Expression vectors containing various DNA and siRNA constructs will be sent for commercial packaging (i.e. Stratech Scientific Ltd) to produce lentiviral particles. Delivery of genetic materials (cDNA and siRNA) will be achieved by viral transduction following injection of the lentiviral particles into the brains of mice which may be either wild-type mice or themselves genetically modified (i.e. carrying stable transgenes and/or with targeted deletion of specific genes).

Commercial vector systems will be used to generate the constructs (e.g. pCDH-CMV-MCS (Stratech Scientific Ltd), pLKO.1 (Open Biosystems), pLenti-EF1 (Stanford University, USA). Packaging, expansion and purification of viruses will not be performed in the laboratory but undertaken at a company using proprietary systems (Cell Biolabs; ViraSafe™ packaging system (pCMV-Eco, pRSV-Rev, pCGP-V)). Viruses will be shipped to the laboratory and stored until use.

Expression vectors containing channel-rhodopsin or halorhodopsin (light sensitive proteins derived from alga (Chlamydomonas reinhardtii) and bacteria (Halobacteria), respectively) will be used for optogenetic studies and will be obtained from Stanford University, USA (http://www.stanford.edu/group/diab/optogenetics). Lentiviral expression vectors will be obtained from commercial sources (i.e. Stratech Scientific Ltd; Open Biosystems) and will be used to construct genetically modified proteins (signalling molecules and ion channels derived from mouse DNA) and siRNA (synthesized commercially). Expression of these constructs will be used to manipulate the signalling mechanisms used by neurons to regulate energy homeostasis.

The lentiviral vector system has been developed with enhanced safety features. It is a third generation lentiviral vector system, with three plasmids consisting of 1) the packaging vector, which contains the minimal set of lentiviral genes required to generate the virion structural proteins and packaging functions; 2) the vesicular stomatitis virus G-protein envelope vector which provides the heterologous envelope for pseudotyping; and 3) the expression vector, which contains the sequence of interest as well as the cis acting sequences necessary for RNA production and packaging. All three components are required to produce a viral particle that is capable of infecting a host organism. The multi plasmid approach increases the safety because viral structural genes have been placed on different genetic units, and multiple recombination events.
must occur before a replication competent virus would be generated. Furthermore, areas of homology have been minimized to decrease the chance of homologous recombination. Virulence genes have been removed from the viral plasmids. The lentiviral particles that will be produced in this study are replication-competent, due to the elimination of wild-type enhancers in the long terminal repeat region. The vectors contain a self-inactivating 3' LTR that renders them unable to produce infectious virus when it integrates into the host chromosome. Once these viral particles have infected the neurons it is highly unlikely that adjacent cells or other organisms can be infected and therefore the risk to the wider environment is extremely low. The lentiviral vector system will only be used to deliver non-transforming sequences (i.e. not oncogenes).

Moreover, expression of the viral constructs will be cre-recombinase dependent which will remove the possibility that expression is permissible in organisms that do not express cre-recombinase (i.e. animals and plants). Therefore the viral inserts will only be expressed in cre-recombinase transgenic mice used in the proposed studies. It is anticipated that manipulation of these signalling molecules will alter the normal regulation of body weight and food intake. To minimize the possibility of self inoculation of the lentiviral particles, personal protection will be used (lab coat, gloves, safety glasses). To minimize any possible aerosol effects of the viral stocks, appropriately capped centrifuge bottles and screw-capped tubes will be used. Stocks of the lentiviral particles will be opened only in class II containment cabinets to avoid inhalation. Trigene advanced at a final concentration of 1:100 has been shown to completely inactivate lentivirus and will be used to thoroughly clean surfaces and equipment used in the studies.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Any liquid waste generated will be treated with Trigene Advance at a final concentration of 1% for 30 minutes, shown by the manufacturer to give complete deactivation.

Solid genetically modified waste material is collected separately in designated 30 litre yellow bins or autoclavable Sharpsafe bins, clearly labelled as genetically modified waste and with the group name. When operator has agreed to receive it, waste will be brought over to the autoclave for treatment. All routes must be internal, and the genetically modified waste must never be left unattended. Gloves and lab-coats should be worn. In the event of a spillage during transport to the autoclave, the area must be isolated and then promptly cleaned with 1% Trigene.

The operator loads the autoclave and runs the plastic discard cycle (134°C for 15 minutes) which has been established sufficient to kill 100% of retroviruses, bacteria and tissue culture cells. The temperature probe is put into the bin to ensure waste in the centre of the bin is inactivated and monitors every run. Chart paper supply and printout are checked before and after each run. Should the autoclave fail a run the loads are not released to the clinical waste route until a fully validated run has occurred. The run number is recorded and the traces and printouts are kept until the waste will have been finally disposed of as clinical waste. All staff operating the autoclave have been trained in manual handling and are also trained in appropriate spillage procedure. 1% Trigene is the disinfectant used in case of inactivated waste being spilled in or out of the autoclave. The autoclave has quarterly checks and an annual 12 point thermocouple test to ensure the efficiency of the cycle.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
The committee considered the risk assessment valid and appropriately classed as category 2 requiring level 2 containment. The laboratories are suitable for this level of work.

**Purposes of the contained use**

The role of human and mouse genes will be studied with particular interest in their effects on cells that might cause or prevent cancer or alter the course of treatment of cancer.
Recipient or parental organism

Host/vector system
Transfection of MuLV derived retroviral vectors, lentiviral vectors and packaging plasmids into 293T cells to generate virus containing supernatant and infection of cells with supernatant

Origin & function

Evaluation of foreseeable effects
Precautions must be taken to ensure operators are not exposed to virus particles that could infect their cells since theoretically infected cells may have an increased chance of developing into cancer

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All solid GM waste (plastic ware) will be autoclaved, Liquid GM waste will be disinfected using Trigene (used at 1:50 dilution consistent with instructions given by the company that produces this product, Medichem International) for a minimum contact time of one hour.

For activities involving GMMs, describe the waste management measures which will apply to the activity

1. Solid wastes contaminated with, or likely to be contaminated with GMOs to be autoclaved at 121 degrees C for 40 minutes to achieve a total kill of all microorganisms.
2. Completion and validation of autoclaving to be confirmed by use of suitable indicator tape.
3. Liquid wastes contaminated with, or likely to be contaminated with GMOs to be retained within original culture vessel or sterile-transferred into fresh vessels and subsequently autoclaved, then disposed to waste drainage.
4. Small volumes of liquid waste and small items of solid waste (eg micropipette tips) may be disposed into a reservoir or biocidal solution (eg Virkon or RBS SR80 made-up according to manufacturers' instructions).
5. The largest cultures used are 1 litre in volume.

**Purposes of the contained use**

Production of cells by virally mediated transduction that can be stimulated with light using Channel Rhodopsins and monitored using genetically encoded fluorescent calcium proteins. Production of fluorescent cells that can be used to track, the identity of neurons and astrocytes.

**Recipient or parental organism**

| Algae for Channel Rhodopsin |
| Jelly fish for RFP and YFP |
| Anenome for CFP adm mCherry |
| Humans for GFAP, CamKII, ubiquitin and synapsin promoter |
| Bacteria for B-Lactamase resistance |
| Cytomegalovirus for CMV promoter |
| Bovine Rhodopsin β2 adrenergic receptor |
| Bovine Rhodopsin α1 adrenergic receptor |
| Gag-pol and Pro form HIV |
| Chicken Gallus gallus for CHS4 insulator element |
| VSV-G vesicular stomatitis virus from simian virus |
| NTera 2.D1 cell line derived from a human testicular tumour |
| RenCell VM cell line derived from human foetal brain |

**Host/vector system**

E. coli DH5α Genotype (F- Φ80lacZΔM15 Δ(lacZYA-argF) U169 recA1 endA1 hsdR17 (rk-, mk+) phoA supE44 λ- thi-1 gyrA96 relA1)

The bacterial host cells (DH5α) are an E. coli K12 derivative categorised as disabled and non-colonising. These cells have biological limitations that preclude their survival in the gut, lung and elsewhere in the body. Due to the autotrophic requirements of these cells, this strain has limited survival capacity in the environment, and is therefore unlikely to survive outside of laboratory culture. This strain belongs to biological agents hazard group 1, for which containment level 1 is appropriate.

The Stbl3™ E. coli strain is designed for cloning direct repeats found in lentiviral expression vectors. Genotype:F- mcrB mrr hsdS20 (rB-, mB- ) recA13 supE44 ara-14 galK2 lacY1 proA2 rpsL20 (Strr ) xyl-5 - leu mtl-1.

The Stbl3™ cells are derived from an E. coli K12 strain designated as disabled and non-colonising. The parental strain belongs to biological agents hazard group 1.

293FT cells

Self inactivating Lentivirus vectors will be produced typically in 293FT cells using a split packaging system. 293FT cell are a human cell line initially transformed with the adenovirus early region, also expressing SV40 T-antigen. Virus particles are produced by co-transfection of vector and helper plasmids as mentioned previously. Due to the presence of the SV40 T-antigen it is recommended that this cell line is handled under at least Biosafety level 2.

ReNcell VM

The ReNcell VM immortalised cell line (Millipore) from the ventral mesencephalon is an immortalized human neural progenitor cell line capable of differentiating into cells of neural lineage upon the removal of growth factors from the medium. Originally derived from the ventral mesencephalon region of human foetal brain tissue the line was immortalised by the incorporation of the V-Myc oncogene by retroviral transduction with the Moloney murine leukemia virus. The cell line is certified pathogen free.
The NTERA-2 cl.D1 cell line is a pluripotent human testicular embryonal carcinoma cell line. This clone differentiates along neuroectodermal lineages after exposure to retinoic acid (RA) or hexamethylene bisacetamide (HMBA). The American Type Culture Collection (ATCC) recommends handling the cell line under at least Biosafety level 1.

**Organotypic mouse brain slices**
Brain slices derived from rodents housed within Aston Universities’ biomedical facility are pathogen free. It is therefore recommend that this material is handled under at least Biosafety level 1.

**Lentiviral vectors**
We will use 2nd generation SIN/replication deficient lentiviruses to allow gene transfer of ChR/OptoXR genes under the control of neuronal/astrocytic gene promoters or inducible promoters (e.g. tetracycline responsive promoters) in postmitotic cells. Control lentiviruses may also be generated expressing green fluorescent protein under the same promoters.

These vectors will also contain drug-resistance selectable markers conferring cell resistance to e.g. Zeocin, Blasticidin, hygromycin or neomycin. This risk assessment also covers the preparation of the DNA genomes of these lentiviral vectors as plasmids in E. coli. This work will be carried out under category 2 containment.

**AVV**
GM adenovirus (replication-defective). We will use adenoviral vector (AVV) to allow gene transfer of Case12 constructs to postmitotic cells. This will be carried out under category 2 containment.

Human Embryonic Kidney 293 cells (HEK293) cells. Derived from human embryonic kidney cells. Since HEK cells express a number of adenoviral genes, they can be used to propagate adenoviral vectors in which these genes (typically, E1 and E3) are deleted. American Type Culture Collection (ATCC) recommends handling the cell line under at least Biosafety level 1.

**Origin & function**

- **Algae for Channel Rhodopsin**
- **Jelly fish for GFP, RFP and YFP**
- **Anenome for mCherry and CFP**
- **Humans for GFAP, CamKII and synapsin promoter**
- **Bacteria for β-Lactamase resistance**
- **Cytomegalovirus for CMV promoter**
- **Bovine Rhodopsin β2 adrenergic receptor (OptoXR)**
- **Bovine Rhodopsin α1 adrenergic receptor (OptoXR)**
- **Human Ubiquitin C promoter**
- **Human for Oct4 promoter**
- **Chicken Gallus gallus for CHS4 insulator element**
- **Gag-pol and Pro form HIV**
- **VSV-G vesicular stomatitis virus from simian virus**
- **Case12 calcium indicator based on GFP variants and Calmodulin**
- **Cameleon calcium indicator based on GFP variants and calmodulin**

Channelrhodopsins are a subfamily of opsin proteins that function as light-gated ion channels. They serve as sensory photoreceptors in unicellular green algae, controlling phototaxis, i.e. movement in response to light. Expressed in cells of other organisms, they enable the use of light to control intracellular acidity, calcium influx, electrical...
excitability, and other cellular processes. Three channelrhodopsins are currently known: Channelrhodopsin-1 (ChR1), Channelrhodopsin-2 (ChR2), and Volvox Channelrhodopsin (VChR1). All known Channelrhodopsins are unspecific cation channels, conducting H+, Na+, K+, and Ca2+ ions.

Opto-XR proteins are chimeric fusions of bovine Rhodopsin and adrenergic G-Protein Coupled Receptors allowing optical control of GPCR signalling cascades. Proteins are activated by 500nm light.

Case12
Case12 genetically encoded sensor is based on the circularly permutated fluorescent protein (cpFP) fused to or inserted into calcium sensitive (calmodulin) domain. Such Ca2+ sensors were constructed by fusing calmodulin and its target peptide M13 (fragment of myosin light chain kinase) to cpFP. In the presence of Ca2+, calmodulin binds to the M13 peptide, causing conformational changes in the vicinity of the chromophore and thereby influencing cpFP fluorescence.

Cameleon
Fluorescence resonance energy transfer (FRET)-based Ca2+ indicator. It was created by fusing BFP, calmodulin, calmodulin-binding peptide M13 and EGFP. In the presence of calcium, Ca2+ binds to M13, which enables calmodulin to wrap around the M13 domain. This brings the two GFP-variant proteins closer to each other, which increases FRET efficiency between them.

CHS4
Chicken Hypersensitive Site 4 Insulator element. The CHS4 insulator element was initially identified at the extreme 5’ end of the chicken β-globin locus where it acts as a domain insulator to insulate proximal genes from the effects of locus control regions present in the β-globin domain. The use of the CHS4 domain in recent years has been in the integration of the domain into expression constructs for stable transfection of mammalian cells. Here it can serve two purposes. It may be used to insulate endogenous genes from the effects of plasmid encoded promoter regions (here the region has been used to prevent insertion activation of genes, when virus mediated transduction of cells is performed). The region has also been described as preventing the epigenetic silencing of inserted genes by heterochromatin closing, thus ensuring the stable expression of inserted genes in transfected cells. Incorporation of this element into the construct would be carried out only in vector based transformations, and the element will be inserted at both ends of the construct where it would be expected to prevent the unintended insertion of genomic genes by promoters in the construct.

eGFP
Enhanced Green fluorescent protein EGFP. The nucleic acid sequence encoding EGFP is included for the expression of EGFP in transfected cells. EGFP has a long history of safe use as a fluorescent reporter protein. No attempt will be made to purify the protein, which will only be expressed in the NT2 cells. GFP is unlikely to pose a risk to the operator or environmental organisms as preliminary data on the deliberate administration of GFP to weaned rats suggested that GFP exhibits low allergenicity and is not likely to represent a health risk (Richards et al 2003).

Cyan / mCherry fluorescent protein
Both Cyan fluorescent protein and Cherry fluorescent protein nucleic acid sequences have been derived from anemone fluorescent protein by site directed mutagenesis. As members of the newer generation of fluorescent reporter proteins, little toxicological data exists on the proteins themselves, but both proteins share a great deal of homology with the eGFP protein and have a history of safe use as fluorescent reporters, including their expression in transgenic animals with no detrimental effects.

hUBC Promoter
The Human Ubiquitin C promoter is a DNA promoter sequence of human origin, which drives expression of the Ubiquitin c protein in mammalian cells. When used to drive expression of reporter genes, the promoter would be expected to result in moderate expression of controlled genes in a constitutive manner in most mammalian cells.

Syn1 Promoter
The Hyman Synapsin 1 promoter is a DNA promoter sequence of human origin containing the 21 bp Neuron restrictive silencer element, restricting the expression of genes from this promoter to neural cells or cells expressing RE1 silencing transcription factor. In neuronal cells this promoter would be expected to drive moderate levels of transcription, and hence production of the target protein. Virtually no protein production would be expected in non target cells.

Oct4 Promoter
The Oct4 promoter is the DNA sequence of the human Oct 4 promoter. The promoter directs expression of the Pou domain protein Oct4 in stem cells. Oct4 expression is seen in undifferentiated stem cells until epigenetic modification of the promoter inactivates transcription of Oct4 with the resulting differentiation of the cells. In undifferentiated stem cells it would be expected that this promoter would drive moderate level expression of the downstream fluorescent reporter gene. Upon differentiation of such cells or after transfection into non stem cell lines, no expression of the downstream gene would be expected.

GFAP promoter
The GFAP promoter drives expression of GFAP (glial fibrillary acidic protein) almost exclusively in astrocytes. Expression of fluorescent reporter genes from this promoter would be expected to be limited to astrocytic cells resulting in moderate expression of the reporter protein. Expression in non astrocytic cell lines would not be expected.

Lentivirus vectors derived from HIV will be second and third generation vectors for expression of ChR/OptoXR, e.g. pLenti-CaMKIIa-hChR2(E123T-H134R)-EYFP, pLenti-CaMKIIa-hChR2-EYFP-WPRE (Karl Deisseroth, Stanford University). These are used to produce lentivirus particles by co-transfection with helper constructs psPAX2 and pmd2g, in which gag-pol (third generation vectors) or gag-pol and pro (second generation vectors) and an envelope protein are expressed from separate co-transfected plasmids in 293FT cells (Natacha Klages et al 2000). All vectors are designed to minimize the chance of recombination events that could incorporate the helper functions to generate a replication-competent virus. Only “self-inactivating” (SIN) lentivirus vectors will be used; these have a deletion within the U3 region of the 3'LTR, which removes enhancer and promoter sequences. Upon completion of one life-cycle from the RNA genome of the virus particle, via reverse transcription to integration into chromosomal DNA, the deleted U3 region is copied to the 5'LTR. As a result, the 5'LTR becomes incapable of transcribing full length viral genomes. This further reduces the possibility of oncogenic potential. Lentiviruses will generally be pseudotyped using the VSV-G envelope glycoprotein; this is widely used as it permits efficient transduction of a wide variety of cell types, and makes the virus particles relatively resistant to shear stress, facilitating their concentration by centrifugation if required to increase the titre.

Lentiviruses are generally considered less prone to cellular transformation than conventional MuLV-based retroviral vectors, although a high frequency of liver tumours has been produced in mice following foetal or neonatal virus administration. The precise cause remains debatable; the tumours appeared not to be associated with HIV-based vectors, and one hypothesis was that the WPRE present in some of the vectors may have been capable of expressing a partial “X-protein”, of which at least the full length version is considered oncogenic. Use of SIN vectors theoretically reduces the chance of activating oncogenes at the site of insertion into target cell DNA.

Adenoviruses
Replication-deficient adenovirus vectors are usually based on adenovirus E1-E3 deletion mutants. Deletion of the E1 gene region (both E1A and E1B) removes a region of the genome associated with cellular transformation and generates a vector that is not only replication-deficient but also cannot activate early phase gene expression. Cell lines that will be used to facilitate initial production, amplification, and titering of replication-incompetent adenovirus such as HEK293 cells contain a stably integrated copy of E1 that supplies the E1 proteins (E1a and E1b) in trans required to generate adenovirus.

The infectious nature of human adenovirus will permit spread by aerosol or ingestion. An individual may be also infected by injection (via sharps) or direct contact with existing wounds and mucosal membranes (e.g. eyes). However, the recombinant viruses are replication-defective, and thus their genomes would soon be lost from the vast majority of infected cells. Chromosomal integration of the adenoviral sequences is a rare event, in the region of one integration event per 10^4 exponentially growing infected cells. Although the numbers of cells undergoing replication in the respiratory tract at any one time is not precisely known, it is generally accepted that only a minor fraction of cells in the infected tissue will be infected. No extension of host range expected; the E1 deletion prevents replicative spread of the virus except in specially constructed cell lines that complement the E1 deletion.

The infectious nature of human adenovirus will permit spread by aerosol or ingestion. An individual may be also infected by injection (via sharps) or direct contact with existing wounds and mucosal membranes (e.g. eyes). However, the recombinant viruses are replication-defective, and thus their genomes would soon be lost from the...
The vast majority of infected cells. Chromosomal integration of the adenoviral sequences is a rare event, in the region of one integration event per 10^4 exponentially growing infected cells. Although the numbers of cells undergoing replication in the respiratory tract at any one time is not precisely known, it is generally accepted that only a minor fraction of cells in epithelial tissues of the respiratory tract are dividing and that the majority of the cells in epithelium are post-mitotic, on the differentiation pathway. It is our opinion that a considerable intake of virus would have to occur to produce an integration event in vivo. Even if such an integration event did occur, it is clear that the expression of CR2 would be insufficient to cause malignant change in a human cell. The risks of tumour formation by accidental infection with an adenovirus/CR2 recombinant must be very small. Nevertheless, appropriate precaution should be adopted to minimise the possibility of accidental infection.

**PcDNA3.1**

PcDNA3.1(+) and PcDNA3.1(-) are 5.4 kb vectors derived from pcDNA3 and designed for high-level stable and transient expression in mammalian hosts. High-level stable and non-replicative transient expression can be carried out in most mammalian cells. The vectors contain the following elements: Human cytomegalovirus immediate-early (CMV) promoter for high-level expression in a wide range of mammalian cells. Multiple cloning sites in the forward (+) and reverse (-) orientations to facilitate cloning. Neomycin resistance gene for selection of stable cell lines. Episomal replication in cells lines that are latently infected with SV40 or that express the SV40 large T antigen.

**pZsGreen1**

pZsGreen1 (Clontech) encodes ZsGreen1, a variant of the Zoanthus sp. green fluorescent protein (ZsGreen1) that has been engineered for brighter fluorescence. The ZsGreen1 coding sequence contains a series of silent base pair changes for optimal expression in mammalian cells. pZsGreen1-DR can be used to monitor transcription from different promoters and promoter/enhancer combinations inserted into the multiple cloning site (MCS), located upstream of the ZsGreen1-DR coding sequence. Downstream SV40 polyadenylation signals direct proper processing of the 3’ end of the ZsGreen1-DR mRNA. The vector backbone contains an SV40 origin for replication in mammalian cells expressing the SV40 large T antigen, a pUC origin of replication for propagation in E. coli, and an f1 origin for single-stranded DNA production. A neomycin-resistance cassette (NeoR) allows stably transfected eukaryotic cells to be selected using G418. This cassette consists of the SV40 early promoter, the neomycin/kanamycin resistance gene of Tn5, and polyadenylation signals from the Herpes simplex virus thymidine kinase (HSV TK) gene. A bacterial promoter upstream of the cassette expresses kanamycin resistance in E. coli. Without the addition of a functional promoter, this vector will not express ZsGreen1.

**pJTI Fast DEST (Invitrogen)**

The pJTI Fast Dest vector contains attR sites compatible with the attP sites in the pDONR vectors, for in vitro recombination of desired DNA inserts. The vector has a pUC origin of replication and also encodes ampicillin resistance under a bacterial promoter for propagation and selection E. coli. The vector is non-mobilisable in the E. coli host strain. The vector also encodes the ccdB gene which interferes with e. coli DNA Gyrase, preventing the growth of the parental vector in E. coli. The vector contains a PhiC31 attB recognition site for targeted integration of the vector into the mammalian genome in the presence of phage PhiC31 integrase. The vector contains no viral origin of replication for propagation in mammalian cells as it is intended to be used only for integration using PhiC31.

The vector also encodes a Hygromycin resistance gene under the control of the herpes simplex virus thymidine kinase promoter for selection of the integrated vector in mammalian cells, expression of which is terminated by the respective HSV Thymidine kinase polyadenylation signals.

**pJTI PhiC31 Int**

The pJTI PhiC31 Int vector encodes PhiC31 integrase from the streptomyces phage under the control of the cytomegalovirus immediate early promoter for high level expression in mammalian cells. The vector has no viral origin of replication for propagation in mammalian cells as it is intended to simply provide a temporal supply of the PhiC31 integrase by transient transfection of target cells. The plasmid has a pUC origin of replication for propagation in E. coli and encodes the ampicillin resistance gene (β lactamase) for selection in E. coli.

Plasmids would not be expected to confer any selective advantage to host cells from cloned elements. However, plasmids do encode antibiotic resistance. The risk of transfer of resistance to organisms in the wider environment would be expected to be low. Plasmid DNA does not contain mobilisation elements and would therefore not be expected to survive for prolong periods outside of lab culture. Bacterial hosts would not be expected to survive outside of lab culture. Thus persistance of plasmid DNA in the outside environment would be limited. Transfer between environmental organisms and the non mobilisable plasmid would be expected to be far less likely.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

No genetically modified organisms will be generated in the course of this project. Only organotypic brain slices obtained from mice will be used in this project.
The use of self inactivating lentiviral vectors effectively limits the virus to a single infective cycle thus after several changes of culture media the final drug selected cells lines will not contain infectious viral particles and could be handled on the bench if required, for cell fixing and cell staining protocols. Imaging of virally transformed cells will not take place until at least 4 weeks post drug selection for stable clones by which time no viral particles would be expected to remain. Hence stably transduced cell lines could be handled under class one conditions for imaging purposes. However this derogation only applies to supervised monitoring of the cell lines. In all other aspects such as storage and disposal level 2 containment will be applied as outlined in the risk assessment.

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

<table>
<thead>
<tr>
<th>Description</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>The production of aerosols is not intended and will be minimised by using capped tubes and flasks in sealed centrifuge buckets. All waste and contaminated glassware and plastics will be autoclaved according to HSE requirements prior to disposal or cleaning and re-use in the 6th floor autoclave. No sharps will be used during the work thus minimising the risk of operator contamination. In the case of accidental spillages of culture media containing cells, the contaminated area can be effectively disinfected with 1% Virkon, and the small volume inherently prevents the spread of contamination to the wider environment.</td>
<td></td>
</tr>
</tbody>
</table>

1% Virkon will be used for most surface decontamination. Disposable plastic tips for micropipettors, may be decontaminated by drawing up Virkon disinfectant, and soaking in Virkon for a minimum of 20 minutes. Disposable plastic pipettes may also be decontaminated by immersion in Virkon as above.

All tissue culture will be carried out in a designated laminar flow hood with filters appropriate for cells of category Biosafety level 2. Safety cabinets are tested and maintained on a regular schedule; class 2 cabinets have a KI discus test and maintenance every 6 months, for class I cabinets this is on an annual basis. The tissue culture expression will be on a small scale of less than $10^8$ cells. Levels of protein expression are unlikely to exceed 1mg/liter. All tissue culture waste will be autoclaved. No sharps will be used. The designated incubator for culture of virally infected cells will be equipped for wet heat sterilization.

Warning lights, and chart recorder, indicate whether or not the autoclave run has achieved the appropriate temperature for the required time. The autoclave is run by trained staff, who are instructed to treat waste as still contaminated if the autoclave run was not to specifications. Under such circumstances the waste would be autoclaved again, after rectifying any reason for the malfunction. The autoclave is inspected and serviced on a regular basis.

All liquid waste is treated by autoclaving at 130°C for 30 minutes, before disposal to drains. Disposable solid waste which is or may be contaminated with GMOs is also inactivated by autoclaving at 130°C for 30 minutes, before removal as “clinical waste” by specialist contractors, with final disposal by incineration.

**Expected degree of kill:**

Autoclaving achieves effectively 100% kill of all GMOs.

The manufacturer’s information indicates efficacy of Virkon against a variety of adenoviruses at 1% concentration, and also against a number of strains of E. coli at dilutions ranging from 1% to 0.125%. Colleagues at Birmingham University have demonstrated that 15 minutes exposure to 1% Virkon achieves >4 log10 kill for adenovirus-infected cell pellets, and >6 log10 kill of adenovirus seed stocks. The effectiveness of Virkon in the deactivation of plasmid DNA was tested with plasmids of a similar size to those that will be created in the work outlined above.

Incubation of plasmid DNA in a 1% solution of Virkon for 2 minutes reduced the transformation efficiency of plasmid DNA in transforming E coli cells from $2.8 \times 10^6$ transformants / µg DNA to $4.2 \times 10^4$ transformants / µg DNA. Incubation for 20 minutes in this 1% Virkon solution completely abolished the ability of the DNA to transform cells. There is no reason to suggest that the plasmids described in this work will be less susceptible to chemical inactivation than those tested.

### Project Additional Information

#### Purposes of the contained use

| To determine the role of transglutaminase in normal cell processes and in models of disease. |
| To deliver shRNA into a variety of transglutaminase-expressing cell types to reduce expression and examine phenotype. To introduce wild-type and mutant transglutaminase proteins into cells to determine alterations in phenotype. |

#### Recipient or parental organism

| A variety of mammalian cell lines including mouse 3T3 fibroblasts, human dermal fibroblasts, mouse embryonic, ECV304, human osteoblasts, chinese hamster ovary (CHO), HEK 293T, human umbilical vascular endothelial cells (HUVEC), IB3-1 airway epithelial cell line, C38 airway epithelial cell line, Beas-2b, Calu-3, 16-HBE, THP1 monocytes PC12, endothelial cell lines. |

#### Host/vector system

| We will use 2nd and 3rd generation lentiviruses to allow gene transfer of transglutaminase genes under the control of viral promoters or inducible promoters (e.g. tetracycline responsive promoters) in cells. Control lentiviruses may also be generated expressing fluorescent proteins. The following lentiviral vectors will be used: pLenti™6, pLKO.1, pLKO-Tet-On, pLenti-Ill-UbC, pFB-ERV, pCFB-EGSH, pLVX-Tet-On/Off Advanced, pLVX-Tight-Puro, psPAX2, pMD2G, FG12, FIGB & FUGW. Other associated plasmids are as follows: pLP1, pLP2, pLP/VSVG, pcDNA3.1(+). |

#### Origin & function

**Transglutaminases**

are a family of enzymes (EC 2.3.2.13) that catalyze the formation of a covalent bond between a free amine group (e.g., protein- or peptide-bound lysine) and the gamma-carboxamide group of protein- or peptide-bound glutamine. Bonds formed by transglutaminase exhibit high resistance to proteolytic degradation.

Transglutaminase mutants will be functionally inactive mutants, to allow determination of the effects of these mutations on the expression, localisation and function of transglutaminases in normal physiology and disease models. shRNA will be used to reduce transglutaminase expression in cell models.

**TGM1**

Keratinocyte transglutaminase is highly expressed in terminally differentiated epidermal keratinocytes where it is responsible for formation of a stable cross-linked corneocyte layer.

**TGM2**

Tissue transglutaminase is expressed ubiquitously. It plays a role in wound healing, apoptosis, extracellular matrix deposition and stabilisation, cell attachment and survival. It is involved in a variety of pathologies such as celiac disease, tissue fibrosis, cancer, neurodegenerative disorders. As well as its transglutaminase activity, TG2 also has GTPase activity, functioning as a G protein participating in signaling processes. It also acts as a kinase, protein disulfide isomerase and deamidase.

**TGM3**

Epidermal transglutaminase, like TGM1, is involved in cross-linking of proteins in the skin cornified envelope.

**TGM6**

Member of the transglutaminase family which is present in the neurological cells and could be responsible for neurological disorders.

**FXIIIa**

Factor XIIIa is the transglutaminase subunit of Factor XIII. It is responsible for the stabilisation of polymerised fibrin in blood clots.
**eGFP**
Enhanced Green fluorescent protein EGFP. The nucleic acid sequence encoding EGFP is included for the expression of EGFP in transfected cells. EGFP has a long history of safe use as a fluorescent reporter protein. No attempt will be made to purify the protein. GFP is unlikely to pose a risk to the operator or environmental organisms as preliminary data on the deliberate administration of GFP to weaned rats suggested that GFP exhibits low allergenicity and is not likely to represent a health risk (Richards et al 2003).

**Cyan/Yellow fluorescent protein**
Cyan and yellow fluorescent protein nucleic acid sequences have been derived from anemone fluorescent protein by site directed mutagenesis. As members of the newer generation of fluorescent reporter proteins, little toxicological data exists on the proteins themselves, but they share a great deal of homology with the eGFP protein and have a history of safe use as fluorescent reporters, including their expression in transgenic animals with no detrimental effects.

**shRNA**
Short synthetic oligonucleotides based on the sequences for mouse and human TGM1, TGM2, TGM3, TGM6 and FXIIIA.

### Evaluation of foreseeable effects

In cell lines transfected via lentiviral infection, expression of high levels of fluorescent proteins such as EGFP would not be expected to alter the potential pathogenicity of the cells. Expression of EGFP would be expected to be contained within cells, and in comparison to expression of the protein in bacteria or yeast, total protein expression will be at relatively low levels. No attempt to purify the protein will be made. EGFP has been shown to demonstrate low allergenicity, and it’s expression in the cell line would not be expected to in anyway interfere with the normal immune response of an operator, to non operator derived mammalian cells.

With respect to the viral work, minimal hazard would be expected of the viral plasmids in E. coli where generation of infectious viral particles would be impossible.

Expression of the transglutaminase proteins TGM1, TGM2, TGM3, TGM6 and FXIIIA, which are normal cellular products and their functionally-inactive mutants in eukaryotic cells is not expected to alter the cells in such a way that could be hazardous to human health.

The main hazard is associated with the lentiviruses that will be generated in packaging cells. The viruses will be capable of infecting human cells, with the consequent insertion of the vector genome into chromosomal DNA. The main hazard is the possibility of oncogene activation at the site of integration. Consideration of the experiences from human gene therapy clinical trials suggests this risk is low, as any accidental exposure would involve many logs fewer virus particles, nevertheless precautions to avoid exposure are appropriate. A further potential hazard is the generation of replication-competent virus. As described above, use of split packaging systems for retrovirus, and second / third generation SIN vector systems for lentivirus, makes this highly unlikely. The use of self inactivating lentiviral vectors effectively limits the virus to a single infective cycle thus after several changes of culture media the final drug selected cells lines will not contain infectious viral particles and could be handled on the bench if required, for cell fixing and cell staining protocols.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**For only GMMs - application for any derogation from full containment for the Class of activity.  (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

It is the responsibility of the person undertaking the work with the GMM to check the correct operation of equipment used, on every occasion. Latex gloves, culture vessels, centrifuge tubes etc should be inspected before and during use, to ensure leak-free operation. The work area and equipment should be checked before and after use for any spillages which might contain GMMs, and appropriate remedial action taken if necessary. The work surface must be decontaminated after use.
Project supervisors have a responsibility to ensure that persons in their group are following the specified containment and control measures, and arranging for appropriate training of new workers.

The work will be carried out in specialist laboratories (MB633, MB634 and MB635) with restricted access through a number-coded security lock and double-doors. Work with live virus particles will be contained to a single laboratory (either MB634 or MB635) with no carriage of virus-containing materials between laboratories. Access will only be available to individuals with a working knowledge of tissue culture and required safety procedures. Signage stating the level of work and the necessary caution will be displayed prominently. There is an operator washing/changing facility outside of the inner culture laboratory.

Designated laboratory coats or tissue culture gowns. Any cuts or abrasions should be appropriately protected (e.g. waterproof dressing or protective gloves).

Storage in appropriately labelled, screw-capped plastic tubes, in secondary boxes within freezer in containment lab. Tube contained within an appropriate secondary container able to contain any potential leaks, if transport between labs is required.

The production of aerosols is not intended and will be minimised by using capped tubes and flasks. All waste and contaminated glassware and plastics will be autoclaved according to HSE requirements prior to disposal or cleaning and re-use in the 6th floor autoclave. No sharps will be used during the work thus minimising the risk of operator contamination. In the case of accidental spillages of culture media containing cells, the contaminated area can be effectively disinfected with 1% Virkon, and the small volume inherently prevents the spread of contamination to the wider environment.

1% Virkon used for most surface decontamination. Disposable plastic tips for micropipettors, may be decontaminated by drawing up Virkon disinfectant, and soaking in Virkon for a minimum of 20 minutes. Disposable plastic pipettes may also be decontaminated by immersion in Virkon as above.

All tissue culture will be carried out in a designated laminar flow hood with filters appropriate for cells of category Biosafety level 2. Safety cabinets are tested and maintained on a regular schedule; class 2 cabinets have a KI discus test and maintenance every 6 months, for class I cabinets this is on an annual basis. The tissue culture expression will be on a small scale of less than 10^8 cells. Levels of protein expression are unlikely to exceed 1mg/liter. All tissue culture waste will be autoclaved. No sharps will be used. The designated incubator for culture of virally infected cells will be equipped for wet heat sterilization.

