furthermore, if any infection were possible, it would not be a productive one and limited use of viral sequence ensures that the likelihood of recombination is significantly reduced. Containment procedures prevent this. Neither the tissue/cell tropism nor host specificity of the virus will be affected by addition of foreign material. Introduction of rodent homeobox genes can alter the differentiation and proliferation of rodent haematopoietic cells and hence could be considered oncogenic, however, the use of restricted tropism and accessibility of human target cells prevents this.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Liquid waste will be disinfected using bleach (>1% w/v) or virkon (>2% w/v) for greater than 1 hour. Solid waste will be autoclaved or incinerated prior to disposal. These procedures will result in complete killing of the retroviral vector.

The Committee believed that the original activity classification of 1 was incorrect and after discussion with was agreeable to changing it to 2-

Project Additional Information

Purposes of the contained use

The purpose of the contained use here is the development and testing of antiviral substances active against human viruses in collaboration with Welsh School of Pharmacy. Virus titers will be determined by quantitation of fluorescence from recombinant viruses expressing E/GFP in susceptible cell lines (high throughput screening). Luciferase reporters will be used for the investigation of viral entry mechanisms. The project is a connected program of work for the evaluation of antivirals against a variety of human viruses (see below).

Recipient or parental organism

The GM organisms we want to notify the HSE about are derived from ACGM L2 classified wildtype viruses and labstrains. These viruses have been modified by various investigators to express green fluorescent protein (GFP) from enhanced forms of GFP (EGEP) or firefly luciferase from (hosts and origins of GM strains see below). Modifications of this type generally attenuate the recipient virus, or do not affect its pathogenicity. There is NO evidence in the literature that expression of fluorescent tags/luciferase increases viral pathogenicity.

Host/vector system

Expression of green fluorescent protein or firefly luciferase allows rapid identification and quantitation of virus early (day 1-2) in the course of infection and with direct observation methods (IF microscopy/flow cytometry/luminometer). The fluorophores/enzymes used are GE? (enhancedEGFP) from Aequorea victoria that fluoresces green when exposed to blue light, and firefly luciferase from Photinus pyralis [Photinus-luciferin:oxygen 4-oxidoreductase (decarboxylating, ATP-hydrolyzing), EC 1.13.127].

Origin & function

AV 3.1 Recombinant measlesviruses: gfp and enhanced gfp tags Measlesvirus IC323-EGFP (obtained from Prof Yusuke Yanagi; Takeda et al., 2000; J Virol 74: 6643-6647) expresses green fluorescent protein in B95a cell syncytia. The EGFP (Clontech) gene unit has been attached to the 5’ end of the measlesvirus genome (5’ of N).

AV 3.2 Recombinant adenoviruses: gfp and enhanced gfp tags Adenovirus ad852-gfp/streplll was constructed in Professor Gavin Wilkinson's lab at the Cardiff University School of Medicine (Stanton et al., 2006; unpublished results). The replication incompetent (delta E) virus will be used to test potential antivirals, infects a wide range of cells, but replicates only in HEK293 cells.
AV 3.3 Recombinant poxviruses (vaccinia virus): luciferase, gfp and enhanced gfp tags
The firefly luciferase expressing vaccinia virus WRLuc-> will be provided by Departamento de Biologia Molecular Celular, CNB, Spain (Rodriguez, et al., 1988; PNAS 85: 1667-1671). The luciferase gene has been cloned into the TK site of vaccinia virus strain WR (Western Reserve vaccine strain).

AV 3.4 Recombinant influenzaviruses: gfp and enhanced gfp tags
We have obtained influenza virus expressing GFP from the NSI reading frame from Institute of Applied Microbiology, University of Natural Resources and Applied Life Sciences, Austria (Kittel et al., 2004; Virology 324: 67-73). This virus grows productively only in MDCK cells and embryonated chicken eggs.

AV 3.5 Recombinant herpesviruses: gfp and enhanced gfp tags
We have obtained the recombinant human Cytomegalovirus UL32-EGFP-HCMV from University of Tuebingen, Germany (Sampaio et al., 2005; J Virol 79: 2754-2767). UL32-EGFP-HCMV infects under laboratory conditions-in vitro- only human fibroblasts (e.g. MRC-5, HEL299, BJ-1).

All described viruses are currently in L2 storage and will be used to test potential antivirals after HSE permission is granted.

Evaluation of foreseeable effects
Expression of gfp does not alter host range nor pathogenicity of the recombinant virus.

The viruses used are classified ACGM L2 and will be used in L2 containment facilities, if procedures are followed there is only negligible risk of infection with the GM organisms, most of which are derived from vaccine strains (except the adeno- and cytomegalovirus recombinants).

All laboratory personnel are vaccinated against measles virus infection (Edmonston strain). The vaccine is very effective. Even with waning immunity, measles virus infections are absent in the immunized elderly (outbreaks in Germany, Italy and UK, 2003-2005). All lab personnel get yearly flu vaccinations.

Overall the risk from the use of the GFP/luciferase tagged viruses is estimated as effectively zero.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All laboratory work involving recombinant viruses will be carried out in L2 containment level labs. All personal will be trained in recognizing virus infections, awareness of human-to-human transmission, and the increased risk for individuals suffering from immune disorders (e.g. atopic dermatitis, severe acne, impetigo, contact dermatitis, psoriasis, chickenpox, steroid medication, pregnancy, infection with other pathogens). The exposure route via the conjunctiva will be particularly stressed and the use of adequate protective gear enforced in the lab. All personnel will be monitored by the Occupational Health Service at the School of Medicine.

Laboratory work will be carried out in class II safety cabinets, with personal wearing gloves. Disposable plastic pipettes and pipette tips will be used. Recombinant viruses will be used under conditions avoiding the generation of aerosols. Flasks containing virus will be kept sealed outside of the safety cabinets. Centrifugation will be carried out in sealed buckets, that will only be opened in safety cabinet. All waste materials will be collected in plastic bags in the safety cabinets, the bags will be sealed inside and then autoclaved. No sharps will be used.

Removable equipment and interior surfaces of the safety cabinets will be sprayed with Incidin® PLUS (Ecolab, Swindon, UK) containing the patented active substance Glucoprotamine with wide effect spectrum against bacteria (also MRSA and TBc), fungi, papova-, adeno-, vaccinia-, herpes-, rota- and hepatitis-8-viruses (HBV) in MADT and antigen test, as well as AIDS agent (HIV)-certified by the German Society for Hygiene and Microbiology (DGHM).

Spillage of GM material will be treated with hypochloride.

For the quality assurance of the disinfection and autoclaving procedures, measles virus contaminated Incidin disinfected and bleached plasticware, as well as autoclaved...
waste material will be rinsed with a small volume of PBS and tested for rest-infectivity on appropriate cells in a standard virus detection assay.

The main concern of the Cardiff University GM committee regarding the measles virus was whether the laboratory personal was vaccinated. The committee accepted the PI's assurance that the measles-vaccination-status of the personal working in the laboratory where measles virus is used is properly controlled. Non-vaccinated personal will be asked to receive a measles virus vaccination form the Occupational Health Unit Cardiff University or be excluded from the access to the laboratory. BSA Cardiff University received no more adverse comments from the Cardiff University GM committee after the principal investigators comments regarding vaccination of personal. The GM committee recommended to submit a notification as Class 2 for the measles virus risk assessment.

Please enter comments on the GM safety committee on the risk assessment

CU2 Project Title Expression of apoptosis regulators in mouse mammary epithelial cells.

Date Project Ceased

Class 2

Culture Vol Class 2 < 1 Litre

Non-GMM Consent Granted Not Applicable

Project notified under transitional arrangements N

Tick if notifying a connected programme of work Y
### Project Additional Information

#### Purposes of the contained use

| The aim of this study is to observe the effects of known apoptosis-related signalling molecules in mouse mammary epithelial cells (MECs) by conditionally expressing these genes, and dominant negative variants, in primary and transformed cultures of mouse MECs. Recombinant genes will be administered to cultured cells by commercially available lentiviral / retroviral vectors and expression will be controlled using the Tet-on gene expression system. Changes in cell survival, motility and/or adhesions will be monitored by fluorescence microscopy and biochemical [assay of cell lysates. |

#### Recipient or parental organism

| Commercial lentivirus vectors (eg. Virapower, Invitrogen) originating from pseudotypes HIV-1 based lentivirus and propagated in the attenuated E. coli strain Stbl3. |

#### Host/vector system

| A third generation HIV-1-based lentiviral vector. It is a self-inactivating (deltaU3), replication-incompetent virus that ‘once transduced is unable to package viral genome The VSV-G gene replaces the HIV-1 envelope gene :pseudotyped), packaging genes are located on three separate non-homologous plasmids and no HIV-1 structural ‘genes are present in the packaged virus- The vector is able to transduce and integrate into the genome of dividing and non-dividing primary mammalian cells with high efficiency upon contact but is non-transmissable subsequently. The most likely route of transmission is via airways and eyes. There is no risk of the infection spreading to the community via human-human contact, and the packaged virus is unstable in the general environment. |

#### Origin & function

| The following will be inserted into the vector sequence for expression in mammalian cells: murine apoptosis inducing genes belonging to BH, BIR and NF-kB gene families and apoptosis suppressing genes belonging to BH3-only, DED/DD and caspase families and apoptosis suppressing genes belonging to BH, BIR and NF-kB gene families will be cloned into a tetracycln conditional lentiviral expression vector Packaged replication defective virus will be generated in 293 cells and used to transduce target mammary epithelial cells (MECs) in culture that already carry the rTA gene necessary for Tetracycline induction of recombinant gene expression. Target primary rTA-MECs will be generated from rTA-transgenic mice while target immortalised rTAMEC lines will be generated by prior stable integration of retroviral or lentiviral rTA constructs. Thus packaged recombinant expression vector and packaged rTA vector will not be used simultaneously. Once transduced, these cells will be maintained in culture and assessed for a variety of cellular responses including apoptosis. After cellular assays are completed the infected cells will be disposed of. |

#### Evaluation of foreseeable effects

| The recombinant vectors will express mammalian apoptosis regulators (both suppressors and activators of cell death). |
Expression of the recombinant genes is dependent upon co-expression of the TetRepressor protein (which is not present in the vector) in combination with the presence of the antibiotic tetracycline (or analogue). Thus accidental infection by the recombinant vector is highly unlikely to result in the expression of the recombinant gene encoding the apoptosis regulator as neither the TetRepressor protein nor tetracycline are present. However there is a low risk that a minimal level of recombinant gene expression could result from 'leaky' expression in the absence of the inducing agents. The TetRepressor protein will be delivered to target immortalised cell lines by attenuated lentiviral or retroviral vector. This protein is non-toxic to mammalian cells in vivo and in vitro. These stable lines will be maintained and stored for use as target cells for the recombinant lentiviral expression vector. Apoptosis inhibitors are potential oncogenes, contributing to tumour progression by prolonging the life of damaged or mutated cells. Clonal expansion of these cells would likely require additional mutations in growth and apoptosis pathways prior to onset of disease. Exposure to the virus could result in low level (uninduced) expression in infected cells. The likelihood that this could result in partial resistance to cell death is low. However the integration of the virus into the genome upon transduction increases the hazard risk. Some apoptosis inhibitors may interfere with intrinsic (target) host cell response to viral infection (ie. apoptosis) but would not be expected to influence cell-mediated immune responses and are unlikely to affect global host defence mechanisms in the host organism.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Primary mammary epithelial cells will be derived from wild-type and genetically modified mice. All animals will be housed in the Designated animal facility within the Biosciences building, killed by schedule 1 method and transferred to the viral containment suite in closed box. Mammary glands will be dissected from the mice in class II cabinets and epithelial cells purified from this tissue. Cells will be cultured within the suite until required for gene expression studies. Carcasses will be disposed of as biohazard waste under the same procedures used by the designated animal facility. Cell lines and stable clones will be archived by freezing and storage in labelled boxes within designated -80°C freezers.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

none requested

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All work involves standard laboratory procedures on a small scale. All cultures performed in sealed flasks and handled in Class II recirculating microbiology safety cabinets with double HEPA filters in a restricted-use culture facility under negative pressure. Gloves, facemasks and lab coats are worn within the suite. Only disposable plasticware, including filtered pipette tips, will be used for contaminated liquids etc. Once used, these will be fully immersed in Virkon for 24 hours, placed into double autoclave bags and disposed of by the School of Biosciences approved decontamination method involving autoclaving. Company product efficiency data (DuPont) and independent test data on Virkon indicate a 100% kill of all known viruses, including lentiviruses, within 10 minutes of direct contact. Work surfaces and spillages will be decontaminated by spreading Virkon. Automated pipettors and plastic pipettes will be used to transfer and dispose of contaminated liquids/media, no mechanical vacuum aspirators will be used. Contaminated liquids will be transferred to Virkon, soaked for 24hrs and disposed by sink. Subsequently, containers will be disposed of as described above.

**Historical Significant Changes**

**Historical Date of Additional Info**

**Significant Change ID**

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

To model the in vivo function of homologues of IL-iC that is expressed by human herpesviruses such as Human cytomegalovirus (HCMV) and Epstein Barr virus (EBV). In particular, to study the effect of IL-10 expression by herpesviruses on tissue tropism and viral replication, and the suppression of host immunity at different sites of viral infection.

**Recipient or parental organism**
The wild type MCMV strain M97.0i will be used as a recipient for mouse IL-10, i.e. the IL-10 gene will be inserted into the M97.01 genome. The M97.01 genome is expressed by the pSM3fr plasmid (reference: Wagner et al., J Vir, 1999, 73:7056) suitable for growth in E.coli.

Host/vector system

The DNA encoding mouse interleukin-10 will be inserted into the M97.01 genome that is expressed by the pSM3fr bacterial artificial chromosome (BAC) plasmid (Wagner et al., J Vir, 1999, 73:7056). The plasmid that subsequently contains MCMV 97.01 genome and mL10 will then be grown up in Ecoli, and then the plasmid isolated and used to transfect mouse fibroblasts for production of the infectious MCMV-IL-10 virus.

Origin & function

The genetic material encodes mouse IL-10. The IL-10 cDNA will be either cloned from mouse genomic DNA, or from a plasmid where the IL-10 cDNA has already been cloned into. This cytokine is specific-specific (i.e does not bind to human IL-b receptor). IL-10 suppresses different aspects of the immune system in vivo. Therefore, MCMV expressing IL-10 will be used to infect mice to study the effect of IL-10 expression by herpesvirus in vivo on different aspects of the immune system in a variety of mucosal and non-mucosal organs in the body. In some experiments, the virus will also be used to infect cells in vitro and the effect of MCMV-IL-10 on different cell functions will be analysed.

Evaluation of foreseeable effects

MCMV-IL-10 infected mice may exhibit prolonged and/or possibly exacerbated weight loss/liquefation than wild type MCMV-infected controls. If MCMV-TL-10 does exacerbate weight loss, infected mice will be observed daily until weight loss returns to pre-infection levels, in line with our Home Office Project License (PPL 30/2442). Expression of IL-10 by MCMV may also suppress the host immune responses to the virus. Therefore, MCMV-IL-10 may display increased replication and may alter tissue tropism in the mouse. In the case of mucosal organs such as the intestines or kidneys, this elevated viral load may result in increased shedding in the urine or kidneys. The SCAN containers used to house MCMV-infected mice are suitable for housing mice infected with lung and gut-associated pathogens. Therefore, this type of housing will effectively contain MCMV-IL-10 even in the unlikely event of the virus displaying increased shedding via “novel” mucosal secretions. Furthermore, MCMV is relatively unstable in the environment, and IL-10 is a non-structural protein. Therefore the inability of the virus to persist in the environment will not be affected by the expression of IL-10 by the virus. Importantly, 11-10 is a mouse protein and does not cross-react with humans. Therefore, like “wild type” MCMV, MCMV-IL-10 also poses no threat to human health.

For only GMOs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not requested.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The following chemical disinfectant methods have been shown to induce 100%, as tested by plaque assay for replicating MCMV. The chlorine-based disinfectant is Haztabs (2500 ppm). The efficacy of this disinfectant has been perfomed with wild-type MCMV and will be repeated with MCV-IL-10 (once constructed) prior to the commencement of the research.

Liquid waste: Empty into waste pots kept inside the flow cabinet. Allow to stand for 60 minutes in chlorine-based disinfectant before emptying down the sink with excess running water.

Solid waste: Plasticware (including tips) that has come into contact with infectious material should be submerged in the waste pot containing chlorine-based disinfectant and left to soak, as described above.

Pipettes: Rinse pipettes up and down in bleach-containing waste pot and leave to soak for 60 minutes. Then dispose of these in large sharps bin.

Spillages: Spillages should be wiped up with tissue soaked in chlorine-based disinfectant for 60 minutes. The tissue will then be disposed of in clinical waste.

Infected carcasses and bedding from cages housing infected mice: Disposed of as clinical waste by a licensed contractor.

Risk assessment suitable and sufficient after minor alterations had been made, in agreement with classification of activity.
Project Additional Information

Purposes of the contained use

Commercial systems are readily available that enable researchers to obtain interfering RNA for any cellular gene (usually human or mouse) already inserted into adenovirus and retrovirus (usually lentivirus) vectors. The application also seeks to cover in-house technology based on replication-deficient adenovirus vector being developed for this purpose. The cover is directed at the delivery of these recombinant viruses to cell culture systems in vitro. The aim being to provide knock-down expression of targeted genes so their independent function or role in a pathway can be determined.

The worst case situation identified in the risk assessment was to knock-out expression of a tumour suppressor protein (examplified by p53, Rb and PML). The intention is for individual researchers in Cardiff University to perform separate risk assessment to cover the application of this technology. Should any future assessment identify an increased hazard (even assessed at ACGM2 level) relative to that assessed, it will be subject to independent notification.

Recipient or parental organism

The vectors will be delivered to cells in culture. Replication-deficient adenovirus vectors are associated with high level transient expression (although can insert into the host genome at low frequency) can be produced in high concentration and can be spread by aerosol to contact. Retroviruses are transducing vectors that integrate into their host to provide long term expression in cell targets and their progeny. The retrovirus will normally be pseudotyped which enhances their stability and may facilitate aerosol spread. In target culture cells knock down or knock out of specific cellular or virus-encoded gene expression gene expression will be sought. Knock-out of cellular of gene expression in the target cell is most likely going to be neutral of detrimental to the cell or virus survival. Depletion of a tumour-suppressor gene is likely to promote cell transformation. Eukaryotic cells require a sophisticated mixture nutrients and environmental conditions and would not be expected to be able to survive free outside of the laboratory. Containment is most needed for viruses and cells expression interfering RNA to tumour suppressors. Exposure to such vectors could promote cellular transformation, and warrants containment.

Host/vector system

Replication-deficient Adenovirus 5 vectors including specifically: AdZ vector based on recombineering (in-house, and detailed independently), AdEasy (He et al, Proc Natl Acad USA, 955, 2509), Admax (Microbix) and Ad-HQ™ (Vector Laboratories).

The Retroviral vectors will be based on established and commercially available technologies that include Super Retro (Oligoengine, Seattle) and Psiren - Retro Q-Zs Green (Clontech), and a commercial library based on MISSION® RNAi lentivirus technology (pLKO.1 puro; Sigma). Virus will be pseudo-typed with the envelope glycoprotein from Vesicular stomatitis virus (VSV-G).

Origin & function

DNA complementory to interfering RNA will be obtained pre-made in vectors or synthesised de novo in vitro. The sequence will generally be designed to contained a short sequence complementary to the target transcript.

Evaluation of foreseeable effects

Delivery of the recombinant will express a short RNA sequence that will anneal to a target transcript so as to promote its degradation or impair expression. Knock down of anti-inflammatory response could impair the cellular immune response eg interferon response. Even with efficient vector delivery in vivo this is likely to be a restricted localised effect that could make an individual more susceptible to infection at this site. A greater hazard was considered to be the knock out of a tumour suppressor protein that could promote cell transformation. Adenovirus and pseudotyped retrovirus vectors are capable of in vivo delivery. Knock-out of a single tumour suppressor protein is by itself not likely by itself to induce a malignancy, but containment is required to avoid operator exposure.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Recombinant viruses will at all times be maintained in an environment designed to prevent aerosol spread. All flasks containing the virus shall be kept closed except when decanting and pipetting which will be conducted in tested class II safety cabinets. Centrifugation steps shall be performed in sealed buckets that will be opened only in...
The use of Sharps when handling virus preparations shall be avoided wherever possible. Contaminated pipettes will be immersed in Actichlor for a minimum of 4 hr prior to transferring to a container for autoclaving. The tissue culture cabinet and any potentially contaminated area will be disinfected with chlorine-based disinfectant according to an approved protocol. Access to laboratories employed for virus work will be restricted.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Recombinant viruses will at all times be maintained in an environment designed to prevent aerosol spread. All flasks containing the virus shall be kept closed except when decanting and pipetting which will be conducted in tested class II safety cabinets. Centrifugation steps shall be performed in sealed buckets that will be opened only in safety cabinets. The use of sharps when handling virus preparations will be minimised. Tissue culture media will be disinfected for a minimum of 2 h by addition of Actichlor (2500 ppm sodium dichloroisocyanurate), this process has been validated in-house for adenovirus. Contaminated pipettes will be immersed in Actichlor for a minimum of 4 hr prior to transferring to a container for autoclaving. The tissue culture cabinet and any potentially contaminated area will be disinfected with chlorine-based disinfectant according to an approved protocol. Access to laboratories employed for virus work will be restricted.

**Project Ref** 130/08.3
Modification of Wnt signalling in human breast and ovarian cancer cells using lentivirus and retrovirus expression vectors.

We have evidence that inhibition of autocrine Wnt signalling by DKK, a secreted antagonist of Wnt signalling which acts at the level of ligand-receptor interaction, in breast and ovarian cancer cells decreased their proliferation and increased apoptosis. We will undertake studies aimed at assessing whether autocrine Wnt signalling plays a role in the resistance of breast/ovarian tumor cells to therapeutic agents. We had identified a sub-set of autocrine Wnt breast cancer cell lines with very high levels of the Wnt co-receptor LRP6 protein and demonstrated that down-regulation of LRP6 by a lentiviral siRNA in one of these cell lines, BC3, resulted in inhibition of uncomplexed β-catenin, suggesting that activation of Wnt signalling depends on high LRP6 levels. We will establish stable expression of Wnt pathway genes in these tumour cells and analyze the ligand effects on RNA and protein LRP6 levels. Should over-expression of Wnt in these tumour cells fail to reduce LRP6 RNA levels, this would suggest that the loss of this feed back mechanism is the cause of high LRP6 levels.

Host organisms are human cancer cell lines, in particular breast and ovarian.

All genes will be introduced into a series of plasmid backbones of the pBABE series of vectors. In the appropriate producer lines these produce ecotropic and amphotropic retroviruses where gene expression cassette will be selected on the basis of drug resistance to G4 18 or puromycin. Alternatively, the inserts will be introduced using the lentiviral vector VIRHD/EP that has been modified to be self-activating, since it lacks the genes to make both the viral envelop and the packaging, so after integration in the host cell DNA the lentivirus cannot reproduce itself.

Members of the Wnt signalling pathway, all are either human or mouse genes.

Wnt-1, Wnt-2, Wnt-3, Wnt3a, Wnt4, Wnt5b, Wnt6, Wnt7a, Wnt7b, FRP, DKK, siRNA to LRP5, siRNA to LRP6, dishevelled, Kremen 1, Kremen 2, reporter constructs for Wnt transcriptional activity: TOP-Flash, FOP-Flash in frame with either luciferase or GFP, LRP5, LRP6, Frizzled 1, dominant negative TCF4.
Please note that this notification is the first part of a connected program of work using these vector systems to introduce members of the wnt signalling system into human cancer cell lines. Any additional sections of the program will be using other members of this signalling pathway into cancer cell lines that may be other than in this notification. However, any such new gene or cell lines will be of similar types with the same overall risk associated and will undergo risk assessment via the local Genetic Modification Safety Committee for approval.

**Evaluation of foreseeable effects**

With regard to the hazards associated with the host/recipient the following have been considered including the pathogenicity of the host strain, virulence, infectivity and toxin production: in this case the recipients and hosts are non pathogenic.

Most of the inserts that will be utilized are not hazardous since they are inhibitors of the Wnt pathway that may result in a small increase in cell proliferation and decrease apoptosis. The most hazardous vectors contain different WNT genes (Wnt-3a, Wnt-1, Wnt-2). Some Wnts are classified as oncogenes, although they have not been shown to cause oncogenic transformation of cells. When Wnt is utilised it can cause a mild increase in cell proliferation, and decreased cell differentiation. However, it must be stressed that the effects of these inserts on cell proliferation are minimal and they would not significantly affect normal cells, as they should not affect proliferation barriers.

With regard to the hazards arising from the alteration of existing pathogenic traits: The tropism of the vector has been altered by the use of the VSVg protein that is not present in the parent strain to enable infection of a wider range of recipient cells. In addition, the WNTd member of the indered gene family has been shown to modify the host defence mechanism in insects: however, there is no mammalian WNTd gene and the mammalian defence mechanism differs from that in insects, so there is no similar situation in mammals and all work is done in a dedicated Class II facility. There is no increase in infectivity or pathogenicity and no disabling mutation within the recipient can be overcome due to the insertion of the foreign gene. Foreign genes do not encode pathogenicity and no disabling mutation within the recipient can be overcome due to the insertion of the foreign gene. Foreign genes do not encode pathogenicity determinants from a related organism.

Considering whether an inserted sequence that does not give rise to harmful phenotype in the recipient micro-organism could give harm as a result of natural gene transfer to another possibly related organism: This is extremely unlikely to occur and if so it is unlikely to have a harmful effect.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable to this application.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable to this application.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All retroviral and lentiviral work will take place in a dedicated Class II facility. All liquid waste is sterilized at point of use by sodium hypochlorite or actichlor. All solid waste is sterilized in an adjacent autoclaving facility. Use of glass and needles will be avoided to reduce the risk of sharps injury.

Autoclave thermocouple tested annually. Also daily monitoring of efficacy of autoclave. Discussed determining the efficacy of disinfectants with HSE inspector on site. Relying on manufacturer's quality control and the very unstable nature of GMOs used.

**Is an emergency plan required according to regulation 20?**

Y
Project passed at meeting at containment level 2. Minor revision requested to clarify risk of affecting host defence mechanisms. The WNTd gene may alter host defence mechanisms in insects, but as the host defence mechanism in mammals is very different this is not thought to be a significant risk. Risk assessment modified accordingly and signed off. In addition, further details of the genes to be inserted have been added.

Project Additional Information
Purposes of the contained use

The purpose of this project is to use a commercial lentiviral system to create stably transfected promoter-reporter cell lines for use in the screening of agents that may alter the wound healing properties of fibroblasts. Lentiviral transduction of the sequence encoding a reporter protein linked to the promoters of wounding responsive/disease specific genes into normal, diabetic wound and chronic wound fibroblast cell lines will allow the activation of wound healing responses to be assayed in disease specific and normal human fibroblast cells and thereby facilitate the screening of possible therapeutic agents.

Recipient or parental organism

Inserting the sequence encoding a fluorescent reporter protein (DsRed and pZsGreen (Clontech)) downstream of the promoter sequences of wounding responsive/disease specific human genes and also a control promoter (GAPDH), into normal (NF-hTERT), diabetic wound (DF-hTERT) and chronic wound human fibroblast (CWF-hTERT) cell lines will allow the activation of wound healing responses to be assayed in disease specific and normal fibroblast cell lines.

The ViraPower™ Promoterless Lentiviral Gateway Vector Expression system (Invitrogen) is a 3rd generation HIV-1-based lentiviral system that has been modified for enhanced safety (DuH et al., 1998, J. Virol. 72, 8463-8471) This can be utilized to transduce these promoter-reporter constructs into normal, diabetic wound and chronic wound fibroblast cell lines using established protocols provided by the manufacturer. Selection of successfully transduced cells will be by antibiotic resistance (blasticidin) to create stable clones.

Replication defective lentiviruses will be produced in a pseudoviral particle producer cell line (293FT). Virions will be generated by co-transfecting 293FT cells with pLenti6/JR4R2N5-DEST (promoter-reporter) plasmid constructs containing the recombinant lentiviral expression cassettes and the pLP1 (gag/pol), pLP2 (rev) and pLPNSV-G (VSV-G envelope) packaging plasmids which contain genes encoding structural and replication proteins required to facilitate viral packaging of the pLenti-based expression constructs.

The viral particles produced in this system are replication incompetent and only carry the aene alpha promoter of interest No other viral species are produced This &so means that none of the structural HIV genes (necessary for replication) are present in the viral genome and are therefore never expressed in the target cell, so no new virus can be produced.

The stable cell lines that are made with the lentiviral system would not contain any of the packaging proteins. These proteins are only used to package the viral particles from the 293FT cells. They are provided in trans, so they are not part of the viral particle themselves, and therefore not present when the target cell is transduced and the gene of interest stably integrated.

Host/vector system

Hosts:

E. coli - DH5 alpha for propagation of pDsRed and pZsGreen plasmids; One-shot Stbl3 for propagation of pENTRw5'TOPO® and pENTR/D-TOPO® plasmids. Pseudoviral particle producer cell line 293FT. Lentiviral particles will be used to infect DF-TERT, NF-TERT and CWF-TERT human fibroblast cell lines. Vector System: Human disease specific promoters and the reporter genes (ZsGreen and DsRed) will be individually cloned into ENTR™5'-TOPO® and pENTR™/D-TOPO® entry plasmids respectively. These plasmids will be propagated in E.coli (DH5 alpha or One-shot Stbl3). The entry plasmids containing the disease promoter sequence and reporter gene of interest will then be recombined with the pLenti6/R4R2/V5-DEST expression plasmid during a MultiSite Gateway® LR recombination reaction (Invitrogen).

The pLenti6/R4R21V5-DEST (promoter-reporter) expression constructs and the ViraPower™ Packaging Mix will then be co-transfected into the pseudoviral particle producer cell line 293FT to produce a high titer of pseudoviral particles. The ViraPower™ Packaging Mix facilitates viral packaging of pLenti-based expression constructs in 293FT cells and contains the packaging plasmids (pLP1 (gag/pol), pLP2 (rev) and pLPNSV-G (VSV-G envelope)). Promoter-reporter constructs packaged in pseudoviral particles are secreted by producer cells into culture media and will be used directly to transduce these constructs into existing DF-hTERT, NF-hTERT and CWF-hTERT human fibroblast cell lines.

The viral particles produced in this system are replication incompetent and only carry the gene(s) of interest. Following transduction into the target cells, promoter-reporter
constructs are reverse transcribed and integrated into the genome of the target cell line. None of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. There is no known toxicity/infectivity/pathogenicity associated with any of the reporter genes used.

Origin & Function

The reporter genes encoding ZsGreen and DsRed (CLONTECH) were originally derived from reef coral (specifically Zoanthus sp. and Discosoma sp. respectively). These commercially available proteins are commonly used as reporter proteins as they are non-toxic, fluorescent and not expressed by mammalian cells. When transduced into human cells, reporter gene is likely to be transcribed in a similar pattern and level to the gene from which the promoter sequence was taken. No reporter gene expression is expected in bacterial cells (used to propagate the plasmid cloning vectors) as they lack the mammalian transcription mechanism.

Human promoter sequences will be generated via PCR from extracted human genomic DNA and inserted into commercially available promoterless lentiviral expression vectors (ViraPowerTM Promoterless Lentiviral Gateway® Vector Expression system (Invitrogen)). Primers designed to facilitate amplification of the region up to 2.5kb upstream of the transcriptional start site of a number of specific human promoters will be utilised. Specific promoter sequences will then be cloned on the basis of their downstream genes pattern of gene expression (and transcriptional activation) in each of the wound healing impaired and normal human fibroblast cell lines (DF-hTERT/CWF-hTERT and NF-hTERT respectively) used in this project both under serum limited culture conditions and in response to a serum stimulus. Gene expression patterns of target genes has been determined by microarray analysis.

The identity and integrity of cloned promoter sequences will be confirmed by DNA sequencing prior to insertion into the lentiviral vector. None of the coding sequence for any of these genes will be present within any of the viral vectors.

involved in developmental regulation.

Promoter and reporter sequences will be cloned into a commercially available lentiviral vector (pLenti6/R4R21'J5- DEST). The pseudoviral particles containing promoter-reporter sequences will be utilized to infect DF-hTERT, NFhTERT and CWF-hTERT cell lines (without the need for additional replication cycles) with the insertion of promoter-reporter genes into target cell lines facilitating the monitoring the transcriptional activity of these disease specific promoters in the presence of therapeutic agents.

- Successfully transduced human fibroblast cells will be selected using antibiotic resistance. The gene encoding blasticidin S deaminase conferring blasticidin resistance is present in the lentiviral vector and will be used to create of stable (promoter-reporter) clones.

Evaluation of foreseeable effects

The viral particles produced in this system are replication incompetent and only carry the reporter gene and promoter of interest. No, other viral sequences are reproduced. This also means that none of the structural HIV genes (nepssarv for production of viral progeny) are present in the packaged viral genome. Gag, pol, rev and envelope genes are not present in the viral genome and are therefore never expressed in the target cell, so no new virus can be produced following transduction. Since packaging and replicative genes are never packaged into the viral genome infective viruses are incapable of undergoing further rounds of replication. The stable cell lines that are made with the lentiviral system would also not contain any of the packaging proteins. These proteins are only used to package the viral particles from the 293FT cells. They are provided in trans, so they are not part of the viral particles themselves, and therefore not present when the target cell is transduced and the promoter and reporter gene of interest stably integrated. As a result retroviral particle production is limited to the producer cell line.

The ViraPowerTM Promoterless Lentiviral Gateway® system is derived from HIV-1, with three genes from HIV-1 used in the system (i.e. gag, pol, and rev). Genes encoding the structural and other components for packaging the viral genome are separated onto four plasmids (i.e. three packaging plasmids and pLenti6IR4R2/V5-DEST). These genes are only present and expressed in the producer cell line (293FT) when the packaging plasmids are cotransfected. All four plasmids encoding the structural and other components required for packaging the viral genome are separated onto four plasmids (i.e. three packaging plasmids and pLenti6IR4R2/V5-DEST). These genes are only present and expressed in the producer cell line (293FT) when the packaging plasmids are cotransfected. All four plasmids have been engineered not to contain any regions of homology with each other to prevent rare, but undesirable, recombination events that could lead to the generation of a replication-competent virus.

The gene transfer vector pLenti6/R4R2N5-DEST has been modified to be ‘self-inactivating’. A deletion has been made in the 3’LTR (called ‘deltaU3’) that has no effect on the generation of viral genome for packaging in the producer cell. However, once the produced virus transduces a target cell, the mechanisms of reverse transcription use the 3’LTR as a template to create the 5’LTR. The end result is an integrated viral genome that is defective in both 5’ and 3’LTRs. Thus, there is no transcription or production of viral particles.
The DsRed and ZsGreen reporter proteins encoded in the lentiviral constructs have previously been shown to have little or no cytotoxic effects in mammalian cells. Insertional mutagenesis is known to be a low risk in retroviral vector systems, although lentiviral vectors appear to pose less of a risk to gene upregulation than retroviral vectors as they preferentially integrate into the 5' region of active genes and are thus most likely to abrogate gene expression.

A potential hazard is obviously the exposure of humans to the lentiviral particles. Exposure to these particles will be minimised by performing all manipulations in a Class 2 Biological Safety Cabinet. All procedures will be carried out whilst wearing laboratory coats and disposable purple nitrile gloves (guaranteed to prevent viral particle penetration). Known routes of transmission include needle stick injury. However, no sharps or glass will be used to minimise the risk of sharps injury, while the use of a Class 2 containment facility will reduce the likelihood of risk to individuals working with this lentivirus.

F. coli K12-derivatives used for subcloning and propagation of plasmids (e.g. DH5 alpha and Stbl3) are disabled hosts and are non-pathogenic, non-reversional and are unable to colonise the human gut. These strains are unlikely to survive outside the laboratory where they would be subjected to sub-optimal growth conditions (nutrients and temperature) and pose a very low/negligible risk to human health or the environment.

Human cell lines have a low capacity to survive, establish, disseminate and/or replace other organisms. Retroviruses are rapidly inactivated outside the host cell line and are highly susceptible to dehydration.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None. All the measures specified as requirements for Level 2 containment will be implemented.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All experiments will be carried out in a Class 2 containment facility with available autoclave and disinfectant. The Class II cabinet will be cleaned before and after use. Before use, the cabinet will be, cleaned with sodium hypochlorite (Effervescent Chlorine Tablets, 1 tablet! litre water, 600ppm concentration), followed by spraying with 70% ethanol. Chlorine tablets have been previously demonstrated by the manufacturers’ to be effective against all viruses at a recommended final concentration of 250ppm. After use, the cabinet will be sprayed with 70% ethanol and cleaned with sodium hypochlorite, before removing any contents (including stripettes, tips, flasks, medium, etc.) from the cabinet. All consumables and byproducts used during and generated as part of the experimental procedure will be soaked in 600ppm sodium hypochlorite overnight and will then be autoclaved before disposal. All liquid waste will be autoclaved prior to disposal.

Degree of kill:
Autoclaving, effectively 100% kill.

Monitoring of each run will be carried out by electronic printout schedule of autoclave cycle parameters to ensure successfully completed autoclave cycle on each occasion in addition to annual validation.

**Purposes of the contained use**

We propose to inactivate genes encoding the following activities: superoxide dismutase; arginase; alanine racemase and inosine hydrolase. This will be achieved using the following GM based approaches; Transposon mutagenesis using Tri917 (encodes resistance to erythromycin) and a targeted mutagenesis approach in which a Cre recombinase system is used to create deletions. Both approaches will result in the further inactivation of an already attenuated strain of B. anthracis. Erythromycin is not a first choice drug for the treatment of anthrax.
Recipients or parental organism

We propose to further inactivate the attenuated Sterne vaccine strain of Bacillus anthracis, a strain which has been approved by HSE for handling and manipulation at containment level 2 conditions. The strain lacks a major plasmid encoded virulence factor and as a consequence has been rendered harmless. The avirulence of this strain has been amply demonstrated over the years and it has been used extensively as a vaccine to protect domestic animals.

Host/vector system

The study will make use of two plasmid vectors, one for transposon mutagenesis and a second in support of the targeted mutation approach using the Cre recombinase system.

Tranposon Mutagenesis

The pLTV-1 plasmid is a temperature sensitive E.coli/B. subtilis shuttle vector plasmid carrying the transposon Tn917-LTV1 originally from Enterococcus faecalis which confers erythromycin resistance and generates lacZ transcriptional fusions when insertions occur within the appropriate orientation. While the plasmid contains additional antibiotic resistance genes they constitute selective markers already in routine use in standard cloning vectors and will be eliminated following growth at the non-permissive temperature. The plasmid contains a Cole1 origin for replication in E.coli and makes use of the temperature sensitive pE194 original replication to drive replication in Bacillus spp. And is considered non-mobilisable in this background.

Cre Recombinase mutagenesis

A non-expressed copy of the B. anthracis gene to be activated is the starting point of this method. The gene will be obtained from Pathogen Functional Genomics Resource Centre of the Craig Venter Institute in the US which provide the sequence on the non-mobilisable pUC based pENTR vector designed to prevent expression from its E.coli host DB3.1 a disable K12 derivative (invitrogen).

This gene is functionally inactivated by the insertion of the loxP-Spectinomycin-LoxP cassette in a disable E.coli K12 host. The resulting insert is then cloned into pHY304 and E.coli/B subtilis vector with a Gram positive temperature-sensitive (permissive 30oC, non permissive 37oC) replicon derived from Lactococcus facts. It is tra-andmob-and contains erythromycin and chloramphenicol as selective markers which are already in routine use in standard cloning vectors. This work is carried out in a disable K12 host. Following construction the plasmid is transformed into B.anthracis were the inactive gene replaces the functional gene on the chromosome. Finally the spectinomycin resistance marker is removed using Cre recombinase to leave behind a single loxP site within the target gene, which disrupts translation.

Origin & function

The aim of this study is to determine the inactivating B. anthracis genes on biological function. The gene targeted for inactivation have been implicated in virulence and regulation of germination and as such their inactivation is likely to further attenuate the strain. No complete biologically functional gene will be used in this study do not encode resistance to the first line antibiotic resistant markers. The resistant markers that will be used in this study do not encode resistance to the first line antibiotics used to treat anthrax and in the case of the targeted mutations using the Cre recombinase system will be eliminated from the final construct. In the event that remains of the target gene are expressed, they are unlikely to be produced in an active form which restores biological function in the inactivated gene. The following genes targeted for inactivation are homologues to genes which have been shown to play the following roles;

- Construction of exosporium - exeA gene homolog (BAS4324) attachment of exosporium to the spore coat exsY (GBAA1238) construction/ attachment of the exosporium
- Regulation of germination - Dal (BA0252) alanine racemase homolog
- Superoxide dismutase - SodA-1 (BA4499) Manganese dependent superoxide dismutase
- SoDFe(BA1489) Iron dependent superoxide dismutase
- Arginase - RocF (BA154)

Evaluation of foreseeable effects

The aim of this study is to determine the effect of inactivating specific B anthracis genes within in the attenuated Sterne vaccine strain approved for use under containment level 2 conditions. This strain will transformed with homologous fragments of B.anthracis DNA for the purpose of creating knockout mutants, the mutations can only reduce the virulence of an already a virulent strain. The target gene will be cloned into E.coli vectors that are not designed for expression. Indeed it is our experience that B. anthracis tend to be extremely AT rich and as a consequence are extremely difficult to express from laboratory strain of E.coli. The use of non-mobilise or mobilisation-defective vectors, disabled non-pathogenic auxotrophic E.coli K12 derived hosts that have very limited ability to survive outside the lab, greatly reduces the likelihood of transfer of cloned DNA fragments from B anthracis to related microorganisms. Further, even in the very unlikely event of transfer to a related micro-organism, the cloned sequences will not express a product that could have toxic or other detrimental effects if delivered to human tissues.
In the case of the transposon mutation experiments we will employ a temperature sensitive, non-mobilisable plasmid to deliver the transposon thusus removing a potential mechanism for host/gene transfer. The resistant marker that does not encode resistance to a first line antibiotic used to treat anthrax. While there is a remote possibility that host sequences flanking the transposon insertion could be mobilized following integration into and excision from the the chromosome it is extremley unlikely that the B. anthracis derived sequences will encode a product that could have toxic or other detrimental effects.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste and contaminated glassware will be autoclaved as per the published Cardiff University instructions. The correct operation and the validation of sterilization and discard autoclaves within in the dept is described in the SOP entitled "The Welsh School of Pharmacy Procedures for the Use of Horizontal Autoclaves for Sterilization and discard"

Laboratory surfaces likely to have been in contact with spores of the attenuated vaccine strain of B. anthracis will be wipes with 10% Sodium hypochlorite. Following a 10 minute contact time the surfaces are washed with water to remove any toxic residue. As part of good working practice all work surfaces will be wiped clean with 10% hypochlorite solution at the end of each experiment and at the end of the the working day.

Laboratory studies have confirmed the effectiveness of this decontamination for B anthracis spores.

Please enter comments on the GM safety committee on the risk assessment

The comments of the university of the university GM safety committee were as follows: the committee were in agreement that the project is a class 2 activity and advised that we consider the choice of disinfectant carefully so that you are sure the disfectant is appropriate for the microrganisms that you will be working with and the particular envirnoment that you will be disinfecting. We have done this.

The committee also commented that the school as a whole should be thinking about decontamination of the rooms where you will be carrying out the work, should the use of this room change. We have also done this.

Purposes of the contained use

Clostridium difficile is a significant cause of morbidity and mortality amongst hospitalized patients, costing the NHS £4000 per case to treat. The financial cost is further increased due to the high rate of relapse. Studies have shown that the stimulation of a robust antibody based immune response plays a key role in mediating protection. Animal studies have confirmed the feasibility of using antibodies to confer passive protection. The C terminal receptor binding domains of the C. difficile major virulence factors, toxin A (tcdA) and toxin B (tcdB), stimulate the production of protective antibodies in animals. In addition vegetative cell surface associated S layer proteins have been shown to induce the production of antibodies which inhibit the binding of the vegetative bacterium to human gut cells. We propose to clone and express codon optimized versions of the C terminal region in E. coli and isolate recombinant proteins. Sequences will be cloned and expressed using a commercially available 6XHis tag expression system produced by QIagen Inc, California. An external company Genscript will construct a cloning vector containin the codon optimised gene sequence. The sequences will be inserted downstream of a 6XHis affinity tag to enable subsequent purification with a Nickel column.

Recipient or parental organism

The host from which proteins will be expressed is SG13009, an attenuated K12 E.coli strain with the following phenotype NalS, StrS, RifS, Thi-, Lac-, Ara+, Mtl-, F-, RecA+, Uvr+, Lon+. As the organism is considered non pathogenic to humans and animals and due to the limited survivability of the organisms in the environment, the risk to human health and the environment is low. The use of auxotrophic strains also reduces the potential risk of the transfer of genetic material. The proteins to be expressed are the fragmented non toxic regions.

Host/vector system
The vector to be used is pUC18 an E.coli plasmid isolated from E.coli DH5α - derived from the non pathogenic E. coli K12 strain. The vector is non transferable.

**Origin & function**

- **Toxin A tcdA** - C terminal domain
- **C. difficile 630 genome nucleotides 801048 to 803975**
- **Toxin B tcdB** - C terminal domain
- **C. difficile 630 genome nucleotides 792643 to 794493**

High molecular weight S-layer protein slpA
Low molecular weight S-layer protein slpA

The C terminal domain of the toxin has been identified as the receptor binding region. It has been shown to be highly immunogenic and is non-toxic. S-layer proteins are believed to be involved in adherence.

**Evaluation of foreseeable effects**

The GMO is an attenuated autrophic E. coli strain, considered equivalent to ACDP hazard group 1. The organism will have limited survivability in the environment and as such poses a low risk to human health, animals and plants and the environment.

The committee queried whether or not the initial cloning of the non toxic fragments of Toxin A and Toxin B would be carried out in Cardiff and have been assured that it will not. References were also requested to show that the C terminal domain has no toxic effect. The Committee were then satisfied that the risk assessment was suitable and sufficient and agreed with the classification of the activity.
**Project Additional Information**

**Purposes of the contained use**

Parkinson's disease is a neurodegenerative disease characterised by the loss of specific dopamine neurons in the brain and the accumulation of proteinous inclusions known as Lewy bodies. In idiopathic Parkinson's disease these inclusions contain a protein called alpha-synuclein. Some genetic forms of Parkinson's disease are caused by mutations of the alpha-synuclein protein. Transgenic animal models expressing mutant alpha-synuclein do not show extensive neuronal loss or motor deficits. However, work by our collaborators in Sweden has demonstrated that administration of the recombinant adeno-associated viral (rAAV) vector containing human wild-type or mutant alpha-synuclein is toxic to the specific dopaminergic neurons in the brain affected in Parkinson's disease. We intend to use rAAV vectors to express human wildtype and mutant alpha-synuclein to create a rodent model of the degeneration observed in Parkinson's disease. The rAAV vectors will be stereotaxically injected into the brains of anaesthetised animals. We will inject the rAAV into selected areas of the basal ganglia, or associated brain regions to examine influences on motor and cognitive
function. This will enable us to identify the role that alpha-synuclein may play in synaptic plasticity and its relationship to the symptoms of Parkinson's disease. In later stages of the study we will determine the efficacy of transplantation of foetal cells to repair this damage and restore function and whether the presence of alpha-synuclein is detrimental to the development of the graft.

Recipient or parental organism

Recipients of rAAV vectors will be rats and mice. During a stereotactic surgery the vector will be injected directly into the target areas in the brain. The injections sites will be in cortical areas and within the Basal Ganglia. The virus is replication incompetent and the small titres (µl volumes) of virus transferred to the brain have no risk of excretion in the urine or faeces of injected animals.

Host/vector system

Vector system: rAAV5, rAAV6. The vectors express the transgene from either a hybrid promoter consisting of an enhancer element from the cytomegalovirus promoter, followed by the chicken b-actin promoter containing a rabbit b-globin intron, termed CBA, or the human synapsin promoter.

The functional recombinant vectors contain the coding sequence for the human wildtype or mutant (A53T, S129D, S129A and S129G) alpha-synuclein gene under the control of the promoter and the human bovine growth hormone poly A site flanked by inverted terminal repeats (ITRs). In addition, matching vectors encoding for GFP marker proteins will be used as controls.

rAAV vectors are replication incompetent (only 4% of the original DNA is left in the rAAV) and the safety of rAAV therapy has been approved by 3 clinical trials which have been completed and published (for review see Bjorklund and Kirik, Biochimica et Biophysica Acta (2009) 703-713; see also references therein).

Origin & function

The production of the rAAV vector will be carried out by our collaborators in at Lund University in Sweden. Prof. Anders Bjorklund and Prof. Deniz Kirik will provide us with a working solution of the rAAV vectors that can be used directly without any further processing.

Even though the rAAV vector is replication incompetent, the vector solution is kept free from adeno helper viruses. The production in Lund follows the so-called helper-free method, which is based on the adenovirus-free transient transfection of all elements that are required for rAAV production in host cells such as HEK293 cells (for further review of rAAV vectors and their production, please see Goncalves Manicure, Virol J. 2005 May 6;2:43).

Evaluation of foreseeable effects

The rAAV vector only contains the inverted terminal repeats (ITRs) from the original virus which make up only 4% of the total DNA. It is replication incompetent even in the presence of the adeno helper virus. The host organism will be a rodent. There will be no transmission from rodent tissues to other organisms (the rAAV vector will be injected directly into the brain). The virus is able to infect cells it comes into contact with, although human transduction efficiency is low.

It is known that overexpression of either wildtype or mutant human alpha-synuclein in the substantia nigra of rodents or non-human primates will lead to the generation of protein inclusions, which closely resemble the Lewy bodies formed in Parkinson's disease. This can lead to a progressive cell death and motor impairments. We intend to use this property of the rAAV vector to generate animal models of disease pathology. Alpha-synuclein is a naturally expressed protein whose function in the human brain is unclear. However, rare genetic mutations of this protein are strongly implicated in the development of familial Parkinson's disease. Although not scientifically determined, it is highly unlikely that these rAAV vectors could cause harm to human health. The rAAV infects human cells with very low transduction efficiency and the wildtype AAV does not cause disease in immunocompetent humans. Toxicity of the rAAV-alpha-synuclein has only been reported following direct administration of high titres into the central nervous system in animals and even in this context, only certain populations of cells appear vulnerable to its effects (e.g. the dopaminergic neurons of the ventral tegmental area are relatively resistant whilst cells in the substantia nigra are significantly affected by exposure to the viral vector). There is no evidence to suggest that wildtype or mutant alpha-synuclein is harmful if it comes in to contact with the skin or blood stream (in the case of a needle stick).

To further minimise any risks, Dr E L was trained by our experienced collaborators at Lund University in how to handle the rAAV vector and how to conduct stereotactic
surgeries with them. All future users of the facility need to be instructed in all safety regulations etc. by the chief animal technician (currently Veronica Walter) and will follow standard operating procedures.

Needle stick - the use of sharps and administration to animals through a glass capillary opens up the possibility of transmission through needle stick. Training from Swedish collaborators on how to work with the vector and two layers of gloves will minimise the risk of a needle stick.

Inhalation - opening a vial or spillage of the virus could cause an aerosol of viral particles although the risk is extremely low. All procedures requiring an open container (loading the injection syringe) will be carried out in an appropriate safety cabinet in our existing and designated virus facility. The viral vector could be transmitted through contact with the skin and eyes. These risks will be minimised following the standard operating procedure of the virus suite. Although not scientifically proven we believe that - as wildtype alpha-synuclein is normally expressed only in neurons - this contamination is unlikely to pose a health risk. Nevertheless, all precautions will be taken to avoid such an event, including minimal use of sharps and two layers of surgical gloves. rAAV vectors do not cross the blood brain barrier, therefore they do not pose a risk of transmission to the central nervous system if the exposure is peripheral.

Rodent hosts will be anaesthetised in a separate area in the virus surgical theatre. The surgical tools used for the surgery will be a dedicated set of surgical instruments that will not leave the room and sterilised therein. The surgical procedure will be performed and the animal then returned to recover in a recovery cage. Transmission through the rodent host will not occur as there is no viral replication and therefore no excretion of the viral procedure. The rAAV vector is in the brain and cannot be excreted from there. Adherence to all standard operating procedures of the facility will ensure no transmission outside of the viral suite.

The viral suite will have special colour lab coats which will not leave the room. Special shoes will be provided and a designated changing area will be marked at the entrance of the viral suite.

Standard operating procedures and emergency instructions will be clearly posted to the walls on laminated paper.

The viral suite will have special colour lab coats which will not leave the room. Special shoes will be provided and a designated changing area will be marked at the entrance of the viral suite.

Super infection with rAAVs of individuals already carrying an adenovirus is unlikely to be an additional risk factor. rAAVs are replication incompetent (only 4% of the original DNA is left in the rAAV) and the safety of rAAV therapy has been approved by 3 clinical trials which have been completed and published (for review see Björklund and Kirik, Biochimica et Biophysica Acta (2009) 703-713; see also references therein).

The virus is replication incompetent and the small titres (µl volumes) of virus transferred to the brain have no risk of excretion in the urine or faeces. The only risks are from aerosols (prevented by syringe loading in a safety cabinet) and with sharps. Use of sharps will be minimal and risk reduced by using blunt ended syringes and double layers of gloves.

Once with the vector is injected into the rats' brain, the animals do not require a level 2 housing facility and do not cause health and safety risks.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
The virus is replication incompetent and the small titres (µl volumes) of virus transferred to the brain have no risk of excretion in the urine or faeces of injected animals (bedding in the holding rooms can be regularly disposed).

The only risks of virus exposure are from aerosols (prevented by syringe loading in a safety cabinet) and plastic/sharps/paper waste.

Use of 1% Virkon (contains a blend of inorganic peroxygen compound, inorganic salts, organic acid and anionic detergent). It has been proven highly effective to kill over 65 strains of virus in over 19 viral families.

Sharps: thorough spraying with 1% Virkon solution before desposition into clinical waste sharps bins for disposal as clinical waste (ready for incineration).

Plastic/paper waste: thorough spraying with 1% Virkon solution before deposition into specially marked biohazard bags and placing into containers for incineration. Pipette tips used for handling of solutions will be disposed into plastic screw bottles. The bottle will be disinfected on the outside and transferred into appropriate container for incineration.

Liquid waste will be collected inside designated bottles containing 10% Virkon and disposed for incineration.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Our application was accepted with 2 minor revisions which have already been corrected. The risk assessment application has now been fully approved (9th of July 2009).

Project Ref 130/10.2

Date Ackn'd CU2 Project Title

02/03/2022
The purpose of the project is to investigate mammalian cell function by manipulating proteins involved in cell signalling and gene regulation. The particular focus is on the genetic modification of cells of the immune system particularly primary leukocytes and lymphocytes. We are interested in molecules found in all parts of the cell, for example cell receptors, kinases and transcription factors and some soluble factors.

Two approaches will be used to alter leukocyte function. Firstly, the manipulation of proteins by the expression of those proteins, or mutants thereof, in cells. This will allow us to study molecular function. Secondly, the reduction in the expression of specific mammalian genes using small interfering RNAs. So called third generation viral vectors will be used to introduce DNA encoding proteins or shRNAs into mammalian cells. For example, to enable analysis of the human and mouse genomes the RNAi Consortium has developed lentiviral shRNA libraries targeting each of the 22,000 human and mouse genes. Lentiviral vectors currently offer the most efficient means for stably introducing genetic material into quiescent cells.

This programme of work will involve the generation of a variety of genetically modified organisms.

Firstly, preliminary manipulations and amplification of DNA will be performed in disabled E.coli strains (e.g. DH5α).

Recombinant lentivirus will be generated in helper-free cell lines (for example, 293T cells).

These viruses will then be used to infect cell lines in culture and will be used to infect primary human and mouse cells (for example: macrophages, antigen presenting cells, B and T cells, fibroblasts and haematopoietic cells).

Finally, the viruses will be used to infect mice.

Purposes of the contained use

Recipient or parental organism

This programme of work will involve the generation of a variety of genetically modified organisms.

Firstly, preliminary manipulations and amplification of DNA will be performed in disabled E.coli strains (e.g. DH5α).

Recombinant lentivirus will be generated in helper-free cell lines (for example, 293T cells).

These viruses will then be used to infect cell lines in culture and will be used to infect primary human and mouse cells (for example: macrophages, antigen presenting cells, B and T cells, fibroblasts and haematopoietic cells).

Finally, the viruses will be used to infect mice.

Host/vector system

Preliminary vector manipulations will be performed in disabled E.coli strains (e.g. DH5α).
The resulting plasmids will be transiently transfected to generate HIV based lentiviruses.

**Origin & function**

This programme of work will generate genetically modified lentiviruses in order to study primary human leucocytes. Viruses containing different genetic material will be generated.

The GMOs that will be generated are disabled. The viral vectors that will be used, for example pLKO-1 or PCMV::R8.91, cannot express any viral proteins. All of the regulatory/accessory genes of HIV-1 have been removed, specifically Nef, Vpr, Vpu, Vif and Tat that are critical for viral replication and pathogenesis. The proteins required for generating virus, which does not include Nef, Vpr, Vpu or Vif, are instead supplied separately on another plasmid(s).

Furthermore, the vector is self inactivating. Self inactivation results from the introduction of a deletion in the U3 region of the 3' long terminal repeat (LTR) of the viral vector used to produce the vector RNA. During reverse transcriptase, this deletion is transferred to the 5' LTR of the proviral DNA and transcriptional activity of the LTR is lost. This reduces the likelihood that replication-competent retrovirus can originate in the vector producer or target cells.

In terms of inserts, it is important to recognise that some of these proto-oncogenes can lead to tumour formation when expressed in transgenic mice or in rodent cells. This demonstrates that they can contribute to cancer and so should be seen as having the potential to be a risk to human health.

However, it is important to note that no one gene has been shown to be sufficient to transform human cells (Hahan and Weinberg "Rules for making human tumour cells" (2002) New England Journal of Medicine, 347 (20), pp. 1593-1603). These authors published a report that shows that introduction of three individual genes was required to transform primary human epithelial or fibroblast cells (Hahan et al, Nature (199) 464-468). Historically, the assays for transformation are usually assessed from non-human cell types, for example chicken or mouse cells either in vitro or in vivo. Human cancer is now accepted to be a multi-step event due to the accumulation of multiple genetic alterations. Thus, it is extremely unlikely that any of the viruses proposed could transform human cells alone.

**Special considerations for work:**

I) Introduction of any proto-oncogene into a lentiviral vector and accidental administration to a worker would only represent a 'single hit' in a cascade and none of the proposed genes of study have been shown to be sufficient alone to transform HUMAN cells.

II) At any one time workers will work with only one proto-oncogene containing lentiviral vector. Experimental cells may be sequentially modified, but individual viral vectors will be handled in isolation to prevent accidents involving 'multiple hits'.

III) When working with human inserts in lentiviral vectors the use of sharps is strictly forbidden.

IV) Human skin has many properties as a protective barrier. However, care should be taken for researchers in which skin is compromised for whatever reason. This includes those with open wounds or those with skin problems. If the wound or problem cannot be adequately covered or protected then consideration should be given to delaying the work.

V) When infecting mice with lentiviral vectors:

- Needles are required, however lentiviral vectors with human sequences will not be used. This ensures that should accidental needle stick injury occur the viral insert sequences are foreign sequences that should be recognised by the immune system.

- The procedure rooms will be isolated from other workers to prevent accidental 'crowding' interference of others increasing the chances of needle-stick injury, which are minimised by good handling practice.

VI) Below we have specifically considered the risks to human health associated with the following 'highest-risk' genes as models of 'worst case' scenarios:

**XAP-70**

Tyrosine kinases were the first identified oncogenes. Viral forms of the proteins were shown to be involved in the growth of tumours in chickens. However, it has not been possible to derive a transformed human fibroblast cell line with any tyrosine kinase, despite the importance of these molecules, for example c-SRC, to numerous human
cancers. ZAP-70 in particular is overexpressed in cells from some patients with chronic lymphocytic leukaemia. However, the functional role of the molecule is poorly understood and it may be a marker of poor prognosis rather than an oncogenic molecule. Thus it would seem essential for this molecule to be expressed with many others to become a risk to humans.

IKK
The serine kinase, IKK, lies upstream of the NF-κB pathway which plays an important role in inflammation and cell survival. This pathway is active in some cancers, including chronic lymphocytic leukaemia. However, IKK is unable to transform cells alone. Furthermore activation of this pathway through IKK would likely cause the activation of an inflammatory response that would be likely to clear the virus and any cells infected with the virus.

Tert
While not a bona fida oncogene, Tert prevents senescence of human cells and is one of the molecules necessary to allow human cell transformation. It can cause cell immortalisation. However, by itself, it cannot cause cancer. This molecule is the focus of research within the School of Medicine and a retrovirus expressing this gene is used. The ability of lentivirus to enter non-dividing cells, the key difference between lentivirus and retrovirus, would be unlikely to provide an extra risk for Tert as Tert activity would not alter a non-dividing cell.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
The GM mice will be contained in a modern animal facility providing a specific pathogen free environment and a series of well tested physical barriers to prevent the escape of the animals to the environment and allow the routine disposal of animal corpses. Class 2 procedures are performed in a dedicated area with biological safety cabinets and mice subsequently housed in filtered cages.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Recombinant viruses will at all times be maintained in an environment designed to prevent aerosol spread. All flasks containing the virus shall be kept closed except when decanting and pipetting which will be conducted in tested class II safety cabinets. Centrifugation steps shall be performed in sealed buckets. The use of Sharps when handling virus preparations will not be permitted. Contaminated pipettes will be immersed in Actichlor, or a similar chlorine based disinfectant, for a minimum of 4hr prior to transferring to a container for autoclaving. The tissue culture cabinet and any potentially contaminated area will be disinfected with 70% ethanol according to an approved protocol. Access to laboratories employed for virus work will be restricted. Recombinant viruses that will be injected into mice cannot replicate and thus virus should not escape into the environment from these mice. Thus, bedding and feed can be disposed of as normal. The only risk is escape from the injection site and this will be controlled by treatment of the injection site with antiviral agents as described in the risk assessment. Carcasses of mice injected with recombinant virus will be labelled, packaged and carried appropriately offsite for incineration. These mice should not contain any live genetically modified organisms. The waste contractors are registered to accept this waste.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N
The Genetic Modification Safety Committee had reservations which have been completely satisfied by the provision of further information and updating of the risk assessment.

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

The purpose of the contained use are the functional analysis of MCV genes in isolation, development of a MCV genes in isolation, development of a MCV cell culture system for the analysis of innate and T cell immunity directed against MCV and the testing of antiviral substances active against MCV in this system.

The project is a collaboration between the PI and GW and BM both of Cardiff University School of Medicine, Wales, UK, FM, INRA Toulouse, France, BM, NIH, Bethesda.
The project is a connected programme of work to accommodate the variety of gene expression systems necessary to study different aspects of MCV infection.

**Recipient or parental organism**

Parental organism to most all proposed GMMs is the Molluscum contagiosum virus (MCV). MCV DNA is stored in a MCV overlapping and redundant genome fragment library available in the Pis lab and submitted to ATCC for distribution in 2009 (Bugert J. (2008) Encyclopedia of virology: molluscum contagiosum virus. 3rd ed. Oxford Elsevier. Pp319-324). MCV genes are prepared in isolation for insertion into the Host/vector system by PCR. Homologs of the MCV mc026 gene from Squirrelpox virus (SPV; gift of CM, Moredun Research Institute, Scotland) will be used in comparative functional studies.

Cellular gene products found to have molecular interactions with MCV gene products, incl. genes of the ESCRT pathway (mc162), will be expressed for functional studies.

**Host/vector system**

MCV 1.1 Maintenance of the MCV gene fragment library, cloning of MCV wildtype genome fragments, and expression of MCV gene products in E. coli: bacterial plasmid hosts are pAT153 and pACYC184; bacterial expression vectors will include pET and the pGEX derived plasmids.

MCV 1.2 Expression of selected MCV genes in mammalian cells using eucaryotic plasmid expression vectors: eucaryotic plasmid expression vectors will include the pIRESneo, pIRES-EGFP, and pcDNA3 derived plasmids.

MCV 1.3 Expression of selected MCV genes in mammalian cells using replication incompetent adenoviral expression vectors: adenoviral expression systems will include the AdX (BD Clontech), and AdEasy (Stratagene) and locally developed derivatives (G W).

MCV 1.4 Expression of selected MCV genes in mammalian cells using vaccinia virus expression vectors: VACV viruses will include the WR and the MVA strains of vaccinia virus, both obtained from Dr B M, NIH. NIAID, LVD, Bethesda, Maryland.

MCV 1.5 Expression of selected MCV genes in mammalian cells using replication incompetent retroviral expression vectors: retroviral expression systems will need to infect resting cells and use the lentiviral system (LentiShuttle - Gruh et al., Leibniz Research Laboratories, Hannover, Germany, BioTechniques, Vol. 38, No 4, April 2005, pp. 530-534) already approved for use in other labs of the Cardiff University School of Medicine.

MCV 1.6 Expression of selected MCV genes in insect cells using baculovirus expression vectors: baculovirus expression systems use the pMEL Bac A, B, C donor system for secretion of the transgene via the honeybee melittin secretion signal sequence (Bac-to-Bac Baculovirus Expression system, Invitrogen).

MCV 1.7 Cloning of selected MCV genes into Shope Fibroma Virus (SFV) donor plasmids; the SFV donor plasmid is a gift from FM, INRA Toulouse, for expression of MCV genes via recombinant SFV and while recombinant virus production and animal experiments will take place in Toulouse.

MCV 1.8 Cloning of selected MCV genes into Fowlpoxvirus (FPV) donor plasmids: expression of MCV gene in FPV in a collaboration with DrM S, Imperial College, London. Here only the plasmid construct will be made in Cardiff (L1), while recombinant virus production and animal experiments will take place in London.

MCV 1.9 Expression of cellular gene products affected by MCV infection in mammalian cells using eucaryotic plasmid expression vectors: eucaryotic plasmid expression vectors will include the pIRESneo, pIRES-EGFP, and pcDNA3 derived plasmids.

MCV 1.10 Expression of cellular gene products affected by MVV infection in insect cells using baculovirus expression vectors: cellular genes will be expressed using the pMEL Bac A, B, C donor system for secretion of the transgene via the honeybee melittin secretion signal sequence (Bac-to-Bac Baculovirus Expression system, Invitrogen).

MCV1.11 Expression of poxviral homologs of MCV genes in E. coli and eucaryotic cells: as in MCV 1-1 and 2.

**Origin & function**

Homologs of the MCV mc026 gene from Squirrelpox virus (SPV; gift of Dr C M, Moredun Research Institute, Scotland) will be used in comparative functional studies.

Cellular gene products found to have molecular interactions with MCV gene products, incl. genes of the ESCRT pathway (mc162), will be expressed for functional studies.
Evaluation of foreseeable effects

Forseeable effects and risk determined by the nature of MCV gene inserts:

MCV genes will be overexpressed in a number of viral and non-viral expression systems and purified to raise gene specific antibodies, establish an MCV ELISA for seroepidemiology and to investigate function and MCV specific T cell immunity.

Most MCV genes (89%) are MCV structural proteins with high homology to other poxviral genes and no known effects on cell cycle or host immunity.

Of the MCV nonstructural proteins to be expressed (initially mc002, mc007, mc080, mc161 and mc162 (Slam homology family), most have no known effects on cell cycle or host immunity.

Our worst case risk assessment will focus on mc007, which has been shown to bind Tb protein and to interfere weakly with the host cell cycle in a non-poxviral expression system (Mohr et al, Jvi (2008) 82: 10625-10633) and mc080 a MCV MHC class I homolog (Moss B et al., Trends Microbiol. (2000) 8:473-477).

Worst case scenarios:

MC007: MC007L gene of human pathogenic MCV encodes a mitochondrial outer membrane (MOM) protein that targets pRb and E2F-1 via a conserved LxCxE motif, which is present in many viral oncoproteins. This oncoprotein induced deregulation of the pRb pathways plays a central role in tumour pathogenesis. Through the LxCxE motifs, MC007L induces a cytosolic sequestration of pRb at mitochondrial membranes, leading to the inactivation of the protein by mislocalization. The disruption of the pRb/E2F protein complex leads to cell proliferation, induction of apoptosis, and cellular transformation (Mohr et al., 2008). Thus the interaction between MC007L and pRb provides a mechanism by which a virus can perturb the cell cycle.

MC080R: The main function of MHC class I molecules is the cell surface presentation of peptides, derived from foreign antigens, for recognition by the immune system. The presence of MHC class I molecules on the surface of cells inhibits NK-cell activation and lysis. The MC080 gene of MCV encodes a glycoprotein that is homologous to the mammalian MHC class I heavy chains. MC080 has a very long signal peptide (69 amino acids) and there is a 24.5% overall amino acid identity between MC080 and the human MHC-1 protein (Bugert et al. 2000). The MCV MHC-1 homologue thus clearly has the potential to inhibit NK recognition of MCV-infected cells by a wide range of mechanisms. NK cell cytotoxicity is controlled by a fine balance between activating and inhibitory signals, the latter generally over-riding the former. Both activating and inhibitory NOK receptors can bind HLA class I molecules. There are several known viral MHC-1 homologs, mostly in herpesviruses, and some of them have already been shown to be inhibitors of natural killer cells (Tomasec et al., 2000).

REFERENCES:

Targeting the Retinoblastoma Protein by MC007L, Gene Product of the Molluscum Contagiosum Virus: Detection of a Novel Virus-Cell Interaction by a Member of the Poxviruses. Journal of virology 82: 10625-10633.

During construction of GMM and gene expression using pro- and eukaryotic plasmid vectors:

Naked viral nucleic acid could be transmitted when using pro- and eukaryotic plasmid expression vectors and during construction of the recombinant viral genomes (via donor plasmid)

Medium risk

Adenoviral and lentiviral donor plasmids use herpes and retroviral transcription control sequences which can be recognized by the human host. The plasmids can be
expressed and the risk is comparable to the risk of the respective recombinant virus GMMs.

Very low risk:
Plasmids with procaryotic transcription signals cannot express transgenes in human cells they could Donor plasmids of baculovirus employ baculoviral transcription control elements which are not recognized in human host. In the case of poxviral donor plasmids, poxviral promoters are not recognized by the eucaryotic transcription machinery. All poxviral nucleic acids will be transcriptionally silent if accidentally transferred into the human host.

Risk of viral vectors used:
Three of the six viral expression systems proposed can cause pathology could cause pathology in the human host independent of transgene expression. The expression pattern in a range of human tissues will depend on the individual transmission and replication characteristics of the each viral expression system.

Adenovirus: can infect and replicate in a wide range of human cells, mostly via the respiratory and faecal oral routes. Wild type Adenovirus infection varies in a clinical manifestation and severity; symptoms include fever, rhinitis, pharyngitis, cough and conjunctivitis. The risk from infection by defective recombinant adenoviral vectors depends both on the dose of virus and on the nature of the transgene. Adenovirus does not integrate into the host cell genome but can produce a strong immune response. Wild type virus is spread directly by oral contact and droplet spread; indirectly by handkerchiefs, eating utensils and other articles freshly soiled with respiratory discharge of an infected person. In the laboratory, care must be taken to avoid spread of infectious material by aerosol, direct contact or accidental injection.

Baculovirus; cannot replicate in human host cells. No known pathology in humans.

Fowlpoxvirus: cannot replicate in human cells efficiently. No known pathology in humans.

Lentivirus: can infect and replicate in a wide range of dividing and resting human cells via all known transmission routes. Considering that up to 30% of the human genome is of retroviral origin, any pathological effects of the unmodified lentiviral vector would be negligible in comparison to ongoing endogenous retroviral activity in the human host (HERVs) Integration of the transgene cassette in the host genome is a deliberate effect when using lentiviral constructs. Accidental infection of a human host would likely result in integration of transgenes into host cell genomes. The outcome would be determined by the physiological/pathological effect of the transgene.

Shope Fibroma virus: cannot replicate in human host cells efficiently. No known pathology in humans.

Vaccinia virus: can infect and replicate in a wide range of human cells. Known routes for vaccinia infections are the skin, through smear infection, and the conjunctivae, through aerosols and messy accidents. The ability of attenuated vaccinia viruses to induce fever, inflammation and death in the human host is much reduced. The most at-risk-individuals are those with a defective immune system. In this case replication competent vaccinia viruses can induce eczema vaccinatum, an extensive skin condition, with a smallpox-like rash. Eczema vaccinatum encephalitis. This condition has been observed in one in a million vaccinees, when vaccination was still widely practised. Vaccinia encephalitis can be lethal, the severity of the condition is, however, tightly linked to the genetic predisposition fo the individual, eg, tendency to develop overwhelming autoimmune responses.

The ultimate compound risk of the various GMMs will be determined by the risk of the MCV viral insert. This is discussed for two examples at the beginning of this section.

The safe containment of the GMM and the prevention of transmission are the most important goals in risk prevention. The most important precautions are therefore use of class II safety cabinets in L2 laboratories, effective disinfection and destruction of waste with chemicals and use of autoclaves, complete personal protective gear in the lab, including goggles (mandatory), and to avoid the generation of viral aerosols

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**Not applicable**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**
All laboratory work involving recombinant viruses will be carried out in L2 containment level labs. All personnel will be trained in recognising virus infections, awareness of human-to-human transmission, and the increased risks for individuals suffering from immune disorders (e.g., atopic dermatitis, severe acne, empetigo, contact dermatitis, psoriasis, chickenpox, steroid medication, pregnancy, infection with other pathogens). The exposure route via the conjunctiva will be particularly stressed and the use of adequate protective gear enforced in the lab. All personnel will be monitored by the Occupational Health Service at the School of Medicine.

Laboratory work will be carried out in class II safety cabinets, with personnel wearing gloves. Disposable plastic pipettes and pipette tips will be used. Recombinant viruses will be used under conditions avoiding the generation of aerosols. Flasks containing virus will be kept sealed outside of the safety cabinets. Centrifugation will be carried out in sealed buckets, that will only be opened in safety cabinets. All waste materials will be collected in plastic bags in the safety cabinets, the bags will be sealed inside and then autoclaved. No sharps will be used.

Removable equipment and interior surfaces of the safety cabinets will be sprayed with Incidin® PLUS (Ecolab, Swindon UK) containing the patented active substance Glucoprotamine with wide effect spectrum against bacteria (also MRSA and Tbc), fungi, papova-, adeno-, vaccinia-, herpes-, rota- and hepatitis-B-viruses (HBV) in MADT and antigen test, as well as AIDS agent (HIV)-certified by the German Society for Hygiene and Microbiology (DGHM). Spillage of GM material will be treated with hypochloride.

For the quality assurance of the disinfection and autoclaving procedures, virus contaminated Incidin disinfected and belached plasticware, as well as autoclaved waste material will be rinsed with a small volume of PBS and tested for rest-infectivity on appropriate cells in a standard virus detection assay.

The Cardiff University subcommittee recommended the attached risk assessment for use of recombinant vaccinia viruses in this connected program of work as exemplary.

The committee requested the PIs to elaborate on the differences between the WR and the MVA strains of vaccinia virus and the relative safety aspects, when potentially oncogenic proteins are expressed. The risk was deemed higher with the replication incompetent (in human cells) MVA, because of the longer stay-on time in infected tissues of the recombinant virus, but still not exceeding Class-2.

Furthermore regarding laboratory access, the subcommittee took note that Dr B’s virus laboratory 1TB115 is located in a NPHS secure area and immune incompetent personnel will be excluded from the access to the laboratory.

Dr R C., BSA Cardiff University, received no more adverse comments from the Cardiff University GM committee.

The GM committee recommended to submit a notification as Class 2 for the Connected program of work and attach the MCV/vaccinia virus risk assessment (MCV 1-4).
Project Ref 130/10.4

Date Ackn'd 20/07/2010

CU2 Project Title Investigation of potential therapeutic targets in myeloid leukaemia

Project Additional Information

Purposes of the contained use
Use of lentiviral gene transfer to identify new therapeutic targets in acute myeloid leukaemia

Recipient or parental organism
Replication-defective lentivirus

Host/vector system
The following expression vectors will be employed: encoding both lentiviral expression vectors and (separate) plasmids for packaging of replication-defective virus

pLenti6/TR
The vector system to be used is a third generation HIV-1 based lentiviral system, with a number of safety features designed to enhance biosafety [J. Szulc, et al., Nat. methods 3 (2): 109-116, 2006]. Distinct packaging vectors are used, none contain the psi or LTR signals. The expression vector 3'-LTR contains a deletion (deltaU3) rendering it "self-inactivating" and thus incapable of packaged virus production following transduction into the target cell. Pseudotyping is implemented with VSV-G replacing the HIV-1 envelope gene.

Evaluation of foreseeable effects

The major safety concern is the possibility of generating of replication competent virus. The vector system employed incorporates multiple safeguards to make the risk of this extremely low (see risk assessment).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Will liquid waste be autoclaved disinfected and then autoclaved

Disinfection:

Product name Actichlor
Generic Chemical Name: NaDCC hypochlorite
Expected degree of kill 1000ppm hypochlorite
How validated commercial source

Solid waste to be autoclaved and disposed of as clinical waste

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
The committee had a number of queries and requests for further information, including the higher risk involving pseudotyping with the VSV-g gene. Alterations were made to the Risk Assessment which satisfied the GMSC.

**Project Additional Information**

**Purposes of the contained use**

Thalamocortical (TC) neurons are characterised by state-dependent firing properties. During quiet wakefulness they exhibit tonic action potential firing, whereas during non-rapid eye movement sleep they fire high-frequency bursts of action potentials riding on low-threshold Ca2+ potentials (LTCP). These LTCPs are generated by T-type...
Ca2+ channel activation and contribute to the emergence of sleep slow oscillations (<1Hz) and delta waves (1-4Hz) in thalamocortical territories. In addition to their physiological roles in sleep, T-type Ca2+ channels have been implicated in a number of pathological brain states, including absence seizures. These are characterised by a brief loss of consciousness and bilaterally synchronised 3Hz ‘spike and wave’ discharges (SWDs) occurring spontaneously in the EEG, in depth EEG recordings and in thalamic areas. Though SWDs had been suggested to be generated by dampened inhibitory (GABAergic) signalling, it has recently been shown that GABA re-uptake mechanisms are disrupted in thalamic astrocytes resulting in excessive inhibition. To further our understanding of the cellular mechanisms underlying thalamocortical oscillations of physiological and pathological states, we now need to selectively manipulate cellular and neuronal network activity using recombinant adeno-associated viral (rAAV) and lentiviral (LTV) vectors to express microbial rhodopsins (light-sensitive cation or chloride channels; 'Opsins') or engineered light-activated ligand-gated neurotransmitter channels ('LALGNCs') under cell type specific promoters. Laser light stimulation of opsins and LALGNCs offers unprecedented temporal (on a millisecond timescale) and spatial (over mm of tissue) control over the activity of discrete cell populations, and will allow us to selectively manipulate and record cellular and neuronal network activity in vitro and in vivo.

Microliter volumes of high titer virus (expressing an opsin or LALGNC) will be targeted to thalamic territories and associated cortico-limbic areas for in vivo and in vitro studies of cellular and neuronal network activity

**Origin & function**

Viruses will be produced on our behalf by a commercial Vector Core in the United States using plasmids originating from the Karl Deisseroth laboratory, available from AddGene.

rAAV and LTV plasmids will contain transgenes encoding for microbial opsins (light-activated cation channels and chloride pumps) or LALGNCs. Opsi and LALGNC transgenes will be fused with genes encoding for fluorescent proteins (eYFP or m-cherry). Fusion opsin-fluorescence transgenes will be driven by exogenous (i.e. not wildtype HIV-1) constitutive or cell-type specific promoters.

Control rAAV or LTV vectors will not carry opsin, LALGNC or optical sensor transgenes. Rather, they will encode for fluorescent proteins (i.e. eYFP or m-cherry), or scrambled DNA sequences fused to a fluorescent protein.

All rAAV vectors (pAAV-MCS) will comprise (reading sense 5' to 3'): an exogenous promoter (i.e. not from wildtype AAV2), the transgene of interest (fused to a fluorescent protein), woodchuck hepatitis B virus posttranscriptional regulatory element (WPRE; used to enhance transgene expression) and polyA sites, flanked by AAV2 ITRs. rAAV vectors will be serotyped with AAV1, 2 or 5 coat proteins.

All LTV vectors (pLECYT) will comprise (reading sense 5' to 3'): HIV-1 Psi+ element, HIV-1 Rev-response element, an exogenous promoter (i.e. not from wildtype HIV-1), HIV-1 cPPT, the transgene of interest (fused to a fluorescent protein) and WPRE, flanked by HIV-1 3' truncated long-terminal repeats (LTRs). LTV vectors will be
Evaluation of foreseeable effects

Viral vector characteristics:
The rAAV (pAAV-MCS) and LTV (pLECYT and pFCK) vectors nominated for use in this study are replication incompetent and will be used in small (µl) volumes. Neither vector type contains pathogenic wildtype viral genes, or those relevant for replication. The vectors contain only those wildtype genes necessary for production of viral core structural proteins, genome packaging and RNA transcription and packaging. The risk of reversion to wildtype is considered minimal as all pathogenic genes have been deleted in pAAV-MCS and VSV-G pseudotyped LTV vectors. The AAV2 ITRs in the pAAV-MCS vector do not share any regions of homology with viral rep/cap-gene containing plasmids, thereby preventing the production of wildtype AAV2 through recombination. Since the majority of wildtype genes (most notably the promoter and enhancer sequences contained within HIV-1 3’ LTRs) have been deleted in pLECYT and pFCK LTV vectors, any risk of recreating replication competent wildtype HIV-1 or wildtype-like viruses by recombination is excluded (see Sliva K and Schnierle B (2010) Selective gene silencing by viral delivery of short hairpin RNA. Virol J, (7): 248).

pAAV-MCS vectors (derived from wildtype AAV2) will be serotyped with AAV1, 5 or 7 coat proteins, altering the tropism of the rAAV vectors compared with wildtype AAV2 (specifically, increasing their tissue spread). The pLECYT and pFCK vectors are derived from HIV-1. All HIV-1 wildtype envelope proteins will be replaced with the vesicular stomatitis virus G-protein (VSV-G) envelope vector; pseudotyping LTV vectors with VSV-G is expected to broaden tissue tropism compared with the parent virus (i.e. wildtype HIV-1 infects only CD4+ T cells, macrophages and microglial cells, whilst VSV-G LTV vectors can infect a broad spectrum of vertebrate cells; Sliva K and Schnierle B (2010) Selective gene silencing by viral delivery of short hairpin RNA. Virol J, (7): 248).