Warning lights, and chart recorder, indicate whether or not the autoclave run has achieved the appropriate temperate for the required time. The autoclave is run by trained staff, who are instructed to treat waste as still contaminated if the autoclave run was not to specifications. Under such circumstances the waste would be autoclaved again, after rectifying any reason for the malfunction. The autoclave is inspected and serviced on a regular basis.

All liquid waste is treated by autoclaving at 130°C for 30 minutes, before disposal to drains. Disposable solid waste which is or may be contaminated with GMOs is also inactivated by autoclaving at 130°C for 30 minutes, before removal as “clinical waste” by specialist contractors, with final disposal by incineration.

Expected degree of kill:
Autoclaving achieves effectively 100% kill of all GMOs.

The manufacturer’s information indicates efficacy of Virkon against a variety of adenoviruses at 1% concentration, and also against a number of strains of E. coli at dilutions ranging from 1% to 0.125%. Colleagues at Birmingham University have demonstrated that 15 minutes exposure to 1% Virkon achieves >4 log10 kill for adenovirus-infected cell pellets, and >6 log10 kill of adenovirus seed stocks. The effectiveness of Virkon in the deactivation of plasmid DNA was tested with plasmids of a similar size to those that will be created in the work outlined above.

Expected degree of kill:
Incubation of plasmid DNA in a 1% solution of Virkon for 2 minutes reduced the transformation efficiency of plasmid DNA in transforming E coli cells from 280000 transformants / µg DNA to 420000 transformants / µg DNA. Incubation for 20 minutes in this 1% Virkon solution completely abolished the ability of the DNA to transform cells. There is no reason to suggest that the plasmids described in this work will be less susceptible to chemical inactivation than those tested.
Reviewer 1: "as a number of labs are mentioned it may be best to try to limit this 1 or two. If they really do need to transport the virus from their main lab to their tissue culture then they need to spell out how they will do this ie double sealed containers, clean gloves labcoats in different areas etc."

Reviewer 2: "it would be wise to contain the work in one lab, rather than allowing it to proceed in 633, 634 and 635. Equally, I note that the cell line 293FT should be "at least" level 2 containment, which is another reason for careful, localised containment."

Reviewer 3: "As far as I can see the application appears to be in order. The risk assessment/safety precautions/containment seem appropriate. A well established disinfectant (Virkon) with BS activity is in place for waste material and hard surface disinfection."

Reviewer 4: "The only thing I would say is to stipulate where the viral work will be performed – at the moment it is spread over 3 labs in which the project is being conducted but I think it should be narrowed down to one lab if not one Microbiological safety cabinet. It then partially segregates the higher risk work from the other projects and the rest of the work that is being conducted, thereby giving greater control."

Reviewer 5: "this is widely used technique and so the potential hazards are well understood and the control mechanisms are widely used. Thus as far I can tell, this application seems to be in order."

Reviewer 6: "the work should be restricted (where possible) to one laboratory and perhaps in a clearly demarcated area within. If this cannot be avoided and transport between areas is necessary, a stringent procedure needs to be in place."

Applicant's reply: The risk assessment has been modified to make it clear that no transport of virus will occur between laboratories.

Project Additional Information

Purposes of the contained use

To test the hypothesis that astrocytes and specifically astrocytic gliotransmitter release is essential for synaptic experience-dependent plasticity (EDP) measured in cortical neurones.

2. To determine if, and how, the optical induction of astrocyte activity can be used to manipulate/control plasticity.

Recipient or parental organism

Algae for Channel Rhodopsin
Jelly fish for mCherry and eYFP
Humans for GFAP, CamKII and synapsin promoter
Bacteria for β-Lactamase resistance
Cytomegalovirus for CMV promoter
Bovine Rhodopsin β2 adrenergic receptor
Bovine Rhodopsin α1 adrenergic receptor
Gag-pol and Pro from HIV1
Chicken Gallus gallus for CHS4 insulator element
VSV-G vesicular stomatitis virus from simian virus
Yeast for GAL4 sequence
Woodchuck Hepatitis Virus for WPRE element
Human for eIFα
Human for NFκB p65 protein element
CASE 12 modified eYFP jelly fish

**Origin & function**

Channelrhodopsins are a subfamily of opsin proteins that function as light-gated ion channels. They serve as sensory photoreceptors in unicellular green algae, controlling phototaxis, i.e. movement in response to light. Expressed in cells of other organisms, they enable the use of light to control intracellular acidity, calcium influx, electrical excitability and other cellular processes. Three channelrhodopsins are currently known: Channelrhodopsin-1 (ChR1), Channelrhodopsin-2 (ChR2), and Volvox Channelrhodopsin (VChR1). All known Channelrhodopsins are unspecific cation channels, conducting H+, Na+, K+, and Ca2+ ions.

Opto-XR proteins are chimeric fusions of bovine Rhodopsin and adrenergic G-Protein Coupled Receptors allowing optical control of GPCR signalling cascades. Proteins are activated by 500nm light.

Case12/GCaMP

Case12 and GCaMP are genetically encoded sensors based on the circularly permuted fluorescent protein (cpFP) fused to a calcium sensitive (calmodulin) domain. Such Ca2+ sensors were constructed by fusing calmodulin and its target peptide M13 (fragment of myosin light chain kinase) to cpFP. In the presence of Ca2+, calmodulin binds to the M13 peptide, causing conformational changes in the vicinity of the chromophore and thereby influencing cpFP fluorescence.

eGFP

The nucleic acid sequence encoding Enhanced Green Fluorescent Protein (EGFP) is included for the expression of EGFP in transfected cells. EGFP has a long history of safe use as a fluorescent reporter protein. No attempt will be made to purify the protein, which will only be expressed in the brain cells. GFP is unlikely to pose a risk to the operator or environmental organisms as preliminary data on the deliberate administration of GFP to weaned rats suggested that GFP exhibits low allergenicity and is not likely to represent a health risk (Richards et al 2003).

Cyan / mCherry fluorescent protein

Both Cyan fluorescent protein and Cherry fluorescent protein nucleic acid sequences have been derived from anemone fluorescent protein by site directed mutagenesis. As members of the newer generation of fluorescent reporter proteins, little toxicological data exists on the proteins themselves, but both proteins share a great deal of
homology with the eGFP protein and have a history of safe use as fluorescent reporters, including their expression in transgenic animals with no detrimental effects.

**hUBC Promoter**
The Human Ubiquitin C promoter is a DNA promoter sequence of human origin, which drives expression of the Ubiquitin c protein in mammalian cells. When used to drive expression of reporter genes, the promoter would be expected to result in moderate expression of controlled genes in a constitutive manner in most mammalian cells.

**Syn1 Promoter**
The Hyman Synapsin 1 promoter is a DNA promoter sequence of human origin containing the 21 bp Neuron restrictive silencer element, restricting the expression of genes from this promoter to neural cells or cells expressing the RE1 silencing transcription factor. In neuronal cells this promoter would be expected to drive low to moderate levels of transcription, and hence production of the target protein. Virtually no protein production would be expected in non-target cells.

**GFAP promoter**
The GFAP promoter drives expression of GFAP (glial fibrillary acidic protein) almost exclusively in astrocytes. Expression of fluorescent reporter genes from this promoter would be expected to be limited to astrocytic cells resulting in moderate expression of the reporter protein. Expression in non-astrocytic cell lines would not be expected.

**2Xsyn1 promoter**
This promoter utilises artificial transcriptional activators to enhance transgene expression from the Syn1 promoter. This strategy involves cell-type-specific expression of the strong chimeric activator GAL4p65 consisting of the transactivation domain of nuclear factor-kappa B (NFκB) p65 protein fused to the DNA-binding domain of the GAL4 protein from yeast. GAL4p65 production is limited to neuronal cells as it is under the control of the Syn1 promoter. The Gal4p65 protein binds to multiple Gal4-binding sites placed upstream of the second copy of the Syn1 cell-specific promoter, leading to amplified expression of the transgene (GFP, YFP, CFP, RFP, ChR2). The Gal4 DNA binding domain, is specific to the promoter sequence, thus expression amplification from the p65 protein will be limited to the inserted transgene.

**Somatostatin promoter**
This promoter drives gene expression in neuroendocrine neurons of the periventricular nucleus of the hypothalamus. Expression of genes from this promoter would be expected to be limited to neuroendocrine neurons of the periventricular nucleus of the hypothalamus resulting in moderate expression of the reporter protein.

**WPRE (Woodchuck Posttranscriptional Regulatory Element) from the**
Woodchuck hepatitis virus is placed directly downstream of the gene of interest. It increases the nuclear export of the RNA transcript thus enhancing transgene expression (Mastroyiannopoulos et al., 2005; Zufferey et al., 1998).

cPPT (Polypurine Tract) from the HIV-1 integrase gene increases the copy number of lentivirus integrating into the host genome (Park, 2001) and allows for a two-fold increase in viral titre. WPRE and cPPT together produce at least a fourfold increase in protein expression in most cell types, compared to other vectors that do not contain these elements.

EIFα
Human promoter for lower but more ubiquitous expression in cells and in vivo with lower risk of promoter shut down.

V5 Epitope Tag for detecting the recombinant protein of interest (Southern et al., 1991)

Blasticidin (bsd) resistance gene for selecting stably transduced mammalian cell lines (Kimura et al., 1994)

Chloramphenicol resistance gene (CmR) located between the two attR sites for Counter selection

attR sites Bacteriophage λ-derived DNA recombination sequences that permit recombinational cloning of the gene of interest / miR/sh RNA and promoter of interest from GatewayR entry clones (Landy, 1989).

ccdB gene Produces the ccdB protein which targets E. coli DNA gyrase, preventing DNA replication of bacterial cells thus permitting negative selection of the plasmid

U3/HIV-1 truncated 3' LTR Allows viral packaging but self-inactivates the 5' LTR for biosafety purposes (Dull et al., 1998). The element also contains a polyadenylation signal for transcription termination and polyadenylation of mRNA in transduced cells.

**Evaluation of foreseeable effects**

It would not be expected that expression of the inserted gene would occur in bacterial hosts or cells used for viral production as proteins are under the control of cell specific promoters. Expression will only be expected to occur in neuronal or astrocytic cells where moderate expression of the optogenetic constructs would be expected from the cells in which the virus has been integrated.

Transformed E. coli cells would not be expected to alter the pathogenicity of the original host. The cells would still have limited survival in human or other hosts, as such the acquired resistance to the antibiotic kanamycin should not pose a risk to human health as the cells should be incapable of establishing an infection.

With respect to the Viral work minimal hazard would be expected of the viral plasmids in E. coli where generation of infectious viral particles would be impossible.

The produced ChannelRhodopsin –XFP, Opto-XR, Case12, are unlikely to pose a risk to the host, operator or environmental organisms.

The main hazard is associated with the packaging of lentviruses in cells. The viruses will be capable of infecting human cells, with the consequent insertion of the vector genome into chromosomal DNA. The main hazard is the possibility of oncogene activation at the site of integration. Consideration of the experiences from human gene therapy clinical trials suggests this risk is low, as any accidental exposure would involve many logs fewer virus particles, nevertheless precautions to avoid exposure are appropriate. A further potential hazard is the generation of replication-competent virus. As described above, use of split packaging systems for retrovirus, and second / third generation SIN vector systems for lentivirus, makes this highly unlikely. The use of self-inactivating lentiviral vectors effectively limits the virus to a single infective cycle thus after several changes of culture media/natural clearance in mice/rats, the final drug selected cells lines/mice/rats will not contain infectious viral particles and could be
The majority of individuals appear to undergo primary infection with Ad5 in childhood, and both humoral and cell-mediated immunity combine to prevent further productive infection in the adult. Such immunity will reduce viral entry into cells, and hasten the immune destruction of infected cells, in the event of accidental human contamination with the recombinant virus. Working practices are designed to minimise the risk of human contamination.

The recombinant virus will not be capable of autonomous spread in the event of accidental operator infection. In the unlikely event that an operator were to receive an 'infectious dose' of virus via the respiratory tract, it would only lead to replication of the GM virus if they had a concurrent infection with wild type virus, and the same cells took up both the wild type and GM viruses. It is known that the subgroup C serotypes (includes Ad5) can persist in the adenoids and tonsils following primary infection, but the mechanism by which the virus is maintained is not known. However, the number of virus-containing cells is very low, and most virus remains cell-associated, and can only be detected after prolonged incubation of the tissue in vitro. Thus the risk of double infection with recombinant and wild type virus is considered to be very low. Attempts to detect such complementation by dual infection in the cotton rat model gave negative results. The possibility of co-infection in the gut must also be considered; while it is known that in some instances there is prolonged shedding of subgroup C viruses via the alimentary canal, there is no evidence that there is long term persistence of the virus, so the opportunity for co-infection of a single cell with both wild type and recombinant is considered remote. In conclusion, it seems unlikely that accidental human infection with the replication-defective adenovirus would result in its rescue, either with helper virus or as a replication-competent recombinant; or that human-to-human transfer would take place.

Contents and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

It is the responsibility of the person undertaking the work with the GMM to check the correct operation of equipment used, on every occasion. Nitrile gloves, culture vessels, centrifuge tubes etc should be inspected before and during use, to ensure leak-free operation. The work area and equipment should be checked before and after use for any spillages which might contain GMMs, and appropriate remedial action taken if necessary. The work surface must be decontaminated after use.

Project supervisors have a responsibility to ensure that persons in their group are following the specified containment and control measures, and arranging for appropriate training of new workers.

Designated laboratory coats or tissue culture gowns. Any cuts or abrasions should be appropriately protected (e.g. waterproof dressing or protective gloves).

Storage in appropriately labelled, screw-capped plastic tubes, in secondary boxes within freezer in containment lab. Tube contained within an appropriate secondary container able to contain any potential leaks, if transport between labs is required.

The production of aerosols is not intended and will be minimised by using capped tubes and flasks. All waste and contaminated glassware and plastics will be autoclaved according to HSE requirements prior to disposal or cleaning and re-use in the 6th floor autoclave. No sharps will be used in the majority of this work thus minimising the risk of operator contamination. In the case of accidental spillages of culture media containing cells, the contaminated area can be effectively disinfected with 1% Virkon, and the small volume inherently prevents the spread of contamination to the wider environment.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

1% Virkon used for most surface decontamination. Disposable plastic tips for micropipettors, may be decontaminated by drawing up Virkon disinfectant, and soaking in Virkon for a minimum of 20 minutes. Disposable plastic pipettes may also be decontaminated by immersion in Virkon as above.

All tissue culture will be carried out in a designated microbiological safety cabinets with filters appropriate for cells of category Biosafety level 2. Safety cabinets are tested and maintained on a regular schedule; safety cabinets have a KI discus test and maintenance every 6 months, for class I cabinets this is on an annual basis. The tissue culture expression will be on a small scale of less than 108 cells. Levels of protein expression are unlikely to exceed 1mg/litre. All tissue culture waste will be autoclaved.
The designated incubator for culture of virally infected cells will be equipped for wet heat sterilization.

Warning lights, and chart recorder, indicate whether or not the autoclave run has achieved the appropriate temperate for the required time. The autoclave is run by trained staff, who are instructed to treat waste as still contaminated if the autoclave run was not to specifications. Under such circumstances the waste would be autoclaved again, after rectifying any reason for the malfunction. The autoclave is inspected and serviced on a regular basis.

All liquid waste is treated by autoclaving at 121°C for 30 minutes, before disposal to drains. Disposable solid waste which is or may be contaminated with GMOs is also inactivated by autoclaving at 121°C for 30 minutes, before removal as “clinical waste” by specialist contractors, with final disposal by incineration.

Expected degree of kill:
Autoclaving achieves effectively 100% kill of all GMOs.
The manufacturer's information indicates efficacy of Virkon against a variety of adenoviruses at 1% concentration, and also against a number of strains of E. coli at dilutions ranging from 1% to 0.125%. Colleagues at Birmingham University have demonstrated that 15 minutes exposure to 1% Virkon achieves >4 log10 kill for adenovirus-infected cell pellets, and >6 log10 kill of adenovirus seed stocks. The effectiveness of Virkon in the deactivation of plasmid DNA was tested with plasmids of a similar size to those that will be created in the work outlined above.

Incubation of plasmid DNA in a 1% solution of Virkon for 2 minutes reduced the transformation efficiency of plasmid DNA in transforming E coli cells from 2.8 x 106 transformants / µg DNA to 4.2 x104 transformants / µg DNA. Incubation for 20 minutes in this 1% Virkon solution completely abolished the ability of the DNA to transform cells. There is no reason to suggest that the plasmids described in this work will be less susceptible to chemical inactivation than those tested.Class II biological safety cabinets will be used for handling of mouse brain slices/cells, in order to maintain sterility for subsequent experiments.

## Project Additional Information

### Purposes of the contained use

The purpose is to manipulate the genetic material of reproductive and vascular tissues, organs and relevant primary cells and cell-lines to create models that will be used to research normal physiological mechanisms and disease processes. The overall object is to generate the adenoviruses, adeno-associated viruses, lentiviruses and retroviruses carrying genetic material and use these viruses in the cells and animals for the study of reproductive and vascular function and diseases.

### Recipient or parental organism

- Cytomegalovirus for CMV promoter
- Woodchuck Hepatitis Virus for WPRE element
- Human for cystathionine gamma lyase (CSE)
- Human for angiopoietin-1 and -2 (Ang-1, -2)
- Mouse for soluble Flt-1, endoglin (sFlt-1, sEng)
- Human for micro RNA
- Human for VEGF family, LRIG1, HO-1, BVR and eNOS
- Jelly fish for mCherry and eYFP
- Bacteria for β-Lactamase resistance

### Host/vector system

For hosts:
- E. coli DH5α Genotype
- E. Coli Stbl3™ Genotype
- 293FT cells
For Vectors:
(i) Standard cloning vectors for manipulation and propagation in E.coli, such as PCR-8 and pENTR 5 TOPO.
(ii) Standard reporter plasmids and expression plasmids, such as pcDNA3.1.
(iii) Tetracycline inducible system vector, pBl-G.
(iv) Adeno-associated virus Type-2, The pHelper AAV system (Stratagene) employs a series of 3 plasmids: pHelper, pRC and pCMV.
(v) Lentivirus, pCLlsin.PPT.hPGK.GFP.pre, pRSV-Rev and pMDLg/pRRE.
(vi) Retroviruses, two systems, (1) The MFG retrovirus vector uses a series of 3 plasmids pMD.MLV(gag-pol), pMD.G(env) and pMMP. (2) LNCX plasmid.

Origin & function
The VEGF family
The VEGF family (VEGF-A –B –C -D –E and placenta growth factor/PIGF) and their cognate receptors (Flt-1, Flt-4, KDR and neuropilin-1/2) are key mediators of angiogenesis, vascular remodeling and maintenance [Yancopoulos et al., (2000) Nature. 407:242]. VEGFs bind the high-affinity Flt-1, Flt-4 and KDR tyrosine kinase receptors, which are largely restricted to endothelial cells, and their functional activities include increased proliferation, migration, and procoagulant activity [Yancopoulos et al., (2000) Nature. 407:242].

The neuropilins (neuropilin-1/-2) have recently been shown to modulate VEGF receptor signaling in endothelium to enhance the activities of KDR and inhibit the actions of Flt-1, in addition to mediating the effects of VEGF in neurons [Neufeld et al., (2002) Trends Cardiovasc Med. 12:13]. Although the VEGF family members are associated with malignant progression through the promotion of tumor angiogenesis and metastasis, they have not been linked to the primary/initiating events involved in cell transformation.

Angiopoietins and Tie receptor families
The angiopoietins (Ang-1 to -4) act in concert with the VEGFs to co-ordinate vascular proliferation, differentiation and maintenance/integrity [Yancopoulos et al., (2000) Nature. 407:242]. Angiopoietins (the most physiologically significant of which are Ang-1 and Ang-2) bind to the Tie-2 receptor tyrosine kinase. Ang-1 activates Tie-2 leading to endothelial cell migration, sprout formation and survival in vitro; and reduces vessel permeability and promotes angiogenesis, vessel branching and stability in vivo. Whereas Ang-2 antagonises Ang-1/Tie-2 signalling and enhances angiogenesis in the presence of VEGF in vivo. Recently, it has been recognised that Ang-2 may also signal via Tie-2 to enhance endothelial cell survival [Yancopoulos et al., (2000) Nature. 407:242]. Tie-2 is an orphan endothelial receptor tyrosine kinase that has also been shown to promote endothelial cell survival [Kontos et al., (2002) Mol. Cell. Biol. 22:1704]. The Angiopoietins and Tie receptors have not been linked with cell transformation. The up-regulation of Ang-2 and autocrine stimulation of Tie-2 is thought to lead to initial regression of parasitized host vasculature that occurs during the development of some tumours [Holash et al., (1999) Science. 284:1994]. In established rodent tumour models Ang-1 and Ang-2 have been shown to either reduce or enhance angiogenesis/malignant progression.

Heme-oxygenase (HO-1/-2)
Heme oxygenase 1 (HO-1) is a rate-limiting enzyme, which catalyses the heme to the carbon monoxide (CO), iron and biliverdin/bilirubin. HO-1 has the cytoprotective function and can be induced by oxidant, apoptosis and inflammation. In angiogenesis, vascular endothelial growth factor (VEGF) up-regulates the expression of HO-1 in vascular endothelial cells, which promote the angiogenesis process and inhibit the preeclampsia [Gozzelino, et al., (2010) Annu Rev Pharmacol Toxicol. 50:323; Idriss, et al., (2008) J Am Coll Cardiol. 52:971].

Biliverdin Reductase
Biliverdin reductase (BVR) was firstly described as NADH-dependent enzyme that converts biliverdin to bilirubin [Schluchter and Glazer, (1997) J Biol Chem 272: 13562].

Cystathionine-γ-lyase (CSE), cystathionine-β-synthase (CBS), and 3-mercapto-sulfurtransferase (MST)

CBS and CSE are expressed in rat and human in utero tissues. Mice genetically deficient of H2S producing enzyme CSE leads to age-dependent hypertension, severe hyperhomocysteinemia, and impaired endothelium-dependent vasorelaxation [Yang et al., (2008) science 322:587]. The homozygous (CSE−/−) and heterozygous (CSE+/−) mutant mice were viable, fertile, and indistinguishable from their control wild-type littermates in terms of growth pattern. In addition, cardiac-specific overexpression of CSE (α-MHC-CGL-Tg mouse) significantly limits myocardial ischemia-reperfusion injury, which is associated with an inhibition of myocardial inflammation and a preservation of both mitochondrial structure and function after injury. [Elrod et al. (2007) Proc. Nat. Acad. Sci.: USA 104:15560]. It has been shown that although CBS−/− mice born at normal rate, but they often suffer from growth retardation, normally die within 5 weeks after birth [Watanabe et al., (1995) Proc. Nat. Acad. Sci.: USA 92:1585].

Endothelial Nitric Oxide Synthesis (eNOS)

Nitric oxideNitric oxide synthases (NOSs) are a family of eukaryotic enzymes that catalyze the production of nitric oxide (NO) from L-arginine. NOS is one of the most regulated enzymes in biology. There are three known isoforms, two are constitutive (cNOS) and the third is inducible (iNOS) [Majano et al., (2001) Hepatology; 34: 1218]. Endothelial NOS (eNOS) generates NO in blood vessels and is involved with regulating vascular function [Dudzinski et al., (2006) Annu. Rev. Pharmacol. Toxicol.; 46: 235; Ahmad et al., (2006) Circ. Res.; 99: 715]. eNOS is also associated with plasma membranes surrounding cells and the membranes of Golgi bodies within cells.

Leucine-rich repeats and immunoglobulin-like domains 1(LRIG1)

LRIG1 is a newly discovered integral membrane protein. The first LRIG transcript was discovered in mouse (also called lig-1) [Suzuki et al., (1996) J. Biol. Chem. 271:22522]. Disruption of LRIG1 gene leads to psoriasiform epidermal hyperplasia and LRIG1 inversely correlates with proliferative ability of epidermal keratinocytes. More recently, LRIG1 was showed as a negative attenuator of signaling by receptor tyrosine kinases [Gur et al., (2004) EMBO J. 23:3270] and negatively regulates EGFR, Met receptor, Ret receptor [Sweeney et al., (2004) J. Biol. Chem.279: 47050; Goldoni et al., (2007) Oncogene 26:368; Ledda et al., (2008) J Neurosci. 28:39]. Furthermore, LRIG1 interacts with EGFR via extracellular domain and subsequently causes receptor internalization and degradation. In our lab, LRIG1 has been show to be up regulated around three fold under pre-eclamptic condition (unpublished data).

LacZ

LacZ encodes β-galactosidase (LacZ), an intracellular enzyme that cleaves the disaccharide lactose into glucose and galactose [Fowler, Zabin, (1970) J. Biol. Chem. 245:5032]. β-galactosidase assay is used frequently in genetics, molecular biology for a blue-white screen, and other life sciences.

eGFP

The nucleic acid sequence encoding Enhanced Green Fluorescent Protein (EGFP) is included for the expression of EGFP in transfected cells. EGFP has a long history of safe use as a fluorescent reporter protein. No attempt will be made to purify the protein, which will only be expressed in the target cells. GFP is unlikely to pose a risk to the operator or environmental organisms as preliminary data on the deliberate administration of GFP to weaned rats suggested that GFP exhibits low allergenicity and is not likely to represent a health risk (Richards et al 2003).

mCherry fluorescent protein

Cherry fluorescent protein nucleic acid sequences have been derived from anemone fluorescent protein by site directed mutagenesis. As members of the newer generation of fluorescent reporter proteins, little toxicological data exists on the proteins themselves, but both proteins share a great deal of homology with the eGFP protein and have a history of safe use as fluorescent reporters, including their expression in transgenic animals with no detrimental effects.
Tetracycline inducible expression lentiviral system
TRE element and mini 35S promoter from pBI-G vector will be used to replace the hPGK promoter in pCCLsin.PPT.hPGK.GFP.pre to make a tetracycline inducible lentiviral vector. Tetracycline or Doxycycline is used to induce the target gene expression in this system. The TRE element and mini 35S act as promoter and drive the target gene expression, but have no transcriptional or translational products.

WPRE
(Woodchuck Posttranscriptional Regulatory Element) from the Woodchuck hepatitis virus is placed directly downstream of the gene of interest. It increases the nuclear export of the RNA transcript thus enhancing transgene expression (Mastroyiannopoulos et al., 2005; Zufferey et al., 1998).

cPPT
(Polypurine Tract) from the HIV-1 integrase gene increases the copy number of lentivirus integrating into the host genome (Park, 2001) and allows for a two-fold increase in viral titre. WPRE and cPPT together produce at least a four fold increase in protein expression in most cell types, compared to other vectors that do not contain these elements.

Chloramphenicol resistance gene
(CmR) located between the two attR sites for Counter selection.

attR
Bacteriophage λ-derived DNA recombination sequences that permit recombinational cloning of the gene of interest / miR/sh RNA and promoter of interest from GatewayR entry clones (Landy, 1989).

ccdB gene
Produces the ccdB protein, which targets E. coli DNA gyrase, preventing DNA replication of bacterial cells thus permitting negative selection of the plasmid.

U3/HIV-1 truncated 3’LTR
Allows viral packaging but self-inactivates the 5’LTR for biosafety purposes (Dull et al., 1998). The element also contains a polyadenylation signal for transcription termination and polyadenylation of mRNA in transduced cells.

Evaluation of foreseeable effects

It would not be expected that expression of the inserted gene would occur in bacterial hosts or cells used for viral production as proteins are under the control of cell specific promoters. Expression will only be expected to occur in cells where moderate expression of the constructs would be expected from the cells in which the virus has been integrated/infected.

Transformed E. coli cells would not be expected to alter the pathogenicity of the original host. The cells would still have limited survival in human or other hosts, as such the acquired resistance to the antibiotic kanamycin should not pose a risk to human health as the cells should be incapable of establishing an infection.

With respect to the viral work minimal hazard would be expected of the viral plasmids in E. coli where generation of infectious viral particles would be impossible.

The produced target genes are unlikely to pose a risk to the host, operator or environmental organisms.

The main hazard is associated with the packaging of viruses in cells. The viruses will be capable of infecting human cells, with the consequent insertion of the vector genome into chromosomal DNA for AAV/lentiviruses. The main hazard is the possibility of oncogene activation at the site of integration. Consideration of the experiences from human gene therapy clinical trials suggests this risk is low, as any accidental exposure would involve many logs fewer virus particles, nevertheless precautions to avoid exposure are appropriate. A further potential hazard is the generation of replication-competent virus. As described above, use of split packaging systems for retrovirus, and second / third generation SIN vector systems for lentivirus, makes this highly unlikely. The use of self-inactivating lentiviral vectors effectively limits the virus to a single infective cycle thus after several changes of culture media/natural clearance in mice/rats, the final drug selected cells lines/mice/rats will not contain infectious
viral particles and could be handled at level 1.

The majority of individuals appear to undergo primary infection with Ad5 in childhood, and both humoral and cell-mediated immunity combine to prevent further productive infection in the adult. Such immunity will reduce viral entry into cells, and hasten the immune destruction of infected cells, in the event of accidental human contamination with the recombinant virus. Working practices are designed to minimise the risk of human contamination.

The recombinant virus will not be capable of autonomous spread in the event of accidental operator infection. In the unlikely event that an operator were to receive an 'infectious dose' of virus via the respiratory tract, it would only lead to replication of the GM virus if they had a concurrent infection with wild type virus, and the same cells took up both the wild type and GM viruses. It is known that the subgroup C serotypes (includes Ad5) can persist in the adenoids and tonsils following primary infection, but the mechanism by which the virus is maintained is not known. However, the number of virus-containing cells is very low, and most virus remains cell-associated, and can only be detected after prolonged incubation of the tissue in vitro. Thus the risk of double infection with recombinant and wild type virus is considered to be very low. Attempts to detect such complementation by dual infection in the cotton rat model gave negative results. The possibility of co-infection in the gut must also be considered; while it is known that in some instances there is prolonged shedding of subgroup C viruses via the alimentary canal, there is no evidence that there is long term persistence of the virus, so the opportunity for co-infection of a single cell with both wild type and recombinant is considered remote. In conclusion, it seems unlikely that accidental human infection with the replication-defective adenovirus would result in its rescue, either with helper virus or as a replication-competent recombinant; or that human-to-human transfer would take place.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

It is the responsibility of the person undertaking the work with the GMM to check the correct operation of equipment used, on every occasion. Nitrile gloves, culture vessels, centrifuge tubes etc should be inspected before and during use, to ensure leak-free operation. The work area and equipment should be checked before and after use for any spillages which might contain GMMs, and appropriate remedial action taken if necessary. The work surface must be decontaminated after use.

Project supervisors have a responsibility to ensure that persons in their group are following the specified containment and control measures, and arranging for appropriate training of new workers.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

1% Virkon used for most surface decontamination. Disposable plastic tips for micropipettors, may be decontaminated by drawing up Virkon disinfectant, and soaking in Virkon for a minimum of 20 minutes. Disposable plastic pipettes may also be decontaminated by immersion in Virkon as above.

All tissue culture will be carried out in a designated microbiological safety cabinets with filters appropriate for cells of category Biosafety level 2. Safety cabinets are tested and maintained on a regular schedule; safety cabinets have a KI discus test and maintenance every 6 months, for class I cabinets this is on an annual basis. The tissue culture expression will be on a small scale of less than 1x10e8 cells. Levels of protein expression are unlikely to exceed 1mg/litre. All tissue culture waste will be
autoclaved. The designated incubator for culture of virally infected cells will be equipped for wet heat sterilization.

Warning lights, and chart recorder, indicate whether or not the autoclave run has achieved the appropriate temperate for the required time. The autoclave is run by trained staff, who are instructed to treat waste as still contaminated if the autoclave run was not to specifications. Under such circumstances the waste would be autoclaved again, after rectifying any reason for the malfunction. The autoclave is inspected and serviced on a regular basis.

All liquid waste is treated by autoclaving at 121°C for 30 minutes, before disposal to drains. Disposable solid waste which is or may be contaminated with GMOs is also inactivated by autoclaving at 121°C for 30 minutes, before removal as “clinical waste” by specialist contractors, with final disposal by incineration.

Expected degree of kill:
Autoclaving achieves effectively 100% kill of all GMOs. The manufacturer’s information indicates efficacy of Virkon against a variety of adenoviruses at 1% concentration, and also against a number of strains of E. coli at dilutions ranging from 1% to 0.125%. We have previously demonstrated that 15 minutes exposure to 1% Virkon achieves >4 log10 kill for adenovirus-infected cell pellets, and >6 log10 kill of adenovirus seed stocks. The effectiveness of Virkon in the deactivation of plasmid DNA was tested with plasmids of a similar size to those that will be created in the work outlined above.

Incubation of plasmid DNA in a 1% solution of Virkon for 2 minutes reduced the transformation efficiency of plasmid DNA in transforming E. coli cells from 2.8 x 106 transformants/µg DNA to 4.2 x 104 transformants/µg DNA. Incubation for 20 minutes in this 1% Virkon solution completely abolished the ability of the DNA to transform cells. There is no reason to suggest that the plasmids described in this work will be less susceptible to chemical inactivation than those tested. Class II biological safety cabinets will be used for handling of mouse brain slices/cells, in order to maintain sterility for subsequent experiments.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  Y

### Project Additional Information

**Purposes of the contained use**

Increased expression of antibiotic drug targets in the ACGM-category 2 microorganisms *Mycobacterium abscessus* and *Mycobacterium bovis BCG* in order to study the effects on microbial physiology and verify mechanism of action.

**Recipient or parental organism**

*Mycobacterium abscessus NCTC 13031, Mycobacterium bovis BCG Pasteur 1173P2, Mycobacterium tuberculosis H37Rv*

*Mycobacterium abscessus NCTC 13031*: M. abscessus is part of a group of environmental mycobacteria and is found in water soil and dust. It has been known to contaminate medications and products including medical devices. M. abscessus can cause a variety of infections. Healthcare associated infections due to this bacterium are usually of the skin and soft tissues under the skin. It is also a cause of serious lung infections in persons with various chronic lung diseases such as cystic fibrosis. People with open wounds or who receive injections without appropriate skin disinfection may be at risk for infection by M. abscessus. Rarely, individuals with underlying respiratory conditions or impaired immune systems are at risk of lung infection. Transmission of M. abscessus can occur in several ways. Infection with M. abscessus is usually caused by injections of substances contaminated with the bacterium or through invasive medical procedures, employing contaminated equipment or material. Infection can also occur after accidental injury where the wound is contaminated by soil. There is very little risk of transmission from person to person. M. abscessus is an ACDP-Category 2 organism.

*Mycobacterium bovis BCG Pasteur 1173P2*: M. bovis is a major cause of tuberculosis in a range of animal species and man. It was the progenitor of the M. bovis bacillus Calmette-Guerin (BCG) strain used as a vaccine against tuberculosis. BCG was derived by serial passage on slices of potato imbibed with glycerol for 13 years, once the strain was proven to no longer be virulent it was disseminated and different laboratories continues this passaging. This particular strain, M. bovis BCG 1173P2, has been passaged 1,173 times at the Pasteur Institute, Paris France. Different centers have different stocks of BCG, which have continued to change with time, accumulating insertions, deletion and single nucleotide polymorphisms. M. bovis BCG is an ACDP-Category 2 organism.
Mycobacterium tuberculosis H37Rv: M. tuberculosis H37Rv is the most studied strain of tuberculosis in research laboratories. It was first isolated by Dr Edward Baldwin in 1905. The strain came from a 19 year old patient with chronic pulmonary tuberculosis at the Trudeau Sanitorium and was initially names strain H37. Over time it was found to have variable virulence in animal models based on which medium it was grown on. Strains with different virulence were then intentionally produced, with H37Rv denoting R (rough) and v (virulent). The strain was used for many laboratory studies and later became the standard for tuberculosis research, with the complete genome published in 1998. M. tuberculosis is an ACDP-Category 3 organism and as a result, only genetic material from this organism is used in our work as we do not have containment level 3 facilities at Aston University.

The above information was extracted from https://www.cdc.gov/hai/organisms/mycobacterium.html

Host/vector system

Mycobacterium abscessus NCTC 13031, Mycobacterium bovis BCG Pasteur and Escherichia coli (strains BL21 DE3 and TOP10) using the following vectors: pMV261, pVV16, pET28b, pET23a

For Mycobacterium abscessus and Mycobacterium bovis BCG, please see "A. 1. The Donor" information.

Escherichia coli TOP10 and BL21 DE3 strains are standard laboratory non-pathogenic strains for gene cloning and manipulation.

pMV261: A shuttle plasmid capable of replication in E. coli and in mycobacterial species (mycobacterial origin of replication from Mycobacterium fortuitum plasmid pAL5000) using kanamycin resistance for selection. The cloned mycobacterial gene will be under the constitutive mycobacterial hsp60 promoter.

pVV16: Derived from pMV261, pVV16 is a shuttle plasmid capable of replication in E. coli and in mycobacterial species (mycobacterial origin of replication from Mycobacterium fortuitum plasmid pAL5000) using kanamycin resistance for selection. The plasmid contains a hystidine-tag and a signal sequence. The cloned mycobacterial gene will be under the constitutive mycobacterial hsp60 promoter.

pET28b: The pET28a-c vectors carry an N-terminal His tag/Thrombin/T7 and is used extensively for recombinant protein production in E. coli. pET28b carries a kanamycin resistance cassette.

pET23a: The pET23a vector carries an N-terminal His tag/T7 promoter and terminator and is used extensively for recombinant protein production in E. coli. It carries an ampicillin resistance cassette.

Origin & function

Rv2763c (dfrA), Rv2764c (thyA), Rv0268c (blaC), Mab_2875

Rv0268c (blaC): Class a beta-lactamase (BlaC). Hydrolyses beta-lactams to generate corresponding beta-aminoacid

Mab_2875: Class a beta-lactamase (BlaC). Hydrolyses beta-lactams to generate corresponding beta-aminoacid

Evaluation of foreseeable effects

Genes (section 7) encoded in pMV261 and pVV16 will be expressed in M. abscessus and M. bovis BCG in order to assess the change in antibiotic sensitivity phenotype. Mycobacterial genes cloned into pMV261 and pVV16 will be expressed via the hsp60 promoter in the host strains. The promoter is constitutively expressed and thus there
is a 'steady' moderate expression, rather than 'overexpression' usually seen with inducible promoters. Genes encoded in pET vectors will be expressed in E. coli and purified my IMAC.

The proposed work is to investigate how the enhanced expression of certain genes impacts the antimicrobial susceptibility to known antimicrobial compounds. This strategy is widely employed in order to establish the mechanism of action of antimicrobials by reducing sensitivity to specific antimicrobial agents, thus indicating target engagement. This work does not increase the pathogenicity of strains, but does result in reduced sensitivity to defined classes of antibiotic as well as all molecular genetics involving antibiotic resistance markers. This does not pose an enhanced risk to human health as the compounds being investigated are not currently administered treatment. If the vector were to enter the body, the genes would not be expressed. Therefore, the GMOs should not represent an increased risk over the parent organism.

M. abscessus can cause a variety of infections. Healthcare associated infections due to this bacterium are usually of the skin and soft tissues under the skin. It is also a cause of serious lung infections in persons with various chronic lung diseases such as cystic fibrosis. People with open wounds or who receive injections without appropriate skin disinfection may be at risk for infection by M. abscessus. Rarely, individuals with underlying respiratory conditions or impaired immune systems are at risk of lung infection. Transmission of M. abscessus can occur in several ways. Infection with M. abscessus is usually caused by injections of substances contaminated with the bacterium or through invasive medical procedures, employing contaminated equipment or material. Infection can also occur after accidental injury where the wound is contaminated by soil. There is very little risk of transmission from person to person. M. bovis BCG is an attenuated strain of M. bovis that is widely used as a human vaccine strain. Although infections due to M. bovis BCG have occurred, these are predominantly in individuals with severe immunocompromisation and therefore the risks of infection are nominal and not enhanced by the genetic modifications proposed. Immunocompromised individuals are at higher risk of infection and disease and will not be permitted to work in the BSL2 laboratory. Both Mycobacterium abscessus and Mycobacterium bovis BCG are categorised as ACDP-Category 2 organisms.

M. abscessus is an environmental mycobacterial strain, therefore the environmental risk is negligible.

Mycobacterium bovis BCG is an attenuated strain and lacks the necessary virulence machinery to infect healthy hosts (including animals). It is a temperature sensitive organism requiring a host body temperature to grow, therefore the environmental risk is negligible. GMOs will be contained and handled without contact to other microbes, therefore the risk of transfer of genetic material is nominal. Likewise other biologicals employed in this work will be handled with the same level of containment. All material will be disinfected by autoclave once work is completed.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

| N/A |

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

| Contaminated tubes, pipette tips, cryovials, loops will be disposed in autoclavable, disposable waste bags and autoclaved. Biocleanse 1:10 dilution will be added to waste liquids (old cultures and culture supernatants) prior to autoclaving. Pipetting and spreading of cultures is likely to generate minimal amounts of aerosols, however as all work with M. abscessus and M. bovis BCG is to be carried out in a Class II cabinet, any minimal amounts of aerosols generated will be contained. No metal or glass-based sharps will be used. Micropipette tips and disposable loops will be disposed of in an appropriate waste bag prior to disinfection by autoclaving. All glycerol stocks will be stored in 2ml cryovials at -80oC inycrovial box. Transportation if required will be done by designated courier services in accordance with conditions of carriage for ACDP Group 2 organisms. The spread of large volume spills will be limited by absorbent materials. The absorbed material will be disposed of in autoclavable waste bags and decontaminated by autoclave. Small spills inside the Class II biosafety cabinet will be disinfected with 1:10 Biocleanse. Disinfection in this manner should prevent the release of genetically modified material. |

02/03/2022
The GMO Risk Assessment for Genetic Manipulation of Mycobacteria sp. was reviewed by Aston University Health and Safety committee and they raised the following questions which were addressed as follows:

1. Will records of training be kept?
   - In this section I have included the sentence “Training and records of training will be completed by Group Leader”.

2. How is this grown. If not at Aston where? How is material obtained.
   - I have included the sentence “Genomic DNA is provided by the BSL-3 tuberculosis laboratory at University of Birmingham. Genomic preparations are screened for absence of viable cells before removal from BSL-3 laboratory.”

3. Should these not be listed before?
   - The host characteristics for E. coli are in the appropriate place as confirmed by Russell Collighan.

4. Clarify the antibiotics used here would not be used in a possible treatment.
   - The text already contained the sentence, “This does not pose an enhanced risk to human health as the compounds being investigated are not currently administered treatment.” For further clarification, I have added, “These are experimental compounds and do not form part of the recommended treatment regime.”

5. Control of exposure? Concerns over shared areas and equipment.
   - I have included the statement, “Equipment that is used for this work is not shared with other groups and the microbiology laboratory (MB327) is a controlled work area with restricted access.”

6. Class of hoods and lab? 2?
   - I have included the statement, “Laboratory MB327 is a BSL-2 laboratory and these organisms will be handled in a class 2 biosafety cabinet.”

7. Will media be decontaminated with Virkon?
   - I have amended the sentence to read, “All material will be disinfected with Biocleanse (as per disposal procedure below), autoclaved and incinerated once work is completed.”

8. Is this proven to kill this strain. Has this been tested in the lab?

- I have added the sentence, "Biocleanse is the recommended disinfectant for Mycobacteria sp. including Mycobacterium tuberculosis ([link to datasheet])."

9. Details. Where stored etc.

- Further clarification on the spill procedure is provided. No specific "spill kit" is required as working volumes are restricted to 100ml and therefore disinfection procedure stated is appropriate (as discussed with Russell Collighan.)

10. Spill kit location

- Please see point 9.

Attached is the corrected .pdf of the GMO Risk Assessment entitled "Cox 2019 GMO Risk Assessment" which was deemed satisfactory by Aston University Health and Safety committee following review.

MOLECULAR GENETIC ANALYSIS OF PATHOGENICITY OF THE RICE BLAST FUNGUS MAGNAPORTHE GRISEA

Purposes of the contained use
The project will use molecular genetic analysis to identify genes from M. grisea that are essential for the fungus to cause plant disease. Recombinant strain of M. grisea will be generated where genes have been mutated by targeted gene replacement or by random insertional mutagenesis. The ability of the recombinant M. grisea strains to cause disease will then be tested. The other principal activity will include generation of reporter gene constructs to investigate regulation of genes involved in causing plant disease.

Recipient or parental organism
Magnaporthe grisea strain Guy11 and derivatives will be used as the fungal host strains in all experiments. Guy11 is a rice pathogenic strain of the fungus originally isolated from French Guiana in 1988. The Escherichia coli K12 strains to be used in this work are JM109 (Promega), XL-1Blue (Stratagene), DH5a (GibcoBRL).

Host/vector system
Plasmid vectors used are all pUC or pBluescript derivatives. The fungal transformation vectors utilise the Hygromycin phosphotransferase (Hph) gene from E. coli or the Bialophos resistance gene encoding phosphinothricin acetyl transferase from Streptomyces hygroscopicus as selectable markers. These genes are regulated by the Aspergillus nidulans. TrpC promoter. An allele of the M. grisea acetolactate synthase gene, ILV1, under control of its own promoter is also used as a selectable marker bestowing resistance to sulfonylurea. The vectors are derived from pCB1004, pCB1265 and pCB1532. These are described in Genbank submissions AF013601 and AF013602. The green fluorescent protein-encoding gene (GFP) will be expressed under control of native M. grisea promoters. The vectors used for fungal transformation cannot replicate extrachromosomally in fungi. The insert into host DNA.

Origin & function
The nature of the work to be carried out is to delete or disrupt native M. grisea genes. The only inserted genes are the selectable marker-encoding genes described above. Complementation analysis will introduce the native M. grisea gene into corresponding gene replacement mutants in order to restore the wild type trait.

Evaluation of foreseeable effects
The GMMs to be generated in this project are likely to be attenuated for virulence and in no case are they anticipated to have any plant pathogenic capabilities that exceed those of the wild type M. grisea Guy11 strain. The GMM strains to be generated will not have harmful properties to human health.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste in the form of agar plate cultures and infected rice plants are disposed of by autoclaving at 121 degrees C at 15 psi for 45 minutes under conditions prescribed by the DEFRA licence. Experiments in the laboratory have demonstrated the effectiveness of this procedure for sterilising material. Liquid waste is disposed of by disinfecting in a 1:100 dilution of Virkon for a minimum of 30 minutes. This procedure has also been demonstrated to be effective in preventing survival of M. grisea in the laboratory.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick if you are claiming exemption from disclosure for section of the risk assessment N

The GMSC noted that M. grisea was a pathogen of rice but not of UK plants: although barley could be infected in the laboratory this required high titres of spores and high humidity; barley was not infected by this fungus in Northern Europe. The risk assessment was confirmed at containment levels 1 (E. coli) and 2 (M. grisea) following specific advice from the GM inspector (GMSC minutes 02/03 and 03.05).

Project Ref 382/03.2

Date Ackn’d 31/03/2003

CU2 Project Title IDENTIFICATION OF GENES INVOLVED IN BIOFILM FORMATION OF

Class 2

CultureVolClass2 1-50 litres

CultureVolumeClass3-4
To identify gene promoters of Salmonella which are preferentially induced during biofilm formation, growth, and maturation when compared to planktonic growth.

Recipient or parental organism

Salmonella enterica serovar Typhimurium SL 1344: ACDP Class 2
Escherichia coli K12.

Host/vector system

Plasmid pZEP08 containing the promoter-less gfp gene: in Escherichia coli K12.

Native promoter-gfp fusions integrated at the chromosomal putPA locus in Salmonella enterica serovar Typhimurium SL1344.

Origin & function

The gfp gene from Aequoria victoria encodes green fluorescent protein (GFP) for use as a reporter to monitor promoter function.

pKD46 from Escherichia coli and its bacteriophage: to enable targeted chromosomal integration of linear promoter-gfp fusion DNA in Salmonella enterica serovar Typhimurium SL1344.

Promoter sequences from Salmonella enterica serovar Typhimurium SL1344 will be cloned in Escherichia coli K12 and then reintroduced back into S. Typhimurium as linear gfp fusions.

Evaluation of foreseeable effects

Salmonella is pathogenic to animals and humans, although it causes only limited gastro-intestinal infection in healthy individuals. Introduction of a promoter-gfp fusion is
not expected to enhance the pathogenicity of S. Typhimurium SL1344 because it will contain only a single copy of a gene promoter, not the entire structural gene, and this is upstream of a gene encoding a harmless protein. In addition, these promoters are naturally occurring in this bacterial genome. Plasmid pKD46 confers resistance to ampicillin but its replication is temperature-sensitive and the plasmid will be lost by exposure to 37 degrees C. Introduction of the fusions onto the chromosome results in a marker that is chloramphenicol resistant and kanamycin sensitive. These are not the drugs of choice for treatment of infections in a mammalian host by these infectious agents and thus would present no selective advantage in the event of an accidental release. Likewise, ampicillin is not the choice of antibiotic for the treatment of such infections. Although most infections do not require the use of antibiotics, in the case of severe or chronic cases Ciprofloxacin would be prescribed.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste materials will be disposed of by autoclaved at 121 degrees C for 60 minutes. Experiments in the laboratory have demonstrated the effectiveness of this procedure for sterilising material. Additionally, all equipment used (including benches) will be swabbed daily with disinfectant (1% Virkon). Experiments within this laboratory have demonstrated the effectiveness of these procedures against Salmonellae.

Project Ref 382/07.1
Construction and Characterisation of Yersinia pseudotuberculosis mutants.

To identify Y. pseudotuberculosis genes and gene products which play roles in disease and which could in the longer term be exploited as targets for antimicrobials or vaccines.

Recipient or parental organism

Yersinia pseudotuberculosis

Origin & function

For mutagenesis, genes will be inactivated by the targeted insertion of plasmid DNA (eg pKNOCK) or the random insertion of DNA (eg Tn5). For allelic replacement mutagenesis a functional copy of the gene will be replaced with an inactivated gene. In all cases antibiotic resistance markers (kanamycin, ampicillin, tetracycline or chloramphenicol resistance) allow the selection of mutants and the levansucrase gene allows the selection of double cross-over mutants. Plasmid pAJD434 encodes trimethoprim resistance and encodes the lambda red recombinase, promoting high efficiency recombination between the PCR product and the target gene. Plasmid pAJD434 is present only during the mutagenesis protocol and is cured before the bacteria are characterised and/or used for virulence studies.

For complementation studies, the inactivated gene is replaced with a functional gene i.e to restore the wild type phenotype. Antibiotic resistance markers (kanamycin, ampicillin, tetracycline or chloramphenicol resistance) allow the selection of complementet mutants. Complemented mutants may express two antibiotic resistance markers.
For example, the marker of the original mutant, and the marker for the complementing plasmid.

Green fluorescent protein (GFP), derivatives of GFP, DsRED 1-E5 or the luxCDABE operon could be expressed in wild type and mutant bacteria to allow the bacteria to be tracked in host cells or host tissues. Antibiotic resistance markers (kanamycin, streptomycin, or chloramphenicol resistance) allow the selection of complemented mutants. The expression of genes of interest could also be monitored by cloning the relevant promoters upstream of reporters such as GFP, derivatives of GFP, DsRED 1-E5 or beta-galactosidase.

Note; Uncomplicated cases of diarrhoea due to Y. pseudotuberculosis usually resolve on their own without antibiotic treatment and with only supportive care (fluids, electrolytes). However, in more severe or complicated infections. Antibiotics such as aminoglycosides, doxycycline, trimethoprim-sulfamethoxazole or fluoroquinolones may be useful. All of the mutants constructed in this study would be susceptible to trimethoprim-sulfamethoxazole and / or fluoroquinolones.

**Evaluation of foreseeable effects**

The most hazardous GMM would be a strain of Y. pseudotuberculosis which is as virulent as the wild type strain but expresses and antibiotic resistance marker(s).

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Where possible all waste from the laboratory will be autoclaved using a destruct cycle, at 125oC for at least 30 min. In addition, disposable plastics used during experimental work will be immersed in 10% chloros. Solid waste materials generated during working will be bagged before autoclaving. Liquid waste (unless otherwise indicated, see below) will be made to a final concentration of 10% chloros and stored in glass bottles before autoclaving. When required, animal waste will be treated with 10 % v/v Teknon Biocleanse overnight before autoclaving.

Autoclave loads will be recorded and the autoclave will be serviced and validated annually using thermocouples.

Where it is not possible to autoclave waste (e.g where it contains phenol or organic solvents) bacteria will be chemically inactivated with 10% chloros, 10 % Teknon Biocleanse or in the case of phenol waste by adding 5% hycolin. Particulate materials within 10 % volume of the material will be collected by centrifugation, washed in phosphate buffered saline and plated onto nutrient agar to establish that viable bacteris are not present. Waste material will be disposed of by incineration when free of viable Y. pseudotuberculosis.

**Project Ref 382/08.3**

Date Ackn'd: 26/08/2008

Date Project Ceased:

CU2 Project Title: Genetic modification of pathogenic fungi

Class: Class 2

CultureVolClass2: < 1 Litre

Consent Granted: Not Applicable

Non-GMM: Yes

Project notified under transitional arrangements: Yes

Withdrawn: No

Tick if notifying a connected programme of work: Yes

**Project Additional Information**

**Purposes of the contained use**

The purpose of this work is to further our understanding of fungal virulence through the use of Candida albicans and Aspergillus fumigatus as model systems. Through this we would also aim to identify and validate novel therapeutic targets.

**Recipient or parental organism**

The ACDP class C. albicans and A. fumigatus in hazard group 2. C. albicans is a commensal of the normal flora and causes opportunistic infections ranging from superficial mucosal infections to systemic infections in the immunocompromised. A. fumigatus is widely distributed in nature and causes opportunistic infections ranging from allergic aspergillosis to systemic infections in the immunosuppressed.
Vectors for transformation will have been constructed in E. coli or amplified directly by PCR. in all cases the vectors will be integrated into the host's genome via recombination.

**Host/vector system**

Origin & function

The majority of the work proposed involves the manipulation and alteration of existing genes (for example gene deletions or promoter replacements). This will involve the targeted insertion of DNA into specific locations in the genome. The inserted DNA will contain an auxotrophic marker for the selection of transformed cells (e.g. URA3, LEU2 HIS1, ADE2 and ARG4 in C. albicans or pyrG, argB, or lysB in A. fumigatus) or positive selection markers (derived from foreign DNA e.g. nourseothricin resistance in C. albicans or hygromycin, phleomycin or pyrimidine resistance in A. fumigatus). Additional foreign DNA present in the inserted DNA will include: 1. S. typhimurium hisG—present as a direct repeat around the C. albicans URA3 gene for gene deletions and subsequent recycling of the marker. 2. Tetracycline transactivator (a fusion between Tn10 tetR and either viral VP16 activation domain or S. cerevisiae HAP4 activation domain) to regulate expression of genes. 3. Reporter genes such as Beta-galactosidase, luciferase, glucuronidase and GFP. 4. Small epitope tags (e.g. V5, SxHis, HA, FLAG or Myc) to allow protein analysis. 5. The E. coli plasmid backbones (pUC and pBR based) that the insert is contained on will in some cases also become inserted into the genome.

**Evaluation of foreseeable effects**

The genetic modifications proposed would not be expected to increase the virulence of the GMO above that of the parental organism. Therefore the risk to human health can be considered equivalent to that of dealing with the parental organism.

The only potential hazard, in healthy individuals, of handling C. albicans would be from exposure resulting in a mucosal infection. However the risk of this hazard being realised, even if exposure occurred, would be low.

The only potential hazard, in healthy individuals, of handling A. fumigatus would be from inhalation exposure causing a mild allergic reaction. Procedures likely to generate aerosols would be conducted in a class 2 microbiology safety cabinet to prevent exposure. Therefore the risk from the organism would be very low.

All the genetic modifications proposed would be non mobilisable therefore the risk of transfer of sequences to other micro-organisms is remote. The GMO’s produced would be potentially as fit as the parental organism and may therefore be able to persist in the environment if a breach in containment occurred. However, the GMO’s would have no selective advantage, the risk to the environment is therefore very low.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All solid waste is double bagged in autoclave bags and collected daily. Waste is autoclaved for 1 hour at 121 °C. The autoclave is serviced and calibrated every 6 months to ensure continued effectiveness.

Liquid waste is also inactivated by autoclaving or for small volumes (< 100 mL) by chemical treatment. Culture vessels and supernatants are decontaminated with a 1:50 dilution of VIRKON (Antec International) and are left for 16 hours prior to disposal down laboratory sink. Glassware is then rinsed and washed by dishwasher, plastic ware is further autoclaved prior to disposal. This method has been validated to give 100% kill.

**Project Additional Information**
M. graminicola is an important pathogen of wheat. This project will enable functional genomic analyses of this organism by a number of molecular methods.

Recipient or parental organism

M. graminicola strain IPO323 (wild type, sequenced) and derivatives thereof. IPO323 was originally isolated from the Netherlands in 1981.

Host/vector system

We will use vectors described below, and others that do not differ substantially, but that have not yet been constructed.

Plasmids constructed using the pGEM-T-EASY system and derivatives thereof, e.g. a hygromycin resistance cassette with 3’ and 5’ gene flanking regions for targeted gene deletion (as described in Kershaw and Talbot, Proc Natl Acad Sci U S A. 2009 Sep 15;106(37):15967-72).

A Clp10-like plasmid that allows targeting to a single gene locus (e.g. Bowler et al., 2010 Mol Plant Pathol 11:691)

M. graminicola entry-level clones in the Gateway vector pDONR221 (Invitrogen)

M. graminicola Gateway destination vectors will be constructed based on the functionality of the Lindquist S. cerevisiae Gateway plasmids (Alberti et al., 2007 Yeast 24:913; 16.)

The vectors used for fungal transformation cannot replicate extra chromosomally in fungi.

Origin & function

Gene deletion mutants: Full knockout or knockdown mutants will be constructed. These will be used to assess the function of genes in the pathogenesis of M. graminicola. For gene inactivation mutants, the foreign DNA will encode an antibiotic resistance cassette e.g. hygromycin or an auxotrophic marker such as URA3, HIS3, LEU2, TRP1 and will not confer resistance to the main anti-fungal treatment for the M. graminicola. i.e. azoles or azoxyxstrobins.

Re-integration mutants: As a control for gene deletion experiments, the parental copy of the deleted gene will be re-integrated into the mutant background by combining the gene with a selectable marker and integration targeted to its native locus.

A set of inducible promoters that can be used in M. graminicola will be generated; for example a promoter sequence from the nitrate reductase gene, NIA1, will be used and its ability to drive nitrate-inducible gene expression of a GFP reporter tested. Both small molecule and nutrient-regulated promoters will be used.

Target M. graminicola genes (or truncations thereof) may be modified to encode an N or C terminal epitope tag (such as 6xHis, FLAG, Myc, HA, TAP), to assist in visualisation or purification. Additionally, for live cell imaging the M. graminicola genes may be fused to GFP, YFP, CFP, or dsRedstar or other such tags. The genes will be inserted into the genome at their native locus under the control of their natural promoter, or the TET promoter (or other inducible promoters), or constitutively active loci.

Controlled over-expression strains will be constructed using over-expression plasmids to study genes whose phenotype is of particular interest/ Standard nonmobilisable vectors will be used in all experiments, thus minimising risk of gene transfer. The cloned genes are not likely to increase the level of risk of transfer. They are also unlikely to be harmful to humans or animals.

Evaluation of foreseeable effects

The genetic modifications involved would not be expected to increase the virulence of the GMO above that of the parental organism, nor would they be envisioned to impact on any other trait such as drug resistance.

The risks associated with transmission of genetic material to other organisms is negligible as the vectors used are not able to replicate in M. graminicola. The only possible
route for transmission of DNA would be via recombination with another eukaryote, and this has not been documented.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

No GM plants or animals will be produced.

Where *M. graminicola* is used to infect plants, this will be carried out in plastic bags by spraying a suspension of spores with an artist's airbrush. The spores land either on the leaves of the plant or the inside of the plastic bag. The plants are sealed in bags for 48 hours and then incubated for a further 2-4 days in a designated growth chamber. The bags used for spraying plants are to be autoclaved after use. The airbrush is sterilised with ethanol. All plant material, including soil, will be autoclaved after use. Pots are sterilised in Virkon for 30 minutes. The growth chamber is to be routinely disinfected with Virkon.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid and liquid waste in the form of agar plate cultures, broth cultures and infected plants are disposed of by autoclaving at 121 °C at 15 psi for 45 minutes under conditions prescribed by the DEFRA licence. Experiments in the laboratory have demonstrated the effectiveness of this procedure for sterilising material. Virkon treatment has been validated experimentally in the laboratory. Autoclaving has been validated experimentally elsewhere.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form  

Tick if you are claiming exemption from disclosure for section of the risk assessment

Please enter comments on the GM safety committee on the risk assessment

The GM safety committee agreed that this work should be carried out at level 2. The assessment at level 2 is considered due to risk to the environment: the organism in question is a significant pathogen of wheat, and the University's DEFRA license for its use mandates that activities should be carried out only in class II cabinets.

<td>pCVB3-eGFP. The vector contained a Ampicillin resistance gene, T3 and T7 promoters. In addition to the vector backbone it has had the full length CVB3 polyprotein linked to eGFP. The polyprotein encodes the viral capsid proteins (VP1-4) and non-structural proteins required to mediate the productive infection of the cell.</td>
</tr>
<tr>
<td>Once this vector has been transfected into pancreatic derived cell lines or HeLa and Hep2 cell lines, the cells will produce and secrete eGFP-tagged CVB3 virus. The supernatant (containing the infectious virus) will be collected and utilised in further infection experiments. This virus will be utilised to monitor and track infection in pancreatic cell lines.</td>
</tr>
</tbody>
</table>
Origin & function

Evaluation of foreseeable effects

The vector itself is not harmful, however the CVB3 it produces is a level 2 pathogen. A specific risk assessment, COSHH form and biosafety manual have been produced for the handling of the virus and this has been approved by our Health and Safety committee.

CONTAINMENT REQUIREMENTS: Biosafety level 2 practices, containment equipment and facilities for all activities involving known or potentially infectious materials. ALL WORK SHOULD BE CARRIED OUT IN A VIRUS ONLY CLASS II BIOSAFETY CABINET WHICH WILL BE UV IRRADIATED AFTER EACH USAGE. ALL CELL CULTURES INFECTED WITH VIRUS WILL BE MAINTAINED IN A SPECIFIC VIRUS ONLY INCUBATOR. ALL EQUIPMENT UTILISED DURING THE CULTURE OF THESE CELLS WILL BE DECONTAMINATED AFTER EACH USAGE BY UV IRRADIATION OR DECONTAMINATION WITH VIRKON (BOTH OF WHICH EFFICIENTLY NEUTRALISE CVBs)

A DETAILED MANUAL HAS BEEN PRODUCED DESCRIBING THIS AND FULL TRAINING WILL BE GIVEN TO ALL LABORATORY PERSONAL WORKING WITH THE VIRUS.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Virkon has been tested against high titre Poliovirus (a member of the same family of enteroviruses as CVB). Solutions (<5 days old) at a concentration of 1% (w/v) inactivate poliovirus within 5 minutes. All liquid waste will be treated for >15 minutes. Data from Virkon MSDS (attached) and associated references. All spills will be treated as below:

SOP
1. Wear gloves and lab coat when dealing with the spill, if not already wearing them.
2. Cover the spill, including any contaminated equipment, with cloth or paper towel to contain it.
3. Ensure others in the area now of the spill and to avoid the spill area.
4. Working from the outside margins of the spill area, towards the centre, apply sufficient 1% Virkon solution (less than 5 days old) on top of the paper towels to soak them.
5. Leave for 10 minutes to allow the Virkon to inactivate any virus present in the spill.
6. Clear away the materials into clear sealable plastic bags prior to disposal in the nearest yellow biohazardous waste bag, including gloves used for clean-up. If any glass or sharps are involved use a dustpan or piece of stiff cardboard to dispose of these materials into the appropriate containers.
7. Complete the spill record table.

In addition, UV light rapidly inactivates CVB. Ref https://www.ncbi.nlm.nih.gov/pmc/articles/PMC126408/#po=40.4762
The virus only biosafety cabinet is subjected to 20 minutes UV irradiation following all procedures. All pipettes are retained within the hood and are subjected to a virkon wipe down and UV irradiation after each use.

CVB virus are also highly susceptible to heat inactivation - 30 minutes at 60C
Stocks of the pCVB3-eGFP vector will be stored in a specified GM labelled freezer.

Control Measures for the CVB3-eGFP virus produced following transfection:
1. Viral stocks are collected from cultured cells within the Biosafety level 2 cabinet with all the normal control measures in place (detailed in Biosafety manual). For long term storage the virus is stored in liquid nitrogen or at -80C. Any vials containing virus will be carefully decontaminated prior to leaving the biosafety cabinet and will be transported in a second closed container that should not open/ break if dropped.
2. Any virus within infected cells in which RNA or protein is to be collected will be completely neutralised by the lysis buffer. All vials will be decontaminated prior to leaving the hood.
3. Any virus within infected cells in which we will subsequently use for immunofluorescence microscopy of for flow cytometry will have virus neutralised during the fixation step (4% paraformaldehyde).
4. All persistently-infected cell lines will be sub-cultured only within the Biosafety level 2 cabinet according to the CVB biosafety manual and maintained in the virus only incubator (RILD 4.20).

Other considerations:
Centrifugation of material containing virus: Any centrifugation steps will be completed using lided centrifuge containers that are loaded with the vials in the Biosafety level II cabinet and surface decontaminated (spray and wipe down with virkon) prior to removal from the hood. In the event of a breakage within the centrifugation container, it will be transferred to the BSC II prior to being opened for decontamination. Any spills and decontamination of equipment will be dealt with as detailed below and in the Spill Clean-up procedures in the CBV Biosafety Manual.

SOP for disposal of CBV contaminated waste (taken from CBV Biosafety manual)

1. Wear gloves and lab coat when dealing with the waste, if not already wearing them.
2. Active virus will only be worked with in the hood and all waste generated within the hood should be treated in the following manner:
   - Liquid containing virus will be removed using the vacuum pump system within the hood, to the sealed waste container (outside of the hood) that is part of the pump system. The waste container will already contain sufficiently strong Virkon solution to allow for the additional liquid that may be added during any procedure. After finishing procedures, as part of the clean-up, users should swirl the waste bottle to ensure that any splashes within the containers are washed with the Virkon solution. At least 10 mins must elapse since the last additional of waste to the container, prior to disposal of the waste down the sink. This has been shown to be sufficient to neutralise CVB viruses.
   - Solid waste or virus contaminated disposable items should be placed in the sealable bag, within the waste bin, inside of the hood. The bag should be sealed after procedures are completed but not removed from the hood until at least 15 mins later (while hood is left running). Prior to removal from the hood spray the outside of the bag with virkon and place the sealed bag gently into the yellow bag, within a cardboard container, for disposal. Following a clean down with Virkon the hood and pipettes will be UV irradiated for 20 minutes to ensure all virus is neutralised.
3. The yellow bin and cardboard container should be labelled with the user’s details when setting it up initially for virus related waste. It should be placed under the virus use only hood and should also be clearly labelled as being for virus related waste only. The bag should be closed when it is ¾ full, the cardboard container closed and the label completed. Always remember to set up a new yellow bin prior to closing the old one, dispose of the gloves used to close the old bag in the new bin. Gloves should not be used when closing the cardboard container. In accordance with standard instructions within the lab, the sealed container should then be placed by the cage in the level 3 freezer room for disposal through already established procedures.
The GM safety Committee have approved this risk assessment.

**Purposes of the contained use**

Autism spectrum disorder (ASD) is one of the the most common neurodevelopmental diseases, affecting social interaction, communication, interests and behaviour. We aim to further understanding of the molecules, cells and circuits that underlie ASD affecting behaviour abnormalities. We will use cell line models to examine the morphological and molecular consequences of genetic variants associated with ASD in humans. We will use a new tool that has revolutionised our ability to model genetic
mutations; the CRISPR-Cas9 gene editing system. This system involves stable transfection of plasmids which are designed to generate constructs for expression or knock down of specific genes in neuroblastoma cell lines and adult mouse neurons. Once stably transfected, the cell lines will be analysed for expression efficiency by Western blotting, RT-PCR and flow cytometry. They will also be used in assays to assess for morphological changes using immunofluorescence microscopy.

Along with the genetic component of psychiatric disorders there is also a known epigenetic component in ASD, Alzheimer's Disease, Bipolar Disorder, Depression, Schizophrenia and Suicide. One change, DNA methylation, has been strongly associated to be altered in patients with these disorders. DNA methylation at known CpG sites has been shown to upregulate or downregulate gene expression dependent on methylation status. We will use cell line models to examine morphological and molecular consequences of altering methylation status of CpGs associated with these neuropsychiatric disorders. We will use CRISPR-Cas9 which has been modified to include a deactivated Cas9 (dCas9) linked to DNMT3a enzyme for targeted methylation and TET1 enzyme for targeted demethylation. This system involves stable transfection of plasmids which are designed to generate constructs for targeted methylation and demethylation of specific CpG sites in cell lines. This plasmid system generates lentivirus containing the plasmids and targeting gRNA plasmid to infect cell of interest. Once cell lines have been transfected they will be analysed for expression efficiency using western blotting, RT-PCR and flow cytometry. They will also be used in assays to assess the methylation status and changes in gene expression following altered methylation.

Recipient or parental organism

List of recipient strain(s): HeLa (human), Neuro-2A (mouse), HEK293 and HEK293T (human), SH-SY5Y (human), HPCOA07 (human), CTXOE16 (human), COS-7 (monkey), 3T3 (mouse), PC12 (rat), Human neuroprogenitor (human), Mouse neuroprogenitor (mouse), Mouse primary culture (mouse)

Virus strain: Human immunodeficiency virus 1 (lentivirus)

Host/vector system

There are three vectors (transfer, envelope and packaging) which we will use together to form a lentiviral system. The presence of gRNA would also be required for CRISPR-Cas9 gene editing to take place. All of our contracts are obtained from commercial or academic sources. The plasmids described here have all been generated previously and used in previous research (where applicable, publications are listed). We are not intending to make any additional alterations to the plasmids, aside from the inserted genes (which are all listed below).

List of vector(s):
- pENTR 221 CYFIP1 (Open Biosystem)
- pCDH GFP Gateway (originally made by Eric Wexler) (pCDH vectors have EF-1alpha promoter and puromycin selectable marker)
- pCDH GFP for control (non toxic)
- pCDH GFP-CYFIP1
- pPS-T2A-RFP Gateway (originally made by Eric Wexler) (pPS vectors have hU6 promoter and ampicillin resistance)
- pPS-T2A-RFP-CYFIP1 (originally made by Asami Oguro-Ando)
- pCMVdeltaR8.74 packaging (contains GAG, POL, REV, TAT labeled as "psPAX2 for lent package vector")
- pMD2.G envelope (contains VSVg, labeled as "VSVG for lent package vector")
- pGIPZ GFP1 for siRNA control (Open Biosystem) (pGIPZ vectors have T7 promoter and puromycin resistance)
- pGIPZ non scramble control (Open Biosystem)
- pGIPZ si CYFIP1 pM3-1 (Open Biosystem)

Commercial plasmids:
- pL-CRISPR.EFS.GFP (Addgene plasmid 57818) (EFS promoter, ampicillin selectable marker)
- pL-CRISPR.EFS.RFP (Addgene plasmid 57819) (EFS promoter, ampicillin selectable marker)
- pLenti-C-mGFP (Origene PS100071) (CMV promoter, chloramphenicol selectable marker)
- pgRNA-modified (Addgene plasmid 84477) (U6 promoter, CMV promoter, puromycin selection marker, mCherry selection marker)
- Fuw-dCas9-Dnmt3a (Addgene plasmid 84476) (UbC promoter, dCas9, DNMT3a, ampicillin resistance, truncated 5' LTR driven by CMV promoter)
1. List of function of inserted gene(s):

Vectors containing sufficient cDNA sequence and promoters/enhancers to allow expression of full-length or mutated protein. Ampicillin, kanamycin, puromycin, neomycin cassettes used for resistance/selection.