There will be no oncogenic sequences present in rAAV or LTV vectors. LTV vectors such as wildtype HIV-1 express their genetic material through integration into the host genome (using the viral enzyme Integrate). Consequently, there is typically a risk of insertional mutagenesis or cellular oncogene activation associated with random integration of the LTV vector. However, we feel this risk will be minimal, due to the deletion of wildtype LTV promoter and enhancer sequences within the LTRs of pLECYT and pFCK vectors, rendering them ‘self-inactivating’ (SIN) (see Miyoshi H et al (1998) Development of a self-inactivating lentivirus vector. J Virol, (72): 8150-8157; Zufferey R et al (1998)).

Possible routes of transmission:
Viral vectors could be transmitted to humans through contact with the skin, eyes or airways, or transmission into the blood stream. These risks will be minimised by following the standard operating procedure of the virus suite.

Needle stick (entry into the blood) - the use of sharps provides an opportunity for transmission to humans via needle stick. Needle stick injuries will be minimised by wearing double thickness gloves and changing to fresh, sterile gloves after handling the virus. Although both rAAV and LTV vectors would be able to infect peripheral human cells they come into contact with (i.e. via a needle stick injury), rAAV vectors exhibit low human transduction efficiency and are unable to cross the blood brain barrier (BBB). Furthermore, wildtype AAV is apathogenic in humans, according to current knowledge. Although not scientifically confirmed, given the size of the particles and their VSV-G pseudotype, it is not expected that LTV vectors will pass through the BBB.

Aerosols (absorption through the eyes or inhalation) - opening or spilling a vial of virus could cause an aerosol of viral particles. All procedures involving an open container will be performed behind the screen of an appropriate Class 2 safety cabinet.

Adherence to all standard operating procedures of the virus suite will ensure no transmission outside of the facility, which has designated colour lab coats that do not leave the room. Designated shoes will be worn only in the virus suite, and changing will occur only in selected areas of the room. Standard working procedures and emergency instructions (including office and out-of-hour phone numbers) will be clearly posted on the walls of the virus suite, which will be locked at all times when not in use. The room is clearly labelled as a virus surgery suite and contains a spill kit (containing absorbent paper towels, goggles, masks, gloves and 5% Virkon solution).

We have not encountered any documentation to suggest that rAAV and LTV vectors could recombine with a wildtype organism in the environment. However, transfer of viral vectors to the environment may occur via infected equipment and aerosol production; since rAAV and LTV vectors may exhibit survival in the environment, appropriate protective clothing (masks, gloves and designated lab coats and shoes) and cleaning of the virus suite with 5% Virkon is necessary (refer to Section 12: Waste Management Strategies). rAAV vectors are relatively resistant to temperature changes, but autoclaving is sufficient to kill the virus. Conversely, HIV-1 is fragile and extremely sensitive to even small fluctuations in temperature and the presence of oxygen. There is no evidence to suggest that pLECYT or pFCK vectors exhibit enhanced environmental survival compared with their parent virus HIV-1, though it should be noted that pseudotyping with VSV-G may enhance LTV survival relative to parental HIV-1.
We consider minimal risk to human health associated with exposure to rAAV or LTV vectors since: all pathogenic genes have been deleted; promoter sequences within LTV LTRs have been deleted to minimise the risk of insertional mutagenesis and cellular oncogene activation; wildtype AAV2 is apathogenic in humans and shows low transduction efficiency; rAAV is non-integrating, thereby minimising the risk of insertional mutagenesis; both viral vectors are replication incompetent; neither viral vector is expected to alter human cellular immunity or defence mechanisms; and there are low risks associated with reversion to wildtype, due to a lack of rAAV-ITR homology with viral rep/cap-gene containing plasmids, and LTV 3' LTR truncation.

Furthermore, opsins and LALGNCs have not been associated with human disease, but rather represent useful tools for studying neuronal network activity.

rAAV vectors are relatively resistant to environmental temperature changes, though autoclaving is sufficient to kill the virus. HIV-1 is fragile and extremely sensitive to even small fluctuations in temperature and the presence of oxygen.

Although (1) there is no evidence to suggest that rAAV, pLECYT or pFCK vectors exhibit enhanced environmental survival compared with their parent viruses (though pseudotyping LTV vectors with VSV-G may enhance LTV survival relative to parental HIV-1); (2) experiments will involve only very small (2-4µl) volumes of viral suspension; and (3) rAAV and LTV vectors are replication-incompetent, all in vitro and in vivo experimental procedures involving viruses will be performed in appropriate Activity Class 2 facilities. All virally infected tissue will be contained and treated as Class 2.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

rAAV vectors are relatively resistant to environmental temperature changes, though autoclaving is sufficient to kill the virus. HIV-1 is fragile and extremely sensitive to even small fluctuations in temperature and the presence of oxygen.

Although (1) there is no evidence to suggest that rAAV, pLECYT or pFCK vectors exhibit enhanced environmental survival compared with their parent viruses (though pseudotyping LTV vectors with VSV-G may enhance LTV survival relative to parental HIV-1); (2) experiments will involve only very small (2-4µl) volumes of viral suspension; and (3) rAAV and LTV vectors are replication-incompetent, all in vitro and in vivo experimental procedures involving viruses will be performed in appropriate Activity Class 2 facilities. All virally infected tissue will be contained and treated as Class 2.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

All infected tissue samples will be double bagged and disposed of as clinical GM waste for incineration. All liquid waste and designated non-disposable equipment (i.e. glassware) will be thoroughly disinfected with 5% Virkon and then autoclaved. Non-biological, non-designated solid waste (i.e. cotton swabs), will be disinfected with 5% Virkon and then disposed of as clinical GM waste. Non-designated disposable sharps (i.e. glass micropipettes and microscope slides) will be disposed of in designated clinical GM waste sharps bins immediately after use. The use of sharps will be minimised. All sharps bins will be sprayed with Virkon inside and out, before being sealed and removed from the viral suite at the end of each batch of experiments. Double thickness gloves will be worn when handling the virus and associated sharps, to minimise the risk of virus to skin contact and needle stick injuries.

Because of these precautions, we do not believe that rAAV or LTV vectors would survive long enough in the environment for gene transfer to occur. Patch-clamp and calcium imaging experiments will require immersion of a microscope lens in perfusion solution that washes over tissue slices; therefore following in vitro experiments, lenses and perfusion lines will be cleaned using 5% Virkon solution. Pulled glass micropipettes used for patch-clamp experiments will be disposed of in designated clinical GM waste sharps bins.

All efforts will be made to contain potential transmission. All work will be performed in appropriate Class 2 facilities (i.e. Level 2 safety cabinets). Any viral spillages will be contained and thoroughly disinfected with 5% Virkon. To further minimise any risks associated with handling tissue injected with rAAV or LTV vectors, gloves, goggles and masks will be worn to minimise skin and eye contact, and inhalation of any potential viral aerosols.
Our application was accepted by Cardiff University's GM Safety Committee with minor revisions, which have already been corrected. The risk assessment application has now been fully approved (August 2011).

### Project Additional Information

**Purposes of the contained use**

To enhance expression of selected proteins and miRNA in cultured primary neurons, using the Sindbis Expression System (Invitrogen).

**Recipient or parental organism**

- Primary neuronal culture

**Host/vector system**

- **DH5alpha E. coli/pSinRep5 (Invitrogen, commercial), DH-BB vector (Invitrogen, commercial)**
- **BHK21 cell line/pSinRep5 (Invitrogen, commercial) DH-BB vector (Invitrogen, commercial)**
- Primary culture neurons/viral particles

**Origin & function**

Sequences encoding the following:
- p75 receptor protein (common receptor for neurotrophins)
- super-repressor IκBα protein (inhibitor of NF-κB canonical signalling)
- siRNA to knockdown expression of endogenous p75, members of the Trk family of receptor tyrosine kinases (the other class of receptors for neurotrophins) or the CaSR (a G-protein coupled receptor that senses the level of extracellular free calcium ions).

Sequences of these proteins and miRNA are from Mus musculus

**Evaluation of foreseeable effects**

pSinRep5 is a 9951 bp vector used to generate recombinant RNA molecules for expression in infected eukaryotic cell in culture. It contains the Sindbis virus non-structural protein genes 1-4 (nsP1-4) for replicating RNA transcripts in vivo, the promoter for subgenomic transcription, and a multiple cloning site. The multiple cloning site allows insertion of the microRNA behind the subgenomic promoter for expression in BHK cells. The recombinant RNA transcripts are synthesized using the SP6 promoter and transfected into BHK cells.

DHBB [Defective Helper] deleted between BspM II and BamH I is a 6729 bp DNA template that contains the genes for the four structural proteins required for packaging of the Sindbis viral genome.

Mechanism of replication of the virus:

The vector RNA encoding non-structural proteins 1-4 (pSinRep5) and the transgene under the control of the subgenomic RNA promote, and defective helper RNA (DHBB) are obtained by in vitro transcription. The virus must be cotransfected with defective "helper RNA" to be packaged into infectious particles in BHK-21 cells. Within the cytoplasm of BHK-21 cells, defective helper RNAs have a large deletion in the nonstructural protein genes (i.e., the replicase genes) and are not self-replicating, but can be replicated and transcribed by the nonstructural proteins provided by the replicon. Helper subgenomic RNAs are translated to provide the structural proteins for replicon assembly under conditions in which helper RNAs are not packaged. Upon infection of cultured neurons used in our proposed studies, the packaged replicons derived by this approach will infect the cultured neurons, but the absence of structural protein genes prevents the generation of new particles.

The primary hazards are accidental parenteral inoculation and droplet exposure of the mucous membranes. The particles produced by transfection are replication defective (Bredenbeek et al. (1993)). The components of the Sindbis Expression System have been designed to guard against any potential health threats.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

There are'nt any procedures likely to generate aerosols.
A safety cabinet will be used and there will be no use of sharps.

Any liquid will be disinfected with Sodium Hypochlorite.
The expected degree of kill is 100% and can be validated by dialyzes of the mixture of bleach and supernatant with viral particles, add the solution to the BHK cells and incubate at 37C. The cells should not be infected.

Solid waste will be autoclaved.

The non-competent recombinant viral vectors will be generated in the basement viral suite of the Life Sciences Building. Primary neuron cultures will be infected with these vectors and grown. Then cells will be either fixed or lised for RNA extractions. We will use standard laboratory procedures.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The genetic modification safety committee requires the work to be carried out in the departmental viral laboratory containment level 2. Some alterations were requested and the risk assessment was deemed to be suitable and sufficient.

</table>
The scientific goal is to characterise structural and functional experience dependent plasticity mechanisms in the cortex with the view of further understanding cortical processing of information, learning and consolidation of memories. Experiments will focus on identifying key regulatory molecules, some of which are linked to neurological disease, and delineating their role in plasticity mechanisms through the use of commercially available and well characterised transgenic models (for example CCR5, DISC1 and GluR1 gene knock out). In addition Cre recombinase/loxP transgenic technology will be used in some experiments to restrict transgene expression to specific tissues such as cortical layer 2/3 neurons. Mature neurons will be virally transfected using the well characterised, safe and commercially available Adenoviral Associated Virus (AAV) vector system (eg. Stratagene, UPEN, Applied Viromics for review see Buning H. et al 2008 J Gene Med). AAV are non-pathogenic viruses naturally occurring in mammals. Genetic inserts will be cloned into viral vector plasmids through the use of E. coli and HEK293 cells. Recipients are transgenic knock-out models for neurological disorders (CCR5, GluR1 and DISC1) and these will be injected with AAV-vectors for the purposes of expressing fluorescently labelled proteins. This will enable structural imaging of the infected neurons in vivo. E. coli and HEK293 cells will be used in the cloning and amplification of AAV-vectors. Adenoviral -Associated-Virus Vectors will be used for the delivery of DNA coding for fluorescently labelled proteins HEK293 AAV and E. coli cells will be used for cloning purposes of AAV vectors. Inserted genes will encompass very safe, well characterised and routinely utilised fluorescent reporter genes such as GFP, YFP, tdTomato, DsRed etc. In addition...
photosensitive receptors expressed on the cell surface such as Channelrhodopsins which are only activated upon specific photostimulation protocols. AAV vectors containing short hairpin (sh-) RNA inserts, coding for the depletion of GluR1, CCR5 and DISC1 will disrupt the expression of these genes but only in neurons directly transduced with the AAV virus (eg. GluR1 - subunit of ionotropic glutamate receptor, DISC1 gene disrupted in schizophrenia and CCR5 - chemokine receptor). Similarly gene inserts encoding for the expression of GluR1, DISC1 and CCR5 will be utilised. In the majority of cases the gene insert expression will be under the control of tissue specific promoters such as CaMKII, limiting expression to neuronal cells. Additional measures for restricting transgene expression are through the insertion of loxP sites around the gene insert, ensuring transgene will only be expressed in cells with Cre-recombinase activity. This genetic material originate from human cDNA, murine cDNA, green algae and parvovirus AAV-DNA.

Evaluation of foreseeable effects

Viral vectors will encode fluorescent proteins which will allow visualisation of specific cells through optical imaging. Inserts in viral vectors will also encode genes for GluR1, DISC1, CCR5.

GluR1 is a member of the ligand-gated ion channels family which are membrane proteins that mediate information transfer at synapses. Their function relies on the ability to respond very rapidly to the transient release of a neurotransmitter to produce a change in membrane potential of the postsynaptic cell. A subset of these ion channels are glutamate receptors, tetrameric cation-selective channels that are activated by glutamate and are abundantly expressed in the brain and spinal cord and mediate responses at the vast majority of excitatory synapses. AMPA receptors are one type of glutamate receptor, and there are four AMPA receptor genes (GluR1-4) which are transcribed to assemble the hetero-terameric receptor. We are investigating ONE of these genes which codes for the GluR1 subunit of AMPA receptors. To produce a functional receptor - dimeric-GluR1 subunits must combine with dimeric GluR2 or GluR4 subunits. Hence expression in non-neuronal tissue results in a biologically inactive protein, as GluR2 and GluR4 genes are not expressed. Only in brain tissue will the GluR1 transgene expression have any biological effect. The biological activity of GluR1 reported in the literature, suggests effects will most likely be cognitive impairment. In neurons AMPA receptors mediate forms of synaptic plasticity such as Long-Term Potentiation (LTP) and Long Term Depression (LTD) which are critical in the development of learning and memory formation and consolidation. Recent studies have demonstrated LTP is reduced in GluR1 knock-out models.

Disrupted in Schizophrenia (DISC1) mutations have been linked to a number of neurological disorders, including Schizophrenia and bipolar disorder. DISC1 is a large scaffolding protein (93 kDa) and as such, has been shown to bind numerous proteins including microtubule associated proteins, kinases (GSK3beta) and phosphodiesterase (PDE4) enzymes involved in key signalling cascades in the brain. No biological activity for DISC1 has been characterised in any other tissue than the brain. Given the wide variety of neuronal binding partners, it is not surprising that DISC1 mediates a plethora of different biological functions, both in vitro and in vivo. Some examples include regulating neuroblast migration or the proliferation of neural progenitors via an interaction with GSK-3beta. Mutations which lead to Schizophrenia have been shown to decrease Wnt signalling, a presumed affect of decreased spatially specific manner has been achieved by generation of a transgene overexpressing a truncated form of DISC1 under the control of an inducible CaMKII promoter. It is this transgenic model that will be utilized in our experiments. Schizophrenia is typically diagnosed in late adolescence or early adulthood, and the Disc1 knockdown model phenotypes relevant to Schizophrenia, including disturbed dopaminergic neurotransmission and interneuron deficits in the cortex, plus several behavioural changes, such as deficits in working memory, become apparent in young adulthood. Numerous studies have demonstrated a disruption in DISC1 is associated with Schizophrenia only at early stages of neural and circuitry development.

Taken together this information suggests the transgene rAAV encoding sh-DISC1 will only have a biological effect in brain tissue at an embryonic or early post natal stage. These biological effects would most likely be cognitive impairment.

CCR5 is a chemokine receptor and ablation of this protein has been shown to inhibit chemotaxis of a subprotein of leucocytes. In contrast increased expression of CCR5 induces pro-inflammatory effects. CCR5 is also a protein recognised by HIV for the binding and entry into cells. Therefore decreased CCR5 is shown to be protective for HIV infection. Murine CCR5 may have biological activity in leucocytes and may demonstrate altered properties of migration. In our study however we will utilize CCR5 transgenes for investigation of it's function in the brain. Disruption of CCR5 expression will most likely result in changes to cognitive function cognitive.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Transgenic models are housed in a secure facility, where all users adhere to standard operating procedures. Standard Operation Procedures include documentation of all
subjects housed in the facility, regular testing for pathogens, relevant safety procedures such as designated clothing, facemasks, gloves to be worn within the facility. The probability of transgenic models in use escaping into the environment are effectively zero, however in such a remote eventuality, subjects will be non viable in the environment, ill equipped to survive predation or acquire food, due to cognitive deficits, and have limited immunity to natural pathogens in the environment. Recombinant AAV vectors will be loaded into injection syringes in a designated viral suite, in a class 2 biosafety cabinet. Standard Operating Procedures are in place for the viral suite. Only registered users documented in training records have access to the suite. All equipment is kept within the suite and designated clothing (gowns and shoes) will be worn in the viral suite and removed prior to exit.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Genetically modified waste will be treated with chemical disinfectants, autoclaved and incinerated. Some GM subjects will be fixed with paraformaldehyde by perfusion for analysis. In these cases paraformaldehyde inactivates any infectious GM material. All tissue and carcases are disposed of in designated clinical waste bags and incinerated. Contaminated and/or biological waste is disposed of in clinical biohazard bags and autoclaved. Standard Operating Procedures for the viral unit require all surfaces and equipment to be wiped down with Virkon 1% or Trigene 4% as per manufacturers instructions. Virkon (potassium peroxymonosulphate). Sodium dodecylbenzenesulfonate, sulphamic acid; and inorganic buffers. Trigene - Halogenated tertiary amine. Both these compounds have broad spectrum activity against vegetative bacteria, spores, mycobacteria and viruses compounds have broad spectrum activity against vegetative bacteria, spores, mycobacteria and viruses.

Please see attached Trigene datasheet

02/03/2022
The aim of this study is to employ the technology of somatic cell reprogramming to derive novel induced pluripotent stem cell lines (iPS) to generate in vitro cell models of disease. The technology involves the simultaneous transduction of somatic cells (e.g. dermal fibroblasts) with up to 5 genes responsible for conferring pluripotency in ES cells (Takahashi et al 2007, Cell 131,861-872,) Genes currently employed for iPS cell generation include Pouf5f1, Sox2, Klf4, Nanog, LN28. Genes are most effectively delivered to cells using lentiviral vectors. Once derived, iPS cells are pluripotent and can be used to derive multiple somatic cell types of interest. To model neurological disease we are also developing strategies to direct the differentiation of pluripotent cells to derive specific neuronal lineages of interest. This will be achieved by genetic programming by ectopic expression or knockdown of selected fate determining genes, which will also be effectively achieved by lentiviral delivery of genes.

Recipient or parental organism

Lentiviral vectors will be used to transduce human and mouse cell cultures in vitro. For iPS cell derivation recipient cell types will include fibroblasts, lymphocytes, or keratinocytes. The recipient cell cultures will either be derived from tissue biopsies and grown as primary or early passage cell cultures, or obtained from cell repositories such as ECACC.
We will use 3rd generation self inactivating HIV based lentiviral vector systems for gene delivery. Disabled and self inactivating viral vector particles based on a HIV system will be generated by co-transfecting HEK293T cells with four plasmids. The plasmids (described below) express a single viral gene and together (following transfection) they represent the minimal number of genes essential for propagation. This VSV-G (vesicular stomatitis virus) pseudotyped vector is self-inactivating and could not recombine with HIV, i.e. the probability of the production of replication competent vectors is extremely small.

Genes will be subcloned into:

a. Standard bacterial plasmid vectors for sequencing and propagation will be used.

B. The standard plasmids are pRRL-CMV-GFP, pRRL-synapsin-GFP, pMPDLg-PrPe, pR-REV and PMD2-VSVGP. All the genes required for producing full length viral RNA and packaging it into viable viral particles (gag-pol), rev and env) have been removed from the pRRL Lenti plasmids. Gag-pol and rev are expressed separately as is the VSV-G coat protein. The plasmids have been engineered so as to have no recombination sequences that would allow those genes to be inserted into the pRRL plasmid. This allows for a viral particle to be produced that can enter any cell, but that once inside does not have the relevant genes necessary to re-package itself or to re-generate full length viral RNA following genomic integration. In addition, following infection of the target cell, the lentivirus is self-inactivating on integration into the host genome. This is achieved because the process of reverse transcription uses the 3' long terminal repeat (3'LTR) as a template to produce the 5'LTR. The U3 region of the 3'LTR has been deleted, resulting in deletions in both 3' and 5'LTRs on integration into the host genome. These deletions are designed to ensure that the viral genome cannot be released from the host genome. Thus this system allows for expression of the gene of interest with little risk of the production of further viral particles.

In some cases we will use commercial 3rd generation lentiviral vector and packaging systems, such as ViraPower™ Lentiviral Expression System (from Invitrogen-Life technologies). These systems carry the same vector and packaging safety features as described above and have been designed for use with minimal risk and are marketed with full user manual and safety instruction.

The sequences that are to be expressed using this system fall into the following categories.

i) Full-length sequences designed to be overexpressed coding for genes that regulate stem cell pluripotency (Pou5f1, Sox2, Klf4, Lin28, Nanog); genes involved in neural fate specification (e.g. transcription factors Gsx2, Foxg1, Dlx2, Mash1, Isl1, FoxP1, Ebf1, Crip2 and growth factors SHH, WNTs). Protein sequences may be expressed:

(1) in their native form,
(2) as chimaeras where part of one protein sequence is placed inside another or
(3) with single or multiple point mutations to investigate the functions of single residues in, for instance, phosphorylation/dephosphorylation cycles or
(4) s tagged sequences where the tag is an antibody recognition sequence (V5, HIS, Flag…etc) and/or fluorescent proteins (GFP, CFP, YFP, DSRED etc).

ii) si/shRNAs designed to reduce or block the expression of proteins involved in the neural differentiation and that interact with pathways regulated by genes described in (i) above, e.g. to knockdown Pax6/Ngn2 expression. Small inhibitory and small hairpin RNAs are generated to be complementary to the mRNA of a target protein. The si/shRNA then acts as a guide for the (RNA-induced silencing complex) RISC to target and degrade its complementary mRNA.

Origin & function

The lentiviral vector and packaging systems described above generate replication incompetent infectious particles. The probability of reversion to the viral wildtype is virtually non-existent due to loss of four structural genes residing on non-homologous plasmids, and lack of a wild-type 3'LTR.

In the case of a HIV-1 infection following lentiviral integration, it has been previously shown that, even under permissive in vitro conditions, wild-type HIV-1 cannot rescue a self-inactivating HIV-1 based lentivirus once integrated into the host genome (Bukovsky et al (1999) J. Virol. 73; 7087-7092), although non-self inactivating vectors can be.

In the case of a worker already infected with HIV-1, the HIV genome will have already integrated into the host genome in infected cells. While it is conceivable that the lentiviral genome will infect the same cells and integrate into a location that will allow for homologous recombination with the native HIV-1 genome, the probability of that occurring is extremely small.

All potential routes of transmission of the virus are known. In the event of an accident, the main routes of transmission to deliver the virus or its products to tissues are airways and eyes. However direct contact of virus with cells, eg, via sharps injury, could also result in infection. So. The identifiable risk to the laboratory worker is infection by aerosol, or through sharps injury. To minimise this risk, no vacuum assisted aspiration, needles or glassware are included in procedures.

There is no potential for the transmission of the naked nucleic acid. The risk of incidental transfection of naked DNA is negligible, if it could happen genes required for replication and transmission are removed.

Evaluation of foreseeable effects

The lentiviral vector and packaging systems described above generate replication incompetent infectious particles. The probability of reversion to the viral wildtype is virtually non-existent due to loss of four structural genes residing on non-homologous plasmids, and lack of a wild-type 3'LTR.
The viral vector does infect human cells since the VSV-G pseudotyping envelope provides increased titres and broader host range, including human. Risk of human infection is nevertheless low. In order for spread of the gene of interest to occur following accidental infection (assuming that this has lead to viral integration), a series of unlikely events would have to occur.

(a) The worker would have to become infected with HIV-1 or to be already infected with the virus.
(b) The viral and lentiviral genomes would have to integrate into the host worker's genome in the same cells and in a position where they could interact to effect homologous recombination.
(c) Recombination would have to occur in just the right regions to allow for transfer of the gene of interest from the lentivirus to the HIV-1 genome, which would also involve the transfer of the HIV-1 genes to the lentiviral genome. In this case, it is just conceivable that a non-self inactivating HIV could be generated that contained the gene of interest but not the rest of the genome it requires. The other gene products could be provided in trans from the lentiviral genome that may now contain the HIV-1 genes or from other HIV-1 integrants.
(d) This could conceivably lead to the production of an infectious particle containing the gene of interest, but again no genes necessary for subsequent replication. In order for another round of infection, the process would have to begin again.

In truth, the affects of lentiviral infection in these circumstances are minor in comparison to the effects of the HIV-1 infection that would be required to effect the spread of the gene of interest. In addition, the scenario described is essentially equivalent to the rescue of the lentiviral genome from the host, which has already been shown not to occur.

Genes to be expressed from the lentiviral vectors encode for proteins with known developmental functions in that they regulate cell reprogramming and cell differentiation. We will purposefully avoid the use of oncogenes such as c-myc for cell reprogramming. Although the recombinant genes to be used have the potential to induce a pluripotent state in host cells providing a potential for growth and teratoma formation. However induction of pluripotency is a low efficiency event requiring the cotransfection of 4 vectors. Most importantly the cell reprogramming mediated by the reprogramming genes also requires very precise culture conditions that would not be present in a living host environment, only being present in stringently defined media conditions in laboratory cell culture. The genes used to regulate neural cell differentiation are not oncogenic. Thus the risk of accidental induced pluripotency and teratoma formation is negligible.

There is no reason to suspect that the tissue tropism or host range of the recombinant virus will be any different from that of the parent vector or virus since similar vectors have been used extensively and no differences in tropism have been reported.

There is also no reason to suspect that the recombinant viruses may have altered susceptibility to host defence mechanisms since no change to viral epitopes will be made that would affect viral immunogenicity or tropism. Neither vector nor inserts would have immunomodulatory function, and recombinant viruses are not likely to have any effects upon immunocompromised host beyond those normally expected with the parent virus. Taken together the recombinant viral particles will pose negligible risk to human health.

The overall likelihood that, in the event of exposure, the GM virus could cause harm to human health is low.

1. It is extremely unlikely that any worker would infect themselves with a significant dose of lentivirus as the volumes that are used for experimental infections are small (<5μl) and will be carried out in a Class II MSC. No significant aerosols will be produced by any of the procedures used and no needles need to be used, so there is no risk of needle sticks to introduce infection to the worker. All work will be carried out under category 2 containment conditions.
2. We cannot rule out the possibility that, when the lentiviral genome integrates into the host genome, it will not lead to the activation of an endogenous oncogene. However, all transcriptionally active long-terminal repeats have been removed as well as all promoter-like elements other than that required to drive expression of the transgene (eg CMV promoter). This should prevent unforeseen activation of such genes. Thus, we do not consider that the use of these lentiviral expression systems will result in a significantly increased risk of oncogenic activation over any other viral delivery system.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All viral waste will be treated by disinfection using 1% Virkon solution. The expected degree of kill is 100% in a 1% solution in 10 minutes. All disposable materials used in the course of viral handling (pipette tips, tubes, culture plates etc) will be soaked in Virkon 1% solution overnight then autoclaved as clinical waste. Procedures will use a Class II safety cabinet and all surfaces will be disinfected using Virkon spray and clinical wipes, that will similarly be disposed of as clinical waste.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

Please enter comments on the GM safety committee on the risk assessment

It was commented to ensure that all staff involved in the project will receive training to understand all identified potential hazards and potential consequences of viral expression and transfer of any harmful sequences. In the event of accident or emergency all relevant information pertaining to risk and inactivation would be conveyed to any emergency worker or health practitioner should a contamination incident occur. Project Risk Assessment information will be printed and filed in the lab for immediate access and reference.

There were also a number of other queries which have now been answered to the Committee's satisfaction.

### Project Additional Information

**Purposes of the contained use**

On one hand, our projects request production of retroviral and lentiviral vectors then to transduce human primary cells and cell lines. These activities, when only vectors have to be produced and used alone, would require to be handled in a Cat2 level laboratory.

On the other hand, we would need to produce HIV viral cultures then to infect human primary cells and cell lines. Any activity involving handling and use of infectious HIV would thus have to be confined in Cat 3 level laboratory.

**Recipient or parental organism**

- For Cat 3 level laboratory activities, all our constructs will be based on HIV proviruses (pR9, pNL-4.3, pR8-Bal). Deletion or mutation of viral proteins according projects requests will be done by PCR-mediated mutagenesis on viral plasmid DNA. The overall likelihood of GM viruses causing harm to human health is medium and comparable to likelihood of parental wild-type viruses.

- For Cat 2 level laboratory activities, our constructs are HIV- or SIV-derived (SIV3), however with important structural and auxiliary gene deletions. Some other vectors are retroviral vectors based on Moloney MLV (pBABE-puro) and, like lentivectors, are lacking the gag, pol and env genes required for viral replication.

**Host/vector system**

- For Category 3 level activities, HIV proviruses and derived mutated strains, obtained upon PCR-mediated mutagenesis of viral DNA template, will be produced by transfection of producer cells (293T cells, HeLa cells) with purified viral DNA in Cat3 level premise. Viral culture will be then purified and concentrated on sucrose gradient by ultracentrifugation. Proviruses obtained will then serve to infect human primary cells and cell lines in Cat 3 level laboratory.

- For Category 2 level activities, retroviral and lentiviral vectors will be produced by transfection of 293T cells with a mix of plasmids compromising the transgene plasmid (providing the genetic material to be encapsidated into the vector thus encoding gene of interest in target cells), the packaging plasmid (encoding for the Gag and Pol gene products) and a plasmid encoding for a heterologous envelope gene product (like VSV-G). Theses highly attenuated lentivirus and retrovirus vectors have shown sufficient biosafety for their inclusion in ongoing human clinical trials as therapeutic vectors. The probability of the lentiviral vectors reverting to wild-type is extremely unlikely given the 3’LTR deletion and loss of some structural genes. Although the viral vectors can potentially infect a wide-range of cell types there is minimal risk of viral replication in infected cells. After serial passage, cells transduced with recombinant retroviruses or lentiviruses can be reclassified as category 1 mainly due to the loss of envelope required to infect neighbouring cells. However, and for a safety concern, all steps from viral vectors production to transduction will be carried out in Cat2 level laboratory.

**Origin & function**

- For Category 3 level activities, Human immunodeficiency viruses and derived mutants will serve to infect human primary cells (mainly Dendritic cells and CD4+ T cells) and cell lines (like Jurkat cell lines) to analyze the impact of infection on cell behaiour and immune functons. Some of these activities will also require the concomitant use of lentiviral vectors, to silence or overexpress specific cellular factors known to restrict HIV infection or influence HIV viral proteins trafficking. Hence, recently, inefficient HIV infection in DC has been challenged but the discovery that pre-transduction of DC with Vpx expressing SIV-derived lentivectors (Vpx-VLPs) could circumvent restriction thus leading to massive HIV infection. While the mechanism of Vpx action is still not known, this discovery allows infection to reach unprecedented levels in DC comparable.
To HIV infection routinely observed in CD4+ T cells. Thus we would need to consistently transduce DC with Vpx-VLPs concomitantly with infection in order to really assess the potential effects of high infection levels on DC immune functions.

- For Category 2 level activities, lentiviral and retroviral vectors will serve to transduce human primary cells or cell lines as above, to silence or overexpress some cellular factors or to express viral proteins fused to fluorescent tags (GFP, YFP). This will allow to analyze viral proteins trafficking and interaction with cellular host factors.

**Evaluation of foreseeable effects**

- Concerning HIV proviruses and mutated strains, even if these viruses are replication competent (so severe consequence of Hazard with acquired immunodeficiency), viral entry and spread would require a direct access to blood, internal mucosal surfaces or broken-skin which gives a low likelihood of Hazard. Hence, lentiviruses and retroviruses do not possess a capacity for air-borne or water-borne transmission and do not survive well in the environment making the possibility of environmental transmission remote. Mammalian cells infected with the viruses would not survive the osmotic challenges presented in the environment and would not survive without optimised nutrient tissue culture medium, pH and temperature.

For safety concerns, all steps from viral production to infection will be carried out in Cat3 level laboratory where the use of sharps when handling virus preparations is strictly forbidden.

- The likelihood of Genetically Modified vectors causing harm to human health is low despite the presence of an amphotropic envelope but given that the viruses are incapable of replication. Hence, integration of lentiviruses into human genome is not known to result in oncogenesis while retroviral integration can lead to oncogenesis but appears restricted to stem cells. After serial passage, cells transduced with recombinant retroviruses or lentiviruses can be reclassified as category 1 mainly due to the loss of envelope required to infect neighbouring cells. However, and for a safety concern, all steps from viral vectors production to transduction will be carried out in Cat2 level laboratory.

Upon initial submission by the applicant, the GM Safety Committee asked for the risk assessments for the Class 2 and Class 3 activities of the project to be made clearer and more distinctive, and for a number of issues to be clarified. Upon revision, the Chairman of the GMSC and a selected number of the GMSC now feel that this has been done and are satisfied that the risk assessments submitted are suitable and sufficient.

### Purposes of the contained use

We intend to investigate aspects of the innate immune response against HCV, comparing replicating HCV with recombinant poxviruses expressing HCV proteins. We will try to isolate new replicating strains and test novel antivirals for activity against HCV. For this purpose, pJFH-1, pCVH77C and chimeric HCV expressing plasmids (see below 'Construction details of the JFH1 derived plasmids') will be used to transfect/infect susceptible cell lines in a L3 containment laboratory.

Four collaborative projects will use the JFH-1 system:

I. In vitro antivirals studies in collaboration with Prof C M, Welsh School of Pharmacy. Infection of cell lines with JFH-1 and SAR studies with candidate compounds. Readout: qPCR, luciferase reporter assay and NS3/4 protease activity. Can start as soon as notified.

II. Study of innate immune responses in JFH-1 infected cells in collaboration with Prof K M and M T, School of Medicine. Infection of cell lines and investigation of novel innate immunity pathways.

Comparison of innate immune responses versus replicating HCV and recombinant poxviruses expressing HCV ORF and subunits (GM130/06.1), as a predictor of vaccine efficacy. Readout: FACS to assays to test TLR and RLR expression in HCV infected cells. Pilot experiments for grant application.

III. Investigation into restricting factors for HCV infection, including BST2/tetherin in hepatoma cells in collaboration with F B and V P, School of Medicine. Construction and use of functional deletion mutants based on the pJFH-1 plasmid. Readout: FACS, confocal microscopy, qPCR, ELISA, luciferase reporter assays. Pilot experiments for grant application.

IV. Identification of replication competent clinical strains of HCV and genetic modification of pJFH-1, pCVH77C and cDNA clones (plasmid) derived form clinical specimen as part of planned clinical fellowship (Dr M B).

Readout: FACS, confocal microscopy, qPCR, ELISA, luciferase reporter assays. Pilot experiments for grant application.

**Evaluation of foreseeable effects**

Summary risk assessment HCV is a hazard group 3 pathogen and needs to be contained at BSL3. All HCV activities in Cardiff BSL3 are covered in an adapted HCV SOP (Blanchett and Ladell, 2010), and informed by UK and Heidelberg University cat 3 HCV working procedures.

The highest risk is associated with HCV infected materials produced in BSL3 and moved out to lower category labs for a number of preparation and readout procedures, where necessary equipment is not available in the cat 3 facility. The safety aspect is determined by the buffers used to collect and store the materials prior to moving them out of the BSL3 and the procedures used to disinfect transport containers externally.

Stability/infectivity of HCV (comparison to HIV): This has been studied in detail by Song et al, in a US/Chinese study published in VIROLOGY JOURNAL (2010) 7:40. Both HCV and HIV and sensitive to all buffers containing detergents or aldehydes, and heat over 60 centigrades for 8 minutes. UV light is sterilizing both viruses after 2 minutes exposure (wavelength= 253.7nm) with an intensity of 450μW/cm2.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Ultracentrifugation: infected cell supernatants will be sealed inside the BSL3 class ll safety cabinet into ultracentrifuge rotor buckets. These will be disinfected externally, moved out of BSL3, used as transport containers, run in the ultracentrifuge and brought back into BSL3, to be opened in the safety cabinet. The samples will be inside sealed SW28 Beckmann tubes and carried in closed SW28 rotor buckets (screw cap with rubber seal). The buckets will be placed in a bucket stand and transported from the JBIOS CL3 lab, through HWRB 3rd floor to basement room inside a biohazard carrier box using the stair case. Elevators will not be used.

Flow cytometry and ELISA: equipment available in BSL3, 1st floor Henry Welcome building. Samples will be transported from the JBIOS class 3 lab, through HWRB 3rd floor inside a biohazard carrier box using the stair case. Elevators will not be used.

qPCR: the buffer used to extract nucleic acids from cells and tissues contains guanidine thiocyanate (GTC), a chaotropic salt. This buffer reduces infectivity of a wide range of viruses, including HCV, to zero (100% kill), after exposure over night and storage at minus 20 degree centigrade followed by thawing. HIV infected materials collected in this buffer are currently moved out of BSL3 as detailed in the HIV/(HCV)SOP.

Immunohistology - confocal microscopy: HCV infected cells are grown on coverslips and fixed in 3% paraformaldehyde in PBS for 30 minutes. This procedure is sufficient to disinfect tenacid vaccinia viruses and adenoviruses. The safety of this material is documented in Heidelberg University SOPs. We will confirm this with independent reinfection experiments of HCV materials in 3% PFA in BSL3, followed by qPCR readout.

Luciferase reporter assays: passive lysis buffer (PLB;PROMEGA) is used to collect and store the samples to be moved out of BSL3. This buffer reduces HCV infectivity to zero (100% kill), after exposure over night and storage at minus 20 degree centigrade followed by thawing. The safety of this material is documented in Heidelberg...
University SOPs. We have conducted reinfection experiments at L2 with the very stable and tenazid vaccinia virus in PLB. Buffer incubation followed by a single freeze/thaw cycle resulted in zero infectivity (100% kill; data of experiment Inf 12/233-3 is available upon request). Once replicating HCV is set up in CL3, we will confirm this with independent reinfection experiments of HCV materials in PLB and 3% PFA in BSL3, followed by qPCR readout. It is planned to eventually buy a luminometer to introduce into the new facility.

1. Transport of large amounts of life virus: samples inside SW28 rotor buckets for ultracentrifugation and enrichment are dropped. The buckets are made of stainless steel and will not break. 2. Samples for CL2 processing (qPCR, immunohistology, luciferase assay): samples are not correctly treated with inactivating buffers: In this case very small quantities of life virus may be present in samples. Samples for PCR will be sealed inside PCR tubes and subsequently heated repeatedly to boiling temperatures. Samples for immunohistology are sealed under coverslips with aceton-containing glue. Samples for luciferase assay will be sealed inside 96 well plates and frozen/thawed. In all cases the risk for workers to be exposed to life virus is effectively zero. As detailed in Song et al., both HIV and HCV are enveloped viruses known to be very sensitive to environmental conditions and disinfectants.

If all safety precautions are followed as detailed in the HCV/HIV SOP, the overall risk is negligible.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation applies

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Viruses will at all times be maintained in an environment designed to prevent aerosol spread. All flasks containing the virus shall be kept closed except when decanting and pipetting which will be conducted in tested class II safety cabinets. Centrifugation steps shall be performed in sealed buckets that will be opened only in safety cabinets. The use of Sharps when handling virus preparations will not be permitted. Contaminated pipettes will be immersed in Actichlor for a minimum of 4hr prior to transferring to a container for autoclaving. The tissue culture cabinet and any potentially contaminated area will be disinfected with chlorine-based disinfectant according to an approved protocol. Access to laboratories employed for virus work will be restricted.

Disinfectant Product Name: Actichlor (2500ppm sodium dichloroisocyanurate). Generic Chemical Name: Chlorine-based disinfectant Expected degree of kill 100%

How validated: HCV infectivity in collection buffers will be validated by a BSL3 reinfection assay using qPCR readout.

Is an emergency plan required according to regulation 20? Y

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form N

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
The risk assessment was discussed extensively in the GM committee, and revisions were required. In the following a listing of the required amendments/changes.

1. The revised risk assessment (version 4) for the use of replication competent HCV strains and reporter constructs, providing new information and corrections, as requested by the GM committee in the meeting on October 5, 2011.

- Name of Institute/department updated: CI3/Medmicro &ID
- Dr L identified as provider of HCV reagents in PI profile.
- CL3 training course mentioned in PI profile
Dr T removed from list of ‘staff of the project’ - no active labwork planned; collaboration planned with materials produced by B and B in the CL3 lab.
- Materials provided by L identified as pFK-JcR2a and Huh7-Lunet/CD81
- Worst case scenarios have been added for samples dropped in transport and insufficiently treated in working buffers.
- Bottom of page 11: GM virus could cause harm to human health - "High" as requested by committee.
- The list of projects in the connected program of work has been updated according to the new listing provided with RA 130/613.
- We have conducted experiments showing that the processing of samples for luciferase reporter assay renders vaccinia virus uninjective. This is a good indication that HCV infected cells treated the same way will be safe outside of CL3. Treatment of immunohistology samples with 3% PFA is a harsher disinfective treatment, so samples will be safe as well. The same procedure has been proposed by Dr B for his HIV infected cells.
- Details have been added regarding the transport of HCV infected cells inside sealed ultracentrifuge rotors to the ultracentrifuge in the basement HWRB: The samples will be inside sealed SW28 Beckmann tubes and carried in closed SW28 rotor buckets (screw cap with rubber seal). The buckets will be in a bucket stand and transported from HWRB 3rd floor to basement inside a biohazard carrier box using the staircase. Elevators will not be used.

Project Additional Information

Purposes of the contained use

Expression of transgenes in T cells in order to carry out short term functional analysis

Recipient or parental organism

Mouse T Cells

Host/vector system

Retroiral vector mIGR

Origin & function

Transduction of T cell in vitro for reintroduction in vivo. The T cells bearing the original T cell receptor (TCR) is known to induce diabetes in susceptible mouse strains. The transgene for the purpose of the project consisting of a modified TCR will be introduced to T cells to direct them to the pancreas.

FoxP3 is a regulatory transcription factor in mouse T cells

T cells transduced with these genes will have a regulatory phenotype designed to protect against diabetes in susceptible mouse strains

Evaluation of foreseeable effects

The inserted genes are the already rearranged T cell receptor alpha and beta chains from a mouse and there is very little possibility of recombination to create an effective protein in humans. Mouse and human foxP3 are not identical and humans have additional splice isoforms that are not present in the mouse and therefore the mouse foxP3 is highly unlikely to be an effective protein in human cells.

The DNA components are located on different plasmids in the vector and packaging cell line so there is no potential for transmission of the naked nucleic acid. The viral vector infects rodents but not human cells. The viral vector used is fragile and has a short life and will be used only in a highly controlled tissue culture environment. Once the T cells are transduced and prepared for injection into mouse hosts, there will be no free viral particles and the following activities, including injection into mice will be class I activities.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All solutions will be treated with bleach before removal from tissue culture hood. All solid waste will be bagged in the tissue culture hood before removal in a sealed container to autoclave in an adjacent room.

Historical Significant Changes

Historical Date of Additional Info
Bacillus anthracis belongs to a group of genetically related organisms (B. cereus, B. thuringiensis) for which the formation of an emperium spore represents a key survival strategy. The spore form confers considerable resistance to chemical and thermal insult hindering attempts to decontaminated exposed environments. Decontamination modalities for anthrax to date have centred on the use of toxic biocides (formaldehyde, chlorine dioxide) or gamma radiation. These approaches suffer from the dual handicap of toxicity to man and the environment and/or are extremely expensive. There is an urgent need for strategies which are environmentally friendly, can be used to decontaminate a range of environments with little or no toxicity to fauna or flora and are cost effective.

We have developed a simple mixture of amino acids and sugars which when applied to soil contaminated with anthrax spores is able to trick the organism into converting from a chemically resistant spore into a chemically sensitive bacterium, a process known as germination. This approach renders the organism considerably more susceptible to biocides and decontaminating agents making it possible to reduce the concentration of toxic agents required to clean up an incident.

Forcing the bacteria to germinate also renders the bacteria susceptible to the attentions of natural soil predictors such as the bacteria eating nematode Caenorhabditis elegans. In preliminary laboratory studies using sterile soil we have demonstrated that a combination of C. elegans and germinants can reduce the B. anthracis spore load of artificially contaminated soil by >95%. To progress this work we will assess the ability of C. elegans to reduce B. anthracis numbers in non-sterile soil. To assist in this task we propose to make use of a GFP expressing variant of B. anthracis by transforming a plasmid expressing GFP from Aequorea victoria (pSW4-GFPmut1), a safe, well established tag used for visualising investigated proteins in cells and bacteria, into an attenuated vaccine strain of B. anthracis. The feasibility of this approach has been demonstrated by colleagues in the United States who have kindly agreed to provide us with pDW4-GFPmut1 (Sastalla et al, Appl Environ Microbiol. 2009 Apr;75(7):2099-110). The pSW4-GFPmut1 plasmid was constructed as follows. A copy of the Aequorea victoria-derived gfpmut1 gene (Cormack et al., 1996 Gene 173:33-38.) was amplified by PCR and inserted downstream of the pag promoter in pSJ115 (Park and leppla, 2000 Protein Expression and Purification 18, 293-302) to replace the lef gene (Pomerantsev et al., 2003 Immun. 71:6591-6606).

E. coli SCS110 (Stratagene)- propagation and maintenance host: The pSW$-GFPmut1 plasmid will be transformed into E. coli SCS110 (Stratagene) which is an endA-derivative of JM110 strain which in turn is derived from E. coli K12. The SCS110 strain is ideal for preparing plasmid or phagemid DNA free of Dam or Dcm methylation so that the DNA can be restriction digested by one or more methylation-sensitive restriction enzymes. The genotype of this strain is as follows; rpsL (Strr) thr leu endA thi-1 lacY galK glaT ara tonA tsx dam dcm supE44 Δ(lac-proAB) [F traD36 proAB laclqZΔM15]. (Genes listed signify mutant alleles. Genes on the F episome, however, are wild-type unless indicate otherwise.) Given that SCS110 is a K-12 derivative and is thus considered non pathogenic for humans the risk associated with its use is low.

2. Attenuated animal vaccine strains of B.anthracis: The ultimate aim of this project is to construct a GFP expressing variant of B. anthracis which can be used to support laboratory studies. This will be achieved by transforming pSW4-GFPmut1 plasmid into an attenuated vaccine strain of B. anthracis called the Sterne strain which has been approved by the HSE for handling and manipulation under containment level 2 conditions in our laboratory.

Host/vector system

The study will make use of one plasmid, pSW4-GFPmut1, which is a GFP expressing E. coli/B. subtilis shuttle vector. In addition to carrying a copy of the Aequorea victoria-derived gfpmut1 gene (Cormack et al, 1996 Gene 173:33-38.) under the control of the pag promoter it also encodes resistance to ampicillin and Kanamycin. The plasmid has a Gram positive (pUB110) origins of replication which is non-mobilisable in B. subtilis (ACGM) and a Gram negative (pBR322 - ColEI ori) origins of replication which is mobilization defective (ACGM).
The aim of this study is to generate a GFP expressing variant of an attenuated strain of B. anthracis. GFP is a well established tag used for visualising investigated proteins in cells and bacteria. In this case the gfpmut1 gene of Aequorea Victoria (Cormack et al. 1996 Gene 173:33-38) has already been cloned into the E. coli/B. subtilis shuttle vector pSW4 under the control of the pag promoter which is expressed during vegetative bacterial growth. Expression from the pag promoter is controlled by the presence of bicarbonate ions meaning that the level of GFP expression can be regulated.

Evaluation of foreseeable effects

Although the Sterne vaccine strain of B. anthracis encodes a number of putative virulence factors it has been shown to be non-pathogenic to humans and animals (Sterne, M. et al. (1942) J. African Med. Vet. Med. Assoc). We do not expect the expression of GFP in B. anthracis to have any effect on host gene expression.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All working areas will be cleaned with hypochlorite (10,000 ppm) prior to and post working with the organisms. All work with this bacteria will take place within a Microbiological Safety Cabinet. A separate incubator will be used for these bacteria. All liquid and solid waste will be autoclaved.

Is an emergency plan required according to regulation 20?  N

The aim of the project is to investigate the antibacterial activity of compounds derived from hops (Humulus lupulus L.) against Mycobacterium smegmatis (MTS) and Mycobacterium abscessus (MCAB). These bacteria belong to a group of genetically related organisms which include Mycobacterium tuberculosis a bacterium which currently infects 1/3 of the world's population and is a leading cause of death worldwide. Its success as a pathogen is due in part to its ability to survive and multiply within the macrophages of the infected individual. In contrast MTS and MCAB lack the ability to initiate infection in healthy individuals (they are classed as hazard group 2 organisms) and this coupled with their ability to grow on standard laboratory media and in macrophages at a rate considerably faster than that of M.tuberculosis makes them ideal substitute organism with which to study the development of antibacterial agents with activity against M.tuberculosis. We are thus seeking to identify new classes of antimicrobial agents which are effective against antibiotic resistant strains of M. tuberculosis. The current focus of our search is the hop plant which have been used for centuries in the brewing industry and is known to contain compounds which are inhibitory to a wide range of organisms including M. tuberculosis. In previous laboratory studies we have confirmed the bactericidal activity of hop extracts against M. smegmatis. To aid us in the task of identifying hop derived inhibitory compounds we propose to employ GFP expressing variants of both MTS and MCAB. These strain will be used to develop high throughput agar and cell culture based screening methods.

The two mycobacterial species which will be used in this study are Mycobacterium smegmatis and Mycobacterium abscessus both of which are classified as hazard group 2 organisms. Bacterial infection with Mycobacterium smegmatis have only been associated with immunocompromised individuals. The ultimate aim of the project is to construct a GFP expressing variant of M. smegmatis which can be used to support laboratory studies. The M. smegmatis strain which we propose to use in this study, ATCC 700084 has been approved the ACDP/HSE for handling and manipulation under containment level 2 laboratory conditions.
M. abscessus (MACB) lung infections are seen in cystic fibrosis patients, but not in healthy individuals. The MACB reference strain CIP104536T has been classified as a class 2 organism. Wild type strains will be provided by Dr M R of the Llandough mycobacterial reference unit (public Health Wales)

**Host/vector system**

The plasmid system which will be used in this study (pSMT3) is a GFP expressing E. coli/Mycobacterium shuttle vector. In addition to carrying a copy of the Aeouora victoria-derived gfmut1 gene (Cormack et al, 1996. Gene. 173:33-38.) under the control of the paq promoter it also encodes resistance to the antibiotic hygromycin however this is not a commonly used antibiotic for any infections arising from this bacterium. The plasmid has a Gram positive (pUB110) origin of replication which is non-mobilisable) and a Gram negative (pBR322 - ColE1 ori) origins of replication which is mobilization defective. (ACGM).

Plasmid pJV53 expresses mycobacteriophage genes (Che9c gp60 and gp61 which are homologous of E. coli RecE and RecT, encoing exonuclease and DNA-binding activities, which substantially elevate homologous recombinations of linear DNA for the production of allelic exchange mutants in mycobacterium ssp. The plasmid can be used for recombineering into M smegmatis.

**Origin & function**

The aim of this study is to generate GFP expressing variants of Mycobacterium smegmatis and Mycobacterium abscessus. The GFP gene which is derived from Aeouora Victoria (Cormack et al., 1996 Gene 173:33-38.) is a well established tag used extensively for the visualisation of proteins expression in bacteria and mammalian cells. Expression of the GFP is constitutive and is driven by the Paq promoter which also drives the expression of the hygromycin resistance gene. As far as we are aware GFP poses no danger to human, animal or plant life.

**Evaluation of foreseeable effects**

Mycobacterium smegmatis ATCC 700084 and MACB strains used are considered non-pathogenic for healthy humans while GFP has been extensively used with no reports of ill efectives and as a consequence the risk associated with use is low. They are not pathogens of animals and plants and thus no specific hazards have been identified.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The Committee found the risk assessment for the project. "The use of natural products and bacteriophages against Mycobacterium spp". To be suitable and sufficient.
The scientific goal is to characterise structural and functional experience dependent plasticity mechanisms in the cortex with the view of further understanding cortical processing of information, learning and consolidation of memories. A large number of molecules and pathways have ben identified and shown to play a key role in synaptic plasticity. Gene defects affecting some of the associated postsynaptic proteins cause neuro-developmental disorders (also known as synaptopathies) such as Fragile X. We will study development plasticity in the primary visual cortex (V1) at the cellular level in mouse models of those disorders using two-photon laser scanning microscopy. The mice to be used carry a knock-out mutation on one of the mouse homologues of human genes associated with neurodevelopmental disorders (FMR1, DLG3) and/or they conditionally express fluorescent proteins that will allow specific populations of cells in the cortex to be identified during imaging. In addition Cre recombinase/loxP transgenic technology will be used in some experiments to restrict transgene expression to specific tissues such as cortical layer 2/3 neurons. Mature neurons will be virally...
Transfected using the well characterised, safe and commercially available Adenoviral Associated Virus (AAV) vector system (Upenn). AAV are non-pathogenic viruses naturally occurring in mammals.

Recipient or parental organism

Recipients are transgenic knock-out models for neurological disorders (FMR1, DLG3) and these will be injected with AAV-vectors for the purposes of expressing fluorescently labelled proteins. This will enable structural imaging of the infected neurons in vivo.

Host/vector system

Adenoviral-Associated -Virus Vectors will be used for the delivery of DNA coding for fluorescently labelled proteins.

Origin & function

Inserted genes will encompass very safe, well characterised and routinely utilised fluorescent reporter genes such as GFP, YFP, tdTomato, DsRed etc. In addition photosensitive receptors expressed on the cell surface such as Channelrhodopsins which are only activated upon specific photostimulation protocols. This genetic material originates from human cDNA, murine cDNA, green algae and parovirus AAV-DNA.

Evaluation of foreseeable effects

Viral vectors will encode fluorescent proteins which will allow visualisation of specific cells through optical imaging.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Transgenic models are housed in a secure facility, where all users adhere to standard operating procedures. Standard Operating Procedures include documentation of all subjects housed in the facility, regular testing for pathogens, relevant safety procedures such as designated clothing, facemasks, gloves to be worn within the facility. The probability of transgenic models in use escaping into the environment are effectively zero, however in such a remote eventuality, subjects will be ill equipped to survive predation or acquire food, due to cognitive deficits, and have limited immunity to natural pathogens in the environment.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Genetically modified waste will be treated with chemical disinfectants, autoclaved and incinerated. Some GM subjects will be fixed with paraformaldehyde by perfusion for analysis. In these cases paraformaldehyde inactivates any infectious GM material. All tissue and carcasses are disposed of in designated clinical waste bags and incinerated. Contaminated and/or biological waste is disposed of in clinical biohazard bags and autoclaved.

Standard Operating Procedures for the viral unit require all surfaces and equipment to be wiped down with Virkon 1% or Trigene 4% as per manufacturer's instructions. Virkon (potassium peroxymonosulphate), sodium dodecylbenzenesulfonate, sulphamic acid; and inorganic buffers. Trigene - Halogenated tertiary amine. Both these compounds have a broad spectrum activity against vegetative bacteria, spores, mycobacteria and viruses.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N
The GMBA committee asked for clarification on a number of minor issues which was provided. These have been dealt with and the committee agree that the risk assessment is suitable and sufficient.

### Project Ref 130/13.4

**Date Ackn'd** 14/05/2013

**CU2 Project Title**

Molecular regulation of mammary epithelial cells Part 1 (Generation and use of replication deficient lentiviruses; Containment Level 2 activity)

**Class** Class 2

**Culture Vol** < 1 Litre

**Consent Granted**

**Project notified under transitional arrangements** N

**Withdrawn** N

**Tick if notifying a connected programme of work** N

**Historical Significant Changes**

**Historical Date of Additional Info**

**Significant Change ID**

**Date of Significant Change**
**Project Additional Information**

**Purposes of the contained use**

To use replication-deficient third generation lentiviral vectors to deliver cDNA and knockdown constructs to mammalian cells (in particular, to mammary epithelial cells) to investigate the molecular regulation of mammary epithelial cell biology, and how this is de-regulated in breast cancer.

Having generated replication deficient lentiviruses, these will be used to transduce mammalian cell cultures. Generation of lentiviral vector constructs will be carried out under Containment Level I conditions. Generation of lentiviral supernatants and transduction of cell cultures will be carried out under Containment Level II conditions. However, providing the supernatants being used have been proven as free of replication competent virus, and the transduced target cells have been washed and free of supernatant for 24 hours, we will return cells to Level 1 containment.

Once the lentivirus has infected the cells it should not be able to replicate. All new batches of virus will be tested for replication competence. Murine NIH3T3 or 3T3-L1 cells will be transduced with fresh or frozen (-70°C) viral supernatant (supernatant 1) (virus containing the gene of interest plus either a selectable marker or GFP) plus 2ug/ml of polybrene and incubated overnight. The following day, cells will be washed with medium and refed. After 24 to 48 hours the number of GFP positive cells will be assessed (or the cells will be put under selection). Cells will be grown for a further 4 to 6 days (splitting cells if necessary) and an overnight supernatant (supernatant 2) harvested from confluent cells. The supernatant will be passed through a .45 micron filter and either used straight away or stored frozen at -70°C. NIH3T3 or 3T3-L1 cells will then be transduced with supernatant 2 plus polybrene. A positive control consisting of supernatant 1 plus polybrene will be included. The cells will be washed the next day and fresh medium added. The cultures will be checked for GFP positive cells 24 to 48 hours later (or put under selection). In the absence of virus in supernatant 2 no green (GFP positive) cells (or resistant colonies if a selectable marker is used) should be seen whereas green cells should be present in cells transfected with positive control supernatant 1.

Cell lines generated using replication-deficient virus (as opposed to short term cultures) will be tested every six months to confirm continued absence of replication competent virus. Supernatant will be harvested from confluent cells, passed through a 0.45 micron filter. NIH3T3 or 3T3-L1 cells will then be 'transduced' with supernatant plus polybrene. The cells will be washed the next day and fresh medium added. The cultures will be checked for GFP positive cells 24 to 48 hours later (or put under selection). In the absence of virus in the supernatant no green (GFP positive) cells (or resistant colonies if a selectable marker is used) should be seen. The positive control will be the cell line from which the supernatant was harvested. The negative control will be NIH3T3 or 3T3-L1 cells not treated with supernatant.

**Recipient or parental organism**

Viruses will be generated by transfection of mammalian cell lines (HEK293FT) with a minimum of three different vectors coding for envelope, expression vectors and packaging proteins.

**Host/vector system**

The vector systems we will use are split vector systems with a minimum of three elements:

1) The expression vector into which the gene of interest is cloned and which also typically contains a fluorescence and/or selectable marker. The expression vectors also contain elements to allow packaging into virions.

2) A packaging plasmid suppling the helper functions in conjunction with structural and replication proteins (in trans) required to produce the lentivirus. In some more advanced biosafety systems, these functions are also split between more than one vector.

3) A plasmid supplying an envelope protein that gives broad tropism.

The 293T line stably expresses the sV40 large T antigen under the control of the CMV promoter. When packaging plasmids and Intiviral vector are co-transfected into the 293 FT cells a replication defective virus is produced. This virus can then be used to transduce both actively cycling and dormant mammalian cells but will not replicate in the
host cells. Once inside the cell, the RNA virus is reverse transcribed, becomes stably integrated into the host genome and the effect of expression of the gene of interest can be studied.

The following vector systems will initially be used. Additional systems with the same minimal safety features will be added as required following local approval by the GMBA Committee.

VECTOR SYSTEM 1: TRONOLAB pWPI SYSTEM

The Trono laboratory lentiviral vector system (pWPI, pMD2.G and psPAX2) will be used for overexpression studies. The lentiviruses are made with a split-genome conditional packaging system. This conditional packaging system acts as a built-in device against the generation of productive recombinants. For expression studies, the gene of interest will be under the control of the human cytomegalovirus (CMV) promoter.

VECTOR SYSTEM 2: pSEW SYSTEM

The SEW expression vector, the packaging construct pCMVR8.91 and the pseudotyping construct pMD2. VSVG will be used for knockdown studies (obtained from B. Groner, Frankfurt). SEW carries a proviral cassette containing the 5' -UTR of HIV-1, followed by an eGFP sequence under the control of the Spleen Focus Forming Virus (SFFV)- promoter and a 3' - self-inactivating LTR. The desired shRNA is cloned into the 3' - LTR of SEW. Since no promoter is present in the 3' - LTR, a promoter for a small RNAs (e.g. H1 promoter: Pol III promoter) has to be cloned in front of the shRNAs before insertion into the SEW-vector. We have also established a variant of this vector in which an EF1a promoter together with a cDNA for a gene of interest can be inserted instead of an shRNA to generate an over-expression vector.

Origin & function

The vectors we are working with are artificial constructs built from a variety of elements of different origin including elements of HIV, Vesicular Stomatitis Virus and Spleen Focus-Forming Virus. The cDNA inserts will come from publicly available repositories of coding sequences. The knockdown sequences will be Synthesised to order. The coding sequences delivered by the viruses will include potential oncogenes.

Evaluation of foreseeable effects

The split vector nature of the viruses means that it is highly unlikely that recombination could occur with related viruses. If there was a loss of containment, neither the packaging cells could not survive long enough in the environment for recombination to occur. Even if widespread dissemination of an oncogene in a virus did occur, that gene would have to infect a mammalian cell already carrying defects in cell cycle checkpoint controls for it to cause cancer.

To our knowledge there are no reported occurrences of a replication-deficient lentiviral construct infecting a laboratory worker or indeed of a 3rd generation virus recombining in such a way to generate replication competent virus. The risk is assessed as Low, because of the use of potential oncogenes, however, providing SOPs and GLP are followed, the risk can be downgraded to negligible. In addition, even in the highly unlikely event of such a potentially oncogenic DNA sequence getting into a human host that does not mean it will cause cancer. Multiple genetic changes are required for tumour formation.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be disinfected with Virkon (Peroxygenic acid; 1 x 5g tablet for each 550ml liquid waste; expected degree of kill >99.999 for 1% solution for bacteria, virus, yeast; See Pub MedID 11073729).
Solid waste will be autoclaved.

Project notified under transitional arrangements **N**

Historical Significant Changes
### Project Additional Information

**Purposes of the contained use**

We wish to determine whether modifications of brain pathway (ERK pathway) induce therapeutic benefits in a mouse model of HD. ERK pathways will be altered by the delivery of a virus into a specific brain region for this purpose.

**Recipient or parental organism**

The recipient organism of the virus is mouse

**Host/vector system**

The vector system is a 3rd generation retrograde self-inactivating lentivirus (LV). Sequences coding gag,pol, env and rev are removed from the transfer vector and provided in trans by three helper constructs. Several lentiviral accessory genes are deleted (vif, vpr, vpu and nef). Tat gene is deleted and the tat-responsive promoter present in the 5’-LTR is replaced by an heterologous promoter in the U3 region.

**Origin & function**

The viral vectors created in the laboratory of Dr R B in the San Raffaele Scientific Institute, in Milan. The nucleic acids were purchased from Thermo scientific (http://thermoscientificbio.com?). The intended function of the viral vectors are to modify a specific molecular (ERK/MAP kinase) pathway in the brain that has been implicated in the development of pathology in a number of neurological disease states. More specifically short hairpin sequences will be used for RNA interference of the mouse ERK1 gene product.

**Evaluation of foreseeable effects**

The virus is not able to replicate and carries no pathological payload, consequently the application of the virus will have no negative consequences to the well being of the mouse or spread beyond the host to the wider environment or to other organism. As this procedure is a therapeutic application we would hope that the virus would improve the disease phenotype in the mouse as demonstrated by ERK/MAPK modifications in other animal models of disease (see Fasano and Brambilla 2011. Font Behav Neurosci 5.79)

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

Project notified under transitional arrangements  N
Recent advances in 3D organoid culture systems recapitulate tissue organization, stem cell behaviour and differentiation. These culture conditions, based on the careful control of Wnt pathway activity, allow maintenance of intra-organoid cellular diversity including tissue and cancer stem cells in a variety of primary tissues including the intestine, liver and mammary gland together with tumours form corresponding issues. Organoids better recapitulate in vivo cell responses and will likely play a significant role in studies of gene function and future drug discovery where there is a major demand for systems that better predict patient responses than 2D cell culture. Human and mouse derived organoids could provide a fast, cost-effective and high-throughput alternative to animal models. For this technology to be maximally exploited, it would ideally be combined with genetic modification techniques.

This project will involve expression of site-specific (eg. Cre-LoxP) recombinases, Wnt signalling pathway regulators and signalling pathway reporters in primary 3D organoid cultures and routine tissue culture cell lines of mouse and human origin (Eg. HEK293, SW480) using aden- and lentiviral vectors. Recombinant gene expression will be controlled using lentiviral or adeno viral expression vectors and morphological and biochemical changes will be monitored by fluorescence microscopy and biochemical assays. Reporter genes will be used to assess the effects of culture conditions on intracellular signalling pathways. Inducible Cre-LoxP and transgene expression will be used to alter gene expression in the organoids and in tissue culture cell lines. Of most interest from a safety point of view are vectors that, following transduction, might alter cellular function in non-target cells (eg. Lab worker tissues) during experiments.

Replication deficient recombinant adenoviruses or lentiviruses will either be bought pre-packed or generated in house. To this end, genes involved in oncogenesis and Wnt signalling regulation will be cloned into commercially available vectors in attenuated E. coli strains (e.g. DH5a, JM109, XL-1 blue, BJ5813, SW102, STbl3). Packaged replication defective viruses will be generated in E+ helper cell lines (e.g. 293 cells and 991 cells) and used to transduce target cells.

Although a range of different adenoviral vector systems are used to generate recombinant viruses, the vectors are all based on Ad5 E1. E3 deletion mutants with essentially identical biological properties. However, we are aware that Ad5 encodes two short virus-associated RNAs (VA-RNAI & VA-RNAII) that do not encode a protein but suppress RNA interference VA-RNA transcription is driven by RNA pol III, is activated late in infection, and theoretically should not affect the use of the replication-deficient vectors for this application. Adenoviruses can infect a broad range of mammalian cells. The Adenoviral DNA genome is generally considered to be stable, remaining episomal and not integrating into the gemome of the host. However, it has been reported to integrate into the genome in rare cases with an integration rate of less than 1 x 10-7 / cell (Stephen et al. 2010). There is therefore only a remote possibility that it may activate or inactivate host cell genes.

The lentiviral vectors are third generation HIV-1 based lentiviral systems with advanced lentiviral safety features (using the third generation vectors with self-inactivation SIN-3UTR), and are replication incompetent once transduced. However the viruses are still able to transduce dividing and non-dividing primary human cells and will stably integrate into the host genome.

**Origin & function**

This project will involve expression of site-specific (E.g. Cre-LoxP) recombinases, Wnt signalling pathway regulators and signalling pathway reporters in primary 3D organoid cultures and routine tissue culture cell lines of mouse and human origin (E.g. HEK293, SW480) using adenoviral and lentiviral vectors.

The vectors will contain cDNA inserts of mouse, human, viral or bacterial origin or synthetic oligonucleotides. The Wnt signalling plays an important role in stem cell regulation, proliferation and cell fate. Mutations in Wnt signalling components have been linked to cancer. However, Wnt pathway dependent oncogenesis occurs normally in combination with 8-10 other genetic changes. These additional changes will not be induced by the viral vectors.

**Evaluation of foreseeable effects**

The recombinant viruses will express potential oncogenes (e.g. Wnt signalling pathway components) with the capacity to trigger unwanted proliferation in infected cells. Therefore there is a very small but identifiable risk to an infected individual of long term alteration of gene expression. However only cells that come in direct contact with the packaged virus could become infected. The route of transmission to deliver lenti- and adenoviruses is through airways and eyes. The laboratory worker is thus under risk from aerosols and through sharp injury during handling. There is no risk of the infection spreading to the community via human-human contact. The packaged virus is unstable in the general environment. And both lenti- and adenoviruses are deleted in the essential E1 gene and are thus rendered replication deficient. Vectors are also deleted in E3 and are therefore disabled with respect to their capacity to evade immune recognition.

In the case of adenoviruses, there is an extremely low risk of reversion to a wild type, since the helper cell line does not contain E3 sequences. Replication -competent adenoviruses could be generated as a result of recombination between the helper cell line and the vector. This is an inefficient process that tends to be associated with transgene deletion. Such viruses tend to grow poorly and are not fully competent.

In lentivirus, the risk of reversion to the wild type is virtually non existent as the lentivirus lacks four structural genes that reside on non homologous plasmids in the packaging line. Furthermore, the experimental vectors lack a wild type 3’ LTR that is essential for efficient viral replication.

The recombinant genes to be expressed from the viral vectors are potential oncogenes, possibly contributing to excess proliferation and prolonging the life of damaged or mutant cells. In addition, lentiviral transduction leads to the stable integration of the virus into the host cell's genome. However, as tumourigenesis is recognised to require multiple events (e.g. further mutations in growth pathways), it is unlikely that a single viral infection will result in the formation of a tumour.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

- Disinfection is achieved using Virkon (peroxyen compound). A 1% Virkon solution is expected to kill 100% in 10 min.
- All liquid waste will be collected and treated with a combination of autoclaving and disinfection methods.
- Pipette tips will be discarded directly into Sharpsafe container, autoclaved, then disposed as clinical waste.
- Plastic pipettes and other solid waste will be soaked in Virkon over night then autoclaved.
- All work surfaces will be treated and wiped down with Virkon.

The Cardiff University Genetic Modification and Biological Agents Safety Committee agreed with the classification of the activity as Class 2. They did, however, have a number of queries concerning the local risk assessment. These queries have now been answered to the satisfaction of the Committee.
**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

The purpose of the project is to modulate expression of genes in eukaryotic cells using lentiviral vectors. Coding sequences of the genes, ribozymes targeting these genes will be cloned into replication-incompetent HIV-1 based lentivirus which will be used to deliver and express the gene of interest in either dividing or non-dividing mammalian cells.

**Recipient or parental organism**

Amplication of constructed lentiviral vectors will be performed using E. coli. Packaging and amplification of the lentiviral particles will use 293 cells.

**Host/vector system**

Following lentiviral vectors will be used in the proposed research: ready to use lentiviral particles for fluorescent proteins (amsbio), 3rd generation lentiviral vector; Pre-made lentiviral expression particles for luciferase (amsbio), 3rd generation lentiviral vector; Promoter-less lentiviral expression vector (amsbio), 3rd generation lentiviral vector; pLenti6/V5-D-TOPO plasmid vector (Invitrogen), 3rd generation lentiviral vector.

Amplication lentiviral vectors will be performed in E. coli, whilst packaging for lentiviral particles will be carried out in 293 cell.

Investigation of the effect on tumour cells and other cell types involved in tumourigenesis, angiogenesis and metastasis including breast cancer (MCF-7, MDA-MB-231, ZR-751 and BT549), prostate cancer (PC-3, DU-145, LNCaP, CAHPV-10), Lung cancer (A549 and SK-ems-1), colorectal (HRT-18, HT-115, CACO2), osteoblast (hFOB), fibroblast (MRC-5) and vascular endothelial cells (HECV, HUVEC and HBMEC).

**Origin & function**

Synthetic cDNA of human mRNA from normal human prostate and breast tissues will be used for amplify CDs pf BMP7, Noggin, Follistatin respectively; cDNA of human placenta tissue will be used to amplify CDs of Gremlin; ribozymes containing complementary oligonucleotides of target genes, i.e. BMP-7, Noggin, Follistatin and Gremlin for knockdown studies; Label the cells with luciferase or fluorescent protein for in vitro and in vivo tumour models.

**Evaluation of foreseeable effects**

Deletion of accessory genes vpr, vpu, vif and nef in the lentiviral vectors lead to an incompetency of replication once the vectors have been transduced into target cells. In addition third generation lentivirus are deleted for the tat gene and carry SIN deletion of the 3’ LTR which results in “self-inactivation” of the lentivirus following transduction of the target cell, which can prevent adventitious activation of the vector by endogenous retroviruses (ERVs) and minimising the risk of recombination with ERVs.

The currently proposed research using lentiviral vectors will focus on the role played by TGF-beta family in bone metastasis from three common cancers, i.e. prostate cancer, breast cancer and lung cancer. The target gene/molecules include TGF-beta and bone morphogenetic proteins (BMPs), their receptors, antagonists and the corresponding intracellular signalling molecules Smads. Inserts into the lentiviral vectors will be the coding sequence of the corresponding human genes, ribozyme or interfering RNA (shRNA or siRNA) targeting the genes. To date none of these genes have been shown to be oncogenic or alter the properties of the genetically modified viral vectors. More details for the genes/molecules and the relevant risks are provided in the Excel spread sheet.

None of the genes in the currently proposed research has been shown to be oncogene. Overexpression or suppression of the expression have been performed in other studies. The alterations in their expression are not expected to result in the expression have been performed in other studies. The alterations in their expression are not expected to result in any form of substantial hazard. To date lentiviral vectors offer the most successful means of transduction in these cells, and can not be avoided.

Gremlin has been indicated as one of upregulated gene in Hereditary mixed polyposis syndrome which may contribute to tumourigenesis in large intestine (Jaeger 2012). However, as this gene is widely expressed by many different types of cells in various tissues. There is no evidence showing a direct link of Gremlin to tumourigenesis. To jeopardize human health, the knock down the expression of a tumour suppressor would have to occur within the human body. Entry into the body and human cells is not very efficient. Should knock down of a tumour suppressor gene occurs in vivo delivery, it is not likely by itself to cause cellular transformation. Additional genetic events would be required. Nevertheless, ACGM2 containment failities are designed to prevent operator exposure and are appropriate to control this potential hazard.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

In accordance with the SACGM Compendium of Guidance, GMM mammalian cells will be handled at containment level 2 and using microbiological safety cabinets. All GM virus waste will be properly inactivated by autoclaving. Spillages will be soaked with tissue paper, which will afterwards be autoclaved. Contaminated surfaces may be decontaminated with 70% Ethanol.

Only plastic pipettes will be used in the tissue culture facilities. Furthermore, all contaminated waste destined for subsequent incineration will be autoclaved. All precautions will be taken to identify procedures or devices that might be used in these projects which could cause an injury to the researchers. Where so identified safe alternative methods or equipment will be sought. Sharps will not be used.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All GM virus waste will be properly inactivated by autoclaving. Spillages will be soaked with tissue paper, which will afterwards be autoclaved. Contaminated surfaces may be decontaminated with 70% Ethanol. Liquid waste will be disinfected using Chlorine-based disinfectant, the expected degree of kill is 100%. How validated the efficacy of the procedure has been demonstrated experimentally (in-house evaluation). Recombinant viruses will at all times be maintained in an environment designed to prevent aerosol spread. All flasks containing the virus shall be kept closed except when decanting and pipetting which will be conducted in tested class II safety cabinets. Centrifugation steps shall be performed in sealed buckets that will be opened only in safety cabinets. Contaminated pipettes will be immersed in Actichlor for a minimum of 4hr prior to transferring to a container for autoclaving. The tissue culture cabinet and any potentially contaminated area will be disinfected with chlorine-based disinfectant according to an approved protocol. Access to laboratories employed for virus work will be restricted.

Human Clinical Applications

02/03/2022
The aims of the project is to generate induced pluripotent stem cells by viral based genetic reprogramming of somatic cells of patient and healthy individuals. Induced pluripotent stem cell (iPSC) technology is a novel method for programming somatic cells directly into pluripotent cells by introducing a defined set of transcription factors such as Oct 4, Sox2, c-Myc, and Klf4. iPSC are functionally equivalent to embryonic stem cells. Thus, via iPSCs, all somatic cells are interconnected by the reprogramming route. Studying iPSC will improve knowledge of the molecular process that occurs during reprogramming as well as to model human diseases. iPSCs offer promising donor sources for autologous cell based therapies. Patient-specific iPSCs provide a new mean to investigate the etiology of complex disorders, such as schizophrenia.

We plan to establish human iPSC lines from human fibroblasts and keratinocytes donated by patients with neuropsychiatric conditions and healthy volunteers. We will generate cortical projection neurons, cortical interneurons and dopaminergic neurons from three iPSC cells and to study the potential pathophysiological defects relevant to the neuropsychiatric diseases.

Recipient or parental organism

Replication deficient Sendai viral vector simultaneouly expressing the four reprogramming factors will be purchased as ready packaged from commercial sources (eg. CytoTune® -iPS 2.0 Sendai Reprogramming Kit from Life Technologies). The virus will be used to transduce human keratinocytes and potentially other somatic cell types of human origin.
The lentiviral vector, pSIN4 come in attenuated E. coli strains Stbl3. HEK293T cells will be used to package these vectors into virus, and the viruses will be used to transduce human fibroblasts.

### Host/vector system

| E.coli: Stbl3  | Host for viral packaging: HEK293T |
| pSIN4 lentiviral expression vector | Sigma -Aldrich 'packaging vector' |
| Sigma -Aldrich 'envelope vector' | SeV/dp Sendai viral vector system |

### Origin & function

The viral vectors will contain cDNA inserts of human origin that encode transcription factors Oct4, Sox2, Klf4 and potentially cMyc. The Oct4, Sox2, Klf4, and cMyc (OSKM) genes are ordinarily expressed in embryonic stem cells. The introduction and expression of these genes in differentiated cell type’s results in the effected cell reverting to an embryonic stem cell-like pluripotent state. The final viral vector is designed to introduce the OSKM genes to the host cell and facilitate long term stable expression of the genes for the purposes of generating iPS cell cultures.

### Evaluation of foreseeable effects

The transcription factors to be used in these experiments come in lentiviral (HIV)-plasmid (pSIN) and will be cotransfected into packaging cells (HEK293T) alongside plasmids for packaging proteins (MISSION lentiviral packaging mix, Sigma-Aldrich) to produce lentiviral particles. The lentiviral vector systems have been developed with enhanced safety features. It is a third generation lentiviral vector system, with two plasmids consisting of:

1. The packaging vector, which contains the minimal set of lentiviral genes required to generate the virion structural proteins and packaging functions. 2. The vesicular stomatitis virus G-protein (pCMV-VSV-G) envelope vector, which provides the heterologous envelope for pseudotyping.

The lentiviral vectors are third generation HIV-1 based lentiviral systems with advanced lentiviral safety features (using the third generation vectors with self-inactivation SIN-3UTR), and are replication incompetent once transduced. However the viruses are still able to transduce dividing and non-dividing primary human cells and will stably integrate into the host genome.

Sendai virus are based on defective and persistent Sendai virus vectors SeVdp) lacking the viral M, F and HN genes, and are non-transmittable. They replicate in the forms of single-stranded RNA in the cytoplasm of the infected cells. They do not go through a DNA phase nor integrate into the host genome. It replicates its genome exclusively in the cytoplasm and does not enter cell nucleus. Therefore, Sendai virus vector is integration free and unlikely to alter the host chromosomes like the conventional viruses.

One of the reprogramming factor (cMyc) is an oncogene with the capacity to trigger unwanted proliferation in infected cells. Therefore there is a very small but identifiable risk to an infected individual of long term alteration of gene expression. However only cells that come in direct contact with the packaged virus could become infected.

To minimize the possibility of self inoculation, personal protection measures will be taken, for example needles will not be used when handling biological agents and appropriate personal protection will be used (Lab coat, gloves, safety glasses). To minimize any possible aerosol effects of the viral stocks, appropriately capped centrifuge bottles and screw-capped tubes will be used. Virkon has been shown to completely inactivate lentivirus and Sendai virus at a final concentration of 1:100 and so will be used to thoroughly clean everything involved in these experiments.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Disinfection is achieved using Virkon (peroxynate compound). A 1% Virkon solution is expected to kill 100% in 10 min.

All liquid waste will be collected and treated with a combination of autoclaving and disinfection methods.

Pipette tips will be discarded directly into sharpsafe container, autoclaved, then disposed as clinical waste.

Plastic pipettes and other solid waste will be soaked in Virkon over night then autoclaved.

All work surfaces will be treated and wiped down with Virkon.

Project Additional Information

**Purposes of the contained use**

To introduce an adenoviral vector (Ad5-CMV-cre or Ad5-cre-IRES-GFP) to specific mouse tissues (ovary and lung). The vector encodes a cre recombinase enzyme and hence causes recombination between loxP sites in DNA, to delete specific genes in relevant genetically-modified mice (as listed in the connected project).

**Recipient or parental organism**

We will use GM mice with 10xP-flanked DNA sequences, such that specific genes will be deleted by introduction of the adenoviral cre. For the ovarian work, we propose to delete the tumour suppressor genes apc and pten, by intra-bursal injection of the virus. For the lung work, the tumour suppressor p53 will be deleted and the k-ras oncogene will be over-expressed, by nasal inhalation of the virus.

**Host/vector system**

Ad5-CMV-cre is a commercially-available, replication-deficient virus which is routinely used to inactivate genes in mice in a tissue-specific manner. It does so by expressing the cre recombinase enzyme in cells in to which it has been delivered, thus allowing recombination in host genes carrying 10xP-flanked sections of DNA. The virus has been attenuated due to deletion of the E1 and E3 regions of its genome. We may also use an additional vector, AdS-cre-IRES-GFP, which is identical to Ad5-CMV-cre, but has an additional marker gene (GFP) to analyse expression of the cre recombinase enzyme.