Amyloid precursor protein (APP)
- Amyloid precursor protein (APP)
- Amyloid precursor protein (APP) domain

Axon guidance receptors and their ligands
- Neurophilin-1
- Neurophilin-2
- Plexins A family
- Class III semaphorins

Calcium-binding proteins
- Parvalbumin
- Neurocalcin-d
- VILIP-1
- Calbindin-1

Contactins
- Contactin1

 Cytoplasmic protein
- FMR1
- CYFIP1

 Transmembrane receptor
- AMPA receptor

 Cell adhesion protein
- CHL1
- NRXN1
- NRXN2
- NRXN3
- NLGN1
- NLGN2
The vectors which individually comprise the lentiviral system are all safe, and only when combined create a level 2 pathogen. A specific risk assessment and COSHH form have been produced for the handling of the virus and this has been approved by the University of Exeter Health and Safety committee.

Containment requirements: Biosafety level 2 practices, containment equipment and facilities for all activities involving known or potentially infectious materials. All work should be carried out in a virus only class II biosafety cabinet which will be UV irradiated after each usage. All cell cultures infected with virus will be maintained in a specific virus only incubator. All equipment utilised during the culture of these cells will be decontaminated after each usage by UV irradiation or decontamination with virkon (both of which efficiently neutralise lentivirus).

The total amount of viral material, even at high titre, will only be several hundred microliters, meaning the exposure to the host will be minimal.

Full training will be given to all laboratory personal working with the virus.

Virkon is a widely used laboratory disinfectant which is known to efficiently neutralise cells. There is no indication that modification of cells, in the manner described in this risk assessment, will make cells more resistant to the cytotoxic effects of virkon. All liquid waste will be treated for >15 minutes. Data from Virkon MSDS (attached) and associated references. All spills will be treated as below:

**SOP**

1. Wear gloves and lab coat when dealing with the spill, if not already wearing them.
2. Cover the spill, including any contaminated equipment, with cloth or paper towel to contain it.
3. Ensure others in the area know of the spill and to avoid the spill area.
4. Working from the outside margins of the spill area, towards the centre, apply sufficient 1% Virkon solution (less than 5 days old) on top of the paper towels to soak them.
5. Leave for 10 minutes to allow the Virkon to inactivate any virus present in the spill.
6. Clear away the materials into clear sealable plastic bags prior to disposal in the nearest yellow biohazardous waste bag, including gloves used for clean-up. If any glass or sharps are involved use a dustpan or piece of stiff cardboard to dispose of these materials into the appropriate containers.
7. Complete the spill record table.

In addition, UV light rapidly inactivates lentivirus. Ref https://www.ncbi.nlm.nih.gov/pmc/articles/PMC126408/#fpo=40.4762
The virus only biosafety cabinet is subjected to 20 minutes UV irradiation following all procedures. All pipettes are retained within the hood and are subjected to a virkon wipe down and UV irradiation after each use.

Lentivirus are also highly susceptible to heat inactivation - 30 minutes at 60C

Control Measures for the lentivirus produced following transfection:
1. Viral stocks are collected from cultured cells within the Biosafety level 2 cabinet with all the normal control measures in place. For long term storage the virus is stored at -80C. Any vials containing virus will be carefully decontaminated prior to leaving the biosafety cabinet and will be transported in a second closed container that should not open/break if dropped.
2. Any virus within infected cells in which RNA or protein is to be collected will be completely neutralised by the lysis buffer. All vials will be decontaminated prior to leaving the hood.
3. Any virus within infected cells in which RNA or protein is to be collected will be completely neutralised by the lysis buffer. All vials will be decontaminated prior to leaving the hood.
4. All persistently-infected cell lines will be sub-cultured only within the Biosafety level 2 cabinet and maintained in the virus only incubator (RILD 4.20).

Other considerations:
Centrifugation of material containing virus: Any centrifugation steps will be completed using lided centrifuge containers that are loaded with the vials in the Biosafety level II cabinet and surface decontaminated (spray and wipe down with virkon) prior to removal from the hood. In the event of a breakage within the centrifugation container, it will be transferred to the BSC II prior to being opened for decontamination. Any spills and decontamination of equipment will be dealt with as detailed below.

SOP for disposal of lentivirus contaminated waste:
1. Wear gloves and lab coat when dealing with the waste, if not already wearing them.
2. Active virus will only be worked with in the hood and all waste generated within the hood should be treated in the following manner: Liquid containing virus will be removed using the vacuum pump system within the hood, to the sealed waste container (outside of the hood) that is part of the pump system. The waste container will already contain sufficiently strong Virkon solution to allow for the additional liquid that may be added during any procedure. After finishing procedures, as part of the clean-up, users should swirl the waste bottle to ensure that any splashes within the containers are washed with the Virkon solution. At least 10 mins must elapse since the last additional of waste to the container, prior to disposal of the waste down the sink. As an interim measure, or if the pump is not working, set up some concentrated virkon solution in a beaker and place this in the hood for liquid waste. If a beaker has to be used ensure that beaker itself is wiped down on removal from the hood, which should be done after the hood has run for the additional 15 mins after completion of work. Solid waste or virus contaminated disposable items should be placed in the sealable bag, within the waste bin, inside of the hood. The bag should be sealed after procedures are completed but not removed from the hook until at least 15 mins later (while hood is left running). Prior to removal from the hood spray the outside of the bag with virkon and place the sealed bag gently into the yellow bag, within a cardboard container, for disposal.
3. The yellow bin and cardboard container should be labelled with the user's details when setting it up initially for virus related waste. It should be placed under the virus use only hood and should also be clearly labelled as being for virus related waste only. The bag should be closed when it is ¾ full, the cardboard container closed and the label completed. Always remember to set up a new yellow bin prior to closing the old one, dispose of the gloves used to close the old bag in the new bin. Gloves should not be used when closing the cardboard container. In accordance with standing instructions within the lab, the sealed container should then be placed by the cage in the level 3 freezer room for disposal through already established procedures.

Project Additional Information

Purposes of the contained use
This project covers a range of specific applications with the overall goal of understanding the regulation and mechanisms of yeast and hyphal growth, yeast-hyphae
morphogenesis, hyphal invasiveness, cell wall biosynthesis, antifungal drug sensitivity, mating and reproduction, micronutrient homeostasis, nutrient and stress responses and pathogenicity in Candida species. These species include Candida albicans, C. glabrata, C. dubliniensis, C. tropicalis, C. parapsilosis, C. orthopsilosis, C. metapsilosis, C. krusei, C. guillermondii, C. lusitaniae, C. haemulonii and C. auris. This project also covers experiments related to understanding immunity against C. albicans, particularly the role of mammalian pattern recognition receptors (PRRs) in these immune responses. The specific goals are to characterise:

1. Regulation and roles of chitin, glucan and mannoproteins and cell wall biosynthetic enzymes in cell wall synthesis, cell wall architecture, cell division and pathogenicity.
2. Regulation and roles of morphogenesis, polarized cell growth and tropic responses.
3. Regulation and roles of other virulence attributes such as secreted hydrolases and biofilm formation on medical devices.
4. Role of signalling molecules, transcription factors, and target genes in stress and nutrient adaptation, microbial assimilation and pathogenesis.
5. Regulation of antifungal drug tolerance and resistance, and the influence of antifungal drugs on virulence attributes and pathogenesis (antifungals include classical antifungal drugs, antimicrobial peptides and anti-Candida antibodies).
6. Interactions between Candida, the microbiota and the immune system during gastrointestinal colonisation.
7. Interaction of Candida cells with cells of the human immune system and mammalian cell lines.
8. Roles of PRRs and their downstream signalling pathways in anti-microbial immunity (primarily anti-fungal immunity, although protection against bacteria and viruses is also examined) and in maintaining homeostasis.
9. The influence of sexual and parasexual processes in generating genetic diversity observed between diverse clinical isolates.

During experiments small amounts of live Candida cells (<10^6 cells/sample) are examined by microscopy, FACS or Fluorescent Microscopy. Local safety procedures have been established for the decontamination and/or disposal of samples and equipment. Samples are transported for FACS analysis and for fluorescent microscopy under controlled conditions, secondary containment procedures. Samples for transport must be contained in sealed, leakproof containers as well as in a further outer sealed containers for secondary containment. Some experiments will involve GM Candida cells being cultured with mammalian culture cells in approximately 250ml volumes using locally established category 2 protocols.

**Recipient or parental organism**

Some recipient organisms include ACDP Hazard Group 2 organisms.

Recipient organisms include the following:

2. *Saccharomyces cerevisiae*: Generally we will use multiply disabled, non-pathogenic derivatives of S288C. Some experiments are performed on clinical isolates of S. cerevisiae (these isolates are less pathogenic than C. albicans. They are unable to establish infections in immunocompetent mice).
3. *Candida albicans*: Standard molecular strains carry disabling markers that are often complemented during transformation. They include CAI4 (ura3, ura3/ura3) and derivatives thereof, CAI8 (ura3, ade2, ura3/ura3, ade2/ade2), RM1000 (his1, ura3, ade2/ade2, his1/his1), BWP17 (his1, ura3, arg4), SN78 (ura3, his1, leu2, ura3/ura3, his1/his1, leu2/leu2), SN148 (ura3, arg4, his1, leu2, ura3/ura3, arg4/arg4, his1/his1, leu2/leu2). Clinical isolates of C. albicans are used in some experiments (SC5314).
4. *Candida glabrata*: Recipient strains carry disabling markers such as ade2, his3, ura3, his3, trp1 or lys2. These strains consist of clinical isolates of C. glabrata, that are to be used in some experiments (ATCC2001/CBS138), BG2 (clinical isolate wild type) and derivatives thereof (ura3 KO), 85/038 (clinical isolate wild type), 1184 (clinical isolate wild type), NCPF3605 (clinical isolate wild type), NCPF3309 (clinical isolate wild type).
5. *Candida dubliniensis*: Recipient strains carry disabling markers such as ura3, a non-revertible deletion. Clinical isolates of C. dubliniensis are used in some experiments (Wu284).
7. *Pichia pastoris*: This non-pathogenic yeast is used for deliberate expression of some specific C. albicans proteins. Recipient strains carry disabling auxotrophic markers (e.g. his4, aox1).

**Host/vector system**

Vectors include:

1. Non-mobilisable E. coli vectors (including pUC18/19, pBluescript, pDONR207, pGEM-T, lac-based expression plasmids such as pET vectors).
2. Lambda ZAPII for expression of cDNAs in E. coli.
3. Non-mobilisable S. cerevisiae vectors, often of the pRS series (including multicopy 2mm vectors; single copy YCp replicating vectors; single copy integrating YIp vectors; single copy GAL-based expression vectors).

4. Specific non-mobilisable C. albicans vectors (low copy replicating and integrating vectors [YPB1, Clp10, Clp20, Clp30]; low copy replicating and integrating vectors for ectopic expression [YPB-ADHpt, pACT1]; integrating expression vectors regulated by methionine [MET3 promoter], maltose [MAL2 promoter], glucose [PCK1 promoter], or doxycycline [tet ON promoter and tet OFF promoter]). Some of these vectors are being used in laboratories all over the world.

Specific non-mobilisable P. pastoris expression vectors with AOX1 promoter and terminator [e.g. pPIC9].

The majority of work proposed is for Candida genes that are annotated on the Candida Genome Database (www.candidagenome.org) and include:

- Chitin synthetic genes (e.g. CHS1, CHS2, CHS3, CHS4, CHS5, CHS6, CHS7, CHS8, GFA1, CDA2, BNI4, CHT1, CHT2, CHT3)
- Mannosylation genes (e.g. MNT1-5, MNN2,5,9,10,11, OCH1, HOC1, PMR1, VAN1, MNN1-family: MNN1, MNN 12, MNN 13, MNN 14, MNN 15, MNN 16; MNN2-family: MNN2, MNN21, MNN22, MNN23, MNN5, MNN51, PMR1, CW4H1, ROT2, MNS1, PFT1, PMT2, PMT6, ANP1)
- Hypha-specific genes (e.g. HYR1, HGC1, ALS8, HWP1, ECE1)
- Other cell wall protein genes (about 100 in total).
- Secreted hydrolases and other virulence-associated genes (e.g. SAP1-10, LIP1-10, CHT1-3)
- Transcription factor genes (e.g. TUP1, SSN6, NRG1, RF1G1, SKO1, GCN4, MNS2/4, CAP1, HST1F, HST2F, RPR1, EFG1, EFH1, CPH1, CPH2, CZF1, CRZ1, RLM1, HAC1, CAS5, BCR1, TEC1, RIM101, CSR1, ZCF gene family)
- Signalling genes (e.g. PIK1-2, C2ST20, HST7, CEK1, CPP1, RAS1, CYR1, TPK1, TPK2, CNB1, BMH1, MKC1, HOG1, CNA1, other annotated kinases and phosphatases)
- Calcium signalling genes (e.g. CCH1, MID1, MID2, FIG1, CNA1, CNB1, CRZ1, PMR1, FIG1, YVC1)
- ABC transporters (e.g. CDR1, BENR)
- Stress mitochondrial function and metabolism genes: (e.g. CTA1, TRX1, TRR1, TRX1, GLR1, ENA22, EBP5, PYK1, PCK1, ICL1, FAA21, POX4, POT11)
- Auxotrophic and dominant selectable markers (e.g. URA3, HIS1, ARG4, ADE2, LYS2, SAT1, NAT1)
- Regulated promoters (e.g. MET3, MAL1, MAL2, PCK1, tet), and “constitutive” promoters (e.g. ACT1, ADH1, TDHS3, TEF1)
- Sterol synthesis genes (e.g. ERG1, ERG11)
- Reporter genes (e.g. yEGFP, yEYFP, yEGFP, Renilla luciferase, Gaussia luciferase, SfLacZ, SaLexA, LIFEACT, IRFP)
- DNA replication and repair genes, as well as meiosis-specific factors which may be involved in the evolution of antifungal drug resistance (e.g. REV1, REV7, SPO11, HOP1, RAD51, DLH1)
- Candida genomic, transposon mutagenesis, over-expression and cDNA libraries.
- Orthologues of a number of the above genes from other Candida species such as C. auris, C. parapsilosis, C. guilliermondii, C. lusitaniae, C. krusei
- Cell polarity genes (e.g. CDC24, CDC42, RSR1, BEN1, BNI1, BNR1, AXL2, RAX2, PXL1, BUD5, BUD2)
- Genes encoding proteins involved in fungal cell division, such as septins (e.g. CDC3, CDC10, CDC11, CDC12, SEP7, SPR3, SPR28), proteases (e.g. KEX2), myosin (e.g. MYO1), cyclins (e.g. HGC1) and cyclin-dependent kinases and phosphatases (e.g. CDC28, CDC14)
- Genes encoding metal ion transporters or proteins involved in metal ion acquisition (e.g. ZRT1, ZRT2, ZRT3, ZRC1, PRA1, orf19.5428, orf19.52, orf19.3874, orf19.3769, orf19.3132)
- Genes involved in acylglycerol and sterol ester metabolism (e.g. orf19.6501, DPP1, DPP2, DPP3, orf19.6941, SMP2, orf19.5426, orf19.4699, orf19.4864, ARE2, orf19.2050, orf19.1887)
- Genes involved with polarised growth and hyphal steering (e.g. CDC42, CDC24, BEN1, PXL1, TPK2, CST20, CLA4, FGR29, SST2).

The work will be kept within the boundaries of Cat2.
Candida spp. are a human fungal pathogen in ACDP Hazard Group 2. Candida spp. are commensals of the natural flora of the human body and are microorganisms of very low pathogenic potential and very rarely affect healthy individuals however when an individual is immunocompromised, such as HIV patients or organ transplant recipients, infection can occur, therefore Candida spp. are classed as opportunistic pathogens.

The genetic modifications proposed in this work are not expected to increase the virulence of the genetically modified micro-organism beyond that which is already associated with the parental organism. Also it is not anticipated that this proposed work would have an effect on any other traits of the GMM such as increased drug resistance therefore the increased risk to human health potentially caused by the construction of these GMM's is essentially equivalent to the risk already proposed by the parental organisms, which is classed as ACDP Hazard Group 2.

The majority of work proposed here involves the alteration of already existing genes, such as gene deletions and promoter replacements, with genes being replaced with auxotrophic markers, such as leu2, ura3, his1, ade2, and arg4, or with positive selection markers that is derived from foreign DNA such as nourseothricin resistance. Other foreign DNA will also be incorporated into the genome such as S. typhinerium HisG, tetR-SchAP4AD which is a tetracycline transactivator, or reporter genes, such as b-galactosidase, luciferase, GUS, GFP and its variants. Therefore it is highly unlikely that a hazard will arise as a result of directly inserting these DNA into Candida spp. Ultimately the genes that are being targetted for this proposed work are believed to have important roles in Candida spp. viability and virulence and we do not anticipate that the introduction of auxotrophic markers, an anti-biotic resistance marker, or any other genetic modification, in the work described here, to enhance the ability of Candida spp. to cause disease above that which is already associated with the parental organism or that it may confer resistance to current clinical antifungal treatments. therefore the risk to human health is essentially equivalent to the parental organism.

The proposed GMMs to be constructed in this project are not expected to show an altered hazard to the environment compared to the wild type strain and as Candida is a commensal fungi of the human population, alteration of existing traits is expected to pose no hazard to the environment. Furthermore, the gene products of the plasmids are not toxic or oncogenic. Candida organisms may be able to persist in the environment if a breach in containment occurred, however the integrated genes into the genome will posses no selective advantage compared to the wild type and will not confer resistance to current anti-fungal treatments, thus gene transfer would not be a hazard. Also the vectors used are non-mobilisable or mobilisation defective, thus cannot be transferred to other microorganisms.

**Evaluation of foreseeable effects**

**Purpose of the contained use**

Candida albicans and Pseudomonas aeruginosa are opportunistic pathogens that can be co-isolated from the cystic fibrosis lung. They have also been used as a model systems for the study of interspecies communication. Previous work by Dr. B has shown that killing of C. albicans hyphae, but not yeast, by the bacterium can occur through the activity of bacterial secreted factors but is more efficient in the presence of the bacterium (Brand et al, 2008). The goals of the project are to: determine the role of P. aeruginosa quorum-sensing (QS) signalling in the killing of C. albicans; elucidate the mode-of-action in the killing of C. albicans by P. aeruginosa; and characterise inter-species interactions in the context of mixed-species biofilms.

**Recipient or parental organism**

The recipient organism is Pseudomonas aeruginosa. All GM modifications in P. aeruginosa will be carried out by collaborators at research institutes/Universities that specialise in genetic modification of P aeruginosa. The strains used in Exeter will not contain vectors, and no vectors or plasmids will be used or held in Exeter.

**Host/vector system**

The P. aeruginosa GM strains used in these experiments are generated in the well-described wild-type backgrounds PAO1 (Stover et al. 2000) and PA14 (Rahme et al. 1995), two fully sequenced strains.

**Origin & function**

**Evaluation of foreseeable effects**

P. aeruginosa is an environmental bacterium that lives naturally in water, moist soil and swamp conditions. It can become an opportunistic human pathogen in patients with compromised epithelial and immune defences, such as sufferers of cystic fibrosis or those with wounds or burns. P. aeruginosa falls within the ACDP Hazard Group 2. The selectable markers confer resistance to the antibiotics gentamicin or tetracycline, which are not commonly used to treat infection by P. aeruginosa. Nevertheless, these antibiotics will not be used routinely in Exeter, since the insertions are stable in the genome.

The inserted genes (fluorescence markers such as GFP) are not associated with significant risk. The disruption of quorum sensing functions is likely to reduce toxin production and the virulence of P. aeruginosa (Williams and Camara, 2009; Rumbaugh et al. 1999; Rumbaugh et al. 2009). The most hazardous GMM is likely to be the wild type parental P. aeruginosa strains as the genetic modifications involve the inactivation of virulence-related functions such as quorum sensing. These mutations are likely to reduce virulence. A human infection by any of these mutants can be eradicated by antibiotic therapy.

The mutants used will have QS genes chromosomally disrupted, so there is little chance of the natural transfer of the mutated gene to other organisms.

Although we are handling a potential pathogen, the risks associated with this project are estimated to be low.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid Waste: Liquid waste will be inactivated using the autoclave at 121°C for 15 minutes or alternatively will be treated with 5% Chemgene and allowed a contact time of at least 20mins. This is sufficient to achieve >99.99% killing (by plating). Treated liquid waste would then be disposed of down a designated laboratory sink.

Solid Waste: Solid waste, such as pipette tips, eppendorf tubes, agar plates etc, will be disposed of into a sealed autoclave bag prior to being sterilised via autoclaving at 134°C for 40 minutes. Autoclave function is assessed and recorded via chart recorder and the autoclave is calibrated and serviced quarterly to ensure continued effectiveness, as well as being tested via 12 point thermocouple testing performed annually. Once inactivated the waste will then be disposed of into yellow clinical waste bags and ultimately disposed of via the university waste management route.

Glassware: Contaminated glassware is to be disinfected using a 5% Chemgene before being sterilised in the autoclave at 121°C for 15 minutes.

Sharps: The use of sharps will be minimised. These will be disposed of in designated sharps cinbins. Once full the cinbins are sealed and locked before being double bagged into clinical waste bags and incinerated.

Spills: In the event of a spill the contaminated area is flooded with concentrated Chemgene (to 5%, final conc.), mopped up with paper towels, and re-swabbed with 5% Chemgene.

**Project Additional Information**

**Purposes of the contained use**

Dermatophyte infections are the most common fungal infections, at any one given moment affecting up to 20% of the population worldwide. These are superficial infections, some of which can be recurrent infections. Little is known about the underlying pathogenicity mechanisms. Therefore, the overall goal of this study is to investigate the pathogenesis of the dermatophytes *Trichophyton rubrum*, *Trichophyton mentagrophytes*, *Microsporum canis* and *Epidermophyton floccosum*. Our specific goals are to examine the regulation and mechanisms of cell wall biosynthesis, host immune responses, and responses to nutrients and stresses.

**Recipient or parental organism**

We will examine dermatophytes isolated from human clinical infections. These include clinical isolates of *Trichophyton rubrum*, *Trichophyton mentagrophytes*, *Microsporum canis* and *Epidermophyton floccosum*.

**Host/vector system**

*Trichophyton rubrum*, *Trichophyton mentagrophytes*, *Microsporum canis* and *Epidermophyton floccosum*. The *Trichophyton mentagrophytes Ku80 null mutant strain* (TmKu80M9) (Yamada et al., 2009 FEMS Micro Letts) may also be utilised as this strain undergoes increased homologous recombination, increasing the likelihood of obtaining the null mutant of interest. We will use targeted gene disruption to create null mutants, or will overexpress specific genes using PCR generated
disruption cassettes or disruption cassettes cloned in E. coli K12. Transformation vectors will either carry the
Hygromycin B phosphotransferase (hbp) gene, the neomycin phosphotransferase (nptII) gene (Yamada et al., 2008 J.
Dermatol Sci), or the nourseothricin acetyltransferase (NAT) dominant selectable marker (Alshahani et al. 201 O Med
Mycol).

Origin & function

Genes to be investigated initially include cell wall synthesis (chitin, melanin and glucan) genes and genes involved in
stress pathways (Hog1 pathway, etc.). Mutants expressing an iRFP (infra-red fluorescent protein) reporter will also be
created to allow in vivo imaging in experimental models.

Evaluation of foreseeable effects

Dermatophyte infections are extremely common, affecting up to 20% of the population at any one given moment, and
can infect anyone, including healthy individuals. There is evidence that treatment with immunosuppressive drugs may
increase the chances of developing a dermatophyte infection. Lab workers are made aware of this risk factor and are
asked specifically in the Local Regulations to make their supervisors (or Occupational Health) aware if they are
exposed to this risk factor.

Dermatophyte fungal infections can affect the skin on almost any area of the body, such as the scalp, legs, arms, feet
groin, and nails. Symptoms of infection include itchiness, redness, scaling, cracking of the skin, or a ring-shaped rash
may occur. Standard antifungal treatments include oral and/or topical antifungal therapy with azoles or allylamines,
particularly itraconazole and terbinafine.

To date, any stable gene disruptions have either led to reduced growth rates or have had no effect on growth.

Similarly, virulence of the strains has either been reduced or unaffected. Transformation methods (biolistic
transformation, electroporation, Agrobacterium-mediated transformation) have not been demonstrated to alter
virulence in other systems.

All strains that are genetically modified will be assessed for altered susceptibility to antifungal agents (azoles) which
could be used to treat infection.

Horizontal gene transfer is extremely rare in fungi. The mutations will be to dermatophyte chromosomal genes, not
placed on mobile genetic elements.

The dermatophyte species in this study are anthropophilic in nature, living exclusively on humans. Other species are
zoophilic, living on animals, or geophilic, living in soil. The majority of human infections occur through contact with an
infected person or due to exposure to contaminated clothing, towels or bedding. However, humans can also become
infected with zoophilic species through contact with infected animals. The risk of infecting wild animals with
anthropophilic species is extremely low; in fact, experimental models of anthropophilic species infection have proved
virtually impossible to establish due to the low infectivity of human-associated species in rodents and other animals.
Therefore, none of the strains generated in this project are likely to present a hazard to the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid Waste: Liquid waste will be inactivated using the autoclave at 121°C for 15 minutes or alternatively will be
treated with 5% Chemgene and allowed to have a contact time of at least 20mins. According to the manufacturer's instructions. Treated liquid waste would then be disposed of down a designated laboratory sink.

Solid Waste: Solid waste, such as pipette tips, eppendorf tubes, agar plates etc, will be disposed of into a sealed autoclave bag prior to being sterilised via autoclaving at 134°C for 40 minutes. Autoclave function is assessed and recorded via chart recorder and the autoclave is calibrated and serviced quarterly to ensure continued effectiveness, as well as being tested via 12 point thermocouple testing performed annually. Once inactivated the waste will then be disposed of into yellow clinical waste bags and ultimately disposed of via the university waste management route.

Glassware: Contaminated glassware is to be disinfected using a 5% Chemgene before being sterilised in the autoclave at 121°C for 15 minutes.

Sharps: The use of sharps will be minimised. These will be disposed of in designated sharps cinbins. Once full the cinbins are sealed and locked before being double bagged into clinical waste bags and incinerated.

Animals and Tissues: All carcases will be autoclaved within the BSU, and all tissues are autoclaved prior to disposal. Our standard procedures for use of Chemgene have been validated to kill 99.99% of dermatophyte species (http://www.starlab.de/download/STARLAB-HLD4L-MicrobiologyTestSummary-v3.pdf)

Autoclaves are validated at least annually by means of biological indicators. In daily use, monitoring is by thermocouple temperature recordings and autoclave stripes included in each load.

On a routine basis, samples from autoclaved waste or Chemgene-treated waste will be plated and assessed for viability.

Once GMMs have been inactivated, normal disposal routes will be followed for liquid and solid waste. Killed waste will be disposed of down the sink drain and inactivated solid waste will be discarded by CFA processing.

Spills: The contaminated area will be flooded with concentrated Chemgene (to a final 5% concentration) and mopped with paper towels, then washed with 5% Chemgene. The contaminated materials will be autoclaved to inactivate any organisms.

**Purposes of the contained use**

We are dissecting the molecular mechanisms that underlie specific pathogenesis related phenotypes in the fungus, *Cryptococcus neoformans*: the re-orientation of tip-growing cells in response to external stimuli; changes in cell morphology and capsule formation that occur during infection; and genes that promote resistance to host immune attack.

**Recipient or parental organism**

*Cryptococcus neoformans* (Serotype A) is a human pathogen in ACDP Hazard Group 2. This fungus is ubiquitous in the environment and can commonly be isolated from decaying wood and soil that is contaminated with bird-droppings. The infectious particles are spores and dessicated yeast cells that become airborne when decaying material is disturbed. Particles enter the respiratory tract through inhalation and are carried and cleared asymptomatically by immunocompetent hosts. *C. neoformans* is an opportunistic pathogen and colonisation can lead to the development of Cryptococcal meningitis but ONLY if the host immune system is severely impaired. For example, presentation with this infection is considered a defining condition in the diagnosis of AIDS. No transmission of Cryptococcosis among animals or humans has been recorded (Faggi et al, 1993, Mycoses) and infection of an individual through microbial manipulation of the organism or spores has never been reported, in more than 40 years of research. *C. neoformans* is
a micro-organism of low pathogenic potential in healthy individuals.

**Host/vector system**

Wild type Cryptococcus neoformans strains (H99, KN99 and clinical isolates). Genes are deleted in wild type clinical isolates of C. neoformans (e.g. H99 and KN99 - opposite mating types). H99 is a clinical isolate that has become the reference strain for this Serotype (Toffaletti et al, 1993, J. Bacteriol.). KN99 is a strain that was created through a series of backcrosses between a clinical isolate a strain, 125.91, and H99 to obtain an congenic a strain that is calculated to be 96.9 % similar to H99 (Neilsen et al, 2003, IAI). In murine and rabbit models of Cryptococcal meningitis, KN99 was no more virulent than the clinical isolate, H99. H99 and KN99 will be used as control strains in this study.

Mutants are generated by other laboratories, e.g. Elizabeth Ballou, Carolina Coelho, Joe Heitman and Andrew Alspaugh (Duke University, USA) and Hiten Madhani (UCSF, USA). The genes are disrupted using a PCR based strategy using primers to amplify a 5’ and a 3’ region of homology (Gene-X-Right and Gene-X-left) to the targeted gene from genomic DNA and the selectable marker (NEO, HYG or NAT).

**Origin & function**

Targetted genes are involved in: calcium signalling (e.g. CCH1, MID1, PMR1/ECA1, calcineurin, CNA1, CNB1, CBP1); the biosynthesis of chitin and chitosan (e.g. CHS1-8, CSR1-3); RhoGTPase cell polarity pathways; metabolism (e.g. ICL1, MLC1); and capsule formation, morphogenesis, stress pathways and virulence factors.

**Evaluation of foreseeable effects**

As stated above, Cryptococcus neoformans is an opportunistic pathogen that can cause Cryptococcal meningitis but ONLY if the host immune system is severely impaired (e.g. in AIDS patients). No transmission of Cryptococcosis among animals or humans has been recorded (Faggi et al, 1993, Mycoses). The risk of contracting Cryptococcal meningitis in healthy individuals is negligible. Lab workers are unlikely to be exposed to the following risk factors:

a) use of cytotoxic or strongly immunosuppressive drugs (e.g. systemic corticosteroids),

b) general immunosuppression (e.g. organ transplant recipient, neoplastic disease)

c) AIDS patients

Lab workers are made aware of these risk factors during their initial induction into the lab and are asked specifically in the Local Regulations to make their supervisors (or Occupational Health) aware if they are exposed to any such risk factors.

Symptoms of Cryptococcal infection include headache, nausea, stiff neck and seizures (common in other forms of brain infection). Standard antifungal treatments include Amphotericin B, azoles and echinochandins.

To minimise the likelihood of infection, C. neoformans strains will be maintained as yeast cells on nutrient agar plates. C. neoformans spores are not aerial, but are embedded within a mating interface matrix. There is little chance of their becoming airborne from a mating plate. Additionally, spore production is relatively inefficient within the time periods necessary for spore collection (3-10 days). The chance of spore inhalation or spore dissemination from a mating plate is very low, and the chances of infection in a healthy human are nearly zero. However, to minimize risk of exposure, Any procedure that may result in aerosols will be carried out in a designated Class II safety cabinet.

The perturbation of target genes is most likely to attenuate the inability of the micro-organism to colonise the host. (Fromtling et al. 1982; Chang & Kwon-Chung 1994; Alspaugh et al., 2000; Ballou et al, 2010; Ballou et al., 2013). Also, the use of hygromycin, neomycin and nourseothricin resistance markers does not compromise treatment of infection with the preferred antifungal agents, Amphotericin B and azoles. The likelihood of natural gene transfer to other species is essentially zero.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

<td>Animals and Tissues: All carcases will be autoclaved, and all tissues are autoclaved prior to disposal. Our standard procedures for the use of Chemgene have been validated experimentally to kill &gt;99.99 % of C. neoformans vegetative cells. Viability tests have been performed on Chemgene -exposed cultures. Autoclaves are validated at least annually by means of biological indicators. In addition, we have validated killing at &gt;99.99 % by plating samples harvested from the centre of autoclaved samples. In daily use, monitoring is by thermocouple temperature recordings and autoclave-indicator tape included in the loads. Bench-top autoclaves in our laboratory are also monitored on a daily basis using autoclave-indicator tape and by checking the external temperature and pressure gauges. Our Laboratory Manager tests these autoclaves on a monthly basis using Browne’s tubes, which are included in the load and change colour on exposure to correct autoclave conditions. Killing by these autoclaves has been validated at &gt;99.99 % by plating from solid and liquid samples taken from the centre of the autoclave. In the event of a spill, the contaminated area is flooded with Chemgene (to 5 % final conc), mopped up with paper towels and reswabbed with 5 % Chemgene. Killing at &gt;99.99 % has been validated experimentally. Contaminated material is autoclaved.</td>

**Project Additional Information**

**Purposes of the contained use**

This application covers a range of specific projects with the overall goal of obtaining an improved understanding of the contributions of specific Aspergillus cell wall components, regulators and metabolic enzymes to the virulence and antifungal drug resistance of this fungus.

The specific goals are to characterise:
1) Molecular host-fungus interactions by analysing PAMPs (pathogen associated molecular patterns) on the Aspergillus cell wall being recognized by PRRs (pathogen recognition receptors) on immune cells (human cells, experimental murine models and alternative experimental infection models as Galleria mellonella wax moth larvae model, and the zebrafish model).

2) PAMPs and PRRs that modulate immune responses.

3) Intracellular signal transduction pathways used by PRRs.

4) Cell wall components of Aspergillus that contribute to its virulence, pathogenesis, drug targets and drug resistance mechanisms.

5) Remodelling of the cell wall structure in response to environmental changes.

6) Regulation of fungal biofilm formation and development.

7) Resistance to, and interaction with, antifungal agents and novel compounds including antimicrobial peptides and monoclonal antibodies.

8) Regulation of cell wall synthesis and architecture.

9) Role of cell wall proteins in cell wall structure and pathogenicity.

10) Function of chitin biosynthetic enzymes in cell wall structure and division.

11) Isolation of fungal cell walls for carbohydrate and proteomics analysis

12) Role of specific O- and N-glycosylating enzymes in cell wall structure and adhesion.

13) Role of specific signalling molecules, transcription factors, and target genes in stress responses, starvation responses, and pathogenicity.

14) Regulation of secreted hydrolytic enzymes and multi-drug transporters.

15) Effects of gene mutation and antifungal compounds on hyphal growth behaviour.

16) Sugar nucleotide biosynthetic pathways contributing to cell wall formation as potential antifungal drug targets.

17) Pathways involved in the generation and detoxification of reactive oxygen and nitrogen species.

Recipient or parental organism

Aspergillus is a human pathogen in ACDP Hazard Group 2. Aspergillus causes three principal diseases following inhalation of the spores: allergic bronchopulmonary aspergillosis (ABPA), pulmonary aspergilloma and invasive aspergillosis. However the clinical manifestations and severity of the disease depends upon the immunologic status of the patient. ABPA is a condition where the fungus causes allergic respiratory symptoms, such as wheezing and coughing, but does not actually invade and destroy tissue. APBA is rarely found in healthy people, and is most common in people with asthma or cystic fibrosis. Pulmonary aspergilloma (or “fungal ball”) usually occurs in people with other forms of lung disease, such as emphysema or tuberculosis. Invasive aspergillosis generally affects people who have severely compromised immune systems, such as people who have had a bone marrow transplant or solid organ transplant, people who are taking high doses of corticosteroids, and people undergoing chemotherapy for cancers, such as leukaemia. Rarely, persons with advanced HIV infection can also acquire the infection. The majority of infections are caused by A. fumigatus, the non-fumigatus Aspergillus species are less frequently encountered as causative pathogens and display a decreased virulence.

To keep things in perspective, it is important to realise that A. fumigatus and the other Aspergillus species are ubiquitous in the environment and are commonly found in soil, on plants, in decaying plant matter, household dust, building materials, and in some foods. Most people breathe in spores of Aspergillus every day and this does not cause harm, as people with healthy immune systems are able to clear this organism without any adverse effects. Thus, Aspergillus species are micro-organisms of low pathogenic potential not affecting healthy individuals and only become a potential medical problem when an individual’s immune responses are impaired. Furthermore, as with most pathogenic micro-organisms, the virulence of Aspergillus strains become attenuated, rather than enhanced, after prolonged laboratory culture.
Therefore, the risk of life-threatening fungal infections with the species described here is negligible in healthy individuals. Lab workers are unlikely to be exposed to the following factors, which increase the susceptibility to infections with Aspergillus:

1. Use of cytotoxic or strongly immunosuppressive drugs (e.g. systemic corticosteroids, chemotherapy for cancer)
2. Patients generally immunosuppressed (e.g. organ transplant recipient, neoplastic disease, severe burns)
3. Pre-existing illnesses that can predispose to infection e.g. Chronic Granulomatous Disorder, Cystic Fibrosis, Asthma.

Lab workers are made aware of these risk factors and are asked specifically in the Local Regulations to make their supervisors (or Occupational Health) aware if they are exposed to any such risk factors. In the event of an infection, standard antifungal treatment includes voriconazole, itraconazole, lipid amphotericin formulations, caspofungin, micafungin, and/or posaconazole.

Host/vector system

We plan to use strains of genetically modified Aspergillus species and clinical isolates which were generated in other Universities. We also plan to disrupt genes in A. fumigatus strain CEA17 (ku80Δ genetic background). This strain is used worldwide for the generation of A. fumigatus mutants as the strain has higher homologous recombination efficiency than wild type strains. Genes are deleted using a positive selectable marker, e.g. hygromycin or pyrithiamine resistance or the pyrG blaster. Alternatively genes may be placed under the regulation of an inducible promoter e.g. A. nidulans alcohol dehydrogenase gene (alcA promoter).

We will not use vectors but will integrate PCR-generated linear DNA cassettes or exploit CRISPR-Cas9 to modify the Aspergillus genome. For most experiments we will be using fungi with mutations which target, either directly or indirectly, the fungal cell wall biosynthetic machinery, signal transduction pathways, metabolism and/or virulence factors. This would include fungi with targeted mutations in genes involved in, for example, metabolism and transcription. Fungi overexpressing fungal or foreign genes, such as GFP, may also be used. Small culture volumes (less than 100ml, in most cases 10 ml) will be used. For in vivo experiments normally up to $10^8$ fungal conidia are administered per animal. Wild type immunologically competent animals are normally resistant to these, and even higher, inocula.

Some of the Aspergillus strains that may be used will be auxotrophic and therefore largely avirulent, but, by necessity (in virulence studies for example) other strains will not be genetically disabled. This includes null mutations in clinical (wild) isolates. It is important to note that a large number of A. fumigatus and non-fumigatus Aspergillus mutants have already been analysed in various laboratories world-wide, but there are NO reports of a mutation that increases virulence in immunocompetent animals. However, a limited number of mutations have been shown to have slight enhancing effects on virulence in studies using severely immunocompromised mice.

In some experiments, we will also use Aspergillus strains ectopically expressing specific genes, such as GFP or luciferase for example. The expression of these genes will have no effect on virulence.

The use of genetically modified strains of Aspergillus species under laboratory conditions represents minimal risk to human health. To date, there have been no reported cases of laboratory-acquired infections using this organism (http://www.phac-aspc.gc.ca/msds-ftss/msds11e-eng.php).

Origin & function

Genes to be modified in Aspergillus may include:

1. Chitin synthetic genes
2. Mannosylation genes
3. Beta-glucan synthetic genes
4. Hyphal-specific genes
1. Cell wall protein genes
2. Cell wall polysaccharide genes
3. Secreted hydrolases and other virulence-associated genes
4. Transcription factors
5. Signalling genes
6. pH-responsiveness genes
7. Calcium signalling genes
8. ABC transporters and efflux pumps
9. Stress and metabolism genes
10. Genes involved in programmed cell death
11. Genes that affect drug resistance
12. Auxotrophic and dominant selectable markers
13. Sterol synthesis and lipid biosynthesis genes
14. Expression of reporter genes (e.g. yEGFP, yEYFP, yEGFP, Renilla luciferase, Gaussia luciferase)
15. Mutant libraries necessary for screening for desired phenotypes.

Few, if any, of the mutations are likely to increase virulence.

Evaluation of foreseeable effects

There is no possibility of genetic exchange between the modified Aspergillus species and human cells.
As described above, there is a possibility of increased virulence for a few of the strains in severely immunocompromised individuals. However, the risk of infection is negligible in immunologically competent laboratory staff.
The likelihood of natural gene transfer to other organisms is essentially zero.
Aspergillus species are saprophytic organisms ubiquitously found in the environment. The risk of infection of wild mammals (such as rodents) through accidental release of laboratory strains of Aspergillus is negligible because to succumb to infection with laboratory strains, the animals need to be immunocompromised and subjected to extremely high infective doses (>10^6 CFU). Therefore, none of the strains used in this project are likely to present a hazard to the environment. Nevertheless, the transport of all organisms between laboratories and facilities as indicated above will be performed in sealed containers.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid Waste: Liquid waste will be inactivated using the autoclave at 121°C for 15 minutes or alternatively will be treated with 5% Chemgene and allowed to have a contact time of at least 20mins. According to the manufacturer's instructions. Treated liquid waste would then be disposed of down a designated laboratory sink.
Solid Waste: Solid waste, such as pipette tips, eppendorf tubes, agar plates etc, will be disposed of into a sealed autoclave bag prior to being sterilised via autoclaving at 134°C for 40 minutes. Autoclave function is assessed and recorded via chart recorder and the autoclave is calibrated and serviced quarterly to ensure continued effectiveness, as well as being tested via 12 point thermocouple testing performed annually. Once inactivated the waste will then be
disposed of into yellow clinical waste bags and ultimately disposed of via the university waste management route.

Glassware: Contaminated glassware is to be disinfected using a 5% Chemgene before being sterilised in the autoclave at 121°C for 15 minutes.

Sharps: Sharps, such as syringe needles, scalpel blades, microscope slides etc, are to be disposed of into designated sharps cinbins. Once full the cinbins are sealed and locked before being double bagged into clinical waste bags and incinerated.

Animals and Tissues: All carcasses will be autoclaved within the BSU, and all tissues are autoclaved prior to disposal. Validation will involve regular testing of the autoclaves by our laboratory using Browne tubes and biannually by independent external assessors to demonstrate, using independent thermocouples placed at the centre of the load, that the correct time and pressure have been reached for the required time.

In the event of a spill, the contaminated area is flooded with Chemgene 5%, mopped up with paper towels, and reswabbed with Chemgene 5% and a final clean with 70% ethanol.

The enclosed GMM application has been accepted by our Exeter GMM Committee, with a view to inspecting the Class 2 Laboratory (Geoffrey Pope 301) once the refurbishment has been completed.

Please enter comments on the GM safety committee on the risk assessment

This application covers a range of specific projects with the overall aim to define the ligand and range of mycobacterial species that are recognised by a C-type lectin receptor, and to determine the physiological role of this receptor in vitro and in vivo. In particular, this project will utilise a range of non-pathogenic mycobacterial species including both wild-type and GM Mycobacterium smegmatis and M. bovis BCG.

Recipient organisms include M. bovis BCG strains Tokyo and Pasteur and M. smegmatis mc2155. All mycobacterial strains used in this project are either listed as hazard group 2 (M. bovis BCG) or are not listed (M. smegmatis). M. smegmatis is a non-pathogenic soil organism, but due to its taxonomic grouping it is being treated as a group 2 organism. M. bovis BCG is routinely used as a vaccine against M. tuberculosis in humans.

In some of the experiments, mycobacterial strains will be tested using standard rodent models of infection in wild-type and receptor knockout mice. Small amounts of these strains will be transported to the BSU in sealed containers and administered into animals by intratracheal inoculation in a containment level 2 facility. The animals receiving these organisms will be housed in individually ventilated cages (IVCs). This will be carried out by trained and licensed personnel. BSU staff will not be directly involved in these experiments but are aware of the associated minor risks and local rules will be posted.

In some of the experiments, tissues which may contain small amounts of live GM bacteria are removed from infected animals and transported back to the lab in sealed containers for various experiments including the determination of bacterial burden and histology. Frozen, unfixed sections may be analysed by fluorescence microscopy. These sections would contain very small amounts of bacteria therefore present minimal risk. Local GM regulations will be posted in all locations.

In other experiments small amounts of fixed GM mycobacterial cells will be analysed by flow cytometry (<106 cells per sample). Local GM safety procedures have been established for the decontamination of samples and equipment. Fixed samples are expelled directly into 5% Tri-gene. Local GM regulations will be posted in all locations.
A microbiological safety cabinet will be used when working with M. bovis BCG or whenever aerosols are expected such as when resuspending cells after centrifugation.

M. smegmatis can survive in the environment but the GMMs will be compromised by their genetic modification. Similarly M. bovis BCG will also be compromised and survival is likely to be very short-lived. The severity of contamination of the environment by any of these mycobacterial strains is therefore likely to be low.

The inserted/modified DNA will not encode known harmful gene products. Thus it is unlikely that the GMMs will have any harmful effects on the environment.

Transport of all organisms between laboratories will be performed in sealed containers.

Origin & function

No new GMOs will be generated in Exeter. The nature of the mycobacterial ligand is currently unknown but possible candidates include genes encoding pathways responsible for the production of cell wall components such as lipids, PIM1,2, PIM6, MAME, LAM, man-LAM, TDM, which could be involved in host cell recognition. More commonly, we will be utilising mycobacterial strains expressing fluorescent markers, such as GFP or commonly used markers for studying immunological processes, such as ovalbumin.

Evaluation of foreseeable effects

All mycobacterial strains used in this project are listed as hazard group 2 (M. bovis BCG and M. smegmatis). M. smegmatis is a non-pathogenic soil organism, but due to its taxonomic grouping it is being treated as a group 2 organism. M. bovis BCG is routinely used as a vaccine against M. tuberculosis in humans. No GM organisms will be generated in Exeter.

The risk of life-threatening infections with M. smegmatis and M. bovis BCG is negligible in healthy individuals. However, M. smegmatis has been reported to cause localized skin and soft tissue infections following traumatic injury or cardiac surgery. Immunocompromised and elderly individuals are more susceptible to M. bovis BCG, which can cause pulmonary infections.

In some of the experiments, mycobacterial strains will be tested using standard rodent models of infection in wild-type and receptor knockout mice. Small amounts of these strains will be transported to the BSU in sealed containers and administered into animals by intratracheal inoculation in a containment level 2 facility. The animals receiving these organisms will be housed in individually ventilated cages (IVCs). This will be carried out by trained and licensed personnel. BSU staff will not be directly involved in these experiments but are aware of the associated minor risks and local rules will be posted.

In some of the experiments, tissues which may contain small amounts of live GM bacteria are removed from infected animals and transported back to the lab in sealed containers for various experiments including the determination of bacterial burden and histology. Frozen, unfixed sections may be analysed by fluorescence microscopy. These sections would contain very small amounts of bacteria therefore present minimal risk. Local GM regulations will be posted in all locations.

In other experiments small amounts of fixed GM mycobacterial cells will be analysed by flow cytometry (<10^6 cells per sample). Local GM safety procedures have been established for the decontamination of samples and equipment. Fixed samples are expelled directly into 5% Tri-gene. Local GM regulations will be posted in all locations.

A microbiological safety cabinet will be used when working with M. bovis BCG or whenever aerosols are expected such as when resuspending cells after centrifugation.

M. smegmatis can survive in the environment but the GMMs will be compromised by their genetic modification. Similarly M. bovis BCG will also be compromised and survival is likely to be very short-lived. The severity of contamination of the environment by any of these mycobacterial strains is therefore likely to be low.

The inserted/modified DNA will not encode known harmful gene products. Thus it is unlikely that the GMMs will have
any harmful effects on the environment. Transport of all organisms between laboratories will be performed in sealed containers. It is extremely unlikely that gene deletion and complementation with heterologous genes will alter the virulence of the GMM compared to that of the parent organism. In fact, deletion of cell wall components is most likely to reduce virulence, as has been demonstrated in the literature (Mahon RN et al, 2012, Smith I, 2003). The likelihood of the cloned DNA being transferred by accident to other organisms via natural gene transfer is very low. The vectors used in mycobacteria are self-replicating plasmids that do not contain identifiable mobilisation functions or they are modified bacteriophage. The latter are derived from a temperature sensitive conditionally replicating lytic phage TM4. There could be transfer therefore of the TM4 derivatives to other mycobacteria but this would lead to lysis of the recipient (30°C) or recombination (37°C) and allele exchange which would compromise the recipient. Both scenarios are likely to be rare.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid Waste: Liquid waste will be inactivated using the autoclave at 121°C for 15 minutes or alternatively will be treated with 5% Chemgene and allowed to have a contact time of at least 20mins. According to the manufacturer's instructions. Treated liquid waste would then be disposed of down a designated laboratory sink.

Solid Waste: Solid waste, such as pipette tips, eppendorf tubes, agar plates etc, will be disposed of into a sealed autoclave bag prior to being sterilised via autoclaving at 134°C for 40 minutes. Autoclave function is assessed and recorded via chart recorder and the autoclave is calibrated and serviced quarterely to ensure continued effectiveness, as well as being tested via 12 point thermocouple testing performed annually. Once inactivated the waste will then be disposed of into yellow clinical waste bags and ultimately disposed of via the university waste management route.

Glassware: Contaminated glassware is to be disinfected using a 5% Chemgene before being sterilised in the autoclave at 121°C for 15 minutes.

Sharps: The use of sharps will be minimised. These will be disposed of into designated sharps cinbins. Once full the cinbins are sealed and locked before being double bagged into clinical waste bags and incinerated.

Slides from microscope facilities: Slides are transported to/from microscope rooms in plastic petri dishes with their tops sealed with tape or parafilm, and then disposed of as per Sharps.

Animals and Tissues: All carcasses are autoclaved within the BSU, and remaining tissues are autoclaved prior to disposal.

Cytometry facility: Fixed samples are expelled directly into 5% Chemgene and equipment will be decontaminated with 5% Chemgene.

**Project Additional Information**

- **Purposes of the contained use**
  
  Our primary goal is to define the roles of C-type lectin-like receptors, Natural Killer lectin-like receptors, Toll-like
receptors and other pattern recognition receptors (PRRs) in immunity. We target PRRs to modulate immune
responses, determine the intracellular signal transduction pathways used by PRRs, follow the temporal dynamics of
phagocytosis and phagosome maturation, and examine the involvement of PRRs in maintaining homeostasis.
To achieve these goals we perform experiments where the cellular functions of PRRs are characterised using cells
which are transduced to express these receptors and examine their interaction with various pathogens, other cell
types, and cellular or serum components.
Most of this work is carried out by transfecting and transducing cell lines and primary murine cells (which is under a
separate application). However, we now need to transfet haematopoietic cells and cell lines, such as macrophages,
which are notoriously difficult to transfect using our current methodology. Therefore, to transduce these cells, we wish
to use lentiviruses as these are much more efficient and increasingly used within the field.

Recipient or parental organism

i) Bacterial expression:
The bacterial organisms are E. coli K12 derivatives and are unlikely to survive in the human gut or elsewhere. None of
the genes expressed here would be expressed in these bacterial cells since the genes lack a bacterial promoter. Even
if expression did occur, it would not be anticipated to confer any pathological advantage to the bacterial host.
ii) HEK293 FT (Invitrogen) and 293 LTV (Cell Biolabs) producer cell lines
These cells are used to produce lentiviral vectors.
iii) Transduced cells
We will use the lentiviruses to transduce primary murine cells and cell lines with PRR or phagosome maturation
regulation encoding genes. We will also use lentiviruses to transduce human cell lines with PRR genes. Primary
human cells will NOT be transduced. Transduced cell lines will be screened to identify stably transduced clones,
which will be selected for long term culture.

Lentiviral vectors:
To generate the packaged lentiviruses for cell transduction, three plasmid vectors are required using the Virasafe
system (Cell Biolabs): pRSV-Rev, either pCMV-VSV-G (amphotropic) or pCMV-ecoEnv (ecotropic) and pCgpV.
- pCgpV packaging Vector- carries the coding sequences for HIV-1 gag (viral core proteins) and pol (viral replication
enzymes for replication and integration of lentivirus) genes. This plasmid contains CMV promoter to allow high level
expression of the HIV-1 gag and pol genes in mammalian cells. It also has the Rev response element (RRE) to permit
- Rev-dependent expression of gag and pol genes and a polyA signal for efficient transcription termination and
polyadenylation of mRNA. A codon wobble sequence is included at the start of the gag gene to reduce sequence
homology with lentivirus expression vector sequences.
- pRSV-Rev carries the open reading frame for HIV-1 Rev which encodes Rev, the protein that interacts with the RRE
on pCgpV to induce gag and pol expression and to promote the nuclear export of unspliced viral RNA for packaging
into viral particles. The plasmid also contains RSV promoter sequence, therefore abrogating the need for the viral Tat
protein.
- pCMV-VSV-G- carries the coding sequence for the envelope G glycoprotein from Vesicular Stomatitis virus to allow
production of pseudotyped lentivirus with a broad host range. The CMV promoter and polyadenylation signal allow
expression of the VSV-G gene in mammalian cells and allows efficient transcription, termination, and polyadenylation
of mRNA.
- pCMV-ecoEnv- carries the coding sequence for the envelope protein (gp70) of Murine Leukaemia Virus (MLV)
allowing production of pseudotyped lentivirus only able to infect mouse and rat cells.
For expression of the PRR receptor and phagosome maturation regulation genes we will initially use the System
Biosciences vector pCDH-EF1-MCS-T2A-puro. This vector uses the EF1 promoter for heterologous gene expression
and contains a Multiple Cloning Site, a WPRE element (to enhance stability and translation of the transcript), a SV40
polyadenylation signal (to enable efficient termination of transcription and processing of recombinant transcripts), a hybrid RSV/5'LTR promoter (to provides a high level of expression of the full-length viral transcript in producer 293 cells), the genetic elements necessary for packaging, transducing, and stably integrating the viral expression construct into genomic DNA (cPPT, gag, env, LTRs etc.), a SV40 origin (which would enable stable propagation of the pCDH plasmid in mammalian cells, a pUC origin (for high copy replication and maintenance of the plasmid in E.coli cells), an ampicillin resistance gene (for selection in E.coli cells), a puromycin resistance gene (to enable selection of mammalian cells), and a T2A peptide-enabled dual expression system (to enable protein co-expression). We may also use pCDH-EF1-MCS-IRES-GFP (System Bioscience) which works on similar principals.

We will also utilise lentiviral vectors such as the pSIH-H1-copGFP vector (System Bioscience) to monitor packaging efficiency and any other vectors required for controls. We also include basic pUC, pEGFP (a pUC based plasmid, Clontech), and pCMV6 (pBR322 based plasmid, Origene) which carry the following murine phagosome maturation regulation encoding genes fused to fluorescent tags (e.g. GFP, RFP): wild-type or functional mutants (constitutively active or dominant negative versions) of members of the Rab GTPase family (i.e. Rab2a, Rab5, Rab7 and Rab14) as well as LAMP-1 and V-ATPase. These plasmids are maintained in E. coli, and are non-transmissible. They are specifically designed for expression of fusion proteins (for e.g. the Rabs in mammalian cells, not E. coli, and therefore these E. coli strains carry minimal risk. These plasmids will only be used in transient transfection assays of murine cells and cell lines.

HEK293 FT and 293 LTV producer cell lines will be transfected with pRSV-Rev, either pCMV-VSV-G (amphotropic) or pCMV-ecoEnv (ecotropic) and pCgpV (see above).

The following safety features ensure that these vectors are unable to replicate:
1. The expression vectors contain a deletion in the 3′ LTR (ΔU3) which causes “self-inactivation” of the lentivirus after transduction of the target cell. Once integrated into the transduced target cell, the lentiviral genome is no longer capable of producing a packageable viral genome.
2. The minimal number of genes from HIV-1 are used in the packaging system and has been reduced to three (i.e. gag, pol, and rev) and tat is no longer required.
3. The VSV-G gene from Vesicular Stomatitis Virus is used in place of the HIV-1 envelope protein.
4. The three packaging plasmids allow expression in trans of proteins required to produce viral progeny (e.g. gal, pol, rev, env) in the 293FT producer cell line. None of them contain LTRs or the Ψ packaging sequence. This ensures that none of the HIV-1 structural genes are present in the packaged viral genome, and are therefore never expressed in the transduced target cell. No new replication-competent virus can be produced.
5. The lentiviral particles produced in these systems are replication-incompetent and only carry the gene of interest. No other viral species are produced.
6. Expression of the gag and pol genes from pCgpV has been made Rev-dependent by the presence of the HIV-1 RRE in the gag/pol mRNA transcript. Addition of the RRE prevents gag and pol expression in the absence of Rev.

Host/vector system

HEK293 FT and 293 LTV producer cell lines will be transfected with pRSV-Rev, either pCMV-VSV-G (amphotropic) or pCMV-ecoEnv (ecotropic) and pCgpV (see above).

The following safety features ensure that these vectors are unable to replicate:
1. The expression vectors contain a deletion in the 3′ LTR (ΔU3) which causes “self-inactivation” of the lentivirus after transduction of the target cell. Once integrated into the transduced target cell, the lentiviral genome is no longer capable of producing a packageable viral genome.
2. The minimal number of genes from HIV-1 are used in the packaging system and has been reduced to three (i.e. gag, pol, and rev) and tat is no longer required.
3. The VSV-G gene from Vesicular Stomatitis Virus is used in place of the HIV-1 envelope protein.
4. The three packaging plasmids allow expression in trans of proteins required to produce viral progeny (e.g. gal, pol, rev, env) in the 293FT producer cell line. None of them contain LTRs or the Ψ packaging sequence. This ensures that none of the HIV-1 structural genes are present in the packaged viral genome, and are therefore never expressed in the transduced target cell. No new replication-competent virus can be produced.
5. The lentiviral particles produced in these systems are replication-incompetent and only carry the gene of interest. No other viral species are produced.
6. Expression of the gag and pol genes from pCgpV has been made Rev-dependent by the presence of the HIV-1 RRE in the gag/pol mRNA transcript. Addition of the RRE prevents gag and pol expression in the absence of Rev.

Origin & function

Constructs will contain the full, part or mutated version of the open reading frame of the gene of interest. In the case of phagosome maturation regulators, specifically the members of the Rab GTPase family under study, the mutations to be introduced will result in either constitutively activated or dominant negative versions of these proteins. Other constructs will be chimeras with the aim of expressing receptors with tags (e.g. haemagglutinin or fluorescent proteins), defined ligand binding domains, or defined intracellular signalling domains. Expression of these constructs will be driven by the promoter in the vector. The protein of interest will be expressed either intracellularly or on cellular membranes.
All genes of interest will be:
- human or mouse PRRs or mouse phagosome maturation regulators involved in vesicular trafficking, cell-cell adhesion and phagosome acidification (e.g. C-type lectins: Mannose receptor, Dectin-1, Dectin-2, CLECSF8, CLEC-1, MICL, CLEC-2, CLEC12B, CLEC9A, MINCLE, DCAR, KLR11, KLR12
- Scavenger receptors: Scavenger receptor B1, Scavenger receptor A1, LOX-1, SCARF1, CD36
- Toll like receptors: TLR1, TLR2, TLR4, TLR5, TLR6, TLR7, TLR8, TLR9, TLR10, TLR11
- Collectins: SP-A, SP-D, MBL
- Integrins: CR3
- Rab GTPases: Rab2a, Rab5a, Rab7a, Rab14
- Lysosomal-associated membrane glycoproteins: LAMP-1
- Proton transporters: V-ATPase

E. coli

There is unlikely to be any hazard to the environment from these bacterial organisms. The host bacterial organisms are E. coli K12 derivatives and they have a proven safe history of use in routine cloning work.

Lentiviral vectors

Lentiviruses require close contact for their transmission and their survival in the general environment is poor; they are temperature, desiccation, detergent, protein denaturant and pH sensitive. Replication deficient lentiviruses cannot propagate so therefore, after infection of a cell they are incapable of further replication. It will be possible to demonstrate that the lentiviral vectors are replication deficient by plating 5% of the vector stock supernatant into mitotically active indicator cells (e.g. 293FT cells) and monitoring for syncitia formation or by PCR analysis of cells that have been transduced with lentiviral vector stocks using primers specific for pro-viral components, such as VSV-G. The insertion of these genes is not expected to alter the tropism of the lentiviral vector. Lentiviral particles carrying phagosome maturation regulation genes represent an increased risk given the possibility of their acquiring tumorigenic potential. However, the strict following of containment level 2 safety practices and decontamination procedures would secure that no worker becomes in contact with these viral particles and that used surfaces are decontaminated after work has ceased.

Factors such as congenital immunodeficiency and secondary immunodeficiency caused by serious illness or chemotherapy would increase the susceptibility to infection by micro-organisms, including the genetically modified micro-organisms described in this application. In carriers of wildtype HIV there may be a theoretical risk of recombination of the lentiviral vector with wildtype virus. Thus, there would be the potential risk of mobilisation and transmission of the recombinant lentivirus to other individuals via the normal routes of HIV-1 transmission. Individuals known to be HIV-positive or to be immunocompromised will not be allowed to work on this project, these risks will be made clear to all personnel in the laboratory.

We would not expect any specific symptoms as the result of an infection with the genetically modified microorganisms described in this application since the lentiviral vectors cannot replicate.

Evaluation of foreseeable effects

We would not expect any specific symptoms as the result of an infection with the genetically modified microorganisms described in this application since the lentiviral vectors cannot replicate.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Liquid Waste: Liquid waste will be inactivated using the autoclave at 121°C for 15 minutes or alternatively will be treated with 5% Chemgene and allowed to have a contact time of at least 20mins. According to the manufacturer's instructions. Treated liquid waste would then be disposed of down a designated laboratory sink.

Solid Waste: Solid waste, such as pipette tips, eppendorf tubes, agar plates etc, will be disposed of into a sealed autoclave bag prior to being sterilised via autoclaving at 134°C for 40 minutes. Autoclave function is assessed and recorded via chart recorder and the autoclave is calibrated and serviced quarterly to ensure continued effectiveness, as well as being tested via 12 point thermocouple testing performed annually. Once inactivated the waste will then be disposed of into yellow clinical waste bags and ultimately disposed of via the university waste management route.

Glassware: Contaminated glassware is to be disinfected using a 5% Chemgene before being sterilised in the autoclave at 121°C for 15 minutes.

Sharps: Sharps will NOT be used for this work.

Gloves and lab coat will be worn, and a microbiological safety cabinet will be required.

Validation will involve regular testing of the autoclaves to demonstrate using independent thermocouples placed at the centre of the load, that the correct time and pressure have been reached for the required time. All autoclaves will be validated at least biannually. High expectation of 100% kill of GM microorganisms exposed to 121°C for 15 minutes.

Standard procedures for use of Chemgene (5% for high level disinfection, Medimark Scientific) have been validated experimentally for HIV lentiviruses and causes apoptosis of cells and denaturation of RNA and DNA.

Autoclaves are validated at least annually by means of biological indicators. In daily use, monitoring is by thermocouple temperature recordings and autoclave strips included in the loads. Bench-top autoclaves in our laboratory are also tested regularly. We test these autoclaves monthly, and in addition they are examined by external experts twice a year.

Once GMMs have been inactivated, normal routes of disposal are used for liquid and solid waste. Killed liquid waste is discarded down the sink. Inactivated solid waste is discarded by CFA processing.

Spills: The contaminated area is flooded with concentrated Chemgene (to 5%, final conc.), mopped up with paper towels, and re-swabbed with 5% Chemgene. Killing at >99.99% has been validated experimentally for enveloped viruses such as lentiviruses. Contaminated material is autoclaved.

All equipment, including microscopes and cytometers, is decontaminated by wiping and flushing with 5% Chemgene.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The enclosed GMM application has been accepted by our Exeter GMM Committee, with a view to inspecting the Class 2 Laboratory (Geoffrey Pope 301) once the refurbishment has been completed.

Project Containment
We aim to establish a transformation protocol for genetic modification of strains from the Sporothrix species complex, by using gene disruption, CRISPR-Cas9 gene editing and overexpression of small RNAs. This genetic manipulation will allow:
(a) The identification the molecular components responsible for the stimuli elicited in innate immune cells by EVs isolated from Sporothrix complex species;
(b) The dissection of putative virulence factors, such as melanin formation, cell wall structure and pathogen-associated molecular pattern molecules (PAMPs);
(c) The investigation of fitness attributes that are important for pathogenicity, such as stress and nutrient responses and;
(d) The examination of potential drug targets, such as regulators of ergosterol and glucan biosynthesis.

Most experiments involve the modification of wild type Sporothrix isolates. Efficient genetic engineering techniques need to be developed for Sporothrix to facilitate important new insights into fungal virulence mechanisms and identify new targets for more effective antifungal therapies.
and animal sporotrichosis. S. mexicana, S. luriei, S. pallida, and S. chilensis belong to the environmental clade that is related to opportunistic infections in immunocompromised patients (Garcia Carnero et al., 2018).

Opportunistic sporotrichosis infections in humans are generally caused by traumatic inoculation via contaminated plant matter or from scratches and bites from infected animals. For this reason, the use of sharps will be banned for experiments with Sporothrix (with the exception of microscope slides). All lab workers will be made aware of the risks of working with Sporothrix and of potential infection via breaks in the skin or, for immunocompromised individuals, via inhalation. Therefore, researchers with any skin conditions or abrasions will wear personal protection equipment (gloves) when handling Sporothrix.

In immunocompromised patients, sporotrichosis can arise through pulmonary infections via inhalation of spores. For this reason, work with Sporothrix spores will be performed in a class 2 biological safety cabinets in a designated Sporulating Fungus Suite within our Cat 2 laboratory.

The treatment for sporotrichosis requires a long-term administration of antifungal drugs, from 3-12 months depending on the severity of the disease, as well as the infecting species. Itraconazole is the drug of choice in uncomplicated cutaneous manifestation. Alternatively, fluconazole, terbinafine or a combination of drugs can be administrated for resistant isolates. For systemic sporotrichosis, the treatment is performed using amphotericin B and itraconazole (Mahajan, 2014).

### Host/vector system

#### Sporothrix:
Recipient strains will include Sporothrix brasiliensis, Sporothrix schenckii, Sporothrix chilensis, Sporothrix globosa, Sporothrix luriei, Sporothrix mexicana and Sporothrix pallida. S. brasiliensis, S. schenckii, S. globosa and S. luriei are clinical (wild type) isolates obtained from patients in South America and the USA. S. chilensis, S. mexicana and S.pallida are environmental (wild type) isolates from South America.

We will attempt to make ku80 and pyrG mutants to enhance homologous recombination in Sporothrix and to provide an auxotrophic marker for transformation (i.e. uracil auxotrophy). Based on other fungal pathogens, this is likely to render the transformation host avirulent strains (Brand et al., 2004).

Transformation will exploit the Hygromycin B phosphotransferase (hbp) gene, the phleomycin gene (Punt & van den Hondel, 1992), the nourseothricin acetyltransferase (NAT) (Alshahni et al., 2010), and the pyrithiamine resistance gene (Kubodera et al., 2000) as dominant selectable markers. In some experiments we will use the PyrG gene to complement the pyrG mutation (selecting for uracil prototrophy) (d’Enfert, 1996).

Disruption and CRISPR-Cas9 cassettes will be generated by PCR and cloned into Jet or pUC19 containing the selection marker (hygromycin, phleomycin, nourseothricin or pyrithiamine resistance). These constructs will be transformed into Sporothrix by excising them from pJet or pUC19 using specific restriction enzymes. If these strategies don’t work, we will exploit the Agrobacterium-mediated co-transformation toolkit to transform Sporothrix.

#### Aspergillus:
The disabled Aspergillus niger and Aspergillus oryzae strains, ATNT ΔpyrG (Geib & Brock, 2017), OP12 pyrG negative (Geib et al., 2019) and those strains deleted for pabA gene (unpublished data)

E. coli: The disabled E. coli strains, DH5-α (NEB), 10-β (NEB) and Stellar (Takara) will be used for cloning of plasmids containing specific Sporothrix genes and, BL21 Rosetta 2 (DE3) (Novagen) will be used as hosts for the heterologous of those genes. Standard non-mobilisable Ampicillin resistance-based plasmids will be used in E. coli.

#### Agrobacterium
Agrobacterium helper strains, such as AGL1, EHA105, LBA1100, LBA1126 or LBA4404 will be used to mediate the transformation of Sporothrix (Hooykaas et al., 2018). Rifampicin, gentamicin, tetracycline, and carbenicillin resistance genes will be used to select positive clones of Agrobacterium (Hooykaas et al., 2018).

### Origin & function

Target genes will include those involved in cell wall synthesis (e.g. chitin, melanin and glucan synthesis) stress pathways (e.g. Hog1 signalling, Yap1-like transcription factors, cell wall remodelling, etc.), and nutrient responses.

Other genes will be investigated as new hypotheses are generated. The GM Committee will be informed of any significant changes in project direction and will be provided with details of genes that are being targeted for genetic modification.

Sporothrix: Most genes will be deleted or inactivated, not inserted.

Aspergillus: Specific Sporothrix genes will be overexpressed (e.g. melanin biosynthesis, enzymes related to secondary metabolites production, antigenic proteins from Sporothrix)

E. coli: Specific genes will be overexpressed (e.g. melanin biosynthesis, enzymes related to secondary metabolites production, antigenic proteins from Sporothrix).
Agrobacterium: plasmids containing interference RNA or gene deletion constructs for transformation of Sporothrix.

**Evaluation of foreseeable effects**

The Sporothrix GMOs are unlikely to be any more hazardous than their wild type parental strains, since we aim to knock out genes associated with virulence or to overexpress antigenic proteins. However, the Sporothrix species of interest are classified as ACDP Hazard Group 2. Therefore, by definition, they have potential to cause harm, but these infections are not life-threatening in healthy individuals.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Liquid Waste: Liquid waste will be inactivated using the autoclave at 121°C for 15 minutes or alternatively will be treated with 5% Chemgene and allowed to have a contact time of at least 20mins. According to the manufacturer's instructions. Treated liquid waste would then be disposed of down a designated laboratory sink.

Solid Waste: Solid waste, such as pipette tips, eppendorf tubes, agar plates etc, will be disposed of into a sealed autoclave bag prior to being sterilised via autoclaving at 134°C for 40 minutes. Autoclave function is assessed and recorded via chart recorder and the autoclave is calibrated and serviced quarterly to ensure continued effectiveness, as well as being tested via 12 point thermocouple testing performed annually. Once inactivated the waste will then be disposed of into yellow clinical waste bags and ultimately disposed of via the university waste management route.

Glassware: Contaminated glassware is to be disinfected using a 5% Chemgene before being sterilised in the autoclave at 121°C for 15 minutes.

Sharps: Sharps, such as syringe needles, scalpel blades, will be banned for work with Sporothrix. Microscope slides will be used for some experiments, and these are to be disposed of into designated sharps binbins. Once full the cinbins are sealed and locked before being double bagged into clinical waste bags and incinerated.

Animals and Tissues: All carcases will be autoclaved within the BSU, and all tissues are autoclaved prior to disposal.

Validation will involve regular testing of the autoclaves by our laboratory using Browne tubes and biannually by independent external assessors to demonstrate, using independent thermocouples placed at the centre of the load, that the correct time and pressure have been reached for the required time.

In the event of a spill, the contaminated area is flooded with Chemgene 5%, mopped up with paper towels, and reswabbed with Chemgene 5% and a final clean with 70% ethanol.

**Project Containment**

02/03/2022
Constructing a replication incompetent adenovirus vector capable of expressing putative immunogenic antigens of the fungal pathogen Aspergillus fumigatus

The often-fatal fungal lung disease invasive aspergillosis (IA) has claimed more than 8 million human lives since its emergence ~ 40 years ago. IA-related mortality is unacceptably high (50-90%) and usually results from respiratory failure due to haemorrhage occurring at sites of fungal invasion. Given the life-saving potential of anti-invasion therapies, a high premium has been placed upon identifying effectors of tissue invasion, against which drugs and vaccines might be engineered. However, the quest for causal associations between tissue-invasive phenotypes and secreted fungal products has repeatedly failed, presumably due to likely functional redundancy amongst the effector repertoire and insufficiency of genetic approaches in A. fumigatus with which to drive high throughput analyses of secreted fungal products. Using mouse models of IA, in vitro infections of cultured human lung cells, functional
genomics and a high throughput A. fumigatus gene deletion methodology we have discovered a first-in-field cohort of 42 effectors of tissue invasion (eTINs) which govern lytic death of human lung cells. We will now combine state-of-the-art genetic, single cell imaging and effector-trap approaches with our established methodological workflow to conclusively define the invasive A. fumigatus secretome and to characterise the modes of entry and/or lytic activity of the individual effectors. This work will reveal for the first time the molecular basis of tissue invasive IA pathologies and define the genomic cohort of targets against which anti-invasion therapies and novel vaccines and diagnostics can be designed.