**Origin & function**

The viruses encode the gene for the cre recombinase enzyme, which originates from Bacteriophage P1. The gene will be expressed only within cells into which it has been introduced. The sole function of the cre recombinase enzyme in these cells is to cause recombination between lox? sites in host DNA, which causes deletion of genetic material between these sites (gene deletion). The lox? sites also originate from Bacteriophage P1 and have been engineered into mice via the germline. Only genes carrying these sites will be affected by the cre recombinase.
Evaluation of foreseeable effects

As the viruses to be used in this project are replication-deficient, due to deletion of their E1 and E3 genes, they are unlikely to cause any effects on humans or the environment. However, human adenovirus is known to cause mild flulike symptoms in humans and, as such, the virus will only be handled in a class II hood, either during aliquotting (in Hadyn Ellis Building viral suite) or during delivery to mice (in JBIOS animal unit, School of Biosciences).

The addition of the genetic modification (the ere recombinase gene) to these viruses is thought to have no effect on their ability to survive in host organisms or the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

GM mice will be housed in a conventional animal unit in standard cages.

Health and Safety

Executive

Following exposure to Adenovirus, mice will be housed in an isolator within the unit for 2 weeks, before being returned to standard caging. Cages used to house the mice within this 2 week period will be disinfected with bleach and all bedding and other disposable material will be bagged, boxed and sent for incineration.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

It is possible that aerosols may be generated during administration of the virus to the mice, hence all such work will be carried out in a class II safety cabinet. All waste generated will be inactivated by autoclaving or appropriately packaging and transporting off site for incineration (SRCL waste contractors).

Mice which have received the virus will be left to survive for at least several weeks following viral administration. Cages used to house the mice within the 2 week period following exposure to virus will be disinfected with bleach and all bedding and other disposable material used in animal care will be packaged and sent for incineration. The carcasses of any infected mice which die or are sacrificed within this period will be disposed of by incineration.

Purposes of the contained use

Globally, an estimated 14 million people are diagnosed with cancer each year, accounting for ~8 million deaths. New, more efficacious treatments for cancer are therefore required urgently to combat this. The purpose of this application is to develop a programme of research seeking to develop viral vectors which can be used, ultimately clinically, as a novel means for treating cancer ("virotherapy" using "oncolytic viruses"). This can promote cell killing through (a) selective viral replication in cancer cells resulting in cellular lysis and spread of virus to surrounding cells (b) expression of an apoptosis inducing protein or cell sensitizing protein (e.g. an enzyme which can convert a nontoxic prodrug into a toxic drug) or protein/antibody designed to increase the immune recognition of the infected tumour.
cell, and (c) increased immunogenicity against the tumour cells through the presence of a viral particle within the cell, promoting an increased host anti-tumour response. With this in mind, I propose to split this connected programme of research into the following areas:

1. Generation of tropism modified adenoviral vectors.

Overview: In this section of work, I will use replication deficient adenoviral vectors available in house, based on human adenovirus serotype 5 (Ad5) to generate a bank of viruses that are "detargeted" for known tropism dictating receptor interactions, including (but not limited to) fiber: heAR interactions, penton base: cellular (Qv~3/5) integrin interactions and hexon interactions with blood clotting factor X (FX)/complement proteins/scavenger receptors. In order to "retarget" tropism more specifically to cancer cells, I will generate Ad5 based vectors incorporating peptides in key capsid proteins (fiber, hexon, penton) which target to receptors upregulated on tumour cells, including (but not limited to) EGFR, FGFR1, Qv~6 integrin, CD133, CD44, nestin. Additionally I will engineer the virus to include biotinylatable peptides so as to enable to linkage of larger targeting ligands (e.g. antibodies) onto the viral capsid. All vectors in this section of work will be encoding reporter genes (e.g. luciferase, B-Gal, eGFP), and findings from this section may be used in the design of targeted oncolytic vectors in future sections of research.

2. Use of wild type adenoviruses from several species, evaluation for cancer cell killing and genome capture for onward manipulation in BACs.

Overview: In this section of work, I will evaluate the ability and selectivity of adenoviruses from alternative adenoviral species, to infect and kill cancer cells. Specifically, I will focus on adenoviruses from species Band D which demonstrate lower seroprevalence rates compared to Ad5 (PMID: 17329340), and utilise as yet undocumented receptors. Furthermore, my preliminary data (from a previous post, some of which is now published, PMID: 17329340) demonstrated that vectors based on species 0 adenoviruses show dramatically increased levels of transduction when compared to Ad5 (widely considered as the "gold standard"). In this section of work I propose to capture the wild type viral genome in a BAC (bacterial artificial chromosome) which will enable onward engineering into a reporter gene expressing, replication deficient vector for further evaluation through recombineering technologies. Derived vectors will be assessed for receptor usage and host protein interactions, and point mutations within key proteins will be introduced to manipulate/prove these interactions. All vectors in this section will either be wild type (i.e. not encoding any transgene) or encoding reporter gene(s).

3. Directed evolution of adenoviral vectors for optimised cancer cell killing.

Overview: in this section of work, I will select for viral recombinants with improved selectivity/cell killing of specific cancer cell lines. Using the same panel of adenoviruses (as described in (2)) at high titers to force recombination and evolution of viral vectors with the best selectivity and cell killing ability in different cancer types (focussing initially on 3 types of cancer, namely Ovarian, Panreatic and Esophageal). This strategy will replicate previous research (PMID: 18560559) which generated the oncolytic adenoviral vector, ColoAd (Enadenotucirev), which is now being evaluated in phase 1/11 clinical trials in colorectal cancer following intratumoural or intravenous delivery. The best candidate chimaeric vectors will be captured within BAC based vectors for onward engineering and development as therapeutics. All vectors tested with in th is section of research will be either "wild type" (i.e. not encoding a transgene) or encoding reporter gene(s).

4. Development of oncolytic forms of adenoviruses selective for cancer cells by introducing mutations in the genome to render the virus replication selective for cancer cells.

Overview: In th is section of work, we will introduce mutations within the adenoviral genome which render the virus "oncolytic", i.e. only able to replicate within cancer cells. These include deletion of the E1 B55k protein, which has been shown to enable replication selective in p53- cells (e.g. see PMID: 9176490), delta 24 mutation in E1A protein (e.g. as utilised clinically in PMID: 23756180), and the potency enhancing T1 mutation (see PMID: 25093639), or
combinations thereof. Viral vectors tested within this section of research will be either "wild type" (not encoding any transgene) or encoding reporter genets).

5. Incorporation of miRNA binding sites or tumour specific promoter sequences to generate cancer selective viral vectors at the level of transcription/translation.

Overview: As alternative strategies to ensure tumour selective viral replication, we will 1. incorporate miRNA binding sites to silence adenoviral expression of essential early viral genes in "off target" cells (i.e. where the relevant miRNA expressed at high levels in off target cells), and/or 2. the inclusion of tumour specific promoters into the adenoviral genome to limit the expression of critical early genes to tumour cells.

6. Development of armoured virotherapies encoding biological genes that may be beneficial in cancer (e.g. that interfere with checkpoint blockade).

Overview: In this section of work, biological genes will be encoded within the selected viruses outlined in sections 1-5. This will allow assessment of efficacy both in vitro and in vivo in preclinical models. Examples of genes that might be encoded would include (but not limited to) genes which express a protein that sensitises a cancer cell to a prodrug (e.g. cytosine deaminase, nitroreductase), genes which affects host immune recognition of tumour cells (e.g. antibodies that interfere with PD-1, PD-1, CTLA-4) or tumour suppressor genes (e.g. p53).

7. Development of visualisable (detectable) oncolytic adenoviral vectors for quantitative evaluation of virotherapy efficacy in preclinical cancer models.

Overview: In this section of work we will seek to develop viruses which can be utilised to visualise oncolysis in real time using fluorescence based techniques. We will use (and compare) both replication deficient and oncolytic Ad based vectors encoding transgenes (most likely GFP) and genetically incorporate a fluorophore, e.g. mCherry in the capsid protein. This will allow us to simultaneously visualise cellular transduction (thought expression of the transgene, GFP) and viral spread (through visualisation of viral capsid protein: fluorophore fusion protein) in real time using sophisticated imaging software. Other combinations of reporter gene/fluorophore may also be evaluated.

Recipient or parental organism

Adenovirus - most work will involve serotype 5 (species C), though large sections of the work will develop a number of species Band 0 adenoviruses also (available from ATCC or ECACC), and generate chimaeric versions of these viruses.

Host/vector system

Manipulation of the adenoviral genome will be achieved by recombineering technologies in bacteria, based on red lambda genetics, and the presence of the viral genome captured within a BAC based plasmid.

Replication deficient Ad based vectors will be propagated in complementing cell lines (e.g. 293, TRex, 911, PerC6 cells), whilst replication competent viruses will be produced in either 293 cell lines or any other relevant permissive cell lines (e.g. A549 cells).

Tropism/cell killing will be evaluated in a wide range of cell lines and primary cells of human origin as well as cells from other origins (e.g. murine).

We expect to advance of leading formulations into model animal systems based on murine tumour xenograft and allograft models.

Origin & function

1. Reporter genes. (a) GFP (Green Fluorescent Protein) refers to the protein first isolated from the jellyfish Aequorea victoria and is a 238 amino acid protein (26.9 kDa) that exhibits bright green fluorescence when exposed to light in the
blue to ultraviolet range. (b) Luciferase refers to the generic term for the class of oxidative enzymes used in
bioluminescence. One example is the firefly luciferase from the firefly Photinus pyralis (62kDa protein, of 1616bp), and
this is the version we will use primarily, although we may also make use of Renilla luciferase, derived from the fancy
sea pansy, Renilla reniformis, (c) β-galactosidase, also called beta-gal or β-gal, is a hydrolase enzyme that catalyzes
the hydrolysis of β-galactosides into monosaccharides. Originally isolated from the bacterium, E. coli, the gene of β-
galactosidase, the lacZ gene, is present as part of the inducible system lac operon which is activated in the presence
of lactose when glucose level is low, (d) mCherry - originally isolated from the mushroom coral Discosoma sp, ie a
fluorophore used as a marker when tagged to molecules and cell components.

2. Prodrug sensitizing genes. In this section of work, genes will be cloned into the virus for potential Virus Directed
Enzyme Prodrug Therapy (VDEPT) approaches. This approach requires the expression of an enzyme within the
target cell that can convert a harmless prodrug into a cytotoxic drug. A table showing possible enzyme/prodrug
combinations that may be evaluated is outlined below

3. Inhibitors of checkpoint blockade. Recent advances in understanding the role of checkpoints in immune tolerance
and the use of antibodies to interfere with these axes (so called "checkpoint blockade") have resulted in dramatic
clinical improvements using antibodies directed at CTLA-4 (Ipilimumab) and the PD-1/PD-L 1 axis (Nivolumab). In this
section of work, antibodies targeted against these key modulators of checkpoint blockade will be incorporated into the
Ad genome for overexpression studies. These DNA constructs have been made available to us in plasmid form (from
Prof Guy Ungerechts and Dr Christine Engerlaand, Heidelberg University, Germany).

4. Tropism modification. In order to alter adenoviral tropism, point mutations will be introduced into the capsid to
abrogate defined receptor interactions or other interactions known to influence viral tropism and toxicity. This will be
performed in combination with the introduction of peptides into the capsid proteins (synthetically produced, sequences
derived from bacteriophage biopanning strategies) that bind to alternative receptors (as outlined in part 1 (section 6)
of the outlined work).

Evaluation of foreseeable effects

For the wider connected programme of work, the following worst case scenarios apply:

1. Generation of tropism modified adenoviral vectors.

WORST CASE SCENARIO: The worst case scenario for this project would be that a worker would inadvertently
inoculate themselves with a huge dose of virus that was (1) targeted to an alternative receptor, and (2) harder for the
immune system to recognise and clear. In this scenario, should the virus enter the bloodstream, the biodistribution of
the recombinant virus may be altered compared to that of a wild type AdS viral capsid (which would predominantly
locate to the liver, and to a less extent the spleen). Mutations introduced to detarget the virus may also render the
virus harder for the host to clear. However, the virus is rendered replication deficient it would not form a productive
infection.

2. Use of wild type adenoviruses from several species, evaluation for cancer cell killing and genome capture for
onward manipulation in BACs.

ENVISAGED WORST CASE SCENARIO: This section of research involved the study of wild type adenovirus. The envisaged worst case scenario therefore in this section of work would be that a worker inadvertently self-innucleated with a high dose of fully replicative, wild type adenovirus. In the vast majority of cases, infection with a wild type adenovirus causes a transient, non-life threatening infections, mainly of respiratory and GI tract, although some species D adenoviruses (e.g. Ad37, Ad19a) may also cause conjunctavitis and tonsilitis. Adenoviral infections are typically transient and self limiting, with virus symptoms typically lasting 7-7 days. The only exception to this is in the immunocompromised individual, and therefore all staff working on this project will be made aware of the requirement to declare if they are using immunosuppressive drugs, and any such individual will be prevented from working with adenovirus. To minimise the potential for infection, all work will be conducted under containment level 2 conditions, including the use of class 2 level biosafety cabinets.

3. Directed evolution of adenoviral vectors for optimised cancer cell killing.

ENVISAGED WORST CASE SCENARIO: This section of research involved the study of wild type adenovirus, and chimeric adenoviruses generated by recombination between viral strains. The envisaged worst case scenario therefore in this section of work would be that a worker inadvertently self-innuclelated with a high dose of either a wild type adenovirus (as in section 2) or a chimeric adenovirus generated through the research programme. In the vast majority of cases, infection with a wild type adenovirus causes a transient, non-life threatening infections of the respiratory and GI tracts, although some species D adenoviruses (e.g. Ad37, Ad19a) cause conjunctavitis and tonsilitis. Adenoviral infections are typically transient and self limiting. As adenoviral infections can be significantly more problematic in the immunocompromised individual, as in section (2), all staff working on th is project will be made aware of the requirement to declare if they are using immunosuppressive drugs, and any such individual will be prevented from working with adenovirus. The chimeric adenoviral variants generated in this programme are unlikely to have different tropism or higher levels of virulence than the parental viral hosts in non-transformed cells, but will be selected for their ability to replicate selectively and rapidly in cancer cells, as previously published (PM ID: 18560559), and therefore this cannot be ruled out entirely. Chimeric viruses generated will be evaluated for their selectivity for replication in cancer cells (compared to non-transformed cells) and any chimeric virus not demonstrating improved selectivity for tumour cells (and therefore an improved safety profile) will not be pursued for onward studies. To minimise the potential for infection, all work wi ll be conducted under containment level 2 conditions, including the use of class 2 level biosafety cabinets.

4. Development of oncolytic forms of adenoviruses selective for cancer cells by introducing mutations in the genome to render the virus replication selective for cancer cells.

ENVISAGED WORST CASE SCENARIO: This section of research involved the study of wild type adenovirus, and viruses that have been engineered to be selective for replication only in tumour cells ("oncolytic" adenoviral vectors). The envisaged worst case scenario therefore in this section of work would be that a worker inadvertantly self-innuculated with a high dose of fully replicative, wild type adenovirus, and therefore the worst case scenario would be as stated for (2) and (3). For the scenario where a staff member self-innuclelated with an "oncolytic" adenovirus, the risk is considered to be lower than with the wild type virus, and viruses based on the described tumour-selective mutations have been trialled clinically, with a similar derivatives (H1 01) having previously gained regulatory approval in China for treatment of Head and Neck Cancer (see PMID: 16507823). An in the previous sections all staff working on this project will be made aware of the requirement to declare if they are using immunosuppressive drugs, and any such individual will be prevented from working with adenovirus. To minimise the potential for infection, all work will be conducted under containment level 2 conditions, including the use of class 2 level biosafety cabinets.

5. Incorporation of miRNA binding sites or tumour specific promoter sequences to generate cancer selective viral vectors at the level of transcription/translation.
ENVISAGED WORST CASE SCENARIO: The envisaged worst case scenario in this section of work would be that a worker inadvertently self-innociulated with a high dose of genetically modified adenovirus, where the transgene is under the control of a tumour selective promoter (so gene expression is only switched ON in tumour cells) or a miRNA binding site (to switch OFF expression of a transgene (at the mRNA level) in non-tumour cells). It is expected that these "safety switches" would lower the potential risk of pathogenesis, and therefore the relative risk is likely to be lower than those outlined above (in 2 and 3). It is likely that any individual self inoculating with such a virus would experience a transient, self limiting infection, as described above, with virus symptoms typically lasting -7 days. As previously, all staff working on this project will be made aware of the requirement to declare if they are using immunosuppressive drugs, and such individual will be prevented from working with adenovirus. To minimise the potential for infection, all work will be conducted under containment level 2 conditions, including the use of class 2 level biosafety cabinets.

6. Development of armoured virotherapies encoding biological genes that may be beneficial in cancer (e.g. that interfere with checkpoint blockade).

ENVISAGED WORST CASE SCENARIO: The envisaged worst case scenario for this section would be that a worker would inadvertently self-inoculate with a large dose of virus that was (1) replication competent, (2) expressing a transgene that has a biological function (e.g. interferes with immune tolerance), (3) shows an altered tropism compared to the parental virus. In this scenario, the worker may experience transient productive infection (although this should be restricted by the mutations that render the virus cancer selective). The infected cells may be nonnative, through the introduction of tropism modifications that render the virus more selective to tumour cells and less selective to "normal" (i.e. non-transformed) cells. Where a productive infection does occur, the infection should be transient and non-life threatening (at least in the non-immunocompromised individual, as is observed for "wild type" adenoviral infections). The expression of a biological gene product interfere with immune recognition (e.g. anti-CTLA4/PD1/PD-L 1) may positively influence the ability of the body to recognise infected cells and targeted them for clearance. As previously, all staff working on this project will be made aware of the requirement to declare if they are using immunosuppressive drugs, and such individual will be prevented from working with adenovirus. To minimise the potential for infection, all work will be conducted under containment level 2 conditions, including the use of class 2 level biosafety cabinets.

7. Development of visualisable (detectable) oncolytic adenoviral vectors for quantitative evaluation of virotherapy efficacy in preclinical cancer models.

ENVISAGED WORST CASE SCENARIO: The envisaged worst case scenario scenario in this section of work would be that a staff member were to self inoculate with a high dose of oncolytic adenovirus that is genetically labelled with a fluorophore in the capsid protein. The presence of the fluorophore in the capsid protein should not have any effect the level of risk, and therefore the risk can be considered to be more or less identical to that outlined in section (4). It is likely that any individual self inoculating with such a virus would experience a transient, self limiting infection, as described above, with virus symptoms typically lasting -7 days. As previously, all staff working on this project will be made aware of the requirement to declare if they are using immunosuppressive drugs, and such individual will be prevented from working with adenovirus. To minimise the potential for infection, all work will be conducted under containment level 2 conditions, including the use of class 2 level biosafety cabinets.

Use of wildtype adenoviruses has previously been notified by Prof Gavin Wilkinson.
All Adenovirus activities in Cardiff are considered as BSL2.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Mice may be used in this study, but will not be genetically modified, rather they will be inoculated with a GMM vector, and therefore will be be treated with suitable control measures, with all animal carcasses and bedding destroyed by incineration. Human adenoviruses cannot replicate in the mouse and therefore there is no possibility of a productive
infection forming in this model. For some aspects of the in vivo work, mice may be inoculated with tumour cells, grown subcutaneously under permission granted in Home Office Project License ref PPL 30/3224.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

NIA

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Viruses will be maintained in an environment designed to prevent aerosol spread (biosafety level 2 tissue culture hoods, under negative pressure). All plastics containing the virus shall be kept sealed/closed except when decanting and pipetting which will be conducted in tested class 11 safety cabinets, and virus containing waste media will be treated with immediately by discarding into a waste chloros (bleach) solution. The use of Sharps when handling virus preparations will be minimised. Contaminated pipettes or other contaminated waste plastics will be immersed in Actichlor for a minimum of 4hr prior to transferring to a container for autoclaving. The tissue culture cabinet and any potentially contaminated area will be disinfected with chlorine-based disinfectant according to an approved protocol. Access to laboratories employed for virus work will be restricted.

Disinfectant Product Name: Actichlor (2500 ppm sodium dichloroisocyanurate)
Generic Chemical Name: Chlorine-based disinfectant
Expected degree of kill 100%
How validated: Adenovirus infectivity in collection buffers can be validated by reinfection assay.
For in vivo studies, all animal carcasses and bedding destroyed by inCineration, and housing will be cleaned down with chlorine based disinfecants prior to washing..

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
Project 1 “Generation of tropism modified Adenoviral vectors” GM130/683, has been fully risk assessed and the risk assessment reviewed by the Committee. The Committee were satisfied that this was a Class 2 activity requiring Containment Level 2 facilities and after a number of queries were answered and alterations made to the risk assessment that the risk assessment was suitable and sufficient.

The Committee also reviewed the the CU2 form with the connected programme of work and the worst case scenarios for each project/part of the programme. They felt that each part could be carried out at Containment Level 2, with the additional control measure used of making staff aware of the requirement to declare if they were using immunosuppressive drugs to declare it as they would be prevented from working on a number of the projects. The Committee agreed that they would be Class 2 activities.

The work on each part of the programme will not be allowed to start until the detailed risk assessment for that part has been reviewed by the Committee with intermediate results from other parts of the programme and published work of others being used to inform the risk assessment. Any results indicating a higher risk requiring higher containment levels will lead to experiments being halted until risk assessments are reviewed by the Committee and appropriate control measures put in place, seeking advice from the HSE re notification of a "significant change".

Project Additional Information

Purposes of the contained use

This notification covers a wide program of work, broken down into sections. Each section will be notified separately to the local GMBA committee for approval. At this time, only the first section of the work will be started, and a detailed risk assessment has been previously submitted to the local GMBA committee as detailed below. The broad aim of the work is as follows:

We have extensive experience working with CMV. CMV has a unique capacity to induce very high levels of polyfunctional T-cells. In the rhesus macaque model of HIV, RhesusCMV is unique in being able to protect against challenge with highly pathogenic SIV. We now seek to harness this ability to protect against cancer.

The sub-sections of this connected project are as follows:
1. CMV is a persistent virus, and will be caught by >90% of people at some point in their lives. In the connected program we have been using the tet-repressor (expressed from a cell line) to control expression of viral genes. This system will be slightly modified to produce a self-contained tet-controlled virus. This will increase the safety of CMV-based vaccine vectors by rendering viruses ‘replication-controllable’, such that they are only able to replicate in the presence of doxycycline. In addition to improving vector safety, this will also enable fundamental questions to be answered surrounding the extent to which chronic replication in vivo is required to generate this unique immune response. This section has been risk assessed in detail and the risk assessment has been reviewed by the local GMBA Committee.

2. Once the tet-regulated vectors have been tested in vitro and in vivo (in mouse), cancer antigens will be inserted into the genomes of the vectors. These viruses will be tested both in vivo and in vitro, in murine models of cancer. We will monitor both the immune response to these antigens, and the ability of these immune responses to control tumour growth and spread. We do not seek permission to perform this work at this time, but will risk assess the procedures in detail through the local GMBA committee, once the safety of the vectors has been assessed (section 1).

Recipient or parental organism

Bacterial artificial chromosome (BAC) clones of the Merlin strain of human CMV, and the smith and K181 strains of mouse CMV. These BACs contain the complete genome of a wildtype HCMV virus or the complete genome of a mouse CMV strain. We already have permission to work with these constructs as part of ongoing projects. CMV is highly species specific, thus MCMV cannot replicate in human tissue and poses little risk to humans, and is ADCP 1. The majority of the population harbour latent HCMV by later life, the virus is controlled by the immune system and does not cause symptoms. HCMV is a cause of congenital malformation if passed to the fetus during pregnancy, thus pregnant workers are given the option of avoiding work in labs where HCMV is being used.

Host/vector system

The HCMV viruses will be grown in human foetal foreskin fibroblasts. The MCMV viruses will be grown in 3T3 cells.

Origin & function

The BACs will be modified such that essential genes are only expressed in the presence of doxycycline (Dox). In the
connected program, we have placed tetracycline operator sites upstream of essential viral genes, and expressed the
tet-repressor (tetR) from a cell line. In this manner we have rendered the expression of these genes under tight doxdependent
control. In this program, we wish to make the system self-contained, by expressing the tet-repressor from
the viral backbone. Thus in the absence of Dox, the tetR binds to the tetO and transcription of the essential genes is
prevented. Since these genes are essential, the vector is rendered replication deficient. However in the presence of
doxycycline, tetR can no longer bind to tetO, and the repression is relieved. Thus the virus becomes replication
competent. In addition to significantly enhancing the safety of the vector, this also enables the construction of
replication defective viruses without the need for complementing cell lines. We may also seek to use a tetON system,
which will be phenotypically identical (i.e, the virus will be replication defective unless Dox is supplied) but differs
mechanistically. In this system, the viral gene is placed under control of a minimal promoter, and is not expressed.
The reverse tet-transactivator (rtTA) is also expressed from the viral genome. When Dox is supplied, it binds to the
rtTA and enables it to bind and activate expression from the minimal promoter.

In the second sub-section (Summary risk assessment below, final paragraph in section 7 'evaluation of foreseeable
effects'. The full detailed risk assessment will be reviewed by the gmba committee when initial work on section 1 of the
connected programme has been carried out), cancer antigens will be inserted into the MCMV/HCMV vectors. These
will cover a number of well established antigens such as 5T4, gp100 and melanA. 5T4 is an oncofetal antigen,
frequently upregulated on cancer cells. gp100 and MelanA are melanoma differentiation antigens.

Evaluation of foreseeable effects

CMV is highly species specific. It is a fragile virus that is highly sensitive to dessication, and thus is highly unlikely to
escape into the environment directly. Although it spreads between humans via infected body fluids (e.g. saliva, urine,
breast milk), spread is relatively inefficient - for example pregnant mothers frequently fail to pass it on to their children.
Spread in the community is markedly reduced by simple hygiene measures such as handwashing.
The only appreciable danger from this work arises from an accident in which a lab worker splashes a solution
containing the virus, and this results in virus accessing mucosal surfaces (e.g, the mouth) of the individual. In the case
of MCMV, replication would be abortive since MCMV cannot repl icate in human cells. Thus MCMV poses negligible
risk. In the case of HCMV, the only differences between our vectors and the parental vector (with which we have
extensive experience) is the presence of tetO sites, and an expression cassette for tetR/rtTA. The effect of these
modifications is to render the virus replication deficient. As a result, the vectors have lower risk than the wildtype virus
- the virus will be unable to spread from the site of infection, and will be unable to establish latency (which requires
gene expression, and occurs following virus spread to CD34+ myeloid progenitors in the bone marrow). However it is
possible that multiple viruses will need to be made, with tet regulation of multiple different genes tested, to determine
a configuration of tetO/tetR/rtTA that results in successful control of replication. Thus there may be viruses produced
which replicate to a similar extent as wildtype virus, despite expressing tetR/rtTA. If a lab worker were to splash a
solution of this virus on their face, and it were to reach mucosal surfaces, this virus would behave the same as a
wildtype virus - i.e. it could establish latency in the individual. The only difference to a wildtype infection is that the
virus would express tetR/rtTA. These proteins are naturally expressed in E.coli, a commensal organism, and are
widely used in vectors intended for gene-therapy applications. The only known function of tetR is to bind to tetO and
control transcription, thus there is no evidence that expression of tetR would have deleterious consequences. In
existing programs of work we have permission to express a wide variety of genes from other species (e.g. GFP,
mCherry) including bacteria (e.g. LacZ, gpt) from CMV. The risk of these new viruses is, under the absolute worst
case scenario (accidental infection of a worker with a virus in which the tet-control fails) identical to the risk of those
previous constructs.

In the second section of this project, cancer antigens will be inserted into the vectors. This will only be done once the
tet-regulated viruses have been evaluated in vivo, and demonstrated to be replication deficient. 5T4 is an oncofetal
antigen, overexpression can disrupt cell1-cell contacts and increase cellular motility. No functions associated with
expression of gp100 and melanA have been reported. All humans tested have a natural CTL response against these proteins, although this response dissipates during cancer. A human trial using a 5T4 expressing modified vaccinia ankara (MVA) vector is currently underway in Cardiff by our collaborators (AGallimore and A Godkin), and other human trials of viral vectors expressing all these proteins were all well tolerated. Given that these antigens have all been well tolerated in human trials already, there is little risk from expressing them in well characterised, replication deficient HCMV vectors. The highest risk antigen is 5T4, since there is a theoretical risk that accidental inoculation of a pregnant worker with a 5T4 expressing vector could induce immunity to 5T4 expressed on the fetus. As mentioned above, this is unlikely to cause problems since all humans have a pre-existing immune response to 5T4 anyway. However to mitigate against any potential risks, as with the 5T4 MVA vector that our collaborators (A.Gallimore and A.Godkin) already have permission to use, pregnant workers will be given the option of avoiding working in a lab where the 5T4 vector is being used. This rule is already in place, since we work with HCMV, and pregnant workers are already given the option of working in different laboratories when HCMV is being used. Once expression of the antigen has been verified, the ability of these vectors to induce a specific immune response in vitro, in humanised mice, and in murine models of cancer will be determined, as will the ability of these immune responses to protect against tumour development, and to prevent metastasis.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

NA

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

The virus will only ever be used at containment level 2.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

CMV is completely killed by 70% ethanol, hypochlorite and autoclaving. Tissue culture flasks are autoclaved, then incinerated. All other plasticware such as pipette tips, pipettes and storage tubes, are soaked overnight in hypochlorite then autoclaved before being incinerated. All surfaces in the class 2 hood are wiped down before and after use with 70% ethanol. These methods are validated by culture.

Whilst handling virus or virus-infected mice in the animal facility, staff will wear two pairs of gloves, disposing of the outside pair once finishing handling vectors infected mice/tissue. All work (including dissections) will be performed in a Class 2 Microbiological Safety Cabinet and mice will be kept in scantainers. These procedures are currently performed routinely and have successfully contained MCMV - as shown by the absence of infection in naive mice housed in adjacent cages to infected mice.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
Sub Section 1 - Risk Assessment GM130/681 has been reviewed by the Committee on several occasions with alterations/additions being made at each stage until the Committee felt that the project had been adequately risk assessed. The Committee agreed with the activity classification and the containment level required.

Sub Section 2 - The Committee reviewed the CU2 form for the connected programme of work and the worst case scenario/summary risk assessment within. The Committee are in agreement with the anticipated activity class and containment level required, however permission will not be given for the work to go ahead until the Committee has reviewed a detailed risk assessment for this work. The Committee also expects that if, during the course of the work, evidence arises pointing to risk levels going beyond what can be contained in Level 2 facilities, that they will be notified by the Principal Investigator and work will be stopped immediately. The Risk Assessment would then be updated and reviewed by the Committee to discuss the class of the activity and the containment measures required. Advice would be sought from the HSE as to whether or not a notification of significant change would be required.

Date of Significant Change
**Project Additional Information**

**Purposes of the contained use**

There are 2 overall aims of this project:

1. **Activity Notification**
   - To generate a recombinant, glycoprotein deleted rabies viral vector pseudotyped for the avian EnvA protein, limiting infectivity to cells expressing the TVA receptor.
   - Using this recombinant vector, trace the pattern connectivity and circuit integration of iPSe derived neurons in vitro.

Recombinant rabies viruses and their wild-type counterparts are highly effective at infecting and traversing mammalian 'nervous systems, spreading transynaptically without generating cytopathology or invading surrounding unconnected cells. These features make them an ideal choice for the study of neuronal systems and structures both in vivo and invitro.

**Recipient or parental organism**

The lentiviral vector, pSIN4 come in attenuated E.coli strains Stbl3, HEK293T cells will be used to package these vectors into virus, and the viruses will be used to transduce human fibroblasts. Replication deficient / Attenuated Rabies viral vector will be purchased from a commercial source (e.g., Addgene.org, a non-profit global plasmid repository). The virus will be used to transduce human keratinocytes and potentially other somatic cell types of human origin.

**Host/vector system**

1. **Host = E coli: Stbl3**
   - Host for viral packaging: HEK293T or hiPSe derived neurons
   - Using Lentiviral Vector plasmids = pSIN lentiviral expression vector pBOB-syn-HT (Addgene ID 30456) and pBOB-synP-HT (Addgene ID 30195)

**Origin & function**

2. **Host = HEK293T or BHK-EnvA cells for use with Recombinant Rabies Vectors**
   - pSAO~G-F3 (Addgene, 10 no. 32634)
   - pcONA-SAOB19N (Addgene, 10 no. 32630)
   - pcONA-SAOB19P (Addgene, 10 no. 32631)
   - pcONA-SAOB19L (Addgene, 10 no. 32632)
   - pcONA-SAOB19G (Addgene, 10 no. 32633)

**Health and Safety**

**Executive**

The morbidity of wild type Rabies virus is due to its ability to spread from the site of infection. However, the recombinant Rabies virus is incapable of spreading from the site of infection due to the genomic deletion of the gene encoding for the viral Glycoprotein.

**Activity**

**Evaluation of foreseeable effects**

Viral Vectors are disabled

Lentivirus:
Lentiviral Expression System allows creation of a replication-incompetent, HIV-1-based lentivirus that is used to deliver and express our gene of interest in either dividing or non-dividing mammalian cells. The plasmid is pSin. It is a self-inactivating virus, with the packing genes located on three separate plasmids. Lentivirus is the more hazardous virus used in this protocol compared to Recombinant Rabies virus, but there are no foreseeable effects.

Recombinant Rabies Virus:
This Rec. Rabies system allows for the generation of viral particles able to infect but not replicate in target mammalian neuronal cell systems due to deletion of the native glycoprotein gene (G). This is also non-transmittable, as the vector in this case has the glycoprotein (G) deleted, rendering the virus incapable of producing infectious particles from infected cells without host expression of the G protein for pseudotyping.

Using this strategy due to its neuronal tropism, pseudotyped rabies virus vectors can be used to study neuronal trafficking or express endogenous genes efficiently in neurons. Lentivirus has one colour i.e. GFP in its plasmid for visualising and the Rabies has another colour i.e. RFP so the initial cell can be identified and the subsequent synapse.

Worst case scenario you may be exposed but it can\'t infect & replicate in normal human tissue due to the pseudotyping, so again no foreseeable effects.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Disinfection is achieved using Virkon (peroxygen compound). A 1% Virkon solution is expected to kill 100% in 10min. All liquid waste will be collected and treated with a combination of autoclaving and disinfection methods. Pipette tips will be discarded directly into sharpsafe container, autoclaved, then disposed as clinical waste. Plastic pipettes and other solid waste will be soaked in Virkon overnight then autoclaved. All work surfaces will be treated and wiped down with Virkon.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The Cardiff University Genetic Modification and Biological Agents Safety Committee agreed with the classification of the activity as Class 2. They did, however, have a number of queries concerning the local risk assessment. These queries have now been answered to the satisfaction of the Committee.
The aim of this project is to increase our understanding of the contributions of specific, anatomically defined pathways in the brain that underlie various forms of learning and memory. The genes that are under study will not encode a product that could act directly to cause harmful effects (e.g. toxin gene or an oncogene), nor will they encode a product that may enable the micro-organism with enhanced pathogenic properties. Viral vectors will be used to genetically manipulate neuronal activity in discrete brain regions and in specific populations of neurons in rodents. These tools provide a wealth of opportunities for investigating the neurophysiology of a variety of learning and memory processes by allowing temporally restricted up or down regulation of neuronal activity and
Recipient or parental organism

Recipient organisms will be rats or mice.

Host/vector system

**EIAV-based lentiviral vectors:**
Self-inactivating lentiviral vectors will be used. Viral vector particles based on the equine infectious anaemia virus (EIAV). The replication competent wild type EIAV can only infect horse cells. The vectors proposed for use here will be generated by a three plasmid co-transfection system (of HEK293T cells) in which separate plasmids expressing gag/pol, envelope and genome are used as a mixed DNA preparation. These minimal plasmids have little or no common sequences therefore the probability of recombination between plasmids and production of replication competent virus is very low. The vectors are pseudotyped with a rabies-G glycoprotein making them neurotropic and allowing retrograde neuronal transport. The pseudotyped vector is self-inactivating and is extremely unlikely to recombine in a patient with HIV, i.e. the probability of the production of replication competent vectors is very small. Once injected into the rodent, the viral particles cannot re-infect any other tissues as: (i) the coat protein is lost following attachment and the DNA is incorporated into the host cell replication deficient; (ii) they are replication deficient. Hence, lentiviral vectors cannot re-infect once injected into the brain. Lentiviral vectors are enveloped RNA viruses that are relatively unstable, highly susceptible to dehydration and rapidly inactivated outside the host. Lentivirus particles have, thus, a short half-life and are unstable at room temperature.

**rAAV vectors:**
Recombinant Adenoviral associated virus (rAAV) are derived from wild type Adenovirus-Associated Viruses (wtAAV) which are non-pathogenic, non-replicative viruses which infect both humans and animals. rAAV lack wtAAV viral protein coding sequences. rAAV vectors are based on rAAV viruses which are non-pathogenic in humans and the vectors themselves are not known to cause any diseases in humans or animals. Although wild type AAV can enter mammalian cells in the presence of adenovirus and their genomes integrate into host cell DNA, AAV vector genomes remain primarily episomal in target cells and have a low (if any) frequency of integration.

In both of the above cases, the viral particles will be received from either Bristol or a recognised commercial source (e.g., UNC Vector Core), consequently in-house cell lines and cultures will not be required.

Origin & function

The scientific goals will be achieved by transducing neurons in the rat/mouse brain with viral vectors containing one or more of the following types of inserts:

a) lacZ
b) DREADDs (designer receptors exclusively activated by designer drugs)
c) A fluorescent protein such as green fluorescent protein (GFP) to tag cells.
d) A channelrhodopsin

a) LacZ is a bacterial gene derived from Escherichia coli and codes for 3-galactosidase, an enzyme, which catalyzes the hydrolysis of 3-galactosides into monosaccharides. Typically it is used to cleave x-gal and the subsequent blue colour produced is used as a reporter of activity and of cellular localization. The viral vectors can be injected into a particular brain region in normal wild-type rats. The particles are retrogradely transported and so accumulate in the brain regions that project directly to the injection site, where the transgene, lacZ is expressed. Subsequent infusion of the commercially available prodrug, Daun02, transiently inactivates just this population of neurons. This occurs as the LacZ gene, codes for ~galactosidase which catalyses the hydrolysis of Daun02 to
Daunorubicin which subsequently inactivates those cells, i.e., creates a temporary, highly selective lesion. It is then possible to behaviourally assess the impact of these inactivation taking advantage of a within-subject design. b) DREADDS are G-protein coupled receptors (GPCR) engineered to respond exclusively to synthetic small molecule ligands, rather than their natural ligand(s). DREADD constructs are typically delivered via a recombinant adeno-associated virus (rAAV) vector and are activated by systemic administration of a prodrug, such as clozapine N-oxide (CNO), enabling the precise spatiotemporal control of GPCR signalling in vivo (Urban & Roth, 2015). For the purposes of the current project a combination of DREADD constructs which, upon activation, act to either enhance or reduce neuronal firing will be used to explore the involvement of particular brain regions and/or neuronal populations in various forms of learning and memory (for an example of a similar approach see Robinson et al., 2014). c) GFP is a non-toxic protein composed of 238 amino acid residues (26.9kDa) that exhibits bright green fluorescence when exposed to light in the blue to ultraviolet range. GFP traditionally refers to the protein first isolated from the jellyfish Aequorea victoria, which has a major excitation peak at a wavelength of 395 nm and a minor one at 480 nm. Its emission peak is at 509 nm, which is in the lower green portion of the visible spectrum. It is used as a means of tagging cells that have been transduced. d) Channelrhodopsins (ChR) are a subfamily of retinylidene proteins (rhodopsins) that function as light-gated ion channels found in certain algae, e.g. chlamydomonas. ChRs can be readily expressed in neurons via either lentiviral or rAAV transduction. Upon integration into the cell membrane of neurons the activity of transduced neurons can then be modulated by photostimulation in order to investigate their role within the neural network Circuitry underlying various types of learning and memory.

None of the proteins listed above have any physiological, pathological and/or pharmacological effect beyond the small number of neurons in which they are expressed. The inserts do not encode a product that could act directly to cause harmful effects (e.g. toxin gene or an oncogene). In addition, none of the proteins are secreted from eukaryotic cells and, therefore, transgene expression will be limited to discrete regions of brain tissue directly infected through injection.

Evaluation of foreseeable effects

Viral vectors could be transmitted to humans via; exposure to mucous membranes of the eyes, nose and mouth, or needle stick injury. When carrying out surgery to inject the viral particles into rodent brains the anaesthetised animals will be injected directly with a stereotaxically mounted needle, therefore needle handling is minimal and the risk of needle stick injury low. Further, the the Hamilton syringes that we use have blunt bevelled ends, making it difficult (but not impossible) to suffer a needlestick injury. A needle stick injury with a Lentiviral vector (EIAV) pseudotyped with a rabies coat protein allows transfection of most dividing and non-dividing cell types. Direct injection as a result of a needle stick injury may lead to transmission of virus to human cells, however, the minute volumes of virus that will be used in rodent experiments means the likelihood of achieving an infective dose for humans through a needle stick injury is effectively zero. The non-replicative nature of the viral vectors to be used means that any virus infection via a needle stick injury will be localised to the immediate penetration site; this would be a T-cell mediated response to the presentation of a foreign protein. rAAV vectors are based on rAAV viruses which are nonpathogenic in humans and the vectors themselves are not known to cause any diseases in humans or animals As the volumes used for infections are small <5(.11) and all handling, aside from surgeries, will be carried out in a Class II MSC, it is extremely unlikely that a worker could infect himself or herself with a viral vector. Syringes for injection will be loaded in the Class 2 hoods and then transported to the surgery suite in a sealed container lined with absorbent paper to minimize the risk of virus leaking from the syringe. Leakage is very unlikely due to the micron sized tip, which would require sufficient pressure from the syringe plunger to dispel liquid. Additionally, the surgery suite is in the adjacent room to the viral suite, with direct access between these two rooms and no need to
go out into the general corridor. Some techniques may generate aerosols (pipetting of aliquots and centrifugation) but this will all be carried out in a Class II MSC. It's worth noting that centrifugation will not be carried out to concentrate the viral particles, only to ensure all of the aliquoted volume is at the bottom of the Eppendorf tube.

Direct injection into the brain with recombinant virus during experiments means the likelihood of transmission to another animal in the animal housing unit is extremely low as the virus cannot cross the blood brain barrier and the vectors are non-replicative. The only risk of transmission through the oral/faecal route would be as a result of systemic infection, which will not occur.

A potential risk for lentiviral expression concerns release into a human population already infected with HIV, allowing for potential recombination events that would incorporate the inserted sequence into a viable, replication competent virus. This scenario is extremely unlikely, and would in any case be unlikely to cause any additional problem. Sequences within the viruses cannot be transferred to other micro-organisms without a very rare recombination event. Thus, we see no conceivable hazard associated with transfer of the expressed sequences. As mentioned above, EIAV is an enveloped RNA virus that is relatively unstable, highly susceptible to dehydration and rapidly inactivated outside the host. These particles have a short half-life and are unstable at room temperature. Therefore, the survivability of the lentiviral vectors is not thought to pose a risk to the environment. rAAV V contains no virulence factors. As the viral systems used are self-inactivating and non-replicative, it is extremely unlikely that accidental release into the environment will cause any environmental damage or risk to others.

Our experiments do not require systemic infection and animals will be injected with virus directly into the brain only. The dose of virus required to transduce brain cells via direct injection is 1000 fold lower than the dose required for systemic infection, so even in the unlikely event that a viral injection reached the systemic circulation, a systemic 'infection' is unlikely to occur. Injections will be targeted to the brain and studies report rAAV serotype 2 does not efficiently cross the blood brain barrier, therefore systemic infection is not perceived as a significant risk. Workers performing the surgical and behavioural tests are required to follow agreed procedures for the handling of animals to reduce the risk from allergens and bites, including the use of appropriate protective clothing and face masks, but there are no extra risks associated with the fact that the animal has undergone the procedures detailed. All workers using animals are required to attend an in-house animal handling course prior to starting work and are then closely supervised by experienced post-doctoral workers and group leaders until competent in all procedures. All in vivo work is carried out with the appropriate licences and permissions from UK regulatory authorities. The animals containing the genetically modified material are healthy and possess no risk to human health. Rodents are likely to survive if released from containment. However, the rodents are housed in secure cages within a secure facility and, therefore, the risk of accidental release into the environment is very low. The inability of the lentiviral vector to propagate in mammalian cells also reduces the risk. Also, as detailed above, lentiviral vectors are enveloped RNA viruses that are relatively unstable; highly susceptible to dehydration and rapidly inactivated outside the host. Lentivirus particles have, thus, a short half-life and are unstable at room temperature. Therefore, the survivability of the lentiviral vectors is not thought to pose a risk to the environment. Other than injection into the intended rodent host, no other organism is likely to be infected with the virus as vectors will be directly injected into the brain only in the designated viral surgery suite. Once introduced into an animals, the viral particles are no longer infective. Expression from the transgenes persist in the animal over a long period of time (more than a year).

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid virus waste will be treated with 4% Virkon (generic chemical name: potassium peroxymonosulphate, sodium dodecylbenzenesulfonate, sulphamic acid; and inorganic buffers) or 10% chlorine bleach, destroying any naked nucleic acids. Solid waste will be autoclaved. Expected degree of kill 100% Following completion of the behavioural experiments, rats required for neuroanatomical studies will be perfused with 4% paraformaldehyde fixative, thereby inactivating any viral particles. Brain slices from fixed tissue will be prepared and analysed by histological techniques. Animal carcasses will be disposed of in designated clinical waste and incinerated.

Date Project 02/03/2022
Wildtype and thermostable Fluc derivatives will be cloned into a pCCl lentiviral vector fused to enhanced blue fluorescent protein 2 (EBFP2) via double serine-glycine linkers. Expression and properties will be tested by transfection of HEK293 cells, e.g. relative light yields at 250°C and 37°C, kinetics and bioluminescence spectra will be measured using the PhotonMAGER Optima (PIO) small animal optical imager (Biospace labs, Paris France). This is a kinetic and multi-wavelength imager designed for imaging up to 5 mice at a time. Subsequently, high titre virus will be produced in HEK cells by triple transfection of pCCl encoding transgenes along with gag pol and env encoding packaging plasmids. Virus titres will be assessed by transduction of HEKs with different amounts of virus and subsequent FACS of EBFP2. Different types of cell lines (e.g. HEK, Raji, Jurkat, mouse cell lines and primary cells and primary human neural stem cells) will be transduced, sorted for equivalent expression levels (by EBFP2 fluorescence) to generate stable cell lines for further study. The HEK cells provide a xenograft model for superficial imaging in mice and the Raji cells (when injected intravenously) provide a systemic lymphoma model in which the effects of blood attenuation on reporter systems can be ascertained. Transduced cell lines will be cryopreserved in small banks of 18 aliquots (each of 3-5 x 10^11 cells) prior to larger scale testing using phantoms (150mm square petri dishes containing agarose or gelatine impregnated with intralipid and/ or blood to mimic mammalian tissue scattering and absorption) and in mice. The native colour of bioluminescence of the firefly system is heavily absorbed by blood within mammals making detection and quantification of deeper signals more problematic. However, synthetic bioluminescence with redshifted analogues and engineered enzymes has the potential to overcome problems associated with blood absorption and with the novel analogue infraluciferin, there is potential to develop deep tissue dual parameter bioluminescence systems.

Vectors prepared from E.coli DH5α and BL21 DE3 plysS (Agilent Technologies, CA, USA) and utilised in recipients: HEK293 (Homo sapiens, ‘embryonic Kidney, ATCC Number: CRI-1573), Jurkat (Homo sapiens, peripheral blood lymphocyte, disease: acute T cell leukemia, ATCC number: TIB-152), Raji (Homo sapiens, tissue: lymphoblast, B lymphocyte, disease: Burkitt's lymphoma, ATCC number: CCI-86), Chinese hamster ovary (CHO- U.S. Patent Number 7,429,644) cells and also primary mouse splenocytes and primary human stem cells. Since the transgenes cause no effects besides luminescence, the risk that modified cell lines pose to Human health and the environment is low.
pCL-Fluc-EBFP2 or pCCL.GFP controls.

## Origin & function

pCL is a third generation lentiviral expression vector to allow the transfer and expression of genes in human cells and contains the hPGK promoter. This vector has a number of biosafety features (Dull et al., 1988, J. Virol. 72: 8463) and can be used to produce lentivirus after triple transfection of cells with additional packing plasmids (it also self-inactivates upon integration into host genomes). The vector backbone was kindly obtained from Dr. Riccardo Brambilla (Cardiff, UK). It is pure plasmid DNA and not live virus. The virus is derived from HIV-1 (lentiviridae) but has been ‘attenuated as described above. They exist as ssRNA and are retrotranscribed to dsDNA in host cells for subsequent integration. It is replication defective and in this work will contain no effector genes, merely reporters.

Inserted sequences: Genes derived from organisms and engineered to act as novel reporter genes: The firefly luciferase gene is originally from Photinus pyralis and contains mutations which improve its properties. Another gene is derived from the coleopteran Pyrophorus plagiopothalamus, known as ‘click beetle red luciferase’. Lastly, enhanced blue fluorescent protein 2 (EBFP2) is an engineered blue fluorescent protein.

## Evaluation of foreseeable effects

There are two major risk factors with using lentiviral (LV) delivery systems: first, the generation of replication competent infective virus and the second the chance of oncogenesis through the random chromosomal insertion of virus in a host genome. Both these risks are heavily mitigated when using third generation self-inactivating vectors such as pCL. The SIN element is caused by a 133 base pair deletion in the U3 region of the 3' TR which transcriptionally inactivates the virus after reverse transcription and chromosomal integration in cells (Miyoshi et al., 1998. Am. Soc. Microbiol. 72: 8150). Furthermore, this vector is not replication competent, i.e. does not contain gag, pol, rev or env genes for viral replication. Gagpol and env are provided on separate helper plasmids for the construction of virus (conditional packaging) (Dull et al., 1998. Am. Soc. Microbiol. 72: 8463). Other deleted genes are vpr, vif, vpu and nef and tat. To mitigate against the second risk (infection and chromosomal integration causing oncogenesis in subjects): firstly, the risks of this occurring are very low (normal immune competent individuals are unlikely to become infected). Secondly, the conditions of virus generation and manipulation are extremely well controlled and no human or animal subjects will be exposed live virus particles in this work. Immunocompromised individuals will not be permitted to work on this project. VSV-g pseudotyped virus will be used to generate stable cell lines for in vitro studies and implantation into mice. Lastly, the risk of oncogenesis depends on the transgene inserted into the vector and in this work no genes other than bioluminescence and fluorescence reporters will be inserted into vectors (and thus subsequently cell lines or mice). This further reduces the risks associated with routine IV vector use in biomedical studies. The effects of the bioluminescence and fluorescence genes are to express proteins which have the function of adenylation of fatty acids and the generation of bioluminescence with the addition of firefly luciferin, and, fluorescence, respectively. Outside of this, these genes have no other known functions. In case of accident, the routes of transmission are known and hazards associated with potential delivery of the virus or its products to tissues where it may be biologically active have been fully considered. Sharps - the use of sharps and administration of luciferin to image mice (given intraperitoneally) has the potential to cause a needlestick injury. In the unlikely event of a needlestick wound, the normal methods for treating the wound will be followed (wound disinfected and cleaned) with the addition of notification to the school health and safety representatives. The risk of needle stick injury will be reduced, by unsheathing needles only at the time of use and also not re-sheathing needles after they have been used. Lastly, needles will be disposed of by placing them into a sharps box immediately after they have been used. Needlestick injuries will be referred to the UHW occupational health (1st floor, Denbigh House in work hours, or the accident and emergency department UHW outside of work hours. Inhalation - opening a vial or spillage of the virus could cause an aerosol of viral particles. Therefore the virus will always be contained within a class II cabinet. If there
is a failure of personal protective equipment, such as gloves, the viral vector could be transmitted through contact with
the skin, transmission into the blood stream or to airways and eyes. These risks will be minimised following the
standard operating procedure of the tissue culture lab. Transmission through the mouse host will not occur as there is
no viral replication and therefore no excretion of the viral product. Adherence to all standard operating procedures of
the facility will ensure no transmission outside of the animal facility (surgery rooms).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Sharps will be placed in clinical, sealable waste sharps bins for autoclaving and disposal.
Liquid waste will be disinfected with generic chemical Virkon which contains a blend of inorganic peroxygen
compound, inorganic salts, organic acid and anionic detergent (pentapotassium •
bis(peroxymonosulphate)bis(sulphate), sulphamidic acid, sodim dodecylbenzenesulfonate. dipotassium
peroxodisuphate), which is expected to kill: 100% of microorganisms in 10 minutes with a 1% solution (validated:
Virucidal efficacy data from Dupont). It has proven highly effective over 65 strains of virus in over 19 viral families,
including the lentivirus HIV.
Solid waste to be autoclaved on site through our in-house waste management facility.
The virus is replication incompetent and the small titres (1..11 volumes) of virus infected cells implanted in mice will have
no risk of virus excretion in the urine or faeces. Animal carcasses and waste will be treated as GM waste and sent
through the appropriate school of Biosciences GM waste route regulated within JBIOS where animal carcases will be
sent for incineration.

02/03/2022
Project Ref 130/17.3

Investigating circuit integration of adult born neurons in mouse neuropsychiatric disease models using modified retrovirus and rabies virus for labelling and monosynaptic tracing.

This project has five aims:
1) To generate a retrovirus (Moloney murine leukaemia virus, MMLV) expressing the avian viral receptor (TVA), rabies glycoprotein (Rgp) and green fluorescent protein (GFP) under control of the neuron specific synapsin promoter (RVSYN-GTRgp).
2) To inject modified MMLV into the dentate gyrus of mice to highly specifically label adult born dentate gyrus granule neurons to assess their structural and functional developmental trajectory.
3) To generate a rabies virus pseudotyped for the avian EnvA protein in which Rgp is replaced by the fluorescent protein mCherry (EnvA-OG-MCh).
4) To inject rabies virus into a) the dentate gyrus of mice in combination with MMLV to trace development of synaptic connectivity and circuit integration in animal models of neuropsychiatric diseases, or to b) use viral vectors in organotypic hippocampal slice cultures with the same aims
5) To characterise the electrophysiological properties of labelled neurons (both MMLV and rabies virus) in ex vivo brain slices and slice cultures at differing developmental stages.
Replication deficient Moloney murine leukemia virus (MMLV, retrovirus) and/or replication deficient rabies virus will be injected into mice/rats to label specific cell types in the brain and to trace synaptic connections in neuronal circuits in order to investigate circuit dysfunction in neuropsychiatric disease.

MMLV will be produced using the human embryonic kidney cell (HEK293T) line and rabies viruses will be produced using the B7GG (BHK-21, baby hamster kidney fibroblast cell line).

Rabies viruses will be pseudotyped with the avian retrovirus envelope protein (EnvA) using the BHK-EnvA cell line.

Host/vector system

**Recipient or parental organism**

Replication deficient Moloney murine leukemia virus (MMLV, retrovirus) and/or replication deficient rabies virus will be injected into mice/rats to label specific cell types in the brain and to trace synaptic connections in neuronal circuits in order to investigate circuit dysfunction in neuropsychiatric disease.

MMLV will be produced using the human embryonic kidney cell (HEK293T) line and rabies viruses will be produced using the B7GG (BHK-21, baby hamster kidney fibroblast cell line).

Rabies viruses will be pseudotyped with the avian retrovirus envelope protein (EnvA) using the BHK-EnvA cell line.

**Host/vector system**

- **Host:** mouse/rat
- **Vector:** RV-SYN-GTRgp or RV-CAG-GFP MMLV virus and/or EnvA-deltaG-MCh rabies virus
- **Host:** HEK293K cells
- **Vector:** pSYN-GTRgp or pCAG-GFP (The Salk Institute), pBS-CMV-gagpol (Addgene #35614), pCMV-VSV-G (Addgene #8454)
- **Host:** B7GG (BHK-21) cells
- **Vector:** pSAD-deltaG-MCh (Addgene #32636), pcDNA-SADB19G (Addgene #32633), pcDNA-SADB19P (Addgene #32631), pcDNA-SADB19N (Addgene #32630), pcDNA-SADB19L (Addgene #32632)
- **Host:** BHK-EnvA cells
- **Vector:** deltaG-MCh rabies virus

**Origin & function**

The recombinant MMLV viruses used are:

- **Health and Safety Executive**
- **RV-SYN-GTRgp:** This virus contains genes from the retrovirus genome, green fluorescent protein (GFP) from the jellyfish *Aequorea Victoria*, the avian tumor virus receptor A (TVA) and the rabies virus glycoprotein (Rgp).
- **RV-CAG-GFP:** This virus contains genes from the retrovirus genome and the green fluorescent protein (GFP) from the jellyfish *Aequorea Victoria*.

The recombinant rabies viruses used are:

- **EnvA-deltaG-MCh:** This virus contains genes from the rabies virus genome and the red fluorescent protein mCherry from the mushroom coral *Discosoma sp.*
- **Moloney murine leukemia virus (MMLV)**
- **HEK293T cells** will be used to package recombinant DNA plasmids into virus particles and these will be used to infect cells in the rat/mouse brain (as described above).

The plasmids used for MMLV are:

- **Transfer plasmids:**
  1. **pSYN-GTRgp** (from Prof. Fred Gage, The Salk Institute, USA): a combination of green fluorescent protein (GFP), avian viral receptor TVA, rabies virus glycoprotein (Rgp). These are expressed as one transcript, linked by self-cleavable peptides, under the control of the synapsin promoter. The nuclear targeted GFP serves to identify and track infected cells, TVA allows for infected cells to subsequently be infected with rabies virus for retrograde tracing, and Rgp allows for production of rabies virus only in cells infected with this retrovirus.
  2. **pCAG-GFP** (from the Salk Institute Vector Core, The Salk Institute, USA): enhanced Green Fluorescent Protein (eGFP), under control of the CAG promoter. This will identify any dividing cells in the infected tissue, and highlight...
their morphology.

Packaging plasmid:
3) pBS-CMV-gagpol (from Addgene #35614): contains genes for the retroviral structural proteins Gag and Pol.

Envelope plasmid:
4) pCMV-VSV-G (from Addgene #8454): contains the gene for the envelope protein VSV-G from the vesicular stomatitis Indiana virus.

Rabies virus B7GG (BH K-21) cells will be used to package recombinant DNA plasmids into virus particles and these will be used to infect cells in the rat/mouse brain (as described above).

The plasmids used for Rabies virus are:
Transfer plasmid:
1) pSAD-deltaG-MCh (from Addgene #32636): The transfer plasmid contains genes from the rabies virus genome and the red fluorescent reporter mCherry gene (originally from the mushroom coral Discosoma sp.).

Packaging plasmids:
2) pcDNA-SADB19G (Addgene #32633), pcDNA-SADB19P (Addgene #32631), pcDNA-SADB19N (Addgene #32630), pcDNA-SADB19L (Addgene #32632): contain genes from the rabies virus genome.

Rabies viruses will be pseudotyped to express the avian retrovirus envelope protein (EnvA) using the BHK-EnvA cell line.

Evaluation of foreseeable effects

MMLV:
MMLV is a group VI, positive sense, single-stranded RNA (ssRNA), lipid encapsulated retrovirus from the genus gammaretrovirus. MMLV is capable of inserting into the host genome at random locations, and infection is therefore potentially oncogenic. Infection can only take place in dividing cells. Systemic infection of MMLV is normally largely asymptomatic in mammalian hosts.

The MMLV retrovirus to be used is replication deficient. In the viral production procedure the genes required to produce virions are separated onto three different plasmids namely the transfer, packaging and envelope plasmid ids. The transfer plasmid which contains the genetic information to be inserted into the infected host cell lacks the necessary genes to produce infectious virus particles. It is, therefore, a self-inactivating virus. The virus is pseudotyped with the VSV-G protein making it possible for it to infect a variety of mammalian cell types including human cells. However, due to the replication incompetent nature of the viral vector, only cells directly exposed to viral particles will be infected and further systemic infection is impossible.

Recombinant rabies virus:
Rabies Virus belongs to the order Mononegavirales, family Rhabdoviridae and genus Lyssavirus characterised by having negative stranded RNA genomes and specialising in the infection of mammalian neuronal systems. The virus is often transmitted via bites from infected animals (often hosted in bats and transmitted to domesticated pets) the pathogen will then infect peripheral nerve terminals at the site of the bite and travel throughout the central nervous system of the infected host by retrograde (post synaptic to presynaptic) infection of connected active synapses. Both wild type and recombinant rabies viruses are well known to neuroscience research. The virus specialises in infecting and spreading throughout the mammalian nervous system whilst leaving infected cell bodies largely intact. This low cytopathology enables researchers to use the vector to trace neurons and map neural connectivity.

The rabies viruses used will be disabled through two mechanisms.
1) The virus to be used in the majority of experiments including all in vivo injections will be pseudotyped with the avian envelope protein EnvA and therefore will only be able to infect cells previously engineered to express the avian viral receptor TVA and not native mammalian/human cells.
2) The virus will be engineered to lack the crucial rabies glycoprotein (Rgp) gene and will therefore be unable to...
produce the Rgp necessary to allow it to infect mammalian cells. During the rabies virus production procedure a rabies virus will be produced in and harvested from B7GG cells and used to infect BHKEvA helper cells to pseudotype the virus for EnvA. This virus will express the Rgp (derived from the helper cells) and therefore present a risk of infection to humans. However, this virus will be replication deficient since the Rgp gene is deleted from the viral genome. The likelihood of infection by this rabies virus is very low as it will be handled in a class 2 biological safety cabinet and with appropriate PPE (lab coat, safety glasses, double gloves).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Contaminated waste will be deactivated locally by chemical disinfection using Distel or Virkon followed by autoclaving prior to disposal via an appropriate route following the steps detailed below. Local deactivation by chemicals and autoclaving prior to collection and disposal by an external company (SRCL) is the preferred disposal route as this is less hazardous and involves smaller volumes.

Preferred local deactivation/disposal pathway:
1) Chemical disinfection by Distel or Virkon.
   Liquid waste (e.g. culture media) will be inactivated with Distel or Virkon® (final concentration 1 %) for at least 1 hour (typically overnight) - according to manufacturer's instructions.
   All solid waste (tissue culture plastics) will be treated with Virkon® for at least 2 hours before autoclaving.
2) Waste placed into autoclave bag.
   Chemically deactivated waste will be placed into autoclave bags and labelled GM 180104.
3) Waste autoclaved locally using the waste cycle at 134°C for 25 mins.
   Solid waste will be autoclaved in the designated autoclave located immediately outside of the viral suite before being placed in a yellow 'Tiger bag' and disposed of as 'offensive waste' (HL 180104).

The autoclave is a Priorclave 60L Benchtop, The machine is serviced annually and a twelve-point thermocouple test is performed annually. Waste material will be inactivated using the waste cycle at 134 degreeC for 25ms ins.
   Waste material will be inactivated using the waste cycle at 134 degreeC for 25ms ins.
   All staff operating the autoclave will have been trained in manual handling and are also trained in appropriate spillage procedure. 1 % Virkon® or Distel is the disinfectant to be used in case of inactivated waste being spilled in or out of the autoclave,
   The operator loads the autoclave and runs the discard cycle (134 degreeC for 25 minutes). The temperature probe is put into the waste to ensure waste in the centre of the bin is inactivated and it monitors every run.
   Once the cycle is complete the load is left to fully cool if possible. On occasion special gloves must be used to prevent burns when taking the load out.
4) Removal and disposal/destruction by SRCL.
   Once cooled, autoclaved waste is placed in yellow 'Tiger bags' and moved to the storage area in Hady Ellis building basement for disposal by SRCL as 'offensive waste' (HL 180104).

Animal waste from GM animals and/or animals injected with GM viruses will be handled using appropriate PPE (gloves and lab coat) and will be double bagged before being placed into a yellow plastic bin (GM180103) and stored in a freezer. Animal waste will be clearly labelled as ‘clinical waste’ containing GM waste. Waste will be disposed of using established local guidelines involving collection and destruction offsite by incineration by SRCL.
For chemical disinfection we will use the following products:

**Product Name: Distel**
- Expected degree of kill: 100%

How validated HLD4 disinfectants are manufactured in the United Kingdom to the highest standards conforming to ISO 9001:2008. HLD4 disinfectants are certified Sporicidal, Mycobactericidal, Virucidal, Fungicidal and Bactericidal under EN protocols. Distel is non-corrosive and non-fragranced. So this is the preferred disinfectant for use in the class II hood.

**Product Name: Virkon**
- Expected degree of kill: 100%

It is sold as tablets or powder which dissolve readily in water. It is intended to be mixed with water to form a 1% to 3% solution (by weight, i.e. 10g to 30g per litre). The pink colour is useful in that it helps gauge the concentration when preparing the Virkon®, and importantly, as the Virkon® ages it discolours, making it obvious when it needs to be replaced. The solution is generally stable for five to seven days. Virkon® has a wide spectrum of activity against viruses, some fungi, and bacteria.

The project risk assessment has been viewed by Cardiff University Genetic Modification and Biological Agents safety committee. The Committee requested some minor modifications to the risk assessment but are now satisfied that the risk assessment is suitable and sufficient. They are in agreement that the Activity is Class 2 requiring Containment level 2 facilities and conditions.

Purposes of the contained use

The specific aims of this project are:
1) To generate recombinant, glycoprotein deleted rabies viruses pseudotyped with the avian EnvA protein.
2) To use these recombinant rabies viruses, in combination with adeno associated viruses (AAVs) expressing the TVA receptor and an optimized rabies glycoprotein, to trace synaptic connectivity in vitro and in vivo.

Recipient or parental organism

Recipient organisms for the virus will be:
- ROSA-tomRITVA ESC line, which expresses the fluorescent protein tdTomato, the rabies G protein and TVA from the ROSA26 locus and can thus be used as the starter population for neuronal tracing in vitro.
- Mouse lines that express Cre recombinase in specific neuronal populations. AAVs that express TVA, mCherry and oG proteins in a Cre-dependent manner will be injected first to generate a population susceptible to be infected by the modified rabies viruses. Modified, self-inactivating rabies virus that expresses the FLP recombinase will be injected 3 weeks later. As our animals will have been bred into a RCE:FRT background, the presynaptic neurons that receive the SiRFLP virus will become green.

Host/vector system

AAVs are defective viruses even in their wild type state. Replication can only be induced by the presence of a helper virus or under conditions of cellular stress, such as genotoxic agents or following UV irradiation. When used as a vector, the whole genome of the virus, except for the inverted terminal repeats, is substituted with genes of interest. Those recombinant viral vectors are not only incapable of replication or spread, but also largely loose the capacity to
integrate into the host's genome. This only happens through a passive mechanism at naturally occurring chromosomal breakpoints for 10% of all double stranded viral genomes. The recombinant rabies system allows for the generation of viral particles that have both restricted infectivity and spreading ability. The rabies virus cannot create any infective viral particles within infected cells due to deletion of the critical viral gene, glycoprotein gene (G). The rabies virus is also pseudotyped with EnvA protein and can only infect cells with the complementary receptor to EnvA (called TVA receptor). Mammalian cells do not natively express TVA receptor. This means that rabies virus cannot infect or spread within mammalian hosts. Hence, there is negligible hazard associated with the recombinant rabies virus if the rabies virus was accidently transmitted to another host (besides the cells in culture/ rodents). In the case of the SiR virus, the hazard is even further reduced, as the destabilised protein N suppresses the viral transcription-replication cycle. Even if the virus was to enter a cell, 2 weeks after infection the viral genome completely dissapears from the infected cell.

Recombinant rabies viruses and their wild-type counterparts are highly effective at infecting and traversing mammalian nervous systems, spreading transynaptically without generating excess cytopathology or invading surrounding unconnected cells. these features make them an ideal choice for the study of neuronal systems and structures both in vivo and in vitro.

All recombinant rabies viral vectors to be used in this project have been designed and tested by other laboratories (Wickersham et al. 2007; Wickersham et al. 2010; Wall et al. 2010; Weible et al. 2010) and have two characteristics: 1) a deletion of the glycoprotein (G) gene, a critical gene for the viral cycle. Viruses that lack the glycoprotein gene cannot spread beyond an initially infected cell. Only if that infected cell can provide the missing viral glycoprotein will the virus be able to spread retrogradely to a presynaptically connected neuron, as the new glycoprotein can be incorporated into the viral particles in a process known as pseudotyping.

2) Pseudotyping with the EnvA envelope protein of the subgroup A avian sarcoma and leukosis virus (AS LV-A). This protein interacts specifically with the TVA receptor, a protein that is found in birds, but not in mammals. In this way, the modified rabies viruses are not only incapable of spreading, but also incapable to infect any mammalian cells that do not display TVA on their surface.

As a result of the alterations explained above, the modified rabies virus can only infect and spread from cells that have been genetically engineered to express TVA and the viral glycoprotein. By labelling both the cells capable of expressing the viral glycoprotein and the recombinant rabies virus with fluorescent tags, we can specifically track the infection of the modified rabies virus from the starter cell to its presynaptic targets, and determine the patterns of connectivity from these specific cells. We will use this strategy to analyse synapse formation in vitro and in vivo.

To study synaptogenesis in vitro, we will use the ROSA-tomRITVA ESC line, which was generated by the Arenkiel lab. It expresses the fluorescent protein tdTomato, the rabies G protein and TVA from the ROSA26 locus and can thus be used as the starter population for neuronal tracing. A mix of ROSA-tomRITVA and other ESC-derived neurons will be infected with the modified recombinant rabies virus and then analysed 3 days later.

For the in vivo analyses, we will first inject AAVs into Cre-expressing mice to generate a population of neurons susceptible to be infected with the modified rabies virus. The AAVs used in this step express TVA, mCherry and oG proteins in a Cre-dependent manner. Therefore, only those neurons that express Cre will become potential starter neurons for presynaptic tracing, allowing us to analyse the presynaptic partners of those specific neurons. The modified, self-inactivating rabies virus that we will inject 3 weeks later expresses the FLP recombinase. As our animals will have been bred into a RCE:FRT background, those presynaptic neurons that receive the SiRFLP virus will become green.
There are no foreseeable detrimental effects regarding the use of the AA V and rabies viruses, beyond the intended experimental results of presynaptic neuronal labeling. The AAV vector is designed to infect mammalian cells in order to deliver the TVA receptor, mCherry and glycoprotein genes necessary for infection of these cells by the recombinant rabies vector. As the AAV will only be carrying this donor plasmid encoding for these genes and not for the viral genes needed for replication, the AAV is replication incompetent. This means the infection of the AAV is contained. In addition, AAVs are not linked to any human diseases, so even in the highly unlikely event that the virus would enter human cells, there is no reason to expect any harm to be caused. The virus is replication incompetent and the genes carried in the recombinant virus are not expected to be detrimental in any way. In addition, expression of the genes in the AAV vector is dependent on the presence of Cre recombinase, so even in the event that the virus would enter a human cell, the genes in the vector would not be expressed. Recombinant AAVs also largely lose the capacity to integrate into the host's genome, so any potential harm due to insertional mutagenesis is also extremely low.

The recombinant rabies vector will be pseudo-typed with the Env-A glycoprotein enabling binding exclusively to a TVA receptor-expressing cell. This means the vector will undergo a single replication cycle only within the neurons that have been genetically engineered to express TVA and rabies glycoprotein. From these neurons the rabies virus can only be transmitted along a single active synapse to a second neuron. After this initial transmission the virus cannot generate any infective particles and is inert because it lacks the glycoprotein gene. The rabies virus doesn't integrate into the host's genome, so there is no risk of insertional mutagenesis. The recombinant rabies virus is also incapable of spreading to neighbouring cells, so the infection would be contained to the very cells infected in the first place. Such an infection would anyway be extremely unlikely, as the pseudotyped virus can only enter cells expressing the avian TVA receptor, and mammalian cells, including human cells, do not express that receptor.

The genes inserted into the vectors (GFP, mCherry, TVA receptor, rabies glycoprotein G and FLP recombinase) are solely included to enable the entry, visualisation and single replication cycle of the recombinant rabies vector within mouse embryonic stem cell derived neurons and the mouse brain.

GFP and mCherry are widely used fluorophores for imaging cells in vitro and in vivo with no hazards associated with their use. The TVA receptor and EnvA proteins are avian in nature and are not known to produce pathology in human tissue. The rabies glycoprotein G has not been associated with pathology in human tissue and in fact has been shown to provide limited protection to rabies infection in murine models. The FLP recombinase has been used in mammalian systems for over 15 years and there is no evidence of any detrimental effects.

**Evaluation of foreseeable effects**

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Live animals are kept in a secure facility and they are killed by schedule one methods before they leave the facility. For the disposal of the animals, the Joint Services’ Biohazard Disposal Route is used, which involves incineration.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Liquid waste (culture media) will be inactivated with Virkon® (final concentration 1 %) for at least 1 hour - according to manufacturer's instructions.

Product Name: Virkon
Generic Chemical Name: Pentapotassium bis(peroxymonosulphate) bis(sulphate) 40 - 55%, Sodium C10-13-alkylbenzenesulphonate 10 - 12%, Malic acid 7 - 10%, Sulphamidic acid 4 - 6%, Sodium toluenesulphonate 1 - 5%, Dipotassium peroxodisulphate <3% and Dipentene <0.25%

Expected degree of kill: 100%

How is this validated? (e.g. is in-house testing carried out, or is there specific data available regarding efficacy against the organisms you are working with).

Explanation: Virkon is sold as tablets or powder which dissolve readily in water. It is intended to be mixed with water to form a 1 % to 3% solution (by weight, i.e. 10g to 30g per litre). The pink colour is useful in that it helps gauge the concentration when preparing the Virkon®, and importantly, as the Virkon® ages it discolours, making it obvious when it needs to be replaced. The solution is generally stable for five to seven days. Virkon® has a wide spectrum of activity against viruses (47 strains/clinical isolates from 35 viruses), some fungi (45 strains/clinical isolates from 17 fungi), and bacteria (300 strains/clinical isolates from 76 bacteria). It has been proven effective against all viral families, including Adenoviridae and Rhabdoviridae (rabies virus).

Solid waste to be autoclaved and/or disposed of as clinical waste.

Equipment that has been in contact with the virus (e.g. tissue culture plates, storage vials, needles) will be autoclaved. Contaminated equipment will be immersed in Virkon for a minimum of 24hr prior to transferring to a container for autoclaving. The tissue culture cabinet and any potentially contaminated area will be disinfected with Distel disinfectant according to an approved protocol. Access to laboratories employed for virus work will be restricted.

Disposal of animal carcases - Carcasses will be contained in a sealed yellow bin bag and kept in the freezer ready for incineration with the other GM waste.

Disposal of animal bedding - the rodents that have received the rabies viral injection into the brain do not shed the recombinant virus. This means animal bedding can be treated in the same manner as other animal waste in the facility.

Health and Safety

Executive

Disposal of animal excrement (faeces and urine) - the rodents that have received the rabies viral injection into the brain do not shed or excrete the recombinant virus. This means animal waste can be treated in the same manner as other animal waste in the facility.

Other control measures to be used:

Gloves and lab-coats will be worn, remembering the standard rule about using the ungloved hand to open doors to prevent contamination by latex or lab-materials.

The virus suite (both in HEB and Bioscience Animal Unit) has specific lab coats and they are not worn outside of this area.

In the event of a spill to clothing (which is unlikely) there is a paper suit in the spill kit available.

In the event of a spillage during transport to the autoclave, the area will be isolated and then promptly cleaned. It is recommended that a boil of disinfectant is to hand to deal with spillages. Distel or Virkon® is the disinfectant to be used.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
The GM safety committee required evidence that Dr. M G had received the appropriate training in the specific techniques described in the risk assessment.

### Project Additional Information

**Purposes of the contained use**

Diarrheal disease is the second leading cause of death in children under five years of age. Multiple microbes may be responsible for these infections, but the majority of diarrheal cases are associated with bacteria called Escherichia.
coli, Salmonella and Shigella. These bacteria can be found in contaminated water and food. After they have been eaten, they colonise the gut, cause inflammation and stop food absorption leading to malnutrition, which can be fatal, especially in children in the poorest countries.

General Scientific purpose:
This form is part of a set of forms related to larger programme (see Appendix-A). The work on each part of the programme will not be allowed to start until the detailed risk assessment for that part has been reviewed by the Committee. Any results indicating there is an increased hazard will lead to experiments being halted with immediate effect. Work will not restart until a 'significant change' has been notified to the HSE and the necessary approval given.

The programme objective is to investigates the cellular and molecular basis of enteric infection by looking at host cell responses to the infection. It will use multiple approaches in order to acquire more specific knowledge on how virulence factors are working during infection. Pathogens used in this project include pathogens that exploit secretion systems and toxins for virulence: Enteropathogenic E. coli (EPEC), non-toxigenic Enterohaemorrhagic E. coli (EHEC), Citrobacter rodentium, Enteroinvasive E. coli (EIEC), Diffusely Adherent E. coli (DAEC), non-typhoid Salmonella and Shigella sonnei. These are all important diarrheagenic pathogens for humans and animals.

1- GM 130/764 - Alteration of the expression of bacterial protein in pathogens
In this section of work our aim is to delete or mutate virulence factors in the pathogenic bacteria to understand their functions. Phenotypes after infection of cultured cells or mice induced by wild type strains or mutant will be compared.

2- GM 130/765 - Bacterial and Eukaryotic proteins cloning and expression in E. coli strains
In this section of work our aim is to clone virulence factors or identified host partner proteins (from GM 130/766) in a different vector and have this vector transformed in E. coli laboratory strains. The plasmids generated will be then used for plasmid production (in order to do transfection (GM 130/767 and GM130/768) or yeast transformation (GM 130/766)), protein production (in order to analyse the biological activities of the proteins in vitro or protein-protein interactions) or for the generation or the complementation of bacterial pathogen mutants (GM 130/764).

3- GM130/766 - Identification of host partner for bacterial protein in yeast
In this section of work our aim is to identify the host target of the bacterial proteins. In order to characterize this interaction, human/mice proteins fused to the DNA-binding domain (BD) or activating domain (AD) of the Gal4 transcription factor will be co-expressed with bacterial protein fused to the BD or AD domain in Saccharomyces cerevisiae. Interaction between the two domains will allow the yeast to grow on a selective media.

4- GM 130/767 - Viral transduction of cell culture lines for virulence factor study
In this section of work our aim is to produce non-replicative virions to transduce cell lines. Plasmids generated previously (GM 130/765) containing the gene of interest will be transfected into packaging cell lines (e.g. 293T cells) to generate VSV-G pseudotyped retrovirus. The non-replicative virion will be harvested and used to transduce cells generating permanent cell lines expressing the gene of interest. Genes of interest will be bacterial effectors, binding partners of the effectors identify previously (GM 130/766), RNA interference targeting pathway playing a role during infection or fluorescent reporter to monitor the activity of transcription factor or protein stability. These cell lines can be infected with bacterial mutant generated in GM 130/764 will be then analysed using various techniques to phenotype them (e.g. Western blot, immunofluorescence).

5- GM130/768 - Protein expression and gene interference in cell culture
In this section of work our aim is to transiently or permanently change gene expression to study their function in vitro. Plasmid generated in GM 130/765 will be transfected in culture cell lines using transfection agents commercially available (e.g. GeneJuice, Lipofectamic). The gene of interest can be either a virulence factor from bacterial pathogens or proteins from the host that have been identified as a partner or involved in the signalling of the virulence factor. Most of this work will reliant on transitory express protein but in some condition permanent cell line could be
generated using selection marker (antibiotics). These cell lines can be infected with bacterial mutant generated in GM 130/764 will be then analysed using various techniques to phenotype them (e.g. Western blot, immunofluorescence).

6- Bacterial pathogen infection in transgenic mice.

In this section of work our aim is to use transgenic mice to study the molecular mechanism required for the infection by bacteria.

Recipient or parental organism

1- GM 130/764 - Alteration of the expression of bacterial protein in AIE pathogens

E. coli/Shigella cause diarrhoea which is sudden, severe, and often bloody. Other symptoms of these infections include fever, loss of appetite and stomach cramping. Symptoms of a serious infection with EHEC may include bruising, blood and bloody urine and a reduced amount of urine. Symptoms usually appear 24 - 72 hours after infection. These symptoms are linked to the expression of the Shiga toxin by these bacteria. Only non-toxigenic strains will be used which eliminates the potential sequel of Haemolytic Uremic Syndrome. No reversion has been reported for these strains in the literature.

All S. sonnei strains are of the same serotype and very closely related (Holt et al, Nature Genetics, 2012) but apparently are becoming less virulent although there is increasing antibiotic resistance. We would not be using the antibiotics recommended for treatment (Azithromycine, Ciprofloxacine and Ofloxacine) in the lab, but would be introducing standard cassettes such as carbenicillin, gentamycin, chloramphenicol, tetracycline, kanamycin and streptomycin resistance. Treatment for mild Shigella infection usually involves just rest and fluids, and the illness resolves on its own without antibiotics. In case of infection during pregnancy, women need to ensure they do not become dehydrated or experience electrolyte imbalances due to diarrhoea from the illness. In patients with acquired immunodeficiency syndrome (AIDS), prolonged, relapsing symptomatic shigellosis and lengthy carrier states have been described despite proper treatment.

Salmonella typhimurium cause watery diarrhoea. Infection is likely to be self-limiting and non-lethal in healthy adults. Antibiotics are required in less than 2 percent of cases. Immunocompromised adults are associated with invasive recurrent bacteraemia and have markedly increased mortality. Salmonellosis during pregnancy may produce severe disease and death of the foetus.

Citrobacter rodentium does not cause infection in humans, it infects mice with a similar infection profile to nontoxigenic E. coli.

All the described bacteria are all transmitted orally. Exposure is easily avoided by good laboratory practices.

2- GM 130/765 - Bacterial and Eukaryotic proteins cloning and expression in E. coli strains

The laboratory E. coli strains are non-pathogenic. The virulence factor by itself will not present any pathogenicity as the bacteria required multi-factor protein to become infectious and provide no risk for the health of humans or animals. These bacteria are classified in Risk Group 1 in biosafety guidelines. Furthermore, they have been designed so that they will not survive long outside laboratory conditions and are neither able to the recombine plasmid or cut the plasmid with endonucleases impairing their abilities to transfer the gene of interest to other bacteria.

3- GM 130/766 - Identification of host partner for bacterial protein in yeast

Saccharomyces cerevisiae commonly known as baker's yeast, is not a pathogen for humans or the environment. The strains used for this study are either auxotrophic for Histidine, Adenine, Leucine and Tryptophan or for Histidine, Leucine, Methionine and Uracil and are unlikely survive in the environment.

4 and 5 - Viral transduction (GM 130/767) and protein expression and gene interference in cell culture (GM 130/768).