Recombinant Adenovirus vectors have been used as a vaccine delivery mechanism in animal models and clinical trials with excellent efficacy and safety profiles, for example the ChAdOx1 Oxford/AstraZeneca SARS-CoV-2 recombinant spike protein vaccine which is now licenced. Novel vaccine delivery mechanisms such as this have reinvigorated interest in developing the first vaccine against an invasive fungal pathogen. This current project aims to construct a replication incompetent adenovirus vector using the commercially available pAdEasy system (human adenovirus serotype 5) that is capable of expressing putative immunogenic antigens of the fungal pathogen Aspergillus fumigatus. Genes of interest will be selected from the cohort of effectors of tissue invasion identified in previous work performed by the Bignell Lab (summarised above). Putative vaccine candidates will be selected according to the strength of association with tissue invasion, expected immunogenicity, lack of cytotoxicity, and lack of human orthologue. To demonstrate proof of concept, pilot work will use an immunogenic epitope from the Aspergillus fumigatus Aspf1 gene since this has been characterised by the Thornton Lab previously and several materials and reagents exist already. Once work flows are established adenovirus vectors containing putative vaccine candidates will be constructed. Downstream we plan to use these vectors as a vaccine delivery mechanism in murine IA model vaccination studies (not the subject of this GM notification).

The construction of an adenovirus vector involves the following steps:
- Clone gene of interest into the pAdTrack-CMV shuttle vector (this vector contains a GFP reporter as well as the gene of interest, both under regulation of CMV promoter).
- Perform homologous recombination of the shuttle vector with the pAdEasy-1 replication-incompetent adenovirus backbone (E1/E3 deleted) using a non-pathogenic strain of E. coli (BJ5183 cells).
- Transfect the recombinant adenovirus vector into a producer cell line - HEK293 cells or derivatives thereof. This allows the growth of a recombinant adenovirus vector stock.
- Purify and concentrate the recombinant adenovirus vector for use in downstream applications.

All procedures will be performed following specific Standard Operating Procedures (SOPs). Steps involving virus transfection and amplification using HEK293 cells will be performed in tissue culture at containment level 2 using a class 2 biological safety cabinet and appropriate PPE. The cloning platform we will use is a commercial product that is marketed for research purposes. The pAdEasy system plasmids and reagents are available through AddGene (https://www.addgene.org/browse/article/1814/). This system has been used extensively by other groups for similar purposes.

https://www.addgene.org/16399/
https://www.addgene.org/16405/

Recipient or parental organism

Adenovirus is a non-enveloped, non-segmented, linear dsDNA virus approximately 36kb in length of the ACDP Hazard Group 2. There are >60 serotypes separated into groups A-G that are associated with human infections. Adenovirus displays broad species and tissue tropism, gaining entry to a human host via the Coxsackie Adenovirus Receptor (CAR) or CD46 (serogroup B only) and readily infects many epithelial cell lines. It then undergoes a two-stage lytic replication cycle intracellularly. Human adenovirus infections most often result in a mild, self-limiting upper respiratory tract infection in an immunocompetent host. The usual duration of illness is five to seven days, although symptoms may persist for up to two weeks. Bacterial superinfections can occur. Less commonly, human adenovirus infections are associated with gastrointestinal, ophthalmologic, genitourinary, and neurologic diseases. Rarely, fatal infections can occur in immunocompromised hosts. Adenoviruses are of great interest
as vectors for gene or vaccine delivery and a variety of recombinant vectors exist for such purposes. The adenovirus vector delivery system used in the Bignell group is ΔE1/E3 human adenovirus 5 (pAdEasy) – all utilised vectors and resulting virus-containing supernatants are replication incompetent and solely single-cycle infectious clones handled in CATEGORY 2 facilities. Rarely, ΔE1/E3 human adenovirus 5 vectors can recombine with E1 provided by the packaging cell line (HEK293 cells), replacing the transgene insert in the adenovirus vector and thus producing a replication competent virus capable of establishing a productive infection in a human host. Therefore, all adenovirus stocks will be checked for the presence of replication competent virus before long-term storage at -80 °C - if replication competent adenovirus is detected then the stock will be inactivated with chemogen and discarded according to local waste disposal policies (detailed below). Adenovirus is a non-enveloped, non-segmented, linear dsDNA virus approximately 36kb in length of the ACDP Hazard Group 2. There are >60 serotypes separated into groups A-G that are associated with human infections. Adenovirus displays broad species and tissue tropism, gaining entry to a human host via the Coxsackie Adenovirus Receptor (CAR) or CD46 (serogroup B only) and readily infects many epithelial cell lines. It then undergoes a two-stage lytic replication cycle intracellularly. Human adenovirus infections most often result in a mild, self-limiting upper respiratory tract infection in an immunocompetent host. The usual duration of illness is five to seven days, although symptoms may persist for up to two weeks. Bacterial superinfections can occur. Less commonly, human adenovirus infections are associated with gastrointestinal, ophthalmologic, genitourinary, and neurologic diseases. Rarely, fatal infections can occur in immunocompromised hosts. Adenoviruses are of great interest as vectors for gene or vaccine delivery and a variety of recombinant vectors exist for such purposes. Rarely, ΔE1/E3 human adenovirus 5 vectors can recombine with E1 provided by the packaging cell line (HEK293 cells), replacing the transgene insert in the adenovirus vector and thus producing a replication competent virus capable of establishing a productive infection in a human host. Therefore, all adenovirus stocks will be checked for the presence of replication competent virus before long-term storage at -80 °C - if replication competent adenovirus is detected then the stock will be inactivated with chemogen and discarded according to local waste disposal policies (detailed below).

Host/vector system

BJ5183 E. coli (AdEasy-1 cells): This non-pathogenic (biosafety level 1) E. coli strain will be used to amplify the plasmid vectors. These competent cells are recombination proficient bacterial cells carrying the pAdEasy-1 plasmid that encodes the Adenovirus-5 genome (E1/E3 deleted). These cells supply the components necessary to execute a recombination event between the pAdEasy-1 vector and an AdEasy® shuttle vector containing the gene of interest, thus generating a recombinant adenovirus genome that contains the gene of interest. They contain streptomycin and ampicillin antibiotic resistance genes for selection.

- Replication incompetent recombinant adenovirus (hAd5 serotype): This ACDP hazard group 2 organism is a first generation adenovirus vector. The E1 (essential for replication and downstream late gene expression) and E3 (role in virus immune evasion) genes are deleted from this construct resulting in replication incompetence. A GFP reporter under the regulation of a CMV promoter is included. A transgene of interest is cloned into the E1 cassette under the regulation of a CMV promoter. The resulting virus, when produced in a producer cell line e.g. HEK293T, is of equivalent hazard to the parental organism (and potentially of lesser hazard given its replication incompetence).

- HEK293T producer cell line: The 293T cell line, originally referred as 293tsA1609neo, is a highly transfectable derivative of human embryonic kidney 293 cells, and contains the SV40 T-antigen. They have been transfected with sheared adenovirus 5 (Ad5) DNA - The Ad5 insert has been cloned and sequenced previously, and it was determined that a colinear segment from nts 1 to 4344 is integrated into chromosome 19 (19q13.2). This cell line is able to produce adenovirus E1 in trans, thus complementing the replication incompetent human adenovirus serotype 5 vector. This is a producer cell line used to amplify a stock of replication incompetent adenovirus vector.

- pAdTrack-CMV: Shuttle vector for use in AdEasy System. For expression of transgenes under a CMV promoter when a GFP tracer is desired. Contains a kanamycin antibiotic resistance gene for selection.

Origin & function

Use of the human cytomegalovirus major immediate-early enhancer to drive expression of both GFP and the 'gene of interest' is expected to direct high-level expression in a broad range of cell types. There are no anticipated hazards associated with the expression of GFP. Aspf1 - the Aspergillus fumigatus gene selected for the initial proof-of-concept work in this project - is a fungal ribotoxin. In preliminary data generated by the Bignell lab, the Aspf1 knockout Af293 Aspergillus fumigatus strain is of equivalent cytotoxicity to the wild-type strain. It is not thought to be a virulence factor in invasive aspergillosis. It has been associated with allergic bronchopulmonary aspergillosis; this is a potential hazard to lab staff working with the adenovirus vectors but since the vector is replication incompetent, all procedures will be conducted at
incubated overnight. The following day, small colonies are picked, grown in 2 mLs LB broth containing kanamycin, and plasmid DNA is extracted using a conventional method.

- GFP: Enhanced Green fluorescent protein - constructed by subcloning the gene encoding enhanced GFP from pEGFP-C1 into the shuttle vector by the original authors. This does not affect the virulence or pathogenesis of the parental organism.
- Aspf1: this is a ribotoxin produced by Aspergillus fumigatus. It is an allergen that has been associated with allergic bronchopulmonary aspergillosis. It is not thought to be a major virulence factor in models of invasive aspergillosis. We will clone a specific epitope sequence from this gene into the adenovirus vector - this epitope has previously been shown by the Thornton lab to not elicit an IgE response and reduces cytotoxicity whilst maintaining the capability to elicit a B cell response. This will remove the risk of inducing an allergic response and cytotoxicity.
- Antibiotic resistance genes - kanamycin or ampicillin: these are used for selection of E. coli containing the plasmid of interest during cloning. The E. coli used in this project are non-pathogenic and unable to survive within a human host or in the environment.
- Other putative immunogenic Aspergillus fumigatus genes: Additional effectors of tissue invasion will be selected from the cohort currently being characterised in the Bignell Lab. Following the initial proof-of-concept phase (construction of Aspf1 epitope-containing recombinant adenovirus vector), additional Aspergillus fumigatus genes of interest will be cloned into the adenovirus shuttle vector and used to generate recombinant adenovirus - an update to this GM application will be written at this stage to include the final selected genes of interest and subsequently submitted to the local GMO committee for approval. Putative vaccine candidates will be selected according to the strength of association with tissue invasion, expected immunogenicity, lack of cytotoxicity, and lack of human orthologue. The literature will be reviewed to gather previous in vitro and in vivo data pertaining to selected genes.

**Evaluation of foreseeable effects**

This project will construct replication incompetent adenovirus vectors carrying an Aspergillus fumigatus-derived transgene insert. Possible hazards to human health include:

- direct contact with adenovirus at mucous membranes or broken skin e.g. splash or spillage
- accidental ingestion
- accidental inhalation following aerosolisation
- accidental inoculation of adenovirus by sharps or broken glass
- exposure to any of the above in an immunocompromised host (any potential harm likely augmented relative to an immunocompetent host)
- generation of replication competent adenovirus (rare - any potential harm following exposure via above mechanisms likely increased)

This project will create recombinant human adenovirus serotype 5 vectors containing transgene inserts (putative vaccine candidates) with a GFP reporter. A GM cell line - HEK293T - is used for amplification of the viral stock. During cloning, chemically competent non-pathogenic E. coli (BJ5183) are used for homologous recombination of the shuttle and adenovirus backbone vectors. None of the modifications used during this project are anticipated to increase the risk to human health or the environment relative to the parental organism.

The adenovirus vector delivery system to be used in the Bignell group is ΔE1/E3 human adenovirus 5 (pAdEasy) – all utilised vectors and resulting virus-containing supernatants are replication incompetent and solely single-cycle infectious clones handled in CATEGORY 2 facilities. Replication incompetent adenovirus vaccines based on a Chimpanzee adenovirus (e.g. ChAdOx1 SARS-CoV-2 recombinant spike protein vaccine) are already licenced and have been distributed to hundreds of millions of people globally with excellent safety records. The ΔE1/E3 human adenovirus 5 (pAdEasy) system we propose to use is very similar to this.

A gene of interest – in this case, an immunogenic Aspergillus fumigatus Aspf1 epitope – is cloned into an adenovirus shuttle vector using either restriction enzyme digestion or the GeneArt Seamless Cloning technology. The adenovirus shuttle vector (pAdTrack-CMV) is a plasmid that allows expression of transgenes under a CMV promoter and contains a GFP reporter for downstream applications. This shuttle vector is subsequently verified, linearised, and transformed into AdEasier-1 cells (BJ5183 non-pathogenic E. coli strain that contains a pAdEasy-1 adenovirus ΔE1/E3 backbone vector). The shuttle vector and the adenoviral plasmid have matching left and right homology arms which facilitate homologous recombination of the transgene into the adenoviral plasmid. The resultant transfectant is plated onto LB/kanamycin plates and incubated overnight. The following day, small colonies are picked, grown in 2 mLs LB broth containing kanamycin, and plasmid DNA is extracted using a conventional method.
alkaline lysis method and purified e.g. Qiagen MiniPrep. Recombinant plasmids are verified, restriction enzyme digested and transfected into HEK293 cells using a lipofectamine transfection method. The E1 gene is trans-complemented by HEK293 cells resulting in the growth of an adenovirus vector stock. Virus replication is monitored using GFP expression with a fluorescent microscope. After 7-10 days, cells are scraped off the flask using a rubber policeman and undergo four freeze/thaw cycles using either a dry ice or methanol bath and a 37°C water bath. Supernatants are either stored at -20°C or used to infect naïve HEK293 cells in a second round of stock amplification. A similar process is followed before a third round of amplification. In these rounds of amplification, no more than 2x T75 tissue culture flasks of HEK293 cells will be required. This typically results in a virus titre of 10^7 or 10^8. Presence of recombinant adenovirus vector is confirmed using Western Blot and/or PCR in a susceptible non-producer cell line e.g. A549 (the Bignell group already works with this cell line). If higher virus titres are required, 15-20x T75 tissue culture flasks will be prepared and followed by purification and concentration using the commercial Agilent Ad5 Adenovirus Purification Kit. All procedures will be performed following specific Standard Operating Procedures (SOPs). Steps involving virus transfection and amplification using HEK293 cells will be performed in tissue culture at containment level 2 using a class 2 biological safety cabinet and appropriate PPE. Adenovirus vector stocks will be stored frozen at -80°C within appropriately sealed containers. Any contaminated materials used in the process will be disposed of in sealed plastic bags and inactivated by autoclaving according to MRC CMM SOPs for waste management and the procedures outlined in the waste management section below. Adenoviruses are often purified by ultracentrifugation on caesium chloride gradients. To avoid the use of needles and risks associated with ultracentrifugation, we have identified a commercial adenovirus extraction kit that does not require the use of needles and we will use this kit.

No alterations to existing traits are anticipated for the adenovirus vector or transgene inserts during the procedures for this project. Specifically, we do not anticipate any change in pathogenicity, host range, tissue tropism, or mode of transmission. The adenovirus vector used in this project is ΔE1/E3 - the ΔE1 renders the vector replication incompetent and the ΔE3 renders the vector more immunogenic (E3 is involved in viral immune evasion). The increased immunogenicity may result in an enhanced inflammatory response inside human cells, but this risk is mitigated by the replication incompetence and immunocompetent host.

Human adenoviruses infect a broad range of human cells and therefore gene transfer following accidental ingestion or through direct skin contact is a possibility. The risk of accidental inoculation by needle stick or aerosolization of high titre viral stocks will be reduced by prohibiting the use of sharps, wearing double gloves during viral culture, ensuring no skin is exposed, and only handling stocks and cultures containing viral particles in a Class II safety cabinet. All work surfaces will be decontaminated after work has been completed and immediately following any spillage. Transport of adenovirus-containing material will only be permitted in double sealed containers.

Adenoviruses are non-enveloped DNA viruses, relatively stable and resistant to dehydration. Viruses can survive for protracted periods in aerosols and water. Most adenovirus vectors have been derived from human viruses, which are not thought to be able to replicate efficiently in animal cells. Therefore, it is unlikely that activities with these vectors will represent any significant risk to the environment. Human Ad5 vectors have been shown to enter (but not replicate efficiently in) cells of mouse, rat and canine origin. Therefore, it is unlikely that the GMM will be able to survive or disseminate in the environment.

All work will be conducted in a class 2 biological safety cabinet. Aerosols may be generated by spillages during centrifugation - samples will be processed in buckets with a lid and loaded/unloaded within the class 2 safety cabinet. The use of sharps will not be necessary for the procedures in the work flow described within this application.

Individuals with a congenital or acquired immunodeficiency would be at increased susceptibility to infection with pathogenic micro-organisms, including adenovirus. Individuals known to be immunocompromised will not be allowed to work on this project, these risks will be made clear to all personnel in the laboratory. We would not expect any specific symptoms following infection with the genetically modified micro-organisms described in this application since the adenovirus vectors are replication incompetent. The E. coli BJ5183 cells used in this project are non-pathogenic strains. Vaccinations or health surveillance are not necessary for the work described in this project.

The genetic modifications proposed in this work are not expected to increase the virulence of the genetically modified micro-organism beyond that of the parental organism. Also it is not expected that this work would have an effect on other traits of the GMM such as increased drug resistance therefore the risk to human health posed by the construction of these GMM's is essentially equivalent to those of the parental organism. The most hazardous GMM is the adenovirus vaccine delivery vector.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste: To be inactivated by autoclave at 121 degrees Celsius for at least 15 minutes. Alternatively, in cases with lower liquid volumes (<100ml), liquid is to be treated with 5% Chemgene HLD4L and allowed to have a contact time of at least 20mins, according to the manufacturer's instructions.

Solid waste: Solid waste is double sealed in autoclave bags prior to being autoclaved and incinerated.

Glassware: Soaked with 5% Chemgene or autoclaved at a minimum of 121°C for a minimum duration of 15 minutes.

Plasticware: To be sterilised by disinfection and autoclaving and incinerated when necessary.

Sharps: Sharps will not be used during the procedures required for this project.

DECONTAMINATION: 5% Chemgene

VALIDATION: Chemgene disinfectant will be used to inactivate virus-containing liquids – the manufacturer has validated efficacy against adenovirus. We will perform a local validation of Chemgene efficacy against adenovirus using the recommended working concentration with the aim of achieving 100% kill. Validation of autoclaves will involve testing on a monthly basis using Browne tubes and biannually by independent external assessors to demonstrate, using independent thermocouples placed at the centre of the load, that the correct time and pressure have been reached for the required time.
Innate immunity against fungal pathogens: manipulation of genes in murine cells using lentiviruses

We focus on understanding innate immunity against fungal pathogens. Fungal pathogens kill over a million humans each year. Our aim is to investigate contribution of immunometabolic genes support immunity against C. neoformans, and other fungal pathogens. We will target murine immune and metabolic genes to define the contribution of those genes in antifungal immunity. We will examine the consequences of manipulating/engineering, generally through deletion, these genes for immune and metabolic functions and their relationship to intracellular signalling pathways. To do this we will manipulate genes via a Crispr-Cas9-lentiviral approach, primarily in immortalized cell lines, albeit gene-engineering of primary cells may be warranted in certain key experiments.

Disabled E. coli strains will be used to amplify the plasmid vectors. Disabled Lentiviruses that express different sgRNA and Cas9 targeting immune metabolic genes will be generated. HEK293 producer cell lines will be transfected with these Lentiviral constructs. Immortalized murine cell lines and when warranted primary murine cells will be transfected with these disabled viruses.

Recipient or parental organism

1. Bacteria-Stbl3 E.coli- derived from K12.

The natural environment of E. coli is in the gut but these experimental strains are laboratory adapted, being classified as disabled hosts in the ACGM guidelines, and are unlikely to survive in the human gut or elsewhere.
2. Lentivirus:
These are a type of retrovirus, unique because they can infect both dividing and non-dividing cells and are stably integrated into the host genome. This is because their pre-integration complex (or virus shell) encodes a localisation sequence that is recognised by the import machinery of the nucleus, enabling the virus to get through the intact membrane of the nucleus of a target cell. HIV is a lentivirus and is surrounded by a lipid bilayer with membrane proteins protruding from it. One of these proteins is gp120 which binds to CD4 receptor on T helper cells. All retroviruses encode three protein components – gag, pol and env (which necessary for virus replication), but HIV also encodes other regulatory and accessory genes. To enable lentiviruses derived from HIV to transduce a wide range of cell types (rather than just CD4 receptor +ve cells), the lentiviral vector are constructed to express a different coat protein, the envelope protein from vesicular stomatitis virus. Lentiviruses have two strands of RNA in the form of a single-stranded positive sense RNA genome with long terminal repeats (LTRs) at either end. At the 5’ end there is a Psi (Ψ) sequence which is required for packaging of viral RNA into viral capsids. Their RNA must be reverse transcribed from RNA into the first strand of DNA which is catalysed by reverse transcriptase that is encoded by the HIV provirus. The host DNA polymerase then syntheses the second strand to give double stranded DNA. Following reverse transcription, the LTRs then mediate the integration of the double-stranded DNA into the host genome.

The next two stages of the lentiviral life cycle involve the gradual infection of T Helper cells and then the rapid production of infective viral particles that are released into the blood by the host cell lysis to infect other cells. These final stages of the lentiviral cycle will not occur when using REPLICATION DEFICIENT lentiviral vectors.

Lentiviral vectors are produced by co-transfecting a packaging cell line (in this case the HEK293 cell line) with the lentiviral expression construct, the envelope plasmid, and the lentiviral packaging system that contains plasmids carrying genes encoding the necessary structural and replicatory proteins detailed below. Thus components are expressed in trans within the packaging cell line. The packaging system may be 1 or 2 plasmids (2nd or 3rd generation, respectively).

The 2nd generation packaging systems contain gag, pol, rev, tat. The 3rd generation packaging systems contain 2 separate plasmids with rev in a separate plasmid from gag and pol, and without tat (requiring a 3rd generation transfer plasmid, whose replication is tat-independent). This results in increased biosafety but significantly reduced yields and efficiency.

The resulting lentiviral vector does not contain any of the genes required for viral replication within the target cell line. We will make our own lentiviral vectors, or obtain them from commercial source or from collaborators.

3. List of recipient cell line(s):
HEK293 (human) only for lentiviral production purposes. These cells are used to produce lentiviral vectors.
Immortalized BV2, J774.16, RAW264.7 (murine macrophages) and Bone-marrow derived macrophages, microglia (murine primary macrophages) and other primary murine cells. These cells are the transduced experimental cells where we wish to achieve gene engineering.

4. List of vector(s), all available through Adgene:
- pMD2.G (Adgene #12259) envelope (contains VSVg): allow production of pseudotyped lentivirus with a broad host range.
- psPAX2 (Adgene #12260) 2nd generation packaging (contains gag, pol, rev, tat): allows production of functional virus at the stage of HEK293 cells. Will not be packaged into newly produced virus, thus making virions replication incompetent, but infectious.
- pMDLg/pRRE (Adgene #12251) & pRSV-Rev (Addgene#12253): 3rd generation lentiviral packaging system (2 plasmids, with rev separate from gag, pol): will not be packaged into newly produced virus, thus making virions replication incompetent, but infectious.

For simultaneous sgRNA and Cas9 transfer:
- lentiCRISPR v2 (Adgene #52961) (contains insertion site for gRNA and only point of modification, S. pyogenes CRISPR-Cas9, ampicillin and puromycin resistance cassettes); 3rd generation transfer plasmid, woodchuck hepatitis B virus regulatory element (WPRE), “self-inactivating” (SIN) lentiviral vectors.
- pSpCas9(BB)-2A-GFP (PX458) (Adgene #48138) - (contains insertion site for gRNA and only point of modification, S. pyogenes CRISPR-Cas9, -A2-GFP to allow for fluorescent screening of transfected cells, ampicillin and puromycin resistance cassettes); 3rd generation transfer plasmid, WPRE, “self-inactivating” (SIN) lentiviral vectors.
For sequential transfection of Cas9 and sgRNA: This allows increased levels of manipulation or increased efficiency in harder-to-transfect cells by first selection and enrichment of cells expressing high levels of Cas9, (cells may be frozen for long-term storage once selection is finished) and followed by a second lentiviral transfection, which contains the sgRNA.

- Cas9: lentiCas9-Blast (Adgene #52962). 3rd generation transfer plasmid, contains S. pyogenes Cas9 sequence, ampicillin and blasticidin resistance), WPRE, "self-inactivating" (SIN) lentiviral vectors.

Control plasmids:
- pLJM1-EGFP transfer-control: this plasmid serves as a transfection control. GFP expression is induced upon efficient transfection. (expresses GFP, ampicillin and puromycin resistance cassettes).

**Host/vector system**

HEK 293 cells will be transfected with envelope, packaging and transfer plasmids (see above in List of vectors). Murine immortalized cell lines and murine primary cells will be infected with the above produced non-infecting virions.

The following safety features ensure that these vectors are unable to replicate:cons

1) The transfer vectors contain a deletion in the 3' LTR (ΔU3) which causes "self-inactivation" of the lentivirus after transduction of the target cell. Once integrated into the transduced target cell, the lentiviral genome is no longer capable of producing a packageable viral genome. This minimizes chances of recombination.

2) The minimal number of genes from HIV-1 are used in the packaging system and has been reduced to four (i.e. gag, pol, rev, tat) in 2nd generation systems and to three (gag, pol, rev) in 3rd generation systems.

3) The VSV-G gene from Vesicular Stomatitis Virus is used in place of the HIV-1 envelope protein.

4) The packaging plasmids allow expression in trans of proteins required to produce viral progeny (e.g. gal, pol, rev, and tat only in 2nd generation packaging systems ) in the HEK293 producer cell line, however none of them contain LTRs or the Ψ packaging sequence. This ensures that none of the HIV-1 structural genes are present in the packaged viral genome, and are therefore never expressed in the transduced target cell. No new replication-competent virus can be produced.

5) The lentiviral particles produced in these systems are replication-competent and only carry the gene of interest. No other viral species are produced.

**Origin & function**

Constructs will generate single-guide-RNA (sgRNA) molecule and the Cas9 enzyme in murine cells, resulting in gene engineering, usually resulting in full abolishment of activity of the gene targeted by sgRNA. After functional validation of gene engineering, the generated cells will be studied in immune and metabolic functional assays to understand their contribution to antifungal immunity.

List of murine genes:
Genes to be engineered are mouse immunometabolic genes, which include:
- Metabolic genes: Irg1/Acod1, Ldh1, Cox6b1, Bcl2a1, Ndufa8a2, Pex7, Abcd5
- Antimicrobial genes: iNOS(NOS2), IFNg, Cybb

Other constructs which will be used include reporter constructs, such as GFP, which will be used to measure transduction efficiency, for example. Other controls include a non-targeting sgRNA and transfection with transfer plasmids without sgRNA (empty plasmid).
There is unlikely to be any hazard to the environment from these bacterial organisms. The host bacterial organisms are E. coli K12 derivatives and they have a proven safe history of use in routine cloning work.

Lentiviral vectors
Lentiviruses require close contact for their transmission and their survival in the general environment is poor; they are temperature, desiccation, detergent, protein denaturant and pH sensitive. Replication deficient lentiviruses cannot propagate so therefore, after infection of a cell they are incapable of further replication. It will be possible to demonstrate that the lentiviral vectors are replication deficient by plating 5% of the vector stock supernatant into mitotically active indicator cells (e.g. HEK293 cells) and monitoring for syncitia formation or by PCR analysis of cells that have been transduced with lentiviral vector stocks using primers specific for pro-viral components, such as VSV-G. The insertion of these genes is not expected to alter the tropism of the lentiviral vector. Lentiviral particles carrying sgRNA to Idh1 and WPRE represent an increased risk given the possibility of their acquiring tumorigenic potential. However, the strict following of containment level 2 safety practices, personnel protective equipment (goggles, gloves, disposable sleeves) and decontamination procedures would secure that no worker becomes in contact with these viral particles and that used surfaces are decontaminated after work has ceased.

Factors such as congenital immunodeficiency and secondary immunodeficiency caused by serious illness or chemotherapy would increase the susceptibility to infection by micro-organisms, including the genetically modified micro-organisms described in this application. In carriers of wildtype HIV there may be a theoretical risk of recombination of the lentiviral vector with wildtype virus. Thus, there would be the potential risk of mobilisation and transmission of the recombinant lentivirus to other individuals via the normal routes of HIV-1 transmission. Individuals known to be HIV-positive or to be immunocompromised will not be allowed to work on this project, these risks will be made clear to all personnel in the laboratory.

We would not expect any specific symptoms as the result of an infection with the genetically modified micro-organisms described in this application since the lentiviral vectors cannot replicate. Whenever possible we will use safer 3rd generation packaging systems.

Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

To minimise the chance of accidental injection: The use of sharps (e.g. needles and scalpels) will be prohibited when handling cultures of cells or bacterial vectors or plasmids, essentially at any stage of this work.

To minimize generation of aerosols (including if accidental spills occur) for steps containing virions:
- Lentiviral virions will only be handled in a class II safety cabinet to minimise the risk of accidental inhalation or ingestion. Whenever possible we will use safer 3rd generation packaging systems.
- Secondary containment for steps containing virions is required during incubation and transport, as well as use of contained centrifuge rotor during centrifugation, as this minimizes risk of accidental spills. Secondary containment should be sealed before leaving biosafety cabinet and only opened inside biosafety cabinet, unless absolutely necessary for microscopy or other analysis. Media with virions will be preferentially used in flasks with screw-on lids (versus plates) to minimize risk of spillage. Flasks/plates will be sprayed with disinfectant on the outside and placed in secondary containment (transport box).
- Use of dedicated and restricted spaces, Work should only be performed when the room is at low occupancy, by trained competent individuals. Appropriate signage on outer TC door, on flow hood and incubators indicating that live infectious virus is present.
- In addition to laboratory coat and gloves, users will double gloves, use a dedicated laboratory coat or disposable sleeves, goggles, to avoid skin or mucosal contact and deposition on surfaces. All work will be conducted in a Containment Level 2 laboratory.
- Mandatory use of filter pipettes and tips for liquid transfers with immediate disposal of liquids into disinfectant (described in waste disposal), and prohibited pouring of liquids.
- Any equipment (microscopes) should be wiped with disinfectant immediately after use, and used during low occupancy periods.
- Additional personnel training will be established.
To minimize generation of aerosols during all other steps (non-infectious):
Primary containment and use of contained centrifuge rotor during centrifugation. Whenever possible we will use safer 3rd generation packaging systems.
In addition to laboratory coat and gloves, users will double gloves.
Further control measures are: use of dedicated and restricted spaces, use of filter pipettes and tips for liquid transfers. Additional personnel training will be established.

LIQUID WASTE:
5% Chemgene high level disinfectant (as per the manufacturer’s instructions)

GLASSWARE:
Soaked with 5% Chemgene and autoclaved at a minimum of 121°C for a minimum duration of 15 minutes

PLASTICS:
All plasticware (tips and pipettes) must be rinsed, by pipetting in a solution of 5% chemgene prior to placing in the small autoclave bags (or cardboard autoclave boxes). This prevents accidental drips containing live virus, which may leak from the autoclave bags. Plates and Flasks after use and in contact with media which may contain virus will be soaked in chemgene for 20 min before removal from biosafety cabinets. There will be a container with 5% chemgene in biosafety cabinet to allow rinsing of all plasticware as the work proceeds. Effectively anything in contact with virus containing liquid will be inactivated prior to leaving the flow hood and entering the waste stream. Plasticware will then be autoclaved.

DECONTAMINATION:
5% Chemgene for 20 min in biosafety cabinet, followed by 70% ethanol wiping all surfaces.

VALIDATION:
Our procedures for the use of Chemgene have been validated experimentally to kill 100% of virus and cells.

02/03/2022
The goal of this work is to characterize the mechanisms through which hypothalamic neurons coordinate their activity to release ACTH-stimulating neuropeptides and regulate the HPA axis. In order to realise this project we will use viral vectors to specifically transduce cells of interest (corticotrophs and hypothalamic neurons, for example). Following transduction we will be able to monitor and/or control the electrical/calcium activity of these cells.

pLenti6-POMC-eYFP-WPRE, pLenti6-POMC-ppANF-eYFP-WPRE, plenti6-POMC-GCaMP6s-WPRE will be transfected (together with packaging plasmids and envelope plasmid) into 293FT HEK cells in order to produce 3rd or 2nd generations lentiviruses.

3rd and 2nd generation lentiviral vectors will be used to transduce:
- AtT-20 cells in order to determine the titre of the virus
- Primary neurons or pituitary cells from wild-type mice/rats.
- Wild-type mice/rats (via stereotaxic injection).
- Primary neurons or pituitary cells from transgenic mice/rats
- Transgenic mice/rats (via stereotaxic injection)
**Host/vector system**

The viral vectors used will be 2nd or 3rd generation lentivirus.

**Origin & function**

The plasmids will be used to introduce genes for:

- Labelling/identifying neurons or pituitary cells (e.g. fluorescent proteins such as GFP and TdTomato)
- Monitoring the activity of neurons or pituitary cells (e.g. genetically-encoded calcium indicators)
- Controlling neurons or pituitary cells (e.g. using opsins such as channelrhodopsin2, archaerhodospin)

**Evaluation of foreseeable effects**

The two main safety concerns surrounding the use of lentivirus are:

- The potential for generation of replication-competent lentivirus.
- The potential for oncogenesis.

The potential for generation of replication-competent lentivirus is addressed by the design of the vectors and by safe laboratory practice. In terms of vector design, 2nd and 3rd generation lentiviral systems separate transfer, envelope, and packaging components of the virus onto different vectors. The transfer vector encodes the gene of interest and contains the sequences that will incorporate into the host cell genome, but cannot produce functional viral particles without the genes encoded in the envelope and packaging vectors. Unless recombination occurs between the packaging, envelope, and transfer vectors, and the resulting construct is packaged into a viral particle, it is not possible for viruses normally produced from these systems to replicate and produce more virus after the initial infection. In this regard, 3rd generation systems are considered even safer than 2nd generation systems because the packaging vector has been divided into two separate plasmids (resulting in a four plasmid system in total).

Additionally, the transfer plasmids pLenti6-POMC-eYFP-WPRE, pLenti6-POMC-ppANF-eYFP-WPRE, and plenti6-POMC-GCaMP6s-WPRE have a deletion in the 3'LTR of the viral genome that is transferred into the 5'LTR after one round of reverse transcription. This deletion abolishes transcription of the full-length virus after it has incorporated into a host cell.

The potential for oncogenesis is largely based on the specific insert contained within the lentiviral transfer vector (dependent upon whether or not it is an oncogene). pLenti6-POMC-eYFP-WPRE, pLenti6-POMC-ppANF-eYFP-WPRE, and plenti6-POMC-GCaMP6s-WPRE do not contain any oncogene and therefore the likelihood for oncogenesis is effectively null.

The original plasmids are designed to transduce cells in a POMC dependant manner, meaning only neurons or pituitary cells that express POMC will in theory express the gene insert. This promoter may be changed in the future in order to target other cell types. Similarly, the sequence of the plasmid might be altered in order to change the gene expressed (e.g. switch the reporter protein eYFP to mCherry). We will not introduce any genes that cause disease or are known to be harmful. After modifying the transfer plasmids and before making viruses, we will sequence the entire plasmid to make sure that the changes will not lead to alteration of pathogenicity, host range, tissue tropism, mode of transmission or host immune response.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Animals will be held in a Class 2 animal facility, however the risk of operator exposure from infected animals that have been inoculated with non-replicating viruses (2nd and 3rd generation lentiviruses) is minimal, as is the potential for virus shedding, and it is therefore appropriate to house these animals in the same manner as non-infected animals.
**SOP for waste management** is as follows:

- Gloves and laboratory coats/gowns will be worn when dealing with waste.
- All virus-containing waste will be treated in the following manner:

  * Virus-containing liquids will be removed using pipettes and placed directly in a container containing 1% Virkon or bleach (4.5-5% sodium hypochlorite). The waste container will contain sufficient Virkon or bleach to allow for additional liquid to be added during the procedure. A period of at least 15 minutes will elapse after the last addition of waste into the waste container, after which the liquid waste will be disposed of in the sink. The sink will be thoroughly rinsed.