Mammalian cell lines sourced from ATCC (e.g. HeLa, A549, Swiss 3T3, COS-7, RAW 264.7, THP-1, HEK 293T, U937, T84, Caco-2). History of cell line screening is provided by ATCC (MSDS and Certificate of Analysis). Manipulation of the cell lines will be done in accordance with the ATCC assigned biosafety level designations. The highest biosafety level designation identified is level 2 for HeLa cells as this cell line contains human papilloma virus
Host/vector system

1. GM 130/764 - Alteration of the expression of bacterial protein in pathogens
   All the vectors used have antibiotic resistances genes however, these antibiotics are not used for the treatment of the diseases associated. These vectors are used worldwide in the laboratory and are considered as safe.
   Bacterial complementation constructs will include pSA10 (high copy number, IPTG inducible expression), pACYC184 (medium copy vector, constitutive expression), pBAD vectors (high copy number, arabinose inducible expression)
   Mutagenesis plasmids include pKD46 (arabinose inducible expression of red recombinase) pACBSR/pAKBSR (arabinose inducible expression of red recombinase and I-SceI endonuclease)

2. GM 130/765 - Bacterial and Eukaryotic proteins cloning and expression in E. coli strains
   All the vectors used have antibiotic resistance genes however, these antibiotics are not used for the treatment of the diseases associated. These vectors are used worldwide in the laboratory and are considered as safe.
   Bacterial complementation constructs will include pSA10 (high copy number, IPTG inducible expression), pACYC184 (medium copy vector, constitutive expression) and commercially developed pBAD vectors (high copy number, arabinose inducible expression)
   Cloning vectors will include commercially available vector pGEM T -Easy or TOPO and pUC 18/19 derivatives
   Protein expression constructs will include commercially developed pACYC Duet (IPTG inducible expression), pET vectors (IPTG inducible expression), pMAL (Arabinose inducible expression) and pGEX (IPTG inducible expression).
   Transfection vectors will include pEGFP, pRK5, pHM6, pCB6, pTRE-Tight-BI and pTRE2-Pur. All these vectors are commercially available.
   Transduction vectors will include pMIX-IP and pRetroX-Tight-Puro. All these vectors are commercially available.
   Yeast expression vectors will include the commercially available vectors pYES2 (Invitrogen), pGBT9, pGAD424, pGBK7, pGADT7 (Clontech)

3. GM 130/766 - Identification of host partner for bacterial protein in yeast
   All the vectors used have antibiotic resistance genes however, these antibiotics are not used for the treatment of the diseases associated. These vectors are used worldwide in the laboratory and are considered as safe.
   Yeast expression vectors will include the commercially available vector pYES2 (Invitrogen), pGBT9, pGAD424, pGBK7, pGADT7 (Clontech)

4. GM 130/767 - Viral transduction of cell culture lines for virulence factor study
   The origin of the virus is the Moloney Murine leukaemia virus. Only 12 to 17% of the WT MMLV genome is encoded in the vector backbone to reduce the chance of viral infection. Plasmids being used all are commercially developed such that they generate replication-defective viruses (e.g. http://www.cellbiolabs.com/retroviral-cloning-and-expressionvectors).
   This is because they lack virulence genes from these viruses and only have a truncated gag, rre and modified long terminal repeats (L TRs), to optimise plasmid packaging and allow gene expression in target cells.
   Packaging will be carried out using separate 2-plasmid systems that supply the packaging proteins Gag + Pol and the VSV-G pseudotyping proteins in trans, to generate the virions that can transduce cell lines and lead to the expression of gene of interest, but, that cannot induce production of new virions.

5. GM 130/768 - Protein expression and gene interference in cell culture
   All the vectors used have antibiotic resistance genes however, these antibiotics are not used for the treatment of the diseases associated. These vectors are used worldwide in the laboratory and are considered as safe. Some of these vectors also have a selective marker for eukaryotic cells (geneticin, hygromycin B, puromycin, or blasticidin).
   Transfection vectors will include pEGFP, pRK5, pHM6, pCB6, pTRE-Tight-BI and pTRE2-Pur. All these vectors are commercially available.
   Transduction vectors will include pMIX-IP and pRetroX-Tight-Puro. All these vectors are commercially available.
### 1- GM 130/764 - Alteration of the expression of bacterial protein in pathogens

Health and Safety

**Executive**

Bacterial effector proteins translocated by bacteria via type III secretion systems (e.g. EPEC EspZ). Type III secretion is an endogenous system that bacteria use to transport bacterial proteins into host cells. Effector proteins have diverse biochemical and physiological functions. Some include kinases (e.g. Salmonella SteC), proteases (e.g. Shigella IpaJ), acetyltransferases (Yersinia YopJ), deubiquitinases (e.g. Salmonella AvrA) and others. Collectively, these proteins affect many different cellular functions including actin dynamics, cellular trafficking, cell signalling, innate sensing and some are cytotoxic upon overexpression in certain cell types (e.g. EPEC EspF). Alone, effectors have a limited effect but collectively they contribute to virulence.

We will also construct mutant strains lacking these genes. These will be anticipated to have lower to equal virulence to wild-type.

In some cases, genes of interest will be expressed in bacteria (with or without a tag). This will be done in bacterial strains already knocked out for these genes, in order to complement the mutation. If there is a virulence defect as a result of the mutation, virulence is expected to go back to wild-type levels. Higher expression using a high copy plasmid can be achieved but are not expecting to impact the virulence as higher expression decrease the efficiency of the secretion system.

### 2- GM 130/765 - Bacterial and Eukaryotic proteins cloning and expression in E. coli strains

Bacterial proteins inserted are virulence factors that are needed for the bacteria to be pathogens, but their biological activities are yet mostly unknown. However, each protein individually does not present any risk of hazard as these proteins cannot be injected into the host by the commercial bacteria as they lack the secretion systems required.

These proteins do not have any biological activity in the bacteria.

The eukaryotic genes inserted have various known or unknown activities. However, none of the proteins are secreted from the bacteria and they do not present any hazard risk.

### 3- GM 130/766 - Identification of host partner for bacterial protein in yeast

Bacterial proteins inserted are virulence factors that are needed for the bacteria to be pathogens, but their biological activities are as yet mostly unknown as their targets are inside the host. However, each protein individually does not present any risk of hazard as these proteins cannot be injected into the host by the commercial yeast as they lack the secretion system required.

The eukaryotic genes inserted have various known or unknown activities. However, none of the proteins are secreted from the yeast and they do not present any hazard risk.

### 4- GM 130/767 - Viral transduction of cell culture lines for virulence factor study

Fluorescence or tagged eukaryotic genes, including point and deletion mutants. Examples are lifeact-mTurquoise, which labels filamentous actin in live cells, and CD63-GFP that is a marker of mature lysosomes.

Reporter genes, such as luciferase or biotin ligase BirA.

Fluorescence or affinity tagged bacterial genes or mutated variants from pathogenic E. coli (e.g. EPEC and EHEC), Shigella, Salmonella spp. which include e.g. espZ. None of the genes is anticipated to create a new hazardous GMM.

Silencing RNA expression gene cassettes, e.g. to downregulate the expression of endogenous eukaryotic genes.

No new GMMs will generate a new hazardous virus or reconstitute the viral vectors.

### 5- GM 130/768 - Protein expression and gene interference in cell culture

Bacterial proteins inserted are virulence factors that are needed for the bacteria to be pathogens, but their biological activities are yet mostly unknown. However, each protein individually does not present any risk of hazard as these proteins cannot be injected into other cells.
The eukaryotic genes inserted have various known or unknown activities. The greatest potential hazard assessed would be the knock down expression of a tumour suppressor function (e.g. p53, Rb or PML). There is no obvious, substantial hazard associated with knock-down expression in a restricted population of cells. Many in vitro cell lines already have defects in tumour suppressor genes and are handled without specific precaution. Should knock down of a tumour suppressor gene occur following in vivo delivery, it is not likely by itself to cause cellular transformation. Additional genetic events would be required.

### Evaluation of foreseeable effects

1- GM 130/764 Alteration of the expression of bacterial protein in pathogens

**HAZARDS ARISING:**

**Health and Safety Executive**

The mutants generated will either be loss of function mutants or carry non-toxic reporter genes. It is not anticipated that bacterial strains, including complemented strains, produced in the laboratory will be more virulent than strains that already exist in the environment even in the case of an increased expression of the specific virulence factor due to a high copy plasmid. Indeed, many strains produced will have deletions in genes, which are required for optimal growth and virulence of the organism. In addition, antibiotic resistance markers (carbenicillin, gentamycin, chloramphenicol, tetracycline, kanamycin and streptomycin markers) used in the laboratory already exist in the host strains found in the environment and hence there is no risk of introducing new resistance genes to environmental strains.

**HARM TO HUMANS OR ANIMALS:**

The WT strain can cause potentially lethal disease in immunocompromised adults or pregnant women. As the source of infection is the ingestion, the risk is easily mitigated by good laboratory practice. EPEC, EHEC, C. rodentium, EIEC, Salmonella spp. and S. sonnei are not pathogens under DEFRA control. EPEC and EHEC can colonized some mammals in the wild. Mutation is very unlikely to revert to WT and should not induce a more severe infection than the WT as we are targeting genes that are required for the infection.

- a. C. rodentium is a mouse restricted pathogen however, wild mice are resistant to the infection.
- b. Salmonella enterica can infect a wide range of animals including dogs and cats. Mutation is very unlikely to revert to WT and should not induce a more severe infection than the WT as we are targeting genes that are required for the infection.
- c. Salmonella bongori colonises cold blooded animals including turtles however, it is not known if these bacteria are associated to any diseases in the environment. As for the other pathogens, mutation is very unlikely to revert and should not induce a more severe infection than the WT.

2- GM 130/765 - Bacterial and Eukaryotic proteins cloning and expression in E. coli strains

**HAZARDS ARISING:**

The virulence factor by itself will not present any pathogenicity as the bacteria required multi-factor protein to become infectious and provide no risk. Antibiotic resistance markers (carbenicillin, gentamycin, chloramphenicol, tetracycline, kanamycin and streptomycin markers) can be used for infection treatment however, the bacteria used have been designed so that they will not survive long outside laboratory conditions.

**HARM TO HUMANS OR ANIMALS:**

These bacteria are classified in Risk Group 1 in biosafety guidelines and not known to induce harm to human or animals.

3- GM 130/766 - Identification of host partner for bacterial protein in yeast

**HAZARDS ARISING:**

Saccharomyces cerevisiae, commonly known as baker's yeast, is not a pathogen for humans or the environment. The expression of the virulence factor or eukaryotic protein will not confer any pathogenicity. Furthermore, the strains used in this study are auxotrophic for some amino acids and cannot survive in the environment.
HARM TO HUMANS OR ANIMALS
These yeasts are classified in Risk Group 1 in biosafety guidelines and not known to induce harm to human and animals

4- GM 130/767 Viral transduction of cell culture lines for virulence factor study
HAZARDS ARISING:
Two main risks raised from the generation of this GMM. The first one is linked to the formation of Replication Competent Retrovirus and the second one is related to gene expressed in the target cells that can be oncogenic or alter the expression of oncogenic genes (p53, Tb, PML). These two risks will be mitigated by controlling the sequence homology between the various components of the vector system and by reducing the risk of exposure by using a Class 2 MSC. No sharps will be used, gloves will be worn and filtered tips will be used for all the manipulations of the virion and the virion-producing cell lines.

HARM TO HUMANS OR ANIMALS:
Recombinant retroviruses (oncoretrovirus) could potentially infect tissues via inhaled aerosols, broken skin, or needle-stick injuries. However, these viruses are defective for replication and no proliferation of the virus should occur. As the virus is defective for replication, it should not impact the host defence mechanism. However, insertional mutagenesis is still a possibility even if a remote one which could lead to alteration of the immune response or could lead to oncogenic.

5- GM 130/768 - Protein expression and gene interference in cell culture
HAZARDS ARISING:
Use of HeLa cells present a risk as these cells have the HPV virus however, the GMM generated does not have a higher risk than the wild type. The HeLa cells will be handled in containment level 2 facilities using good microbiological practise. The greatest potential hazard assessed would be the knock down expression of a tumour suppressor function (e.g. p53, Rb or PML) in a permanent cell line. There is no obvious substantial hazard associated with knock-down expression in a restricted population of cells. Moreover, many in vitro cell lines already have defects in tumour suppressor genes. Should knock down of a tumour suppressor gene occur following in vivo delivery, it is not likely by itself to cause cellular transformation. Additional genetic events would be required. Containment facilities are designed to prevent operator exposure and are appropriate to control this potential hazard.

HARM TO HUMANS OR ANIMALS:
GM cells generated do not have increased risk from existing traits. Viruses pathogenic for humans are one of the most likely biohazards presented by cell cultures.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
For some aspects of the in vivo work, mice may be inoculated with GM bacteria under the permission granted in Home Office project licence (application under submission)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

LIQUID WASTE:
Disinfectant Product Name: VIRKON
Health and Safety Executive
Generic Chemical Name: Oxone (potassium peroxymonosulfate), sodium dodecylbenzenesulfonate, sulfamic acid,
and inorganic buffers
Expected degree of kill: 99.999%
How is this validated? Antec supplies the independent test report. All the bacteria associated with a risk for humans that we are using were tested including Salmonella, E. coli and Shigella.

SOLID WASTE:
Autoclave
Expected degree of kill: 99.999%
How is this validate: Autoclave calibration is assessed every year as part of the normal procedure within the School of Biosciences

**Please enter comments on the GM safety committee on the risk assessment**

The connected programme outlined above was initially submitted to the University Genetic Modification & Biological Agents Safety Committee as two risk assessments. However, due to the number of different approaches being used, the committee advised Dr. Berger that it would make better sense to submit the work as 5 individual risk assessments that comprise the connected programme presented here. There is an additional GM animal form to be submitted to the University GMBA Safety Committee, which will be reviewed locally in due course, which hasn't been included with this notification paperwor.

During the process of separating the initial two risk assessments into the suggested connected programme, the GMBA Safety Committee required Dr. Berger to (1) make clear what work would be undertaken in each aspect of the programme, and (2) provide a clear explanation on how each risk assessment fits into the overall connected programme. This was not clear in the original submission but has subsequently been addressed in each of the individual risk assessment forms and in the appendix depicting the programme (appendix included in the paperwork as part of this notification).

The committee also asked for a number of minor amendments to be made to all of the risk assessments, all of which have been addressed. Typical examples of such amendments would be the reconsideration of the most hazardous GM to be constructed in GM130/764. Initially the link between the use of high copy number plasmids and a potential increase in virulence had not been considered. The committee also asked for confirmation that the plasmid vectors were non-mobilizable.

Project Additional Information

i) Scientific Purpose:
This application covers research aimed at understanding the interaction of the immune system and fungi. We are particularly interested in how the immune system recognises fungi via surface receptors and soluble factors. These studies will involve in vitro studies.
Aims include:
Determining the role of recognition systems in the host response to infection.
Targeting of specific receptors to modulate immune responses.
Examining the role of receptor systems in homeostasis.
Examining the dissemination of infectious organisms within the host.
Examining differences in the host response to different Candida species.

ii) Types of genetically modified microbes to be used:
This application will not involve generation of genetically modified fungi, it is rather an application to cover their use in in vitro and in vivo experimentation.
Various strains of different Candida species including C. albicans, C. tropicalis, C. parapsilosis, C. dubliniensis and C. glabrata will be used and they will be obtained from other institutions throughout the world.
Recipient or parental organism

Candida species including C. albicans, C. glabrata, C. tropicalis, C. parapsilosis, C. dublinensis

Host/vector system

To generate the GM Candida the types of vectors used were specific non-mobilisable C. albicans vectors (low copy replicating and integrating vectors [YPB1, Clp10, Clp20, Clp30]; low copy replicating and integrating vectors for ectopic expression [YPB-ADHpt, pACT1]; integrating expression vectors regulate by methionine [MET3 promoter], maltose [MAL2 promoter], glucose [PCK1 promoter], or doxycycline [tet promoter and reverse tet promoter]. Some of these vectors were developed in the laboratories of Prof. Brown, Gow and Odds (Aberdeen), the suppliers of most of the strains to be used in this study, and they are being used in laboratories all over the world.

Origin & function

The genetic material was sourced from Candida, prokaryotes and recombinant reporters. NOTE: We will not modify Candida. This large scale modification has already occurred and is ongoing in the laboratories of our collaborators (e.g. Prof Gow, Aberdeen, Prof Julian Naglik):

Nature of the genetic modification:
Most experiments will involve fungi with mutations which target, either directly or indirectly, the fungal cell wall biosynthetic machinery and/or virulence factors. This will include fungi with targeted mutations in genes involved in, for example, metabolism and transcription. Fungi overexpressing fungal or foreign genes may also be used (e.g. fluorescent reporter molecules).

Examples of modified genes include:
- Chitin synthetic genes
- Mannosylation genes
- Beta-glucan synthetic genes
- Hypha specific genes
- Cell wall protein genes
- Secreted hydrolases and other virulence factors
- Transcription factors
- Signalling genes
- Calcium signalling genes
- ABC transporters
- Stress and metabolism genes
- Genes involved in programmed cell death
- Auxotrophic and dominant selectable markers
- Regulated promoters
- Sterol synthesis genes
- Expression of reporter genes (e.g. fluorescent molecules or luciferases)
- Transposon mutant libraries

These modifications will not endow the Candida species with any harmful properties, in fact they usually result in less virulent Candida.

Proposed methods:
In vitro experiments will be performed.
For example, bone marrow derived macrophages, bone marrow derived dendritic cells, neutrophils or monocytes from wild type mice or from genetically altered mice, lacking certain receptors such as C-type lectin like receptors or certain
cytokines or cytokine receptors such as IL-27R or IFNAR, will be incubated with different Candida species/strains. Immune functions such as cytokine/chemokine production and host cell signalling will be examined and Candida killing assays will be performed. For these types of assays, candida will be incubated with cells and cytokine/chemokine production will be measured by ELISA. For cell signalling experiments, cells will be lysed and cell signalling will be examined by western blot. For the candida killing assays, cells will be lysed and candida will be plated and cultured for 24h to determine the cells ability to kill candida. In some instances, cells will be prestimulated with certain cytokines such as IFN-b to increase candida killing ability.

Evaluation of foreseeable effects

C. albicans is a human pathogen in ACDP Hazard Group 2. C. albicans causes superficial infections of mucosal epithelia (thrush) (Odds [1988] Candida and Candidosis, Balliere Tindall). C. albicans can also cause systemic infections which can be fatal, but these only occur in severely immunocompromised patients. To keep things in perspective, it is important to realise that C. albicans is widely distributed. C. albicans is carried commensally at least 60% of the healthy population and most Candida infections arise as an overgrowth of the strains resident in the normal microflora. It is a micro-organism of low pathogenic potential that rarely affects healthy individuals. It only becomes a potential medical problem when an individual's immune responses are significantly impaired. Furthermore, as with most pathogenic micro-organisms, the virulence of C. albicans strains is likely to become attenuated rather than enhanced after prolonged laboratory culture.

Many of the C. albicans strains that will be used are auxotrophic and are largely avirulent. However, by necessity, in virulence studies for example, other strains will not be genetically disabled. This includes null mutations in clinical (wild) isolates. It is important to note that a large number of P. aeruginosa mutants have already been analysed in various laboratories world-wide, but there is no report of a mutation that increases the virulence of this yeast (e.g. Gow et al. [1994] PNAS 91, 6216; Leberer et al. [1996] PNAS, 93, 13217; Hube et al. [1997] Infect. Immun. 65, 3529; Sanglard et al. [1997] Infect. Immun., 65, 3539; Navarro-Garcia et al., (2001) FEMS Microbiol. Rev. 25: 245-268). This is not surprising, since all evidence to date indicates that virulence in C. albicans is a multi-factorial process at the molecular level, with no single virulence factor of over-riding importance. Therefore, mutations, even in wild isolates, are expected to have a neutral or negative effect upon virulence.

In some experiments, we will use C. albicans strains ectopically expressing specific genes, such as GFP or luciferase for example, although we may also use strains which over express cell-wall specific or other genes. We will also use strains where genes have been deleted and then reintegrated (Moyes [2016] Nature 532,7597). The ectopic expression or re-expression of these genes has no affect on virulence, and in some cases it even reduces C. albicans virulence. While all strains that will be tested will not have been fully characterised, it is important to note that the probability of increasing virulence by ectopic expression of a single gene is very low, because pathogenicity is a complex and polygenic trait requiring a high level of fitness of the C. albicans cell (Odds [1994] ASM News, 60, 313). Indeed, there is evidence that ectopic expression of factors involved in virulence traits does not increase virulence (Bailey [1997] PhD thesis, University of Aberdeen; Leng [1999] PhD thesis, University of Aberdeen; Rodaki et al. [2006]).

Experiments will also be performed with genetically modified strains of C. glabrata, C. tropicalis, C. parapsilosis and C. dubliniensis. These species are Closely related to C. albicans, they generate similar types of infections in humans, but they are considered to be less virulent than C. albicans. C. glabrata does not even form hyphae, unlike C. albicans and C. dubliniensis. It will therefore be entirely appropriate to use similar precautions to those used for our C. albicans experiments.

Thus the use of genetically modified strains of Candida strains under laboratory conditions represents minimal risk to human health. Furthermore, even upon accidental infection, normal individuals would clear the doses that are used experimentally from their bloodstream within minutes [MacCallum and Odds (2005) Mycoses 48, 151-161]. Lab workers are unlikely to be exposed to the following factors, which increase the susceptibility to systemic Candida
infections:
1. Use of cytotoxic or strongly immunosuppressive drugs (e.g. systemic corticosteroids)
2. Use of catheters/any intravascular prosthetic device
3. Age (very young or very old individuals are more prone to infection)
4. Serious trauma, particularly when the abdomen is involved
5. Abdominal surgery
6. Patients generally immunosuppressed (e.g. organ transplant recipient, neoplastic disease, severe burns)
7. Long-term use of antibiotics

Lab workers are made aware of these risk factors and are asked specifically to make their supervisors (or Occupational Health) aware if they are exposed to any such risk factors. As a precaution, on occasions where staff/students are undergoing corticosteroid treatment or exposed to some other relevant factor, they are asked to refrain from working with or around fungal pathogens during this time and for an appropriate time after cessation of treatment.

Systemic infections usually only occur in severely immunocompromised patients. Symptoms of systemic Candida infection include fever, rigors and other similar non-specific indicators of sepsis. Standard antifungal treatments include amphotericin B, azoles, and echinocandins.

Symptoms of superficial Candida infection include local rashes (e.g. oral or vaginal) and white aphthae on mucosal surfaces. Azoles or other antifungal agents provide effective antifungal treatment.

With the exception of vaginal infections, none of the above forms of Candida infection are likely to be seen in an immunologically competent, ambulatory person of the type employed as laboratory staff.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

No larger GMOs will be used.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogations requested.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

A safety cabinet will be used, liquid waste will be disinfected with Bleach and solid waste will be autoclaved. The expected degree of kill is >99.99%. Disinfected liquid waste will be disposed of via drain. Autoclaved solid waste will be sent for disposal as Tiger Bag waste to a suitably permitted or licensed landfill site.

Laboratory and associated peripheral workers will be made aware of the risk factors involved with work with Candida.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment
The Committee requested clarification on a number of issues including how the GM Candida were produced, whilst acknowledging that the planned activity at Cardiff involves use of these without further modification. The Committee now agrees that enough information has now been provided and that the risk assessment is now suitable and sufficient.

### Project Additional Information

**Purposes of the contained use**

The main aim of this project is to provide tools to better understand the molecular mechanisms which underlie the increased psychiatric risk associated with the 1q21.1 copy number variant.
Copy number variants (CNVs) provide an important tool for modelling increased susceptibility to psychiatric disorders, as they are highly penetrant compared to single nucleotide polymorphisms and can be easily modelled. The simplest method to assess these mutations is to make induced pluripotent stem cells (iPSCs) from patients carrying these CNVs. These iPSCs will be created by reprogramming human fibroblasts into iPSCs using Sendai virus based reprogramming methods.

Once these iPSCs have been characterized and validated, they can be reprogrammed into different neuronal lineage cells including astrocytes, neurons, oligodendrocytes and microglia, as well as brain-specific organoids. However, current production of astrocytes and oligodendrocytes from human iPSCs using classical developmental patterning approaches is highly complex and time consuming. Therefore, we will be attempting to directly reprogram iPSCs into astrocytes, neurons and oligodendrocytes by overexpressing key transcription factors known to be critical in these cell types.

Having generated these cell types from the 1q21.1 iPSC lines these cells will then be assessed for any abnormal phenotypes. To aid in the delineation of what may be complex and multifactorial phenotypes, we will exploit the ability to selectively express markers such as GFP, RFP and luciferin within certain cell populations to track and monitor specific subpopulations within our cell systems.

Finally, having identified key mediators associated with specific phenotypes caused by the 1q21.1 CNV, we will then perform knockdown experiments to prove the precise mechanisms underlying these phenotypes and their link to the 1q21.1 CNV. These knock downs will be carried out by viral mediated shRNAs.

Recipient or parental organism

**Lentivirus:**

Plasmids required to produce the virus will be generated and modified in bacteria, specifically a lab based E. coli (either TOP10 or 10-beta). To produce the virus plasmids will be combined in HEK293T cells.

**Sendai virus:**

Purchased from Thermo Fisher Scientific under the product name CytoTune™-iPS 2.0 Sendai Reprogramming Kit

Host/vector system

**Lentivirus:**

Vectors used in this study are commercially available 2nd generation HIV-1-based lentiviral systems, engineered to maximise biosafety by separating the genes required for viral generation onto 3 separate plasmids. The key separation is that of the expression (gag, pol and rev) genes and envelop (VSV-G) gene from the packaging signal contained on the transfer plasmid therefore preventing the expression of envelope genes from integrating into the virus. Additionally, none the plasmids involved contain any of the four essential viral accessory genes required to be replication competent. Consequently, the nucleic material contained within the virus lacks the majority of genetic information to produce further viral particles. Furthermore, the transfer vectors 3'-LTR contain a deletion which prevents the transcription of the full viral genome thereby rendering the virus self-inactivating.

**Sendai virus:**

Sendai virus, in this case, is based on defective and persistent Sendai virus vectors (SeV) lacking the viral M, F and HN genes, and are also non-transmittable. They replicate in the forms of single-stranded RNA in the cytoplasm of the infected cells. They do not go through a DNA phase or integrate into the host genome. It replicates its genome exclusively in the cytoplasm and does not enter the cell nucleus. Therefore, the Sendai virus vector is integration free and is unlikely to alter the host's chromosomes like the conventional viruses.

Origin & function
Sendai Virus:
Although cMyc is a known oncogene, and the other genes are found to be up-regulated in tumour cells, Oct4, Sox2, Klf4, and cMyc (OSKM) genes are also ordinarily expressed in embryonic stem cells. The introduction and expression of these genes in differentiated cell type's results in the effected cell reverting to an embryonic stem cell-like pluripotent state rather than a tumour. The final viral vectors are designed to introduce the OSKM genes to the host cell and facilitate the stable expression of the genes for the purpose of generating iPS cell cultures. The CytoTune® - iPS Sendai Reprogramming Kit contains a temperature sensitive mutant of c-Myc that facilitates the clearance of this vector. It has been shown that c-Myc persists in the cells longer than the other vectors. However, as this virus is nonintegrating the OSKM genes will be cleared and expression will be maintained by endogenous expression.

Lentivirus:
Lentiviruses will contain transcription factors (specific to the induction of astrocytes and oligodendrocytes), imaging constructs (including GFP, RFP and Luciferin) and shRNAs to specific transcription factors. The transcription factors used in this study will be specific to the oligodendrocyte and astrocyte lineage and are not currently considered oncogenic. These vectors will alter the transcriptional regulation of a large number of genes with the aim of making induced astrocytes of oligodendrocytes. The insertion of GFP, RFP or luciferin is unlikely to have any major effect on the cells as this is a routine procedure with little to no reported side effects. Finally the use of shRNA will be limited to specific genes identified as key regulators in phenotypes associated with the 1q21.1 CNV and will only be able to knock down these specific genes with no other effect on the cells.

Evaluation of foreseeable effects

1. The CytoTune® - iPS Sendai Reprogramming Kit contains a temperature sensitive mutant of c-Myc that facilitates the clearance of this vector. It has been shown that c-Myc persists in the cells longer than the other vectors. However, as this virus is non-integrating the OSKM genes will be cleared and expression will be maintained by endogenous expression. Further checks are in place to demonstrate the clearance of this virus as by doing gene expression analysis as this is necessary for the continued use of these cell lines. Therefore, while these viruses have significant effects on the cells they are introduced into they are not maintained or propagated and therefore will not have any effect beyond the originally infected cells.

2. The iPSC cells generated do not form tumours and has clear potential to differentiate into any neural lineage cells when stimulated with specific growth factors and cultured in appropriate conditions. This approach is named developmental reprogramming and its potential for regenerative medicine is being explored. We will perform the gene expression analysis of the derived cells which will confirm the cells don't express tumor associated genes.

3. The genes and constructs which will be expressed in this study are considered non-harmful, and while the transcription factors used have a broad effect on the transfected cells, they are not considered oncogenic and will be under the control of an inducible promoter. The genes contained within the transfer plasmids will have no effect on the viral stability, activity, infectivity or resistance. Therefore, the effect of infection with these viruses is likely to be minimal other than integration of the transfer genes, with larger effects occurring when the transfer genes are induced.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Product Name: Virkon
Expected degree of kill: 100%
Health and Safety

It is sold as tablets or powder which dissolve readily in water. It is intended to be mixed with water to form a 1% to 3% solution (by weight, i.e. 10g to 30g per litre). The pink colour is useful in that it helps gauge the concentration when preparing the Virkon®, and importantly, as the Virkon® ages it discolors, making it obvious when it needs to be replaced. The solution is generally stable for five to seven days. Virkon® has a wide spectrum of activity against viruses, some fungi, and bacteria.

Product Name: Chemgene
Expected degree of kill: 100%

Chemgene is supplied as liquid and is extensively tested against viral, bacterial and fungal species and subtypes. Literature supplied by the manufacturer indicates >log4 reduction in HIV when Chemgene is used at a concentration of 1:50. In House SOP is to add chemgene at a minimum of 1:50 dilution to spent media containing viral particles in a sealed container for a minimum of 24 hours before liquid is considered decontaminated. Any plasticware which has come into contact with viral particles is disinfected as above and then autoclaved and any consumable material including gloves, spent media bottles or other material which has not come into direct contact with virus but has been used while performing work using the viruses is autoclaved before disposal.

Cardiff University GMBA Committee agreed that the activity described is a Class 2 activity requiring Containment Level 2. After some queries and subsequent additions/alterations regarding the source of the human fibroblasts and what type of Lentiviral vectors were to be used, the Committee are now satisfied with the risk assessment for this project.

Project Ref 130/20.1

Characterisation of host responses to infectious organisms

This work focuses on the use of pathogens modified to contain a reporter genes as tools to characterise host responses to and regulation of infectious organisms. A number of pathogens with a broad range of replication characteristics are included to gain a maximum understanding of host responses to infection.

Recipient or parental organism

Mice (C57BL6)/Immortalised mouse cell lines/immortalised human cell lines! Primary human cells! Primary mouse cells

Host/vector system

Herpes simplex virus (HSV) 1 or 2, Human Cytomegalovirus (HCMV) (H2B5, UL 127, Power, ts, ts66, Towne, Gery, Toledo, Towne long, Fiala-P6, FK7), Murine Cytomegalovirus (MCMV) (Smith, Rm461, MIEP-GFP RM427+, ES, Rm408, Rm427, Power, C3X, C3X-ES, ME97.01, Smith) + mutants (ie1 and 3 knockouts + revertants), Epstein Barr virus (EBV) B95.8 strain restricted to B95-1 cells, Murine Herpesvirus 68 (mHV-68), Bacterial artificial chromosomes (BACs) e.g. ZEN-Ub1 for gene knockout. Influenza A virus (Udorn/72 (H3N2) and A/WSN/33 (H1 N1 )), Human adenovirus (E1 deficient), Vaccinia (Ankara), Baculovirus expressing HCMV pp65, Lentivirus (HIV-1 derived and attenuated)

Origin & function

For reporting/ purifying cells/ viruses: Jellyfish - GFP, RFP, YFP, Firefly luciferase, Renilla luciferase, Bacterial
antibiotic resistance genes
To analyse gene function in vitro: PCR amplified human and mouse genes - Gpr84, Gpr43 Hk3, Olah and Ch25h
(No oncogenes), Lab generated short RNA sequences and hairpins
For reverting mutated mCMV: PCR generated ie1 and ie3 from mCMV
To enhance gene expression: SV40 promoter from Simian Virus - into adenovirus plasmids, CMV promoter from
hCMV - into lentiviral plasmids and adenovirus

Evaluation of foreseeable effects

Herpesviruses (ACDP Hazard Group 2 suitable for Containment Level 2 conditions)
HSV-1 and HSV-2 are naturally occurring neurotropic a-herpesviruses, and whilst morbidity/mortality can be high in
eonates or immunocompromised people, infection of healthy individuals causes a self-limiting subclinical primary
infection in healthy individuals. Neither vaccine nor anti-serum is available, and treatment of severe cases is local
or systemic use of acyclovir. Despite a high (~90%) global prevalence, HSV-1 and HSV-2 present a potential risk to
humans and are classified as ACDP Hazard Group 2.
CMV is a human J3-herpesvirus endemic in 40-100% of the population depending on geographic location/socioeconomic
status, and infection occurs largely in childhood by direct contact with infected bodily secretions. Primary
infection is largely benign in healthy individuals but causes severe opportunistic infections in the
immunocompromised and is the major cause of congenital infections which can cause severe CNS abnormalities.
There is no vaccine available, but infection can be treated by hyperimmunoglobulin, ganciclovir and valganciclovir.
CMV present a potential risk to humans and are classified as ACDP Hazard Group 2.
EBV is a human v-herpesvirus with very high (~90%) seroprevalence in UK adults. Primary infection causes
infectious mononucleosis, and infection remains latent in B-cells. EBV is associated with Burkitt's lymphoma,
nasopharyngeal carcinoma, Hodgkin's lymphoma and gastric cancer. Due to high prevalence, and very rare
occurrence of re-infection, experimental work with EBV poses no additional threat to normal exposure to the virus.
EBV present a potential risk to humans and are classified as ACDP Hazard Group 2.
MCMV is a murine-specific b-herpesvirus and poses no threat to human health and safety.
mHV68 is a murine-specific v-herpesvirus and poses no threat to human health and safety.
Human adenoviruses (HAdV) are transmitted by aerosols and faecal-orally and cause acute infections the
respiratory tract, pharyngitis, conjunctivitis, cystitis and gastroenteritis. Zoonotic transmission to humans has been
reported (from bovine, simian and feline adenoviruses) but is asymptomatic. Infection is diagnosed serologically, or
by PCR and whilst there is no vaccine available, patients with severe infection are treated with Cidofovir. HAd V are
classified as ACDP Hazard Group 2, and CL2 conditions are suitable for their growth.
Influenza A is a segmented RNA virus infecting aquatic birds, but zoonosis to humans causes highly virulent
respiratory tract infections. Season-specific vaccines, containing the currently Circulating species and
neuraminidase inhibitors (Osaltamivir and Zanamivir) are available. Influenza subtypes B, and much rarer subtype
C, also infect humans and the nature of the segmented genome means co-infection is common and there is the potential to generate strains with altered
pathogenicity/tropism due to genome re-assortment. For this reason, work
will be restricted to human virus strains, and those classified as ACDP Hazard Level 2. These will include Influenza
AIUdorn/72 (H3N2) and AIWSN/33 (H1 N1), CL2 conditions are appropriate for growth of these strains.
Lentivirus: These are genome integrating viruses which can potentially pose a hazard to human health by
integrating into host DNA. Although lentivirus synthesised from the vectors has the ability to enter all cells within the
body they are replication deficient thus pose relatively little risk. As these viruses integrate into the host genome,
they can potentially produce cancerous cells, therefore no oncogenes will be inserted to effectively eliminate this
risk.
Baculovirus is incapable of replicating in mammalian cells.
All viruses that infect humans may potentially be transmitted to workers by ingestion, injection and droplet or
aerosol exposure of mucus membranes. All work will be carried out in a class 2 biosafety cabinet with full protective equipment (lab coat, gloves, glasses). The modifications of viruses to insert reporter genes are not expected to alter virulence.

E. coli K12 and 8 derivatives, such as DH5a and DH10- used to propagate individual viral and host gene expression plasmids, are disabled laboratory adapted strains unable to survive outside culture conditions or colonise the human gut. They are generally non-hazardous to human health.

Well characterised and pathogen-permissive mammalian cell lines or primary cells will be used for the culture and propagation of wild-type and mutant pathogens under Containment Level 2. Cell lines used include HeLa cells (human epithelial cells), A549 cells (human lung epithelial cells), THP-1 cells (human monocyte), RAW 264.7 (murine macro phages), 3T3/NH (murine fibroblasts), p53 -/- MEFs and STAT1 -/- MEFs (murine embryonic fibroblasts), Mewo cells (human melanoma cells), MRC5 cells (human lung fibroblast cells), HEK-293 and 293T cells (human embryonic kidney cells), and 895-1 cells (EBV-positive lymphoblastoid cells).

Mice will be genetically modified, however the modifications are not anticipated to endow the GMO with any novel harmful properties and will not provide the GMOs with a survival advantage. Knockout of these genes will have potentially harmful phenotypic effects on the animal, which are recorded on the Jackson website. No new genetically modified mice will be created so this data is available. The likelihood of these effects spreading to the environment are effectively zero because this would require cross breeding with wild-type mice that must escape our secure animal containment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The animals are contained in specific pathogen free environments and virally infected mice will be housed in sellotainer cages all inside a secure animal facility which has barriers to prevent any animal escape if they got out of their cage. Cages are checked for mouse numbers every day. All work conducted on virus infected animals will be carried out under a biosafety level 2 cabinet in category 2 designated rooms.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste will be treated with 10,000 ppm Sodium Hypochlorite (HazTabs) for 4h before disposing down the sink, this treatment will kill all GMMs used in this protocol - tested by viral and cell culture attempt. All solid waste, including sharps, will be disposed of via clinical incineration. In the case of virus waste solids will be treated where appropriate with sodium hypochlorite and autoclaved before incineration.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
Minor corrections were asked for such as typo's and also in regard to where the terminology used drifted between that used in the UK and USA e.g. containment level/biosafety level. Please see section 17 for further comments.

### Project Additional Information

**Purposes of the contained use**

Type 1 Diabetes is a result of the targeted attack on the insulin-producing beta cells within the pancreatic islets of Langerhans. Antigen-specific immunotherapy is one promising avenue for preventing/reversing autoimmune diseases, like type 1 diabetes, by restoring tolerance to autoantigens. However, to date, it has proved very challenging to monitor the antigen-specific response using peripheral blood samples as the frequency of relevant
cells is very low. Our group has developed a protocol to sample draining lymph nodes (LN) in humans via ultrasound guided fine needle aspiration. Lymphocytes are harvested pre- and post-intradermal treatment with islet derived peptide/antigens (GAD-alum or pro-insulin C19-A3) for phenotypic analyses. Single cell (bar-coded) RNAseq next generation sequencing is used to phenotype individual LN-derived cells. Through this technology, the T cell receptor (TCR) sequence can be determined including the appropriate pairing of alpha and beta chains. Single cell analysis also identifies if unique TCRs are expressed by 2 or more cells, indicating clonal expansion. To complete this approach to monitoring the antigen-specific T cell response, we require technology to identify the antigen specificity of T cells of interest, such as those clonally expanded. The remaining single cell RNAseq data provides the complete transcriptome of each cell which can then be matched to antigen specificity to characterise phenotype and likely function (e.g. T reg, Teff, Tcm etc). I will generate hybridomas expressing the TCR sequences identified by RNAseq from human LN. Vectors are generated with custom oligos based on patient sequencing and ligated with established packaging vectors. DH5alpha cells will be transformed. PCR and sequencing will confirm vector construction. Phoenix-ECO cells will be transfected to generate mouse stem cell virus particles with packaging and TCR which will be used to transduce 5KC mouse cells, which lack a T cell receptor. Cells expressing the vector will be selected based on CD3 expression. Peripheral blood will be used as antigen presenting cells to challenge the generated hybridomas with GAD protein and/or insulin peptide C19-A3. Testing these cells will identify the antigen specificity and phenotype of T cells in patients with type 1 diabetes undergoing immunotherapy. Of importance, if T cells specific for GAD or Insulim-are identified, these cells will be evaluated for phenotypic changes during the trial.

Recipient or parental organism

The retrovirus used in this system is murine-specific thus presenting no risk to humans. Phoenix-ECO cells will be transfected to generate mouse stem cell virus particles with packaging and TCR which will be used to transduce 5KC mouse cells, which lack a T cell receptor. The Phoenix cells are treated with mitomycin c to prevent cell replication, resulting in cell death after the initial shedding of virus. There is no risk associated with expression of T cell receptors on the transduced cells.

Host/vector system

Murine stem cell virus (MCSV) is as mouse-specific retrovirus that infects embryonic and hematopoietic cells. The vector lacks Pol/gag/env, which is provided by the packaging cell line (Phoenix-ECO). The retrovirus is mouse specific and does not infect human cells.

Origin & function

Inserted genes encode the alpha and beta variable chains of the T cell receptor based on next generation sequencing of patient samples. DNA oligos are provided from Twist Bioscience for insertion to vector. Antigen specificity will be evaluated via expression of the TCR on murine 5KC cells.

Evaluation of foreseeable effects

The virus is murine specific and does not infect human cells. The virus in replication deficient. The vector encodes for human T cell receptor variable regions which are specific for HLA and would not recognize mouse MHC.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Work will be conducted in a class 2 biological cabinet following appropriate guidelines for safe handling. Solid waste will be put in yellow bags for autoclaving. Liquid waste will be collected in bottles and treated with 10% bleach overnight to provide full inactivation of viral proteins.

**Project Ref**  130/20.4

**Date Ackn’d**  26/08/2020

**CU2 Project Title**  Gene and epigenome editing for expanded CAG/CTG repeat disorders in human cells

**Class**  Class 2

**CultureVolClass2**  ≤ 1 Litre

**CultureVolumeClass3-4**

**Non-GMM**  Consent Granted

02/03/2022  Page 3753 of 15326
We are developing new ways of treating a family of over 20 different neurological, neuromuscular, and developmental diseases that affect over 1 in 400 people worldwide. These are caused by the expansion of tandem repeats in the genome and include Huntington’s disease, myotonic dystrophy type 1, as well as several spinocerebellar ataxias. Specifically, we will use gene editing (via CRISPR-Cas9 nickase) approaches to contract the repeat tracts, or deliver chromatin modifying enzymes that could lead to the silencing of the allele containing the expanded repeat tract. We also plan to make knockout of specific factors individually or as part of screens to understand how these processes work and thus how to make them more efficient and safer. The cDNA of the candidates that we identified (e.g., DNA repair genes) will also be overexpressed.

**Recipient or parental organism**

Human cell lines, patient-derived cells, mice, E. coli, S. cerevisiae

**Host/vector system**

Non-replicating lentiviral vectors, plasmid DNA, gutless Adeno-associated viruses

**Origin & function**

We will use these vectors to deliver inside human cells human cDNAs, as well as the bacterial Cas9 enzyme and/or a single-guide RNA. We will use genome-wide libraries and thus the genes mutated have varied roles that are explained in details in the accompanied risk assessments.

**Evaluation of foreseeable effects**

E. coli has been used extensively for molecular cloning, using the plasmids containing genes granting antibiotic resistance to ampicillin, kanamycin, chloramphenicol, tetracycline, and/or spectinomycin. The strains of E. coli used, e.g., DH5α, are recombination deficient (for example because of the presence of recA or recBCD mutations) and non-pathogenic.

S. cerevisiae will be used to construct plasmids for expression of specific recombinant DNA. This yeast strain, W303, is not pathogenic and contains a number of
spontaneously occurring auxotrophies that reduce its fitness.

Mus musculus will be generated with a Cas9 nickase knocked in at the ROSA26 locus. Another line will express a dual colour reporter for detecting changes in CAG/CTG repeat size in vivo. This reporter will also be knocked into the ROSA26 locus. This reporter will be crossed to the R6/1 Huntington mouse model. Given that the risk of using these strains of yeast and bacteria is negligible, we request that this work be class 1. The mouse strains also do not pose a threat to the health of the workers beyond the risks associated with handling mice. In addition, the mice are held in secure mouse facilities, greatly minimizing the chance that they escape into the wild. Thus, we request class 1 for these as well.

Adeno-associated viral viruses: AAVs are non-replicating by nature as they require the help of adenoviruses or herpes simplex viruses. We will use them with the Cas9 nickase or a sgRNAs packaged into them. The packaging will be outsourced to the UKDRI facility in King’s college or to an outside company. These vectors will be tested in the lab before being used in vivo. Although these viruses are considered class 1 by the HSE, we will be using them in large quantities and they can infect (but not cause disease) if a worker is already infected by helper viruses. Therefore they will be treated as class 2 agents. PPE will be used and the workers will be trained accordingly.

Lentiviral vectors: We will use lentiviral vectors that are replication-deficient and use 3rd generation packaging for reducing the risk of generating proficient viruses by recombination. Lentivirus are clearly a class II organism and will be treated as such (see below for details). The risk of infection of a worker is highest while making the viruses and early in the first few days of the experiments. Sharps will be avoided, and the viruses and infected cells will be handled in category 2 hoods. PPE will also be used and the workers will be trained accordingly.

The mice are housed in specific rooms inside the facility with at least three doors to get in and out that are card-accessible. There is no window to escape. The mice are inside the cages and are ID’ed. There is a daily check on them and thus any missing mouse will be noticed within 24 hours. There are traps that are routinely checked for function in the facility to catch any mouse that escapes the cages (eg. during cage changes). The number of people having access to the premises is limited and requires card access, reducing the chances that someone deliberately walks in to “free” the mice. Any new faces are challenged and only those that undergo a full induction by the facility manager would be allowed access. All control measures are carried out under the guidelines of Joint Services.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Centrifugation can lead to aerosol formation and containment of such activities to minimize cross contaminants is necessary. All tubes will be wiped down with ethanol prior to being opened in a category 2 hood. SOP of wiping the hood down prior to use and after use is necessary as well as use of UV light for decontamination.

Liquid waste will be disinfected using Presept tablets (2.5g), Chemogene or similar 2500ppm, sodium Dichloroisocyanurate (chlorine-based disinfectant). We expect that this will kill 100% of the viruses within 4 hours.

Recombinant viruses will at all times be maintained in an environment designed to prevent aerosol spread. All flasks containing the virus shall be kept closed except when decanting and pipetting which will be conducted in tested class II safety cabinets. Centrifugation steps shall be performed in sealed buckets and centrifuge tubes containing the virus will be opened only in safety cabinets.

Contaminated plastic pipettes will be submerged in Presept disinfectant, or a similar chlorine based disinfectant, for a minimum of 4hr prior to disposal. The tissue culture cabinet and any potentially contaminated areas will be disinfected with 70% ethanol. Waste that has been decontaminated will then be double-bagged and autoclaved.

Users will wear double gloves when handling viruses, and the outer glove removed when moving out of the safety cabinet.
Solid waste will be autoclaved.

The Committee were satisfied that the separate projects could be linked as a connected programme of work. The highest risk activities are Class 2 activities. The Committee were in agreement of the Containment level of the facilities required. The Committee had a number of queries which have been answered to their satisfaction. They also required that Professor Dion reorganise some of the forms and produce a diagram to clearly indicate the connections between the parts of the programme. These are all submitted with this notification.

02/03/2022

Page 3756 of 15326
This programme of work aims to investigate the pathogenic mechanisms underlying neurodegenerative disease processes implicated in Alzheimer’s disease, Parkinson’s disease and frontotemporal dementia. Our approach includes the manipulation of disease linked genes as a model system for biological investigation. We will manipulate gene expression levels (knockdown and over expression) to investigate cellular changes, as well as introduce tagged proteins to facilitate biochemical analysis.

We will manipulate expression levels of target genes in rodent primary neurons, stable neuroblastoma and microglial cell lines using constructs expressing cDNA to increase expression, or short hairpin RNA sequences (shRNA) to knock down expression of genes linked to neurodegenerative disorders (motor neuron disease, frontotemporal dementia), autophagy and mitochondria biology.

This project will only use commercially available vectors obtained from Horizon Discovery/Dharmacon, OriGene, VectorBuilder and Genscript. Manipulated cells will be investigated using a variety of techniques including morphological analysis by fluorescent microscopy, molecular biology and biochemical assays. Lentiviral vectors and particles will not be produced under this proposal.

Recipient or parental organism

- BV2 mouse neonatal microglia (RRID:CVCL_0182)
- SH-SY5Y human neuroblastoma stable cells (ATCC CRL-2266)
- HEK293 (RRID:CVCL_0045)
- Mouse embryonic (E17) cortical neurons

Host/vector system

- SMARTvector Lentiviral shRNA - Commercial short hairpin RNA expressing known vector (Dharmacon)
- pGFP-C-shLenti Lentiviral shRNA - Commercial short hairpin RNA expressing known vector (Origene)
- pLK0.1[shRNA] - U6-promoter driven Knockdown vector derived from the third-generation lentiviral vector system.

Origin & function

- LVs contain shRNA will target:
  - TBK1: TANK binding kinase 1, kinase with broad activity in immunity, mitophagy and autophagy
  - p62: autophagy adapter molecule targeting intracellular molecules for degradation
  - OPTN: autophagy adapter molecule targeting intracellular molecules for degradation
Gene expression LVs will contain human or mouse cDNAs for the below, either with or without fusion with the biotin protein ligase BirA R118G:

- ABI3; ABI Family Member 3,
- BIN1; Bridging Integrator 1,
- CD2AP; CD2 Associated Protein,
- CD33; Sialic Acid-Binding Ig-Like Lectin 3
- INPP5D; Inositol Polyphosphate-5-Phosphatase D, immune cells.
- PICALM; Phosphatidylinositol Binding Clathrin Assembly Protein,
- PILRA; Paired Immunoglobulin-like receptor
- PLCG2; Phospholipase C Gamma 2,
- PTK2B; Protein Tyrosine Kinase 2 Beta,
- SPI1; Spleen Focus Forming Virus (SFFV) Proviral Integration Oncogene
- TREM2; Triggering Receptor Expressed on Myeloid Cells 2
- MS4A6A; Membrane Spanning 4-Domains A6A.
- CLNK; Cytokine Dependent Hematopoietic Cell Linker,
- SCIMP; SLP Adaptor and CSK Interacting Membrane Protein
- MEF2C; Myocyte Enhancer Factor 2C,

In addition to the gene specific cDNA or RNAi sequences, LVs will contain combinations of the following standard viral vector components: Woodchuck hepatitis virus posttranscriptional regulatory element, Simian virus 40 early polyadenylation signal, eGFP/RFP, antibiotic resistance cassette (Ampicillin, Kanamycin, Puromycin, Neomycin), promoter (U6, CMV, EF1a) and an Internal ribosome entry sequence.

**Evaluation of foreseeable effects**

The lentiviral vectors used in this project pose a low biohazard risk as though capable of transducing human cells, however the virus is replication incompetent. Replication requires sequences coding gag, pol, env, and rev, which are removed from these third-generation vectors and would be required to be provided in trans by helper constructs. There is no evidence to suggest that the recombinant virus may alter susceptibility to host defence mechanisms. All DNA components of the recombinant virus are routinely used in biological research, and are not known to have effects on susceptibility of host immune systems. To reduce risk in this project we have considered foreseeable circumstances where there is a risk of transmission of the vectors.

**Routes of transmission:**

- Needle stick – needles will not be used in these experiments.
- Inhalation - opening a vial or spillage of the virus could cause an aerosol of viral particles. As such, all tasks where there is a risk of aerosols being produced will be carried out inside the safety cabinet.
- Skin contact - The viral vector could be transmitted through contact with the skin, transmission into the blood stream or to airways and eyes. These risks will be minimised following the standard operating procedure of the virus suite and use of double gloves to minimise risk of skin contact through piercing of gloves. The only consequence of exposure we envisage is some irritation/inflammation caused by the immune response which may be caused by the vector. Normally, if an immediate action is taken, i.e. washing the exposed area with detergents, no significant consequence will occur.

The BCL-II viral suite will have designated lab coats (green) which also will be stored in the viral room.
Standard working procedures and emergency instructions (phone numbers including after work phone numbers) will be clearly posted to the walls on laminated paper. A spill kit will be provided in the room.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Transduced cell lines that are free of infectious virus will be moved from the virus suite for microscopy/opera phenix imaging. Stable cells will also be used for immunocytochemistry and will therefore need to be moved to a fume cupboard/LEV for formaldehyde fixing.

Assuming a maximum dose of 10,000,000 TU per well and lentiviral particle half-life of eight hours (Higashikawa and Chang, 2001) it will take approximately eight days for there to be less than one viral particle per well. We will therefore use conservative 12 day cut-off before moving cells.

We will periodically (six months) test that the stable cell lines are still free from infectious virus particles by concentrating media in a spin column and testing for residual "free" virion RNA using RT-PCR and primers designed to the 5' LTR and 3' LTR region of the lentiviral vector.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Preferred local deactivation/disposal pathway:

1) Chemical disinfection by Chemgene or Virkon.

Liquid waste (e.g. culture media) will be inactivated with 5% Chemgene or Virkon® (final concentration 1%) for at least 1 hour (typically overnight) - according to manufacturer’s instructions.

All solid waste (tissue culture plastics) will be treated with Virkon® for at least 2 hours before autoclaving.

2) Waste placed into autoclave bag.

Chemically deactivated waste will be placed into autoclave bags.

3) Waste autoclaved locally using the waste cycle at 134°C for 25 mins.

Solid waste will be autoclaved in the designated autoclave located immediately outside of the viral suite before being placed in a yellow ‘Tiger bag’ and disposed of as ‘offensive waste’ (HL180104).

The autoclave is a Priorclave 60L Benchtop, the machine is serviced annually and a twelve-point thermocouple test is performed annually. Waste material will be inactivated using the waste cycle at 134°C for 25 mins.

All staff operating the autoclave will have been trained in manual handling and are also trained in appropriate spillage procedure. 1% Virkon® or 5% Chemgene is the disinfectant to be used in case of inactivated waste being spilled in or out of the autoclave.
As this is a closely connected programme of work there were common discussion points throughout the 3 risk assessments that make up the programme.

Minor amendments e.g. additional information asked for in Table 1.
Discussion on the suggested use of FFP3 masks in the viral suite (The GMBA advised these will not be needed in addition to the Class 2 MSC). This does not effect any local rules on face coverings/PPE that may be required in regard to Covid-19 restrictions.
Additional information (protocol included with this notification) was required to show transduced cells were virus-free when moved to CL1.

Historical Significant Changes
Aquaculture is a diverse industry and the fastest growing food sector. In 2016, 110 million tons of seafood were produced worldwide with an estimated value of $243 billion. This industry, however, faces multiple challenges from global warming to increased infection rates and multi-resistant drug pathogens. Because the physiopathology of bacterial infections is still poorly understood, few preventative or curative treatments are available.

**General Scientific purpose:**

Aeromonas hydrophila, A. salmonicida, Edwardsiella spp., Vibrio anguillarum, V. salmonicida and Yersinia ruckeri are well-recognised fish pathogens that create a strong burden for the fish industry and the environment. All these pathogens are Gram negative bacteria that use different molecular mechanisms to infect their host. Unfortunately, they have a high antibiotic resistance panel, can infect humans (opportunistically) and other animals through the food chain. In humans, they will cause gastroenteritis.

All these pathogens use numerous virulence factors to infect their host including toxin and secretion systems. More specifically, type 3 secretion system (T3SS) and type 6 secretion system (T6SS) clusters have been identified by genome sequencing. These secretion systems allow pathogens to translocate bacterial proteins, named effectors, directly from the bacterial cell into the host cell cytoplasm. Following translocation, the effectors take control of cell signaling for the benefit of the adherent pathogen allowing the bacteria to invade and replicate inside the cells. But only a few effectors have been so far identified and the mechanism of action is poorly understood.

**Specific Scientific purpose and goals:**

Our aim is to delete or mutate virulence factors in the pathogenic bacteria to understand their functions. Phenotypes after infection of cultured cells in Petri dish or fish in aquarium (from 1L up to 160L) by wild type strains or mutant will be compared. Infection with GM bacteria may happen in different rooms simultaneously. Transfer of the GM bacteria from one room to another will be done using a second seal containment. Fishes tested for this project include rainbow trout, guppy (Poecilia reticulata) and zebrafish (Danio rerio).

**Type of GMM to be constructed:**

Bacterial genes of interest will be deleted from bacteria by site directed mutagenesis. Most of the bacterial genes targeted have unknown function but are suspected to be linked to the pathogenicity of the bacteria (secretion system effector, toxin, adhesins and pili). Wild type or mutated genes will be also reintroduced into the mutants by direct gene reinsertion or using plasmid (low and high copy). Random insertional mutagenesis using mini-Tn5

**Recipient or parental organism**
Edwardsia spp., Aeromonas hydrophila, A. salmonicida, Vibrio anguillarum, V. salmonicida and Yersinia ruckeri can cause gastroenteritis and infect open wounds in humans mostly in young children and people who have compromised immune systems. Workers associated with this project will be informed of the risk and will sign a risk assessment form. The pathogens are already present in the environment.

Host/vector system

All the vectors used have antibiotic resistances genes, however, these antibiotics are not used for the treatment of the associated diseases. These vectors are used worldwide in the laboratory and are considered safe. They also are not mobile and should not be transferred by conjugation.

Bacterial complementation constructs will include pSA10 (high copy number, IPTG inducible expression), pACYC184 (medium copy vector, constitutive expression), and pBAD vectors (high copy number, arabinose inducible expression).

Mutagenesis plasmids include pKD46 (arabinose inducible expression of red recombinase) and pACBSR/pAKBSR (arabinose inducible expression of red recombinase and I-SceI endonuclease).

Origin & function

Bacterial effector proteins are translocated by bacteria via type 3 and 6 secretion systems. Type 3 and 6 secretions are endogenous systems that bacteria use to transport bacterial proteins into host cells. Effector proteins have diverse biochemical and physiological functions. Collectively, these proteins affect many different cellular functions including actin dynamics, cellular trafficking, cell signalling, innate sensing and some are cytotoxic upon overexpression in certain cell types. Alone, effectors have a limited effect but collectively they contribute to virulence.

We will construct mutant strains lacking these genes or genes involved in the adhesion of the pathogen (flagella and pili).

These will be anticipated to have lower to equal virulence to wild-type.

In some cases, genes of interest will be expressed in bacteria (with or without a tag). This will be done in bacterial strains already knocked out for these genes, in order to complement the mutation. If there is a virulence defect as a result of the mutation, virulence is expected to go back to wild-type levels. Higher expression using a high copy plasmid can be achieved but with no expected impact on the virulence as higher expression decreases the efficiency of the secretion system.

Evaluation of foreseeable effects

HAZARDS ARISING:
The mutants generated will either be loss of function mutants or carry non-toxic reporter genes. It is not anticipated that bacterial strains, including complemented strains, produced in the laboratory will be more virulent than strains that already exist in the environment even in the case of an increased expression of the specific virulence factor due to a high copy plasmid. Indeed, many strains produced will have deletions in genes, which are required for optimal growth and virulence of the organism. In addition, antibiotic resistance markers (carbenicillin, gentamycin, chloramphenicol, tetracycline, kanamycin and streptomycin markers) used in the laboratory already exist in the host strains found in the environment and hence there is no risk of introducing new resistance genes to environmental strains.

HARM FOR HUMANS OR ANIMALS:
The listed pathogens are pathogenic to aquatic animals (mostly fishes) and are found in the environment however, they are not pathogens under DEFRA control.

E. tarda can infect invertebrates, amphibians, reptiles, birds and mammals, including humans, cattle, swine, dogs, and Weddell seals.

Aeromonas hydrophila can also infect some vertebrates (lizards).

Aquariums ‘infected’ with GM organisms will be housed in suitable containment tanks capable of holding the whole volume of water held in the aquariums.

As the source of infection is from ingestion, the risk is easily mitigated by good laboratory practice.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For some aspects of the in vivo work, fish may be inoculated with GM bacteria under the permission granted in Home Office project licence. Aquariums 'infected' with GM organisms will be housed in suitable containment tanks capable of holding the whole volume of water held in the aquariums.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

LIQUID WASTE:
Disinfectant Product Name: VIRKON
Generic Chemical Name: Oxone (potassium peroxymonosulfate), sodium dodecylbenzenesulfonate, sulfamic acid, and inorganic buffers
Expected degree of kill: 99.999%
How is this validated? Killing of vibrio spp. and Edwardsiella has been reported in the literature (Machen et al. 2008; Mainous et al. 2010). At the end of the experiment in an aquarium, Virkon powder will be added to disinfect the water to reach the terminal disinfection concentration (1kg/100L) during 15 min before extensive washing with water.

SOLID WASTE:
Autoclave
Expected degree of kill: 99.999%
How is this validate: Autoclave calibration is assessed every year as part of the normal procedure within the School of Biosciences

ANIMAL WASTE:
Dead infected animals will be disposed according to Cardiff University rules and regulations established for animal facilities housing animals.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Please enter comments on the GM safety committee on the risk assessment

The University G MBA Committee had queries regarding the use of sharps and also regarding disinfection of large volumes but those queries have now been answered.
The Committee were satisfied that this work could go ahead in Containment Level 2 facilities

Project Containment
Purposes of the contained use

Alzheimer's disease has a strong genetic component, however much of the heritability of late-onset Alzheimer's disease is thought to be polygenic, i.e. due to multiple gene variants that individually have a weak impact on Alzheimer's disease, but when combined together have a stronger effect to increase the risk of Alzheimer's disease. To date, Alzheimer's disease polygenic risk has not been well-studied. To study the effect of Alzheimer's disease polygenic risk on cell biology, we need to capture real patient genetics in a cell model that can be cultured in a dish, and can be transformed into multiple relevant brain cell types. Therefore we propose to take blood cells donated by human patients with high polygenic risk for Alzheimer's disease, and convert ("reprogram") them into induced pluripotent stem cells (iPSC), which have the ability to be differentiated into any human cell type (i.e. pluripotency). In order to generate iPSC, four genes must be overexpressed to establish pluripotency (Oct3/4, Sox2, Klf4, cMyc), which we will achieve by transducing the blood cells with commercial Sendai virus vectors that contain the pluripotency genes. Sendai virus vectors are considered to be a high-efficiency method for establishing pluripotency of human cells, which is necessary since only limited numbers of patient samples are available.
The recipient cells are human peripheral blood mononuclear cells taken from healthy controls and Alzheimer's disease patients. The highest associated hazard is the potential for samples to harbour human blood-borne virus pathogens (e.g. HIV1), and accidental contamination of field or lab workers. Subjects are asked prior to blood collection if they have been diagnosed with a blood-borne virus, and excluded if this is the case, so the hazard applies only to subjects who have undiagnosed blood-borne virus infections at the time of the blood collection. After genetic modification, the recipient cells will transiently express the Sendai transgenes and become iPSC, with the Sendai vectors (and transgenes) completely eliminated after 5-15 passages. The risk to human health and the environment of the iPSC is extremely low, as iPSC survival and pluripotency requires specific maintenance media, and specific environmental conditions (temperature of 37 degrees Celsius and minimum of 5% carbon dioxide). If iPSC were directly injected into a human, any that survive would most likely immediately differentiate into a local specialized cell type and cease replicating. If a large number were injected into a human, teratoma formation is theoretically possible at the site of injection (Xiang et al 2019. Theranostics, 9(1): 290–310). Teratomas are self-limiting, benign tumours, and not likely to cause significant harm to health.

Host/vector system

The vector system is based on Sendai virus, in the form of the commercial kit "CTS CytoTune-iPS 2.0 Sendai Reprogramming Kit" from Life Technologies. The highest associated hazard is accidental infection of lab workers with the Sendai virus. The kit pre-packaged viruses have the ability to infect human cells, with the most likely route being mucosal exposure to aerosols. Once cells are infected, the vector lacks a fusion gene and is therefore unable to produce competent virus particles for onward transmission, except in the very unlikely event that it recombines with another RNA virus within the host.

Origin & function

The viral vectors are designed to introduce the Oct3/4, Sox2, Klf4, and cMyc transgenes to the host cell, and facilitate transient expression of the genes for the purpose of establishing induced pluripotent stem cell cultures. These genes are ordinarily expressed in embryonic stem cells, and their transient expression is sufficient to induce sustained pluripotency. There are three Sendai virus vectors that must be mixed together at the right ratio and then applied the cells to achieve iPSC reprogramming, one contains human c-Myc alone, one contains human Klf4 alone, and one is polycistronic with Klf4-Oct3/4-Sox2. The transgenes and viral vector are eliminated after 5-15 passages of the cells, with elimination confirmed by ICC and qPCR. The highest associated hazard is accidental infection of lab workers with the three viruses simultaneously when the pre-prepared kit vectors are handled, with the most likely routes being via aerosol inhalation or sharps injury, and the potential that this could cause teratoma formation at the site of infection due to cell de-differentiation and proliferation. Teratomas are self-limiting, benign tumours, and not likely to cause significant harm to health. An additional hazard is that cMyc is considered to be potentially oncogenic, thus there is a hypothetical possibility that infection with cMyc alone could cause malignant transformation of cells, although this vector will only be handled very briefly on its own since a mixture of three viruses will be added to cells. The likelihood of accidental exposure of lab workers to the Sendai vectors will be mitigated by the control measures put in place, e.g. secure storage of viruses, handling within a Class 2 biosafety cabinet with good aseptic technique, use of protective gloves and labcoat, procedures with minimal aerosol production, no use of sharp items that could puncture gloves, controlled waste disposal etc. After the transduction step there is negligible risk to human health from the vectors, since virus produced by the human cells will be fusion incompetent.

Evaluation of foreseeable effects

The GMO will originate from human blood, which carries a risk of exposing workers to undiagnosed blood-borne viruses, however the risk is low and is further minimised by wearing of appropriate PPE, handling the blood only within a Class 2 biosafety cabinet, and never using sharps in experimental procedures.

Creation of the GMO involves handling Sendai virus vectors that are capable of infecting human cells, and contains transgenes that induce pluripotency when co-expressed, including the cMyc gene that is a proto-oncogene. The risk of accidentally infecting lab workers is low and is further minimised by handling the virus only within the Class 2 virus lab facility, within a class 2 biosafety cabinet, workers wearing appropriate PPE, waste inactivation procedures, minimising production of aerosols while handling the virus/cells (e.g. not using an aspirator), and no usage of sharps.

During the reprogramming phase, the GMO human cell cultures will contain cytoplasmic Sendai vectors expressing Oct3/4, Sox2, Klf4, and cMyc genes. After 5-15 passages the vectors and transgenes will be eliminated, and elimination confirmed by ICC and qPCR. After elimination there will be no risk from the Sendai vector or transgenes. To minimise any further risk from blood-borne viruses, the induced pluripotent stem cells will be tested for the blood-borne viruses HIV1/2, Hepatitis A/B/C, and HTLV1/2, using an external pathogen testing laboratory.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste (culture media) will be inactivated with Chemgene (5% at final concentration) for at least 24 hours, and then disposed down the sink. 5% Chemgene is expected to cause 100% kill of viruses and human cells. All solid waste (tissue culture plastics) will be treated with 5% Chemgene for 24 hours before disposal into the biological waste bin that is then autoclaved. Autoclaving will take place in a Priorclave 60L Benchtop autoclave (serviced annually), set at 134°C for 25 minutes, with a temperature probe in the centre to ensure that the correct temperature is achieved to fully inactivate waste. After waste bags are autoclaved and cooled, they will be placed into “Tiger bags” and moved for disposal by SRCL into the 770L Yellow Bin / disposal area in the Hadyn Ellis Building delivery compound. The GM waste is never be left unattended – the 770L yellow SRCL bins are locked.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The University GMBA Safety Committee raised several comments that were based on minor issues and the need for clarification of certain aspects of the assessment. The Principal Investigator was therefore asked to add this additional information to the risk assessment before final approval. The information was provided before the assessment was approved internally.

The summary of the comments is provided here:

1. All those listed on the risk assessment were asked to complete the University GM induction course.
2. The GMBA required the PI to include additional information on how bloods were to obtained and the associated risks/control measures.
3. The GMBA required information on how host cells were tested to ensure they were virus-free before being moved outside of the virus suite.
4. The GMBA asked them to revise their original residual risk level for questions 3A.8, 11 & 19.
5. The GMBA asked for information on control measures for questions 3B2/3.

Human Clinical Applications

02/03/2022
## Purposes of the contained use

Gastrointestinal (GI), liver and genitourinary (GU) cancers are leading causes of cancer-related deaths in the UK and is a huge health and financial burden. Thus, developing novel therapies and diagnostics is an urgent clinical need.

The aim of this project is to understand GI/GU/liver cancer biology from the transformation of normal cells, through stem cell activation, regeneration, tumour progression and finally metastasis to gain a comprehensive view of the disease. We have four objectives which will focus on mammalian (human/mouse) GI/GU/liver epithelial cells:

1. To test the in vivo influence of Wnt, PI3K, MAPK, AR and DDR signalling on the function of normal tissue, stem cell function and tissue damage/regeneration.
2. To develop new preclinical GEMMs of GI/liver/GU cancers that can act as accurate reporters of therapeutic activity to test new diagnostic and therapeutic strategies, and to identify new molecular biomarkers.
3. To test the cell intrinsic/extrinsic influence of genes that regulate Wnt, PI3K, AR, MAPK and DDR signalling and cell function on tumour biology including initiation, growth, progression and metastasis.
4. To use the knowledge gained in the previous aims to determine the therapeutic benefit of inhibiting newly identified targets genetically (and/or pharmacologically), for the treatment of GI/GU/liver cancers.

We will manipulate target gene expression in primary/established human and normal/genetically engineered mouse GU/GI/liver/bone/stromal epithelial cells using constructs expressing cDNA to increase expression, introduce an oncogenic mutation or express a reporter construct, and/or short hairpin RNA sequences (shRNA) or small interfering RNA (siRNA) sequences to knock down expression.

This project involves the generation of gamma-retroviruses and 3rd/4th generation lentiviruses to generate stable GMMs, as well as transient approaches using commercial reagents (e.g. lipofectamine). Manipulated cells will be investigated using a variety of techniques, including morphological analysis by fluorescent microscopy, molecular biology, ex vivo organoid culture and biochemical assays. Manipulated cells will also be investigated in vivo, to determine cellular functions of genes of interest during
tumour biology (e.g. to establish their role during tumour formation/progression/metastasis) and therapeutic intervention.

Recipient or parental organism

Established or immortal GI/GU/liver/bone/stromal cells from either:
(a) GEMM (PBCre/ PSAcre, Ptenflofl, Pik3caHR, RB1, TP53, hiMyc), or
(b) human (PC3, DU145, 22RV1, PrEC, BPH1, LNCaP, PNT1/2A , AGS, MET5a, MKN7, MKN45, MKN48, MKN28, SNU-1079, TFK1, LP1, hFOB.1.19 and BMMSCs + derivatives).

Primary derived cells from GI/GU/liver and bone/stromal cells:
(a) human PDXs/CTCs (P5460 (LN-NEPC-1), 202.1/2, 27.1/2, Maitland/ Phesse PDX lines) or
(b) GEMMs (PSACre-ERT2, AhCre, AhCre-ERT2, VillinCre-ERT2, LGR5Cre-ERT2, PBCre, Tff1-Cre, CL18-CreERT2, Col1a2-CreERT2, R26;LacZ, R26;RFP)

Host/vector system

For human cells: Viruses will be grown in E1 helper cell lines (e.g. Lenti-X 293T, HEK293T, 293FT/phoenix and 911 cells).
For mouse cells: Viruses will be grown in MMLV Gag, Pol, and Env protein positive cell lines (e.g. EcoPACK HEK293)

Replication-deficient retroviral vectors:
- pCL-Ampho
- pBABE
- pcDNA
- pMSCV
- pLPCX
- pRetrosuper

Replication-deficient 3rd/4th lentiviral vectors:
- pMD2.VSV-G
- pCMVΔR8.91 pFH11UTG
- pWPI
- pMD2.G psPAX2
- pEF
- pTRE.ITS/rtTA

Origin & function

Gene silencing via shRNAs, siRNA, and DNA sequences to enforce gene expression (wt or mutant) in the following human/mouse genes:

Non-canonical WNT pathway components:
- SCRIB; Scribble Planar Cell Polarity Protein
- PTK7; Protein Tyrosine Kinase 7
- VANGl1/2; Van Gogh-Like Protein 1/2
- CELSR1-3; Cadherin EGF LAG Seven-Pass G-Type Receptor 1-3
- ROR1/2; Receptor Tyrosine Kinase Like Orphan Receptor 1/2
- CTHRC1; Collagen Triple Helix Repeat Containing 1
- PRICKLE1-2; Prickle-like protein 1/2
- FZD1-10; Frizzled Class Receptor 1-10
- LKB1; Serine/Threonine Kinase 11
- Axin2; Axis Inhibition Protein 2
- ZNRF3; Zinc And Ring Finger 3
- ZEB1; Zinc Finger E-Box Binding Homeobox 1
RNF43; Ring Finger Protein 43
Canonical Wnt pathway components:
CTNNB1; Catenin Beta 1
TCF1-4; Transgenic T cell factor 1-4
APC; Adenomatous polyposis coli
PORCN; Protein-serine O-palmitoleoyltransferase
WNT1-19; Wingless and Int-1-19
DVL1-4; Dishevelled 1-4
CDH1; Cadherin-1 (E-cadherin)
LGRs; Leucine-rich repeat-containing G-protein coupled receptors
LRPs; Low density lipoprotein receptor-related proteins
sFRPs; Secreted Frizzled Related Proteins
MYC; MYC Proto-Oncogene, BHLH Transcription Factor
MAPK pathway components:
HRAS; Harvey rat sarcoma viral oncogene homolog
KRAS; Kirsten Rat Sarcoma virus
BRAF; v-Raf murine sarcoma viral oncogene homolog B
DDR pathway components:
TP53; Tumor Protein P53
BCL2; B-cell lymphoma 2
BCL3; B-cell lymphoma 3
BRCA1/2; Breast cancer gene 1/2
ATM; Ataxia Telangiectasia Mutated Serine/Threonine Kinase
ATR; ataxia telangiectasia and Rad3-related protein
PARP1-3; poly(ADP-ribosyl)transferase 1-3
CHEK1; Checkpoint kinase 1
RB; Retinoblastoma
PI3K pathway components:
PIK3CA; Phosphatidylinositol-4,5-Bisphosphate 3-Kinase Catalytic Subunit Alpha
PTEN; Phosphatase and tensin homolog
mTOR; Mechanistic Target Of Rapamycin Kinase
PHLPPs; PH domain and Leucine rich repeat Protein Phosphatases
SGK1-3; Serum/Glucocorticoid Regulated Kinase 1-3
FKBP5; FK506 binding protein 5
RICTOR; RPTOR Independent Companion Of MTOR Complex 2
RAPTOR; Regulatory Associated Protein Of MTOR Complex 1
RABs; Ras Related Proteins
STX1-17; Syntaxin 1-17
AR pathway components:
AR; Androgen receptor
PSA; Prostate specific antigen
Immunocompromised GEMMs:
NSG; Spontaneous Prkdc mutation, Il2rg null
NSG (KbDb): Spontaneous Prkdc mutation, Il2rg null, H2-K1, H2D1 and H2Ab1 mutations
Athymic nude mice: Spontaneous FOXn1nu mutation
In addition to gene specific cDNA/shRNA/siRNA sequences, viral vectors will also contain combinations of standard viral vector components:
Reporters: LacZ, GFP (green fluorescent protein), YFP (yellow fluorescent protein), RFP (red fluorescent protein, Cherry, dTom reporters, luciferase, and AR,
non-homologous end joining/Homologous recombinationNHEJ/HR GFP I-SceI and TET-ON/OFF constructs.
Antibiotic resistance cassette: Puromycin, Kanamycin Gentamicin, Neomycin, Hygromycin, Zeomycin
Promoter: U6, CMV, EF1a
Internal ribosome entry sequence

Evaluation of foreseeable effects

The viral vectors used in this project pose a low biohazard risk as although they are capable of transducing human cells, the virus is replication incompetent. Replication requires sequences coding gag, pol, env, and rev, which are absent from the viral vectors used, and would be required to be provided in trans by helper constructs or packaging cell line. There is no evidence to suggest that the recombinant virus may alter susceptibility to host defence mechanisms. All DNA components of the recombinant virus are routinely used in biological research, and are not known to have effects on susceptibility of host immune systems. To reduce risk in this project we have considered foreseeable circumstances where there is a risk of transmission of the vectors.

Routes of transmission:
Needle stick – needles will not be used in these experiments (needles will only be used to inject genetically modified cells into mice with cells that are free from virus).
Inhalation - opening a vial or spillage of the virus could cause an aerosol of viral particles. As such, all tasks where there is a risk of aerosols being produced will be carried out inside the Class II microbiological safety cabinet.
Skin contact - The viral vector could be transmitted through contact with the skin, transmission into the blood stream or to airways and eyes. These risks will be minimised following the standard operating procedure of the virus suite and use of double gloves to minimise risk of skin contact through piercing of gloves. The only consequence of exposure we envisage is some irritation/inflammation caused by the immune response which may be caused by the vector. Normally, if an immediate action is taken, i.e. washing the exposed area with detergents, no significant consequence will occur.
The viral suite will have designated lab coats which also will be stored in the viral room.
Standard working procedures and emergency instructions (phone numbers including after work phone numbers) will be clearly posted to the walls on laminated paper. A spill kit will be provided in the room.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All animals are contained within the JBIOS Biosciences, T2, IVC suite and Heath Park facilities at Cardiff University. Handling and disposal procedures of animals will adhere to the standard operating procedures of this facility. Waste will be disposed of by an approved waste route. Animal carcasses will be disposed of by an approved route. Good laboratory practice will be employed. Good practice standards in the animal house will be used to ensure that all door barriers are maintained.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Preferred local deactivation/disposal pathway:
1) Chemical disinfection by Chemgene or Virkon.
Liqid waste (e.g. culture media) will be inactivated with 5% Chemgene or Virkon® (final concentration 1%) for at least 1 hour (typically overnight) - according to manufacturer’s instructions.
All solid waste (tissue culture plastics) will be treated with 5% Chemgene inside the Class 2 MSC (or a sealed jar) for at least 2 hours before being drained, rinsed and disposed of (double bagged). Waste is initially autoclaved (ante-room, Level 3, HEB, adjacent to the viral suite), followed by incineration (NB: Syringe barrels are not autoclaved after soaking, draining and rinsing, instead they are disposed of in a sharps bin and sent for incineration).
2) Waste placed into autoclave bag.
Chemically deactivated waste will be placed into autoclave bags (double bagged) and labelled GM180104.

02/03/2022
3) Waste autoclaved locally using the waste cycle at 134°C for 25 mins. Solid waste will be autoclaved in the designated autoclave located immediately outside of the viral suite before being placed in a yellow ‘Tiger bag’ and disposed of as ‘offensive waste’ (HL180104) by Stericycle/SCRL. The autoclave is serviced annually and a twelve-point thermocouple test is performed annually. Waste material will be inactivated using the waste cycle at 134°C for 25 mins. All staff operating the autoclave will have been trained in manual handling and are also trained in appropriate spillage procedure. 1% Virkon® or 5% Chemgene is the disinfectant to be used in case of inactivated waste being spilled in or out of the autoclave. [NB: Chemgene is primarily used on the surface of the Class 2 MSC, as Virkon has been found to rust the hoods].

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The University GMBA Safety Committee required several minor corrections/additions to be made to the risk assessments before they were internally approved.

For GM130/807:
1. Several typographical errors were asked to be corrected.
2. They were asked to highlight processes where aerosols were likely to be produced and how they were to be controlled.
3. They were asked to add a brief paragraph into 3A.1 on retrovirus
4. Q3A.13 - an inconsistency in the information on virus tropism was asked to be corrected.
5. Q3B.8 - they were asked to briefly discuss the risk of recombination with other viruses

For GM130/808:
In section 2 (project description) they were asked to confirm that transduced cells administered to the animal models were virus-free. They were also asked briefly explain how the cells would be administered.

Project Ref 130/21.3
Investigation of the effects of gene knock-down on Huntington's disease molecular phenotypes

To examine the effects of lowering the expression of specific genes on cellular and molecular phenotypes associated with Huntington's disease.

Recipient or parental organism

1. U20S (ATCC HTB-96) and 2. a series of induced pluripotent stem cells.

The U20S cells have a stable insert that expresses a human huntingtin exon 1 sequence containing an expanded CAG repeat of 18, 50 or >100 CAG, fused to p2A (66bp) followed by an in frame luciferase reporter (Nanoluc 516bp), stop codon, CMV promoter and DS-Red. The induced pluripotent stem cell lines are derived from patients with Huntington’s disease. We have several lines available with HTT exon 1 CAG starting lengths of 22, 60, 109, 125 and 180. Our main line is the HDQ109i line, derived from a juvenile patient, that originally had 109CAG and its isogenic pair, HDQ22i with 22CAG.

Host/vector system

We will infect the cells with human shRNAs against genes of the DNA repair pathways including: MSH3, MLH1, FAN1, POLQ, MLH3 and potentially others in the future. We will use the MISSION TRC shRNA clones from Merck. We will receive the lentiviral transduction particles, that are self-inactivating replication incompetent viral particles. Individual constructs are provided as a 200 μL frozen stock containing a minimum of 1.0 x 106 TU/ml.

Origin & function

We will use the MISSION shRNA lines which are lentiviral particles. These belong to the retrovirus family and are thus characterized by their ability to convert their RNA genome to DNA by reverse transcription. They contain three major coding domains: gag (encodes the structural proteins matrix, caspid and nucleocaspid), pol (encodes protease,
reverse transcriptase and integrase) and env (encodes surface and transmembrane components of the viral glycoprotein). Upon entry into the cell, the virus replicates through the interaction of cellular and viral components in order to produce a viable virus. The major concerns regarding lentiviral vectors are 1) Potential generation of replication competent lentiviruses, 2) in vivo recombination with lentiviral sequences and 3) insertion of proviral DNA in or close to active genes may trigger tumor initiation or promotion. Consequently, safety features have been built into the synthetic vectors to be used by a Contract Research Organisation.

Each MISSION® shRNA clone is constructed within the lentivirus plasmid vector pLKO.1-Puro or TRC2-pLKO-Puro followed by transformation into Escherichia coli. The pLKO.1–Puro and TRC2-pLKO-Puro vectors contain bacterial (ampicillin) and mammalian (puromycin) antibiotic resistance genes for selection of inserts in either bacterial or mammalian cell lines. Each gene is represented by multiple individual shRNA constructs or clones targeting different regions of the gene sequence. Therefore, a range of knockdown efficiency, with at least one construct from each gene set being >70%, can be expected when using these clones. This allows one to examine the effect of loss of gene function over a range of gene knockdown efficiencies. Each shRNA construct has been cloned and sequence verified to ensure a match to the target gene. We will be sent the clones in the lentiviral transduction particle format. Safety features of the recombinant replication-deficient lentivirus include:

(1) Splitting of the viral genome into three plasmids such that if the recombination between the different plasmids were to occur, no wild type HIV can arise. Furthermore, the virus is pseudotyped which cannot cross cell layers and can only infect the primary cell layer of encounter.

(2) Deleting the genes encoding accessory factors of HIV, known to be essential for HIV pathogenecity (Nef, Vif, Vpr, & Vpu).

(3) Using of self-inactivating (SIN) vectors that have inactive LTRs, thus preventing potential transcriptional activation of any (onco)genes downstream of the integration site.

The improvements in vector technology make it highly unlikely for a viral disease including HIV to occur as a consequence of an accidental exposure to a lentiviral vector. As a result, HSE have deregulated to Level 1. However, the high efficiency of transduction by these vectors could pose an increased risk for accidental introduction of potentially hazardous genes (e.g. oncogenes) into the experimenter making consideration of risk associated with the expression products a high priority. This is outlined below for the specific genes to be undertaken in the proposed work and extrapolated to other genes that may be used in the future. Any additions to the work will be notified to the University GMBA committee for review.

Scale of work

This assessment covers tasks undertaken at a scale such that less than 100 microlitres of purified lentiviral stock with a titre of up to 5x 10^9 will be handled at any one time. The equipment used in handling the virus, such as contained cell culture vessels will minimise the risks of accidental spillage. In the event that spillage does occur the quantity of a resultant spill will be such that it can be disinfected and a clean up operation performed within the confines of the laboratory where the spillage has occurred and without significant risk of escape to the environment. The University has a standard spillage protocol and a spillage kit available in the virus suite (see 12 below).

Evaluation of foreseeable effects

Describe the nature of the inserted genes and the properties of the final genetically modified viral vector.

We plan to generate stable cell lines expressing shRNA from a number of DNA repair genes of interest because they carry variants that modify the age at onset of Huntington’s disease. The read out in our U2OS system will be somatic expansion of the inserted HTT CAG repeat tract. We aim to achieve stable knock down of these genes in the cells. In each case the expression product is biologically active but not expected to have a deleterious effect because its concentration would not approach normal body levels. Only MLH1 is a known human tumour suppressor gene: the evidence for the other genes being tumour suppressors is not robust and they do not show any selection against damaging variants at the population level.
(1) MSH3

MSH3 forms an obligate heterodimer with MSH2 to form MutSα, part of the post-replicative DNA mismatch repair sequence. MutSα initiates mismatch repair through recognition of the lesion then recruiting other proteins in an ATP-dependent fashion. Defects in this gene are a potentially associated with susceptibility to endometrial cancer and Familial Adenomatous Polyposis 4, though there is no evidence of selection in human populations against deleterious or loss of function variants of MSH3.

Elevated microsatellite alterations at selected tetranucleotide repeats (EMAST) is a type of microsatellite instability that is enhanced with MSH3 reduction. Furthermore, genetic reduction or mutation of MSH3 has been reported to stabilise trinucleotide repeat expansion sequences and conversely, overexpression of MSH3 has been shown to exacerbate repeat instability. Msh3 KO in mice is well tolerated and does not shorten life span or induce oncogenic transformation.

Reduction or removal of MLH1 abrogates somatic instability of trinucleotide repeats in vitro and in vivo.

(2) FAN1

FAN1 (FANCD2/FANCI associated nuclease 1) (KIAA1018) is an enzyme that is encoded by FAN1. FAN1 is a structure dependent endonuclease that is thought to play a role in the Fanconi Anemia pathway. FAN1 protein possesses endo- and exo-nuclease functions to remove interstrand DNA crosslinks. The presence of the FANCD2/FANCI complex is unaffected by knockdown of FAN1 as it is a downstream contributor to the pathway.

Indeed, FAN1 is not confidently categorised as a FA gene given mild ICL agent sensitivity and chromosomal fragility with microdeletions affecting the FAN1 chromosomal location. Mutations in FAN1 can result in chronic kidney diseases such as recessive karyomegalic interstitial nephritis (KIN) and neurological conditions, and it has been associated with hereditary colorectal cancer due to defective DNA repair. There is no evidence of selection in human populations against deleterious or loss of function variants of FAN1.

Variants of FAN1 with increased expression appear to stabilise trinucleotide repeat expansion sequences and conversely, variants with reduced expression or function of FAN1 have been reported to exacerbate repeat instability. Fan1 KO in mice leads to renal tubular karyomegaly with polyploidy and defects in ICL repair with age, which is exacerbated by treatment with ICL-inducing agents.

Reduction or removal of FAN1 promotes somatic instability of trinucleotide repeats in vitro and in vivo.

(3) MLH1

The MLH1 gene encodes MutL homolog 1 protein and is commonly associated with hereditary non-polyposis colorectal cancer in addition to other cancer syndromes. This protein is one component of a system of DNA mismatch repair proteins that work co-ordinately in sequential steps to initiate repair of mismatch lesions in humans. MLH1 is one of two obligate heterodimer units in the MutL proteins and is common to all three isoforms: MutLα is formed of MLH1 and PMS2; MutLβ consists of MLH1 and PMS1 while MutLγ comprises MLH1 and MLH3. In addition to cancer-causing mutations, MLH1 can also be silenced through epigenetic alterations. Mlh1 KO, cKO or G67R knock in mice have high levels of molecular defects together with the presentation of cancer and fertility defects and a reduced lifespan.

To reach the tissues most susceptible to reduced MLH1 expression in the gut the lentiviral particles would need to be ingested. This is unlikely in the laboratory setting where the viral particles will be used in small quantities in an appropriate Class 2 environment. There is an association with an increased risk of other cancers including skin cancers. The skin is the most accessible organ but if the viral particles reach the skin they would be in small amounts and the skin itself would act as a barrier to reaching any deeper layers to enter cells with any replicative potential. In addition any spill would be small as we are using small quantities and can be washed off. If ingested viral particles would be broken down in the digestive tract. The risk of the MLH1 shRNA reaching the organs associated with
The MLH3 gene encodes MutL homolog 3 protein which together with MLH1 functions as an obligate heterodimer, MutLalpha. Somatic mutations in this gene occur in tumours exhibiting microsatellite instability and germline mutations have been linked to hereditary nonpolyposis colorectal cancer type 7. The MLH1-MLH3 heterodimer is an endonuclease that makes single strand breaks; and can bind specifically to Holliday Junctions. Knockout of Mlh3 has been shown to retard somatic instability of trinucleotide repeats in mouse models. It is also associated with molecular and phenotypic defects albeit to a much lesser extent than Mlh1 KO mice. The risk of the MLH3 shRNA reaching the organs associated with cancers that it might contribute to is very low. Knock out of MLH3 prevents meiosis, but the chance of the viral particles reaching the gonads in any quantity is minimal as we are using small quantities and appropriate PPE.

DNA polymerase theta is encoded by the POLQ gene and plays a role in microhomology-mediated end-joining, which is an alternative nonhomologous end-joining pathway triggered in response to double stranded DNA breaks. The polymerase activity is highly promiscuous and low-fidelity, it is also involved in somatic hypermutation of immunoglobulin genes. Pol is required for the viability of BRCA- mutated cancer cells. Polq KO in mice leads to hypersensitivity to radiation and DNA double stranded breaking agents. There is no evidence of selection in human populations against deleterious or loss of function variants of POLQ.

The viral vectors will only produce shRNAs. These give hypomorphs and not complete knock out of the gene product. None of the genes proposed to be used here are oncogenes or proto-oncogenes. The conditions of virus generation and manipulation are extremely well controlled, the virus will only be present in low volumes and no human will be exposed live virus particles in this work.

The most risk in this application is associated with knock down of MLH1. MLH1 heterodimerizes with PMS2 to form MutL alpha, a component of the post-replicative DNA mismatch repair system (MMR). DNA repair is initiated by MutSalpha (MSH2-MSH6) or MutSbeta (MSH2-MSH3) binding to a double strand DNA mismatch, then MutL is recruited to the heteroduplex. Assembly of the MutL-MutS-heteroduplex ternary complex in the presence of replication factor C and proliferating cell nuclear antigen (PCNA) activates the endonuclease activity of PMS2. This introduces single-strand breaks near the mismatch and generates new entry points for exonuclease EXO1 to degrade the strand containing the mismatch. DNA methylation would prevent cleavage and therefore assure that only the newly mutated DNA strand is going to be corrected. MutL alpha (MLH1-PMS2) interacts physically with the clamp loader subunits of DNA polymerase III, suggesting that it may play a role to recruit the DNA polymerase III to the site of the MMR. MLH1 is also implicated in DNA damage signalling, a process which induces cell cycle arrest and can lead to apoptosis. MLH1 also heterodimerizes with MLH3 to form MutL gamma which plays a role in meiosis. If the mismatches are not repaired, DNA damage accumulates. Many cells will not replicate if the damage is not repaired but in a proportion of cells the damage can eventually lead to uncontrolled growth and cancer.

MLH1 has reduced expression in hereditary non-polyposis colon cancer (HNPCC) – and people with Lynch syndrome which can be caused by loss of function or damaging mutations in MLH1 – are at high risk of HNPCC and of a number of other cancers including increased risk of cancers of the stomach, small intestine, liver, gallbladder ducts, urinary tract, brain, and skin. This is the main risk associated with reducing expression of MLH1.

In addition, to cause any substantial risk of harm the viral particles would need to replicate and these particles are replication deficient and rendered incapable of infecting cells. It is possible that recombination events could render
them replication efficient again, but more than one recombination event would need to occur as several genes required for replication have been removed, and as each recombination event is unlikely, the chances of this happening are low.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

This assessment covers tasks undertaken at a scale such that less than 100 microlitres of purified lentiviral stock with a titre of up to 5x 10^9 will be handled at any one time. The equipment used in handling the virus, such as contained cell culture vessels will minimise the risks of accidental spillage. In the event that spillage does occur the quantity of a resultant spill will be such that it can be disinfected and a clean up operation performed within the confines of the laboratory where the spillage has occurred and without significant risk of escape to the environment. The University has a standard spillage protocol and a spillage kit available in the virus suite (see 12 below). Maximum volumes of 100mls medium containing diluted viral particles for each experiment, though most experiments will use individual culture wells of 1-2ml of medium.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be disinfected using Chemgene HLD4L concentrate (Didecyldimethylammonium Chloride, Propan-2-ol, C9-C11 Alcohol Ethoxylate, Polymeric Biguanide Hydrochloride and Alkyl (C12-16) Dimethylbenzylammonium Chloride). This gives 100% kill. HLD4 formula is Article 95 compliant and has been developed with the Biocidal Products Regulations (BPR), REACH, CLP (Classification of Labelling and Packaging) and CDG (Carriage of Dangerous Goods) regulations. HDL4 disinfectants are certified Sporicidal, Mycobactericidal, Virucidal, Fungicidal and Bactericidal under EN protocols. Chemgene is non-corrosive and non-fragranced. This is the preferred disinfectant for use in the class II hood (2% Chemgene) as well as disinfecting wastes (5% Chemgene). Liquid waste will be inactivated with 5% Chemgene for 24 hours before disposal. Tissue culture waste will be treated with 5% Chemgene for 24 hours before disposal into a biological waste bin that is subsequently autoclaved. All waste is identified with the name of the responsible PI and the researcher responsible for it, and the GM risk assessment identifier. Solid waste is kept locked in the virus suite until autoclaved.

Solid waste will be autoclaved in a Priorclave 60L Benchtop autoclave. The machine is serviced annually and a twelve-point thermocouple test is performed annually. The autoclave includes a temperature probe to ensure that the waste reaches the appropriate temperature to inactivate all the waste. Users are trained in manual handling and in spillage procedures, PPE is worn with dedicated lab coats for the viral suite, double gloves and a spillage kit available. The autoclaved waste is disposed of through the building biological waste route which has designated bins for biological waste housed in a locked compound.
The Committee debated the classification of this activity as Prof Jones had originally proposed Class 1 however after consideration of SACGM Guidance Note 2, Section 2.2 Point 24, with the potential of downregulating targeted genes it was agreed that this was a Class 2 Activity.

### Project Ref 130/21.4

- **Date Ackn'd**: 25/11/2021
- **CU2 Project Title**: Introduction of leukocyte-homing molecules to mammalian cells using retroviral and lentiviral vectors
- **Class**: Class 2
- **CultureVolClass2**: < 1 Litre
- **Non-GMM Consent Granted**: Yes
- **Date Project Ceased**: 25/11/2021
- **Withdrawn**: No
- **Tick if notifying a connected programme of work**: Yes

### Purposes of the contained use

The aim of this research is to boost the immune system to fight cancers and viruses by improving the recruitment or ‘homing’ of white blood cells such as T-cells to diseased tissues. Adoptive T-cell therapy is already being used in the clinic to treat cancers and chronic virus infections, but it does not work in all patients. This shortfall in
GM mice are either deficient in genes or overexpress genes that prevent normal functioning of the immune system. They are generated by intranuclear injection of synthetic

house for testing, the GM cells will be tested and analysed to ensure there is no residual virus remaining. (regarding human cell targeting vectors), the genes may become active and induce immune responses. However appropriate safety measures put in place (i.e. PPE and Cat 2 safety cabinet use and SCANtainer containment of mice receiving GM cells) will render the likelihood of viral contact with operator leukocytes extremely remote. Moreover, before transfer of the GM cells to the animal house for testing, the GM cells will be tested and analysed to ensure there is no residual virus remaining.

Recipient or parental organism

Cell lines to receive the genetic material will be designated viral packaging cell lines such as HEK293T and Platinum-E cells which are widely used in the field for the production of recombinant lentiviral and retroviral particles. Cell lines to subsequently receive the harvested recombinant virus will be immortalised human or murine immune and tumour cell lines such as Molt3, Jurkat, NALM6, B16-F10, LLC and MC38. Additionally, the recombinant virus will be delivered to primary human PBMCs and primary mouse T-cells. Once insertion of the gene of interest has been confirmed in the relevant cell lines (and in vitro analysis of activities and behaviours have been ascertained), the modified cell lines will then be introduced into wild type and GM mouse models for in vivo analysis. GM mice to be used will be deficient in genes required for a functioning adaptive immune system and will of no increased risk than wild type mice.

Host/vector system

Recombinant viruses to be constructed will be based on pantropic retroviral or lentiviral delivery systems depending on the specific size, design and preferences for the relevant gene insert. Regarding retroviral platforms, all retroviral vectors to be used in this project are derived from moloney murine leukaemia virus, myeloproliferative sarcoma, and murine stem cell virus (MSGV). They contain viral LTRs on a plasmid backbone and do not produce viral proteins due to a lack of gag, pol and env genes (rendering the viral particles non-replicative). Specific ecotropic packaging cell lines are required to provide the viral proteins required for packaging of retroviral particles. Regarding the lentiviral vectors, the ones to be employed are based on human immunodeficiency virus type 1 (HIV-1). All vectors are third generation lentiviral systems with tat gene deletion. An altered 3’LTR renders the vector “self-inactivating”, and a heterologous coat protein (e.g., VSV-G) is used in place of the native HIV-1 envelope protein to enable transduction of a wider range of cell types. All lentiviral vectors to be used are devoid of replicative capacities as are lacking regulatory and accessory genes such as tat, vpr, vpu, vif and nef, gag, pol and env.

Origin & function

The genes to be introduced are associated with immune cell function and homing mechanisms in humans and mice respectively. Specifically, these include leukocyte cell surface proteins involved in antigen presentation, antigen recognition, immune cell activation, adhesion and homing (e.g., CD8, CD19, CARs, TCRs, L-selectin, L-selectin mutants) and transmembrane and intracellular signalling proteins (e.g., 4-1BB, CD3z,) which are components of the signalling platform downstream of the surface proteins. Additionally, in some instances intracellular and surface reporter genes will be introduced (e.g. luciferase, dsRED, GFP, NGFR) for the purpose of experimental monitoring and evaluation of cellular activity. GM cells will be evaluated in vitro and following administration to either wild type or GM mice.

Evaluation of foreseeable effects

The genetic cargo of the viral particles (to be delivered to the cells) will have no impact, influence, or alter the behaviour of these well-established viral delivery systems. It is anticipated that the genetic modification of the cells (via viral integration of the genes of interest) will improve immune cell recognition of antigens. Through the introduction of molecules and complexes responsible for immune cell activation, adhesion and homing it is expected that the modification will enhance the ability of immune cells to recognise and destroy their target cells. Moreover, they should have improved transport through the lymph and vasculature to target sites of tumours and/or chronic inflammation. As a result, the GMO cell lines will hypothetically have an enhanced ability to deal with chronic infection and cancerous tumours in vivo.

The highly attenuated lentiviral and retroviral vectors to be used have shown sufficient biosafety in the research field. The probability of viral vector reversion to wild-type is extremely unlikely, therefore there is minimal risk of viral replication in infected cells or other cell lines (and, as a result, will not compromise the immune system of an operator if exposed). Additionally, the recombinant viruses pose no oncogenic risk as they will not contain any oncogenes. As the genes to be introduced are involved in natural immune cell responses, there is an extremely small risk that, if successfully integrated into a worker’s leukocytes (regarding human cell targeting vectors), the genes may become active and induce immune responses. However appropriate safety measures put in place (i.e. PPE and Cat 2 safety cabinet use and SCANtainer containment of mice receiving GM cells) will render the likelihood of viral contact with operator leukocytes extremely remote. Moreover, before transfer of the GM cells to the animal house for testing, the GM cells will be tested and analysed to ensure there is no residual virus remaining.

GM mice are either deficient in genes or overexpress genes that prevent normal functioning of the immune system. They are generated by intranuclear injection of synthetic...
DNA into either embryonic stem cells or isolated blastocysts which is either incorporated into the genome (transgene) or deletes the targeted gene from the genome (knockout). GM Stem cells/blastocysts are transferred into pseudopregnant mice and offspring genotyped for the targeted gene and interbred to homogeneity. The resulting GM mice are immunodeficient (e.g. SCID, RAG knockouts) and pose no increased risk over and above wild type counterpart.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Mice will be housed in individually ventilated SCANtainers in rooms designated for Class 2 work. Mice will be handled only in Class 2 biological safety cabinets by fully trained staff wearing full PPE. Warning signs will be added to any cages that houses animals that have received GM cells. All biological and non-biological material exposed to mice received transfused GM cells will be double-bagged and disposed of by incineration. Work with mice transfused with GM cells will only be carried out by fully trained staff.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All contaminated waste will be handled in Class II safety cabinets until safely sealed. Contaminated solids (e.g. pipettes) will be immersed in a sealed container of Haz Tab solution (Triclosene Sodium Dihydrate) with 1 HazTab tablet per 100 mL used. Waste will be immersed in this solution for a minimum of 24hr prior to transferring to a container for autoclaving and/or incineration. Liquid waste will be dealt with in a similar way, whereby liquid waste containing GMM will be poured into a container housing Haz Tab solution, sealed and left for 24 hours to ensure total destruction of viral particles prior to disposal. Triclosene Sodium Dihydrate solution (Haz Tabs) is common-place in laboratories to disinfect surfaces from viral contaminants with 100% kill rate. HazTabs are already in use for this purpose in other laboratory in the Henry Wellcome Building of Cardiff University. The tissue culture cabinet and any potentially contaminated areas will be disinfected with chlorine-based disinfectant. The safety cabinets will then additionally be disinfected with 70% ethanol and a UV lamp used in the hood after each operation. Annually, the hoods are decontaminated with formaldehyde by designated personnel and serviced. Additionally, the laboratory premises are routinely inspected by health and safety officers.

N

**Please enter comments on the GM safety committee on the risk assessment**

The GMBA Committee were in agreement that GM130/813 was a Class 2 GM activity, however they did have some queries and asked for clarification on a number of issues, including how the transfected cells were tested to ensure that they were virus free and control measures to be used during aerosol formation. The Committee were satisfied that the use of GM animals in GM130/816 was a Class A or Class 1 GM activity, however appropriate control measure would need to be used when the animals were injected with virus free cells. Further information was provided and the Committee were satisfied that the risk assessments were suitable and sufficient.

### Project Additional Information

**Purposes of the contained use**

Recombinant vaccinia viruses will be used for several purposes:

1. To immunise mice with recombinant antigens
2. To measure immunity against recombinant antigens.
3. To infect cells in vitro for the purpose of screening immune responses.

The antigens to be used represent non-functional proteins either of viral or mammalian origin.

Laboratory work involving recombinant vaccinia viruses will be carried out at ACGM Containment Level 2 with the use of a microbiological safety cabinet. In laboratory situations, sharps will not be used and workers will wear gloves at all times. In the case where animals will be inoculated with recombinant vaccinia viruses, virus will be delivered via the intraperitoneal, intravenous or subcutaneous routes. In all cases needles will be used. Workers involved in inoculation of animals will be trained to a high level to minimise the risk of needle-stick injuries. The highest inoculum used will be 10 million plaque forming units per mouse. Vaccinia virus infection does not spread within mouse or human communities. The virus does not cause persistent infection since it lyses cells upon infection. Infection with recombinant vaccinia virus may however lead to some blistering or scabbing during the acute phase of infection. Tissues recovered from infected animals will be manipulated within microbiological safety cabinets and animal carcasses will frozen and later disposed of by incineration.
The recombinant vaccinia viruses to be used have already been constructed through homologous recombination of plasmid DNA (pSC11) into the thymidine kinase gene of vaccinia virus (Western Reserve, WR). Inserted genes encode for: 1) mouse melanocyte antigens; 2) the glycoprotein of murine leukaemia virus; 3) influenza antigens; 4) antigens from lymphocytic choriomeningitis virus and 5) non-functional murine proteins. A complete list is shown in Appendix 1. These inserted genes pose no risk. Indeed, insertion of these genes into vaccinia virus WR, reduces the virulence of the virus 10,000 x (Buller et al. 1985. Nature 317: 813).

Host/vector system

The recombinant vaccinia viruses to be used have already been constructed through homologous recombination of plasmid DNA (pSC11) into the thymidine kinase gene of vaccinia virus (Western Reserve, WR).

Origin & function

Inserting genes encode for: 1) mouse melanocyte antigens; 2) the glycoprotein of murine leukaemia virus; 3) influenza antigens; 4) antigens from lymphocytic choriomeningitis virus and 5) non-functional murine proteins. A complete list is shown in Appendix 1. These inserted genes pose no risk. Indeed, insertion of these genes into vaccinia virus WR, reduces the virulence of the virus 10,000 x (Buller et al. 1985. Nature 317: 813).

Evaluation of foreseeable effects

Use of recombinant vaccinia viruses within the laboratory will be confined to a class II microbiological safety cabinet. In some situations it will be necessary to infect mice and therefore to transport viruses from the laboratory to the animal house. Vials containing vaccinia viruses will be transported from the laboratory to the animal house within sealed containers. The possibility of spillage from sealed containers is very unlikely. In the event that a spillage does occur, the spillage will be dealt with according to local rules at the University of Wales College of Medicine.

With regards to environmental risks, it is known that there was no colonisation of domestic or wild animals in the UK following widespread administration of vaccinia virus to humans in the smallpox eradication campaign, nor has the recombinant vaccinia virus that has been used to control rabies in part of Belgium and France led to colonisation of wild species. There is no reason to believe that recombinant vaccinia viruses produced in this work are any more likely to survive and become established in the environment than the wild-type virus. Thus, taking into account the control measures assigned above, the overall risks to the environment from the modified organisms produced in this work are effectively zero. Therefore no additional containment or control measures are considered necessary to protect the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables including plasticware and pipettes will be autoclaved for at least 15 minutes at 121-130 degrees C. Subsequently autoclaved waste will be disposed of by incineration with other clinical waste. Liquid waste will be treated with Hycolin for 30 minutes prior to discharge to drains.

Animal bedding will be autoclaved and animal carcasses will be destroyed by incineration.

Degree of Kill:
Autoclaving, effectively 100% kill (annual validation)
Incineration, effectively 100% kill (licensed incinerator)
Additional detail required in environmental assessment - now added. Advice should be sought regarding avoidance of handling virus by persons with sensitive skin conditions, eg eczema. Agree with assessment as Class 2 activity requiring Containment Level 2 facilities.

Project Additional Information

Purposes of the contained use

This project aims to use replication deficient adenoviral vectors to investigate intracellular signalling in cell lines and in human cells from diseased synovial tissue. This replication deficient adenoviruses can still infect cells but not replicate within them. Thus, if some person would deliberately or accidentally inhale these viruses or rub them into his eyes, a mild rhinopharyngitis (similar to a common cold) or conjunctivitus (harmless eye inflammation), lasting a few days at most, would ensue. Many people have immunity due to previous exposure, however, as this is a common pathogen. The project will not involve the production of new recombinant adenoviruses on site using vector DNA, but will involve growup of adenoviruses from imported stock using the 293 cell line, and infection of cells.

Recipient or parental organism

No in vivo studies are planned.

Host/vector system

This project aims to use replication deficient adenoviral vectors to investigate intracellular signalling in cell lines and in human cells from disease synovial tissue. These replication deficient adenoviruses can still infect cells but not replicate within them. Thus if some person would deliberately or accidentally inhale these viruses or rub them into his eyes, a mild rhinopharyngitis (similar to a common cold) or conjunctivitus (harmless eye inflammation), lasting a few days at most, would ensue. Many people have immunity due to previous exposure, however, as this is a common pathogen. The project will not involve the production of new recombinant adenoviruses on site using vector DNA, but will involve growup of adenoviruses from imported stock using the 293 cell line, and infection of cells.
into his eyes, a mild rhinopharyngitis (similar to a common cold) or conjunctivitus (harmless eye inflammation), lasting a few days at most, might ensue. There could be no other complications unless a massive dose of virus was deliberately injected intravenously. The project will not involve the production of new recombinant adenoviruses on site using vector DNA, but will involve growth of adenoviruses from imported stock using the 293 cell line, and infection of cells. These imported stocks are all from the Kennedy Institute of Rheumatology and have been carefully monitored to exclude contamination with wild-type adenovirus.

Origin & function

It is primarily planned to use

1) A replication deficient adenovirus with no insert (as a control).
2) A replication deficient adenovirus transferring the beta-galactosidase gene. This is a non-harmful molecule that is useful for determining viral infectibility.
3) A replication deficient adenovirus transferring the green fluorescent protein gene. This is a non-harmful molecule that is useful for determining viral infectibility.
4) A replication deficient adenovirus transferring the gene for I-kappa-B the natural inhibitor of NF-kappaB, an anti-inflammatory molecule.
5) A replication deficient adenovirus transferring the dominant negative form of the I-kappa-B kinase-2, a modification that would also be expected to have an anti-inflammatory effect.
6) A replication deficient adenovirus transferring the dominant negative form of the p38 MAP kinase, a modification that would also be expected to have an anti-inflammatory effect.

All of these have been constructed from plasmids at the Kennedy Institute, London. These molecules are all anti-inflammatory rather than pro-inflammatory, as would be expected if they would be any use as treatment for inflammatory diseases. No adenoviruses with oncogenic genes or sequences will be used. No animal work is planned.

The adenoviral work will take place in a category II facility with a class II vented hood designated for adenoviral work. A locked, designated -70 degree virus freezer will be used for virus storage. There is a designated incubator for infected cells.

Evaluation of foreseeable effects

All vectors used will be based on adenovirus serotype 5, and will be replication deficient due to disabled in the E1 region by an insert that prevents the packaging of viable particles. The E1 region is replaced with inserted foreign DNA. These replication deficient adenoviruses can still infect cells but not replicate within them. Thus if some person would deliberately or accidentally inhale these viruses or rub them into his eyes, a mild rhinopharyngitis (similar to a common cold) or conjunctivitus (harmless eye inflammation), lasting a few days at most, might ensue, in case the person infected did not, like the majority of the population, already possess antibodies to the wild type virus. All inserted gene products will be anti-inflammatory rather than the opposite. None will have mutagenic or oncogenic effects. They should not cause any excess risk. There will be no alteration of existing pathogenic tracts, except for the replication deficiency mentioned above, which will not cause any hazard but rather the opposite. Since all inserted gene products in this study will be anti-inflammatory rather than the opposite, and none will have mutagenic or oncogenic effects, they should not cause any excess risk compared with an adenovirus without an insert. There is thus a risk of very slight and time limited harm should a non-immune person be exposed to these adenoviral vectors.

It is known that recombinant adenovirus reverts to wild type at a low frequency (10^-7). To monitor this and exclude any risk, cytopathic assays are regularly used every 2-3 months to check for replication-competent virus. Since all inserted gene products in this study will be anti-inflammatory rather than the opposite, and none will have mutagenic or oncogenic effects, they should not cause any excess risk compared with an adenovirus without an insert.

The parental virus is ACDP Hazard Group 2. Since all inserted gene products in this study will be anti-inflammatory rather than the opposite, and none will have mutagenic or oncogenic effects, they should not cause any excess risk compared with an replication deficient adenovirus without an insert. Therefore the provisional containment level is 2.

It is not thought that these replication incompetent adenoviruses would pose a risk to animals or plants in the environment, particularly as good care is taken to protect human health. Nor would there, as these viruses will be kept in a locked freezer, be any risk of exposure in a fire, landslide or flooding.

Since the decision was made to apply containment level 2, the activity class is confirmed as Class 2.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No application for derogation is made.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste will be autoclaved prior to incineration. The laboratory is separated from the rest of the building by means of a lockable door. Culture medium and liquid waste should be disinfected using 10% Microsol, with exposure at least 1h prior to disposal in the sink.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

The committee was in principle satisfied with the risk assessment for this project and that the work requires Containment level 2 facilities and is class 2.

**Date Ackn’d** 26/04/2005

**CU2 Project Title** GENERATION OF DEFINED DELITIONS IN THE HUMAN CYTOMEGALOVIRUS (HCMV) AND HUMAN HERPESVIRUS-6 (HHV-6) GENOMES WILL BE PERFORMED TO INVESTIGATE GENE FUNCTION

**Class** Class 2

**Culture Vol Class 2** 1-50 Litres

**Non-GMM Consent Granted** Not Applicable

02/03/2022
Generation of defined deletions in the human cytomegalovirus (HCMV) and human herpesvirus-6 (HHV-6) genomes will be performed to investigate gene function. To further analyse betaherpesvirus gene function sub-genomic or cDNA fragments will be subcloned and expressed using a range of prokaryotic and eukaryotic expression vectors.

HCMV and HHV-6 are both ACDP category 2 pathogens that are both predicted to encode a large number of open reading frames (in the order of 200). Currently functional information is available for a relatively small number of their genes. Both viruses are associated with mild disease in healthy individuals but occasionally HCMV causes severe disease in immunocompromised individuals. There is no compelling evidence to link either virus with cancer. Both virus are species-specific with productive replication being effectively restricted to human cells. Deletion of genes would usually be expected to reduce virus pathogenicity. Both viruses are expected or known to encode genes that modify cellular physiology and others that modulate the immune response.

The cloning of such genes in a replication-deficient Ad vector will generate recombinant viruses that are more readily transmitted, will provide high level expression and may induce the expression of protein that have a biological effect both in humans and animals. Adenovirus is a ADCP category 2 pathogens although the deletion of the E1 gene region will make both unable to replicate or promote efficient early phase gene expression. Being replication-deficient the recombinant viruses have limited potential for lateral spread, although this could be facilitated by a co-infection with a wt Ad. Wild type Ad type 5 is capable of productive replication in very few species and is associated with mild upper respiratory tract infection in childhood.

For the generation the HCMV genome will be used in the first instance. The HCMV strain AD169 and Toledo genomes will be used in preference. Deletion of the HHV-6 genome is planned in future but will be dependent on the development of better systems for growing the virus.
HCMV strains AD169 and Toledo are characterised laboratory isolates. The Strain AD169 genome is sequenced and published and there is extensive sequence data available for strain Toledo.

HHV-6 strain Z29 and U1102 have been fully sequenced. We intend also to investigate sequence variation in a range of fresh clinical isolates.

**Evaluation of foreseeable effects**

The expression of individual HCMV or HHV-6 genes in cells transiently or in established lines is of low potential hazard. Both viruses are expected or known to encode genes that modify cellular physiology and others that modulate the immune response. The cloning of such genes in a replication-deficient Ad vector will generate recombinant viruses that are more readily transmitted, will provide high level expression and may induce the expression of protein that have a biological effect both in humans and animals. HCMV encodes 6 gene that modulate class I presentation, two functions that modulate resistance to NK cells and both viruses encode chemokine and chemokine receptor homologues.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Virus in solution (tissue culture media or buffers such as PBS) is inactivate by adding to less than equal volume 2500 ppm Sodium Dichloroisocyanurate (Actichlor), after 4h solution can be discarded to mains drainage. Pipettes immersed in 2500 ppm Sodium Dichloroisocyanurate for 4h before transferred to plastic container for autoclaving, all plasticware is autoclaved after exposure to virus. Actichlor is effective against all viruses and te high concentration overcomes high organic content of media. Animals may be inoculated in a contained isolator or if Class I or Class II microbiological safety cabinet. All animal waste is incinerated.

Date of Significant Change

Project Additional Information

Purposes of the contained use

This notification covers the development of adenovirus vectors designed to facilitate the induction/modulation of specific immune responses by transgenes expression of. Host immune responses to vector components can be proinflammatory and often over-ride or subvert potential biological effects associated with the transgene. Specific mutations in the E2, E3, E4, L5 genes will be incorporated into adenovirus type vectors to limit breakthrough expression from replication-deficient adenovirus vectors. Ad5 vectors utilises CAR as a primary receptor for virus infection. We intend to deliver transgenes to cells that do not express detectable levels of CAR (notably lymphocytes). Using established technology, we intend to modify the fibre gene so that the expressed protein will no longer recognise its native CAR receptor and so that it will recognise specific receptors present on target cells. The modified fibre will not be inserted into an adenovirus genome but expressed as a complementing function in a helper cell line. Many individuals have been exposed to adenovirus type 5 and will also generate strong immune responses on exposure to this vector. Adenovirus type 4 has been used as a live viral vaccine. Fewer individuals have seroconverted to adenovirus type 4 and it can potentially also be used in combination with Ad 5 vectors in prime:boost vaccination protocols. We wish therefore to develop replication-competent and replication-deficient adenovirus type 4 vectors. A range of tumour-associated and virus antigens will be expressed in these vectors.

Recipient or parental organism

Preliminary prokaryotic cloning steps are necessary to generate the recombinant adenoviruses. Genetically disabled E.coli K12 strains specifically developed for application in recombinant DNA cloning experiments will used. These strains have limited potential to colonise the gut or survive in the environment. Adenovirus is an ACDP category 2 pathogen. Ad5 is primarily associated with mild upper respiratory tract infections of childhood. Adenovirus type 4 infection is also associated primarily with mild, debilitating respiratory tract infections but can occasionally cause an acute respiratory disease (ARD), acute haemorrhagic conjunctivitis or
rarely a fatal non-bacterial pneumonia. To protect against infection, a non-attenuated live Ad4 vaccine has been administered to military recruits in North America. This live viral vaccine consists of an enteric-coated tablet containing live, non-attenuated, tissue culture grown Ad4 virus. The enteric coating prevents infection of the respiratory tract and when swallowed virus is only released from the tablet in the stomach where it infects the gut inducing protective immunity but not disease. Over half a million doses of this vaccine has been administered without complication and it has proved to be effective in preventing ARD. It has been proposed that this vaccine and method of administration might be used as a vector to generate an immune response against both Ad4 and the heterologous immunogens. Ad4 recombinants expressing a range of viral genes have been generated and tested in animals and humans with promising results. The Ad4 virus strain used in the vaccine virus will be used as the basis for all Ad4 vectors and recombinants constructed.

Deletion of the E1 gene region will render the adenovirus vectors replication-deficient. Replication-deficient Ad4 vectors by their nature have limited potential for lateral spread although this could be facilitated by co-infection with a wt adenovirus. Both wild type Ad4 and Ad7 exhibit a severe host restriction and are capable of productive replication in very few species other than man.

Host/vector system

E.coli strains JM109, TOP10 and XL1-blue will be used. Prokaryotic vectors include pcDNA3.1/ct-GFP-Topo, pBLUETOPO, pUC-based vectors containing the HCMV major IE promoter (pMV100), adenovirus transfer vectors pAL200 (and variants with alternative cloning sites). Commercial Ad5 vector systems will be used as the basis for vector development. From Microbix (Canada) pJM17 (contains the complete Ad5d309 genome) and the Admax TM vector system will be used. From Qbiogene (Hareford, Middx) the Ad5 based AdEasy TM vector system, which involves all recombination events be performed in E.coli, will be used.

Ad4 vectors will be generated de novo from the vaccine strain.

Replication-deficient adenoviruses will be propagated in a helper cell line expressing an E1 helper function (eg 293 or 911 cells) and then used to infect target cells in vitro or in vivo. A 293 cell line expressing E4 will be obtained from a commercial source (Microbix). Additional helper cell lines will be constructed in 293 or 911 cells.

Origin & function

A number of human and murine tumour-associated antigens will be cloned.

</table>
| Human cytomegalovirus and Human herpes virus 6 are closely related human herpesviruses capable inducing disease in immunocompromised individuals but with no recognised association with cancer. Genes from both these viruses will be cloned into adenovirus vectors for the purpose of generating and measuring immune responses. Venezuelan Equine Encephalitis virus (VEEV) is an Alphavirus that replicates in the cytoplasm of infected cells. The virus particle contains genomic RNA packaged in a capsid consisting of core proteins and an envelope containing the glycoproteins Env1 and Env2. Two other proteins Env3 and 6k may also be found in the virus particle. These two small proteins contain the translocation signal sequence for Env1 and Env2. Being an Alphavirus, the structural proteins are translated from a subgenomic RND as a single polyprotein that is then cleaved by cellular proteases. Env2 contains a major protective epitope. Replication-competent and replication-deficient adenovirus recombinants encoding VEEVEnv3Env2/6K will be generated.
Some of the tumour-specific antigens are expressed in melanocytes and are involved in the melanin biosynthetic pathway. All such proteins are expressed either in normal testis or in melanocytes. None of these proteins in isolation have any toxic, oncogenic, carcinogenic or allergenic properties since they are all expressed in normal cells. The risk of any autoimmune disorder triggered by an overexpression of these proteins is negligible because no autoimmune effect has been reported in healthy volunteers and melanoma patients with high frequencies of cytotoxic T lymphocyte specific for these proteins. (Van Pel et al., Immunological Review. 145:229, 1995; Coullie et al., J Cancer 50:289, 1992). The immune response specific to colon carcinoma antigens is still ill defined, and very few proteins have been shown to be specifically expressed by colon cancer cells. One of the most promising family of newly characterised colon cancer proteins are the SSX proteins, which are expressed in a high proportion of colon.

The expression of individual HCMV or HHV-6 genes in cells transiently or in established lines is of low potential hazard. Both viruses are expected or known to encode genes that modify cellular physiology and others that modulate the immune response. The gene product of VEEV E3, E2 and 6k sequences are not known to be toxic, allogenic or oncogenic although E2 is associated with a strong humoral immune response. The cloning of such genes is a replication-deficient Ad vector will not generate recombinant viruses that are more readily transmitted, will provide high level expression and may induce the expression of protein that have a biological effect both in humans and animals.

This work involves standard laboratory protocols and there are no unusual procedures that require additional containment measures. A more detailed risk assessment was performed for the local ACGM safety committee.

Date of Significant Change

Project Additional Information

Purposes of the contained use
I wish to study the molecules involved in lymphocyte growth. This will take place in B and T-lymphocyte cell lines as well as primary human cells. The molecules chosen include ras, P13K, Jak, and STATs, all of which are activated in response to T-cell receptor or cytokines, the molecules that result in T-cell growth. Human primary lymphocytes are not easily transfected and infection remains the best way to modulate their genotype.

Recipient or parental organism
The GMO that will be generated are retroviruses based on the murine (MuLV) system containing molecules involved in lymphocyte growth and signalling.

Host/vector system
A retroviral vector system has been chosen. DNA corresponding to molecules involved in lymphocyte signalling will be introduced in the pinco retroviral plasmid. This plasmid will be introduced into the Phoenix AM cell line that allows the production of amphotropic retroviruses. Phoenix is a second-generation retrovirus producer line for the generation of helper free ecotropic and amphotropic retroviruses based on the murine (MuLV) system. The lines are based on the 293T cell line. The Phoenix cell line was chosen because it is a well established cell line that has been extensively tested for helper virus production and established as been helper-virus free. The cell line
contains two separate plasmids for the generation of the env protein and the gag-pol protein. Both the gag-pol and envelope constructs with non-moloney promoters were used to minimise recombination potention. Different retrovirus cannot be produced from these cells.

Origin & function

The genetic material for the retroviruses are derived from the murine (MuLV) system. The genes that will be introduced into these vectors are mammalian in origin. Each of these have been chosen because of their role in the manipulation of the immune system. While all of these molecules play an important role in growth and/or survival, none have been shown to induce lymphocyte malignancy alone. Wild type, active and inhibitory forms of the molecules will be studied.

Evaluation of foreseeable effects

The retroviruses by themselves do not constitute a risk. DNA corresponding to many different proteins have been described on the attached sheet. Details from each of these gene products have been given. When considering the possible hazard to human health it is appropriate to consider the gene product that has the most potential to cause harm. The virus with the most potential to cause harm is the V12-ras retrovirus. However, this has been used safely in other Departments within the University of Wales College of Medicine. This retrovirus could result in the expression of V12 in human cells. However this would only cause harm if administered in large doses or were to become infectious. However, the amounts of virus generated will be low and there are many features of the retroviral system that proscribe the ability of the retrovirus to become infectious.

Three other important factors:
(1) While V12 is an oncogene, it is unable to transform primary human cells alone. The short half life of the virus minimises the duration of any exposures. None of the other inserts are oncogenic.
(2) The pathogenicity of the retrovirus is unaffected by any of the inserts and there is unlikely to be any transfer of harmful sequences to related viruses.
(3) The viruses generated cannot cause a productive infection.

### Project Additional Information

**Purposes of the contained use**

The immune system is controlled by a complex balance between the innate and the adaptive immune responses. IL-10 is associated with shifting the balance of the immune response away from a TH1 and towards a TH2 response. Work in other centres has demonstrated that adenovirus (Ad) vectors encoding the Epstein Barr virus (EBV) interleukin 10 (IL-10) homologue is effective in suppressing inflammation in animal gene therapy models of autoimmune disease (Apparailly et al. 1998 J Immunol. 160, 5213). Recently, a functional human cytomegalovirus IL-10 homologue has also been identified (Kotenko et al. 2000 PNAS 97, 1695). We wish to use Ad recombinants encoding human, rat, EBV and HCMV IL-10 in both in vitro and in vivo assays. An Ad vector is required for efficient expression of these molecules. We intend to test the relative efficiency of the various versions of IL-10 on Dendritic cell (differentiation and maturation), CD8+ cytotoxic T cells (CTL) and NK cell function in vitro. Major histocompatibility class I molecules play a key role in functional interactions of all these three cell types and are regulated by IL-10. As part of this programme...
of work, we seek permission of express both classical (HLA A-C) and non-classical (HLA-E and HLA-G) molecules in replication-deficient Ad vectors. HLA A-C are highly polymorphic and a number of variant genes may be expressed. In contrast HLA-E and HLA-G are highly conserved but subtle variants do exist and may be expressed. The capacity of NKX2.5 to modulate myeloid cell function in vitro will be examined in a pilot study. LIR-1 is an inhibitory receptor found on cells of the myeloid lineage, T cells and NK cells that interacts with classical MHC-1 molecules and HCMV MHC-1 homologue gpUL18. We intend examining functional interaction between HCMV gpUL18 and LIR01. This notification covers the limited use of Ad recombinants designed to modulate immunological responses by transgene expression. In particular, we intend testing replication-deficient adenovirus recombinants encoding the EBV and HCMV IL-10 homologues in an established in vivo experimental model of rheumatoid arthritis.

Recipient or parental organism

Preliminary prokaryotic cloning steps are necessary to generate the recombinant adenoviruses. Genetically disabled E-coli K12 strains specifically developed for application in recombinant DNA cloning experiments will used. These strains have limited potential to colonise the gut or survive in the environment.

Adenovirus is an ACDP category 2 pathogen. Ad5 is primarily associated with mild upper respiratory tract infections of childhood. Deletion of the E1 gene region will render the adenovirus vectors replication-deficient. Replication-deficient Ad vectors by their nature have limited potential for lateral spread although this could be facilitated by co-infection with a wt adenovirus or gene rescue from the helper cell line.

Host/vector system

E coli strains JM109, BJ583 and XL1-blue will be used.

Commercial Ad5 vector systems will be used as the basis for vector development. For the construction of replication-deficient adenovirus recombinants: The Admax vector system from Microbix, Canada (pDC511, pDC512, pDC515 and pDC516, PBHGfrtDE1,3FLP, pXCXL-based transfer vectors, pJM17) will be used. From Qbiogene (Hareford, Middx) the Ad5 based AdEasytm vector system (pAdEasy-1, pShuttle, pShuttle-CMV, pShuttleCMV-LacZ) will be used. Replication-deficient adenoviruses will be propagated in a helper cell line expressing an E1 helper function (e.g 293 or 911 cells) and then used to infect target cells in vitro or in vivo.

Origin & function

Human, rat, EBV and HCMV IL-10 genes will be used to evaluate their relative capacity to modulated a range of immune responses in vitro and in vivo assays. NKX2.5 is a transcription factor associated with maturation of cardiomyocytes, its effect on myeloid cell maturation will be evaluated. HLA-A, HLA-B, HLA-C, HLA-E, HLA-5 and teh human cytomegalovirus MHC-1 homologue UL18 as test ligands of Lir-1 and to examine function of IL-10. LIR-1 is an inhibitory receptor originaly identified by high-affinity binding to synthetic gpUL18 and subsequently shown to bind a broad range of MHC-1 molecules. All DNA are cDNA clones obtained commercially or gifts from collaborators. DNA sequences are known and will be confirmed in adenovirus transfer vectors prior to generation of recombinant virus.

Evaluation of foreseeable effects

It is recognised that there is a potential hazard associated with using Ad recombinants encoding transgenes capable of modulating the immune response IL-10 is a 17-18kDa homodimer that can be secreted by T cells, macrophages and EBV- transformed B cell lines. IL10 functions by binding the IL-10 receptor. IL-10 was first recognized for its ability to inhibit activation and effector function of T cells, monocytes, and macrophages, and is a multifunctional cytokine with diverse effects on most haemopoietic cell types. The principal routine function of IL-10 appears to be to limit and ultimately terminate inflammatory responses. In addition to these activities, IL-10 regulates growth and/or differentiation of B cells, NK cells, cytotoxic and helper T cells, mast cells, granulocytes, dendritic cells, keratinocytes, and endothelial cells. hIL-10 is active on both mouse and human cells, whereas mIL-10 is effective only on mouse cells. The mature hIL-10 and EBV viral IL-10 (vIL-10) amino acid sequences are 84%
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

This construct is thus expected to have a biological function following in vivo delivery. There is evidence in mouse and humans that elevated IL-10 production usually imposes some limits on the effectiveness of antipathogen immun responses, especially innate immunity and adaptive Th1 responses. This cost if often outweighed by the ability of IL-10 to protect the host from collateral damage by antimicrobial cytokines and effector molecules. IL-10 has been considered an attractive candidate for therapeutic use based on its potent in vitro immunomodulating activities and proven effects in animal models of acute and chronic inflammation, autoimmunity, cancer and infectious disease. Phase I and II clinical trials investigating safety, tolerance, pharmacokinetics, pharmacodynamics, immunological and hematological effects of single or multiple doses of IL-10 administered by intravenous (iv) or subcutaneous (sc) route. IL-10 has been tested in specific patient populations including those with Chrohn's disease, RA, psoriasis, and patients suffering from chronic hepatitis C infections. Administration of IL-10 (7 days iv) reduced the Cohrohn's disease activity index score in patients with steroid-refractory Crohn's disease and showed some clinical benefit in a larger 28-day sc safety and efficacy study in patients with chronic active Crohn's disease. Similarly, a trend towards efficacy and a good safety profile was observed when IL-10 was administered for 28 days to RA patients. Since intravenous (iv) or subcutaneous (sc) doses of IL-10 resulted in transient dose-dependent changes in white blood cell populations, including increases in total white blood cells and neutrophils.

There are a number of theoretical hazards associated with this experiment. First, as the recombinant virus is intended for in vivo use, there is the potential that the virus could spread from animal to animal and hence get into the natural population. However any in vivo injections will be local and given the fact the virus cannot penetrate more than a few layers of cells, the systemic spread of the virus should be negligible. Even in the highly unlikely event of the spread of the virus systemically, the recombinant virus is replication deficient, is not maintained in dividing cells and as such is incapable of horizontal spread throughout a population. Additionally wild-type Ad type 5 is able to undergo productive virus replication in very few non-human cells.

A second potential hazard is the exposure of humans to the recombinant virus. All manipulations of the virus will be performed in a class II biological safety cabinet in the laboratory. In vivo injections of Ad recombinants encoding recombinant genes into animal models will be carried out in an animal isolator, a negative pressure facility (i.e. in a class I cabinet) or a class II cabinet. A potential human infection will be a needle stick injury. Use of sharps will be kept to a minimum but are required for animal inoculations. In this event, gene expression from the Ad recombinant should be localised and the potential inhibition of complement localised and transient. In the unlikely scenario that the recombinant inhibitor becomes systemic, for the reasons stated above (inability to replicate without E1 complementation and the loss of the virus in dividing cells) the effect of the complement inhibitor should be transient. Also the effect of the complement inhibitor in humans should be minimal as the dose will have been designed for a rate and should therefore be at too low a level for a significant effect in humans. Horizontal spread of the recombinant virus through the human population is not likely for the same reasons as it is not likely in the rat population.

Classical and non-classical MHC molecules are widely expressed on human cells. The over-expression on non-classical HLA A-C molecules could promote antigen specific or allospecific immune responses and expression of any of the classical or non-classical HLA molecules could suppress NK recognition but should this occur the risk is minimal. LIR-1 (also known as ILT-2) is an inhibitory receptor thus its over-expression in lymphocytes or myeloid cells could suppress the function of that the target cell. The Ad5 vector infects lymphoid and myeloid cells relatively inefficiently. It is extremely unlikely that with the natural biological containment that the gene could be delivered with sufficient efficiency to exert a biological effect in man or animals. NKX2.5 transcription factor (a cell specific expression marker in cardiomyocytes) that will be subcloned into an replication-deficient Ad vector. There is no known transforming activity or toxicity associated with this gene. Use of this construct has been independently approved at ACGM 2 level elsewhere.

These recombinant viruses will be contained using ACGM level 2 procedures as stipulated in the risk assessment.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Virus in solution (tissue culture media or buffers such as PBS) is inactivate by adding to less than equal volume 2500 ppm Sodium Dichlorocyanurate (Actichlor), after 4h solution can be discarded to mains drainage. Pipettes immersed in 2500 ppm Sodium Dichlorocyanurate for 4h before transferred to plastic container for autoclaving, all plasticware is autoclaved after exposure to virus. Actichlor is effective against all viruses and the high concentration overcomes high organic content of media.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

A minor modification was made to the title for accuracy.

Notification of this project as an extension of a connected programme of work would be necessary.

THE PROPOSED PROJECT INVOLVES THE CONSTRUCTION OF ADENOVIRAL RECOMBINANTS FOR THE EXPRESSION OF COMPLEMENTARY INHIBITORY MOLECULES IN CELL LINES IN VITRO AND EVENTUALLY IN ANIMAL MODELS OF DISEASE.

Purposes of the contained use

Recipient or parental organism

Preliminary prokaryotic cloning steps are necessary to generate the recombinant adenoviruses. Genetically disabled E-coli K12 strains JM109 and XL1-blue specifically developed for application in recombinant DNA cloning experiments will be used. These strains have limited potential to colonise the gut or survive in the environment. Adenovirus is an ACDP category 2 pathogen. Ad5 is primarily associated with mild upper respiratory tract infections of childhood. Deletion of the E1 gene region will render the adenovirus vectors replication-deficient. Replication-deficient Ad vectors by their nature have limited potential for lateral spread although this could be facilitated by co-infection with a wt adenovirus or recombination with the E1 gene in the helper cell line.

Host/vector system

E.coli strains JM109 and XL1-blue will be used. Prokaryotic vectors include pUC-based vectors including the Ad transfer vector pAL119. A commercial Ad5 vector systems provided by Prof Frank Graham will be used as the basis for the vector (Microbix, Canada). pJM17 contains the complete Ad5dl309 genome vector system cloned into the pBR322-based vector pBRX. Recombinant viruses will be generated following recombination in 193 cells.

Prokaryotic cloning experiments are required to manipulate the complement inhibitory genes prior to recombination into the Ad genome. Expression will not be sought in E. coli and no specific hazard has been identified for prokaryotic manipulation. Replication-deficient adenoviruses will be propagated in a helper cell line expressing an E1 helper function (e.g., 293 or 911 cells) and then used to infect target cells in vitro or in vivo.

Origin & function

The molecules of interest include human CD59, DAF (Decay Accelerating Factor), MCP (Membrane Cofactor Protein) and CR1, the rat analogues of DAF, CD59 and MCP and the rat complement inhibitor Crry. It is intended to clone these molecules in two forms: a) the natural form which includes the sequence necessary to anchor the protein to the cell surface and b) with a deletion of the sequence responsible for anchoring the protein to the membrane so that it is secreted from cells in a soluble form. Secreted forms of complement inhibitors do occur naturally. We also intend to perform mutagenesis on the predicted active sites of the complement inhibitors to examine function. Such constructs can be expected to have reduced hazard potential under most circumstances, although a dominant mutation could possibly reduce the efficiency with which complement action is inhibited.
DAF and CR1 have decay accelerating activity of the bimolecular enzyme complexes which constitute the convertase in both the classical and alternative complement activation pathways. They dissociate the C2a or the Bb subunits from the formed convertases and may also prevent the subsequent association of their procatylitic precursors C2 and B with membrane bound C4b or C3b molecules. Hence by accelerating the decay of preformed convertases and inhibiting the formation of new ones, DAF and CR1 can prevent amplification of the C3 activation on the host cell surface. Cr1 also acts as a cofactor for the cleavage of iC3b to C3c and C3d.g (iC3b can bind and activate neutrophils via CR3). CR1 also acts in vivo to mediate phagocytic binding of particles opsonized with C3b and participates in the transport of immune complexes on erythrocytes.

Like CR1, MCP acts as a cofactor for the factor-I cleavages of C3b and C4b and hence prevents the formation of active C3/C5 convertases. Although this inhibits both the classical and alternative pathways of the complement system, MCP is thought to act preferentially on the convertase of the alternative pathway.

CD59 works at the end of the complement pathway by inhibiting the assembly of the MAC (Membrane Attack Complex). It does so by incorporating into the partially formed MAC by binding to C5b8 and interfering with the subsequent binding and polymerization of C9.

The specific mechanism for Crry function is still unclear although it is thought to be a functional homologue for human MCP and/or DAF.

The main function of the complement system is its role in both the adaptive and humoral immune system in killing foreign microorganisms. Other biologically important functions mediated by the complement system include:

1) Low molecular weight anaphylotoxins C3a, C4a, and C5a which promote smooth muscle contraction and increase vascular permeability.

2) Large C4b and C4b fragments involved in the binding to the complement activator and therefore interact with specific receptors to allow efficient clearance of the activating cell of particle including virus.

3) Degradation of the fragments of C3b to iC3b, C4d.g and C3d which are also important in the clearance of the immune aggregates and the triggering of the receptor mediated activities including the regulation of the immune response.

Hence expression of the human (only) complement inhibitory proteins could result in a reduction/inhibition of systemic complement in man and potentially inhibit to varying degrees one, some or all of the above activities leading to an increased susceptibility to infection and the accumulation of immune complex precipitates.

The recombinant virus will be based on an Ad5 dl309 background with an additional deletion in the E1 gene at which site the insert will be inserted. The deletion of the E1 gene make the Ad recombinant replication-deficient and thus replication of the virus requires complementation by a helper function. 293 or 911 cells both carry an integrated copy of the Ad5 E1 gene and hence will be used for the construction and propagation of new recombinant virus. The complement inhibitory genes will be inserted at the site of the E1 deletion.

**Evaluation of foreseeable effects**

Activation of complement is known to be an important factor in numerous diseases including the development and propagation of inflammation of the rheumatoid joint. Efficient inhibition of complement could therefore ameliorate disease. This has been shown previously in the case of rheumatoid arthritis, by systemic and local inhibition of complement using complement inhibitory proteins. This project is an extension of this work but is intended to avoid repeated protein injections by assessing the viability of in situ expression of complement inhibitors using adenoviral vectors.

There are a number of theoretical hazards associated with this experiment. Firstly, as the recombinant virus is intended for in vivo use, there is the potential that the virus could spread form animal to animal and hence get into the natural population. Complement inhibitors exhibit host specificity and can be considered as a significant hazard only in the homologous species. However any in vivo injections will be local and given the fact the virus cannot penetrate more than a few layers of cells, the systemic spread of the virus should be negligible. Even in the highly unlikely event of the spread of the virus systemically, the recombinant virus is replication deficient, is not maintained in dividing cells and as such is incapable of horizontal spread throughout a population. Additionally wildtype Ad type 5 is able to undergo productive virus
replication in very few non-human cells.

A second potential hazard is the exposure of humans to the recombinant virus. All manipulations of the virus will be performed in a class 11 biological safety cabinet in the laboratory. In vivo injections of Ad recombinants containing human complement inhibitory proteins into animal models will be carried out in an animal isolator, a negative pressure facility (ie in a class 1 cabinet) or a class 11 cabinet. A potential human infection will be a needle stick injury. Use of sharps will be kept to a minimum but are required for animal inoculations. In this event, gene expression from the Ad recombinant should be localised and the potential inhibition of complement localised and transient. In the unlikely scenario that the recombinant inhibitor becomes systemic, for the reasons stated above (inability to replicate without E1 complementation and the loss of the virus in dividing cells) the effect of the complement inhibitor should be transient. Also the effect of the complement inhibitor in humans should be minimal as the dose will have been designed for a rat and should therefore be at too low a level for a significant effect in humans. Moreover there are a total of 10 known complement regulatory molecules and the transient increase of one or two of these molecules should not significantly imbalance the immune system. Horizontal spread of the recombinant virus through the human population is not likely for the same reasons as it is not likely in the rat population.

### Project Additional Information

**Purposes of the contained use**

I wish to study the molecules involved in lymphocyte growth. This will take place in B and T-lymphocyte cell lines as well as primary human cells. The molecules chosen include P13K, Jak, and STATs and other molecules that modulate cell growth and gene expression. Human primary lymphocytes are not easily transfected and infection remains the best way to modulate their genotype.

**Recipient or parental organism**

The GMO that will be generated are adenoviral system containing molecules involved in lymphocyte growth and signalling.

**Host/vector system**

The adenoviral host vector systems are commonly used and well-characterised. All adenovirus vectors will be replication deficient due to deletion in the E1 gene region; this is a recognised safety feature. Repair of the deletion in the E1 gene region may occur due to homologous recombination with the E1 gene in the helper cell line (an extremely unlikely event) or following co-infection of a cell with a wild type Ad. In the unlikely event of such a recombination, it is likely to result in concomitant deletion of the transgene.

**Origin & function**

The genetic material for the adenoviral system are derived from the human Ad5 system. The genes that will be introduced into these vectors are mammalian in origin. More information is shown on the attached sheet. Each of these have been chosen because of their role in the manipulation of the immune system and gene expression. While all of these molecules play an important role in growth and/or survival, none have been shown to induce lymphocyte malignancy alone. Wild type, active and
inhibitory forms of the molecules will be studied.

Evaluation of foreseeable effects

The adenoviruses by themselves do not constitute a risk. When considering the possible hazard to human health it is appropriate to consider the gene product that has the most potential to cause harm. The virus with the most potential to cause would be the active PKB or dominant negative PML. Both of these proteins have the capacity to enhance cell survival and proliferation. However neither alone is sufficient to cause malignant transformation. Cells of the haematopoetic system are most at risk from these proteins. However, these cells are poorly infectible by adenovirus. Furthermore, the transient nature of expression following adenoviral infection makes the expression unlikely to affect human health.

As the Ad is replication deficient, ie cannot replicate in host cells unless E1 sequences are provided in trans (eg in HEK 293 cells for virus propagation). It is considered highly unlikely that this will happen spontaneously. Furthermore efficient delivery of large number of virus particles would be required to infect cells. Expression using the Ad vector is only transient and is quickly lost in dividing cells as it only integrates DNA at a low frequency. The Ad vector is unlikely to cause any permanent change in cells it infected.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not Applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste contaminated with GMMs will be treated with freshly prepared 2500ppm sodium dichloroisocyanurate. This completely destroys the adenovirus.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The GMSC found the risk assessment to be suitable and sufficient.

Project Additional Information

Purposes of the contained use

The dominant negative and wild-type protein kinase C constructs will be transfected into cells in order to determine the role of isoforms of this enzyme in cell signalling leading to volume regulation, cell proliferation and drug resistance.

Recipient or parental organism

Recipient myocytic cells are only capable of proliferating to a couple of generations before they terminally differentiate, transfection of these cells is therefore unlikely to pose a hazard, however all work with the transfected cells will be conducted in a class 2 laminar flow cabinet and all media and labware treated with Virkon solution.

Breast cancer cell lines such as MCF-7 and our Tamoxifen resistant derivative thereof are able to grow in culture for significant periods of time. Transfection with the virus however would only be transient and the biological hazard therefore negligible. These cell lines do not contain other viral particle which might recombine with the vector beginning introduced, such as has been found in cell such as Hela cells. Again all work will be conducted in a class 2 laminar flow cabinet and all media and labware treated with Virkon before disposal.

Host/vector system

The host vector system is well characterised and available commercially. All adenovirus vectors used will be replication deficient due to deletion in the E1 gene region; this is a recognised safety feature. Repair of the deletion in the E1 gene region may occur due to homologous recombination with the E1 gene in the helper cell line (an extremely unlikely event) following co-infection of a cell with a wild-type adenovirus. Such a recombination event is likely to result in concomitant deletion of the transgene, is extremely unlikely but not impossible. Such recombinations also only usually occur within a subgenus not between subgenus. Adenovirus vectors are associated with...
extremely efficient in vivo delivery and can be spread by aerosol. This hazard will be contained by restricting manipulation with the virus to biological safety caninets and sealed centrifuge rotors. Adenovirus have no mechanism for cytolysis so in culture most viral particles remain cell-associated, although they can spread to neighbouring cells, leading to plaque formation.

Origin & function

PKC- 'Gutless' tetracycline - regulated binary adenoviral vectors will be supplied (Harding et al., 1997, J. Neurochem 69 2620-3 and Harding et al., 1998, Nature Biotech 16: 553-5) (Hussain S, Assender JW, Bond M, Wong LF, Murphy D, Newby AC 2002; "Activation of protein kinase-C is essential for cytokine-induced metalloproteinase-1, -3 and 9 secretion from rabbit smooth muscle cells and inhibits proliferation." J. Biol Chem.: 277; 30: p27345-52). The original kinase defective (point mutation within the ATP binding site 275 Lys> Trp) dominantnegative mutant was obtained from Dr Moscat, Universidad Autonoma de Madrid.

PKC-a and : Wild-type and kinase defective (point mutations within the ATP binding site) dominant negative mutants of PKC-a and PKC- have been obtained from Dr Ohba, Instit of Mol. Oncology, Showa University, Tokyo (Nature 325: 161-66, 1987; Mol Cell Biol 18: 5199-5207, 1998; EMBO 13: 2331-2340, 1994). Rabbit PKC-a cDNA (-4~+2647), mouse PKC- cDNA (-13+2525/genbank:X60304), Dom neg PKC-1 cDNA (-42647 with 1 nucleotide mutation, AAGATCC>ACGATCC: 368 k>r), Dom neg PKC- cDNA (-13+2525 with 4 nucleotide mutation AAGTGTC>GCATGCC: 376 k>a). These will be used to determine the effect of over or non-expression of these signalling molecules on cell proliferation and Tamoxifen resistance in breast cancer and regulatory volume decrease in myocytes.

Evaluation of foreseeable effects

There is a potential hazard associated with using adenovirus recombinants to express transgenes that are overtly transforming or have a strong capacity to prime host cell proliferation. Protein kinase C is a signal transduction molecule associated with cell proliferation in a number of cellular systems. Although not thought to be the driving force behind cell replication, it does appear to act as a reostat, enhancing proliferation/apoptotic responses. The inserted gene product could therefore potentially be harmful, however due to the transient nature of the infection (see below), this risk is thought to be minimal. Dominant negative mutants of protein kinase C have previously been widely used in other laboratories and by the co-applicant. "Activation of protein kinase-C is essential for cytokine-induced metalloproteinase-1, -3 and 9 secretion from rabbit smooth muscle cells and inhibits proliferation". J Biol Chem.: 277 (30): p27345-52).

As the adenovirus is replication-deficient due to E1 and E3 deletions, they can not replicate in host cells unless E1 sequences are provided in trans (eg in HEK 293 cells for virus propagation). It is considered highly unlikely that this will happen spontaneously. Furthermore efficient delivery of large numbers of virus particles will be required to infect target cells, which is unlikely to happen, in vivo. Furthermore, since the adenovirus is replication deficient, no persistant long term effects are likely.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Virus in solutions (such as tissue culture media or buffers such as PBS) will be inactivated by addition of more than an equal volume of sodium Dichloroisocyanate (Actichlor, 25000 ppm). After 4h, the solution will be discharded to main drains. Pipettes will be totally immersed in 2500 ppm sodium dichloroisocyanurate for 4 h before transferring to plastic containers for autoclaving. All plasticware will be autoclaved after exposure to the virus. Acticlor is a broad spectrum and rapid acting biocide, effective against all viruses. The high concentrations used here will ensure that the high organic content of the media is overcome and 100% killing should be achieved.

## Project Additional Information
Purposes of the contained use

The aim of the project is to manipulate the levels of activity of the interferon signalling pathways in cultured human cells, both normal and immortalised, and potentially in combination with infection with other human retroviral vectors, already covered by HSE notifications in our laboratory, such as that encoding Ras.

We have identified the interferon pathway as an important area of investigation due to our previous study of the effect of activated Ras in thyroid cells. Ras confers a limited proliferative potential to thyrocytes. However the cells eventually cease to divide. We have analysed gene expression in this arrested state using DNA microarrays and it appears that the interferon pathway is involved. This project will involve manipulating the interferon response pathways in a background where mutant Ras has already been introduced.

Interferons play key roles in mediating antiviral and antigrowth responses and modulating the immune response, particularly in response to viral infection. Interferons are proteins naturally produced by many cells in the body. The interferons are pleiotropic cytokines that are induced in response to virus infection and act in a paracrine fashion to elicit an antiviral state in nearby cells. Binding of interferons to their cell-surface receptors induces a tyrosine kinase signalling cascade that leads to the activation of latent cytoplasmic signal-transducer-and-activator-of-transcription (STAT) factors. Activated STATs then translocate into the nucleus, where they are targeted to conserved promoter-enhancer sites to induce the transcription of interferon-responsive genes, that encode for protein with potent antiviral, growth-inhibitory, anti-tumour and immunomodulatory properties. There are 3 classes of interferon: interferon alpha, beta and gamma. Interferon alpha and beta signal through the Type 1 pathway, and interferon gamma uses the closely-related Type II pathway.

We are interested in altering the levels of various members of the interferon signalling pathways, to attempt to modulate signalling of each pathway. We intend to do this by over-expression of various components of the pathways, the use of inhibitory genes, either naturally occurring (e.g. IRF2) or known dominant negative mutant alleles (e.g. of STAT 1). Cells will be studied in culture (e.g. phase contrast microscopy, the response to drug or other treatments), or killed and then subjected to cellular and molecular biology assays, such as immunocytochemistry, Western blotting, and extraction of RNA and DNA for subsequent analysis.

We may also during the course of this work generate dominant negative and loss-of-function versions of the genes specified on accompanying risk assessments and below. These will be tested in the same manner as the wild type genes, as described above.

Recipient or parental organism

Host organisms are primary human cells in particular thyrocytes. These cells may also have been infected with retroviruses expressing mutated RAS.

Host/vector system

All genes will be introduced into a series of plasmid backbones of the pBABE series of vectors. In the appropriate producer cell lines these produce ecotropic and amphotropic retroviruses where gene expression is driven by the MMLV LTRs. All retroviruses are replication defective as many helper functions are supplied by the producer cell lines psiCRIP and Omega E. Cells that have stably integrated the retroviral expression cassette will be selected on the basis of drug resistance to hygromycin, G418 and puromycin.

Origin & function

Cytokines: Interferons alpha, beta and gamma
Interferon alpha/beta receptor: Cell-surface receptor for interferon alpha and beta
Interferon gamma receptor: Cell-surface receptor for interferon gamma
Components of interferon signalling pathway: Interferon Regulatory Protein 1 (IRF1); Interferon Regulatory Protein 2 (IRF2); Interferon Regulatory Protein 3 (IRF3); Interferon Regulatory Protein 5 (IRF5); Interferon Regulatory Protein 6 (IRF6); Interferon Regulatory Protein 7 (IRF7); Interferon Regulatory Protein 8 (IRF8, ICSBP); Interferon Regulatory Protein 9 (IRF9, p48); Janus Kinase 1 (JAK1); Janus Kinase 2 (JAK2); TYK2; SHP-2 (tyrosine phosphatase); Cytosolic phospholipase A2 (CPLA2)
Components of interferon signalling pathway and transcription factors: Signal Transducer and Activator of Transcription 1 (STAT1); Signal Transducer and Activator of Transcription 2 (STAT2); Signal Transducer and Activator of Transcription 3 (STAT3); CREB -binding protein (CBP/p300)
Inhibitor of IRF-1: Nucleophosmin (NPM)

Evaluation of foreseeable effects

With regard to the hazards associated with the host/recipient the following have been considered including the pathogenicity of host strain, virulence infectivity and toxin production. In this case recipients and hosts are non pathogenic.
With regard to the hazards rising directly from the inserted gene these are non oncogenic and are downstream members of signalling pathways. Considering whether an inserted sequence, that does not give rise to harmful phenotype in the recipient micro-organism could give rise to harm as a result of natural gene transfer to another possibly related organism this is extremely unlikely to have a harmful effect.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not Applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not Applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All retroviral work will take place in a dedicated Class II facility. All liquid waste is sterilised at point of use by sodium hypochlorite. All solid waste is sterilised in adjacent autoclave facility. Use of glass and needles will be avoided to reduce the risk of sharps injury. Autoclave thermocouple tested annually, also daily monitoring of efficacy of autoclave. Discussed determining efficacy of disinfectants with HSE inspector on recent visit. Relying on manufacturer's quality control and the very unstable nature of GMOs involved.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Project passed at meeting at containment level 2. Minor revision requested in order to clarify justification of project. Risk assessment modified accordingly and signed off.

Project Ref 312/03.1
We intend to perform a systematic investigation of Human cytomegalovirus (HCMV) gene function by the cloning and expression of HCMV genes in cell lines, baculovirus vectors and replication-deficient adenovirus vectors. The vast majority of assays will be performed using cultured cells in vitro. Occasionally, animals will be inoculated with Ad recombinants primarily to generate antibody specific for the expressed transgene.

Recipient or parental organism

Preliminary prokaryotic cloning steps are necessary to generate the recombinant adenoviruses. Genetically disabled E. coli K12 strains specifically developed for application in recombinant DNA cloning experiments will used. These strains have limited potential to colonise the gut or survive in the environment. Continuous cell lines expressing HCMV gene is also envisaged. Prokaryotic cloning experiments, transient and continuous cell lines will be at ACGM category 1 level.

Adenovirus is an ACDP category 2 pathogen. Ad5 is primarily associated with mild upper respiratory tract infections of childhood. Deletion of the E1 gene region will render the adenovirus vectors replication-deficient. Vectors will also contain defined deletions in the non-essential E3 gene region. Replication-deficient Ad vectors by their nature have limited potential for lateral spread although this could be facilitated by co-infection with a wt adenovirus or gene rescue from the helper cell line. The use of more disable Ad vectors, specifically gutless vectors, is envisaged when feasible.

Baculovirus vectors are replication competent in insect cells but replication-deficient in mammalian cells. The vectors lack the non-essential polyhedrin gene.

Host/vector system

E. coli strains DH5a, JM109, BJ583 and XL1-blue will be used. Details of vectors for ACGM1 work is given in the risk assessment.

Commercial Ad5 vector systems will be used as the basis for vector development.

For the construction of replication-deficient adenovirus recombinants:

The Admax vector system from Microbix, Canada (pDC511, pDC512, pDC515 and pDC516, pBHGrfDE1,3FLP, pXCXL-based transfer vectors, pJM17) from Qbiogene.

We intend to perform a systematic investigation of Human cytomegalovirus (HCMV) gene function by the cloning and expression of HCMV genes in cell lines, baculovirus vectors and replication-deficient adenovirus vectors. The vast majority of assays will be performed using cultured cells in vitro. Occasionally, animals will be inoculated with Ad recombinants primarily to generate antibody specific for the expressed transgene.
Replication-deficient adenoviruses will be propagated in a helper cell line expressing an E1 helper function (e.g., 293 or 911 cells) and then used to infect target cells in vitro or in vivo.

Baculovirus Vectors: Introgen Insect Select and Novagen BacVector System. SF9 cells for virus growth of baculovirus vectors. HCMV genes may be placed under the control of the baculovirus polyhedrin promoter to provide for high level expression in SF9 cells. Genes may also be inserted into the baculovirus vector under the control of a constitutive promoter namely the HCMV major IE promoter. Baculovirus can infect (inefficiently) but not replicate in mammalian cells. Baculovirus vectors thus can thus be used as a replication-deficient gene delivery system in mammalian cells as an alternative to adenovirus vectors.

Tissue culture cells including primary fibroblasts, U373, THP-1, primary myeloid cells. Animals may be inoculated with Ad recombinants, primarily with the intention of generating polyclonal or monoclonal antibodies for the further characterisation of gene products.

Genes will be cloned from any human cytomegalovirus isolate including the laboratory strains AD169, Towne and Toledo. Sequences will also be cloned from clinical isolates. HCMV is a ubiquitous herpesvirus with the largest genome of any characterised human virus (approx. 235Kb). It is designated as an ACDP 2 agent. The virus is extremely well-adapted to its host with the vast majority of infections passing unnoticed. Between 50-100% of adults are seropositive depending on socio-economic conditions. In healthy individuals primary infection is normally asymptomatic or associated with a mild febrile infection, followed by lifelong persistence (clinically silent) in its host. The virus is thought to establish 'latency' in a subset CD34+ myeloid progenitors with reactivation accompanying cellular differentiation. However, HCMV is an occasional cause of heterophile-negative infectious mononucleosis and a major viral cause of congenital malformation. In severely immunocompromised individuals (notably late stage AIDS patients and bone marrow recipients), HCMV disease is associated with morbidity and mortality. HCMV is not believed to cause cancer nor to encode oncogenes. 'Transforming regions' of the genome have been defined but have extremely low potency (Macasrski and Courcelle, 2001; In Fields Viology, ed; DM Knipe & PM Howley pp2675-2705. Lippencott William & Wilkins, Philadelphia). Although HCMV is known to encodes a number of immunomodulatory genes, there is no compelling evidence that HCMV infections are immunosuppressive.

The complete sequence of the laboratory-adapted HCMV strain AD169 was determined by Chee et al (1990) and was predicted to encode 208 non-overlapping ORFs of greater than 80 amino acids. However, strain AD169 is known to harbour a number of defects, most spectacularly a 15 kb deletion that has since been sequenced in strain Toledo. Mocarski and Courcelle (2001) have recently updated the analysis of the HCMV genetic content and this was used as a basis for the risk assessment (attached). The complete sequencing of the HCMV clinical isolate Merlin is now being undertaken in the University of Glasgow (A. Davison, personal communication). The HCMV isolate Merlin will be used in the majority of our studies to avoid issues of genetic instability associated with laboratory-adapted strains. However, we also envisage a need to clone DNA fragments and genes from other HCMV laboratory strains and primary isolates to analyse sequence variation. The definition of HCMV ORFs by Mocarski and Courcelle (2001) is known not to be definitive. More detailed analysis will identify additional functional ORF and delete spurious ones. HCMV also encodes untranslated transcripts (eg the B2.7 gene). We seek to cover the expression of all HCMV genes including untranslated transcripts. The herpesviruses encode a core set of genes associated with nucleic acid metabolism, DNA replication, capsid assembly and the production of infectious viruses that can be readily predicted from their sequence. A number of functions associated with transcriptional regulation and immune function have been identified, some by homology to cellular proteins. However, clearly a large proportion of the HCMV genome awaits detailed analysis.

There are few antibodies available to HCMV proteins. HCMV ORFs will therefore also be expressed as fusion proteins with GFP/RFP or YFP variants, a 6xHis tag, a streptavidin-binding peptide tag, a tetracycisteine peptide tag or an Fc fusion protein to monitor expression, facilitate purification or identify binding ligands.

Most HCMV genes either have no known biological functions or encode functions that have no predictable detrimental effect when expressed in the proposed vectors. A risk analysis is performed on HCMV gene product with known functions that have the highest potential to cause harm. The virus does not encode any known oncogenes or toxins. HCMV gB is involved in virion attachment to a currently unknown cellular receptor. Recently, microarray experiments and other systems indicated that the binding
of gB to its receptor modulates the transcription of a large number of cellular genes including the induction of an interferon-life response (Simmen et al, PNAS 2001; 98: 7140). Recombinant gB thus has the potential to induce transcriptional effects when expressed. Although normally a membrane protein, secreted forms of gB would have the potential to effect cells in trans. An Ad5 recombinant expressing HCMV gB is capable inducing a neutralising immune response (Marshall et al, J. Infect. Dis, 162, 1177). Ad is not enveloped so expression of gB does not have the potential to effect Ad5 tropism. Ad5 recombinants encoding cell-associated or soluble versions of gB have the capacity to transiently modulate expression in trans following in vitro or in vivo administration. There is a potential hazard with Ad-gB recombinant viruses that should gB released from cells it has the potential to modulate transcription in adjacent cells. This effect may be similar to an interferon response, is liable to be detrimental to the cell but should be transient.

IE2 is the predominant regulatory protein in the virus. It is a promiscuous transactivator that interacts with a wide range of cellular factors (including p53 and Rb), may inhibit apoptosis, promotes cell cycle progression and cell cycle arrest in G1/S. By itself IE2 is not transforming, indeed expression of this protein in mammalian vectors has proved problematical as it appears incompatible with long term cell survival, probably due to the block in cell cycle progression. IE2 has some capacity to rescue an Ad E1a deletion but does not rescue a complete E1 deletion. An ADIE2 recombinant has been shown in microarray analysis to increase the levels of RNA moleculares that promote cell cycle progression (Song and Stinski, PNAS 99, 2836). Infection with an Ad5 1E2 construct is liable to be inconsistent with the long term survival of the cell (as is a wt Ad5 infection) but would not be expected to result in the release of virus nor cell transformation. HCMV encodes a series of additional regulators of cellular gene expression that appear to be significantly less potent than IE2; including IE1 (weak transactivator; disperses PML-bodies), pUL36 (IE) the virion proteins ppUL82 (pp71), ppUL69, pIRS1 and pTRS1. There is no clear potential for hazard associated with the expression of these molecules.

HCMV has become a paradigm for investigating virus modulation of cellular immune systems. A number of immunomodulatory genes have been characterised and it is anticipated that a significant number of uncharacterised HCMV genes will be found to interact with immune systems. The expression of genes capable of modulating immunological responses in Ad5 vector systems constitute a potential hazard.

HCMV UL111a is a functional IL-10 homologue. IL-10 used therapeutically to suppress immunological responses yet is well tolerated and in high doses could predispose to infection. Ad recombinant encoding cellular and EBV vIL-10 have been used in animal models to suppress immunopathologies. The CMV homologue is believed to be of lower potency. As a secreted virokin Ad recombinants have a theoretical potential to induce transient, localised suppression of Th1 immune responses. There is a low level potential hazard with Ad-UL111a recombinant viruses that has recently been approved at ACGM2 level in a separate notification from this laboratory. HCMV encodes a number of putative secreted immunomodulators that may be considered to represent a comparable hazard level to the UL111a gene product and a substantial number of additional secreted glycoproteins is predicted by analysis of ORFs and preliminary expression studies. Preliminary data indicates the hypervariable UL146 gene product (vCXc-1) to be an IL-8-like chemokine that induces chemotaxis of neutrophils. UL147 also exhibits cysteine spacing and weak homology to CXC chemokines. Additional uncharacterised chemokine-like ORFs are expected to be functional.