  * Smaller virus-contaminated solid waste items will be placed in a container filled with 1% Virkon or bleach for 5 minutes, and then placed in a bucket containing 5% Virkon for at least one hour. The waste will then be disposed of in a biohazardous yellow bin. Larger solid waste may be sprayed with 1% Virkon or bleach, and then placed into a sealed autoclave bag in the biosafety cabinet. The bag will be sprayed with 1% Virkon; then at least 15 minutes later the bag will be taken out to be autoclaved.

  * Sharp waste will be treated with 1% Virkon (as described above for small solid waste) and then disposed of in a biohazardous sharp container.

Virkon has been tested against high titre lentiviruses. A solution (<5 days old) at a concentration of 1 % (v/w) inactivates lentiviruses within 5 minutes. All liquid waste will be treated for >15min.

**SOP for spills** is as follows:

- Wear gloves and lab coat when dealing with the spill.
- Cover the spill, including any contaminated equipment with cloth or paper towel to contain it.
- Ensure others in the area know of the spill and avoid the spill area.
- Working from the outside margins of the spill area towards the centre, apply sufficient 1% Virkon solution on top of the paper towel and soak it.
- Leave for 10 minutes to allow the Virkon to inactivate any virus present in the spill.
- Clear away the material into clear sealable plastic bags prior to disposal in the nearest yellow biohazardous waste bag, including gloves used for clean-up. If any glass or sharps are involved use of dustpan or stiff piece of cardboard to dispose of these materials into the appropriate containers.
- Complete the spill record table.

**Animal waste:**

- All virus-infected carcasses and body parts will be bagged up in clinical waste bags and stored in a freezer; these bags will be disposed of in a clinical waste bin which is collected once per week for incineration.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

**Is an emergency plan required according to regulation 20?**

Project Additional Information
Purposes of the contained use

We aim to express the f1 filamentous phage protein IV (pIV) in P. aeruginosa, with the aim of increasing the uptake of antibiotics into bacteria.

Recipient or parental organism

P. aeruginosa is an opportunistic human pathogen that can cause a variety of diseases. Most cystic fibrosis patients are chronically colonized with P. aeruginosa and it is the leading cause of death by Gram-negative bacteria. Localized infection following surgery or burns commonly results in a generalized and frequently fatal bacteremia. Urinary tract infections following surgery or burns commonly results in a generalized and frequently fatal bacteremia. Necrotizing P. aeruginosa pneumonia may occur in other patients following the use of contaminated respirators. P. aeruginosa can cause severe corneal infections following eye surgery or injury. It is found in pure culture, especially in children with middle ear infections. It occasionally causes meningitis following lumbar puncture and endocarditis following cardiac surgery. It has been associated with some diarrheal disease episodes. Since the first reported case of P. aeruginosa infection in 1890, the organism has been increasingly associated with bacteremia and currently accounts for 15% of cases of Gram-negative bacteremia. The overall mortality associated with P. aeruginosa bacteremia is about 50%. Some infections (e.g., eye and ear infections) remain localized; others, such as wound and burn infections and infections in leukemia and lymphoma patients, result in sepsis.

P. aeruginosa rarely causes disease in healthy persons. Treatment options for P. aeruginosa infections include quinolones, cephalosporins, tobramycin and polymyxins.

Host/vector system

Escherichia-Pseudomonas shuttle vector pHERD30T (1). pHERD30T contains an araBAD promoter, gentamicin resistance and a multiple cloning site.

Origin & function

To express pIV in P. aeruginosa, we will clone gene IV (gIV) from the E. coli expression plasmid pPMR132 into the Escherichia-Pseudomonas shuttle vector pHERD30T. Plasmids will be introduced to P. aeruginosa (PA14 and PA01) by electroporation, and tested for pIV protein expression using SDS-PAGE and Western blot using an anti-pIV antibody. We will plate cells onto agar containing different antibiotic strips/discs to determine MIC levels. We will also test a mutant of pIV with a Ser to Gly substitution at position 324 (pIV-S324G).

Evaluation of foreseeable effects

Transformed P. aeruginosa will contain antibiotic resistance to gentamycin as detailed above. They will also express the pIV protein, which is controlled. The protein is not a virulence factor or a toxin and there is no reason to believe that it will increase the virulence of the organism. It is more likely that pIV will make the GMO less toxic than the parent as pIV expression causes membrane stress and will potentially allow the uptake of a broader range of antibiotics.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste will be disposed of according to the General GM waste disposal guidance (GMG-010).

Chemical disinfection should be used routinely for decontamination of discarded liquid cultures, possibly small amounts of solid material (e.g. small sample tubes), surfaces and spillages. GM contaminated tissue culture plates, pipettes etc must either be autoclaved or chemically disinfected by soaking in 1% w/v Virkon, or 1,000 ppm Presept (four 0.5g tablets into one litre of water) for at least two hours before discharging any excess liquid via drains or autoclaved at 121°C at 1.15 bar, for 15 mins.
Autoclave function is assessed and calibrated and serviced annually to ensure continued effectiveness. The outcome is recorded in the log book.

Is an emergency plan required according to regulation 20?

### Project Additional Information

#### Purposes of the contained use

Social traits, such as co-ordinated behaviour, anticompetitor toxins and iron-scavenging, can be important for the success of pathogenic bacteria. We are addressing under which conditions these traits are beneficial to the bacteria, and how the expression of these traits affects their pathogenicity in animal (caterpillar) hosts. Mutation rates can affect the evolution of these traits, and we are also investigating this question.

#### Recipient or parental organism

Pseudomoas aeruginosa is a hazard group 2 pathogen which can cause infection of immunocompromised individuals, people with cystic fibrosis, and can potentially establish an infection through burns and cuts. Infections can be fatal if untreated.

#### Host/vector system

All genetically modified strains of Pseudomonas aeruginosa to be used are knockouts. The majority of which are transposon-insert mutants (with associated tetracycline resistance cassettes from Escherichia coli) obtained from external sources.

MutS knockout was made by digesting the wildtype allele, liberating an internal fragment, and then ligating. This non-functional allele, and an associated kanamycin resistance cassette from E. coli, was then inserted back into the wild type background by conjugation from an E. coli donor.

#### Origin & function

- **bacteriocin (pyocin) mutant (pys2 knockout)** - Bacteriocins cause cell lysis of susceptible P. aeruginosa strains.
- **pyoverdin mutant (pvdF knockout)** - Pyoverdin is the primary iron-scavenging siderophore of P. aeruginosa.
- **Quorum sensing (QS) mutants (lasR, rhlR knockouts) and knockouts of genes under the control of QS expression (lasB, rhlA; which encode elastase and rhamnolipid, respectively)** - QS describes changes in gene expression in a wide range of genes (such as those coding for proteases (eg elastase) and surfactants (rhamnolipids)) in response to high concentrations of diffusible signal.
- **Type IV pili mutant (pilA knockout)** - Type IV pili are involved with social motility.
- **mutS knockout** - Results in less efficient DNA repair, and hence an approximately 100-fold higher mutation rate. Strain.

#### Evaluation of foreseeable effects

- Pyoverdin mutants have reduced ability to obtain iron, hence are likely to grow less well, and are expected to be less virulent, in humans. There is no reason to suspect the growth or virulence of the pyocin mutant would be altered in human hosts.
- Quorum sensing mutants do not express a range of traits, including many traits crucial for successful growth of bacteria in vivo, such as proteases (elastase), polysaccharides for biofilm formation and surfactants (rhamnolipid). They will therefore be less virulent.
- The type IV pili mutants have reduced motility and attachment, so would be less efficient at colonising human hosts.
- The mutS mutant typically shows reduced virulence in published in vivo studies using mouse models.
- The antibiotic cassettes are not the antibiotics typically used for treatment of P. aeruginosa, hence they will not increase risks to human health.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS2646, Part 3 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration.

Caterpillar carcasses - Autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), dispose via clinical waste stream for incineration.

Degree of kill

- Autoclaving, effectively 100% kill (annual validation)
- Incineration, effectively 10% kill (licensed incinerator)

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

### Project Additional Information

#### Purposes of the contained use

The aim of this project is to define, at a molecular level, the virulence attributes of fungi, in particular Aspergillus fumigatus, Aspergillus nidulans, Aspergillus flavus, Candida albicans and Candida glabrata. We also intend to investigate selected attributes in the model fungus Saccharomyces cerevisiae.

#### Recipient or parental organism

**Escherichia coli:** strains in common laboratory use e.g. DH 5 alpha, XL-20 will be used as cloning tools. These strains, which are generally derivatives of the K12 strain, have a widespread and long history of safe use. They also contain numerous mutations eg thi-1 which render the strains auxotrophic and therefore unlikely to survive outside the laboratory environment.

**Aspergillus nidulans:** there are a huge number of classically produced mutant strains of A.nidulans. These have been constructed in many strain backgrounds and often have been crossed many, many times. These strains have a long history of safe laboratory use and usually contain auxotrophic mutations eg argB that would prevent survival outside the laboratory.

**Aspergillus fumigatus:** Af237,D141 and ATCC46645, Af293 and CEA 10 and auxotrophic derivatives thereof eg pyrG or antibiotic selection-mediated gene disruption derivatives thereof eg hygromycin-resistant clones, will be used to construct knock-out, regulatable and reconstituted strains. These backgrounds have a long and safe
history of use worldwide. Additionally the pyrG auxotrophies would prevent survival outside the host.

Candida albicans: SC5314, CA14 and CA110 and auxotrophic derivatives thereof eg his3/his3, ura3 will be used to construct knock out regulatable and reconstituted strains. These strains have a long and safe history of use worldwide.

Candida glabrata: ATCC2001 and auxotrophic derivatives thereof eg his3, ura3, trp1 will be used to construct knock-out, regulatable and reconstituted strains. These strains have a long and safe history of use worldwide.

Pichia pastoris: GS115 and SMD 1163 and auxotrophic derivatives thereof eg his4 will be used to express selected fungal proteins. These strains have a long and safe history of use worldwide.

Saccharomyces cerevisiae: the majority of laboratory strains are derived from three major wild type lineages S288C, W303 and Σ1278b. Most contain multiple auxotrophies and would not survive outside the laboratory.

### Host/vector system

We will use standard E.coli and S.cerevisiae vectors eg pUC, pBluescript, YE, YI and YC series.
We will use a series of C.glabrata episomal vectors (Kitada et al, Gene 175:105, 1996)
Mobilisable Aspergillus vectors will not be used.

### Origin & function

The majority of inserted genes will be from the same species, eg used to complement a null allele to create a reconstituted strain, and therefore do not constitute the construction of a GMM.
We are investigating fungal virulence and wish to analyse all attributes associated with the ability to cause disease. Current examples of genes under investigation (and the functions that they are known, or predicted to encode) include C. glabrata ACE2 (transcription factor) C.glabrata CTS1 (endo-chitianse) and A.fumigatus PacC (transcription factor). We will also analyse other genes related to virulence in these species.

We will also construct Aspergillus and Candida DNA libraries in S.cerevisiae.
We will also add selected tags eg GFP, TAP, HA, etc to selected genes.
We will use heterologous antibiotics genes eg ampR, bleR, hygR as markers of transformation.

### Evaluation of foreseeable effects

The GMM are disabled and are unlikely to be able to survive in the environment and the modifications proposed (gene inactivation) would not confer a selective advantage even if they were to be transferred to a wild type organism. The likelihood of hazard is therefore considered to be no greater than that of the parental strains.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste: Liquid waste (culture media) will be treated by the addition of Virkon to a final concentration of 1% and then left for at least 120 mins. According to manufacturer's data this treatment results in 100% killing of the GMMs. Treated liquid waste will be then disposed of via a designated sink.
Solid waste in plastic bags (tissue culture flasks, plastic pipettes, pipette tips and eppendorf tubes) will be autoclaved at 134°C for 30 mins. This will result in 100% killing of the GMMS. A chart recorder will indicate the successful completion of the autoclave cycle and the autoclave is tested by 12 point thermocouple testing. The waste will then be disposed of by the clinical waste route.

Q 1.3 not really answered. If none of the proposed GMMs are likely to be any more hazardous than the host without an insert, then this should be stated, and a justification given e.g. perhaps there are no known toxins in any of the fungal pathogens being used, or measures will be taken to specifically exclude any toxin genes from being expressed?

Reviewer 2:
2.2.1.1 PI needs to consider the worst case scenario for strains that do not contain auxotrophies.

Reviewer 3:
The hazards need to be identified and then explanations of how the risks are reduced by operational practices mentioned here.
1.21 Paragraph3: give some examples of genes being disrupted and/or replaced. Write explicitly the kind of phenotype assays that will be carried out to test the effects of the genetic modifications.
1.23 Give more details of the plasmids used for transformation of the fungi (Aspergillus sp and Candida sp). Specify the selectable markers used.
2.1.1.2 List the hazards to human health posed by the organisms used. Explain the diseases caused, not just the reasons to think that the risks are mitigated by the auxotrophies.
2.1.1.3 Give examples of the "majority" of genes. List some examples of the remaining "minority". Here is the first mention of complementation of the auxotrophies by the transforming plasmids. This appears to negate some of the mitigating effects described extensively in preceding sections. Therefore clear statements about this must appear in many of the introductory paragraphs.
2.3.2.1 In order to study the function of putative virulence genes, phenotypic assays including infection models require an infectious GMM: this will by definition be a hazard to humans and the environment. Hence this MUST be explicitly stated in the introductory paragraphs to all sections.

Tick if you are claiming exemption from disclosure for sections of the risk assessment
Purposes of the contained use

The aim of this project is to generate replication-defective lentiviruses that express marker genes including firefly or renilla luciferases and/or destabilised variants, GFP and related fluorescent proteins or bacterial nitroreductase under the transcriptional control of various human, viral, or synthetic gene regulatory elements including normal or site-mutated variants of the human telomerase hTR and hTERT promoters, the human p16, p 21 and CDK4 promoters and commonly used "constitutive" viral promoters. The constructs will be used to assess basal activity and, through the use of small molecules, siRNA, or transient overexpression of cell signalling genes, regulatory mechanisms of cancer and senescence associated gene promoter by reporter assay or cell ablation studies in a variety of cancer and normal cell types including primary haematopoietic and stem or progenitor cells.

Recipient or parental organism

Recipient cells will include both commonly used normal (untransformed) cell strains such as W138 and MRC5 and common cell lines that are widely used by research laboratories and are not considered to pose any inherent hazard to human health nor have the capacity to survive outside laboratory and do not harbor any adventitious agents. Examples of cell lines to be used include:
Human cancer and vitro immortalised cell lines 5637, A2780, C33A, HCT116, A549, HT29, Colo320, HeLa, Jurkat, K562, MCF7, HEK293, GM847, KMST6. Additional recipient cells include sub-clones of common cell lines such as 293T, A2780-CP70 and HCT116-p53-/- and stably transfected variants such as BJ-hTERT wherein the genetic and epigenetic traits associated with the sub-clone or transgene are not considered to increase the overall inherent hazard to human health of the cell line itself or following transduction with lentivirus. Additional recipients are to include normal or tranformed primary human cells obtained from donors with appropriate consent such as T-lymphocytes, CD34+ haematopoietic progenitors, mesenchymal stem cells and cells derived from ascitic fluid of patients displaying advanced tumours of the peritoneal cavity. Additional recipients are to include primary cells from animals obtained under appropriate license including rat primary neural cells. All such primary cells will be cultured exclusively under category II containment.

**Host/vector system**

Host Bacteria for growth of the plasmids are standard disabled laboratory strains of E.Coli such as DH5a and JM109 or the Invitrogen proprietary strains Stbl£ (F-mcrB mrr hsdS20(rB-, mB-) recA13 sup E44 ara-14 galK2lacY1 proA2 rpsL20(StrR) xyl-5 * leu ntl-1) or TOP10 (F-mcrA *mrr-hsdRMS-mcrBC *80lacZ*M15 *lacX74 recA1 araD139 *(araleu) 7697 galU galK rpsL (StrR) end A1 nupG). * replaces a symbol as symbols can't be shown

The system to be used for lentivirus construction is the Invitrogen ViraPower Promoterless Lentiviral Gateway Expression System (www.invitrogen.co, catalogue number K5910-00). The system combines gateway cloning and lentiviral cloning technologies for construction of a 3rd generation lentivirus pseudotyped with the G Glycoprotein gene from vesicular stomatitis virus. The system allows incorporation of any transgene and gene regulatory element in the lentiviral vector. The system comprises:

1. The pENTR 5'-TOPO® TA Cloning Kit for production of a gateway entry clone containing a gene/promoter of interest> The vecotr contains no sequences necessary for virus production.
2. A promoterless pLenti6/R4R2/V5-DEST destination vector into which the promoter and gene of interest are transferred. This expression plasmid contains elements that allow packaging of the construct into virions.
3. Additional packaging plasmids pLP1, pLP2, and pLP/VSVG. And 293FT packaging cells. The packaging cells will be 293FT which will be used for the initial rescue of the virus from transected DNA and for general virus propagation and will also express the marker genes of interest.

Vector features necessary for viral production:

- **pLenti6/R4R2/V5-DEST:**
  - Rous Sarcoma Virus (RSV) enhancer/promoter for Tat-independent production of viral mRNA in the producer cell line.
  - Modified HIV-1 5' and 3' Long Terminal Repeats (LTR) for viral packaging and reverse transcription of the viral mRNA (Note: The U3 region of the 3' LTR is deleted (*U3) and facilitates self inactivation of the 5' LTR after transduction to enhance the biosafety of the vector.
  - HIV-1 psi (*) packaging sequence for viral packaging.
  - HIV Rev response element (RRE) for Rev-dependant nuclear export of unspliced viral mRNA.
  - HIV gag/pol coding sequences encoding genes required for structure and replication of the virus.
  - HIV Rev response element (RRE) for rev-dependent expression of gag/pol genes.

- **pLP1:**
  - HIV Rev OTF under transcriptional control of the RSV promoter encodes the Rev protein, which interacts with the RRE on pLP1 to induce gag and pol expression, and on the pLenti6/V5 expression vector to promote the nuclear export of the unspliced viral RNA for packaging.

- **pLP2:**
  - HIV Rev OTF under transcriptional control of the RSV promoter encodes the Rev protein, which interacts with the RRE on pLP1 to induce gag and pol expression, and on the pLenti6/V5 expression vector to promote the nuclear export of the unspliced viral RNA for packaging.

- **pLP/VSVG:**
  - VSVG coding sequence under control of the CMV promoter encodes the envelope G glycoprotein from Vesicular Stomatitis Virus to allow production of a pseudotyped virus.

The system comprises numerous biosafety features designed to produce a self-inactivating, replicacation defective lentivirus with a negligible risk of homologous recombination between the different plasmid elements. Risk of mobilisation is therefore negligible.

- A deletion in the 3' LTR (*U3) results in "self-inactivation" of the lentivirus after transduction of the target cell.
- The number of genes from HIV-1 that are used in the system has been reduced to three (gag, pol, and rev).
- The VSV-G gene from Vesicular Stomatitis Virus is used in place of the HIV-1 envelope.
Genes encoding structural and other components required for packaging are separated onto four plasmids. All four plasmids have been engineered not to contain any regions of homology with each other to prevent recombination events. None of the packaging plasmids contain LTRs of the packaging sequence. Thus, none of the HIV-1 structural genes are present in the packaged viral genome. The lentiviral particles produced in this system are replication-incompetent and only carry the gene of interest. No other viral species are produced. Expression of the gag and pol genes is prevented in the absence of Rev.

A constitutive promoter (RSV promoter) has been placed upstream of the 5' LTR in the pLenti6/R4R2/V5-DEST vector to offset the requirement for Tat.

Origin & function

No protein is expected to be expressed in bacterial strains used for plasmid propagation. The marker gene products will be expressed in the transfected cells used for virus propagation and in the target cells. All of the protein coding gene sequences to be used in this study have previously been widely used in similar studies and none are considered to present a significant hazard to human health. Renilla and firefly luciferases derived from commercially available pGL3 or pGL4 (firefly) or phRG orpRL vector families (Promega) encode reporter proteins which catalyse luminescent conversion of the substrates luciferin and coelenterazine.

Nitroreductase (NTR) is an E.Coli derived flavoprotein which catalyses the reduction of a variety of nitroaromatic small molecules such as the nontoxic substrate CB1954, which is converted to a toxix bifunctional alkylating agent in NTR expressing cells. NTR has been used by several laboratories for enzyme/pro-drug gene therapy applications and cell ablation studies and has been safely expressed in human tissues in clinical trials.

Fluorescent proteins such as GFP (green fluorescent protein), or related proteins CFP, RFP, and YFP are used widely as reporter proteins to mark cells in which transgene is expressed on exposure of transfected cells to appropriate wavelengths of light.

The hTR and hTERT promoter sequences direct expression of the encoded transgenes exclusively in cells with telomerase activity such as cancer cells or some stem cells. Senescence associated gene promoters p16 and p21 are expected to limit transgene expression to cells undergoing senescence. Viral promoters such as SV40 or CMV will be used as positive controls and are expected to direct expression of the encoded transgenes in all cells.

Evaluation of foreseeable effects

The final genetically modified cells will contain stably integrated DNA copies of the lentiviral vectors encoding the transgene expression cassettes. The cells will be free of lentivirus. As a result they will pose no hazard to human health or the environment, since they are unable to colonise humans or survive outside the laboratory culture. Nevertheless, it will be important to prevent human exposure or environmental release of the replication defective lentiviruses which are used to transiently effect gene transfer. The worse case scenario in case of infection is at a site that disrupts expression of a gene necessary for tumour suppression. Risk against this will be reduced through the use of appropriate physical containment and inactivation processes. Hazard containment II is therefore recommended and all work will be carried out in Class II biological safety cabinets.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

To minimise the risk to human health it will be essential to prevent exposure to retrovirus. Virus generation and infection of target cells will be carried out in Class II biological safety cabinets in the Class II containment laboratories, with access restricted to authorised staff. The amount of retrovirus or lentivirus handled will be limited to no more than 25ml of virus stock. The most likely routes through which individuals could be exposed to virus are needle-stick injuries or aerosols generated during experimental procedures. No needles or sharps will be used during virus preparation, whilst the use of Class II biological safety cabinet will guard against exposure to aerosol. In addition, cell cultures will be contained within clearly labelled boxes during incubation to prevent accidental spillage of medium. All viral supernatants and spent medium will be inactivated using Presept tablets (10,000 ppm chlorine) before removal from the Class II laboratories and autoclaved prior to final consignment of waste to approved contractor. Autoclaves will be validated by annual thermocouple mapping and each run is monitored using Thermalog-S indicator test strips. These processes will...
result in 100% inactivation of infectious virus. Cells will be cultured using designated bottles of medium that will not be used to passage other cell cultures. Authorised staff will wear dedicated lab coats in the Class II laboratories that are not worn in the general laboratory area. Positive clones will be expanded and checked for virus production before removal from the category II laboratory. Infected target cells will be cultured under the above regime until medium supernatants have been shown to be free of replication competent virus as judged by infection of appropriate indicator cells or assay of reverse transcriptase activity. Once these criteria are met the infected target cells will be removed from Class II containment and handled using standard tissue culture processes.

Project Additional Information

Purposes of the contained use

The aim of this project is to amplify wild-type and deletion mutant oncolytic adenovirus vectors already produced in the applicant's previous lab; to evaluate their anti-tumour efficacy in in vitro and in vivo models of human malignancy, particularly ovarian cancer.

Adenovirus serotypes Ad5, Ad11 and Ad35 will be used as reference standards for work performed with Ad5 (mainly E1A) deletion mutants.

Replication competent and replication defective mutants will be constructed using the 'Ad-Easy' system to infect permissive human cell lines. These new mutants may encode transgenes that could induce tumour cell killing alone or enhance the anti-tumour properties of replication-competent deletion mutants.

Evaluation of viral efficacy of mutants will be performed on Human and Murine cell lines by a variety of methods.

Viral manufacture of replication defective vectors will be performed in HEK293 cell line to provide the E1 'in-trans'.

Concentration of adenoviral constructs from 750ml final cultures will be via Caesium Chloride centrifugation.

Recipient or parental organism

The recipient cell lines HEK293 or A549 will be used. Both are commercially available cell lines which require specific laboratory culture and as such pose negligible risk to humans.

HEK 293 is rated Biosafety level 2 because of an E1 fragment of adenovirus embedded in it. It is this fragment that is essential to this series of experiments with E1 deletion adenoviral mutants.

Cell line A549 is rated Biosafety level 1.

Host/vector system

One vector system will be oncolytic deletion mutants of Adenovirus. Replication of oncolytic deletion mutants of Adenovirus is attenuated in normal cells/tissue.

Multiple mechanisms for this attenuation exist, depending upon the nature of the deletion. Publications attest to the selectivity of replication –between normal human cells compared to a panel of human malignant cells – see Heise et al Nature Med (2000) 6:1134. In addition, multiple phase I and II trials of oncolytic adenovirus have shown no replication in normal tissues.

Wild-type adenoviral vectors, used as reference standards, are replication competent and could infect humans. However, wild-type adenovirus infection in humans with an intact immune system leads to a mild and self-limiting 'flu-like illness.

Origin & function

Mammalian genes are to be inserted into the adenovirus genome and have been chosen to perform their intended function; either to increase tumour-specific killing by the virus (e.g. tumour suppressor or apoptosis-inducing genes), to inhibit the activity of oncogenic pathways or to increase the immunogenicity of infected tumour cells.
Documentation exists to indicate that this can be achieved safely. No wild-type oncogenes or direct toxins will be inserted.

The virus will be applied to various established human and murine ovarian carcinoma cell lines; obtained from ATCC and other reputable sources and have consequently been screened for bloodborne viruses. In addition, the human cell lines have also all been previously STR verified and are known to be mycoplasma-free.

**Evaluation of foreseeable effects**

The deletions induced in adenovirus vectors are designed to narrow the host range, so that there is reduced replication and killing within normal cells, thus increasing the therapeutic index in ovarian cancer cells. Mechanisms to achieve this will include introduction of specific deletions to restrict replication and the use of tumour and tissue-specific promoters.

During process development for clinical grade manufacture of one of the mutants being used, no recombination between vector and HEK293 sequences was detected (limit of detection 1 in 109 genomes) – thus it is believed that the risk of reversion to wild-type virus following amplification in HEK293 cells is extremely low.

Replication-deficient viruses are incapable of replication in cells lacking adenovirus E1 function. Infection of normal human cells as well as malignant cells results in no infectious virion production.

The replication competent adenoviruses used will contain mutations within the viral genome that attenuates replication in normal cells and tissues. The deletions occur in regions of the viral genome that are necessary for replication in normal cells but are complemented by the altered gene expression in cancer cells. Mutants used can only replicate efficiently in cells with deregulated p53 and pRB pathways respectively.

The tumour selective mutants can infect normal cells but the ability to replicate is highly attenuated.

Wild-type adenoviral vectors are replication competent and could infect humans. Wild-type virus infection in humans with an intact immune system leads to a mild and self-limiting 'flu-like illness.

The normal route of adenovirus infection is via aerosol. The use of correctly trained and supervised staff, ClassII biological safety cabinets, lab coats and gloves, disinfection and autoclaving of waste will reduce the likelihood of exposure to an extremely low level.

The virus will be applied to various established human and murine ovarian carcinoma cell lines. Because ovarian cancer cells do not contain any adenovirus genomic DNA, there is no risk of recombination of deletion mutants to generate wild-type revertant virus. Thus, generation of adenoviruses and infection of ovarian cancer cells is not considered to pose any inherent hazard to human health. The GM viruses do not have the capacity for survival outside of the laboratory. The recipient cells will therefore not have any foreseeable effect on human health.

E.coli strains are highly attenuated laboratory strains and do not present any hazards to humans.

Human adenoviruses do not replicate in murine tissue - this is true of wild-type, replication-restricted oncolytic viruses and replication-defective E1-deleted vectors.

The only replication following injection into in vivo tissue will be in malignant tumour tissue.

All injections of virus into vivo tissue will be undertaken in class II hoods within the specialist unit, thus minimising the risk of an aerosol-mediated infection during the injection process.

Multiple human studies demonstrate that virus shedding after intraperitoneal, intravenous or intratumoural injection is undetectable. Thus, the risk to humans from murine cell line tissue is negligible as the viruses are replication-deficient or tumour specific and the gene products are not considered harmful to health.
Full containment level 2 will be used, as set out in the Regulations, including appropriate treatments for bulk, contaminated solid waste.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full containment level 2 will be used, as set out in the Regulations; i.e. Virus generation and infection of target cells will be carried out in Class II biological safety cabinets in the Containment Level II laboratories, with access restricted to authorised staff. including appropriate treatments for bulk, contaminated solid waste.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All viral supernatants and spent medium will be inactivated using 10,000 ppm free chlorine before removal from the Containment Level II laboratories for final disposal. This process will result in 100% inactivation of infectious virus.

Solid waste will be bagged in biohazard bags prior to removal from the Containment level II lab and then placed in boxes which are sealed prior to removal from the CL2 suites. Boxes remain sealed and are autoclaved before the contents is removed for collection by accredited waste contractors. Autoclaves produce a digital record of load temperature achieved and are validated by annual thermocouple mapping. This process will result in 100% inactivation of infectious virus.

Project Ref 383/02.1

Date Ackn’d 11/06/2002  
CU2 Project Title GENE TRANSFER USING DISABLED ADENOVIRUS VECTORS CONTAINING  
Class 2  
CultureVol Class 2 < 1 litre  
CultureVolumeClass3-4

02/03/2022
The purpose of this study is to develop replication-defective disabled adenovirus vectors for the transfer of enzyme-prodrug systems regulated by telomerase gene promoter sequences. The telomerase gene promoters targets and restricts expression of the cancer therapeutic enzyme-prodrug systems to cancer cells. The telomerase targeted adenovirus vectors will be examined for their potential to express the enzyme-prodrug system in cell lines. The long-term aim is to use adenovirus vectors for the treatment of cancer.

The cells to be used are immortalised human cancer cell lines and human epithelial and haematopoietic cells. Human cells in culture are not considered to pose any inherent hazard to human health, nor do they have the capacity to survive autonomously outside of the laboratory. It is not anticipated that the proposed modification will alter these properties. The final GMO cell lines will therefore not exert any foreseeable effects on either human health or on the environment.

The vectors under development are based on a commercially available replication-defective disabled adenovirus vector system based on adenovirus serotype 5(Ad5). The Adeasy adenovirus vector is deleted for E1 and E3 virus sequences rendering the virus replication defective. The virus is unable to replicate except in a complementing cell lines such as 293 cells (a human embryonic kidney cell line which expresses the left 11% of the Ad5 genome). The replication defective vector can be considered unlikely to cause disease but will be classified in hazard group 2. This combined with the rigorous waste inactivation procedure and inherent fragility of adenoviruses means that there are no foreseeable effects on either human health or on the environment.

The genetic material to be introduced into the cell lines consists of adenovirus vectors containing cancer specific therapeutic genes. It is anticipated that these studies will lead to a better understanding of cancer development and lead to new therapeutic options for cancer treatment.

The replication defective adenovirus vectors carrying the non-toxic inserts of cancer therapeutic genes are unlikely to be hazardous to humans. The possibility of exposure to recombinant viruses generated by recombination with wild type virus needs to be considered but the inserts are non-toxic and so are unlikely to represent an increased hazard over wild type virus. Careful attention will be placed on containment and control measures that minimise aerosol production and opportunity for recombination and complementation. This combined with the rigorous waste inactivation procedure and inherent fragility of adenoviruses means that there are no foreseeable effects on either human health or on the environment.
human health or on the environment. Level 2 containment will be implemented using biological safety cabinets.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

To minimise the risk to human health it will be essential to prevent exposure to adenovirus. Virus generation and infection of target cells will be carried out in Class II biological safety cabinets in the Class 2 containment laboratories, with access restricted to authorised staff. The amount of adenovirus handled will be limited to no more than 25 ml of virus stock with the titre range of 10^10 to 10^11 particles/ml. The most likely routes through which individuals could be exposed to virus are needle-stick injuries or aerosols generated during experimental procedures. No needles or sharps will be used during virus preparation unless essential, whilst the use of the Class II biological safety cabinet will guard against exposure to aerosol. In addition, cell cultures will be contained within clearly labelled boxes during incubation to prevent accidental spillage of medium. All viral supernatants and spent medium will be inactivated using Precept tablets before removal from the Class 2 Laboratories for autoclaving and final disposal. Solid waste will be double-bagged in biohazard bags prior to removal from Class 2 laboratories and autoclaved prior to disposal. Cells will be cultured using designated bottles of culture medium that will not be used to passage other cell cultures. Unused medium will not be removed from the Class 2 laboratories without inactivation with Precept tablets. Authorised staff will wear dedicated lab coats in the Class 2 laboratories that are not worn in the general laboratory area.

Project Ref 383/09.1

Purposes of the contained use

Replication-deficient lentiviral vectors (pFG12 vector) will be used to deliver the activated oncogenes RasV12 and BRAFV600E to primary human cell lines to induce senescence. This strategy will be used to further analyze the senescence pathway.

A replication-deficient retroviral vector (pBABE-puro) will also be used to deliver the activated oncogene RasV12 to the human fibroblast cell line IMR-90 (ATCC Number CCL-186) in order to induce senescence. This strategy will be utilized in order to investigate mechanisms of the senescence pathway.

Recipient or parental organism

The GMM will be transfected into 293FT cells in order to produce virus and the virus will then be applied to primary human cell lines, such as fibroblasts, melanocytes and keratinocytes, which are widely employed in laboratories and have all been screened for HIV, Hep B, Hep C and EBV. There is no risk from the cells infected. Cells are typically obtained from ATCC.

The GMM (pBABE-puroRasV12) will be transiently transfected into Phoenix cells, a 293T-derived packaging cell line that contains the Gag, Pol and Env viral proteins required for making active virus. Subsequently, viral supernatants produced by Phoenix cells will be used to infect human fibroblasts (IMR-90). Both the Phoenix packaging cell line and IMR-90 fibroblasts are used extensively in laboratories and have been screened and found to be negative for HIV, Hep B, Hep C and EBV. There is no risk from the infected cells. Cells are obtained from ATCC and have been rigorously characterized.

Host/vector system

The ViraPower Lentiviral Expression System (Invitrogen) uses a pLenti expression vector that contains a deletion in the 3' LTR that results in "self-inactivation" of the lentivirus after transduction of the target cells. When integrated into the target cell the lentiviral genome is therefore no longer capable of producing packagable viral genome. This third generation vector system is based upon a HIV-1 lentivirus, although it is lacking all HIV-1 genes except gag-pol and env, which are provided in trans by
a transient transfection strategy. Also, the virus produced is to be pseudotyped with VSV-G envelope protein rather than HIV-1. The vector requires three other packaging plasmids that allow expression in trans of proteins required to produce viral progeny (e.g. gag, pol, rev, env) in the 293FT producer cell line. These packaging plasmids separately allow for the expression of gag and pol, a RRE-containing sequence, and the rev protein sequences from HIV-1. None of the packaging plasmids contain LTRs or the Ψ packaging sequence, and therefore, none of the HIV-1 structural genes are actually present in the packaged viral genome so they are never expressed in the transduced target cell. No new replication-competent virus can be produced. (Dull, et al., J. Virology, 8463-8471, 1998).

The pBABE vector system is a retroviral vector construct that has been derived from Moloney murine leukemia virus (MMLV). As with lentiviral constructs, the pBABE retroviral vector also requires three additional packaging plasmids that drive expression in trans of proteins required to produce viral progeny (i.e. gag, pol, rev and env) upon transfection into a producer cell line (Phoenix). The pBABEpuro vector has been designed to avoid homology between the vector and packaging constructs, in order to decrease the chance of homologous recombination in the Phoenix packaging cells.

Origin & function

The Ras and BRAF genes belong to the MAP kinase pathway, which mediates cellular responses to growth signals. When constitutively activated through mutation (RasV12 and BRAFV600E) senescence is conferred through the upregulation of the tumor suppressors p53 and p16INK4a. Activating BRAF mutations are present in up to 80% of melanomas while mutations in the ras gene are very common in adenocarcinomas of the pancreas (90%), the colon (50%), and in myeloid leukemia (30%). Although these gene products are very common in human cancers, additional mutations are required to drive a malignancy. Also, the hazards of the activated oncogene are very minimal due to the inability of the 293FT and Phoenix cells to create a replication-competent virus. In addition to the inserted oncogenes, the carrier plasmid (FG12) contains the woodchuck hepatitis virus posttranscriptional regulatory element (WRE) to increase the level of transcription. Although controversial, WRE may have oncogenic activity but should not pose a hazard due to the safety precautions that are already built in for the activated oncogenes.