US2, US3, US6 and US11 encode glycoproteins that act on infected cells to downregulated cell surface expression of MHC-1, and thus they can be expected to promote evasion of CD8+ CTLs. The leader sequence from UL40 acts to upregulate cellular HLA-E expression and thus promote protection against attach by CD94/NKG2A+NK cells. gpUL16 promotes the intracellular retention of ligands for the NK activating ligand NKG2D and this may also impede NK recognition. GpUL18 is expressed on the cell surface where it binds the inhibitory ligand Lir-1 that is present of NK subsets, T cell subsets anad myeloid cells. The functional role of gpUL18 is controversial, it may inhibit NK and T cell subsets. Four HCMV genes (UL33, UL78, US27, US28) are predicted to encode 7TM receptors. US28 encodes a functional C-C chemokine G-protein-coupled receptor (GCR) which binds both CC and CX3C chemokines and signals in response to some. Experiment by others using an AdUS28 recombinant infecting vascular smooth muscles cells indicate that US28 expression can direct cells movement (Sgtrebnow et al, Cell 1999; 99, 511). HCMV is predicted to encode additional NK inhibitory mechanisms and additional glycoproteins that may be expected modulate the expression of existing surface glycoproteins, to promote intracellular signalling and/or promote interaction with other cells. All these genes would normally only be expected to functions only in the transgene-expressing cell and thus are of lower potential hazard. The hazard with cell surface inhibitory receptors (eg UL18) may be increased if expressed as soluble forms to a hazard level similar to that of cmvIL-10 (UL111a). There is a potential hazard associated with the expression of biologically active molecules in native and modified (soluble or epitope tagged) forms. The hazard is reduced by the vector being replication-deficient. Although, the Ad vector has the potential to provide for relatively efficient in vivo delivery of these agents, in both animal models and in clinical trials it has been difficult (although possible) to deliver transgenes with Ad vectors efficiently enough to induce therapeutic effects with immunomodulatory cytokines such as IL-2 and IL-10. Hazards associated with using replication-deficient Ad recombinants encoding HCMV immunomodulatory genes are similar to those with human cytokines. This hazard should be controlled by providing ACGM-2 containment.
Baculovirus recombinants have the potential for environmental harm due to their capacity to kill insects. Enhanced baculovirus pathogenesis/virulence as a consequence of expressing a novel transgene is therefore to be avoided or controlled. Baculovirus is an enveloped virus and HCMV protein expressed in a baculovirus recombinant have the potential to be incorporated into baculovirus virions. HCMV has an extreme restricted tropism productively infecting only certain human cell types. HCMV infection also requires a complex series of events involving a number of HCMV glycoproteins acting together (gB, gH, gL, Go). While the HCMV receptor has not been characterised, the complex nature of the HCMV infectious process makes it extremely unlikely that the expression of an HCMV gene product would be capable of modifying the tropism of the baculovirus vector. The immune system of insects and humans has diverged. The HCMV immune modulators have evolved to have very precise effects on the human immune system. It is extremely unlikely that an HCMV-encoded immune modulator would be able to mediate a significant function in insects. Soluble chemokines and virokines depend on interactions with a matched receptors. Genes involved in MHC-1 downregulation and NK evasion also depend on highly specific interactions with molecules such as the MHC-1 proteins, TAP or NK ligands that are not likely to have survived evolutionary divergence. Baculoviruses-expressing HCMV genes have an extremely low likelihood of having enhanced virulence in insects. In certain cases HCMV genes may also be inserted into baculovirus under the control of a constitutive promoter for transgene expression to mammalian cells. Specific baculovirus recombinants would then have the potential to express HCMV immune modulators in human cells as with replication-deficient Ad vectors. The potential hazard is lower because Baculoviruses infect human cells relatively inefficiently and following infection there is an absolute barrier to replication. There is extremely low likelihood of enhanced environmental hazard with these constructs, for the same reasons as given above.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Animals are inoculated in a Class 2 safety cabinet. The site of inoculation is disinfected according to agreed protocols before the animals are placed in filter-top cages. It is not anticipated that the virus will remain viable in the animal nor be secreted from the animal. Nevertheless, both the animal and waste are incinerated according to standard procedures in Biomedical Services approved by the Health and Safety Unit.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

The committee queried 'whether or not the environmental Risk Assessment was sufficient for the use of baculovirus'. One has now been appended to the Risk Assessment.

The committee was happy that the containment level and classification of work assigned was appropriate. Class 1 Containment Level 1 for prokaryotic organism and cell lines. Containment level 2 for adenovirus and baculovirus.

Project Containment
### Project Information

**Project Ref:** 312/03.2

**Date Ackn'd:** 26/04/2005

**CU2 Project Title:** Identifying the functions of Epstein-Barr virus (EBV) genes using plasmid vectors and recombinant virus vectors (baculovirus, vaccinia virus, and replication-deficient adenovirus vectors)

**Class:** Class 2

**Culture Volume:** 1-50 Litres

**Non-GMM Consent Granted:** Not Applicable

**Project notified under transitional arrangements:** N

**Historical Significant Changes:** Project transferred from GM312 on 26/04/2005

**Historical Date of Additional Info**

**Significant Change ID**

**Date of Significant Change**

### Project Additional Information

**Purposes of the contained use**

We intend to perform a systematic investigation of human Epstein-Barr virus (EBV) gene functions by the cloning and expression of EBV genes in cell lines using baculovirus, vaccinia virus and replication-deficient adenovirus vectors. Previous work by our group has focussed mainly on the limited number of 'latent' viral genes expressed in B lymphoblastoid cell lines growth-transformed by EBV. However, the virus contains about 80-90 genes in total. Most of these are expressed only in cells entering the lytic virus productive cycle. The functions of some lytic cycle genes are quite well characterised (eg the BZLF1 immediate-early gene, encoding a transcriptional activator which initiates a cascade of viral gene expression) while the products and functions of many other genes are uncharacterised. The broad aims of this project are to investigate the mechanisms regulating induction and progress through EBV lytic cycle, and to screen for novel functions of EBV genes, particularly those which modulate immune responses. Experiments involving the use of replication-deficient recombinant adenoviruses may also include the use of a plasmid expression vector for the adenovirus receptor (CAR) to render specific cell lines susceptible to infection. Other components of the work designed to elucidate the mechanisms of EBV immunomodulating genes may also involve expression of components of the antigen processing pathway (eg HLA and TAPs). The vast majority of experiments will be performed on cell lines, but animals may occasionally be inoculated with Ad-recombinants primarily to generate antibodies specific for the transgene.
Preliminary prokaryotic cloning steps are necessary to generate the recombinant viruses. Genetically disabled E.coli K12 strains specifically developed for application in recombinant DNA cloning will be used. These strains have limited potential to colonise the gut or survive in the environment. Prokaryotic cloning experiments will be at ACGM category 1 level.

Adenovirus is an ACDP category 2 pathogen. Ad5 is primarily associated with mild upper respiratory tract infections of childhood. Deletion of the E1 gene region renders the adenovirus vectors replication-deficient, which limited the potential for lateral spread. Theoretically, lateral spread could be facilitated by co-infection and a wt adenovirus or by gene-rescue from the helper line.

Vaccinia virus is an ACDP category 2 pathogen. Recombinant viruses may retain the pathogenic potential of wild-type vaccinia. The WR strain is a replication-competent lytic virus which has the potential to cause lesions, whereas the MVA strain is non-lytic and has to be generated in chicken embryo fibroblast (CEF) or BHK-21 cells. However, neither WR nor MVA recombinants are compatible with cell survival. Insertion of foreign genes into the thymidine kinase (TK) locus results in a TK phenotype which is attenuated relative to wild-type virus. The MVA strain is already highly attenuated.

Baculovirus vectors are replication competent in some insect cells but are replication-competent in mammalian cells. The vectors lack the non-essential polyhedrin gene.

**Host/vector system**

- **Prokaryotic hosts:** E. coli strains DH5a, JM109, BJ583 and XL-blue will be used.
- **Adenovirus recombinants:** Commercial Ad5 vector systems will be used. The Admax vector system from Microbix, Canada; the AdEasy vector system from Qbiogene, Hareford, Middx. Additionally, the gutted Ad vector as described by Schneider et al (J. Virol. 2002, 76:1600). Replication-deficient adenoviruses will be propagated in a helper cell line expressing an E1 helper function (eg 293 or 911 cells) and then used to infect target cells in vitro or in vivo.
- **Vaccinia virus recombinants:** These will be made in the Western Reserve (WR) or in the Modified Virus Anraka (MVA) vaccinia strains. WR virus will be repared in TK 143 cells, while MVA will be prepared in CEF or BHK-21 cells.
- **Baculovirus recombinants:** Commercial Insect Select (Invitrogen) and BacVector (Novagen) systems. Sf9 insect cells for growth of baculovirus vectors.
- **Target cells:** Tissue culture cells, including human tumour lymphoid (eg Burkitt’s lymphoma B cell lines, and Jurkat T cell line) and epithelial cell lines (eg Hele, 293). Primary lymphoid and fibroblast cells.
- **Animals may be inoculated with Ad recombinants, primarily to generate polyclonal or monoclonal antibodies.**

**Origin & function**

Genes will be cloned from Epstein-Barr virus isolates, including B95.8 and Raji which have been used to generate a complete ‘wild-type’ sequence (EBV-wt; accession number AJ507799) of 171,823 basepairs with approximately 80-90 known or postulated genes. Epstein-Barr virus is a category 2 ACDP pathogen. It is a lymphotropic/epitheliotropic gamma-herpesvirus that is carried as a life-long persistent infection by more than 90% of adults. Despite the asymptomatic nature of EBV infection, the virus has the potential to transform one of its principal target cells, B lymphocytes, and experimental infection of B cells in vitro leads to the establishment of lymphoblastoid cell line (LCL). These LCL carry EBV predominantly as a ‘latent’ (ie non-productive) infection. In healthy EBV-positive individuals, the persistent virus infection is effectively controlled by immune mechanisms, particularly cytotoxic T cells (CTLs). Since EBV is a virus with transforming potential, one potential hazard of the vectors to be generated is the possibility that the expressed genes may be oncogenic. The role of EBV genes in cellular transformation is well studied. At least five of the ‘latent’ genes are known to be absolutely essential for the ability of EBV to transform human B cells. The main function of the EBNA1 protein is maintenance of the EBV episome during cell replication. EBNA2, EBNA3A and 3C are nuclear proteins that activate and/or repress transcription of EBV and cellular genes. LMP1 is a membrane protein that mimics a constitutively active receptor of the CD40/TNFR superfamily. Both LMP1 and EBNA3C have been defined as having oncogenic or immortalizing
properties in rodent fibroblast assays. However, all attempts to demonstrate conversion of non-malignant human cells to a full malignant phenotype with any single EBV gene have been unsuccessful. While some of this work will necessitate using EBV 'latent' genes in recombinant adenovirus or vaccinia virus expression vectors, the main objective of this project is to identify functions of the lytic cycle genes, most of which are poorly characterised, if at all. The original impetus for this work derived from a wish to identify those genes responsible for down-regulating expression of components of the antigen processing pathway in cells harbouring EBV as a productive, lytic infection. Therefore, it can be deduced that we expect some EBV genes to have immunomodulatory functions. Indeed, one well-characterised gene (BCLF1) is known to encode an IL10 homologue. However, there is no compelling evidence to suggest that EBV infection is immunosuppressive; on the contrary, it elicits potent immune-responses.

In addition to vectors expressing wild type EBV genes and mutated genes, other constructs will be required for this project. The use of adenovirus vectors on B lymphocytes, a natural host for EBV, is hampered by the fact that these cells often express only low levels of adenovirus receptor (CAR). Therefore, a human or porcine CAR-expression plasmid will be used to make stable transfectants of established cell lines to generate lymphocytes that can be efficiently infected with replication-deficient adenovirus vectors. The potential risk of the CAR expression plasmids in this context is minimal.

Some experiments, designed to establish the mechanisms by which EBV genes modulate antigen presentation, will also require the use of expression plasmids or recombinant viruses for components of the immune recognition process (eg human MHC, TAP, NK receptors).

Other experiments will use a number of reporter plasmids with specific transcription factor binding motifs to characterise signalling functions or to indicate activation of lytic cycle. Furthermore, reagents generated from related notified projects ("modulation of lymphocyte function with adenoviral vectors" - Dr Brennan; and "Analysis of Epstein-Barr virus latent gene functions" - Prof Rowe) will be used to assist elements of this project. For generation of new expression plasmids, we will use well characterised constructs, some of which are designed to incorporate 'tags' to allow detection and/or isolation of the expressed proteins. These tag sequences are unlikely to pose any significant additional hazard.

Evaluation of foreseeable effects

Most EBV genes have no known biological functions or functions that have no predictable detrimental effect when expressed in the proposed vectors. The 'latent' genes associated with the growth-transforming functions of EBV may be considered to constitute the greatest potential hazard when expressed in the proposed vectors. Both LMP1 and EBNA3C have been defined as having oncogenic or immortalising properties in rodent fibroblast assays. However, it is clear that EBV requires the co-operative action of at least 5 genes (EBNA1, EBNA2, EBNA3A, EBNA3C, and LMP1) to immortalize human B cells. Therefore, the hazard posed by accidental expression of these genes is substantially reduced. Furthermore, the adenovirus and vaccinia virus vectors should give only transient expression whereas the potentially pathogenic effects of the latent genes require persistent expression. Finally, all EBV latent genes (with the possible exception of EBNA1) are effectively targeted by cytotoxic T cell immune response. Thus, the potential hazard with regards possible transformation of human cells infected with Ad virus recombinants expressing EBV latent genes is acceptably low. This view is supported by the fact that similar work has already been approved at Birmingham (Rickinson Group) and Liverpool (Blaake group) and is being performed under category 2 containment.

The effects of most EBV lytic cycle genes on cellular gene expression and phenotype is unknown - which is the very reason for undertaking this project. However, none of the lytic cycle associated EBV genes studies have been reported to show oncogenic properties. Indeed two of the immediate-early genes (BZLF1 and BRLF1) have been expressed by others in Ad virus vectors and have been shown to selectively inhibit growth of EBV-positive tumours (J. Virol., 2002. 76:10951). Unlike many other members of the herpesvirus family, EBV encodes relatively few genes that are obvious homologues of immunomodulatory molecules. The notable exception is BCRF1 which is highly homologous to IL-10 and shares functional properties with the human cytokine. IL-10 is used therapeutically to suppress immunological responses, and is well tolerated in high doses although it may predispose to infection. Ad recombinants encoding cellular and EBV vIL-10 have been used in animal models to suppress immunopathologies. As a secreted virokine, vIL-10 Ad recombinants have a theoretical potential to induce transient and localised suppression of Th1 immune responses. Therefore, there is a low level potential hazard with Ad-BCRF1 recombinant viruses.

Adenoviruses are ACDP level 2 agents that are naturally infectious to the respiratory tract as aerosols. If accidental inoculation were to occur, the viral DNA would be introduced into a number of cells giving transient expression of the transgene over a period of a few days to weeks. However, all Ad vectors used will be replication-deficient due to deletion of the E1 and E3 gene regions; this is a recognised safety feature. Therefore, following accidental inoculation, further spread would not occur. With time, the genome will be lost from the infected cells, this process being more rapid in proliferating cells. Chromosomal integration of Ad virus sequences is a rare event (in the region of one integration in 10(4) exponentially growing cells). It is generally agreed that most cells of the respiratory tract epithelium are post-mitotic and...
on the differentiation pathway. Therefore, it is our opinion that a considerable intake of virus, much greater than $10^5$ pfu, would be required to produce a single integration event. Working practices are designed to minimise the risk of any human contamination, and the likelihood of accidental infection followed by viral integration is almost negligible. Repair of the E1 deletion of the Ad vectors could potentially occur in vitro due to homologous recombination with the E1 gene in the helper cell line, or in vivo following the unlikely event of coinfection of a single cell with recombinant Ad virus and a natural wild-type Ad virus. Such recombination events are likely to result in concomitant deletion of the transgene in the E1 locus. Generation of a replication-competent Ad carrying the whole or part of the transgene is not impossible, but extremely unlikely. It is notable that attempts to detect such complementation by dual infection in the cotton rat model gave negative results. The potential hazard of the recombinant adenoviruses should be adequately controlled by adhering to ACGM-2 containment.

Vaccinia viruses are ACDP category 2 agents which have the ability to infect a wide range of cells in human and non-human hosts. Vaccinia may cause pustular lesions at the site of infection, and can cause severe disease in individuals with active skin disorders such as eczema or psoriasis. Acute conjunctivitis may occur after inoculation into the eye but permanent eye damage is rare. Disseminated vaccinia necrosum can occur in immunosuppressed or immunodeficient individuals. Recombinant viruses may retain the pathogenic potential of wild-type vaccinia. The WR strain is a replication-competent lytic virus which has the potential to cause lesions, whereas the MVA strain is non-lytic and has to be generated in chicken embryo fibroblast (CEF or BHK-21 cells. However, neither WR nor MVA recombinants will be compatible with cell survival. Therefore only transient expression of the inserted genes will be obtained, and the additional risk posed by the inserted genes will be low. It is not clear whether EBV glycoproteins would be expressed in the vaccinia virus envelope, but it is not expected that this would alter the tropism of the virus. The potential hazards of the recombinant vaccinia viruses should normally be adequately controlled by adhering to ACGM-2 containment. However, individuals with skin disorders are at greater than normal risk for working with vaccinia viruses and should seek additional advice.

Genetically modified baculoviruses retain the ability to infect cells of the insect host species but do not efficiently infect human cells. During infection of insect cells, expression of the gene insert will occur under the control of the Polyhedrin or P10 promoters, but these promoters are not expected to be functional in human cells. It is not clear whether EBV glycoproteins would be expressed in the baculovirus envelope, but the complexity of the EBV infection process makes it extremely unlikely that insertion of a single EBV protein would alter the tropism of a recombinant baculovirus. Therefore the nature of the EBV gene insert in recombinant baculovirus itself is not expected to pose any additional risk to human health or to the environment. A case could be made for using the recombinant baculoviruses at ACGM level 1, but taking a more cautious view we propose to adhere to ACGM-2 containment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Virus in solution (tissue culture medium or buffers such as PBS) will be inactivated by adding at least an equal volume of 2500 ppm sodium dichloroisocyanurate (Antichlor). After 4 hr, the solution can be discarded to mains drainage and flushed with excess water. Contaminated pipettes are immersed in 2500 ppm sodium dichloroisocyanurate (Antichlor) for 4 hr prior to transferring to a containing for autoclaving. All plasticware is autoclaved after exposure to virus. Actichlor is effective against all viruses and the chosen concentration overcomes the high organic content of tissue culture media.

Animals may be inoculated with recombinant adenoviruses in a Class 2 microbiological safety cabinet. The site of inoculation is disinfected according to agreed protocols before the animals are placed in filter-top cages. It is not anticipated that the virus will remain viable in the animal nor be secreted from the animal. Nevertheless, both the animal and all animal waste is incinerated according to standard procedures in Biomedical Services approved by the Health and Safety Unit.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N
Did want care taken over RA. RA now suitable and sufficient. Agreed by Chair.

### Project Additional Information

**Purposes of the contained use**

To identify and study the behaviour of mammalian epithelial stem cells. After the basic epithelial stem cell patterns have been established, work will examine how intrinsic stem cell patterns are altered by the forced expression of certain genes that are putatively associated with control of stem cell growth and differentiation. This project will use combined techniques of stem culture, retroviral transduction, tissue reassembly to determine: a) the size and distribution of stem cell territories in a range of human and murine epithelia of differing complexities, b) the influence of stromal/epithelial interactions in determining stem cell patterns, c) how stem cells are alterer in malignancy, and d) how stem cell behaviour is influenced by the expression of genes associated with cell differentiation and cell death.

**Recipient or parental organism**

The recipient or parental organism for the standard cloning are disabled non-pathogenic E coli strains. The recipient cell lines for expression of the proteins are standard cell culture lines which cannot survive out of culture and which are kept free from any adventitious agents as far as can be determined by our routine assays for contaminating agents which are problematic in tissue culture, e.g. mycoplasma.

**Host/vector system**

- **Host** - DH5a (bacterial cloning)
- **Vector** - pPinco

**Origin & function**

- **Source of Nucleic Acid:**
  - GFP cDNA
  - Alkaline phosphatase cDNA
  - Galactosidase cDNA

- **RAS human cDNA**
- **Bcl-2 related human cDNAs**

---

**Description of DNA to be manipulated:**

Transferred to GM130 on 26/04/2005
Modified jellyfish gene, Mammalian placenta & E.Coli - Lineage markers

Mammalian GTPase & Mammalian homologs of C.Elegans ced genes - Potential modifiers of Stem cell behaviour

**Evaluation of foreseeable effects**

To introduce modified oncogenes and anti-oncogenes into mammalian cells in culture, the cDNA of the gene in question is sub-cloned into a replication defective retroviral vector plasmid. This is transfected into a "packaging" cell line which therefore secretes retroviral virions capable of coding for the inserted sequence. These are able to infect human cells but are not capable of further cycles of replication. There is therefore no risk of subsequent spread of infection. The viruses are extremely fragile and are extremely sensitive to desiccation, the recipient cell lines are unable to survive outside culture conditions.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All cells and media which may contain infectious virus are handled by designated specially trained workers in a class II biological safety cabinet equipped with external ducting. All liquid waste will be sterilised at point of use by sodium hypochlorite, as per College and Trust sterilisaation and disinfection policy. All solid waste will be sterilised in an adjacent autoclaving facility which is regularly tested by Cardiff and Vale Trust engineers.

02/03/2022
The function and the structure of the extracellular matrix (ECM) is controlled by regulatory molecules as well as by modifying enzymes which can crosslink or cleave matrix constituents. Some of these molecules have functions in the ECM and also control cells residing in the matrix by regulating the availability of cytokines or by direct effects on cells: (1) decorin (see below) can regulate collagen fibril formation as well as TGF-B availability and has direct effects on cell differentiation and survival (Kresse & Schonherr, 2000, J. Cell Physiol. 189:266). (2) Tissue transglutaminase does not only influence cell-matrix interactions but also has GRPase activity and via this activity can contribute to the regulation of intracellular signalling cascades that control cell spreading and motility (Stevens et al., 2004, J. Cell Sci. 117:3389). To investigate the contribution of these distinct functions to biological effects, we plan to use adenoviruses for the expression of wild type or mutant components in different types of cells. Adenoviral gene transfer is necessary (a) to mimic the situation in vivo (because naturally these molecules are induced and not constitutively expressed), (b) the cells used in the investigation (eg endothelial cells, primary fibroblasts, macrophages) are difficult to transfect and easily damaged and © adenoviral infection allows a reproducible induction of a specific molecule.

Small leucine-rich proteoglycans (SLRPs) are multifunctional regulatory molecules of the extracellular matrix. Members of this family are decorin, biglycan, fibromodulin and lumican. In the past, SLRPs were primarily considered as organizers of collagenous networks. More recently their interactions with TGF-B and their direct effects on cells have come into focus. We showed with the help of adenoviral vectors that decorin induces capillary formation and survival of endothelial cells, but it induced programmed cell death in tumour cells (Schonherr et al. 1999, Eur. J. Cell Biol. 78:44; Tralhao et al. 2003 FASEB J.. 17:464). Our studies on endothelial cells further indicated that protein kinase B (Akt) is involved in decorin-mediated signalling leading to cell differentiation and survival (Schonherr et al., 2001, J. Biol. Chem 276, 40687). In collaboration with Dr P. at this institution we plan to use adenoviruses that have already been prepared to investigate signalling cascades in other cell systems. These adenoviruses will allow us an in dept analysis the decorin signalling pathways(s). We will use these viral vectors to transfect endothelial cells and fibroblasts in culture. The already existing adenoviral vectors will allow us to carry out in depth analysis of decorin-induced intracellular signalling pathways(s). We plan to use adenoviral vectors containing different mutated forms of SLRPs to analyse which parts of these molecules have specific functions. Therefore, we will use the cDNAs of the SLRPs which are
available in our laboratory to construct new adenoviral vectors. The resulting replication deficient viruses will subsequently be used in different cell culture models to analyze the function of SLRP mutants.

Transglutaminases are enzymes that have extracellular as well as intracellular functions. One of the best characterised members of this family of multifunctional enzymes is tissue transglutaminase (TGase2). In the extracellular matrix, this enzyme can catalyse the formation of isopeptide bonds leading to protease resistant high molecular weight complexes, while intracellularly, the enzyme acts as a G-protein in signal transduction and mediates PKCa activation via regulation of PLC81. Recent evidence demonstrates that TGase2 controls cell morphology, differentiation and survival by modulating cell-matrix interactions. We have shown that fibroblasts deficient in TGas1 are defective in cell spreading, migration and matrix assembly (Stevens et al., 2004 J.Cell Sci. 117:3389). Recent work by us and others also showed that lack TGases2 have delayed healing of skin wounds and have a deficiency in TGR-B1 production (Szondy et al., 2003. Proc. Natl. Acad. Sci. USA 100:7812). While previous cell culture data also implicated the enzyme in the activation of latent TGF-B the mechanism has not been elucidated. At present it is unclear whether the effects in the wound healing relate to defects in fibroblasts or in cytokine release by macrophages and also which of the activities of the enzyme is are essential for normal wound healing. We plan therefore to generate different adenoviruses which contain transglutaminase and different transglutaminase to determine whether we can rescue the phenotype of cells isolated from mice lacking transglutaminase and to analyse which activity of the enzyme is relevant for which biological function.

Recipient or parental organism

Adenovirus is an ACDP category 2 pathogene. Ad5 is primarily associated with mild upper respiratory tract infections of childhood. Deletion of the E1 gene region renders the adenovirus replication deficient. Replication deficient adenoviral vectors by their nature have a limited potential for lateral spread, although this could be facilitated by co-infection with wild-type adenovirus or gene rescue from helper cells.

To generate new replication deficient adenoviruses containing transgenes preliminary prokaryotic cloning steps are necessary. Genetically disabled E. coli K12 strains specifically developed for the applications in recombinant DNA cloning experiments will be used. These strains have limited potential to colonise the gut or survive in the environment.

Host/vector system

E. coli strains JM109, TOP 10, INV a F’ and DH5a will be used.

A commercial Ad5 vector system will be used for the construction of the replication deficient adenovirus (rendered replication deficient through deletion of the complete E1a and E1b gene function and further disabled by partial deletion of E3 gene). The Ad5 based AdEasy vector system from Stratagene. This system comprises pAdEasy-1, pShuttle, pShuttle-CMV, pShuttle-CMV-LacZ (control).

Replication deficient adenoviruses will be propagated in HEK-293 cells (a helper cell line expressing the E1 helper function). The resulting adenoviral vectors will be used to infect target cells in vitro.

Origin & function

All DNA are human and mouse cDNA clones previously generated by us or gifts from collaborators. DNA sequences are known and will be confirmed prior to generation of recombinant virus.

Replication deficient adenoviruses containing wild type human decorin and variant forms of decorin and variant forms of decorin have been previously generated with the AdEasy System in Germany or the USA (Schonherr et al. 1999, Eur. J. Cell Biol. 78:44; Tralhao et al. 2003FASEB J. 17:464). New adenoviral vectors containing additional mutations in the transgene will be prepared using the same technology. In addition, adenoviral bvectors for other members of this protein family, ie human biglycan, fibromodulin, and lumican will be generated. The effect of transgenes cloned into these vectors on endothelial cells and fibroblast will be investigated using a number of established biological assays to study extracellular matrix assembly and angiogenesis. New adenoviral vectors containing mutants of human decorin using the same technology will be prepared.
Replication deficient adenoviruses containing mouse dominant negative and positive Akt were gifts from Boston USA (Fujio Y & Walsh K, 1999, J Biol. Chem. 274:16349). These adenoviruses will be used to investigate the decorin signalling in target cells in culture. In addition, replication deficient adenoviruses approved by Genetic Modification Sub-Committee (GM 312/DWT./PB/3) will be used in collaboration to investigate pathways in these cells in culture.

Replication deficient adenoviruses containing human and mouse transglutaminase or mutants thereof will be generated to determine whether we can rescue in vitro in cell culture assays the phenotype of cells isolated from mice lacking transglutaminase and to analyse which activity of the enzyme is relevant for which biological function.

Evaluation of foreseeable effects

From experiments using adenoviral gene transfer of decorin we already know that the expression of decorin leads to differentiation and survival of normal cells (endothelial cells, primary fibroblasts). In addition, we and others have shown that decorin expression in tumour cells leads to a more differentiated phenotype or programmed cell death. Therefore, the transient expression of decorin in cells in culture does not present a foreseeable hazard. Furthermore, as these experiments should mimic the situation in vivo, no large scale over-expression of the transgene is planned and thus fairly low concentrations of the adenoviruses will be used.

The generation of other adenoviral vectors containing the cDNA of molecules related to decorin is of low risk, because none of the SLRP's has been shown to have a transforming capacity. In contrast eg the lack of lumican or decorin expression in mammary tumours has been shown to be associated with a bad prognosis. In addition, over expression of biglycan in the pancreas carcinoma cells cause G1-arrest.

Potentially the largest risk is the use of the existing adenovirus containing active Akt which can enhance cell survival and proliferation. However, Akt alone is not sufficient to cause a malignant transformation of human primary cells. In addition, active Akt will only be used infrequently and only at a dose that results in activity mimicking the normal levels of activation in response to decorin. The adenovirus transducing the dominant negative form of Akt (which prevents Akt signalling) will be used to much greater extent. The potential hazard presented by these experiments is perceived to be low.

The generation of other adenoviral vectors containing the cDNA of transglutaminase which is a protein cross linking enzyme is also perceived to be very low. Transglutaminases have no transforming effect on cells. These enzymes strongly promote cell adhesion and several studies have shown that the malignant potential of cancer cell lines is reduced upon transfection with vectors directing constitutive expression of transglutaminase.

The host vector systems which will be used in the experiments are commercially available and well characterised. As the used adenoviruses are replication deficient they can only replicate in host cells which contain E1 sequences that have been deleted from the viral vector (these sequences are present eg in HEK-293, which are used for virus propagation). It is highly unlikely that the replication deficient viruses would regain spontaneously the ability for replication. In addition, large numbers of virus particles would be necessary for a sustained infection. Expression using the adenoviral vectors is only transient and is lost in rapidly replicating cells. Therefore, adenoviral vectors are unlikely to cause any permanent change in infected cells.

A potential hazard is the exposure of humans to recombinant virus. All manipulations of the virus will be done in a class 2 biological safety cabinet in the designated laboratory facility. The access will be limited to staff trained ACGM level 2 procedures. Any disposable materials that had contact with the virus will be disinfected chemically as well as by autoclaving prior to disposal. The use of sharps will be avoided to prevent accidental injury related risk. Therefore, any risk of the exposure of humans or the environment is very low.

Evaluation of foreseeable effects

From experiments using adenoviral gene transfer of decorin we already know that the expression of decorin leads to differentiation and survival of normal cells (endothelial cells, primary fibroblasts). In addition, we and others have shown that decorin expression in tumour cells leads to a more differentiated phenotype or programmed cell death. Therefore, the transient expression of decorin in cells in culture does not present a foreseeable hazard. Furthermore, as these experiments should mimic the situation in vivo, no large scale over-expression of the transgene is planned and thus fairly low concentrations of the adenoviruses will be used.

The generation of other adenoviral vectors containing the cDNA of molecules related to decorin is of low risk, because none of the SLRP's has been shown to have a transforming capacity. In contrast eg the lack of lumican or decorin expression in mammary tumours has been shown to be associated with a bad prognosis. In addition, over expression of biglycan in the pancreas carcinoma cells cause G1-arrest.

Potentially the largest risk is the use of the existing adenovirus containing active Akt which can enhance cell survival and proliferation. However, Akt alone is not sufficient to cause a malignant transformation of human primary cells. In addition, active Akt will only be used infrequently and only at a dose that results in activity mimicking the normal levels of activation in response to decorin. The adenovirus transducing the dominant negative form of Akt (which prevents Akt signalling) will be used to much greater extent. The potential hazard presented by these experiments is perceived to be low.

The generation of other adenoviral vectors containing the cDNA of transglutaminase which is a protein cross linking enzyme is also perceived to be very low. Transglutaminases have no transforming effect on cells. These enzymes strongly promote cell adhesion and several studies have shown that the malignant potential of cancer cell lines is reduced upon transfection with vectors directing constitutive expression of transglutaminase.

The host vector systems which will be used in the experiments are commercially available and well characterised. As the used adenoviruses are replication deficient they can only replicate in host cells which contain E1 sequences that have been deleted from the viral vector (these sequences are present eg in HEK-293, which are used for virus propagation). It is highly unlikely that the replication deficient viruses would regain spontaneously the ability for replication. In addition, large numbers of virus particles would be necessary for a sustained infection. Expression using the adenoviral vectors is only transient and is lost in rapidly replicating cells. Therefore, adenoviral vectors are unlikely to cause any permanent change in infected cells.

A potential hazard is the exposure of humans to recombinant virus. All manipulations of the virus will be done in a class 2 biological safety cabinet in the designated laboratory facility. The access will be limited to staff trained ACGM level 2 procedures. Any disposable materials that had contact with the virus will be disinfected chemically as well as by autoclaving prior to disposal. The use of sharps will be avoided to prevent accidental injury related risk. Therefore, any risk of the exposure of humans or the environment is very low.
2500 ppm. After 4 h, solutions can be discarded. Nevertheless, the solutions will be autoclaved prior to being discarded through the main drain. Pipettes immersed in 2500 ppm sodium dichloroisocyanurate for 4h will be transferred to plastic bags for autoclaving. All plastic ware is autoclaved after virus exposure. Actichlor is effective against all viruses and the high concentration overcomes the high organic contents of media.

Is an emergency plan required according to regulation 20?

### Project Additional Information

#### Purposes of the contained use

Recombinant vaccinia virus will be used to infect target cells in vitro, normally human B-lymphocytes derived from patients with cancer of the cervix. The recombinant (TA-HPV) is derived from the Wyeth strain of vaccinia and expresses human papilloma virus 16 and 18 fusion protein E6/E7. The virus is replication-competent and is not attenuated. Infected B cells will be used as in vitro targets to monitor the success of a vaccination schedule carried out using dendritic cells loaded with E6/E7 in vivo. The purpose of the vaccination is to induce an immune response to cancer cells expressing E6/E7 in vivo. The recombinant will be obtained from the University of Wales College of Medicine and no further genetic modification of the virus will be carried out at Velindre. Patients will not be exposed to vaccinia.

#### Recipient or parental organism

The recombinant (vaccinia TA-HPV) expresses an HPV16 and 18 E6/E7 fusion protein which is produced from the two separate sequences by a modification of the E6 termination codon. It is known that expression of E6 and E7 in mammalian cells is able to induce both immortalisation and a transformed phenotype so that infection of an individual with TA-HPV must be considered to increase the risk of carcinogenicity. However, vaccinia is a lytic virus, so that all infected cells die. In addition, the E7 sequence has been modified to abolish its ability to bind Rb and hence to cause immortalisation. Both these factors are considered to reduce the risk of carcinogenicity. Vaccinia itself is a pathogen and is in ACDP Hazard Group 2. The recombinant is considered to pose an elevated risk compared to wild-type Wyth strain vaccinia.

#### Host/vector system

**Vector:** Wyeth strain vaccinia virus (TA-HPV) expressing human papilloma virus fusion protein E6/E7. The sequence has been modified to reduce Rb binding and hence the risk of immortalisation of the host cell. The virus is replication competent, unattenuated and lytic.

**Host:** Mammalian cells in vitro. These will normally be human B-lymphocytes derived from patients with cancer of the uterine cervix.

#### Origin & function

The vaccinia recombinant TA-HPV has been constructed elsewhere and will be obtained from the University of Wales College of Medicine, Cardiff. Mammalian cells infected in vitro with TA-HPV will express the human papilloma virus 16 and 18 fusion protein E6/E7. These cells will then be used as targets for T-cells derived from vaccinated patients before vaccinia-induced lysis occurs.

#### Evaluation of foreseeable effects

Pathogenicity of vaccinia: Vaccinia is in ACDP Hazard Group 2. The Wyeth strain has been widely used in vaccination programmes and its effects are well characterised.
Infection can lead to a vesicular lesion usually accompanied by a generalised infection. The lesion generally heals in about 10 days. In a recent case involving the accidental infection of a laboratory worker, lesions appeared on the finger and on a recently-pierced eyebrow. However, it is considered unlikely that infection will lead to a serious long-term sequelae. Skin penetration or mucosal contact is required for infection to occur.

Pathogenicity of TA-HPV recombinant: The recombinant expresses the human papilloma virus 16 and 18 fusion protein E6/E7. These proteins are known to have immortalisation and transforming potential; however, the E7 sequence has been modified to reduce binding to Rb which will minimise the probability of immortalisation. Also, the fusion of E6 and E7 reduces the risk of transformation. Nevertheless, the E6/E7 sequence must be considered to be potentially oncogenic so that pathogenicity of the recombinant is greater than that of the wild-type. However, the probability of carcinogenesis in vivo is reduced by cell lysis caused by vaccinia.

Hazard to the environment: Wyeth strain vaccinia has been widely used in wild animal vaccination programmes involving the release of genetically modified virus into the environment. This work has demonstrated that there is a low risk of environmental damage due to vaccinia. It is unlikely that this risk will be significantly greater in TA-HPV than in the wild type.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

NONE

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Small-scale solid and liquid waste will be generated (less than 100gm). All waste will be inactivated by autoclaving, and chemical disinfectants will not be permitted unless they are compatible with subsequent autoclaving.

Autoclaving will be carried out using a sterilizing criterion of 126°C held for 10 minutes. These conditions within the load are verified annually using positioned thermocouples. Autoclaved waste will be sealed in a yellow bag for incineration off-site as clinical waste.

Is an emergency plan required according to regulation 20? Y

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Risk assessment suitable but requested more information on transport of GMO from UWCM to Velindre, and procedure for seeking emergency advice from Occupational Health Service. Additional information now provided.

Project Containment
### Project Additional Information

**Purposes of the contained use**

To examine the ability of cells over expressing the ADH gene to be damaged by excess acetaldehyde production following exposure to ethanol.

**Recipient or parental organism**

The adenovirus employed in these experiments is adenovirus serotype 5 (ad5). This virus is associated with childhood respiratory infections and most adults will have antibodies to the wild type virus. The virus has had the genes for the E1 gene (nucleotides 1-3533) completely removed. This gene is an absolute requirement for replication and so its removal makes it unable to replicate and so incapable of making infectious viral particles.

The removal of the E1 gene has the effect of minimising the pathogenicity of the virus to human contacts. This removal places the virus in the ACGM Hazard group 1 'unlikely to cause human disease'.

The gene of interest is inserted into the site of the disabling mutation. This should minimise the theoretical possibility of recombination with wild type adenovirus.
Cancer cell lines including; HBL 100, Hela, Jurkat, Daudi.

Host/vector system

Adenovirus serotype 5
The virus is made replication deficient due to deletion of E1 locus. (ref He et al; PNAS 95; 2509-2514).

Human alcohol dehydrogenase beta 2 (ADH b2) enzyme cDNA. Obtained from human liver cDNA (ref Ikuta et al PNAS 83; 634-638)

Origin & function

Adenovirus serotype 5
The virus is made replication deficient due to deletion of E1 locus. (ref He et al; PNAS 95; 2509-2514).

Human alcohol dehydrogenase beta 2 (ADH b2) enzyme cDNA. Obtained from human liver cDNA (ref Ikuta et al PNAS 83; 634-638)

Evaluation of foreseeable effects

The risk to human health is low as;
The virus has very low infectivity for human cells outside of the in vitro experimental setting.
The virus is non-replicating.
In infected cells the gene is expressed for 3-4 days only.
The gene encoded is a normal human gene expressed in many cells.
The virus and the cDNA are non-oncogenic, non-toxic and harmless to human health.
The modification to the virus will not expand the host range of the virus.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All the cells, containers, pipettes etc used in the project using the adenovirus will be disposed of via the on site autoclave. This is validated annually and has an assumed 100% kill.
Laboratory surfaces/hoods etc will be disinfected with sodium hypochlorite solution.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
The committee are happy that this project poses a negligible risk to both human health and the environment. Purely for GM purposes it would be allocated to containment level 1, but as the work will involve primary human cells the project will need to be performed a category 2.

Page 3858 of 15326
For activities involving GMMs, describe the waste management measures which will apply to the activity

All small scale laboratory waste is decontaminated before disposal by autoclaving at 121 degrees C for 20 minutes or by treatment with disinfectants. The effectiveness of the disinfectants on viability having been validated.

All the larger scale processing equipment operates to "Contained Use" within a building that has contained drains directly linked to the site effluent treatment plant. The maximum volume possibly released at any one time is 35,000 litres, due to loss of vessel integrity, but this would be totally contained within the fabric of the building and collected into the site effluent system for treatment. Historically this event has not happened during, at least, the last 25 years and all vessels are regularly maintained and insurance validated.

All SB Worthing site liquid effluent undergoes chemical treatment prior to disposal, to kill process organisms, including GMMs, to comply with current EA and EC regulations. Laboratory experiments determined the operational parameters for the effluent treatment process to ensure that GMM numbers are controlled to the requirements of the regulations.

The site operates controlled waste disposal using a detailed "What Goes Where Guide" for other solids and general waste material.

The effluent treatment plant is a state of the art facility, fully automated and controlled by a central computer with numerous plant interlocks to prevent operation outside of specified parameters. The process is continually monitored to ensure the required treatment conditions are maintained. In addition, the process has been fully validated by monitoring to determine that the organisms have not survived after treatment. Procedures are in place for this validation to be repeated on a regular basis to maintain assurance that there is no release of GMMs to the environment.

All operations are controlled by a site Quality change control procedure with annual reviews of recorded data and modifications, which are regularly assessed and approved by the site GMSC.

**Project Additional Information**

**Purposes of the contained use**
To determine the effect of PAX3-FKHR protein expression in myocytes

**Recipient or parental organism**
GMOs generated from this activity have no foreseeable effects to human health or safety

**Host/vector system**
Hosts: Disabled K-12 derived E.coli SURE
Vector: Full length PAX3-FKHR cDNA has been cloned into the mammalian expression vector PBK-CMV under the control of the MyoD promoter/enhancer sequence. This construct includes a Kozak sequence, the PAX3-FKHR coding sequence, an estrogen receptor and a poly A tail. The host vector system proposed presents negligible risk to human health or the environment. ACGM Compendium of Guidance Part 2A Annex II.

**Origin & function**
PAX3-FKHR is a fusion protein generated from a chromosomal translocation, which occurs in the paediatric tumour Alveolar Rhabdomyosarcoma. Evidence suggests it is responsible for the aggressive malignant phenotype of this disease. Previous in vivo experiments have shown that PAX3-FKHR is a transcriptional activator that significantly enhances transcription and mitotic index in several cell types. This project will investigate the role of the PAX3-FKHR oncogene by expressing the abnormal protein in a model system.

**Evaluation of foreseeable effects**
The host and vector systems used to generate the constructs present minimum risk to human health and safety and could be handled adequately as a class 1 activity under level 1 containment. However, as this project involves the generation of naked oncogenic DNA it will be subject to the appropriate containment and control measures for a class 2 activity and level 2 containment. Although there is no direct evidence that direct contact with naked oncogenic DNA can lead to tumours in humans it is intended to incorporate measures which will limit accidental inoculation or transmission of these DNAs to the laboratory workers. All experiments will be carried out in the ACDP level 2 laboratories with emphasis on the following points in accordance with our local rules and recommendations given in ACGM Compendium of Guidance Part 2A-Annex III and Part 3A-Annex 1
1. Gloves will be worn at all times and changed when working elsewhere.
2. Steps are in place to limit aerosol production and aerosol contamination (filter tips)
3. Limited use of sharps and glassware to avoid accidental inoculation
4. Staff are aware of the hazards of handling oncogenic DNA

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
n/a

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**
none

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**
Waste for GMMs will be handled according to our local rules. Bacterial cultures will be inactivated by chemical treatment with fresh Chloros for a minimum of 24 hours. All plastic disposables and gloves will be autoclaved and incinerated.

The risk assessment for this activity has taken into account the oncogenic potential of the DNA sequence to be inserted in the GMO. The activity has therefore been designated as Class 2. Suitable precautions to limit the risk of accidental inoculation of naked oncogenic DNA are already practiced in the laboratories designated for Level 2 containment. All other working practices described are in accordance with our local rules.

### Project Additional Information

#### Purposes of the contained use

1. To ascertain the extent and significance of inactivation of the tumour suppressor gene p15 in childhood leukaemia.
2. To investigate the relationship between p15 and other known molecular abnormalities in childhood leukaemia.

#### Recipient or parental organism

GMMs generated from this activity have no foreseeable effects to human health or safety. The hosts are all disabled or non-colonising in humans and plasmid and cosmid vectors are non-mobilisable.

#### Host/vector system

#### Origin & function

p15 is a known tumour suppressor involved in cell cycle regulation and its loss in human tumours is thought to contribute to the malignant phenotype. Overexpression of this gene leads to suppression of cell division and cell death. This activity involves the use of vectors containing several known oncogenes eg c-ABL (J Mol Appl Genet 1983;2(1):57-68) and chimeric gene products that have potential to induce increased cellular proliferation and have been shown to be leukaemogenic in in-vivo systems. Eg MLL/AF9 (EMBO J 1999 Jul 1;18(13):3564-74)

#### Evaluation of foreseeable effects

The host and vector systems used to generate the constructs present minimum risk to human health and safety and could be handled adequately as a class 1 activity under level 1 containment. However, as this project involves the generation of naked oncogenic DNA it will be subject to the appropriate containment and control measures for a class 2 activity and level 2 containment.

Although there is no direct evidence that contact with naked oncogenic DNA can lead to tumours in humans it is intended to incorporate measures which will limit accidental inoculation or transmission of these DNAs to the laboratory workers.

All experiments will be carried out in ADCP level 2 laboratories with emphasis on the following points in accordance with our local rules and recommendations given in ACGM Compendium of Guidance Part 2A - Annex III and Part 3A - Annex 1.

1. Gloves will be worn at all times and changed when working elsewhere.
2. Steps are in place to limit aerosol production and aerosol contamination (filter tips)
3. Limited use of sharps and glassware to avoid accidental inoculation.
4. Staff are aware of the hazards of handling oncogenic DNA.

Project Ref 133/01.3

Date Ackn'd 02/03/2022
### Purposes of the contained use

1. To propagate conditionally immortalised cells from human normal and malformed kidneys and those affected by inherited metabolic diseases.
2. To study the effects of alterations in expression of the lysosomal membrane protein Cystinosin by transfection and antisense oligonucleotides.

### Host/vector system

- Packaging line PA317 producing a temperature sensitive SV40Tag transducing replication-defective virus
- PcDNA3.1 zeo+ expression vector (Invitrogen)
- E coli strain PS disabled but has copies of F'

### Origin & function

The vector used in this experiment is a replication deficient amphotrophic retrovirus. The vector introduces into the host genome in-frame coding sequences for neomycin resistance and a temperature sensitive Simian Virus 40T antigen (SV40TAg: tsA58 and U19 mutations). Permissive temperature is 33°C and non-permissive temperature 37°C to 39°C. Strong eukaryotic promoters derived from SV40 and retroviral LTR drive expression of both genes.

Cytinosin is an integral lysosomal membrane protein (Town et al Nature Genetics 1998:18:319-324) which is mutated in patients with nephropathic cystinosis.

### Evaluation of foreseeable effects

**SV40TAg**

The neo resistance gene is not harmful to humans but the SV40TAg must be regarded as having oncogenic potential, however this is likely to be considerably reduced in-vivo as the transduced gene has been engineered to produce a protein that is functionally inactivated at mammalian body temperature (37°C).

Transduction experiments are not to be performed at ICH.

Transduced cells will be tested for production of wild type virus before introduction into the ICH laboratories. The production of RCRs is a highly unlikely event since the vector is engineered to be replication deficient. Moreover, even if these cells were to accidentally enter the body of an operator (eg through an abrasion or be inhaled)
would be most likely be immunologically rejected on account of HLA incompatibility. It should be noted that control cells would not be derived from personnel involved in the project.

Cystinosin.
Overexpression is unlikely to be damaging. Conversely, ablation of expression may induce direct damage to a cell and reduce its life expectancy and changes of replication. Accidental inoculation of naked antisense cDNA may be of potential risk to the operator.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste will be disposed of according to our local rules.
All cellular and bacterial liquid waste is treated with 10% chloros before disposal.
All contaminated disposable plastic ware (tips, pipettes and tissue culture flasks) are treated with chloros, bagged immediately in autoclave bags and autoclaved and disposed of at the end of the day.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The initial transduction experiments will be carried out elsewhere. Only stable cell lines without recombinant wild type virus will be used at the ICH site.

The retroviral experiments are performed in designated class 2 facilities with restricted access.
All personnel involved in the experiments are aware of the potential risk to human health from both retroviral experiments and the handling of potentially damaging cDNA.
All waste is disposed of according to our local rules, which are appropriate for level 2 containment.

### Project Additional Information

**Purposes of the contained use**
To investigate the role of PAX3, the human proto-oncogene c-met and hepatocyte growth factor (HGF) in tumour progression in Rhabdomyosarcoma using Tetracycline inducible antisense constructs.

**Recipient or parental organism**
Human Rhabdomyosarcoma cell lines.

**Host/vector system**
Disabled K-12 derived E. coli SURE
Tetracycline inducible plasmids pUHG 17-1, pUHG 13-3 and pUHG 10-3

**Origin & function**
Antisense constructs to the proto-oncogene c-met and its ligand hepatocyte growth factor (scatter factor) the oncogene PAX3-FKHR will be amplified by PCR and cloned in antisense orientation into the tetracycline inducible vectors. Evidence from mouse models which are homozygous for PAX3 suggest it has an important role in the migration of immature muscle cells (Goulding et al Development 1994, 120(4):957-571). Similar phenotypes are seen in homozygous mice deficient in c-met. It is suggested that PAX3 may drive cellular migration and tumourigenesis via the transcriptional upregulation of the c-met/HGF pathway. The effect of antisense constructs in humans is not
known however possible harmful effects could conceivably occur if the naked DNA were to contaminate laboratory workers and insert into tissues in which the MyoD promoter is active (ie muscle stem cells).

**Evaluation of foreseeable effects**

The host and vector systems used to generate the constructs present minimum risk to human health and safety and could be handled adequately as a class 1 activity under level 1 containment. However, as this project involves the generation of naked oncogenic DNA it will be subject to the appropriate containment and control measures for a class 2 activity and level 2 containment.

Although there is no direct evidence that contact with naked oncogenic DNA can lead to tumours in humans it is intended to incorporate measures which will limit accidental inoculation or transmission of these DNAs to the laboratory workers.

All experiments will be carried out in ADCP level 2 laboratories with emphasis on the following points in accordance with our local rules and recommendations given in ACGM Compendium of Guidance Part 2A - Annex III and Part 3A - Annex 1.

1. Gloves will be worn at all times and changed when working elsewhere.
2. Steps are in place to limit aerosol production and aerosol contamination (filter tips)
3. Limited use of sharps and glassware to avoid accidental inoculation
4. Staff are aware of the hazards of handling oncogenic DNA.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Waste from GMMs will be handled according to our local rules.
Bacterial cultures will be inactivated by chemical treatment with fresh Chloros for a minimum of 24 hours.
All plastic disposables and gloves will be autoclaved and incinerated.

**Is an emergency plan required according to regulation 20?**

**If yes, tick to confirm that it is attached to this form**

**Tick to confirm that you have attached a risk assessment to this form**

**Tick if you are claiming exemption from disclosure for section of the risk assessment**

The risk assessment for this activity has taken into account the oncogenic potential of the naked DNA sequence to be inserted in the GMMs and GMOs. Activity has therefore been designated as Class 2. Suitable precautions to limit the risk of accidental inoculation of naked oncogenic DNA are already practiced in the laboratories designated for level 2 containment. All other working practices described are in accordance with our local rules.

The risk to the environment or human health from the GMMs is negligible.
**Project Additional Information**

**Purposes of the contained use**

Primary immunodeficiencies (PID) are congenital disorders that affect the function of the immune system. In recent years, a number of genes causing PID have been cloned, which has made gene replacement therapy for these diseases a realistic alternative for bone marrow transplantation. With increased knowledge of haematopoietic stem cell (HSC) biology and improved retroviral transduction protocols, it is now feasible to use onco-retroviral vectors for efficient corrective gene transfer into HSCs of affected individuals. Since transduced self-renewing HSCs are capable of reconstituting a complete immune system, this approach potentially provides a life-long cure of the disease.
HSCs isolated from cord blood, bone marrow or mobilised peripheral blood will be transduced ex vivo in a closed system with clinical grade retroviral supernatant.

Host/vector system

Vector: Moloney Murine Leukemia Virus (MoMuLV) based retroviral vectors, containing retroviral 5’ and 3’ LTRs, packaging signal and part of the gag gene, expressing full-length human cDNAs encoding wild type PID causing genes.

Host: Human CD34+ haematopoietic cells isolated from cord blood, bone marrow or mobilised peripheral blood.

Origin & function

MoMuLV based replication deficient retroviral particles pseudotyped with the envelope of Gibbon Ape Leukemia Virus (GALV), will be used to transduce human CD34+ cells. The GALV envelope has been shown to mediate efficient transduction of HSCs. Replication deficient retroviral particles were generated in packaging cell lines, which provided retroviral gag/pol and env helper functions in trans. The MoMuLV-based retroviral vector was introduced into the packaging cell independently and replication competent retrovirus (RCR) can only be generated after three independent recombination events, which is very unlikely to occur. The production of clinical grade retroviral supernatant, with all the required safety testing, was performed by a licensed commercial organisation.

In the vector, the retroviral genome is replaced by the cDNA encoding the appropriate corrective gene, whereas only 5’ and 3’ viral LTRs, the packaging signal and part of the gag coding sequence (for optimal protein expression) are still present.

Clinical grade retroviral supernatant is provided by a commercial organisation licensed to undertake such a process and has been tested extensively for the presence of RCR. The transduced CD34+ cells will be returned to the patient and the patient will be monitored over time for RCR.

Evaluation of foreseeable effects

The patient will be monitored extensively for the possible production of PCR, though as discussed, this possibility has been minimised by the use of packaging cell lines providing the gag, pol and env functions in trans. Expression of the inserted gene will be monitored by PCR, protein and functional assays. The inserted gene is not judged to be an oncogene or growth factor which could cause potentially harmful effects. The gene is unlikely to act alongside existing characteristics of the cell as to endow the cell with altered pathogenic properties.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The work with CD34+ haematopoietic cells constitutes no higher risk than work with fresh blood or blood-related products. Patients will be screened for presence of pathogens prior to donation of cells.

To reduce the risk, all the work is performed in a Class II safety cabinet and cells will be grown in a closed system.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All processes will take place in a closed system inside a class II tissue culture cabinet.

The class II tissue culture cabinets will be swabbed with 70% IMS before and after use, and any spillages will be dealt with immediately using 1% Virkon followed by 70% IMS. In the event of a larger spill, paper towels will be used prior to disinfection.

All solid waste, such as discarded bags, pipettes, tips, towels, etc will be disposed of in autoclave bags. These will be removed when full and autoclaved prior to incineration.

The use of sharps (eg needles, Pasteur pipettes) will be avoided, however when use is unavoidable they will be safely disposed of using sharps bins.
These processes should give 100% kill.

The genetic modification safety committee was satisfied with the risk assessment and had no further comments.

Please enter comments on the GM safety committee on the risk assessment

The genetic modification safety committee was satisfied with the risk assessment and had no further comments.

Historical Significant Changes PROJECT TRANSFERRED TO GM 14 AND GM CENTRE CLOSED

Historical Date of Additional Info
### Puriposes of the contained use

c-Jun Activation domain Binding protein (JAB1) and Geminal centre kinase Like Kinase (GLK) have been shown to interact with the tumour suppressor gene p15 in the yeast two-hybrid system. These nature and significance of these novel interactions will be tested in the mammalian system using both in-vitro and in-vivo techniques.  

**In-vitro expression:** Full length cDNA and partial constructs of GST-JAP1 and GST-GLK chimeric proteins will be expressed in bacteria and tested for interaction with endogenous p15 protein extracted from established human cell lines.  
Both proteins will also be transcribed and translated in-vitro using the rabbit reticulocyte system and tested for interaction with in-vitro translated p15.  

**In-vivo expression:** Full length cDNA and partial constructs of JAP-1 and GLK and p15 will be cloned into mammalian expression vectors and transiently expressed singly or in combination in established human cell lines.

### Recipient or parental organism

**Bacteria:** JM109, SURE, DH5a  
All bacterial hosts used in this study are K-12 derivatives and non-pathogenic in humans. They are able to survive for short periods in the gut and lung of mammals but are non-colonising. They are able to survive for a similar time in the environment. The plasmid vectors used in this study express antibiotic resistance genes eg ampicillin or neomycin. The vectors are non-mobilisable and are defective in one or more functions required to transfer to other hosts. Although transfer of antibiotic resistance to other bacterial hosts is possible, the likelihood is low.

**Cell Lines:** Hela, MM6, Jurkat, CEM  
All human cell lines are established and characterised. Conditions for growth include maintenance at a constant temperature (37 degrees C) in low CO2. They are unable to survive outside these conditions. Both parental and modified cell lines present negligible risk to human health or the environment.

### Host/vector system

**Vectors**  
pGex-6p-2, pGEMT, pCDNA3.1, pEGFP-N1, pDsRed1-N1, pGADT7  
**Hosts**  
Disabled K-12 derived E.coli vectors: Sure, JM109, DH5a

### Origin & function

**p15** full length and partial c-DNA sequences promotor region and exon 1 antisense cDNA. p15 is a known tumour suppressor involved in cell cycle regulation and its loss in human tumours is thought to contribute to the malignant phenotype. Although functional loss of p15 is associated with many human malignancies, there is no evidence to suggest that loss of p15 expression alone is a transforming event. Overexpression in mammalian cells can lead to cell cycle arrest or retardation of proliferation.  

**JAB-1** full length and partial c-DNA sequences. JAB-1 is expressed in a wide range of normal cells and is involved in several signalling pathways involving gene transcription, (JNK), cell cycle control (p27) and integrin signalling. JAB1 is also known to regulate protein levels of the cell cycle regulator p27 by promoting its degradation. Overexpression may lead to cellular proliferation, apoptosis or differentiation.  

**GLK** full length and partial c-DNA sequences. GLK is involved in cellular stress pathways (JNK). It is also expressed in a wide range of tissues. Overexpression may lead to growth retardation or apoptosis.

### Evaluation of foreseeable effects

The non-mobilisable GMMs used for this study contain full length and partial cDNA sequences designed for maximum expression in mammalian cells and as GST fusion proteins in bacteria. They are propagated in bacterial hosts, which are disabled or non-colonising in humans. Should the bacteria or GMMs be accidentally released into...
the environment their chance of survival is negligible and the potential to cause harm is effectively zero.

HUMAN HEALTH
Inserts into the pGEX vector are designed to be expressed as a fusion protein with glutathione-s-transferase (GST). The expressed proteins are unlikely to change the properties of the parental recipient. Inherent risks and outcomes are the same as the unmodified recipient. i.e. the risk to human health is negligible. Expression of single and multiple proteins from these genes in mammalian cell lines may alter their growth properties. The most likely outcomes are growth arrest and/or cell death. However, overexpression of JAB1 protein may lead to cellular proliferation in some instances. Over expression of either GLK or JAB1 may inhibit the regulatory nature of p15 allowing greater cell proliferation. Expression of antisense p15 is likely to have a similar effect. Accidental insertion of naked cDNA into humans may lead to limited protein expression, however normal immunological response would rapidly eliminate foreign DNA or protein. Modified cell lines present no additional risks or hazards compared with the parental lines.

CONTROL MEASURES
Accidental inoculation of CDNA sequences or GM cell lines into laboratory workers by stick injury or entry via cuts and abrasions may constitute a hazard and therefore use of needles and scalpels will be limited, cuts and abrasions will be covered and gloves will be worn at all times. All cell work is carried out in Class 2 Safety hoods and use of filter tips limits aerosol formation.

All experiments will be carried out in ADCP level 2 laboratories with emphasis on the following points in accordance with our local rules and recommendations given in ACGM Compendium of Guidance Part 2A-Annex III and Part 3A-Annex 1.

1. Gloves will be worn at all times and changed when working elsewhere.
2. Steps are in place to limit aerosol production and aerosol contamination (filter tips)
3. Limited use of sharps and glassware to avoid accidental inoculation.
4. Staff are aware of the hazards of handling potentially damaging cDNA.

GM human cell lines. Accidental inoculation of sequences into laboratory workers by stick injury or entry via cuts and abrasions may constitute a hazard and therefore use of needles and scalpels will be limited, cuts and abrasions will be covered and gloves will be worn at all times. All cell work is carried out in Class 2 Safety hoods and use of filter tips limits aerosol formation.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

a) Waste from bacterial cultures will be inactivated by chemical treatment with fresh Chloros for a minimum of 24 hours. All plastic disposables and gloves will be autoclaved at 121 degrees C for a minimum of 15 mins and incinerated (100% kill).

b) Cellular waste is treated with Virkon and all disposable plastic ware is bagged and autoclaved and incinerated (as above) before disposal.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

**Project Additional Information**

**Purposes of the contained use**

Apoptosis regulatory genes and oncogenes will be introduced into established mouse and human cell lines in order to study the effects of these genes on apoptosis and their transforming capacity. Disabled retroviral vectors will be used to transduce the cells with members of the Bcl-2-gene family and with the oncogenes, MLL-AF4,
Recipient or parental organism

E. coli K-12 multiple auxotroph XL1-Blue bacteria will be used. These bacteria are unlikely to survive in the human gut, lung or elsewhere in environment and are non-pathogenic to humans.
NIH-3T3, BaF/3 and s49.1 mouse cell lines and primary cells. 293T human cell line.
The mouse and human cell lines used are all long-term established cell lines and present no apparent hazard to workers or the environment. Work with primary mouse cells constitutes no higher risk than work with fresh tissue. Animals will be screened for the presence of pathogens prior to the donation of cells. All cells will be grown in a closed system. Despite the possibility that some of the genetic alterations planned may confer growth advantages to the cells, the derivative cell lines would not survive outside the culture conditions (i.e., in the environment) used for their propagation. In the extremely unlikely event, that the cells are accidentally introduced into humans the cells would be very unlikely to survive because host allo- and zeno-immune responses would lead to their total destruction.

Host/vector system

pcDNA3.1 and pBluescript plasmid vectors
The plasmid vectors used in this work will not cause expression of inserted genes in XL1-Blue cells and they are non-mobilisable or mobilisation-defective. It is envisaged that neither the original XL1-Blue cells nor their genetically modified derivatives will be harmful to humans, since the risks of the bacteria infecting and persisting in humans and/or transferring genetic information to other micro-organisms is very low.
pMSCV and pRwevTRE retroviral vectors. Both these vectors are disabled retroviral vectors since they do not contain the gag (structural), pol (reverse transcriptase/integrase) and env (coat glycoproteins) genes necessary for particle formation, infection and replication. Replication-incompetent retroviral particles will be made by transfecting the retroviral vectors into the ecotropic Phoenix-eco (ATCC) packaging cell line. This cell line has the gag, pol and env genes stably integrated in its genome. For both the gag-pol and the env constructs non-moloney promoters were used to minimize recombination potential and different promoters for gag-pol and env were used to minimize their inter-recombination potential. After transfection with disabled retroviral vectors, the Phoenix-eco cells produce ecotropic viral particles containing envelope proteins derived from the Moloney Murine Leukaemia virus, which are only capable of infecting murine cells. The Phoenix-eco cell line has been established as being helper-virus free) Recombination would also be limited since retroviral vectors would only be transiently transfected into packaging cell lines and the cells would be disposed of after virus harvest (48 hours after transfection), thus long-term culture of packaging cell lines containing retroviral vectors would be avoided. In the extremely unlikely event of a replication competent virus being made, this would only be ecotropic and thus would not infect humans.

Origin & function

The DNA sequences that will be used in the project belong to the Bci-2 family of apoptosis regulatory molecules or are known and presumed oncogenes.
Gene sequences: Oncogenes MLL-AF4, MLL-ENL, MLL-AF9, TEL-AML, TEL-JAK2
Apoptosis regulatory molecules Bcl-2, BclXL, BclX, Bid, Bim, Bak, Bax, Bad

Evaluation of foreseeable effects

It is expected that the gene sequences will be active in mammalian cells and affect their growth and differentiation characteristics. Measures to avoid accidental inoculation and transmission of these sequences to the laboratory workers will be adhered to. For these sequences to be dangerous to humans or other organisms in the environment, they would have to integrate into the genome of the organism in question. Although there is a small risk of this once the DNA sequences are introduced into bacterial and mammalian cells, the use of non-mobilisable and mobilisation defective vectors, disabled retroviral vectors and disabled bacteria will minimise this risk.

Although there is no direct evidence that contact with naked oncogenic DNA can lead to tumours in humans it is intended to incorporate measures which will limit accidental inoculation or transmission of these DNAs to the laboratory workers.

All experiments will be carried out in ADCP level 2 laboratories with emphasis on the following points in accordance with our local rules and recommendations given in AcGM Compendium of Guidance Part 2A - Annex III and Part 3A - Annex 1.

1. Gloves will be worn at all times and changed when working elsewhere.
2. Steps are in place to limit aerosol production and aerosol contamination (filter tips)
3. Limited use of sharps and glassware to avoid accidental inoculation
4. Staff are aware of the hazards of handling oncogenic DNA

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
- The work with the genically modified primary cells and established cell lines constitutes no higher risk than work with the parental cells.
- Work with these cells is performed in a Class II safety cabinet and cells will be grown in a closed system.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
- All processes will take place in a closed system inside a class II tissue culture cabinet.
- The Class II tissue culture cabinets will be swabbed with 70% IMS before and after use, and any spillages will be dealt with immediately using 1% Virkon followed by 70% IMS. In the event of a larger spill, paper towels will be used prior to disinfection.
- All solid waste, such as discarded bags, pipettes, tips, towels, etc will be disposed of in autoclave bags. These will be removed when full and autoclaved prior to incineration.
- The use of sharps (eg. needles, Pasteur pipettes) will be avoided, however when use is unavoidable they will be safely disposed of using sharps bins.
- These processes should give 100% kill.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
- The risk assessment for this activity has taken into account the oncogenic potential of the naked DNA sequences to be inserted in the GMMs and GMOs. Activity has therefore been designated as Class 2. Suitable precautions to limit the risk of accidental inoculation of naked oncogenic DNA are already practiced in the laboratories designated for Level 2 containment. All other working practices described are in accordance with our local rules.
- Under these conditions, the risk to the environment or human health from the GMMs is negligible.

Project Containment
Investigating interactions of human cells with Neisseria meningitidis.

We are conducting a number of projects looking at inflammatory and immunological responses of human dendritic cell, neutrophils, endothelial cells in vitro to the organism Neisseria meningitidis. We will use genetically modified strains lacking a number of known virulence factors (lipopolysaccharide and capsule) to explore the relevance of their presence or absence on these responses.

Recipient or parental organism

Neisseria meningitidis serogroup B will be the recipient organism for this work. This is a gram negative organism which only infects humans. It is carried by up to 25% of the population, and can cause meningitis and/or meningococcal sepsis, particularly in children between 0-5 years, and young adults between 15-19 years old. Meningococcal disease (where there is both meningitis and sepsis) has a case fatality rate of approximately 10%.

There is currently no vaccine for this serogroup.
The strains are already transfected with linearised DNA containing an antibiotic resistance cassette, which results in the disruption of the gene of interest (lpxA and siaD). These are stable transfectants and do not harbour transmissible plasmids. The kanamycin cassettes released from puc17 and the gene of interest is cloned in proprietary cloning vector pcr2.1. The gene is then excised by restriction digest and the antibiotic resistance cassette inserted. These are subcloned in E.coli, extracted and then linearised by restriction digest.

Origin & function

The bacterial strains to be used were generated by insertional inactivation of enzymes involved in the lipopolysaccharide biosynthesis and capsulation. In general all the mutant strains involve loss of virulence compared to the wild type parent strain. For example, one strain, lpxA (1) lacks any LPS, the major virulence factor in N.meningitidis. Other strains to be used include lpxA gene under control of an isopropyl-BD-thiogalactopyranoside (IPTG)-inducible promoter allowing for controlled biosynthesis of LOS by the bacteria (2). In the presence of IPTG, this strain will have similar virulence potential to the wild strain but in the absence of external source of IPTG, bacteria harbouring sequence cannot produce LPS. Another mutant strain, salD-, lacks the enzyme required for capsule biosynthesis (3). Almost all infection with N.meningitidis are due to capsulated strains therefore this mutant is of no greater virulence than wild type and potentially less.

The mutated strains will not be modified further in any way. These were kindly provided by Dr. Peter van der Ley from the National Vaccine Institute, RIVM, Bilthoven Netherlands. The description of the mutants are available in full in the following references:

They are only intended for in vitro stimulation work and will not be modified in any other way.

Evaluation of foreseeable effects

The genetically modified strains should have no more and probably less virulence potential than their wild type derived strains. For the purpose of the projects, they will be handled in the same fashion as the wild type organism.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

- Culture volumes will not exceed 40mls but in the main are only 5mls.
- Bacteria will be inactivated for use by 20 minute exposure to 2% paraformaldehyde, or heat inactivation at 560C for 30 minutes. This is accepted practice in laboratories used to dealing with this organism. Testing for killing is not normally performed if equipment is functional; ie thermocouple thermometer in water bath is accurate and reagents are freshly prepared.
- Tissue culture incubated with live bacteria will be inactivated in either 2% formaldehyde or 4% paraformaldehyde. Liquid waste will be disposed of in 5% Hycolin (phenolic surface disinfectant), contained in pot within Class 1 cabinet. This is disposed of by laboratory staff at the end of each working day.
- Dry waste and agar plates are autoclaved.
- Sharps are incinerated.
- Small spills can be inactivated with squeeze bottle of 5% Hycolin allowed to soak for 30 minutes and mopped up with absorbent paper and autoclaved.
- All these waste management procedures are monitored and quality controlled in the Microbiology laboratory which has CPA accreditation.
All laboratory workers should have the necessary training and supervision on any work involving Genetically Modified Neisseria Meningitides and all safety precautions and measures should be placed in the laboratories carrying out this type of work. Furthermore, where possible, culture volumes should be kept to a minimum and all waste disposals should be treated with the appropriate detergent and disposed into designated clinical waste for incineration.

Project Ref 133/10.1

Identification of genes promoting lethality of MYCN-amplified neuroblastoma cells using genome-wide RNAi screening

Class CultureVolClass2 CultureVolumeClass3-4
Class 2 1-50 Litres

Tick if notifying a connected programme of work N
Purposes of the contained use

In this research project we aim to identify genes that promote cell lethality in the most aggressive forms of neuroblastomas using shRNAmir library.

Neuroblastomas is a paediatric tumour that derives from primitive sympathetic neural precursors. Amplification of MYCN oncogene is very frequent in a neuroblastoma and is often associated with advanced disease stages with poor prognosis and resistance to therapy. Interestingly, overexpression of MYCN protein in non MYCN-amplified cells can sensitize cells to drug treatment and induce cell death. This could suggest that survival and growth of MYCN-amplified tumour cells relies on expression of genes triggered by MYCN overexpression. When certain gene becomes essential for cell survival in response to MYCN overexpression, this gene can be called "synthetically lethal" partner of MYCN. The mechanism of synthetic lethality is very attractive for the development of drugs that could selectively kill tumour cells, since targeting the synthetic lethal partner of MYCN will cause growth inhibition of MYCN-amplified aggressive tumour cells leaving normal cells relatively intact.

The shRNAmir library consists of over 70,000 pGIPZ individual lentiviral vectors. Each vector contains a unique hairpin sequence designed to target and reduce the expression of most/all genes within the human neuroblastoma cell lines with the shRNAmir library. We will follow the change in relative abundance of individual shRNA over time by microarray hybridization to detect genes essential for cell proliferation since shRNAs important to cell survival will disappear from the population. We will pick the candidate genes by comparing the lethality profile of MYCN-amplified and non MYCN-amplified neuroblastoma cell lines and will validate the candidates after screening using available human neuroblastoma cells. The group of genes common for MYCN-dependent synthetic lethality in several neuroblastoma cell lines will be selected as the potential clinical targets that can selectively kill MYCN-amplified neuroblastoma cells.

Recipient or parental organism

Recipient/Parental organisms:
- Bacterial E.coli strains - HB101, XL1-blue, Top10F, DH5alpha.

Associated risks and likeliness of occurrence:
The bacterial strains used are attenuated non-colonising strains so are incapable of causing human infection and are therefore harmless to humans. The viral vector to be used will be pseudotyped with the envelope protein VSV-G from Vesticular Stomatis Virus so, if introduced into the body by injection, ingestion or through a wound, the virus could enter human cells and integrate into cellular DNA. Although the virus is replication incompetent (does not carry gag, pol or env genes) so it cannot make a new progeny virus and establish a productive infection, its insertion into cellular DNA could result in a potentially oncogenic mutation. The recipient cells are harmless to humans.

The viral vectors are replication incompetent so therefore can not self-replicate and transfer to another host so are harmless to the environment. The cell that will eventually receive and integrate the DNA cannot survive in the environment as they are only viable under culture conditions and therefore are harmless to the environment. The bacterial strains used are attenuated non-colonising strains that cannot survive outside culture conditions and are therefore harmless to the environment. The viral vectors are replication incompetent so therefore can not self-replicate and transfer to another host so are harmless to the environment. The cell that will eventually receive and integrate the DNA cannot survive in the environment as they are only viable under culture conditions and are therefore harmless to the environment.

Host/vector system

Lentiviral vectors:
Commercial pGIPZ vectors fro Open Biosystems.

Associated Risks and likelihood of occurrence:

The viral vector used is a lentiviral vector that contains the CMV (PolI) promoter to drive expression of the hairpin cassette. The lentiviral vector does not contain the appropriate accessory elements to form a viral particle itself and therefore poses no harm to health and the environment. Packaging and envelope proteins are contained on two additional plasmids to the lentiviral expression vector and these plasmids must be introduced into the cell and expressed alongside the lentiviral vector for viable lentiviral particles to be produced.

Woodchuck hepatitis B virus post-transcriptional regulatory element (WPRE) sequence is also incorporated into the pGIPZ vector in order to enhance the stability and translation of the transcripts. This negates the need for rev in the lentiviral vector packaging systems and improves biosafety by eliminating lentiviral genes from the system. However, the WPRE has potential promoter activity and the potential to express part of the X protein form woodchuck hepatitis virus (WHV) which may be oncogenic.

There is no direct experimental evidence of oncogenic activities of the truncated fragment of X protein. Moreover, there is low probability that it would be expressed from the X promoter that is present in the WPRE since many studies have suggested that the X promoter is not functional in the absence of a second enhancer, which is not present in the WPRE. There is possibility of expression directed form other promoter/enhancer at chromosomal integration sites as well as the possibility that truncated X protein fragment has oncogenic properties. However, the likelihood of this is very low.

Origin & function

The inserted RNAi hairpins are sequences that have been derived de novo and are not from an organism. The sequences contain a 22bp sense and antisense sequence that is homologous to the gene of interest to which the hairpin is designed. These sequences are separated by a small loop sequence and flanked by mir-30 sequences. When transcribed in the cell, the RNA will form a hairpin structure which will initiate a normal cellular in vivo downstream cascade of processing events in response to foreign cellular single-stranded RNA intruder molecules. This process results in the post-transcriptional down regulation of the gene to which the hairpin sequence is designed and targeted by destroying the corresponding mRNA molecules prior to translation. The utilization of this normal endogenous pathway to down-regulate genes of interest is known as RNA interference.

Evaluation of foreseeable effects

Risks and likelihood of risks:

- The bacterial strains to be used are non colonising and incapable of surviving in the environment or causing human infection. They pose no risk to users or the environment.
- None of the DNA viral vector plasmids are harmful to health or to the environment and do not supply a survival advantage to any microorganisms. The packaging viral components are from the HIV-1 virus. HIV-2 is harmful to humans, however, the packaging vector does not contain full length HIV-2 molecule. Many components of HIV-1 that are critical for HIV-2 infection have been removed from the packaging vector. Only those essential for viral packaging remain.
- The most dangerous GMM is the lentiviral preparations of pGIPZ particles and the most dangerous step is the collection, concentration and use of this lentivirus, however this risk is minimal. Lentiviral vectors can infect human cells and therefore if introduced into the body by injection, ingestion or through a wound, the virus could potentially enter cells and integrate its genome into cellular DNA. If the inserted sequence were to be expressed in humans after accidental transfer the hairpin could lead to the down-regulation to the gene to which it targets via RNA interference. This could be a gene essential for growth regulation such as a tumour suppressor gene therefore resulting in a potentially oncogenic mutation. Additionally, physical insertion of the virus into the genome of the host cell could potentially disrupt a tumour suppressor or oncogene, however the likelihood of this is very low. Theoretically the virus can also infect other mammalian cells and knockdown the gene of interest. However this is extremely unlikely as the hairpin is targeted to human genes and many hairpins are not homologous with the genes from other species. The overall risk is very low.
- Woodchuck hepatitis B virus post-transcriptional regulatory element (WPRE) in the pGIPZ vector has potential promoter activity and the potential to express part of the X protein from woodchuck hepatitis virus (WHV) which may be oncogenic. However, there is no direct experimental evidence of oncogenic activities of the truncated fragment of X protein and the likelihood that the expression of this protein would be directed from the promoter/enhancer at chromosomal integration sites in mammalian cells is very low. Any infection would not be severe as the virus is replication incompetent and therefore self-inactivating (does not carry gag, pol or env genes) so it cannot make new progeny virus and establish a productive infection. Also, it would only be a small number of cells and would not impact on the pathogenic outcome of an exogenous viral infection. Additionally, the viral particles are labile and do not survive on environmental surfaces outside the laboratory making infection unlikely.
- The cell lines used cannot survive outside the laboratory incubators and as such pose no threat to health or environment.
Precautions in place to minimize risks:
The Institute of Child Health is secured by restricted access at all entrances and additionally to all laboratory areas. Additionally, Molecular Haematology and Cancer Biology Unit has level 2 facility. All work involving viruses will be performed in class 2 cabinets in containment level 2 laboratories specified particularly for retroviral and lentiviral GMM work. All DNA plasmids containing viral proteins will be grown separately to avoid opportunity for recombination. To prevent contamination of workers by virus, when handling any GMM or GMM-derived DNA virus, no glass or other sharps will be used in the rooms where the viruses are prepared and used and workers will be protected by a lab coat and nitril gloves. Skin lesions will be covered with a bandage in addition to the protective wear described above. Specific guidelines will be in place to ensure all viral preparations are handled, labelled, stored, transported and cleaned up correctly. A separated clearly labelled compartment in the freezer to store viral supernatant will be used to prevent access to the stored materials for departmental staff and students, who are not involved in the project. All those involved in the project will be made aware of the guidelines and the associated risks as well as anyone else who may use the laboratory. Persons involved on project from other Institutes will work under the supervision of a competent trained worker from this project. No-one visiting the laboratory that is not involved in the work will work on this project. All persons entering the facility will be made aware of the safety precautions upon entering the facility. All equipment used in the level 2 laboratory will be available in other general purpose laboratories for general use so it should not be necessary for others who are not involved in retroviral or lentiviral work to enter the laboratory.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

1% Virkon (w/v) will be used to treat liquid waste (18 hours) and also used to decontaminate any spills and for disinfection of any reusable bottles or other equipment and laboratory materials used. Liquid waste is subsequently poured down the sink after treatment with Virkon. Work surfaces will be wiped down with 1% Virkon and 70% IMS after use. Virkon is certified by the PHLS to provide 100% viricidal and GMO kill under these conditions by denaturing and inactivating viral and cellular proteins. Virkon will be used with their lifespan to ensure required kill is achieved. Solids waste will be disposed of into biological waste bags, sealed and autoclaved 132° for 15 mins by trained staff then bagged in yellow biohazard bags and removed by UCL waste services. Autoclave runs are regularly validated by waste management staff.

02/03/2022
The aim of this project is to generate induced pluripotent stem (iPS) cells from mouse and human fibroblasts by employing lentiviral vectors coding for 4 reprogramming genes Sox2, Oct4, Klf4 and c-Myc. iPS cell technology has the potential to transform regenerative medicine especially in the areas of stem cell transplantation and patient-specific gene therapy. Briefly, mouse and human fibroblasts will be infected with 4 different lentiviral constructs and reprogrammed to become embryonic stem (ES) cell like cells which are known as iPS cells. Once generated, these cells can be expanded at will maintaining their undifferentiated pluripotent state and can be subjected to differentiation pathways eventually leading to the formation of terminally differentiated somatic cells. As for example, these iPS cells can be induced to become different kinds of blood cells. The efficiency of reprogramming is pretty low (0.01-0.05%) and to obtain sufficient number of iPS cell generation. Upon successful execution, the iPS cells generated from this project will help us to study various genetic defects either from murine disease models or from human patient samples and would be crucial in our therapeutic approaches.

E.coli disabled strains (e.g. DH5alpha), Mammalian cell lines (established, commercially available) and mammalian primary cells. Neither of these are pathogenic to humans, nor capable of survival in the environment.
Prokaryotic plasmids, eukaryotic expression vectors, replication-deficient self-inactivating (SIN) lentiviral vectors, The lentiviral vectors used are multi-attenuated meaning it is devoid of all potentially pathogenic HIV-1 encoded functions (1.2). In addition it is replication-defective which means that the vector cannot multiply on its own unless supplied by certain proteins in trans. It is self-inactivating which means that the viral promoter in the U3 region of the 5' LTR has been disabled by genetic manipulation. Only a very unlikely event of multiple recombinations during the process of generation of the viral vector can expose the person to a wild type HIV-1. The probability of such an event is extremely low.

Mus musculus, Homo sapiens sapiens
Production of transcription factors that will reprogram the somatic cells to become iPS cells
The vector sequences (sox2, oct4, klf4 and c-myc) code for oncogenic products which if accidentally transferred to a human host might cause tumour formation depending on the size of the inoculums but is most likely expected to be nullified by immuno-competent individual.
Sequences cannot cause harm if transferred to species in the environment; the donor organism is not pathogenic

Evaluation of foreseeable effects
The donor organism does not have apathological or harmful characteristics
Only a very unlikely event of multiple recombinations during the process of generation of the viral vector can expose the person to a wild type HIV-1. The probability of such an event is extremely low. The most hazardous GMM are the lentivector viruses and the most hazardous step is the harvesting of the viral supernatant before infecting the target cells.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All GMMs are inactivated for disposal using standard biosafety level 2 procedures. Briefly, liquid and solid wastes are treated with PRESEPT effervescent disinfecting tablets (2.5g). All plastic ware used in tissue culture are autolaved. Work surfaces are decontaminated on completion of work or at the end of the day and after any spill or splash of viable material with disinfectants that are effective against the agents of concern. Proline and IMS are used which have been shown to be 100% effective in tissue-culture related decontamination.

Purposes of the contained use

To undertake gene therapy on autologous HSC from patients with Wiskott Aldrich Syndrome. The study is summarised below.

Phase 1/2 clinical trial of haematopoietic stem cell gene therapy for the Wiskott-Aldrich Syndrome
This is an open labelled, non-randomised, single centre, phase I/II, cohort study involving a single infusion of autologous CD34+ cells transduced with the w1.6_hWASP_WPRE (VSVg) lentiviral vector in up to 5 patients with WAS.

Primary Objectives
To safely administer a lentiviral gene therapy vector encoding the human WAS cDNA to stem cells from WAS patients.
To provide sustained engraftment of WASP-expressing transduced cells, reconstitution of humoral and cell mediated immunity, and correction of microthrombocytopenia

Secondary Objectives
To improve the overall health of the patient, including reduction in frequency of infections, resolution of autoimmunity, and improvement in eczema, reduction in bruising and bleeding episodes.
To evaluate the longitudinal clinical effect in terms of augmented immunity.

Recipient or parental organism
The lentiviral vector (LV) vector used in the proposed clinical trial is a 3rd generation replication-defective hybrid viral particle made by core proteins derived from Human Immunodeficiency virus type 1 (HIV-1) and the envelope of the unrelated Vescicular Stomatitis Virus (VSV). The transfer vector encodes the 12 exons of the human WAS cDNA under control of a 1.6 kb endogenous promoter sequence and leads to the integration of a 5.6 kb sequence.

Host/vector system
Lentiviral vector (w1.6_hWASP_WPRE (VSVg). There is no recommended International Nonproprietary Name (INN). The vector is pseudotyped with the VSV.G envelope.

The lentiviral vector is a 3rd generation replication-defective, self inactivating, hybrid viral particle made by core proteins derived from HIV-1 and the envelope glycoprotein of the unrelated Vescicular Stomatitis Virus (VSV). The transfer vector encodes the 12 exons of the human WAS cDNA under control of its native promoter. This lentiviral vector leads to the integration of a 5.9 kb proviral sequence into the cellular genome.
The system is based on 4 non-overlapping expression constructs in order to maximize the segregation of cis and transacting functions. The system is engineered in such a way that minimal homology regions are present between packaging and transfer vectors, thus minimizing the likelihood of homologous recombinational events and the generation of replication competent lentiviruses (RCLs).

In addition, the packaging construct is deleted of all HIV accessory proteins (vpu, vpr, nef, vif) and Tat. The conditional packaging system segregates gag/pol and rev genes in two separate plasmids. The Rev responsive element (RRE) maintained in the gag/pol plasmid makes the gag/pol gene expression rev dependant. As the transcripts of gag and pol genes contain cis acting repressor sequences, they are expressed only in the presence of Rev, expressed in trans on separate plasmid, which promotes their nuclear export and expression by binding to RRE.
The transfer vector codes for the therapeutic human WASP gene and for the sequences necessary for expression, capsidation, reverse transcription and integration of the viral genome. RRE sequences permit the nuclear export and expression of the viral RNA. In order to minimize the risk of RCL generation, the 3' LTR of the transfer vector has been deleted in the U3 region. The introduction of this 400 bp deletion abolishes the production of full-length vector RNA in transduced cells by exploiting the reverse transcriptase mechanism which generates both U3 regions from the 3' of the viral genome, thus transferring the deletion to the 5' LTR of the proviral DNA. The lentiviral particle is therefore conceived with a self-inactivating mechanism that enables the production of infective particle only in the presence of accessory plasmids.

Origin & function
The human WAS protein (WASp) is expressed exclusively in haematopoietic cells where it functions as a regulator of actin cytoskeleton reorganisation by linking various
types of signals to Arp2/3-mediated actin polymerization. Two main molecular activators of WASP are Cdc42 and PIP2. In T cells, WASP is an essential component of the signal transduction cascade initiated by T cell receptor engagement contributing to the establishment of immunological synapse and T cell activation.

Risk of transfer to environmental species is negligible, and would not be expected to cause harm

Evaluation of foreseeable effects

The potential for harm is negligible. Work will be at level 2 containment.

All personnel involved in the ex vivo transduction of HSC at ICH/GOSH are trained in GMP cell processing procedures and there competency is assessed every 6 months. Sharps will not be used for the direct manipulation of vector.

A policy is in place for accidental needlestick injuries and can then be assessed via our hospital website (section 2.2.3 http: www.ich.ucl.ac.uk/clinical_information/clinical_guidelines/cpg_guideline 00121. A copy of the document is appended

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

NA

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Autoclave facilities are in an adjoining building. However, all waste will be double bagged and transported by the lab worker in accordance with a written operating procedure to the autoclave facility and this will be recorded in the batch manufacturing record. Sharps will be disposed of in appropriate puncture-proof containers

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

For routine cleaning all surfaces are wiped down with 70% ethanol after use. Liquid GMM waste is first disinfected using Sanichlor (effervescent chlorine tablets) to give a final concentration of 2500ppm chlorine overnight before being disposed of down the sink. This is a standard procedure and viability is below detectable levels. Any solid GMM waste is placed in autoclave bags, labelled with the department's name and autoclaved at the ICH. All sharps are placed in puncture-proof containers and disposed of through the central collection service for contaminated waste. All spillages are cleaned using 1% sodium hypochlorite or 70% ethanol.

Project Containment
Kidney and urinary tract malformations are the commonest cause of end-stage renal failure in children, whilst progressive destruction of normal kidney tissues by cysts or interstitial fibrosis account for most cases in older patients. Very few of these conditions are monogenic but we have an increasing understanding of the processes involved in maldevelopment, cyst formation and fibrosis, which highlight potential targets for therapies. An example is the multifunctional lectin, galectin-3; this molecule is expressed in normal collecting ducts in the developing kidney and exogenous therapy reduces growth of collecting duct-derived cysts in vitro.

Lentiviruses are excellent tools for gene delivery, due to their relatively large packaging capacity and ability to infect a wide range of cell types when coated with different envelopes. Gene therapy requires a functional version of a gene to be delivered and then expressed over long periods. The aim of this project is to develop lentiviral vectors to modulate galectin-3 in the kidney.
Mammalian cell lines (established, commercially available such as human embryonic kidney 293 cells, renal proximal tubular epithelial cells, inner medullary collecting duct cells and Madin-Darby kidney cells) Mammalian primary cells (primarily kidney-derived, such as glomerular, proximal and collecting duct cells, and human fetal renal progenitor cells)

Whole kidneys in organ culture

Mice strains

The bacteria and recipient cells used in this project are not hazardous to human health because they are incapable of causing human infection. Nevertheless, we will still maintain the highest standards to prevent accidental spillage or splashing of workers, and ensure that the equipment is cleaned and disposed of correctly.

The infected mice are no greater than normal animals because the virus is not shed; hence standard animal handling precautions will be used. These currently include a gown, protective clothing, gloves and masks (to reduce mouse allergen exposure of the workers). Injection involves use of a needle which would be hazardous in a mobile, mature mouse. However, we use newborn mice which are easily immobilised by hypothermia, and the injection procedure is then carefully controlled by two workers - one places the needle into the vein and holds it in position whilst the other does the injection. These procedures will be done in quiet rooms with limited access, that meet containment level 2 standards, using disposable materials that will be removed at the end of the procedure. The area will then be cleaned and signed off as ready for future work by our personnel.

Host/vector system

Recombinant (inactivated non-replicating) lentiviral vectors. Replication deficient lentivirus particles are generated in cell lines following co-transfection of three different plasmids. These supply the self-inactivating transfer vector containing galectin-3 and viral long terminal repeat (LTR) (but lacking any expression of HIV genes; packaging and structural proteins, gag/pol; and envelope (env), vesicular stomatitis virus g (VSV-g). The vector itself is self-inactivating due to a deletion in the promoter enhancer region of the 3LTR. The only expression from the vectors is of the transgene cDNA, controlled by an internal promoter such as SFFV. Galectin-3 mRNA has been cloned into a VSV-G pseudotyped HIV-1-based vector be GeneArt, a commercial biotechnology company. This strategy is similar to the production of Mertk as described in Tschemutter M et al. Gene Ther. 2005 12:694-701.

There is a finite (albeit very small) risk that lentiviral vectors could infect human cells, but we will be using multi-attenuated lentiviruses that are replication incompetent because they lack the gag, pol or env genes. Hence, they are unable to spread even if workers are accidentally exposed by injection, ingestion or through a wound; risk of entry through these routes will be limited by wearing appropriate labwear and gloves, and completely covering open wounds. Although replication incompetent, lentivirus could theoretically insert into cellular DNA and this might result in a potentially oncogenic mutation. The infection with high titre lentiviral vectors encoding growth promoting molecules and selection in vivo for cells with altered growth potential. No adverse affects have ever been described through accidental exposure to retroviral vectors. The major risks in this project are when the lentivirus is being prepared and then injected but this will be done into immobilised mice by experienced staff, in quiet CL2 standard rooms, wearing a laboratory coat and latex or nitrile gloves.

Origin & function

Gene Sequences: cDNAs encoding human and wils-type and modified galectin-3

Origins and functions of the genetic material involved: Galectin-3 is a lectin that modulates cell adhesion, differentiation and proliferation. It is normally expressed during mammalian development in the kidney, and reactivated in diverse diseases. We predict that increased galectin-3 will reduce the severity of cyst formation and fibrosis in vivo.

Will the sequences cause harm if expressed in humans? Galectin-3 is involved in multiple cellular processes including cancer but the lectin does not have any direct oncological effects by itself, indeed treatment with recombinatn galectin-3 protein has been shown to reduce cancer metastases in mice models and the severity of several other renal diseases. Therefore, any accidental increased expression of galectin-3 is unlikely to have any detrimental effects on humans.

Will the sequences cause harm if transferred to the environment? Galectin-3 is a naturally occurring lectin and therefore highly unlikely to cause environmental harm. The potential routes of transmission or escape to the environment of the virus that may occur are known (air or liquids) and full protective measures will be taken to minimise or prevent the access of the virus to other organisms and the environment.

Evaluation of foreseeable effects

The biggest potential harm would be accidental transfer and overexpression of galectin-3 in humans by needlestick injury when the virus is being injected. These risks will...
be reduced by carefully controlling the mice, procedure and environment for the injection. We use new born mice which are easily immobilised by hypothermia, and the injection procedure is then done by two workers - one places the needle into the vein and holds it in position whilst the other does the injection. Dr ****, will teach us how to do this procedure and he has already done this over a thousand times without mishap. Even with accidental human injection, the risks are minimal because we are using multi-attenuated lentiviruses which are unable to spread in humans even if they do infect cells.

In addition, we have in place in association with UCL Biological Services various specific control measures for the lentivirus experiments to minimise exposure and have completed a separate risk assessment for all personnel involved in the animal work. The general work will be performed in a containment level 1 environment but preparation work with virus handling will be in level 2 safety cabinets and injection will be in a quiet room that meets CL2 requirements; personnel involved with the virus work will wear gloves, glasses and a mask.

In the case of a laboratory accident, such as defective/leaking plasticware or dropped samples leading to viral spillage, all the necessary procedures will be applied to eliminate any potential hazardous effects of the virus in the environment. These include: wash with virkon, detergents, and disinfectants. Both wild-type and optimised lentiviruses are sensitive to UV, temperature and other physical agents so their chances of survival are low. All of the liquid waste will be treated with virkon and autoclaved; solid waste will be autoclaved and disposed as biohazard materials.

In the case of a needlestick injury, we will contact occupational health immediately or attend an Accident and Emergency Department immediately to assess injury and treatment required for the penetrating wound. Risks from viral inoculation are minimal as described above.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

1. 5% Virkon or equivalent PHLS certified treatment will be used to treat liquid waste (18 hours) and also any spills and for disinfection of equipment and laboratory materials. Work surfaces will be wiped down with this and 70% ethanol after use. Sharps will be placed in sharps bins that will be autoclaved.

2. 199%

3. Virkon is certified by the PHLS to provide 100% viridical kill under these conditions. Additionally, we will ensure that only in-date products are used to maintain optimal efficiency. Autoclave runs are regularly validated by waste management staff.

4. Solid waste will be double-baged in biological waste bags and sharps in sharps bin. Both are autoclaved at 132° for 15 minutes, then collected for disposal (usually incineration) by the contractors employed by ICH to handle potentially infectious clinical waste.

PROJECT TRANSFERRED TO GM 14 AND GM CENTRE CLOSED

**Project Additional Information**

**Purposes of the contained use**

The shRNAmir laboratory is available from Open Biosystems through UCL, and consists of over 70,000 individual E. coli glycerol stocks containing the pGIPZ lentiviral vector. Each stock contains a unique hairpin sequence within the pGIPZ vector designed to target and reduce expression of most/all genes within the human genome via RNAi interference. We will also use other selected shRNA sequences that we will clone into either pGIPZ or another lentiviral vector, pLL3.7, ourselves in case hairpins from the Open Biosystems stocks are ineffective, or if knockdown in non-human cell lines is required.
This project will involve maintenance, storage and use of this shRNAmir library for use in various projects. Specifically, this project will involve lentiviral production from either pGIPZ or pLL3.7 plasmids and the subsequent use of this lentivirus in cell based screening functional assays. Additionally, clones will be pooled at the bacterial, DNA and viral level to make various intermediate pools of clones to be used to transduce cells in screens and subsequently undertake functional assays.

### Recipient or parental organism

**Cell lines:**
- ATDC5, canine-MDCK, DK, D17, C2F; feline-AH927, CRFK, Mya1; Human-HeLa, TE671, HT1080, 293T, HEL, HFFF, BJ1, Jurkat, CEM, supT1, C8166, A549, LECs, tMSCs; Mouse-MDTF, NIH3T3, Avian- QT36; Marsupial- SC300; Bat Tb1u; non-human primate- FRhK4, LLCMK2, CV1, VERO, Pindak, SMLF; bovine- MDBK, IMR31; Porcine- PK15, SKL, CPK, STIOWA; Mink- mv-1-lu; Rabbit- SIRC, eREP, ratHSN, RAT2, 9L, NRK, TenRPE, human and mouse ES cell lines.
- Mouse-MDTF, NIH3T3; Avian- QT36; Marsupial- SC300; Bat Tb1u; non-human primate- FRhK4, LLCMK2, CV1, VERO, Pindak, SMLF; bovine- MDBK, IMR31; Porcine- PK15, SKL, CPK, STIOWA; Mink- mv-1-lu; Rabbit- SIRC, eREP, ratHSN, RAT2, 9L, NRK, TenRPE, human and mouse ES cell lines.
- Primary Human cells: Derived from various human tissues including peripheral blood derived lymphocytes and macrophages.

The bacterial strains used are attenuated non-colonising strains so are incapable of causing human infection and are therefore harmless to humans. The viral vector to be used will be pseudotyped with the envelope protein VSV-G from Vesticular Stomatitis Virus so, if introduced into the body by injection, ingestion or through a wound, the virus could enter human cells and integrate into cellular DNA. Although the virus is replication incompetent (does not carry gag, pol or env genes) so it cannot make new progeny virus and establish a productive infection, its insertion into cellular DNA could result in a potentially oncogenic mutation. The recipient cells are harmless to humans.

### Host/vector system

**Lentiviral vectors:** Commercial TZV vector from Tranzyme and derivatives (including pGIPZ and pLL3.7). Lentiviral Gag/pol expression vectors p8.9 and derivatives (HIV-1).
- The viral vector used is a lentiviral vector that contains the CMV (Pol II) promoter to drive expression of the hairpin cassette. The lentiviral vector does not contain the appropriate accessory elements to form a viral particle itself and therefore poses no harm to health and the environment. Packaging and envelope proteins are contained on two additional plasmids to the lentiviral expression vector and these plasmids must be introduced into the cell and expressed alongside the lentiviral vector for viable lentiviral particles to be produced.

### Origin & function

The RNAi hairpins are sequences that have been derived de novo and which will initiate a downstream cascade of events leading to knockdown of the target gene to which the hairpin was designed.

The accessory proteins are from the HIV-1 virus.
The hairpin sequence will be transcribed and the RNA will then form a hairpin structure. The hairpin structure will induce a normal cellular in vivo downstream sequence of processing events in response to foreign cellular single-stranded RNA intruder molecules that will result in the post-transcriptional down regulation of the gene to which the hairpin sequence is targeted.

If the inserted sequence were to be expressed in humans after accidental transfer the hairpin could lead to the down-regulation of the gene to which it targets via RNAi interference. This could be a gene essential for growth regulation such as a tumour suppressor gene therefore resulting in a potentially oncogenic mutation. This, however, would not be as severe as the virus is replication incompetent and therefore self-inactivating as none of the structural genes are actually present in the packaged viral genome, such that no new virus can be produced and no other cells can be infected. Physical insertion of the virus into the genome of the host cell could potentially disrupt a tumour suppressor or oncogene, however the likelihood is very low.

VSV-G pseudotyped lentivirus can only infect mammalian cells. Potentially the hairpin could be expressed in another mammalian species and lead to the down-regulation of a growth regulatory gene such as a tumour suppressor gene resulting in a potentially oncogenic mutation. This, however is extremely unlikely as the hairpin is targeted to human genes and many hairpins are not homologous with the genes from other species. If the hairpin were to target and lead to the reduction of a gene via RNA interference it would not be as severe as the virus is replication incompetent and therefore self-inactivating as none of the structural genes are actually present in the packaged viral genome so no new virus can be produced and no other cells can be infected.

The envelope protein is VSV-G from the Vesicular Stomatitis Virus so, if introduced into the body by injection, ingestion or through a wound, the virus could potentially enter cells and integrate into cellular DNA. Although the virus is replication incompetent (does not carry gag, pol or env genes) so it cannot make new progeny virus and establish a productive infection, its physical insertion into cellular DNA could result in a potentially oncogenic mutation. This would be a very unlikely event and if so only a very small number of cells and would not impact on the pathogenic outcome of an exogenous viral infection. The packaging viral components are from the HIV-1 virus. The full length HIV-1 virus is harmful to humans, however the packaging vector used does not contain the full length HIV 1 molecule. Many components of HIV-1, that are critical for HIV-1 infection but not required for viral packaging, have been removed so the virus is attenuated.

The de novo hairpin donor sequences could potentially be expressed in cells and lead to the knockdown of certain genes leading to the increase of oncogenic potential of the virus. This would, however, only be a very small number of cells and as the virus is replication incompetent and cannot make new viral progeny, it would not impact on the pathogenic outcome of an exogenous viral infection.

This would, however, only be a very small number of cells and as the virus is replication incompetent and cannot make a new viral progeny, it would not impact on the pathogenic outcome of an exogenous viral infection.

The most dangerous GMM is the lentiviral preparations of pGIPZ particles. The most dangerous step is the collection, concentration and use of the lentivirus.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

2.5% Trigene advance or Virkon (v/v) will be used to treat liquid waste (18 hours) and also used to decontaminate any spills and for disinfection of any reusable bottles or other equipment and laboratory materials used. Liquid waste is subsequently poured down the sink after treatment with Virkon. Work surfaces will be wiped down with 5% Trigene advance and 70% ethanol after use. Virkon and Trigene advance are certified to provide 100% vircidal and GMO kill under these conditions by denaturating and inactivating viral and cellular proteins. Trigene advance and Virkon will be used with its lifespan to ensure required kill is achieved. Solid waste will be double bagged in biological waste bags, sealed and autoclaved 132°C for 15 mins by trained staff then bagged in yellow biohazard bags and removed by UCL waste services. Autoclave runs are regularly validated by waste management staff.

Date Ackn'd 23/06/2011

Date Project Ceased

CU2 Project Title Immortalization of human cells

Class CultureVol Class2 CultureVolume Class3-4

Class 2 < 1 Litre Consent Granted

Non-GMM
The aim of this project is to immortalize human cells (e.g. skeletal muscle derived myoblasts and stem cells, blood-derived stem cells and fibroblasts). Cells will be prepared from normal individuals and from patients with neuromuscular diseases (e.g. Duchenne muscular dystrophy). Myogenic cells have a limited life span in culture, which prevents their expansion to sufficient numbers for experimentation and seriously limits any potential use in cell replacement or ex vivo gene therapy. An immortalization protocol for normal human cells (e.g. myoblasts) would allow one to isolate cellular models from various neuromuscular diseases, thus opening the possibility to develop and test novel therapeutic strategies. We intend to use a method developed by M and colleagues (names removed. Aging cell. 2007 Aug; 6(4):515-23. Epub 2007 Jun 8: names removed Biochem Biophys Res Commun. 2009 Oct 16;388(2):333-8. Epub 2009 Aug 6). Cells will be infected with lentiviruses coding for hTERT and cdk-4, selected by antibiotic resistance, expanded in culture and stored in liquid nitrogen. Immortalized cells will be stored and distributed under the auspices of the MRC Centre for Neuromuscular Diseases Biobank.

Recipient or parental organism

- HIV.PGK.Puro.CMV.hTERT
- HIV.PGK.Neo.CMV.cdk4
- Human myoblasts, fibroblasts and stem cells.

The lentiviral vectors used are multi-attenuated, meaning they are devoid of all potentially pathogenic encoded functions. In addition they are replication-defective which means that the vector cannot multiply on its own unless supplied by certain proteins in trans. It is self-inactivating which means that the viral promoter in the U3 region of the 5' LTR has been disabled by genetic manipulation. Only a very unlikely event of multiple recombinations during the process of generation of the viral vector can expose the person to a wild type HIV-1. The probability of such an event is extremely low.

The intended recipient organisms are not capable of independent survival in the environment and will not infect or transfer to other hosts.

Host/vector system

- HIV-derived lentiviruses, prepared in 293 Cells:
  - HIV.PGK.CMV.hTERT
  - HIV.PGK.Neo.CMV.cdk4

The lentiviral vectors used are multi-attenuated, meaning they are devoid of all potentially pathogenic encoded functions. In addition they are replication-defective which means that the vector cannot multiply on its own unless supplied by certain proteins in trans. It is self-inactivating which means that the viral promoter in the U3 region of the 5' LTR has been disabled by genetic manipulation. Only a very unlikely event of multiple recombinations during the process of generation of the viral vector can expose...
the person to a wild type HIV-1. The probability of such an event is extremely low.

WPRE is not present in either lentivirus.

Origin & function

Mus musculus, Homo sapiens sapiens

Lentiviruses - can infect human cells.
Puro and Neo - antibiotic resistance genes.

H-TERT - catalytic subunit of telomerase, that lengthens telomeres in DNA strands. Expression of telomerase bipasses telomere-dependent senescence so that cells that would otherwise become postmitotic and undergo apoptosis exceed the Hayflick limit and become potentially immortal.

Cdk4 is the catalytic subunit of the protein kinase complex that is important for cell cycle G1 phase progression; its expression prevents p16INK4a-associated premature growth arrest.

Cdk4 therefore extends life span and immortalization is induced by hTERT.

There would be a risk of cell immortalization if cdk-4 and h-TERT were introduced into human cells.

The risk of transfer to species in the environment is negligible, but would be a risk of cell immortalization if cdk-4 and h-TERT were introduced into human cells.

The lentiviruses are HIV-derived, but are replication-deficient, therefore represent a low risk.

The donor organism has no pathological or harmful characteristics

Evaluation of foreseeable effects

The lentiviruses are HIV-derived, but are replication-deficient, therefore represent a low risk.

The donor organism has no pathological or harmful characteristics.

Only a very unlikely event of multiple recombinations during the process of generation of the viral vector can expose the person to a wild type virus. The probability of such an event is extremely low. The most hazardous GMM are the lentivector viruses and the most hazardous step is dealing with concentrated viral stocks before infecting the target cells.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All GMMs are inactivated for disposal using standard biosafety level 2 procedures. Briefly, liquid waste is treated with 1% Virkon. Work surfaces are decontaminated on completion of work, or at the end of the day, or after any spill or splash of viable material, with 1% Virkon. Virkon has been shown to achieve 100% GMO kill when used as
directed. After decontamination, liquid waste is disposed of via the sink. Solid waste is double-bagged in biological waste bags, sealed, transported to the autoclave, autoclaved and then removed by waste services.

A representative group of the UCL Institute of Child Health GMSC has reviewed this project, and the forms being amended according to their recommendations, agrees this work should be classified as an activity class 2 (AC2) notification.

HEAT INACTIVATION
This is the preferred method and should be followed where practicable. This should be used for solid waste (e.g., disposable pipettes, petri dishes, tips, disposable test tubes etc.) and small scale liquid cultures contained within disposable tubes. The waste should be transported to the autoclave without spillage in a robust metal container with a lid, that can be placed directly into the autoclave. Material should be inactivated using one of the autoclaves provided for this purpose (1966 Wing or Clinic). After autoclaving the waste should be transferred to a yellow plastic bag, tied and labelled with the laboratory of origin and transported to the waste containers at the back of the Clinic. The waste will be collected by outside contractors and destroyed by incineration.

CHEMICAL INACTIVATION
This should be used for larger volumes of liquid culture waste (up to but never exceeding 10 litres at any one time), and for treatment of glassware or other equipment that is to be reused. These should be inactivated by addition of, or immersion in, a chemical agent that is appropriate to the organism in question. A number are available of which the most commonly used are: hypochlorites (e.g., Chloros); phenolics (e.g., Stericol); alcohols (e.g., 70% ethanol); and peroxygen compounds (e.g., Virkon). Effective disinfection with any of these depends on activity (whether it is effective against the target micro-organism), concentration (use of the correct dilution/concentration in the particular circumstances, also allowing for age of the solution if this affects effectiveness), and contact (intimate contact for sufficient time). Refer to the manufacturers guidance or contact the Biological Safety Co-ordinator if you are unsure how to use a chemical agent. Once inactivation has been performed liquid waste/solutions are either disposed of via the sink, flushing with copious amounts of tap water, or stored for disposal by contractors. The latter route should be used where the chemical agent itself presents a hazard and the solution cannot be safely disposed to the drains.

GENETICALLY DISABLED MUTANTS OF LEISHMANIA MEXICANA

Date Project Ceased

Non-GMM Consent Granted

Project notified under transitional arrangements

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

Project Additional Information

Purposes of the contained use

The specified purpose of the contained use is to create mutant lines of Leishmania mexicana with altered expression of specific enzymes or antigens. This is part of ongoing research aimed at identifying targets for chemotherapeutic (drugs) or immunological (vaccines) intervention against Leishmania parasites.

Recipient or parental organism

Leishmania mexicana is a parasite protozoan that causes cutaneous leishmaniasis in Central and South America. It is a Hazard Group 2 organism as defined in the ACDP code and presents a hazard to human health.

Host/vector system

The vector systems to be used are derivatives of pX63-HYG (Cruz et al. 1991, Proc. Natl. Acad. Sci. USA88: 7170-74)

Origin & function

Genes encoding surface membrane, secretory and biosynthetic enzymes and antigens of Leishmania mexicana will be isolated using standard PCR or cloning techniques and constructs assembled in vitro.

Evaluation of foreseeable effects

Any GMO created is very likely to exhibit reduced pathogenicity compared to the normal wild type organism, and in many cases this will be the deliberate purpose of the manipulation - creation of a knock-out organism lacking a key protein. The general reduction on pathogenicity results from the need for an extended period of in vitro manipulation in order to create the mutant lines, and this process invariably leads to a loss of virulence. There is no foreseeable additional pathogenicity of the recipient organism as a result of the creation of a GMO.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Waste management employs a "belt and braces" approach: disinfection followed by autoclaving. Both individual procedures are capable of achieving 100% killing of Leishmania organisms.

Specific disinfection procedures:
- Three disinfectants are used: 70% ethanol, Virkon and Stericol. All are 100% effective against Leishmania when used properly, as verified by absence of viable organisms upon microscopical examination and lack of growth in culture following treatment. Each is applied in a different way and for different purposes, as detailed below:
  i) Surface sterilisation. Hard surfaces such as the work surface in a sterile hood or benches are disinfected with 70% ethanol both before and after completion of work. Wash bottles containing 70% ethanol are used to wet a piece of blue towelling and this is wiped over the surfaces (wear gloves). The towelling is disposed into waste for autoclaving.
  ii) Pipettes. Pipettes are placed and fully submerged into pipette canisters on the floor by each sterile hood. These contain 5% (w/v) Virkon. Virkon is a pink powder, which when dissolved acts as a very effective wide spectrum disinfectant: a 1% solution can be used for general disinfection purposes and is 100% effective against Leishmania. Fresh solutions are prepared weekly as Virkon solutions are effective for a limited period of time. Pipettes are then placed into waste for autoclaving.
  iii) Slides. Microscope slide with live material are placed into large plastic jars with lids containing 5% (v/v) Stericol (a dark brown liquid). Stericol is a phenolic and had an unpleasant smell (which is why it is not used in open pipette canisters). However, it does not lose effectiveness with time. Slides are then placed into waste for autoclaving.
  iv) Cultures. Liquid cultures in flasks etc. are inactivated by addition of a small volume of neat Stericol from the wash bottle by each hood. The final concentration should be > 1% (v/v). Stericol is added to the flask, this is firmly capped and shaken to mix. The flask is then placed into waste for autoclaving.
  v) Spillages. Small spillages are suspected contamination on hands, gloves or work surfaces should be disinfected immediately with 70% ethanol. To inactivate large volume spillages add Virkon powder directly to the contaminated area, leave for 10 minutes then wash with 1% Virkon solution.

Autoclaving: Waste material from flip-top bins (paper waste) is rendered safe by autoclaving. After autoclaving, solid waste is collected and destroyed by incineration, sterile liquid waste is discharged to the drains.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The committee was satisfied with the risk assessment and conclusions reached. Discussion emphasised the importance of ensuring that existing Codes of Practice were adhered to and that new work was properly supervised. It was noted that any proposed future change of activities, for example, dealing with a new gene sequence would need to be carefully considered so that any possible increase in virulence of the pathogen as a result of genetic manipulation could be properly assessed.

02/03/2022
The general aim of the project is to investigate the role of African trypanosomes (i.e. Trypanosoma brucei brucei and Trypanosoma congolense) genes that may be important or essential for this parasite to colonize, establish or produce infectious life forms in the tsetse fly vector. In addition, we are interested in genes involved in tissue tropism and migration within the fly. We are particularly interested in regulating the expression of genes encoding for a family of surface metalloprotease MSP-B, glycosylation enzymes and sugar transporters, flagellar proteins, GPI-anchored proteins, metabolic enzymes, cell cycle and differentiation and those involved in amino acid uptake and metabolism.

Trypanosoma brucei brucei strains Lister 427 (wild type), 427.29.13 (containing tet repressor and HYG in Pol1 large subunit locus, and T7 RNA polymerase, neomycin resistance gene and tet repressor in the alpha tubulin locus), 2T1 (containing T7 RNA polymerase, Tet operator, PAC (puromycin resistance gene) and a partial hygromycin resistance gene (HYG) in the rRNA locus) and AnTat1.1 Trypanosoma brucei brucei is in ACDP hazard group 2. Strain Lister 427, clone 29.13, will be used in the procyclic (tsetse midgut) form. 2T1 and AnTat1.1 strains will be cultured in the bloodstream form but AnTat1.1 will also transform to procyclic form when fed to tsetse flies.

Origin & Function

The T. b. brucei MSP-B (major surface protease B) gene, portions of this gene and its 5’ and 3’ flanking regions will be cloned for overexpression, RNAi and knockout constructs, respectively. Proline uptake/metabolism gene fragments (for RNAi), PIP39 (phosphatase involved in control of stumpy to procyclic form progression) gene portions (for RNAi), genes involved in glycosylation and glycosylphosphatidylinositol anchor addition (for RNAi). In addition to the endogenous genes investigated, the following antibiotic resistance selective markers will also be integrated as selective markers: Streptomyces alboniger puromycin N-acetyl transferase (PAC), Aspergillus terreus elasticin S-deaminase (BSD), Streptococcus lactisus bie (phleomycin resistance), Escherichia coli strain K12 neomycin phosphotransferase (G418/Neomycin resistance) and Escherichia coli hygromycin phosphotransferase (HYG). The acceptor strains for the genetic modification will already have been modified with the bacteriophage T7 RNA polymerase and T7 promoter, and the Escherichia coli tet repressor and tet operator. This allows for the transcription of the inserted genetic material to be induced by the addition of Tetracycline to the media. EGFP, derived by mutation of Aequorea victoria GFP will be used as an in vivo marker for trypanosomes in the tsetse fly.

Evaluation of foreseeable effects

It is very unlikely the genetic modification will make the trypanosomes more hazardous. Some of the modifications might make T. b. brucei more infectious to the tsetse flies. However, gene knock outs or knock down by RNAi are usually disadvantageous to T. b. brucei.

No effect on the pathogenicity to mammalian hosts is anticipated. This is because changing the transmissibility of the parasite through the tsetse fly does not change the pathogenicity of the parasites to animals or humans. T.b. brucei will remain non infectious to humans. The antibiotic resistance genes do not encode resistance to the drugs that would be used to treat T. b. brucei infections in animals, so would not impact on any potential treatment of infections.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not Applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not Applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste comprised of culture flasks, contaminated serological pipettes and tips, and infected flies and the microscope slides on which they are dissected:

(i) Contaminated serological pipettes and plastic pipette tips will be soaked in Virkon solution (minimum 1%) solution for at least 24 hours and then destroyed by incineration.

(ii) Plastics, slides and infected flies will be autoclaved then sent for incineration. Kill by heat treatment will be confirmed by viewing autoclaved material under the microscope to check for death of parasites. Printed records will confirm that the autoclave run completed satisfactorily.

Liquid T. b. brucei culture waste is decontaminated for at least 24 hours by Virkon solution (minimum 1%). A 10 minute immersion in 1% bleach (sodium hypochlorite, NaOCl) is used to decontaminate feeding trays and membranes with small quantities T. b. brucei in blood. This is sufficient to kill all the parasites (Wang et al 2008, Parasites and Vectors 1:35).
The GM committee requested additional information be given on the vectors to be used in the genetic modification of the trypanosomes so that the risk could be fully assessed including any change to patenogicity to humans.

Further information concerning waste disposal and the procedure for disinfecting spills was requested.

The committee deemed the risk assessment satisfactory with inclusion of the requested details.

Please enter comments on the GM safety committee on the risk assessment

CU2 Project Title Immortalisation of Brugia malayi cells for the development of a nematode cell line

Class 2 CultureVolClass2 ≤ 1 Litre CultureVolumeClass3-4

Non-GMM Consent Granted

Project notified under transitional arrangements N

Historical Significant Changes
### Project Additional Information

**Purposes of the contained use**

To induce proliferation of an immortalised cell line from *Brugia malayi* for the development of a celabased screening assay for macrofilaricides.

**Recipient or parental organism**

Isolated primary cells from *Brugia malayi* adult female worms.

**Host/vector system**

Lentivirus (Moloney Murine Leukemia Virus, MMLV) containing plasmids encoding green fluorescent protein and one of the oncogenes SV40, hTERT, HPV-16 E6/7, CD4K, p53 or MycT588A.

**Origin & function**

Commercially available vectors from Applied Biological Materials, Inc. Distributed in UK by NBS Biologicals Ltd.

**Evaluation of foreseeable effects**

Viruses are replication incompetent so cannot proliferate following transduction into the target organism, Gag/Pol/Rev deletion from the viral genome, so immortalised *Brugia malayi* cell line will not shed virus. Insertion of oncogene vectors could occur accidentally into operator but do not replicate following insertion. Work will be conducted in a class II safety cabinet and operators will wear lab coat, gloves and safety glasses to guard against splashes. Sharps will not be used to prevent puncture accidents. Neither the *Brugia Malayi* primary cells or immortalised cell line or the lentivirus cultures will be able to survive outside laboratory culture so provide minimal risk to other than laboratory personnel and the environment.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid contaminated waste is disinfected with a 10% Virkon solution, followed by autoclave treatment. Liquid media are made to 10% with Virkon and incubated overnight to ensure kill of organisms. Inactivated waste is sent for incineration.

Comments from LSTM GSC, 06/05/15:
1. Include information on potential routes of accidental entry for the viral vectors.
2. Confirm routes of waste disposal and provide information on the efficacy of Virkon against lentivirus.
3. Review available hazard information from AMB and provide a safety data sheet if available for the lentivirus vectors.

02/03/2022
Understanding the host-pathogen interactions in Mycobacterium tuberculosis and HIV co-infections in human immune cells

Project Additional Information

Purposes of the contained use
To define the host-pathogen relationships in immune cells containing co-infections of HIV and Mtb.
Host cells will include established cell line THP1 and isolated human immune cells: dendritic cells, neutrophils and alveolar macrophages. GM HIV-1 expressing GFP and a GM respiratory knock-out mutant of MTB expressing mCherry will be used.

Recipient or parental organism
HEK-293 cells will be used as host for the HIV-1 BAL_GFP to produce the infectious virus particles.
Mtb cell line H37RV will be used

Host/vector system
pGFP plasmid for green fluorescent protein has been inserted into the HIV-1 BAL
pENVY10 plasmid for mCherry has been inserted into M tuberculosis strain H37Rv

Origin & function
HIV-1 BAL expressing GFP is obtained from the University of Liverpool ref: GM445 (UoL)
Mtb strain H37RV expressing GFP or m Cherry is already in use at LSTM, ref: GM107 (LSTM)

Evaluation of foreseeable effects
HIV-1 BAL contains the full HIV-1 genome. Insertion of the pGFP plasmid is
not thought to affect the virulence of the strain, which is equivalent to clinical isolates. Mtb strain H37Rv is a respiratory knock-out mutant which is less virulent than wild-type Mtb. The pENVY10 plasmid encodes for a hygromycin antibiotic resistance to aid expression. Hygromycin is not an antibiotic used against Mtb so the virulence of the knock-out mutant is not affected by insertion of this plasmid.

Containment level 3 will be used for this work as this is required for both HIV and Mtb as ACDP HG3 organisms.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste for HIV and Mtb will be made to 5% with Surfanios disinfectant and incubated overnight, prior to autoclaving at 122°C for 4 hours. Solid contaminated waste is immersed in 5% Surfanios overnight followed by autoclaving at 122°C for 4 hours. Other waste from CL3 laboratory is autoclaved at 122°C for 4 hours. Following autoclave all waste is sent for incineration.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form  

Tick to confirm that you have attached a risk assessment to this form  

Tick if you are claiming exemption from disclosure for section of the risk assessment
Points raised at the LSTM GM review:
• SOP’s to be provided with detail of the work with HIV which can be referenced in this Risk Assessment.
• Reference risk assessment (non-GM) for the HIV work, i.e. how to work safely with HIV.
• Details of how training and instruction will be given to ensure competence to work with HIV and MTB.
• What evidence will be available to demonstrate competence of workers? Include evidence of training from University of Liverpool and at LSTM.
• Include the GM information for the GM MTB from risk assessment GM107v3 as this will be used in the project.
• Include information of the plasmids used to generate the HIV either a reference paper or plasmid map.
• Include assessment of the risk from unscreened blood as a source of MDM and DC cells.
Ensure an inventory is set up for storage of any GM HIV within the CL3 lab. Ensure adequate control and segregation from other HG3/GM organisms stored within the laboratory.

CU2 Project Title Expression of Streptococcus exotoxins in E.coli

Class 2

Consent Granted

Project notified under transitional arrangements N

Tick if notifying a connected programme of work N

Historical Significant Changes

Historical Date of Additional Info

02/03/2022
### Project Additional Information

#### Purposes of the contained use

To confirm in vitro the efficacy of neutralising antibodies to the exotoxins

#### Recipient or parental organism

Non-pathogenis laboratory strains of Escherichia coli (Top10 and BL12DE3)

#### Host/vector system

Plasmid pDESt14 (Thermoscientific) using IPTG promoter. DNA inserts will be directly cloned into the vector through restriction sites.

#### Origin & function

Streptococcus pyrogens exotoxin genes SpeA, SpeB, SpK, Ssa and Sla will be inserted into E.coli to over express the functional exotoxins.

#### Evaluation of foreseeable effects

E.coli strains are non-pathogens. All genes have signal peptides removed to prevent secretion into growth media. Expression of exotoxins only occurs with IPTG promoter. Foreseeable effects with IPTG promoter. Expressed exotoxins will be functional with estimated LD50 of 150mg/kg.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

CL2 laboratory. Use of class II safety cabinet for liquid handling procedures. Sealed centrifuge buckets. Waste inactivated by use of 1% Virkon or autoclave then sent for incineration.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste made to 1% Virkon; solid waste autoclaved to achieve 100% kill. Virkon well documented as suitable disinfectant for E.coli. Autoclave cycle confirmed at each run. All waste sent for incineration post disinfection.

LSTM GMM review panel met on 4/10/17 and the following comments were raised:

- Class 2 GMM accepted rather than class 1. Although lab strain of E.coli to be used and Streptococcus exotoxins are routinely used in immunology and well characterised there is potential for causing illness if contamination with the GMM.
- The room location used for the work with GMM should be added to the risk assessment.
- Indicate use of sealed centrifuge buckets/rotor within control measures, (section 4.1)
- Add information indicating the stage at which GMM is inactivated during purification of the exotoxins. Reference the SOP for purification of the exotoxins.

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

The development or acquisition of antimicrobial resistance often result in a fitness cost to bacteria as resistance can be metabolically expensive, however sometimes resistance is accompanied by a fitness benefit. The overall aim of the project is to determine whether the evolutionary trajectory of the emergence of antimicrobial resistance can be predicted and taken advantage of in order to inform clinicians of particular antibiotic combinations which consistently result in unfit antimicrobial resistant bacteria. Genetic background of an isolate is of particular importance in this respect. We will select for naturally occurring mutations and / or horizontal gene transfer events in bacteria that confer resistance to various clinically used antimicrobials by growing them in subinhibitory concentrations of antibiotics (mutation) and together with suitable sensitive recipient organisms. Following this the strains will be sequenced and the mutations and acquisition events determined.

To confirm that these mutations result in antimicrobial resistance (and are not part of a compensatory mutational effects) we will do two things:

1. clone the mutated gene into a suitable vector in a laboratory strain of E. coli and replace (using homologous recombination ) or complement the wild-type gene in the original, wild-type, sensitive ancestor. This should lead to a resistant strain as seen in our evolutionary experiments.

2. will also complement / repair the mutation to demonstrate reversion to sensitivity.

Therefore the only genetic modification we are requesting to be covered in this application is the complementation of naturally occurring mutations to resistance (leading to sensitivity) and the cloning of mutant alleles in susceptible strains to replicate the naturally occurring mutations which we detect during the evolution of our strains (this will lead to resistance).

**Recipient or parental organism**

Clinical isolates of Escherichia coli and Klebsiella pneumoniae isolated from clinical samples from the UK, Malawi and Uganda. These isolates will be susceptible to the majority (if not all antibiotics) normally used to treat infections caused by the organisms.

E.coli (α-select), JM109 and BL-21 , E. coli classified as disabled or non-colonising hosts. These strains will be our general cloning strains and all construction will be carried out in these. This category of hosts has been defined by ACGM as those which are non-pathogenic, are unlikely to survive outside of culture media and have a history of safe use.

**Host/vector system**

The vectors used will be standard, non-mobilisable cloning and expression vectors for use in Escherichia coli and Klebsiella pneumoniae. These are based on a colE1 replicon and will include the following plasmids:

- pBR322 (copy number 15-20 per cell. Ref; Chang and Cohen; 1978) [PMID:149110]
- pUC18 (copy number 500-700 Ref; Messing; 1983) [PMID: 6310323]
- pET (Non-mobilisable expression vector. Novagen).

**Origin & function**

During the course of the evolution experiments we will determine naturally occurring mutations in genes resposible for resistance and fitness (e.g. in an efflux pump or a change in a ribosomal protein). In order to determine if these mutation(s) are solely resposible for resistance we will engineer this mutation in the original sensitive strain. Antibiotic resistance genes will be present in vectors (ampicillin or chloramphenicol) and genetic modification as detailed above will give rise to phenotypic resistance.
towards our antibiotic of choice. These include amoxicillin, chloramphenicol, ciprofloxacin, gentamicin, co-trimoxazole and ceftriaxone.

**Evaluation of foreseeable effects**

**Direct Effects:**
In some of the clones, where we are replicating the naturally occurring mutation to resistance, the genetic material will make the host more resistant to clinically relevant antibiotics. We will never make the strains resistant to more than two clinically relevant antibiotics thus ensuring there are multiple, clinically used antibiotic susceptibilities remaining.

**Indirect Effects:**
The genetic material may increase or decrease the fitness of the isolate compared to the ancestor strain.

02/03/2022
Using infectious clones and genetically altered arboviruses to study virus-host interactions

Purposes of the contained use

Virus sequences, wild-type and mutated, will be cloned into plasmids and transformed into bacteria for amplification (virus particles will not be produced at this stage). Plasmids will be purified and used to produce stocks of infectious virus particles in mammalian and/or insect cell cultures. Stocks of infectious virus will maintain a standard infectious viral population that can be rescued without further passage. Altered viruses will express fluorescent or luciferase proteins either as a fusion protein with a viral gene or sequentially on a separate promoter. In addition, specific mutations will be engineered into viruses to examine the genetic basis of infection in mosquitoes. We evaluate the replication, dissemination and transmission of viruses in cells or insects by observing the presence of a fluorescent or luciferase reporter that is expressed by the virus. These are standard techniques used in many laboratories.

Recipient or parental organism

Zika virus (ZIKV), Semliki Forest virus (SFV), o’nyong’nyong virus (ONNV)

Host/vector system

Whole virus genomes will be cloned into standard pUC plasmid for
amplification in E. coli, RNA polymerase promoter sequence will be added for in vitro transcription.

**Origin & function**

For GFP or luciferase labelling the sequence for either the fluorescent protein or luciferase will be added onto the structural or non-structural polyprotein sequences of the viruses. Additional mutations to the wild-type sequence will be made to assess the ability of the virus (e.g., fidelity mutants, vaccine candidates) to disseminate through the insect host or to create non-infectious, replicating particles (replicons) to view susceptible cells in mosquito tissues. Mutations will be made in both structural and non-structural sequences and will decrease virulence.

**Evaluation of foreseeable effects**

There is no increased risk associated with cloning ZIKV/SFV/ONNV whole genome into standard pUC plasmids for amplification in E. coli because transcription of viral RNA and translation of viral proteins will not be initiated so no virus particles will be produced in E. coli. There is no risk associated with cloning RNA polymerase promoter sequence as this does not produce virus particles and requires additional steps for RNA to enter cells. There is no risk associated with cloning sequence for fluorescent or luciferase protein onto the structural or non-structural polyprotein sequences as none of these encode sequences for virulence factors. Virus strains used in containment laboratory are unlikely to persist outside of the lab because there is no natural virus vector in the UK. Infected insects will not survive outside the lab as they are tropical species.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste will be autoclaved at 122C for 30 minutes to ensure 100% kill. Autoclave cycle will be confirmed from record printout and and recorded for each run. Liquid waste will be made to 2% Virkon solution followed by autoclaving at 122C for 30 minutes. Autoclave cycle confirmed as above.
All waste is sent for incineration

Project Additional Information

Purposes of the contained use

This work will involve the culture of a number of clinically important intracellular pathogens. We wish to gain a better understanding of what influences susceptibility to disease and to develop novel treatment strategies to improve clinical outcome.

Recipient or parental organism

- Neisseria gonorrhoeae (HG2)
- Escherichia coli (HG2)
- Listeria monocytogenes (HG2)
- Staphylococcus aureus (HG2)
- Chlamydia trachomatis (HG2)
- Mycobacterium ulcerans (HG3)

Host/vector system

1. pFCCGi plasmid (rpsM::mCherry and PBAD::EGFP); constitutive mCherry and inducible GFP expression.
2. pDiGc plasmid (rpsM::EGFP and PBAD::dsRed); constitutive GFP and inducible dsRed expression.
3. pSW002 plasmid (psbA::dsRed); constitutive dsRed expression.
4. prpsM-DsRed.T4 plasmid (rpsM::dsRed); constitutive dsRed expression.
5. pZEP17.1 plasmid (rpsM::EGFP); constitutive GFP expression.

Origin & function

Knock-out (KO) mutants will be generated by site directed mutagenesis in the LSTM laboratory.

The inserted genetic material will code for a variety of fluorescent proteins. The plasmid-borne expression of fluorescent proteins will be used to track internalisation and growth/survival by flow cytometry and confocal microscopy. These plasmids have been used previously, or designed, for applications like that proposed here (Helaine et al., 2010, Mengesha et al., 2006, Saliba et al., 2016, Wilton et al., 2017).

**Evaluation of foreseeable effects**

All KO mutants are expected to be less virulent than the wild-type. GMMs created by site-directed mutagenesis will not express key genes associated with pathogenesis. As a result, they are expected to be less able to survive and replicate and will exhibit reduced virulence compared to the wild-type.

Fitness of mutants will be assessed using intracellular assays. Evidence of increased fitness (improved invasion and/or increased intracellular replication) will be recorded. It is hypothesised that mutants which carry fluorescence expression plasmids will incur a fitness cost and will be less virulent. The impact of all modifications on growth and drug sensitivity will be determined as part of strain characterisation.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

**Historical Significant Changes**

**Historical Date of Additional Info**

**Significant Change ID**

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

Bacterial symbionts of mosquitoes will be modified to investigate host-microbe interactions and paratransgenic control strategies for arthropod vectors. Bacteria will be transformed with plasmids expressing fluorescent proteins and genes conferring antibiotic resistance. Native gene over-expression will also be undertaken exploiting plasmid expression. These plasmids contain normal antibiotic resistance genes (Ampicillin, Chloramphenicol or Kanamycin) for selection on agar plates. Genome engineering approaches will also be undertaken which utilize CRISPR-Cas9 gene editing approaches in combination with recombineering. Genome modification will entail creating mutations or integrating genes into the bacterial chromosome. Paratransgenic studies will involve over-expression of dsRNA from plasmids or via integration into the genome. This work will be undertaken in bacteria that associate with mosquitoes which commonly includes bacteria from the Proteobacteria, Bacteroidetes, and Actinobacter phyla

**Recipient or parental organism**

E.coli BL21, K-12 MG1655, DH5alpha
Aeromonadaceae such as Aeromonas hydrophila
Enterobacteriaceae such as Cedecea netari, Enterobacter cloacae, Pantoea agglomerans, Serratia mercescens,
Acetobacteria such as Asaia bogorensis
Pseudomonadaceae such as Pseudomonas fluorescens Holomonadaceae such as Zymobacter palmae
Wolbachia
Leucobacter
Chysdeobacterium
Stenotrophomonas

Host/vector system

Original or modified version of commonly used vectors for bacteria including pKDsgRNA-ack (Spectinomycin resistant) and pCas9-CR4 (chloramphenicol resistance) (Reisch and Prather 2015; 10.1038/srep15096), pRed/ET (Tetracycline resistant) (Trehan et al 2016; doi: 10.1038/srep19121), pET28a/Cas9-Cys (Kanamycin Resistant) (Ramakrishna et al, 2014 10.1101/gr.171264.113.), pRAM-mCherry (Kanamycin and Rifampicin Resistant), pRAM-GFP (Kanamycin and Rifampicin Resistant), pRAM-CFP (Kanamycin and Rifampicin Resistant) (Burkhardt et al. 2011; 10, 1371/journal.pone.0029511), pBAVIK-T5-gfp(Kanamycin Resistant) (Bryksin and Matsumura 2010; 10, 1371/journal.pone.0013244), shuttle vectors such as pGEM-T easy (ampicillin resistant).

Origin & function

Native symbiotic bacteria of mosquitoes will be transformed with plasmids for gene over-expression. Genes that will be over-expressed include but are not limited to i) fluorescent proteins, ii) antibiotic resistance genes iii) bacterial genes and iv) dsRNAs

For CRISPR gene editing approaches, we will edit the genome of bacteria to mutate or integrate genes into the bacterial genome. Potential target sites for integration and mutation include bacterial genes (such as OmpA, Waal, hns, ifhB, aroD, aroG, yfB, lip, secB, lon, pdl, ycbJ and RscA) or sites within intergenic regions. Mutant bacteria will likely be less fit in mosquitoes compared to their WT relatives.

Gens to be integrate include but are not limited to i) fluorescent proteins, ii) antibiotic resistance, iii) cassette for dsRNA expression and iv) native bacterial genes. Integrated genes will be driven from native, inducible or constitutive promoters. dsRNA will target mosquito genes or viral sequences with the aim of creating mosquitoes that are incapable of harbouring or transmitting viruses.

Cloning of plasmids will be undertaken using conventional approaches in E. coli.

Evaluation of foreseeable effects

The work entails transforming native bacterial symbionts that commonly associate with mosquitoes with expression plasmids and plasmid used for genome modification. Symbionts are classified as hazard group 1 or 2. Genomic integration or plasmids possess gene(s) expressing antibiotic resistance, cas proteins, fluorescent protein, bacterial membrane or cytosolic proteins, and dsRNA fragments.

The protein expressed from the inserted genetic material might be harmful to humans if injested or inhaled. These proteins will be expressed in the controlled manner inside the bacterial cells and will not come in direct contact with the humans. The proteins expressed in the bacterial cell will have minimal effect on the environment. Antibiotic resistance may give bacteria a selection advantage but only in cases where antibiotics are present. More likely, possessing these genes would be a fitness cost for the bacteria as evidenced by studies showing the plasmids are lost from bacteria after successive passages. These antibiotic resistance genes are already present in the environment. Containment of these genes to the laboratory mitigates these risks.
Gene transfer, although unlikely, may result in novel phenotypes in these mosquito symbionts. These may alter the fitness, either positively or negatively, compared to the wild type strains. In the unlikely event of a gene transfer, containment procedures will mitigate any risk to the environment. Infections of mosquitoes are done under Category 2 containment insectaries.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Infections of mosquitoes are done under Containment Level 2 insectaries.

Infected arthropods will be held in appropriate CL2 facilities separate from non-infected arthropods. The insectaries will be separated by multiple doors (security clearance required to enter anteroom, enter another door to access insectary containing pathogens), and with measures to prevent escape and detect escapees (mesh over vents, use of white trays, light coloured walls, ceilings, etc.). Access will only be granted to personnel with documented training and with satisfactory techniques.

Infected arthropods will be kept in double containers (e.g. carton with mesh covering inside a plastic clip-top container or netted enclosure). Labels for containers will include the arthropod species, number of arthropods and pathogen. Live challenged arthropods will not be imaged. Live challenged arthropods will have saliva collected and tissues will be dissected. In these instances, arthropods will be immobilized by cold prior to manipulation. Saliva collection will only be performed on immobilized insects (anesthetized or legs/wings removed). Collected samples will be used for plaque assays and/or inactivated prior to RT-PCR.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Solid wastes e.g. agar media, killed insects, will be disinfected using validated autoclave cycle, followed by incineration. Liquid wastes will be disinfected by making to 1% with Virkon, or use of autoclave, followed by incineration of the disinfected waste in either case.

*Is an emergency plan required according to regulation 20?* N

*If yes, tick to confirm that it is attached to this form* N

*Tick to confirm that you have attached a risk assessment to this form* Y

*Tick if you are claiming exemption from disclosure for section of the risk assessment* N

**Please enter comments on the GM safety committee on the risk assessment**

This project was reviewed by the LSTM Biological Safety Committee via email.

The following comments were raised:
Additional information was requested about the plasmids and bacterial targets for mutation to clarify the intended work.
Confirmation of the hazard grouping of the bacterial symbionts indicates some are hazard group 2 so GM class 2 is appropriate for the work with the use of necessary control measures.
Clarification of any potential effect of the GM bacteria on human health or the environment.

**Project Additional Information**

**Purposes of the contained use**
- To provide safety data to allow vaccine to enter the clinical trial stage

**Recipient or parental organism**
- Ad35 Adenovirus

**Host/vector system**
- Replication deficient Ad35 human adenovirus vector encoding HIV-1 antigens gag, RT, In, nef and gp 140

**Origin & function**
- See above host/vector system, function is to provide immunogenicity against HIV, however the purpose of this study is to look for possible toxicity or tissue damage at the site of injection.

**Evaluation of foreseeable effects**
- Non-replicating viral vector being used to evaluate possible toxicity/tolerance effect.
- No foreseeable effects predicted.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
- N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**
- Not required

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**
- Inactivation (kill) will be two part but achieve 100% kill.

Animals will be fully necropsied at the end of the study. All tissues will be retained for histology and be preserved in formaldehyde which inactivate any remaining viral material. Blood samples will be frozen and retained for further analysis.

Any remaining tissues, bedding and cage debris will be double bagged, sealed, placed in a yellow euroskip then sent directly for incineration in the on-site PPC authorised clinical waste incinerator. All cages and racking will be cleaned by washing at 82C using standard detergents and cleansers.
The GMM will be supplied via the sponsor, no genetic manipulation will be carried out on the site. The predominantly closed environment and non-replicating nature of this material would imply that it would be considered a very low risk study.

Please enter comments on the GM safety committee on the risk assessment

The GMM will be supplied via the sponsor, no genetic manipulation will be carried out on the site. The predominantly closed environment and non-replicating nature of this material would imply that it would be considered a very low risk study.

Project Ref 139/18.1

Date Ackn'd 08/02/2018

CU2 Project Title Intermittent dose studies of various adenovirus (Ad) serotype

Class 2

Culture Class Vol 2 Not Applicable

Consent Granted Not Applicable

Project notified under transitional arrangements N

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID
### Project Additional Information

#### Purposes of the contained use

To provide preclinical data to allow the materials under investigation to enter clinical trials, or to provide anti-serum that will be used in subsequent testing to indicate that the materials are safe for use clinically.

#### Recipient or parental organism

Various replication deficient adenovirus (Ad) serotypes that incorporate sequence(s) of amino acids or proteins that act as antigen(s). The antigens are non-pathogenic and do not present a higher risk than the parent virus.

#### Host/vector system

Replicant deficient Ad vectors. The HSE guidance document at [http://www.hse.gov.uk/ukbiosafety/gmo/acgm/acgmcomp/part2.pdf](http://www.hse.gov.uk/ukbiosafety/gmo/acgm/acgmcomp/part2.pdf) provides full details on Ad vector strains and indicates that these may be handled at containment level 1 if there is sufficient attenuation demonstrated. All vectors in this programme of work will have been rendered replicant deficient, or attenuated. The Ad vector serotypes that will be used include (but not limited to) Ad4, Ad5, Ad26, Ad35 and Ad 48.

#### Origin & function

The supplied materials are provided from a sponsor company, there is no genetic manipulation on site. Information including a certificate of analysis and material safety data sheet is provided for each material. The intended function of the material is to provide prophylactic treatment for the prevention of diseases or the therapeutic treatment for management of diseases.

#### Evaluation of foreseeable effects

The materials are under investigation are nonreplicating/attenuated viral vectors being used to evaluate toxicity/tolerance effects in experimental animals or for anti-serum production. There is little, or no, established risk with wildtype reversion. See waste disposal section (section 12). There are no foreseeable effects predicted.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

#### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

#### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Animal waste such as bedding and cage debris will be handled as per site procedures, solid waste is sealed in bags and placed in skips that are sent for on-site incineration. Animals that are subject to terminal procedures with tissues being retained for histology and preserved in formaldehyde which inactivate any remaining viral material. Carcasses are sealed in bags and placed in specific skips.
as per site procedures and sent for on-site incineration. Blood samples are either handled on site within a central laboratory or plasma/serum are prepared and frozen for off site shipping or retained for further analysis. Off site shipping is handled by a dedicated shipping department and all local national laws are followed with regards shipping preparation and documentation. All cages and racking are cleaned on site in a custom designed cage washing facility by sterilisation/washing using standard detergents and cleansers that are known to inactivate the vector.

Date of Significant Change

Project Additional Information

Purposes of the contained use

To provide preclinical data to allow the materials under investigation to enter clinical trials or for GMP lot release. To provide anti-serum that will be used in subsequent testing to indicate that the materials are safe for use clinically.

Recipient or parental organism

Replication incompetent lentiviral vectors that incorporate sequence(s) of amino acids or proteins.

Host/vector system

Replicant deficient lentivirus vectors. The HSE guidance document at http://www.hse.gov.uk/biosafety/gmo/acgm/acgmcomp/part2.pdf provides full details on lentivirus vector strains and indicates that these may be handled at containment level 1 if there is sufficient attenuation demonstrated. All vectors in this programme of work will have been rendered replicant deficient, however sharps will be used therefore classification is determined as containment level 2.

Origin & function

The supplied materials are provided from a sponsor company, there is no genetic manipulation on site. Information including a material safety data sheet is provided for each material. The intended function of the material is to provide therapeutetic treatment for diseases.

Evaluation of foreseeable effects

Not applicable.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Laboratory and animal waste will be handled as per site procedures, solid waste is sealed in bags and placed in skips that are sent for on-site incineration.

Animals that are subject to terminal procedures with tissues being retained for histology and preserved in formaldehyde which inactivate any remaining viral material.
Carcasses are sealed in bags and placed in specific skips as per site procedures and sent for on-site incineration.

Blood samples are either handled on-site or plasma/serum are prepared and frozen for off site shipping or retained for further analysis. Off site shipping is handled by a dedicated shipping department and all local/national laws are followed with regards shipping preparation and documentation.

All cages and racking are cleaned on site in a custom designed cage washing facility by sterilisation/washing using standard detergents and cleansers that are known to inactivate the vector.

The genetically modified materials will be supplied from a sponsor company, with no genetic manipulation being carried out on the site. The predominantly closed environment in which they will be handled and non-replicating nature of these materials would imply that they are considered a low risk. The current site procedures are considered adequate to mitigate any potential risk.

02/03/2022
This project intends to utilise the well characterised ability of Pseudomonas aeruginosa to form a biofilm mode of growth to establish whether bacterial biofilms could be used as a method to transfer proteins for gene therapy usage.

Pseudomonas aeruginosa has been shown to preferentially assume a biofilm mode of growth, embedding itself in a gelatinous organic polymer matrix composed primarily of alginate. There is a lack of understanding of the in situ regulation of biofilm matrix polymer formation nor whether the genetic promoters of the biofilm could be utilised to express non-biofilm genes in a formed biofilm. This project intends to address both aspects.

The contained use activity is required as part of this study involving vectors constructed at the Paterson Institute encoding the algC or the algD gene that encodes the enzyme phosphomannomutase or GDP-mannose dehydrogenase respectively that are both critical enzymes in the formation of the biofilm under the genetic control of the tetracycline response element or their natural promoters driving a non biofilm gene.

In the first experiments we must determine the activity our algC or algD promoter that has been inserted into our non-mobilisable vector. This can only be done in the wild-type strain (PAO1) as we require all the genetic components required for biofilm formation to be intact. Furthermore PAO1 is genetically identical to the delta strains of...
P. aeruginosa (PAO1 algC and PAO1 algD) that is also being used in this study. It is hypothesised that when the transformed wild-type P. aeruginosa is grown under conditions that will allow the formation of the biofilm that expression of a non biofilm reporter gene such as B-galactosidase or green fluorescent protein will increase as this will be placed downstream of our algC or algD promoter.

We will then compare this data to that acquired by the transformation of the PAO1 alg C and the PAO1 algD (avirulent defined mutants) with the algC or algD gene under the control of the tetracycline promoter where it is hypothesised that addition of tetracycline to the medium will allow the induction of a biofilm. The final stage of this project will then look at whether the algC or algD promoter can be utilised to drive expression of non-biofilm genes within this tetracycline induced biofilm.

Recipient or parental organism

Pseudomonas aeruginosa strain PA01. The most widely used laboratory stain with complete physical and genetic maps being available and the genome sequenced. The original strain was isolated from a wound in 1955 by B Hollowoway described in detail in 1969 in Bacteriology Review. The environmental bacterium is a gram negative prototrophic bacteria that like many is an opportunistic human pathogen that causes bacteraemia in burn victims, urinary tract infections in catheterised patients and is the predominant cause of morbidity and mortality in cystic fibrosis patients.

Host/vector system

All vectors are based on non mobilisable vector systems. They will either be pUC, pGEM, pBluescript, pSP (Promega), pPROTet (Clonetech) based vectors.

Origin & function

E. coli - galactosidase gene or Aquae Victoria green fluorescent protein (GFP) under the control of the O, aerygubisa algC or algD promoter that normally promotes the expression of phosphomannomulase or GDP mannose dehydrogenase respectively in the wild type organism.

Evaluation of foreseeable effects

The algC and algDpromoters regulate the formation of the P.aerugosa biofilm and so therefore it is foreseen that when the bacteria is grown under conditions to form a biofilm the algC and algD promoters will drive expression of the downstream B-galactosidase for GFP gene.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Animals will not be used in these experiments.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applied for.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste materials (e.g gloves, plastic ware, agar plates, cell pellets) are rendered inactive by either autoclaving or disinfection using 1% Virkon and are subsequently incinerated along with clinical waste.

Liquid waste [culture & medium - volumes <5l] is disinfected using Virkon at either 2% or 3% for a minimum contact time of 1 hour prior to disposal to sewers.

Is an emergency plan required according to regulation 20? 

Y

If yes, tick to confirm that it is attached to this form

N

Tick to confirm that you have attached a risk assessment to this form

Y

Tick if you are claiming exemption from disclosure for section of the risk assessment

N
The committee have reviewed the amendments to the risk assessment 02/614 to include the use of Pseudomonas aeuringinosa strain PA01 as a host and agree with its conclusions.

- **Date Project Ceased**: 19/10/2006

**Withdrawn**
N

**Project notified under transitional arrangements**
N

**Historical Significant Changes**
TRANSFERRED TO GM CENTRE 541.

### Project Additional Information

**Purposes of the contained use**
To evaluate the effects of activation or inhibition of expression of the Notch and Wnt signalling pathways in mammalian cell lines and mammalian cell lines. Notch and Wnt signalling pathways are highly conserved cell-fate determination pathways, and play a central role, at the cellular level, regulating morphology, proliferation, motility and cell fate. Abnormalities in the components of these pathways are associated with a number of developmental disorders and cancer. Modulating the expression...
of the pathways will help to understand the intricacies of the signalling system and understand the effects on cell development and cancer induction. If any of these translated sequences were over expressed, after self inoculation, in a target cell it could possibly result in transformation of that cell. Although this has not been proven, there is a risk factor associated with the production of vectors expressing such sequences.

Recipient or parental organism

Adenovirus serotype Ad5-Adenoviridae are classified as ACDP hazard group 2
Lentivirus - Human Immunodeficiency virus (HIV-1) is classified as ACDP hazard group 3
Retrovirus - MuLV based

Host/vector system

Non-viral systems
Bacterial Host-Escherichia coli k-12 derivaties (TG1, TOPO 10 series and DH5-alpha)
Plasmid vectors-pcDNA3.1, pBluescript (Strategene) and TOPO (Invitrogen) based plasmid vectors.

Viral systems
Adenoviral vectors deleted for E1 (cell transformation and tumourgenicity) and E3 genes (non-essential genes for in vitro growth). E1 is provided in trans by 293T packaging cell line.
Adenoviral vectors deleted of all viral lytic cycle genes. Coding sequence (except for E1) provided by helper virus and E1 provided by 293T cells.
Replication defective E1 vectors in themselves can be considered unlikely to cause disease according to the HSC’s advisory committee’s compendium of guidance on genetic modification.

Lentiviral and retroviral vectors are deleted of any viral expressed sequences. Genes for packaging provided by Transient plasmid transfection in to producer cells.

Origin & function

Reporter genes, including GFP, dsRed, Luciferase, will be used to assess modulation of the notch and wnt pathways in vivo.
Genetic material of human, murine, rat and Xenopus origin will elucidate the relative contributions of wnt and notch signalling on the differentiation of mesenchymal stem cells to chondrogenic, dipogenic or osteogenic lineages.
Due to the nature of the inserted genetic material (i.e oncogenic) containment level 2 controls and procedures will be employed in this project.

Evaluation of foreseeable effects

The Adenoviral, Retroviral and Lentiviral based vectors are replication incompetent. Thus whilst they pose an infection risk to humans and other species, they are unable to initiate further rounds of replication/infection cycles.

If self-inoculation occurs with adenoviral constructs the chances of seroconversion are minimal due to double deletion of genetic material from replication deficient plasmid.
The most likely course of events is that a localised immune response will clear the inoculated pathogen without any chances of further contamination. The retroviral and lentiviral vectors contain no viral genes so are essentially “gutless” shells. The chances of seroconversion are again minimal especially as the retrovirus is a murine pathogen.

The heterologous genes do not encode viral specific proteins, nor do they interfere with the known activities of the virus and as such are unlikely to have an effect upon the basic nature of the recombinant adenovirus and lent or retrovirus.
However since they are oncogenic the appropriate containment level to be used is CL2.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not Applicable
No animals will be used in this project

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid Waste materials (e.g. gloves, plastic ware, agar plates, cell pellets are rendered inactive by autoclaving and are subsequently incinerated along with clinical waste. Surfaces are disinfected with 1% Virkon solution.
Plastic ware that can be effectively disinfected is treated with 1% Virkon solution for a minimum of 1 hour prior to incineration.
Glassware is treated with 1% Virkon for a minimum of 1 hour prior to cleaning.
Liquid waste (culture & medium - volumes < 5l) is disinfected by the addition of Virkon to give a 1% using Virkon at either 2% or 3% for buffered solutions (i.e. culture media) A minimum contact time of 1 hour is allowed prior to disposal to sewers.

Validation

Autoclaving

The discard autoclave is subject to regular three monthly service and annual validation. Records of service and validation are kept on site.

Disinfectant

For the modified bacteria, Lentivirus/retrovirus/adenovirus, Virkon is routinely used according to the manufactureres (Antek) guidelines. Antek report a 4 log kill for retrovirus at a dilution of 1:2000 i.e. 0.05% after 30 minutes. Our protocols require 2% & 1% Virkon which is excess of the validation concentration.

For bacterial systems we have carried out in-house tests and have shown that Virkon will provide effective kill at a concentration of 1% after 10 minutes contact time. We routinely allow a minimum contact time of 1 hour to ensure complete inactivation.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The GMSC assessed the project as GM Class 2.
The following points were highlighted.
The production of virus to be carried out in a dedicated virus containment room.
The recovery of viral particles/DNA by ultracentrifugation would involve the use of sharps. Only suitably trained and experienced persons allowed to carry out this specific procedure.

**Project Additional Information**

**Purposes of the contained use**

shRNA technology will be used to reduce the expression of genes of interest in primary murine haemopoietic cells and murine and human haemopoietic cell lines. Lentiviral vectors will be used to deliver the sequences of interest. Targets will be identified through proteomic assessment of proteins involved in stem cell biology and oncogenic transformation of haemopoietic cell lines. An example of such a target is the protein FMIP which is involved in M-CSF signalling.

**Recipient or parental organism**

Lentivirus parental organism - Human Immunodeficiency virus 1 (HIV-1) is classified as ACDP hazard group 3.

**Host/vector system**

Bacterial host - Escherichia coli k-12 derivatives (e.g DH5-alpha).
Plasmid vector - pSuper and Bluescript (Strategene) or similar based vectors which are Bom-,Mob- and Tra-
**Viral vectors** - Recombinant Lentiviral vectors pseudotyped with VSV-G envelopes will be used in 293T cells.

**Origin & function**

Origins - genes of interest will arise from studies in primary murine haemopoietic cells and murine and human haemopoietic cell lines.

Genes of interest will be identified using proteomic analysis of stem cell differentiation and the process of transformation by leukaemic oncogenes. Protein profiles will be obtained by Mass Spec analysis of differentiating cells and the consequences of leukaemic oncogene expression on the proteome will be assessed. This will enable the identification of proteins that change during these processes. shRNAi will then be designed to target these genes.

An example of such a target is the protein FMIP which is involved in M-CSF signalling.

It is not intended to target known tumour suppressor genes or genes that could be inferred as such.

The project will be reviewed on a six or twelve month basis, in this regard: the exact frequency being dependent on the progress of this work.

**Evaluation of foreseeable effects**

The recombinant viral vectors are highly disabled vectors based on the HIV lentivirus. These self inactivating vectors have had regulatory and accessory genes deleted ensuring that viral particles produced in the packaging cells are replication incompetent. Thus whilst they pose an infection risk to humans and other species, they are unable to initiate further rounds of replication/infection cycles. The chances of seroconversion are minimal.

Whilst the VSV-G envelope extends the cellular tropism and confers greater stability and environmental survivability it is thought there is NO significant increase of the likelihood of transfection via airborne routes of exposure. Besides the control measures identified are appropriate to guard against the associated risks.

The target genes do not encode viral specific proteins, nor do they interfere with the known activities of the virus and as such are unlikely to have any effect upon the basic nature of the recombinant lentivirus.

However since they are oncogenic by ACGM definition the appropriate containment level to be used is CL2.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

No animals will be used in this project.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

- Solid waste materials (e.g. gloves, plastic ware, agar plates, cell pellets are rendered inactive by autoclaving and are subsequently incinerated along with clinical waste.
- Surfaces are disinfected with 1% Virkon solution.
- Plastic ware that can be effectively disinfected is treated with 1% Virkon solution for a minimum of 1 hour prior to incineration.
- Glassware is treated with 1% Virkon for a minimum 1 hour before cleaning.
- Liquid waste (culture & medium - volumes <5l) is disinfected by the addition of Virkon to give a 1% using Virkon at either 2% or 3% for buffered solutions (i.e. culture media). A minimum contact time of 1 hour is allowed prior to disposal to sewers.

**Validation**

**Autoclaving**

The discard autoclave is subject to regular three monthly service and annual validation. Records of service and validation are kept on site.
Disinfectant
For the modified bacteria, and Lentivirus, Virkon is routinely used according to the manufacturers (Antek)

The GMSC assessed the project as GM Class2.
The following points were highlighted

- The recovery of viral particles/DNA by ultracentrifugation should not involve the use of sharps.
- The project needs to be reviewed on a 6 or 12 monthly basis, depending on the progress of the work, in the context of reviewing any genes of interest which may be of uncertain function, in case this affects the risk assessment in any way (e.g. unknown tumour suppressor genes)
- It was confirmed that the expression of shRNA may block normal self renewal and differentiation. It may also lead to the induction of cell death.

Please enter comments on the GM safety committee on the risk assessment

The project contains...
Retroviral vector systems will be used to transfect well-studied cell lines either transiently or to establish stable cell lines. The project hopes to elucidate further, the role of Rho GTPases in tumourgenesis.

pLZRS is derived from the Moloney murine leukaemia virus (MMLV); the env pol sequences being replaced by the LacZ gene; which in turn was replaced with a multiple cloning site, followed by an internal ribosomal entry sequence (IRES) and either neomycin or zeocin resistance gene.

The vectors used are disabled vectors based on the Moloney murine leukaemia virus. They are used in conjunction with eco or amphotrophic versions of the Phoenix cell line. The systems used are designed such that viral particles produced in the packaging cell lines are replication incompetent. Thus whilst they pose an infection risk they are unable to initiate further rounds of replication. The chances of seroconversion is minimal.

From a functional perspective RAS is a "worst case scenario" being a known oncogene. Other oncogenes will also be used.

The target genes do not encode viral specific proteins, nor do they interfere with the known activities of the virus and as such are unlikely to have any effect upon the basic nature of the recombinant virus.

However since some of the target genes are oncogenic the appropriate containment level to be used is CL2.
Solid waste materials (e.g. gloves, plastic ware, agar plates, cell pellets) are rendered inactive by autoclaving and are subsequently incinerated along with clinical waste. Surfaces are disinfected with 1% Virkon solution. Plastic ware that can be effectively disinfected is treated with 1% Virkon solution for a minimum of 1 hour prior to incineration. Glassware is treated with 1% Virkon for a minimum of 1 hour prior to cleaning.

Liquid waste (culture and medium-volumes <5L) is disinfected by the addition of Virkon to give 1% using Virkon at either 2% or 3% for buffered solutions (i.e. culture medium). A minimum contact time of 1 hour is allowed prior to disposal via sewers.

Autoclave validation-the discard autoclave is subject to annual validation. Records of service and validation are kept on site.

02/03/2022
We have identified a number of genes that are overexpressed in childhood leukaemias. One of these, a cathepsin, appears to be involved in B-cell differentiation and may be involved in cell adhesion and/or migration. We propose to study this by (i) transducing human leukaemic cell lines with lentiviral vectors (either expression or RNAi) (ii) transducing human haematopoietic cells obtained from cord blood. We hope to show that overexpression of the protein leads to an invasive phenotype in leukaemic cell lines and altered development in HSC’s.

Recipient or parental organism
Lentivirus parental organism - Human immunodeficiency virus-1 (HIV-1) is classified as ACDP hazard group 3.

Host/vector system
Bacterial host - BL21 (DE3)pLysS
Plasmid vector - Bluescript plasmids (Stratagene)
Viral vectors - A minimum of a 3-plasmid system will be used. A SIN-lentivector with a pseudotyped VSV-G capsule will be derived using 293T packaging cells.

Origin & function
Origins - gene of interest - The cathepsin, asparaginyl endopeptidase (AEP).
This is expressed at various levels during the normal maturation of a lymphoblast and is not oncogenic.
The cDNA has been cloned from a human cDNA pool and will be expressed in both its active and inactive forms and shRNA will be synthesised prior to insertion.
**Evaluation of foreseeable effects**

The recombinant viral vectors are highly disabled vectors based on the HIV-1 lentivirus. These self inactivating vectors have had regulatory and accessory genes deleted ensuring viral particles produced in the packaging cells are replication incompetent. Thus whilst they pose an infection risk they are unable to initiate further rounds of replication / infection cycles. The probability of seroconversion is minimal. The VSV-G envelope extends the cellular tropism and confers greater stability and environmental survivability. It is thought that there is NO significant increase in the likelihood of transfection via the airborne route of exposure. The control measures utilised are appropriate to guard against this eventuality and associated risks. The target gene does not encode viral specific protein, nor does it interfere with known activities of the virus and so is unlikely to have any effect upon the basic nature of the recombinant lentivirus.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Please enter comments on the GM safety committee on the risk assessment
The GMSC assessed the project as GM Class 2.

It was noted that there is considerable experience of using such lentiviral vector systems are already in the Institute. The project needs to be reviewed within 12 months, depending on the progress of the work, to ensure that the risk assessment remains valid.

Responsibility as defined in legislation lies with the Head of of research group. They have managerial control and responsibility for ensuring suitable and sufficient risk assessments are undertaken and that work is conducted in accordance with Institute Codes of Practice, which have been drawn up to ensure compliance with HSE guidance.

**Project Additional Information**
We wish to investigate the roles of non-cancer cells within tumour. It is already known that these non-carcinoma cells promote tumour growth. We intend to culture the non-cancer cells and modify expression levels of particular candidate genes using lentiviral siRNA and retroviral cDNA expression vectors. This technology will help us elucidate molecular mechanisms by which the non-carcinoma cells promote tumour growth.

Recipient or parental organism

Lentivirus parental organism- Human Immunodeficiency virus-i (HIV-1) is classified as ACDP hazard group 3 Moloney Murine Sarcoma virus (MMSV) parental organism - hazard group I. Causal agent of sarcoma in mice and rats.

Host/vector system

Bacterial host- E. Coli- XL1O Gold, Stbl3, and DH5 alpha.

VECTORS: PLKO1 siRNA lentiviral vector; pWPI lentiviral cDNA expression vector; pHAGE-CMV-eGFP lentiviral expression vector; PBabe retroviral cDNA expression vectors (puro! Neo!Hygro!Zeomycin); pWZL Blast retroviral cDNA expression vector. Retroviral expression vectors MSCV IRES GFP; pLV-rTRIKRAB-red; iDuetl 01 (tetEF. GFP. PGK. hygro) - MI NON-mobilisable. Viral vectors/ Host systems- SEE ADDITIONAL SHEET.

Origin & function

Genes of interest are: Human SDF-1/CXCL12 cDNA; human CXCR4 cDNA; human CXCR7 cDNA; humanTGF-beta cDNA; human EphB2 cDNA; human p16INK4A cDNA.

The first 4 genes and their gene products play a role in tumour progression and proliferation. EphB2 and p16INK4 play a role in the regulation of cell positioning and proliferation.

More detailed functional information for the above are given in appendix 2 of the risk assessment.

Evaluation of foreseeable effects

The recombinant lentiviral vector utilised is a highly disabled vector based on HIV. It is a self inactivating vector which has had regulatory and accessory genes deleted ensuring that viral particles produced in the packaging cells ( HEK 293T) are replication incompetent. Thus whilst they pose an infection risk; in that they can integrate in to the chromosome, they are unable to pop-out and initiate further rounds of replication/ infection cycles. The probability of seroconversion is thought to be minimal.

Whilst the VSG envelope extends the cellular iropism and confers greater environmental survivability, it is thought that there is no increase in the likehood of transfection via the airborne route of exposure. Besides, the control measures utilised for this work are appropriate to guard against the associated risks.

It is worthy of note that the HIV specific envelope protein that targets CD4 T cells is exchanged for the ubiquitous VSV-g (Vesicular stomatis virus C protein), which makes it more visible to the immune system.

The target genes do not encode viral specific proteins, nor are they likely to interfere with known activities of the virus and so are unlikley to have any effect upon the baisc nature of the recombinant lentivirus.

Likewise the recombinant Moloney reirovirus used ( MMSV) is similarly disabled and is replication incompetent. MMSV is thought to be fragile and has poor environmental survivability capabilities. Again workplace precautions and controls will minimise the likehood of risk to human health and the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste materilas ( e.g. gloves, plastic ware, cell pellets etc) are rendered inactive by autoclaving (100% kill) in a validated machine located in the same building. Subsequently the solid waste enters the clinical waste route and goes for incinercation.
Virkon is routinely used as per the manufacturer’s recommendations: Solid surfaces are disinfected with 1% Virkon solution.
Plastic ware that can be effectively disinfected is treated with 1% Virkon for a minimum of 1 hour prior to incineration. Any contaminated glassware is treated with 1% Virkon solution for a minimum of 1 hour prior to cleaning.
Liquid waste (culture and medium) is disinfected by the addition of Virkon to give a 1% final working concentration. 2% or 3% solutions of Virkon are used for buffered solutions. A minimal contact time of 1 hour is allowed prior to disposal to sewers. (as per manufacturer’s recommendations).
The autoclave undergoes annual validation. Records are kept on site.

**Project notified under transitional arrangements** No
Microarray experiments previously performed have identified a number of candidate genes that may be critical regulators of normal haematopoietic and/or leukaemia stem cells (LSC5). This project seeks to evaluate the role of these genes in these cell types in murine and human model systems using genetic knockdown experiments. Briefly, murine or human bone marrow cells will be transduced using lentiviral vectors containing shRNAs and cells will then be functionally evaluated using a combination of in vitro and in vivo techniques, the latter involving transplantation of cells into mice. Three lentiviral vector systems will be used: (i) pLB, which provides constitutive expression of shRNAs from a Pol III promoter, (ii) pSicoR, which provides constitutive expression of shRNAs from a Pol II promoter with the option of irreversible Cre-mediated conditional inactivation of knockdown, and (iii) pSLIK, which provides the option of inducible knockdown from a tetracycline-responsive promoter.

**Recipient or parental organism**

Lentiviral parental organism- Human Immunodeficiency virus-i (HIV-i) is classified as ACDP hazard group 3

**Host/vector system**

Bacteria host:
- E. coli Stbl3 (for generating lentiviral system plasmid)
- E. coli DH5alpha (for all other plasmids)

Lentiviral vector systems:
- pLB- see appendix 1 risk assessment
- pSicoR- see appendix 1 risk assessment
- pSLIK- see appendix 3 risk assessment

Used with 293 FT cells

**Origin & function**

Origins- genes of interest- Human

Microarray experiments have identified the genes of interest as candidates for regulation of normal haematopoietic and/or leukaemia stem cells (LSC5).

These include:
- Bbx- an HMG-box transcription factor of unknown function
- Bmprl- a TGFβ family receptor
- Transcription factors- Myb; E2f6; Mycn
- Cell cycle regulatory proteins Cdk1,2 and 6
- RNA binding protein- Igf2bp3
- Chromatin regulatory proteins- Arid2; Cbx 5; Hmgb3; Smarc2 and 5
The recombinant viral vector vectors are highly disabled vectors based on the HIV lentivirus. They are self inactivating vectors, which have had regulatory and accessory genes deleted, ensuring that viral particles produced in packaging cell lines are replication incompetent. Thus whilst they pose an infection risk they are unable to initiate further rounds of replication/infection cycles. The probability of seroconversion is minimal (Details of the origins and deletions within the lentiviral constructs are given in appendix 1 and 3 of the risk assessment).

Whilst the VSV-G envelope extends the cellular tropism and confers greater stability and environmental survivability, it is thought there is NO significant increase in the likelihood of transfection via the airborne route of exposure. Control measures utilised are appropriate to guard against the associated risks. The target genes do not encode viral specific protein, nor do they interfere with known activities of the virus and so are unlikely to have any effect upon the basic nature of the recombinant lentivirus.

Knock-down of some of the target genes which are cell cycle inhibitors or tumour suppressors may accentuate oncogenesis. Whilst knock-down of others, which are potential oncogenes, may inhibit oncogenesis.

The target genes do not encode viral specific protein, nor do they interfere with known activities of the virus and so are unlikely to have any effect upon the basic nature of the recombinant lentivirus.

Knock-down of some of the target genes which are cell cycle inhibitors or tumour suppressors may accentuate oncogenesis. Whilst knock-down of others, which are potential oncogenes, may inhibit oncogenesis.

The VSV-G envelope confers greater stability and environmental survivability, control measures employed will minimise risks to the environment. These control measures include rendering all solid or liquid waste inactive within the building (either by autoclaving or use of Virkon); work carried out in containment 2 laboratories or Home office inspected animal facilities; work within Class2 microbiological safety cabinets, routine disinfection of work surfaces; all staff are suitably trained in GM work and employing the necessary risk control measures.

Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Whilst no transgenic mice are generated in this project; transduced cells will be transplanted in to C571 BL6 mice by intravenous injection. This procedure will be carried out by specifically trained staff only. The Biological Resource unit (BRU) houses all mice in sealed individually ventilated cages. All handling is within cabinets. The rooms are secured with sealed drains and close sealed doors. There are no open ducts within the room. Corridors are sealed with electronically locking flush fitting doors. All corridor risers are sealed. The unit is inspected regularly by Home Office inspectors to ensure that it meets the required standards.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste materials (e.g. gloves, plastic ware, cell pellets etc) are rendered inactive by autoclaving (100% kill) in a validated machine located within the same building. Subsequently the solid waste enters the yellow bag clinical waste route and goes for incineration. The autoclave is performance validated by 12-point thermocouple tests on an annual basis. Records are kept on site.

Virkon is routinely used as per the manufacturer’s recommendations: Solid surfaces are disinfected with 1% Virkon solution. Plastic ware that can be effectively disinfected is treated with 1% Virkon for a minimum of 1 hour prior to incineration. Any contaminated glassware is treated with 1% Virkon solution for a minimum of 1 hour prior to cleaning. Liquid waste (culture and medium) is disinfected by the addition of Virkon to give a 1% final working concentration. 2% or 3% solutions of Virkon are used for buffered solutions. A minimal contact time of 1 hour is allowed prior to disposal to sewers (as per manufacturer’s recommendation).

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y
A query as to the risk to workers from any free virus whilst administering transduced cells to mice was raised. This is answered in appendix 8 of the risk assessment.

The need to refer workers to the Institute GM Code of Practice and the local Virus room Code of Practice was raised. This was subsequently inserted in to section 7 vi and section 9.2 of the risk assessment.

The GMSC agreed that it was a GM Class 2 project.

# Purposes of the contained use

The project aims to investigate the biology of human leukaemia stem cells (LSCs) using a xenogeneic murine model system. Briefly, leukaemia is experimentally initiated in mice by infecting primary human bone marrow cells with retroviruses which carry oncogenes that are associated with human leukaemia. The transduced bone marrow cells are then transplanted in to irradiated recipient immune deficient mice.

## Recipient or parental organism

Murine Stem Cell Virus (MSCV) viral vector system was derived from the Murine Embryonic Stem Cell Virus (MESV) and the LN retroviral vectors (first described in Hawley et al., (1992) Journal of Experimental Medicine 176:1149). The vectors achieve stable, high-level gene expression in hematopoietic and embryonic stem cells through a specifically designed 5' long terminal repeat (LTR). This LW is from the murine stem cell PCMV virus, and it differs from the M0MuLV LTR used in other retroviral vectors by several point mutations and a deletion. These changes enhance transcriptional activation and prevent transcriptional suppression in embryonic stem and embryonal carcinoma cells. As a result, the LTR drives high-level constitutive expression of a target gene in stem cells.

## Evaluation of foreseeable effects

The recombinant viral vectors are disabled vectors. They have had regulatory and accessory genes deleted, ensuring that viral particles produced in packaging cell lines are replication incompetent. Thus whilst they pose an infection risk they are unable to initiate further rounds of replication! infection cycles. The probability of seroconversion is minimal. (Details of the origins and deletions within the MSCV constructs are given in appendix 1 of the risk assessment). Whilst the VSV-G envelope extends the cellular tropism and confers greater stability and environmental survivability, it is thought there is NO significant increase in the likelihood of transfection via the airborne route of exposure. Control measures utilised are appropriate to guard against the associated risks.

The target genes do not encode viral specific protein, nor do they interfere with known activities of the virus and so are unlikely to have any effect upon the basic nature of the virus. Whilst the VSV-G envelope confers greater stability and environmental survivability, control measures employed will minimise risks to the environment. These control measures include rendering all solid or liquid waste inactive within the building (either by autoclaving or use of Virkon); work carried out in containment 2 laboratories or Home office inspected animal facilities; work within Class2 microbiological safety cabinets, routine disinfection of work surfaces; all staff are suitably trained in GM work and employing the necessary risk control measures.

## Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Transduced cells will be transplanted in to immune deficient mice by intravenous injection. This procedure will be carried out by specifically trained staff only. The Biological Resource unit (BRU) houses all mice in sealed individually ventilated cages. All handling is within cabinets. The rooms are secured with sealed drains and close sealed doors. There are no open ducts within the room. Corridors are sealed with electronically locking flush filling doors. All corridor risers are sealed. The unit is inspected regularly by Home Office inspectors to ensure that it meets the required standards.

02/03/2022
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste materials (e.g. gloves, plastic ware, cell pellets etc) are rendered inactive by autoclaving (100% kill) in a validated machine located within the same building. Subsequently the solid waste enters the yellow bag clinical waste route and goes for incineration. The autoclave is performance validated by 12-point thermocouple tests on an annual basis. Records are kept on site.

Virkon is routinely used as per the manufacturer’s recommendations: Solid surfaces are disinfected with 1% Virkon solution. Plastic ware that can be effectively disinfected is treated with 1% Virkon for a minimum of 1 hour prior to incineration. Any contaminated glassware is treated with 1% Virkon solution for a minimum of 1 hour prior to cleaning.

Liquid waste (culture and medium) is disinfected by the addition of Viricon to give a 1% final working concentration. 2% or 3% solutions of Viricon are used for buffered solutions. A minimal contact time of 1 hour is allowed prior to disposal to sewers (as per manufacturer’s recommendation).

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

A query as to the risk to workers from any free virus whilst administering transduced cells to mice was raised. This is answered in appendix 5 of the risk assessment.

The need to refer workers to the Institute GM Code of Practice and the local Virus room Code of Practice was raised. This was subsequently inserted in to appendix 6 of the risk assessment.

The GMSC agreed that it was a GM Class 2 project.

Project Ref 141/08.3
### Project Additional Information

**Purposes of the contained use**

Recombinant Lentiviruses will be used to express genes involved in stress signalling pathways in primary mouse cells and mammalian cell lines. The gene products may be involved in signal transduction eg p3BMAPK and JNK, or downstream target genes eg the dusp family of dual-specificity phosphatases. We will not use Lentiviruses to express genes that we could reasonably predict to have potentially harmful effects in humans eg oncogenes and pro-inflammatory cytokines.

The transduced primary mouse cells will be transplanted into mice and investigated in in vitro systems. Mouse, mouse primary cells and mammalian cell line responses to environmental stresses (e.g. chemotherapeutic agents) will be evaluated.

**Recipient or parental organism**

Lentiviral parental organism- Human Immunodeficiency virus-I (HIV-1) is classified as ACDP hazard groups

**Host/vector system**

Lentiviral vector System:
- pCMV-VSVG
- pMDL9/RRE
- pRSV-REV
- pRRL

Host : HEK 293 cells

**Origin & function**

- **Historical Significant Changes**: Transferred to GM541

### Project Additional Information

**Purposes of the contained use**

Previous studies, such as microarrays, have identified a number of candidate genes that may be critical regulators of normal haematopoietic cells development. This project seeks to evaluate the role of these genes in murine model systems using genetic knockdown of forced expression experiments. Briefly, murine cell populations will...
be transduced using lentiviral vector, retroviral vectors or transfected with normal plasmids containing shRNAs or the cDNA of the gene of interest. The cells will then be functionally evaluated using a combination of in vitro and in vivo techniques, the latter involving transplantation of cells in to mice.

**Recipient or parental organism**

- Lentivirus parental organism- Human Immunodeficiency virus-1 (HIV-1 is classified as ACDP hazard group 3
- Murine stem Cell Virus- derived from the Murine Embryonic Stem Cell Virus (MESV) and the LN retroviral vectors (first described in Hawley et al, (1992) Journal of experimental medicine 176:1149

**Host/vector system**

- Recombinant lentiviral vectors pseudotyped with VSV-G envelopes, will be used with 293T cells
- MSCV used with Phoenix A and Phoenix GP cells

**Origin & function**

Candidate regulator genes for normal haematopoietic cell development will be obtained in the form of cDNA originating from murine genomic or RNA libraries

**Evaluation of foreseeable effects**

The recombinant viral vectors are disabled vectors. They have had regulatory and accessory genes deleted, ensuring that viral particles produced in packaging cell lines are replication incompetent. Thus whilst they pose an infection risk they are unable to initiate further rounds of replication/infection cycles. The probability of seroconversion is minimal (details of the origins and deletions within the MSCV and lentiviral constructs are given in appendix 1 of the risk assessment).

Whilst the VSV-G envelope extends the cellular tropism and confers greater stability and environmental survivability, it is thought there is NO significant increase in the likelihood of transfection via the airborne route of exposure. Control measures utilised are appropriate to guard against the associated residual risks.

The target genes do not encode viral specific protein, Nor do they interfere with known activities of the virus and so are unlikely to have any effect upon the basic nature of the virus.

Whilst the VSV-G envelope confers greater stability and environmental survivability, control measures employed will minimise risks to the environment. These control measures include rendering all solid or liquid waste inactive within the building (either by autoclaving or use of Virkon) work carried out in containment 2 laboratories or home office inspected animal facilities; work within class2 microbiological safety cabinets, routine disinfection of work surfaces; all staff are suitably trained in GM work and employing the necessary risk control measures.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Solid waste materials (e.g. gloves, plastic ware, cell pellets etc) are rendered inactive by autoclaving (100% kill) in a validated machine located within the same building. Subsequently the solid waste enters the yellow bag clinical waste route and goes for incineration. The autoclave is performance validated by 12-point thermocouple tests on an annual basis. Records are kept on site.

Virkon is routinely used as per the manufacturer’s recommendations –

- Solid surfaces are disinfected with 1% Virkon solution.
- Plastic ware that can be effectively disinfected is treated with 1% Virkon for a minimum of 1 hour prior to incineration.
- Any contaminated glassware is treated with 1% Virkon solution for a minimum of 1 hour prior to cleaning.

Liquid waste (culture and medium) is disinfected by the addition of Virkon to give a 1% final working concentration. 2% or 3% solutions of Virkon are used for buffered solutions. A minimal contact time of 1 hour is allowed prior to disposal to sewers (as per manufacturer’s recommendation).

A query as to the risk to workers from any free virus whilst administering transduced cells to mice was raised. This is answered in appendix 4 of the risk assessment.

The committee agreed it was a GM Class 2 project.

Purposes of the contained use

Viruses have been explored as agents to target cancer either in a gene therapy setting (through the delivery of cytotoxic gene payloads or alike) or as attenuated strains which replicate within tumour cells leading to the subsequent destruction of that cell. The replication competent virus approach is being explored in the clinical setting with a number of different viruses including reovirus and adenoviruses. Whilst attractive, there are a number of potential barriers which the viruses need to efficiently overcome in order to drive tumour destruction including efficient tumour cell targeting, infection and replication. This project seeks to use gene-modified replication competent viruses to investigate whether the approach can be improved in model systems.

Recipient or parental organism

Adenovirus type 5 (Replication Competent): ACDP Hazard Group 2
The actual genetic modification work will be carried out by colleagues in The Netherlands. In this project the already modified virus will be used for in vitro and in vivo (mouse) experiments.
The modification removes the ability for the modified virus to infect via the coxsackie B adenoviral receptor (CAR).
The modification enables the virus to infect cells via the Carcinoembryonic antigen (CEA), which is highly expressed in a number of solid tumours, but only in the luminal side of the gastro intestinal tract of a normal human adult. Thus the tropism of the virus has been affected. This characteristic of the virus targeting CEA is realised by the incorporation of a 58 aa affibody specific for the tumour antigen.
The immunogenicity of the affibody is currently unknown - as such, if immunogenic, it may further drive the immune response against the virus.

Host/vector system

Not applicable - the already modified virus will be supplied by collaborators based in the Netherlands

Origin & function

Gene-modified adenovirus targeted to CEA. The gene modification involves the deletion of amino-acids within the fibre domain which disrupts the normal infective route of the virus (through CAR) and incorporates an affibody for targeting. An affibody is effectively a very small antibody type domain that is small enough to permit efficient expression on the adenoviral fibre without significantly reducing viral titre. Viruses directed to the Her2/neu antigen have been described (Myhre S et al. (2009) Gene Therapy 16:252-261). In effect, these modifications of the virus re-direct the virus to target known tumour antigens thereby improving the specificity of targeting of the virus.
Origin of the affibody.

Affibodies have been generated using combinatorial protein approaches - effectively the antigen binding domain was generated from synthesised library cDNA's and tested using a screening approach to bind antigen. The cDNA of the affibody was then cloned into the H1 loop of the adenoviral fibre domain which contains mutations destroying natural CAR binding and then introduced into the Ad5 genome by homologous recombination replacing the endogenous Ad5 wild-type fiber. The Ad5 genome is then used to generate functional viruses using standard methods.

Evaluation of foreseeable effects

The virus is essentially wild-type but with mutations of the fibre domain which prevents binding to the normal virus receptor (coxsackie adenovirus receptor - CAR) and incorporation of a 58 aa affibody specific for the tumour antigen. Initially, the target antigen used will be Carcinoembryonic antigen (CEA) which is highly expressed on a number of solid tumours but only within the luminal side of the gastro-intestinal tract of the normal human adult. The fibre attenuation prevents the normal route of viral infection and the CEA specificity will result in targeting to CEA expressing cells. These viruses have only recently been generated and part of this proposal is to test the level of specificity of infection driven by the affibody.

The affibody/fibre mutations will modify the range of cell the virus will be able to infect. Normal targeting should be severely reduced and targeting of target antigen cells increased; consequently, this will alter the tropism of the virus. The mutations will otherwise have no major effect upon the individuals except that the immunogenicity of the affibody is currently unknown - as such, if immunogenic, it may further drive the immune response against the virus.

Currently we do not have any information on the shedding of the modified virus during animal experiments. As the virus lacks CAR binding, it is possible that more virus could be shed since there isn't the extensive pool of cells to soak up the virus. However, all work using this virus will be performed in the class 2 containment room within BRU. Waste disposal procedures are stringently adhered to (see section 12).

Further viral modifications may be generated at a later date. But these will be submitted to the local GMSC for consideration.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste material (e.g. gloves, plastic ware, cell pellets etc) are rendered inactive by autoclaving (100% kill) in a validated machine located in the same building. Subsequently the solid waste enters the clinical waste route and goes for incineration.

Virkon is routinely used as per the manufacturer's recommendations:-
Solid surfaces are disinfected with 1% Virkon solution.
Plastic ware that can be effectively disinfected is treated with 1% Virkon for a minimum of 1 hour prior to incineration.
Any contaminated glassware is treated with 1% Virkon solution for a minimum of 1 hour prior to cleaning.
Liquid waste (culture and medium) is disinfected by the addition of Virkon to give a 1% final working concentration.
2% or 3% solutions of Virkon are used for buffered solutions. A minimal contact time of 1 hour is allowed prior to disposal to sewers. (as per manufacturer's recommendations).

The autoclave undergoes annual validation. Records are kept on site.
With regard to the animal work: clarification on viral shedding and treatment of waste bedding was asked for, the information provided was supplied and incorporated in to the risk assessment.

Purposes of the contained use

We wish to study the role of the transcription factor ATF2 in tumour cells. By knocking down the expression of ATF2 in a variety of cell lines, we will assess the contribution ATF2 makes to the transformed phenotype. Knockdown will be achieved using Lentiviral based gene transfer. Genetic modifications include the sub-cloning steps involved in the production of a Lentiviral expression plasmid, co-transfection of this expression vector together with packaging vectors into a host cell line to produce virus, and subsequently, use of Lentiviral stocks to infect target cell lines that will stably express the miRNAi of interest.

Recipient or parental organism

Lentiviral parental organism - Human Immunodeficiency virus-1 (HIV-1) is classified as ACDP hazard group 3

Host/vector system

Bacterial host - E.coli XL1-Blue
Plasmids - all have pUC origin of replication and all are mobilisation defective.

Lentiviral vector system- commercially available BLOCK-it Lentiviral miR RNAi Expression System from Invitrogen.
HEK 293 cells is packaging cell line.
The ’Block-It Lentiviral miR RNAi expression system’ (Invitrogen cat no K4937-00) is a four plasmid virus production system and consists of:

pLenti6/V5 DEST - packaging vector into which the target sequence of interest is sub-cloned.
pLP1 - encodes Gag (viral structural protein) and Pol (viral replication protein).
pLP2 - encodes Rev (viral transcription factor)
pLP/VSVG - encodes the VSV-G glycoprotein for production of pseudotyped virus.

Target cells for viral vector are:- Ramos, Raji, Nmalwa, SudHL4, CRL 2261

Origin & function

ATF2 - Human - both tumour suppressing and tumour promoting phenotypes have been described for ATF2 gene. It functions as a transcription factor.

Evaluation of foreseeable effects

The recombinant viral vectors are highly disabled vectors based on the HIV lentivirus. They are self inactivating vectors, which have had regulatory and accessory genes deleted, ensuring that viral particles produce in packaging cell lines are replication incompetent. This whilst they pose an infection risk they are unable to initiate further rounds of replication/infection cycles. The probability of seroconversion is minimal.

Whilst the VSV-G envelope extends the cellular tropism and confers greater stability and environmental survivability, it is thought there is NO significant increase in the likelihood of transfection via the airborne route of exposure. Control measures utilised are appropriate to guard against the associated risks.

The target gene does not encode viral specific protein, nor do they interfere with known activities of the virus and so are unlikely to have any effect upon the basic nature of the recombinant lentivirus.

Whilst the VSV-G envelope confers greater stability and environmental survivability, control measures employed will minimise risks to the environment. These control
measures include rendering all solid or liquid waste inactive within the building (either by autoclaving or use of Virkon); work carried out in containment 2 laboratories or Home office inspected animal facilities; work within Class 2 microbiological safety cabinets, routine disinfection of work surfaces; all staff are suitably trained in GM work and employing the necessary risk control measures.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Animal work will be carried out by trained staff only. Intravenous injection of cell line satably expressing miRNA of interest only. NO live virus will be injected in to mice, therefore shedding of virus is not an issue.

The Biological Resource unit (BRU) houses all mice in sealed individually ventilated cages. All handling is within cabinets. The rooms are secured with sealed drains and close sealed doors. There are no open ducts within the room. Corridors are sealed with electronically locking flush fitting doors. All corridor risers are sealed. The unit is inspected regularly by Home Office inspectors to ensure that it meets the required standards.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Solid waste materials (e.g. gloves, plastic ware, cell pellets etc) are rendered inactive by autoclaving (100% kill) in a validated machine located within the same building. Subsequently the solid waste enters the yellow bag clinical waste route and goes for incineration. The autoclave is performance validated by 12-pont thermocouple tests on an annual basis. Records are kept on site.

Virkon is routinely used as per the manufacturer's recommendations:-
Solid surfaces are disinfected with 1% Virkon solution.
Plastic ware that can be effectively disinfected is treated with 1% Virkon for a minimum of 1 hour prior to incineration. Any contaminated glassware is treated with 1% Virkon solution for a minimum of 1 hour prior to cleaning.

Liquid waste (culture and medium) is disinfected by the addition of Virkon to give a 1% final working concentration. 2% or 3% solutions of Virkon are used for buffered solutions. A minimum contact time of 1 hour is allowed prior to disposal to sewers (as per manufacturers recommendation).

Dead mice carcasses are disposed of via the clinical waste route.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

Please enter comments on the GM safety committee on the risk assessment

Since the project employs a lentiviral system with a gene that shows both tumour promoting and suppressor activities it was thought GM Class 2 was appropriate and this agreed with the applicants classification.

**Project Containment**

02/03/2022
# Project Ref

**141/10.1**

## Purposes of the contained use

Human tumours are frequently found to contain activating mutations in the ras family of oncogenes. Expression of oncogenic ras in cells leads to aberrant signalling and acute activation of the AP-1 family of transcription factors. We wish to study the signalling events occurring downstream of oncogenic ras and subsequent changes in gene expression with a particular focus on ATF2-dependent gene expression. To do this we need to differentiate between events occurring early (within a few hours), after ras expression, and those occurring later (several days). This will be achieved by generating high-titre recombinant adenoviruses that express oncogenic ras. This allows the synchronous infection of all the cells in a sample followed by a rapid onset of ras gene expression (within 8 hours). Given the hazardous nature of the ras oncogene we are proposing to undertake and emplou a range of control measures, as detailed in the risk assessment.

## Recipient or parental organism

**Adenovirus:** ACDP Hazard Group 2
**Host/vector system**

Bacterial Host; E. coli X-l1 or DH5alpha

Vector systems: pCDNA series, pBluescript, pUC, pAxwit2 (TaKaRa), pAxCAwtit (TaKaRa)

Viral System: Adenovirus/Hek293 cells

Target cells: Human and murine fibroblasts and hepatoblasts, A549 and HeLa

**Origin & function**

Human cDNA encoding HRasG12V, KRasG12V. These are oncogenes frequently found to be mutated in human cancers. Their expression causes constitutive activation of MAPK and P13K signalling pathways and acute activation of the AP-1 family of transcription factors. We will carry out experiments intended to gain a better understanding of their role in tumourigenesis of interest and these cause aberrant expression and acute activation of the AP-1 family of transcription factors.

**Flp recombinase. Required to initiate a recombination event to remove the STOP cassette and allow expression of ras in cells co-infected with recombinant ras-Adenovirus**

**Evaluation of foreseeable effects**

The recombinant Adenovirus lacks the E1 region and so is replication-incompetent. However, it is possible that an adverse recombination event occurring within the 293 packaging line, (or theoretically in human tissues, since adenovirus is ubiquitous in humans), could lead to generation of a recombination-competent virus (RCV). We plan to use a well characterised PCR-based assay to screen our virus stocks for RCV (indicated by the presence of the E1a gene). We will carry out this test each time we expand the virus. Furthermore we will check our stocks by infection of either HeLa or A549 cells which do not contain the E1 region. Only if RCV is present will this lead to cytopathic effects in the infected cells.

The recombinant Adenovirus possesses a STOP cassette located upstream of ras which essentially prevents its expression. Gene expression requires removal of the STOP cassette by a recombination event mediated by Flp recombinase. Flp will be expressed by means of a second recombinant adenovirus. Therefore, ras gene expression only occurs if both the ras-expressing virus and the Flp-expressing virus co-infect the same cell. This will significantly reduce the risk of workers accidentally expressing oncogenic ras in their own tissues. We will undertake not to handle open tubes of the ras-expressing and the Flp-expressing virus stocks at the same time.

Stringent disinfection regimes are applied in the laboratory along with autoclaving of all solid contaminated waste. The use of biosafe rotors and microbiological safety cabinets are also employed to protect human health and the environment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste materials (e.g. gloves, plastic ware, cell pellets etc) are rendered inactive by autoclaving (100% kill) in a validated machine located in the same building. Subsequently the solid waste enters the clinical waste route and goes for incineration. The autoclave has an integral "pass" or "fail " alert for each cycle processed in the machine. This is displayed on the autoclave at the end of each cycle and this is monitored by the end-user.

Virkon is routinely used as per the manufacturers recommendations:-

Solid surfaces are disinfected with 1% Virkon solution

Plastic ware that can be effectively disinfected is treated with 1% Virkon for a minimum of 1 hour prior to incineration. Any contaminated glassware is treated with 1%
Virkon solution for a minimum of 1 hour prior to cleaning. Usually the contact time is longer, typically overnight. Liquid waste (culture medium) is disinfected by the addition of Virkon to give a 1% final working concentration. 2% or 3% solutions of Virkon are used for buffered solutions. A minimal contact time of 1 hour is allowed prior to disposal to sewers. (as per manufacturer's recommendations).

The autoclave undergoes annual validation by a third party. Records are kept on site.

**Project Additional Information**

**Purposes of the contained use**

5T4 and related molecules will be introduced or knocked down in cell lines to investigate their biological functions. These goals will be achieved with the use of lentiviral vectors which are able to infect dividing and non-dividing cells and stably integrate into their genome. The vectors will encode the desired genes under constitutive or inducible promoters. Gene knock down will be achieved by the use of vectors encoding for shRNA against target genes. The system for lentiviral vector production is available from Invitrogen. The system utilises SIN (self inactivating) vectors which have had regulatory and accessory genes deleted to ensure that viral particles produced in packaging cell lines are replication incompetent.

**Recipient or parental organism**

Lentiviral parental organism- Human Immunodeficiency virus-1 (HIV-1) is classified as ACDP hazard group 3.

**Host/vector system**

Bacterial: E. coli One Shot Stbl3
Plasmids: pLP, pcDNA, pLenti, pENTR, pDONR, pMDLg/pRRE, pRSV-Rev and pMDg.2 plasmid vectors for packaging of lentiviral particles.

**Origin & function**

Human and mouse 5T4 coding sequence cloned from cDNA of respective species and is deposited in NCBI database. The sequences of other 5T4 related genes will be cloned from cDNA obtained from human or mouse cell lines. siRNA sequences targeting genes of interest will be designed and/or purchased from Invitrogen. Fluorescent protein genes are commercially available. High expression of 5T4 is very strongly expressed in normal placental trophoblast. We therefore believe 5T4 is “Oncogenic by ACGM definition” and this is highlighted in the risk. Assessment (section 7 (iv))

**Evaluation of foreseeable effects**

The recombinant viral vectors are highly disabled vectors based on the HIV lentivirus. These self inactivating vectors have had regulatory and accessory genes deleted ensuring that viral particles produced in the packaging cells are replication incompetent. Thus whilst they pose an infection risk they are unable to initiate further rounds of replication/infection cycles. The probability of seroconversion is minimal.

Whilst the VSV-G envelope extends the cellular topism and confers greater stability and environmental survivability it is though that there is NO significant increase in the likelihood of transfection via the airborne route of exposure. Besides, the control measures utilised are appropriate to guard against the associated risks.

The target gene does not encode viral specific protein, nor does it interfere with known activities of the virus and so is unlikely to have any effect upon the basic nature of the recombinant lentivirus.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste materials (e.g. gloves, plastic ware, cell pellets etc) are rendered inactive by autoclaving (100% kill) in a validated machine located in the same building. Subsequently the solid waste enters the clinical waste route and goes for incineration.

Virkon is routinely used as per the manufacturer's recommendations:-
Solid surfaces are disinfected with 1% Virkon solution.
Plastic ware that can be effectively disinfected is treated with 1% Virkon for a minimum of 1 hour prior to incineration. Any contaminated glassware is treated with 1% Virkon solution for a minimum of 1 hour prior to cleaning.

Liquid waste (culture and medium) is disinfected by the addition of Virkon to give a 1% final working concentration. 2% or 3% solutions of Virkon are used for buffered solutions. A minimal contact time of 1 hour is allowed prior to disposal to sewers. (as per manufacturer's recommendations).

The autoclave undergoes annual validation. Records are kept on site

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N

Committee agreed with the GM Class 2 classification of the work.
It asked if 5T4 was expressed in foetal cells. 5T4 is expressed in normal placental trophoblasts although the risk to any pregnant females is considered to be very low, due to the nature of the viral vector system used which generates replication competent viral particles. No pregnant females work on project. This will be kept under review.

Project Additional Information

Purposes of the contained use

We seek to investigate the role of normal and activated fibroblasts in tumour-stromal interactions upon knockdown or overexpression of genes of interest. Fibroblast are known to exert tumour-promotive as well as tumour-suppressive functions depending on cell and expression level context. We intend to co-culture fibroblast cells with breast cancer cell lines and analyse proliferation, migration and molecular markers with Western blot, real-time PCR and Elisa.

Recipient or parental organism

Lentivirus parental organism - Human Immunodeficiency virus (HIV-1) is classified as ACDP hazard group 3.

Retroviral system parental organism - Moloney Murine Leukaemia virus (MMLV)

Host/vector system

Bacterial host: E. coli DH5 alpha and Stbl3

Viral vector/Host system - 3 plasmid based systems will be used

Lentiviral system is a self-inactivating lentivector system with a pseudotyped VSV-G capsule. Viral particles will be produced using HEK 293T packaging cell line.

Retroviral system: pBABE system with packaging plasmids pCMV-VSVG and pUMVC3-gag-pol. Viral particles produced are replication incompetent. System is available
from Adgene. (More detailed descriptions of vector system characteristics are given in Appendix 1 of risk assessment)

Target cell lines for recombinant virus are Fibroblast cell lines 522 and 544 (see Appendix 4 of risk assessment) and breast cancer cell lines (MCF7, T47D, ZR75.1, MDA-MB-231, MDA-MB-468). Other tumour, non-tumour epithelial and stromal cell may be investigated. Amendment and GMSC approval would be sought beforehand.

### Origin & function

Human genes TGF beta receptor2 has suspected tumour promoter and suppressor functions. See appendix 2 of risk assessment for more detail. (Obtained from colleagues in PLKO1 plasmid as a knockdown). Lentiviral vector system will be utilised to generate knockdown versions of this gene; whilst the MSCV retroviral system will be used to over express these genes in the target cells.

Cyclin D1 is a tumour promoter gene (cDNA from Adgene) will be knocked down and over expressed with the same systems as above; within the breast cancer cell lines given in section 4 of the risk assessment.

### Evaluation of foreseeable effects

The recombinant viral vectors are disabled vectors. They have had regulatory and accessory genes deleted, ensuring that viral particles produced in packaging cell lines are replication incompetent. Thus whilst they may pose an infection risk they are unable to initiate further rounds of replication/infection cycles. The probability of seroconversion is minimal.

Whilst the VSV-G envelope extends the cellular tropism and confers greater stability and environmental survivability, it is thought there is no significant increase in the likelihood of transfection via the airborne route of exposure. Besides, control measures utilised are appropriate to guard against the associated risks.

The target genes do not encode viral specific protein, nor do they interfere with known activities of the virus and so are unlikely to have any effect upon the basic nature of the virus.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Solid waste materials (e.g. gloves, plastic ware, cell pellets etc) are rendered inactive by autoclaving (100% kill) in a validated machine located in the same building. Subsequently the solid waste enters the clinical waste route and goes for incineration. The autoclave has an integral "pass" or "fail" alert for each cycle processed in the machine. This is displayed on the autoclave at the end of each cycle and this is monitored by the end-user.

Virkon is routinely used as per manufacturer's recommendations:

- Solid surfaces are disinfected with 1% Virkon solution.
- Plastic ware that can be effectively disinfected is treated with 1% Virkon for a minimum of 1 hour prior to incineration. Any contaminated glassware is treated with 1% Virkon solution for a minimum of 1 hour prior to cleaning. Usually the contact time is longer, typically overnight.
- Liquid waste (culture and medium) is disinfected by the addition of Virkon to give a 1% final working concentration. 2% or 3% solutions of Virkon are used for buffered solutions. A minimal contact time of 1 hour is allowed prior to disposal to sewers. (as per manufacturer's recommendations).

The autoclave undergoes annual validation by a third party company. Records are kept on site.
The committee agreed with the GM Class 2 classification.

# Project Additional Information

## Purposes of the contained use

The work involves the study of Rho proteins (a family of GTPases involved in many cell signalling functions), their regulators and pathway-related genes along with their mutant forms. Frequently we use either overexpression or RNAi knockdown as a method of study. We have identified some important cell lines where lentiviral transduction may be required to get acceptable expression levels either transiently or to produce stable cell lines.

## Recipient or parental organism

Lentivirus parental organism - Human Immunodeficiency virus (HIV-1) is classified as ACDP hazard group 3.

## Host/vector system

- **Bacterial host:** E. coli NEB 10-beta (DH10B derivative) from New England Biolabs
- **Viral vector/Host system:** 3 plasmid based systems will be used from sigma and/or Invitrogen (PLkO.1 and pLenti respectively).

Lentiviral system is a self-inactivating lentivector system with a pseudotyped VSV-G capsule. Viral particles will be produced using HEK 293T packaging cell line.

**Target Cells:** Well established cell lines such as MDCK II (dog) and human cancer cell lines (e.g. breast cancer cell line MDA 231 and osteo-sarcoma cell line HOS and MG63).

## Origin & function

Cloning will typically be subcloning of existing vectors (pcDNA) or if not available from a cDNA library. This will include versions of mammalian species including human, mouse and dog. Target siRNA sequences are designed from existing databases.

## Evaluation of foreseeable effects

The recombinant Lentiviral viral vector systems consist of disabled vectors. They have had HIV regulatory and accessory genes deleted, ensuring that viral particles produced in packaging cell lines are replication incompetent. The systems employed will be Self Inactivating (SIN) vector systems. Thus whilst they may pose an infection risk they are unable to initiate further rounds of replication/infection cycles. The probability of seroconversion is minimal.

Whilst the VSV-G envelope extends the cellular tropism and confers greater stability and environmental survivability, it is thought there is no significant increase in the likelihood of transfection via the airborne route of exposure. Besides, the risk control measures utilised are appropriate to guard against the associated risks. These include the use of safety cabinets, biosafe rotors and prescribed disposal routes for waste, wearing of appropriate PPE and no use of any sharps.

The target genes do not encode viral specific protein, nor do they interfere with known activities of the virus and so are unlikely to have any effect upon the basic nature of the virus.

## Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Solid waste materials (e.g. gloves, plastic ware, cell pellets etc) are rendered inactive by autoclaving (100% kill) in a validated machine located in the same building. Subsequently the solid waste enters the clinical waste route and goes for incineration. The autoclave has an integral "pass" or "fail" alert for each cycle processed in the machine. This is displayed on the autoclave at the end of each cycle and this is monitored by the end-user. The autoclave undergoes annual validation by a third party company. The performance test results generated during validation are kept on site.

Virkon is routinely used as per the manufacturer's recommendations:
- Solid surfaces are disinfected with 1% Virkon solution.
- Plastic ware that can be effectively disinfected is treated with 1% Virkon for a minimum of 1 hour prior to incineration. Any contaminated glassware is treated with 1% Virkon solution for a minimum of 1 hour prior to cleaning. Usually the contact time is longer, typically overnight.
- Liquid waste (culture and medium) is disinfected by the addition of Virkon to give a 1% final working concentration 2% or 3% solutions of Virkon are used for buffered solutions. A minimal contact time of 1 hour is allowed prior to disposal to sewers (as per manufacturer's recommendations).

<td>Constitutive and Inducible Protein Knockdown and Overexpression of Drug Targets</td>
<td>Class 2</td>
<td>&lt; 1 Litre</td>
<td></td>
</tr>
</tbody>
</table>
Novel molecular based therapeutics work by targeting enzymes, such as kinases or substrate transporters. However, these drugs frequently have off-target effects and it is important to know exactly what the mechanism of action of the drug is. To demonstrate that a drug is acting through its main target one can either knock-down the target by RNAi or overexpress a dominant negative version of the protein and show that this produces the same effect as the drug (both approaches are required for convincing proof of on target effects). This also allows for dissection of downstream pathways to ascertain the effectors responsible for drug related changes. The work needs to be carried out in a variety of cell lines and for a variety of targets due to the varied nature of Clinical and Experimental Pharmacology, which not only depends on the results obtained with different drugs but also the availability of drugs which depends on collaborations with pharmaceutical companies. Some of the cell lines we work with, mainly small cell lung cancer cell lines, are impossible to transfect with conventional transfection approaches (e.g. Lipofection or electroporation and therefore a lentiviral based approach has been chosen. As knocking-down/overexpressing some of the targets of interest may prove lethal to the cells ability to carry out inducible knock-down/overexpression is key to this proposal.

**Host/vector system**

**Bacterial Hosts:** E. coli DH5 alpha and ccdB survival 2 (genotypes are given in appendix 2 of the risk assessment).

**Plasmid Vectors:**
- pENTR/pSUPER+; pENTR/pTER+ (used for RNAi delivery in to cell lines expressing target mRNA/protein via lipid based transient transfection).
- pENTR4; pENTR4-FLAG (used for protein expression studies).
- pLenti X1 GFP-Zeo; pLenti X2 Puro; pLenti CMV TetR Blast; pLenti X 2 Puro; Lenti CMV TetR Blast; pLenti CMV Puro; pLenti CMV/TO Puro; pLenti CMV/TO GFP-Zeo; psPAX2; oMD2.G (used for lentiviral particle generation)

**Viral vector system:** HEK293 cells will be used to generate lentivirus particles

The lentivirus vector system is a Self-inactivating (SIN) vector system. Disablement characteristics of the system is given in Appendix 4 of the risk assessment.
### Wild-type and mutated (activating or inactivating mutations) genes of the following proteins

- TDP2, MCT-1, MCT-4, c-Myc, p110alpha, p110beta, AKT1, AKT2, AKT3, PDPK1, K-Ras and other PI3K interacting proteins. Also Bcl-2 family members including Mcl-1, Bcl-2, Bcl-xL, Bax, Bak, Bim, Bid, Bad Puma and Noxa.

The genetic material is mainly human in origin, but some genes may be animal in origin (mainly murine). The genetic material will be in the form of cDNA. The function or suspected functions of these genes are listed in Appendix 3 of the risk assessment. They are also listed below.

#### Biological function of proteins of interest.

**TDP2** - Resolves DNA-topoisomerase adducts induced by topoisomerase poisons such as etoposide. Overexpression may result in resistance to topoisomerase. Unlikely to be oncogenic.

**MCT-1 and MCT-4** - Monocarboxylate transporters. Involved in the influx and efflux of molecules such as lactate from cells. Unlikely to be oncogenic.

**C-Myc** - Transcription factor involved in expression of numerous prosurvival and proliferation genes. Frequently activated in cancer and known to be oncogenic when overexpressed in presence of other mutations which promote cell survival.

**K-Ras** - GTPase known to activate the prosurvival and proliferation signalling pathways PI3K and MAPK. Frequently activated in cancer and oncogenic when activated.

**P110 alpha and beta** - PI3K catalytic subunits which generate secondary messenger PIIP3. Frequently activated in cancer and oncogenic when activated.

**AKT1, 2 and 3** - Main PI3K downstream effector which promotes survival, proliferation and migration. Frequently activated in cancer but not oncogenic by itself.

**PDPK1** - Required for activation of AKT downstream of PI3K signalling. Frequently activated in cancer but not oncogenic by itself.

Other PI3P3 interacting proteins - Biological function not clear but likely to be activated in cancer and could potentially be oncogenic.

**Mcl-1, Bcl-2** - Anti-apoptotic (pro-survival) Bcl-2 family members which inhibit Bax and Bak. Frequently upregulated in cancer but not oncogenic by themselves.

**Bax and Bak** - Pro-apoptotic proteins which cause release of cytochrome C from mitochondria. Frequently downregulated in cancer but require other mutations for their tumour suppressor function to be apparent.

**Bim, Bid, Bad, Puma and Noxa** - Pro-apoptotic BH3 only proteins which inhibit anti-apoptotic Bcl-2 family members and therefore activate Bax and Bak. Frequently downregulated in cancer but require other mutations for their tumour suppressor function to be apparent.

### Evaluation of foreseeable effects

The recombinant Lentiviral viral vector system consists of disabled vectors. They have had HIV regulatory and accessory genes deleted, ensuring that viral particles produced in packaging cell lines are replication incompetent. The system employed is a Self Inactivating (SIN) vector systems. Thus whilst they may pose an infection risk they are unable to initiate further rounds of replication/infection cycles. The probability of seroconversion is minimal.

Whilst the VSV-G envelope extends the cellular tropism and confers greater stability and environmental survivability, it is thought there is no significant increase in the likelihood of transfection via the airborne route of exposure. Besides, the risk control measures utilised are appropriate to guard against the associated risks. These include the use of safety cabinets, biosafe rotors and prescribed disposal routes for waste, wearing of appropriate PPE and no use of any sharps.

The target genes do not encode viral specific protein, nor do they interfere with known activities of the virus and so are unlikely to have any effect upon the basic nature of the virus.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste materials (e.g. gloves, plastic ware, cell pellets etc) are rendered inactive by autoclaving (100% kill) in a validated machine located in the same building. Subsequently the solid waste enters the clinical waste route and goes for incineration. The autoclave has an integral "pass" or "fail" alert for each cycle processed in the machine. This is displayed on the autoclave at the end of each cycle and this is monitored by the end-user. The autoclave undergoes annual validation by a third party company. The performance test results generated during validation are kept on site.

Trigene is routinely used as per the manufacturer's recommendations:
- Solid surfaces are disinfected with 2% Trigene solution.
- Plastic ware that can be effectively disinfected is treated with 10% Trigene for a minimum of 1 hour prior to incineration.
- Any contaminated glassware is treated with 10% Trigene solution for a minimum of 1 hour prior to cleaning. Usually the contact time is longer, typically overnight.
- Liquid waste (culture and medium) is disinfected by the addition of 10% Trigene. A minimal contact time of 1 hour is allowed prior to disposal to sewers. (as per manufacturer's recommendations).

Project Additional Information

Purposes of the contained use
Over-expression or knockdown of kinases to study the role of various kinases in cell lines and patient samples. Genetic modifications include the sub-cloning steps involved in the production of a Lentiviral expression plasmid, co-transfection of this expression vector together with packaging vectors into a host cell line to produce virus, and subsequently, use of Lentiviral stocks to infect target cell lines that will stably express the protein of interest. Downstream analysis of stable cell lines will involve Western blotting, FCAS analysis and microscopy.

Recipient or parental organism
Lentivirus parental organism-Human Immunodeficiency virus (HIV-1) is classified as ACDP hazard group 3

Host/vector system
Bacterial: E.coli Oneshot stbl3; E. coli ccdB survival 2; E.coli TOP10; E.coli Oneshot Omnimax. Bacterial hosts are disabled. Genotypes of bacterial host are given in Appendix 2 of the risk assessment.

Viral vector system: Lentivirus (VSV-G) with 293FT as host. This system is a self-inactivating (SIN) vector system. The system is a 4-plasmid system. Details of the biosafety features of this system are given in appendix 4 of the risk assessment.

Target cells: ATCC catalogue lung cancer cell lines and patient B-cell lines or fibroblasts, HTCC116 DLD-1 colon cancer cell lines and additional catalogue colon and breast cancer cell lines.

The likelihood of the presence of adventitious agents in patient derived cells is considered in Appendix 7 of the risk assessment.
Biological Functions of Proteins of Interest are given below. They are all of human origin.

PKC - Protein kinase C (PKC) is a family of serine- and threonine-specific protein kinases. PKC family members phosphorylate a wide variety of protein targets and are known to be involved in diverse cellular signalling pathways PKC family members also serve as major receptors for phorbol esters, a class of tumor promoters.

MLK4 - MLK4 is a member of the mixed lineage family of kinases activated by environmental stress, cytokines and growth factors. This family of kinases lies upstream of the kinase MKK4 and these kinases are critical regulators of the JNK pathway. In addition MLKs can activate the MKK3/6-p38 pathway and the Raf/Mek/Erk pathway.

FRK - The protein encoded by this gene belongs to the TYR family of protein kinases. This tyrosine kinase is a nuclear protein and may function during G1 and S phase of the cell cycle and suppress growth.

PAK3/7 - Both are Ser/Thr p21 activated kinases that have been described to regulate the Raf-Mek-Erk pathway and play a role in regulating the cell cycle.

Abl 1/2 - Is well studied tyrosine kinase that plays a role in CML and other cancers where the kinase is constitutively activated by a translocation to create a fusion protein BCR-ABL. Activated form can be oncogenic.

Csnk1g2 - This is an undescribed kinase that is in the casein kinase family.

Evaluation of foreseeable effects

The recombinant viral vectors are disabled vectors. They have had regulatory and accessory genes deleted, ensuring that viral particles produced in packaging cell lines are replication incompetent. Thus whilst they may pose an infection risk they are unable to initiate further rounds of replication/infection cycles. The probability of seroconversion is minimal.

While the VSV-G envelope extends the cellular tropism and confers greater stability and environmental survivability, it is thought there is no significant increase in the likelihood of transfection via the airborne route of exposure. Besides, control measures utilised are appropriate to guard against the associated risks. These include the use of Class II safety cabinets, disinfection of liquid biological waste and autoclaving solid waste. The use of sharps is minimised in this project. Their use is not thought to be necessary. Any use will conform to the measures outlined in the Institute's Code of Practice.

The target genes do not encode viral specific protein nor do they interfere with known activities of the virus and so are unlikely to have any effect upon the basic nature of the virus.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste materials (e.g. gloves, plastic ware, cell pellets etc) are rendered inactive by autoclaving (100% kill) in a validated machine located in the same building. Subsequently the solid waste enters the clinical waste route and goes for incineration. The autoclave has an integral "pass" or "fail" alert for each cycle processed in the machine. This is displayed on the autoclave at the end of each cycle and this is monitored by the end-user. The autoclave undergoes annual validation (12-point thermocouple testing) by a third party company. Records are kept on site.
Trigene is routinely used as per the manufacturer's recommendations:
Solid surfaces are disinfected with a 1 in 50 dilution of Trigene.
Plastic ware that can be effectively disinfected is treated with a dilution of 1 in 50 dilution of Trigene overnight.
Any contaminated glassware is treated with a 1 in 50 dilution of Trigene.
The contact time is overnight.

Liquid waste (culture and medium) is disinfected by the addition of Trigene to give a working dilution of 1 in 50; and left overnight before disposal to sewers.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form N

Date Project Ceased  25/05/2017

Project notified under transitional arrangements  N
The aim of the project is to develop a vaccine for childhood Acute Lymphoblastic Leukemia (ALL). As BCG is safely used as a childhood vaccine against tuberculosis, a childhood ALL specific recombinant BCG vaccine will be developed and tested in a mouse model. BCG has been shown to be an effective vaccine vector due to its adjuvant properties and ability to cross-present antigens to the MHC class I processing pathway. The TEL/AML fusion protein occurs in 25% of cases of childhood ALL. T-cell peptide epitopes have been identified in this protein and will be cloned into wildtype BCG to make a recombinant vaccine.

Recipient or parental organism
Mycobacterium Bovis BCG Pasteur strain (BCG) (attenuated with a long history of safe use). ATCC 35734.
Nucleotide sequence. AF095590

Host/vector system
Plasmid vectors:
pCR3.1 (non-mobilisabe).

Bacterial hosts:
Echerichia coli DH5 alpha and TOP 10 series.
Mycobacterium Bovis BCG Pasteur strain (BCG) (attenuated with a long history of safe use). ATCC 35734

Origin & function
Genes of interest will be of human origin.
Genes of interest will be junctional peptides from the TEL-AML1 and BCR-ABL. Either the whole gene, gene fragments or peptides will be used.

The TEL-AML1 fusion peptide is a small 30aa sequence taken from the TEL-AML1 fusion protein which is an oncogenic fusion protein that is an initiating lesion in childhood ALL. However, this protein will not be used. The fusion peptide which will be cloned into the BCG and is not known to have any biological activity.

Evaluation of foreseeable effects
The BCG strain used in this project is close relative of the commercially available BCG vaccine strain which has been used to vaccinate millions of patients. This strongly suggests that there would be minimal risk from the BCG strain used in this work. The expressed tumour proteins should not be functional in the bacterial strain and given the nature of the vaccine approach, the bacterial vector with human proteins should be rapidly degraded by the innate immune system and used to prime an immune response. The risk to human health from the GMM is likely to be minimal.

The genetic insert would not alter the pathogenicity of the BCG but may impact upon deleteriously upon the growth of the bacteria since the expression of heterologous
genes is commonly associated with reduced growth rates of the individual vector.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste materials (e.g. gloves, plastic ware, cell pellets etc) are rendered inactive by autoclaving (100% kill) in a validated machine located in the same building. Subsequently the solid waste enters the clinical waste route and goes for incineration. The autoclave has an integral "pass" or "fail" alert for each cycle processed in the machine. This is displayed on the autoclave at the end of each cycle and this is monitored by the end-user. The autoclave undergoes annual validation (12-point thermocouple testing) by a third party company. Records are kept on site.

All liquid laboratory waste will be inactivated prior to removal from the Class II microbiological safety cabinets employed for this work.

Virkon is routinely used as per the manufacturer's recommendations:-
- Solid surfaces are disinfected with 1% Virkon solution.
- Plastic ware that can be effectively disinfected is treated with 1% Virkon for a minimum of 1 hour prior to incineration.
- Any contaminated glassware is treated with 1% Virkon for a minimum of 1 hour prior to cleaning. Usually the contact time is longer, typically overnight.
- Liquid waste (culture and medium) is disinfected by the addition of Virkon to give a 1% final working concentration 2% or 3% solutions of Virkon are used for buffered solutions. A minimal contact time of 1 hour is allowed prior to disposal to sewers (as per manufacturer's recommendations).

Project Additional Information

Purposes of the contained use

The aim of this project is to overexpress or knock-down genes of interest using lentiviral transduction in both fibroblast and epithelial cell lines to investigate the importance of these genes in both cancer cells and the associated stromal compartment in order to investigate effects on cancer cell growth, tumour-stoma interactions in co-cultures between stromal fibroblast cells and cancer cells, and in cancer cell metabolism.

For stable knockdown experiments, lentiviral particles containing shRNA sequences targeting genes of interest will be custom made or purchased from Santa Cruz or Genocopia. The lentiviral particles are a pool of concentrated transduction ready viral particles containing target specific constructs encoding the specific shRNA under the control of a CMV promoter. Details of the viral vectors are provided in appendix 1 of the risk assessment.

For overexpression, pre-made or custom made lentiviral particles will be purchased from GeneCopoeia. The full coding sequences of the candidate genes will be inserted by the company into the viral vectors under the control of a CMV promoter and a puromycin resistance gene for selection purposes after transduction.

The viral particles are prepared by the company in the following manner. An OmicsLink™ ORF lentiviral expression plasmid (GeneCopoeia Cat. No EX-EGFP-Lv105) was constructed using GeneCopoeia proprietary RecJoin™ technology. This plasmid was co-transfected into 293Ta cells (GeneCopoeia Cat Np CLv-PK-01) with the Lenti-Pac HIV Packaging Mix (GeneCopoeia Cat. No HPK-LvTR-20). Lentivirus-containing supernatants were harvested 48 hours after transfection. Pre-made lentivirus titer ranges from 10^7 copies/ml for crude version to 10^9 copies/ml for purified lentivirus. Lentifect lentivirus production process involves stringent quality control processes including sequence verification of the insert, qRT-PCR based titer estimation, etc.

We intend to use these particles on a variety of cell lines in both monoculture and co-culture of fibroblast cells with breast cancer cell lines and look at cell metabolism.
autophagy, mitophagy, proliferation, migration and molecular markers with Western blot, immunocytochemistry and flow cytometry, as well as biochemical assays of products of metabolism such as lactate and ketones.

### Recipient or parental organism

**Lentivirus parental organism - Human Immunodeficiency virus (HIV-2) is classified as ACDP hazard Group 3.**

### Host/vector system

**Target Cells for Viral vector**

Fibroblast cell lines BJ5TA, BJ1, 218, 522 and 544

Epithelial cancer cell lines MCF7, MCF10A, MDA-MB-231, SKBR3, T47D, BT20, BT474, MBA-MB-468 (all breast cancer cell lines) see appendix 2 in risk assessment for more details of the cell lines to be used.

Other epithelial cell lines may be investigated, and amendment to the risk assessment would be obtained beforehand

### Origin & function

**Genes of interest:**

- cDNA: Human Caveolin -1 and related genes
- cDNA: Human Autophagy/mitophagy related genes - including ATG16L, LAMP, TOM-20, LC3
- cDNA: Human Lactate transporter genes including MCT1 and MCT4
- cDNA: Human Transcriptional regulator genes - Including CAPER
- cDNA: Human genes associated with glycolysis and glucose transport - including GLUT-1
- cDNA: Human genes associated with senescence such as WNT5a, FBX032 and the CDK family of genes
- siRNA: to target Caveolin and related genes
- siRNA: to target MCT1, MCT4 and related genes
- siRNA: to target CAPER and associated transcriptional regulators.

As we will be studying a variety of similar and related genes within the above families, we will review the risk assessment when we look at other genes to ensure the assessment is still valid.

For knock-down experiments - Lentiviral particles containing shRNA sequences targetting genes of interest will be purchased from Santa Cruz or Genocopia.

For over-expression custom made particles will be purchased from Genocopia.

### Evaluation of foreseeable effects

The recombinant viral vectors are highly disabled vectors based on the HIV lentivirus. They are self inactivating vectors, which have had regulatory and accessory genes deleted, ensuring that viral particles produced in packaging cell lines are replication incompetent. Thus whilst they pose an infection risk they are unable to initiate further rounds of replication/infection cycles. The probability of seroconversion is minimal.

Whilst the VSV-G envelope extends the cellular tropism and confers greater stability and environmental survivability, it is thought there is NO significant increase in the likelihood of transfection via the airborne route of exposure. Control measures utilised are appropriate to guard against the associated risks.

The target genes do not encode viral specific protein, nor do they interfere with known activities of the virus and so are unlikely to have any effect upon the basic nature of the recombinant lentivirus.

Whilst the VSV-G envelope confers greater stability and environmental survivability, control measures employed will minimise risks to the environment. These control measures include rendering all solid or liquid waste inactive within the building (either by autoclaving or use of disinfectant); work carried out in containment 2 laboratories, work within Class 2 microbiological safety cabinets, routine disinfection of work surfaces; all staff are suitably trained in GM work and employing the necessary risk control measures.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste materials (e.g. gloves, plastic ware, cell pellets etc) are rendered inactive by autoclaving (100% kill) in a validated machine located within the same building. Subsequently the solid waste enters the yellow bag clinical waste route and goes for incineration. The autoclave is performance validated by 12-point thermocouple tests on an annual basis. Records are kept on site. Trigene is routinely used as per manufacturer's recommendations:-
Solid surfaces are disinfected with Trigene trigger spray solution.
Plasticware that can be effectively disinfected is treated with final concentration of v/v 1% Trigene for a minimum of 1 hour prior to incineration. Any contaminated glassware is treated with 1% Trigene solution for a minimum of 1 hour prior to cleaning. Liquid waste (culture and medium) is disinfectd by the addition of Trigene to give a 1% final working concentration. A minimal contact time of 1 hour is allowed prior to disposal to sewers.

Project Ref 141/12.4
Previous studies have identified the attraction to, and the ability to cross the bone marrow endothelium as being pivotal in the metastatic process of prostate cancer. Previous studies have identified a number of candidate genes involved in targeting and crossing the endothelial membrane towards bone marrow stroma. This project seeks to evaluate these candidate genes in established cell line models of prostate epithelial metastasis. Cell lines used will be human bone metastatic cell line PC-3 and non-bone metastatic cell line LNCaP to assess action of these genes. Cell lines will be transduced with genes of interest or their corresponding siRNA pools using lentiviral vectors and analysed using a combination of human bone marrow stroma co-culture assays which model binding, transendothelial migration, colony formation and expansion.

Recipient or parental organism

Lentivirus parental organism - Human Immunodeficiency virus-1 (HIV-1) is classified as ACDP hazard group 3

Host/vector system

Bacterial host: E.coli JM109

Host cell; HEK293

Target cells for viral vector:-
Human bone metastatic cell line PC-3
Non-bone metastatic cell line LNCaP
Ephrin receptors:- EphA1, EphA2, EphA4, EphB, 2EphB3, EphB4, EphB6
Eph receptors are a group of receptors activated by the ephrin and form the largest known subfamily of receptor tyrosine kinases (RTKs). Both Ephs and their corresponding ephrin ligands are membrane-bound proteins that require direct cell-cell interactions for Eph receptor activation. Subsequent downstream pathways have been shown to regulate motility, cell adhesion and cell polarity through the Rho family of GTPases. Eph/ephrin signalling regulates a variety of biological processes including the guidance of axon growth cones, formation of tissues boundaries, cell migration, and contact inhibition of locomotion (CIL). Additionally, Eph/ephrin signalling has recently been identified to play a critical role in several processes including long-term potentiation, angiogenesis, and stem cell differentiation.

Genes listed are expressed in prostate epithelial cells.

Ephrin A1, A3, A4, A5; Ephrin B1, B2, B3:- The Ephrin family are a family of proteins that serve as the ligands of the Eph receptors, which compose the largest known subfamily of receptor protein-tyrosine kinases (RTKs). Both ephrins and Eph receptors are membrane-bound proteins binding and activation of Eph/ephrin intracellular signalling pathways only occur via direct cell-cell interaction. Subsequent downstream pathways have been shown to regulate motility, cell adhesion and cell polarity through the Rho family of GTPases.
Eph/ephrin signalling regulates a variety of biological processes including the guidance of axon growth cones, formation of tissue boundaries, cell migration, and contact inhibition of locomotion (CIL). Additionally, Eph/ephrin signalling has recently been identified to play a critical role in several processes including long-term potentiation, angiogenesis, and stem cell differentiation.

2 classes of ephrin:
Ephrin A - GPI (glycosylphosphatidylinositol) linked ephrins
Ephrin B - Transmembrane linked ephrins

Gene listed are expressed in prostate epithelial cells.

Caveolin: Cav-1 Cav-2:- Family of integral membrane proteins which are the principal components of caveolae essential for receptor-independent endocytosis. Caveolins act as scaffolding proteins within caveolins have also been shown to have lipid binding properties and mediate aspects of cholesterol and fatty acid metabolism.
The caveolin gene family has three members in vertebrates: CAV1, CAV2, and CAV3, coding for the proteins caveolin-1, caveolin-2, caveolin-3, respectively.

Evaluation of foreseeable effects
The recombinant Lentiviral vector system consists of disabled vectors. They have had HIV regulatory and accessory genes deleted, ensuring that viral particles produced in packaging cell lines are replication incompetent. Thus whilst they may pose an infection risk they are unable to initiate further rounds of replication/infection cycles. The probability of seroconversion is minimal.

Whilst the VSV-G envelope extends the cellular tropism and confers greater stability and environmental survivability, it is though there is no significant increase in the likelihood of transfection via the airborne route of exposure. Besides, the risk control measures utilised are appropriate to guard against the associated risks. These include the use of safety cabinets, biosafe rotors and prescribed disposal routes for waste, wearing of appropriate PPE and no use of any sharps.

The target genes do not encode viral specific protein, nor do they interfere with known activities of the virus and so are unlikely to have any effect upon the basic nature of the virus.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Solid waste materials (e.g. gloves, plastic ware, cell pellets etc) are rendered inactive by autoclaving (100% kill) in a validated machine located in the same building. Subsequently the solid waste enters the clinical waste route and goes for incineration. The autoclave has an integral "pass" or "fail" alert for each cycle processed in the machine. This is displayed on the autoclave at the end of each cycle and is monitored by the end-user. The autoclave undergoes annual validation by a third party company. The performance test results generated during validation are kept on site.

Virkon is routinely used as per the manufacturer's recommendations:-
Solid surfaces are disinfected with 1% Virkon solution.
Plastic ware that can be effectively disinfected is treated with 1% Virkon for a minimum of 1 hour prior to incineration. Any contaminated glassware is treated with 1% Virkon solution for a minimum of 1 hour prior to cleaning.

Liquid waste (culture and medium) is disinfected by the addition of Virkon to give a 1% final working concentration. 2% or 3% solutions of Virkon are used for buffered solutions. A minimal contact time of 1 hour is allowed prior to disposal to sewers. (as manufacturer's recommendations).

The committee agreed with the classification.
It asked the author for more information about the genes of interest and these were supplied and are listed in section 7 of this form and as a table appended to the risk assessment.

Please enter comments on the GM safety committee on the risk assessment

</table>
(stem) cells in vitro and in vivo

Purposes of the contained use

Primary aim: to monitor and isolate breast cancer (stem) cells in vitro and in vivo.

Micrometastases are a major problem in breast cancer as they are resistant to standard therapies and have the potential to kill the host. It is known that breast cancer cells preferentially metastasise to the lungs, liver and bone, however the timing of this progression and the processes underpinning it are not clear. Understanding how and when breast cancer cells metastasise and how micrometastases are regulated in their environment will aid the development of new strategies to inhibit their formation or progression.

We plan to monitor cellular dissemination of breast cancer (stem) cells using in vivo imaging and isolation from mouse tissues. We have obtained bicistronic luciferase and green (GFP) and red (RFP) fluorescent cDNA vectors for lentiviral transduction from Standford University, USA (FULG and FULT vectors from (Liu et al., 2010)) for this purpose. We will transfect both breast cancer and cell lines and primary breast xenografts with the fluorescent vectors and inject them into mice. We will then monitor the spread of breast cancer (stem) cells to metastatic sites. The advantage of the bicistronic vector is that injection of luciferein can be used to detect as few as 10 cells in a metastatic site and the GFP/RFP+ cells can be localised in the excised tissues and sorted from host cells by FACS.

Recipient or parental organism

Lentivirus parental organism- Human Immunodeficiency virus (HIV-1) is classified as ACDP hazard group 3.

Host/vector system

Bacterial: E. coli Stbl3 (from Invitrogen)

Viral vectors; pMDLg/pRRE, pRSV-Rev, pMD2.G, pCMVdelta8.91 lentiviral packaging plasmids

Lentiviral system: This is a self-inactivating lentivector system with a pseudotyped VSV-G capsule. Viral particles will be produced using the HEK293T packaging cell line.

FLUG and FULT plasmids contain multifunctional reporter genes firefly luciferase and fluorescent proteins

Target cells: Continuous human breast cancer cell lines: MCF-7; T47D; MDA-MB-231; BT474 - All from ATCC Primary human tissue samples from Christie Hospital Biobank.
The FULG and FULT plasmids are described in Liu et al, 2010 (PNAS vol. 107 p18115-18120). They are multifunctional reporter genes used to analyse disease models by linking in vivo and ex vivo assays. They contain both firefly luciferase (Luc+) for whole body tracking of cells via bioluminescence imaging, and fluorescent proteins to allow intravital imaging and ex vivo analyses. In FUKG and FULT Luc2 is fused to either enhanced GFP (eGFP) (FULG) or the red fluorescent protein tomato (FULT).

**Evaluation of foreseeable effects**

The recombinant Lentiviral vector systems consist of disabled vectors. They have had HIV regulatory and accessory genes deleted, ensuring that viral particles produced in packaging cell lines are replication incompetent. The systems employed will be Self-inactivating (SIN) vector systems. Thus whilst they may pose an infection risk they are unable to initiate further rounds of replication/infection cycles. The probability of seroconversion is minimal.

Whilst the VSV-G envelope extends the cellular tropism and confers greater stability and environmental survivability, it is thought there is no significant increase in the likelihood of transfection via the airborne route of exposure. Besides, the risk control measures utilised are appropriate to guard against associated risks. These include the use of safety cabinets, biosafe rotors and prescribed disposal routes for waste, wearing of appropriate PPE and no use of any sharps.

The reporter genes do not encode viral specific protein, nor do they interfere with known activities of the virus and so are unlikely to have any effect upon the basic nature of the virus.

**Origin & function**

The reporter genes do not encode viral specific protein, nor do they interfere with known activities of the virus and so are unlikely to have any effect upon the basic nature of the virus.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

The mice used in this study will not be GM animals. GM human tumour cells will be injected into mice. These will not have the ability to infect the animals cells.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste materials (e.g. gloves, plastic ware, cell pellets etc) are rendered inactive by autoclaving (100% kill) in a validated machine located in the same building. Subsequently the solid waste enters the clinical waste route and goes for incineration. The autoclave has an integral "pass" or "fail" alert for each cycle processed in the machine. This is displayed on the autoclave at the end of each cycle and this is monitored by the end-user.

The autoclave undergoes annual validation (12-point thermocouple testing) by a third party company. Records are kept on site. It also undergoes a quarterly maintenance regime as recommended in BS2646.

Any plasticware that can be effectively disinfected is treated with 1% virkon and left overnight before entering the clinical waste route.

Liquid waste (culture and medium) is disinfected by the addition of Virkon to give a 1% final working concentration. A minimal contact time of 1 hour is allowed prior to disposal to sewers. (as per manufacturers recommendations) but it is usual to leave overnight until disposal to drains.

**Historical Significant Changes**

- Transferred to GM541

**Project Additional Information**

**Purposes of the contained use**

We seek to investigate the role of normal and cancer-activated fibroblasts in tumour-stromal interaction using knockdown or overexpression of genes of interest. Fibroblasts are known to exert tumour-promoting as well as tumour-suppressing functions dependent upon micro-environmental conditions and the metabolic state of the contributing cell types. We intend to co-culture fibroblast cells with breast cancer cell lines and analyse cell functionality (proliferation, migration, invasion, stem cell expansion) as well as biochemical states (molecular markers by western blot, real time PCR and Elisa).
Moloney Murine Leukemia Virus (MMLV)-based retroviral vectors pBabe, pWZL and pLNCX used to generate recombinant viral particles using a HEK293T based packaging cell line.

### Host/vector system

Phoenix-amphotropic HEK293T packaging cell line. Provides the env gene and protein which determines the virus particle infectivity range. In this case- amphotropic.

Retroviral vectors pBabe; pWZL and pLNCX MMLV-based retroviral vectors

Details of the host vector system are given in Appendix 1 of the risk assessment

### Origin & function

The host-vector system will produce recombinant virus particles which will then be used to infect a range of cell lines. These cell lines are human breast cancer cell lines and human and murine fibroblast cell lines.

The genes of interest comprise a wide range including those involved in proliferation, migration, invasion and stem cell expansion; as well as biochemical states. The known or suspected functions of these genes are listed in Appendix 2 of the risk assessment.

### Evaluation of foreseeable effects

The recombinant virus has its structural genes deleted, which disables the virus and so prevent its growth in the absence of complementing cell lines or co-transfection of appropriate plasmids.

The amphoteric envelope, conferred by the packaging cell line, changes cellular tropism to most mammalian cells including human. It may be able to confer greater stability and environmental survivability of the virus. However, appropriate work practices will prevent the replication incompetent viruses from being released in to the environment.

The absence of the use of sharps in this work should help minimise risks to workers

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste materials (e.g. gloves, plastic ware, cell pellets etc) are rendered inactive by autoclaving (100% kill) in a validated machine located in the same building. Subsequently the solid waste enters the clinical waste route and goes for incineration. The autoclave has an integral "pass" or "fail" alert for each cycle processed in the machine. This is displayed on the autoclave at the end of each cycle and this is monitored by the end-user.

Virkon is routinely used as per the manufacturer's recommendations:-

- Solid surfaces are disinfected with 1% Virkon solution
- Plastic ware that can be effectively disinfected is treated with 1% Virkon for a minimum of 1 hour prior to being placed in to the clinical waste route and then goes for incineration
- Any contaminated glassware is treated with 1% Virkon solution for a minimum of 1 hour prior to cleaning. Usually the contact time is longer, typically overnight.
- Liquid waste (culture and medium) is disinfected by the addition of Virkon to give a 1% final working concentration 2% or 3% solutions of Virkon are used for buffered solutions. A minimal contact time of 1 hour is allowed prior to disposal to sewers. (as per manufacturer's recommendations).
The autoclave undergoes annual validation by a third party. Records are kept on site.

Historical Significant Changes: Transferred to GM541
Microarray and single cells expression profiling experiments previously performed have identified a number of candidate genes that may be critical regulators of normal and tumourigenic prostate progenitor cells. Genes expressed in the stromal compartment of the prostate may also have a critically important function in the regulation of normal prostate and tumour-initiating cells. This project seeks to evaluate the role of these genes in these cell types in murine and human model systems using genetic knockdown experiments. Briefly, murine or human prostate cells will be transduced using lentiviral vectors containing shRNAs and cells will then be functionally evaluated using a combination of in vitro and in vivo techniques, the latter involving transplantation of cells in to mice. One retroviral vector system will be used: pSHAG-MAGIC2, which provides constitutive expression of the shRNA from MSCV promoter. Two lentiviral vector systems will be used: (i) pLKO.1, which provides constitutive expression of shRNAs from a Pol III promoter, and (ii) pSicoR, which provides constitutive expression of shRNAs from a Pol III promoter with the option of irreversible Cre-mediated conditional inactivation of knockdown. In some cases, we would like to ensure that the genetic alteration is restricted to specific prostate lobe/area in vivo. For this, adenovirus or lentivirus will be injected intraprostatically to genetically modified mice and their control counterparts.

Bacterial hosts: Escherichia coli Stbl3 (for use with lentiviral vector system plamids)  
Escherichia coli Dh5 alpha (for general cloning purposes)

Bacterial recipients are none-infective strains and have multiple auxotrophic requirements. Growth and survivability is unlikely out of laboratory growth medium. Transformation with plasmids used in this work will not alter this phenotype.

Target cell lines- Primary murine and human prostate cells (please see appendix 7 for cell use criteria)

Growth and survivability of modified and un-modified cells is unlikely outside of laboratory growth medium.

Lentivirus pLKO.1 and pSicoR systems: parental organism is Human Immunodeficiency virus (HIV-1) and is classified as ACDP hazard group 3. Used with HEK 293 FT cells.

More details can be found in appendix 1 and 3 of the risk assessment.

The pSHAG-MAGIC2 retrovirus system: parental organism is Murine Stem Cell Virus. Used with Phoenix-E and Plat-E cells.

More details can be found in appendix 3 and 4 of the risk assessment.

Target cells: primary murine and human prostate cells

shRNAs expressed will target the genes listed in appendix 2 of the risk assessment, for knockdown. The function of these genes in leukaemia stem cells is not known formally, however, genes such as Pten, Brca1, and ATM are cell cycle/dna damage regulators/tumour suppressors so their knockdown may accentuate oncogenesis.
### Evaluation of foreseeable effects

The recombinant viral vectors are highly disabled vectors based on the HIV or MSC virus. These vectors have had regulatory and accessory genes deleted ensuring that viral particles produced in the packaging cells are replication incompetent. Thus whilst they pose an infection risk they are unable to initiate further rounds of replication/infection cycles. The probability of seroconversion is minimal.

For the lentivirus, whilst the VSV-G envelope extends the cellular tropism and confers greater stability and environmental survivability it is thought that there is NO significant increase in the likelihood of transfection via the airborne route of exposure. Besides, the control measures utilised are appropriate to guard against the associated risks.

The target genes do not encode viral specific protein, nor does they interfere with known activities of the virus and so are unlikely to have any effect upon the basic nature of the recombinant lentivirus or MSC retrovirus.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

The committee agreed with the classification. It asked for clarification on the regime for training workers in this work. This was supplied to the committees satisfaction. Likewise the committee asked for a standard operating procedure for dealing with breakages in centrifuges used in this work. Again this was supplied to the committees satisfaction.

Project Additional Information

Purposes of the contained use

The proposal concerns the immortalisation of primary cells that can be readily expanded in a number for experimental investigations. Specifically, the primary cells of interest will be those that comprise the tumour microenvironment. This
is a broad set of cell types but the aim of the work is to attempt to generate mixed cultures of cells that re-capitulate key aspects of the tumour microenvironment including immune suppression. Consequently, cells that would be of interest include tumour and non-tumour stromal cells including fibroblasts and the diversity of immune cells. We have expertise in disaggregating tumours and expanding T cells for in vesteation and also immortalising B cells employing EBV. We also have performed short-term tumour cell growth for co-culture assay. However, in the absence of immortalisation, cell number is usually a limiting factor for the breadth of potential experiments that can be performed. For this project, we propose to exploit the directed expression of single genes that have been shown to immortalise a range of primary cells.

Recipient or parental organism
Primary human tumour or peripheral blood cells

Host/vector system

Retroviral vectors.
Retroviral viral gene transfer vectors have been extensively engineered to eliminate all virus protein coding sequences within the vector itself. Vector particle are generated by co-expression of gag/pol and env genes with the retroviral vector within a packaging cell. The gag/pol and env genes are encoded on separate plasmids and engineered to reduce homologous sequences with the retroviral vector. This degree of engineering reduces the possibility of generating a replication-competent retrovirus to essentially zero based upon the extensive history of use of retroviral vector technology in the pre-clinical and clinical situation.

Lentiviral vectors.
Lentiviral vectors have been engineered as described below:
An enhancer deletion in the U3 region of 3’LILTR ensures self-inactivation of the lentiviral vector following transduction and integration into the target cell ’s genomic DNA.
• The number of lentiviral genes necessary for packaging, replication and transduction is limited to three (Gag/Pol/Rev), and their expression is derived from different plasmids, all lacking packaging signals. These plasmids share no significant homology to the expression vector, thus preventing the generation of replication-competent virus by recombination events .
• None of the Gag, Pol, or Rev genes will be incorporated into in the packaged viral genome, thus making the mature virus replication-incompetent.

Origin & function
The genes to be used are sourced commercially with sequences as listed below.

Immortalising genes.
SV40 large and small T antigen sequences. Full sequence available here: http://www.abmgood.com/SV40-CellImmortalization.html
hTERT. Full sequence available here: http://www.abmgood.com/hTERT-Cell-Immortalization.html#

siRNA targets to aid immortalisation:
pRB siRNA. Full sequence available here: http://www.abmgood.com/Myc-p53-Rb-Ras-Cell-Immortalization.html

Evaluation of foreseeable effects
Both retroviruses and lentiviruses are lack any potentially immune avoidance gene products that are encoding within the wild type viruses hence they are unlikely to have the same degree of immune protection as that afforded to the
wild type virus. The envelope glycoproteins lend to be derived from other viruses which possess different and, most often, increased immunogenicity profiles compared to the retrovirus lentivirus envelope glycoproteins. Indeed, the VSVg envelope commonly used to pseudotype lentiviral vectors is sensitive to complement mediated destruction in human serum. Overall, the replication deficient virus vectors are most likely to possess an increased immunogenicity profile as compared to the wild type vector suggesting that in the immune-competent individual, these vectors are more likely to be subjected to immune-mediated clearance.

For the target cells...
The genes to be expressed facilitate the modified cell to overcome cellular senescence and to allow the transduced cell to become immortalised.

The modified cells require specific conditions to survive including maintenance at 37 degrees C and cultured in incubators flushed with CO2. Outside of this environment, the cells could survive in media for a period of time but would be unlikely to expand in number. However, with evaporation, solute concentrations would build within the remaining media and the cells would either die of that level of toxicity or die through drying out. Outside of the media environment, cells would last only a short period of time (hours) before dying due to dehydration.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMOs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste materials (e.g. gloves, plastic ware, cell pellets etc) are rendered inactive by autoclaving (100% kill) in a validated machine located in the same building. Subsequently the solid waste enters the clinical waste route and goes for incineration. The autoclave has an integral "pass" or "fail" alert for each cycle processed in the machine. This is displayed on the autoclave at the end of each cycle and this is monitored by the end-user. The autoclave undergoes annual validation (12-point thermocouple testing) by a third party company.

All liquid laboratory waste will be inactivated prior to removal from the Class II microbiological safety cabinets employed for this work. Virkon is routinely used as per the manufacturer's recommendations: Solid surfaces are disinfected with 1% Virkon solution. Plastic ware that can be effectively disinfected is treated with 1% Virkon for a minimum of 1 hour prior to incineration. Any contaminated glassware is treated with 1% Virkon solution for a minimum of 1 hour prior to cleaning. Usually the contact time is longer, typically overnight. Liquid waste (culture and medium) is disinfected by the addition of Virkon to give a 1% final working concentration. 2% or 3% solutions of Virkon are used for buffered solutions. A minimal contact time of 1 hour is allowed prior to disposal to sewers. (as per manufacturer's recommendations).

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y
This project involves over expression of the PDGFRAIB in human lung cancer cells from the ATCe. The PDGFR gene is implicated in lung cancer and we wish to introduce and express these genes in a small range of cell lines.
gene will be introduced into the cell by chemical means e.g. lipofectamine. Downstream analysis, involving cell sorting and various assays will be carried out. Other genes of interest involved in lung cancer may be used subsequently (e.g. AMPK, 81M, NIKRAS2) but the Biosafety Committee will be informed beforehand. We also intend to transfect a small range of cell lines with microRNAs. miRNAs will be introduced into the cell lines using premade Lentiviral particles resulting in integration into the cell genome. The modified cells will then be analysed using standard laboratory assays and techniques such as western blotting. Whilst we have identified the use of two miRNAs which we intend to use, other miRNAs may be used later in the project. The Biosafety Committee will be informed beforehand if this occurs. We also plan to stably silence important oncogene targets of the identified microRNAs using the shRNA lentiviral particles. We will purchase ready for use Lentiviral particles from Santa Cruz Biotechnology. Lentiviral particles are replication-incompetent and are designed to self-inactivate after transduction and integration of shRNA constructs into genomic DNA of target cells.

Recipient or parental organism

Lentiviral systems: Lentivirus parental organism- Human Immunodeficiency virus-1 (HIV-1) is classified as ACDP hazard group 3

Host/vector system

Recipient or parental organism

Bacterial HosU Vector system: E.coli TOPO 101 pCMV expression vectors

Viral/Host systems: Custom made lentiviral particles from Santa Cruz Biotechnology for transduction of shRNA constructs into target cells

miRNA lentivector expression systems from System Bioscience (SBI), involving co-transfection of expression and packaging vectors in HEK293 cells, resulting in pseudo-viral particles harbouring miRNA expression constructs for transduction into target cells

Target Cells: A549 lung cells from ATCC, H292 lung cells from ATCC

Origin & function

Human PDGFR Gene eDNA Clone (full-length ORF Clone), expression ready, C-HA-tagged

Vector: pCMV3-C-HA

HA Tag Sequence: TATCCTTACGACGTGCCTGACGCC

Species: Human

Gene Synonym: PDGFR- Beta and PDGFR-Alpha

Gene Bank ref 10: NM_002609.3 and NM_002609.4

Health and Safety Executive

PDGFR is implicated in lung cancer in humans. Other genes implicated in human lung cancer, such as AMPK, 81M and NIKRAS2 and genes of similar functional profile, may also be investigated.

Evaluation of foreseeable effects

The recombinant viral vectors are highly disabled vectors based on the HIV lentivirus. They are self-inactivating vectors, which have had regulatory and accessory genes deleted, ensuring that viral particles produced in packaging cell lines are replication incompetent. Thus whilst they pose an infection risk they are unable to initiate further rounds of replication infection cycles. The probability of seroconversion is minimal.

Whilst the VSV-G envelope extends the cellular tropism and confers greater stability and environmental survivability, it is thought there is NO significant increase in the likelihood of transfection via the airborne route of exposure. Control
measures utilised are appropriate to guard against the associated risks. The target genes does not encode viral specific protein, nor do they interfere with known activities of the virus and so are unlikely to have any effect upon the basic nature of the recombinant lentivirus.

Whilst the VSV-G envelope confers greater stability and environmental survivability, control measures employed will minimise risks to the environment. These control measures include rendering all solid or liquid waste inactive within the building (either by autoclaving or use of disinfectant); work carried out in containment 2 laboratories, work within Class2 microbiological safety cabinets, routine disinfection of work surfaces; all staff are suitably trained in GM work and employing the necessary risk control measures.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Solid waste materials (e.g. gloves, plastic ware, cell pellets etc) are rendered inactive by autoclaving (100% kill) in a validated machine located in the same building. Subsequently the solid waste enters the clinical waste route and goes for incineration. The autoclave has an integral "pass" or "fail" alert for each cycle processed in the machine. This is displayed on the autoclave at the end of each cycle and this is monitored by the end-user. The autoclave undergoes annual validation (12-point thermocouple testing) by a third party company.

All liquid laboratory waste will be inactivated prior to removal from the Class II microbiological safety cabinets employed for this work. Virkon is routinely used as per the manufacturer's recommendations: Solid surfaces are disinfected with 1% Virkon solution.

Plastic ware that can be effectively disinfected is treated with 1% Virkon for a minimum of 1 hour prior to incineration. Any contaminated glassware is treated with 1% Virkon solution for a minimum of 1 hour prior to cleaning. Usually the contact time is longer, typically overnight.

Liquid waste (culture and medium) is disinfected by the addition of Virkon to give a 1% final working concentration. 2% or 3% solutions of Virkon are used for buffered solutions. A minimal contact time of 1 hour is allowed prior to disposal to sewers. (as per manufacturer's recommendations).