Evaluation of foreseeable effects

It is not anticipated that the inserted sequences will alter the host-range or tissue tropism of the virus. Some of the genes we wish to express will oncogenic proteins. Current knowledge indicates that the de-novo transformation process of human cells requires the perturbation of six-pathways (Rangarajan et al, Cancer Cell, 2004 (2):171-83) and therefore manipulation of individual pathways is not expected to confer a serious cancer risk to normal human cells. None of the genes we wish to manipulate encode toxins.

Hence, it is unlikely that replication defective viruses would be effective carcinogens in humans in the short term. Single oncogenes are not generally considered sufficient to convert primary human cells to full malignancy, and replication defective viruses are not capable of dissemination even in a permissive host, however there is potential for harm to human health in the event of infection. It will however, be important to prevent human exposure or environmental release of the replication defective adenoviruses which are used to transiently to effect gene transfer. This will be achieved through the use of appropriate physical containment and inactivation processes.

The possibility of exposure to recombinant viruses generated by recombination with wild type virus needs to be considered and may, although unlikely, cause pathological effects in humans. Careful attention will, therefore, be placed on containment and control measures that minimise aerosol production and opportunity for recombination and complementation.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

### Project Additional Information

#### Purposes of the contained use

Retroviral vectors will be used to produce retrovirus in order to generate a variety of human and murine, normal and cancer cell lines stably expressing the below proteins. These will be used to study apoptosis, autophagy and mitochondria in relation to cancer development and treatment response.

#### Recipient or parental organism

Producer cells: Phoenix Ecotropic and Phoenix Amphotropic packaging cells These were obtained from Dr. Gary Nolan, University of Stanford and are extensively used for retroviral generation.

Target cells: Hela, MCF-7, SVEC 4-10, NIH3T3, L929, NIH SA, SV40 transformed murine embryonic fibroblasts, U20S, HT90, Caco-2, Jurkat, These cell lines are widely used by research laboratories, are well characterized, and have been obtained from either ECACC or ATCC and subsequently been screened for human pathogens including HIV, HBV, HCV and EBV. They do not harbour adventitious agents. They are not considered to pose any inherent hazard to human health nor do they have the capability to survive outside the culturing environment of the laboratory.

#### Host/vector system

Retroviral vectors: pBabe puro, pBabe hygro, pLZRS ires zeo, PMX ires GFP, pRsuper retro

The vectors are again widely used by research laboratories and have been developed to provide the viral package signal, transcription and processing elements, and a target gene. The Packaging cells, into which the vectors are inserted, provide the envelope components.

#### Origin & function

- **Inserts:**
  - **Apoptosis related:** Bcl-XL, Mcl-1, tBid, PUMA, Bax, Bad, Bak, Bfl-1, Mcl-1, Bcl-2, Caspase-3, DD Caspase 3, Caspase-9, Caspase-8, RIP3K, RIP1K, FADD, TNFR-1, Trail, Fas, PGAM5, Drp-1, Cytochrome-c GFP, Smac mCherry, Omi mCherry, caspase activity FRET reporter probe, Parkin, PINK1
  - **Autophagy:** mCherry LC3, eGFP LC3, eGFP mCherry LC3, eGFP p62, mCherry p62, Atg7, Atg5, Atg12, DD Atg5
  - **Mitochondrial:** mito matrix dsRed, mito matrix YFP, mitochondrial outer membrane targeted GFP, mitochondrial intermembrane space targeted Cre recombinase

#### Evaluation of foreseeable effects

Hazards associated with target/recipient cell lines
Phoenix Ecotropic or Phoenix Amphotropic cells are extensively used for retroviral generation. The target cells have been sourced from either ECACC or ATCC and subsequently been screened for human pathogens including HIV, HBV, HCV and EBV. They are widely used within and outside the Institute and are unable to survive outside a laboratory environment. Consequently, the cells should not have any foreseeable effects on human health or the environment.

Hazards associated with the vector system and inserted gene products

pBabe puro/pBabe hygro (Addgene), pLZRS zoe (Addgene), pMX ires GFP (Addgene), pSuper Retro (Addgene) are all replication incompetent retroviral vectors that allow production of retroviruses encoding proteins or shRNA targeting proteins of interest. Stable cell lines will be selected with puromycin (pBabe puro/pSuper retro), zeocin (pLZRS zeo), hygromycin (pBabe hygro) or sorted for GFP expression (PMX ires GFP).

Using the Phoenix cells and the above plasmids, viral progeny are only produced following transfection of the plasmid encoding the gene of interest (because this provides the viral packaging signal in trans). Produced virus are replication incompetent, since they lack various genes essential for viral replication. The genes, including Gag-Pol and Env are provided in trans by the Phoenix packaging cell line.

None of the gene inserts to be used are known oncogenes in themselves. Pro-apoptotic proteins such as Bax and Bak can only kill cells upon massive overexpression, it is not anticipated that retroviral transduction will attain the required levels. Many of the fluorescent fusion proteins are used solely as reporters, with no known toxic or oncogenic properties. None of the gene inserts to be used are expected to alter viral tropism.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Virus generation and infection of target cells will be carried out in Class II biological safety cabinets in the Containment Level II laboratories, with access restricted to authorized and trained staff. The amount of retrovirus handled will be limited to no more than 5ml of virus stock. The most likely routes through which individuals could be exposed to virus are needle-stick injuries or aerosols generated during experimental procedures. Plastic ware will be used throughout and no needles or sharps will be used during virus preparation. The use of the Class II biological safety cabinet will guard against exposure to aerosols.

All cell cultures will be contained within clearly labelled boxes during incubation to prevent accidental spillage of medium. All viral supernatants and spent medium will be inactivated using Presept tablets (10,000 ppm free chlorine) before removal from the Containment Level II laboratories for final disposal.

Solid waste will be double bagged in biohazard bags prior to removal from the Containment Level II laboratory and then autoclaved before final consignment of waste to approved contractor. Autoclaves will be validated by annual thermocouple mapping and each run is monitored using Thermalog-S indicator test strips. These processes will result in 100% inactivation of infectious virus.

Cells will be cultured using designated bottles of medium that will not be used to passage other cell cultures. Authorised staff will wear dedicated lab coats in the Containment Level II laboratories that are not worn in the general laboratory area.

Infected target cells will be cultured under the above regime until medium supernatants have been shown to be free of replication competent virus as judged by infection of appropriate indicator cells and assays of reverse transcriptase activity. Only once these criteria have been met will the infected target cells be removed from Containment Level II laboratory and handled using standard tissue culture procedures.
The project was approved as Class II by the Safety Committee on 12 June 2012.

# Project Additional Information

## Purposes of the contained use

The aim of this project is to evaluate the therapeutic potential of selectively replicating ('oncolytic') Herpes simplex virus 1 vectors in human cancers, especially ovarian cancer. Specifically, we aim to evaluate the pathways of cell death activated by oncolytic HSV in ovarian cancer and the role of innate and adaptive immune responses in modulating therapeutic efficacy of oncolytic HSV1 vectors.

## Recipient or parental organism

- Human ovarian cancer cells; murine ovarian cancer cells; African green monkey kidney cells

## Host/vector system

- HSV-1

## Origin & function

All vectors will be based upon the vector 1716, which is HSV-1 deleted in the neurovirulence gene ICP34.5. 1716 itself has no inserted viral gene products. There are also derivatives of 1716 encoding GFP, Firefly luciferase and RFP. Further double deletion mutants (eg ICP34.5 and ICP47) with increased selectivity for malignant cells may also be evaluated.

## Evaluation of foreseeable effects

Deletion of ICP34.5 dramatically reduces neurovirulence. Although 1716 remains capable of replicating within malignant cells, replication is dramatically attenuated in normal neuronal tissue, as confirmed in clinical trials of 1716 and other ICP34.5-deleted vectors. Risk to human health is therefore effectively zero. Parental Wild-type HSV1 causes fatal encephalitis in mice. However, previous data show that 1716 is avirulent in mice, including by direct intracranial injection. There is no reason to suspect that 1716 has enhanced environmental survival factors or altered host range compared with HSV-1, which is already present in the environment. Overall risk to organisms other than humans and to the environment is therefore effectively zero.

## Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

To minimise the risk to the laboratory staff all work will be undertaken within dedicated MSC class 2 cabinets within class 2 tissue culture facilities. All materials will be decontaminated in 10,000 ppm chlorine (e.g. Virkon, Chlorsept) before removal from MSC class 2 cabinets and autoclave-mediated destruction. Virus is stored at -80°C in cryovials. Following defrosting on ice, cryovials are not opened until placed within MSC class two cabinets, thus minimising the risk of spillage within the lab. In the case of accidental spillage either within or without the MSC class two cabinet, all materials will be decontaminated with 10,000 pm chlorine.
For only GMMs - application for any derogation from full containment for the Class of activity.  (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

**Project Ref** 383/14.2
Construction and use of retro- and lentiviral vectors to express normal or mutated proteins and shRNA constructs in primary and immortalized murine/human cells (Ref:25/09.1)

---

**Project Additional Information**

**Purposes of the contained use**

The project will utilise retro- and lentiviral vectors to deliver shRNA, reporter genes and dominant negative constructs directed against autophagy, metabolism and epigenetic pathways to human and murine cells including leukaemic stem cells and other tumour cell lines.

**Recipient or parental organism**

Murine/human leukaemic cell lines, solid human tumour cell lines, human fibroblast cell lines, murine stem- and progenitor cells and primary human blood cells.

**Host/vector system**

Replication deficient retro-and lentiviral vector system.
Additional vectors to project 25/09.1:
Retroviral vectors: pBabe, pWZL, MIGR-1, pSUPER.Retro.
Lentiviral vectors: pGIPZ, pLKO.1-puro, pLKO.1-GFP, pLenti-CMV.
Packaging plasmids: p-CMV-HIV1 and psPAX (encode for Gag-encoded capsid proteins, Pol-encoded reverse transcriptase and integrase enzymes) and VSV-G (encodes for glycoprotein envelope).

**Origin & function**

Retroviral system: The majority of retroviral vectors have been derived from oncogenic retroviruses, such Moloney murine leukemia virus (MoMLV), that efficiently infect actively dividing cells. The viral env gene, produced by the package cell line, encodes the envelop protein, which determines the viral infectivity range. Transfection into a package cell line, such as HEK239FT (a human embryonic kidney cell line transformed with adenovirus E1a and carrying a temperature sensitive T antigen; Invitrogen) or HEK293T derivatives Phoenix-Eco or Phoenix-Ampho (second-generation retrovirus producer lines for the generation of helper free ecotropic and amphotropic retroviruses; Orbigen Inc.) produces high-titer, replication-incompetent viruses. pBabe, pWZL, MIGR-1 and pSUPER.Retro vector systems contain the bacterial origin of replication, antibiotic-resistant (puromycin, hygromycin or neomycin) gene for the growth of infected cells to select stable cell lines.
Lentiviral system: Lentiviral vectors have become widely used due to their ability to infect non-dividing cells, which gives them an advantage over retroviral vectors for certain applications. pGIPZ (Open biosystems), pLKO.1 (Open biosystems/Sigma) and pLenti-CMV (Addgene) are replication-incompetent lentiviral vectors chosen for expression of shRNAs (pGIPZ/pLKO) or mRNA (pLenti-CMV). This lentiviral system allows for transient and stable transfection of RNA and also production of viral particles using lentiviral packaging cell lines, such as HEK293FT. pGIPZ, pLKO.1-puro and pLenti-CMV contain antibiotic resistance marker (puromycin) and pLKO.1-GFP contains fluorescent (GFP) selectable marker that allows selection of stable cell lines.

As stated above, the project will utilise retro- and lentiviral vectors to deliver shRNA, reporter genes and dominant negative constructs directed against human and murine cells including tumour cell lines.

Evaluation of foreseeable effects

The retro- and lentiviral system includes a number of safety features designed to enhance its biosafety and to minimize its relation to the wild-type virus. The reverse transcriptase and integrase proteins are split from the native Gag-Pol polyprotein structure and are provided 'in trans' on a separate plasmid. Removing the reverse transcriptase and integrase from the packaging construct prevents the viral replication machinery from functioning. This system prevents the generation of recombinant viral particles that possess the required functional Gag-Pol structure for DNA mobilization and the emergence of replication competent virus. The probability of reversion to the wild type is effectively zero.

Although the packaging and envelope (p-CMV-HIV1/psPAX2/pVSV-G) plasmids allow expression in trans of genes required to produce viral progeny (e.g. gag, pol, rev, tat, env) in the HEK293FT producer cell line, none of them contain LTRs or the Ψ packaging sequence. This means that none of the structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. This ensures that the retro- and lentiviral vectors are unable to replicate and infect surrounding cells, thus making them safe to use in the laboratory without any risk of viral infection to cells in the environment.

The potential routes of transmission of the virus are known; retro- or lentivirus may possibly be delivered to epithelial cells through accidental inhalation, skin exposure, or oral ingestion; or accidentally to the bloodstream via a wound in the skin. Although the risk of infection to humans is effectively zero, it is important to prevent human exposure or environmental release of the replication defective viruses.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Amphotrophic retro- and lentiviruses are capable of infecting a range of mammalian species, however the viruses are replication defective and therefore incapable of causing infectious disease.

All liquid and solid waste will be inactivated by treatment with precept tablets and/or autoclaving prior to disposal to ensure that live virus does not come into contact with the environment. Furthermore, retro- and lentiviruses are fragile and unlikely to survive in the environment for sufficient time to encounter a susceptible host.

Combined with the containment measures to protect human health, these considerations indicate that the risk posed to the environment by the proposed activity is effectively zero.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None requested

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Disinfection
All materials potentially contaminated with retro- or lentivirus will be decontaminated in 10,000ppm chlorine in solution (e.g. Chlorsept) before removal from laminar flow hoods.

Autoclaving
All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving, using the following regime; gradual pulsing of temperature and pressure to final pressure of 3040mBar and temp of 134 °C - 39 mins, sterilisation cycle @ 3040mBar, 134 °C - 20min, Pressure venting - 1min drying and pressure vent –
30s. air wash, pressure vent and cooling - 3mins, air Break - 1min, cooling - 11mins (100% kill), prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored by continuous chart (or digital) recording of the temperature/time profile.

Following disinfection and autoclaving, all waste will be disposed of as clinical waste.

Date Ackn'd: 27/07/2016

CU2 Project Title: In-depth characterisation of central nervous system leukaemia

Class: Class 2

Culture Volume: Class 3-4

Class Culture Volume: Class 2 < 1 Litre

Non-GMM: Consent Granted

Project notified under transitional arrangements N

Withdrawn: N

Tick if notifying a connected programme of work N
Our group is focused on the unravelling of acute lymphoblastic leukaemia (ALL) survival mechanisms when cancer cells escape primary tumour sites (bone marrow) and reach secondary sites such as the central nervous system (CNS). In order to better understand the underlying mechanisms, we intend to either knock down (KD) or knock out (KO) key genes in fatty acid/lipid synthesis cascade (and associated pathways) in established human leukemic cell lines SEM (DSMZ:ACC-546) or REH(ACC-22) and study the biological consequences of those KDs or KOs on the tumour cell survival.

Constructs will be amplified in non-pathogenic E.Coli (DH5alpha or Stbl3) bacteria strain. Viral particles will be produced in cell lines such as HEK293T (human kidney cells, ATCC® CRL-1573™). Human leukemic cell lines such as SEM (DSMZ:ACC-546) or REH(ACC-22) will be infected with viral particles.

Replication deficient lentiviral vector systems such as: 2nd generation Tet-ON PLKO-1 euro, or later generation vector systems. Packaging plasmids (for production of viral particles) such as: psPAX2 (Addgene#12259) and VsVg (Plasmid #8454 Addgene).

Packaging plasmids (for production of viral particles) such as: psPAX2 (Addgene#12259) and VsVg (Plasmid #8454 Addgene). Plasmids such as Tet-ON PLKO.1-puro-based plasmids subcloned with shRNA or CRISPR construct against SCD1 and/or other genes in related metabolic pathways (PLKO-backbone from Addgene Plasmid #21915).
Evaluation of foreseeable effects

The retro/lentiviral system we are going to use includes a number of safety measures both to increase biosafety and minimise the biological risks to experimenters/third-party humans and the environment. It is replication incompetent. The reverse transcriptase and integrase proteins are split from the original Gag-Pol polyprotein structure and are provided on a separate plasmid, which prevents the viral replication machinery from functioning. This thus prevents the emergence of a fully functional replication competent virus. Although the packaging and envelope (psPAX2, pVsVg) plasmids allow trans expression of genes necessary to the production of viral particles (gag, pol, tat, rev) in the HEK293T producer cell line, none of them contains LTR packaging sequences. That means that none of the structural genes are present in the packaged viral genome and are ever expressed in the transduced target cell. This ensures that retro/lenti viruses are very unlikely to replicate and infect surrounding cells, thus making relatively safe to use in the laboratory without any risk of viral infection to cells in the environment. Retro and lentiviral vectors will encode shRNAs or CRISPR constructs (targeting specific mRNAs involved in fatty acid and lipid synthesis and catabolism, along with related pathways). The final genetically modified cells will contain stably integrated DNA copies of the viral vectors encoding the transgene expression cassette but will be free of virus. As a result they will pose no hazard to human health or the environment, since they are very unlikely to colonise humans or survive outside the laboratory culture. In addition the insert targets proteins with no known oncogenic potential or suspected physiological, pathological and or pharmacological effect. Although the risk of infection to humans is relatively low, it is important to prevent human exposure or environmental release of the replication defective viruses which are used transiently effect gene transfer. The worst case scenario in case of infection is chance integration at a site that disrupts expression of a gene necessary for tumour suppression. However, there is only very slight chance that this could occur.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All materials will be decontaminated in 10,000 ppm chlorine in solution (E.g. Virkon) before removal from laminar flow hoods autoclave-mediated destruction. Virus may be stored at -80 degrees in cryovials. Following defrosting on ice, cryovials are not opened until placed within a Class II biological safety cabinets, thus minimising the risk of spillage within the lab. In the case of accidental spillage either within or without the Class II biological safety cabinets, all materials will be decontaminated with
10,000 ppm chlorine solution.
Disinfection:
All materials potentially contaminated with lentiviruses will be decontaminated in 10,000 ppm chlorine solution before removal from the laminar hood.

Autoclaving:
All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving, using the following regime: gradial pulsing of temperature and pressure to final pressure of 3040mBar and temperature of 134 degrees Celsius: 39 mins, sterilisation cycle at 3040mBar and temperature of 134 degrees Celsius, 20 mins, Pressure venting, 1min drying and pressure vent, 30s air wash pressure vent and cooling, 3mins air break, 1min, cooling 11 min (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment such as glassware. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored by continuous chart (or digital) recording of temperature/time profile.

Waste Disposal:
Following disinfection and autoclaving, all waste will be treated as a clinical waste.

Production of retro- and lenti-viral vectors for transfection of patient derived cell lines (PDCLs) from a pancreatic cancer cohort

Project Additional Information

Purposes of the contained use

Different genetic inserts will be used throughout the project. Some will encode shRNA constructs designed to interfere with the mRNA of genes suspected to facilitate PC progression, while others will contain those genes themselves to be inserted into the host genome. Although these gene inserts may be considered oncogenic, they are primarily likely only to contribute to cancer progression within the context of PC, therefore induction of expression itself is highly unlikely to transform infected tissue. Inserts that code for fluorescent reporter genes such as GFP and RFP will also be used, with each insert containing additional antibiotic selection markers. No viral particle generated will be replication-competent, with very little chance of reversion to replication competency, and genetically modified host cells will be free from virus after initial exposure period, limiting the risks involved in handling culture material.

Genes to be repressed via shRNA or overexpressed via cDNA expression include those known to regulate epigenetic components within the cell, such as SWI/SNF complex member, ARID1A and EZH2, a subunit within the polycomb repressive complex 2 (PRC2) methyltransferase, as well as transcriptional regulators such as HNF1A, NR4A1, FAK.

Recipient or parental organism

Three sets of PC PDCLs, all derived from human tissue and generated at various cancer research centres, will be exposed to viral infection over the course of this project. The majority of cell-lines were established The Kinghorn Cancer Centre (TKCC), Australia, obtained from patient derived xenografts (PDXs). Additional cell-lines involved were generated via the outgrowth method at the Technische Universität Dresden, Germany, as well as derived from tissue samples from patients grown directly on collagen at the Mayo Clinic, USA. All PDCLs involved in the project have been cleared for use within a Containment Level 1 environment.

Host/vector system

The DH5α strain of E. coli will be used to amplify plasmid vectors, and HEK293T cells will be transfected with expression vector + packaging system plasmids to produce non-replicating virus particles from the pLenti-C-mGFP-P2A-Puro expression vector and a 2nd or 3rd generation 2-vector packaging system: pMDLg/pRRE, encoding Gag and Pol, and pRSC-Rev, encoding Rev. PC PDCLs established by external collaborators as previously described will be exposed to virus/viral vectors.

2nd Generation Packaging Vector: psPAX2, encoding Gag, Pol, Rev and Tat viral proteins.

3rd Generation Packaging Vectors: pMDLg/pRRE, encoding Gag and Pol, and pRSC-Rev, encoding Rev.

3rd Generation Transfer Vectors: pLenti-siRNA-GFP, pLenti-puro and pLKO.1 puro, all encoding LTRs (with truncated 5’ LTR), Psi region and custom genomic insert.

The viral vectors involved in this project are comprised of two primary genetic components, a transfer vector and a packaging system. Transfer vectors allow for the production of proviral cDNA strands modified to contain specific genes, while the packaging system contains genes that facilitate the generation of viral particles. 3rd generation vector systems separate packaging elements across two plasmids, thus further limiting the possibility of reversion to replication competency in the event of recombination. Packaging cells that are induced to express both constructs, as well as a viral envelope protein, are therefore able to generate infectious, non-replicating virus particles carrying those genes of interest that will be inserted into the host genome postinfection.

Evaluation of foreseeable effects

The DH5α E. Coli strain is highly attenuated, and does not present hazards to humans. The viral particles produced by the packaging cell line are non-replicative, and have been constructed to prevent any possibility of reversion to wild-type virus. Use of a 3rd generation packaging system splits the genes capable of generating infectious viral particles in trans across separate plasmids to limit the possibility of a reversion event, and packaging plasmids lack any Psi packaging and LTR sequences. This renders the lentivirus particle replication-deficient upon infection of host cells, as the only inserts which are incorporated into the host genome are present in a separate transfer vector. Only a recombination event that transfers all essential packaging genes, as well as the additional VSV-G envelope gene onto the transfer vector could lead to replication-competent virus, which is highly unlikely to occur in 3rd generation system where packaging genes are split across multiple plasmids.

Origin & function

The viral vectors involved in this project are comprised of two primary genetic components, a transfer vector and a packaging system. Transfer vectors allow for the production of proviral cDNA strands modified to contain specific genes, while the packaging system contains genes that facilitate the generation of viral particles. 3rd generation vector systems separate packaging elements across two plasmids, thus further limiting the possibility of reversion to replication competency in the event of recombination. Packaging cells that are induced to express both constructs, as well as a viral envelope protein, are therefore able to generate infectious, non-replicating virus particles carrying those genes of interest that will be inserted into the host genome postinfection.

Initial experiments are planned to assess effects of overexpressing epigenetic modulators, such as ARID1A and EZH2, as well as transcriptional regulators such as HNF1A, NR4A1, FAK. Evidence suggests that these epigenetic/regulatory genes may act as either tumour suppressors or oncogenic drivers in a contextual dependent manner, and thus overexpression alone is highly unlikely to be transformative.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Full level 2 containment will be used as set out in the Regulations:
Virus generation and infection of target cells will be carried out in Class 2 biological safety cabinets in Containment Level 2 environments, with access restricted to authorised staff.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All viral work will be carried out within Class II biological safety cabinets in order to maintain sterile tissue culture conditions, which will incidentally reduce the possibility of accidental exposure to and limiting existing routes of transmission of viral particles. All materials used within safety cabinets will be decontaminated via disinfection before removal from the cabinet, thus preventing any chance of viral escape. In the case of any accidental spillages of medium containing virus particles, any potentially infected surfaces and materials will be decontaminated with Virkon solution. All viral supernatants and spent medium containing viral particles will be inactivated using 10,000 ppm free chlorine before removal from Containment Level 2 laboratories for disposal. All contaminated solid materials will be bagged in biohazard bags prior to removal from Containment Level 2 lab and placed in boxes which are sealed prior to removal from the CL2 suites. Boxes will remain sealed until contaminated waste can be inactivated by autoclaving using the following regime: gradual pulsing of temperature and pressure to a final temperature of 134°C and pressure of 3040 mBar for 39 minutes; 20 minute sterilisation cycle at 3040 mBar and 134°C; 30 seconds of pressure venting; 3 minute air wash, pressure vent and cooling; 1 minute air break; 11 minutes cooling (100% kill). This is prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclave activity is validated by annual thermocouple mapping and each run is monitored by digital recording of the temperature/time profile. Once disinfected and autoclaved, waste generated will be disposed of as by accredited waste contractors.
This project was assessed as Class 2 by the GM383 Safety Committee in November 2018 and signed by PI and GMBSO in May 2021.

### Purposes of the contained use

The purpose of the contained use is to assess whether polymorphism of the human PrP gene are controlling susceptibility and resistance to prion diseases, also known as Transmissible Spongiform Encephalopathies of TSEs. The variants in question have altered amino acid codons and have been found in individuals affected by TSEs but it remains to be proven that there is a direct causal link between the codon change and the TSE disease. The details of the study are confidential in order to protect intellectual property and a successful project may result in a patent application so commercial confidentiality is also claimed. Disclosure would adversely affect the competitive position of the Institute for Animal Health in a highly competitive area of research. Exemption from disclosure is allowed by the Environmental Information Regulations 1992 as amended in 1998 and the relevant exemption is intellectual property protection and commercial confidentiality.

### Host/vector system

For the laboratory cloning steps, a section of the mouse PrP gene cloned into pBluescript vector will be subjected to in vitro mutagenesis to introduce the required nucleotide changes. The newly created sequences will be cloned into plasmid pBluescript. All constructs will be maintained in disabled E. coli bacterial cultures. Details of the constructs and cloning steps are claimed as confidential. Exemption from disclosure is allowed by the Environmental Information Regulations 1992 as amended in 1998 and the relevant exemption is intellectual property protection and commercial confidentiality.

### Origin & function

The origins of the genetic material involved are cloned sections of the mouse PrP gene already available in this laboratory from other projects. The intended function of the mutagenised cloned sequences is to make gene targetted transgenic animals expressing a single copy of the transgene under the control of the endogenous PrP gene promoter. The details of this project are claimed to be confidential exemption from disclosure is allowed by the Environmental Information Regulations 1992 as amended in 1998 the relevant exemption is intellectual property protection and commercial confidentiality.

### Evaluation of foreseeable effects

The GMMs and human health:

**Hazard identification**

It would be theoretically possible for a laboratory worker to swallow the Ecoli containing human disease associated amino acid codons within the mouse PrP gene. The plasmid pBluescript II is not a prokaryotic expression vector and in combination with the fact that the inserted mouse PrP gene fragment is of large size it is very unlikely that any PrP protein is expressed in these Ecoli and therefore for this altered PrP protein to appear in the gut. If despite this assessment altered PrP protein would be produced and released into the gut, the hazard would be very low as it has been shown that recombinant PrP made in Ecoli is not infectious (Scott et al 1988 Protein Engineering 2: 69-76) Those who believe TSEs (or prion diseases) are caused by an infectious protein put this down to misfolding and non-glycosylation of the Ecoli expressed protein however recombinant PrP expressed in mouse cells (Caughey et al 1988 PNAS 85: 4657) or monkey COS cells (Scott, et al, idid) or converted in vitro to protease resistant form (Hill et al 1999 J Gen Virol 80: 11-14) are also not infectious.

**Capacity to survive in the human gut.**

The bacteria to be used are recombination deficient so would not be expected to transfer plasmids to other bacteria or to be able to compete successfully with wild-type bacteria.

**Assessment of likelihood - low.**

There are extensive measures in force at the Institute for Animal Health in Edinburgh to protect staff from any infection with TSEs. All TSEs are treated in the same way in order to make sure procedures are remembered and followed diligently. CJD and BSE in addition, are handled at containment level 3 at the moment.

**The minimal containment level within the building is level 2.** Some closed, locked and access restricted rooms are used for work with CJD and BSE. These are higher containment than level 2 without being full level 3.
Briefly: No eating or drinking is allowed in laboratory areas
No mouth pipetting is allowed
Protective clothing (lab coats, aprons if necessary) is worn all the time
Disposable gloves are worn, eye protection is worn
Any procedures which could generate aerosols are carried out in safety cabinets
Visors are used if splashing is possible
Closed systems are used for mixing, homogenisation, centrifuging etc
Plastic disposables are used whenever possible in preference to sharps
Waste is disposed of by treating with 20,000 ppm chloros or autoclaving at 134C for 1 hour and followed by removal in hermetically sealed waste bins for incineration
Dedicated rooms are used for procedures involving CJD and BSE infectivity.
Records are kept of all accidents.
A Quality Assurance system is being set up with IAH to closely monitor all procedures, experiments and safety controls.

Assessment of consequence - High
Although expected to be unlikely, if any infectivity is generated by Ecoli containing human disease associated amino acid codons in the mouse PrP gene, this would not be expected to infect humans because of the safety measures in place. However, the consequences might potentially be grave if it did.

Estimation of risk - low
The measures in place to protect human health and safety are well above level 2 containment standards.

The GMMs and Environmental Risk
Hazard Identification
The Ecoli used to replicate the plasmid constructs containing human disease associated amino acid codons within the mouse PrP gene inserts could be discharged from the labs through the drains or in lab waste and affect animals and people in the environment. The plasmid pBluescript II is not a prokaryotic expression vector and in combination with the fact that the inserted mouse PrP gene fragment is of large size it is very unlikely that any PrP protein is expressed in these Ecoli and therefore for this altered PrP protein to appear in the environment. If the altered mouse genes were to be expressed in the Ecoli and this could enter and colonise the gut of animals or people, it might be that the altered mouse PrP protein would be expressed in the gut as well. However, this worst case scenario is highly unlikely as the Ecoli strain used are highly disabled and unable to compete with wild type bacteria. In addition recombinant PrP made in Ecoli is not infectious (Scott et al 1988 Protein Engineering 2: 69-76) Those who believe TSEs (or prion diseases) are caused by an infectious protein put this doen to misfolding and non-glycosylation of the Ecoli expressed protein however recombinant PrP expressed in mouse cells (Caughey et al 1988 PNAS 85: 4657) or monkey COS cells (Scott, et al ibid) or converted in vitro to protease resistant form (Hill et al 1999 J Gen Virol 80: 11-14) are also not infectious.
More details are presented with the risk assessment.

Capacity to survive in the environment.
The Ecoli strain used is recombination deficient and should not be able to trans fer plasmids to other bacteria, nor would it be expected to survive in competition with other wild type bacteria. If, however unlikely, an infectious agent was to be generated in the Ecoli cells, it may persist in the environment for long periods.

Assessment of likelihood - low
Escape of Ecoli containing human disease associated amino acid codons in the mouse PrP gene is considered highly unlikely. All bacterial cultures are treated with 20,000 ppm chloros prior to disposal or autoclaved at 134C for 1 hour. These treatments are the reliable methods of inactivating TSE agents. All nucleic acid preparations would be considered to be non-infectious due to the use of phenol or guanidinium in the preparative procedures. Any protein preparations would not leave the building unless treated as above to inactivate any infectivity. Waste then leaves the building in hermetically sealed, tamper proof clinical waste bins for incineration.

Assessment of consequence - Low
Human TSE diseases (CJD and GSS) are very rare - worldwide incidence less than 1 in a million new cases per year. There is no evidence of contagious spread of TSEs in humans and no evidence of maternal transmission. Any bacteria which found their way out of the labs would be dead because of standard decontamination procedures. Any protein remaining within them would be at low levels as high expressing promoters would not have been used.

Estimation of risk - low
The standard measures in place will protect environmental, human and animal health and safety.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**GM animals:**
Institute for Animal Health, Edinburgh is housed in a building with restricted and controlled access at the entry doors (computerised key locking system). The SPF barrier animal house is highly secure with restricted and controlled access at the entry doors. Doors to the animal house are locked with entry only via computer controlled unlocking or number coded locks. Containment of animals is routinely very high for the reason of prevention of contamination of other experiments and animals are housed in a range of facilities all with at least level 2 containment. The mouse is regarded as a closed system with regard to prion diseases but dissections are performed in safety cabinets. For the present study, animal tissues would be prepared and analysed in closed locked dedicated laboratories with higher containment than level 2 (but not full level 3). Disposal of carcasses: autoclaving at 134 C for 1 hour then removal for incineration in hermetically sealed bins. Our standard inactivation procedures reduce TSE infectivity to undetectable levels and containment and decontamination procedures are monitored for compliance. IAH is at the moment in the process of setting up a QA system to cover all activities from experiments to waste disposal.

**GM ES cells:**
Embryonic stem (ES) cell culture is performed in a dedicated locked laboratory with access restricted to essential personnel. Work is performed using disposable plastic equipment wherever possible. All liquids are treated with 20,000 ppm chloros. Tissue culture flasks, plates and falcon tubes (15 ml or 50 ml) which have been in contact with ES cells (targeted or untargeted) are sealed with parafilm and placed in waste bags which are removed from the tissue culture suite by a designated operator and autoclaved at 134C for 1 hour. The waste is then removed for incineration in hermetically sealed. Our standard inactivation procedures reduce TSE infectivity to undetectable levels and containment and decontamination procedures are monitored for compliance. IAH is at the moment in the process of setting up a QA system to cover all activities from experiments to waste disposal.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**
No derogation is claimed for the cloning steps of the project using GMMs.

It is not clear to us where on this form to ask for Derogation for GMOs which are not micro-organisms, so we do so here and in the confidential section 17 which contains the details of the reasoning and the experimental design. Derogation to Class 2 containment is requested for the embryonic stem cell stage of the project and the transgenic mice. Confidentiality is claimed for the details of this request. Exemption from disclosure is allowed by the Environmental Information Regulations 1992 as amended in 1998 and the relevant exemptions are intellectual property protection and commercial confidentiality.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**
All bacterial cultures are treated with 20,000 ppm chloros prior to disposal or autoclaved at 134C for 1 hour. These methods kill E.coli bacteria. These treatments are also reliable methods of inactivating TSE agents to undetectable levels. All nucleic acid preparations would be considered to be non-infectious in terms of TSE infectivity due to the use of phenol or guanidinium in the preparative procedures which inactivate protein (Rowher RG (1991) Current Topics in Microbiology and IMMunology 172: 195-232). Any protein preparations would not leave the building unless treated as above to inactivate any infectivity. Bacterial culture plates, ES cell plates and mouse carcasses are autoclaved at 134C for 1 hour prior to disposal. Waste then leaves the building in hermetically sealed, tamper proof clinical waste bins for incineration.

**Is an emergency plan required according to regulation 20?**

If yes, tick to confirm that it is attached to this form

02/03/2022

Page 6695 of 15326
This proposal was discussed in detail during 2 separate meetings of the GM safety committee and the proposers provided relevant additional information as requested. The committee members were concerned about various procedures to ensure they were sufficiently contained. The committee members were happy that all safety measures were in place for other projects already. The local N PU Safety officer is part of the GM committee. Staff are entitled to join a union and are represented by appropriate safety officers. Full details of the GM committee deliberations are presented in the confidential sections of this form. Confidentiality is claimed on the grounds of intellectual property protection and commercial confidentiality. These exemptions are allowed under the Environmental Information Regulations 1992 as amended in 1998.

#### Historical Significant Changes

PROJECT TRANSFERRED ON MERGER OF GM235 WITH GM 386

#### Project Additional Information

**Purposes of the contained use**

The studies proposed are based on the use of recombinant viral vectors for gene delivery in vitro in primary neuronal cultures to investigate the pathogenic mechanisms involved in neurodegenerative disorders, including Alzheimer's disease and amyotrophic lateral sclerosis (ALS). Two viral delivery systems will be used: lentiviral vectors and adeno-associated viral vectors to over-express proteins encoded by genes mutated in familial forms of AD and ALS or protein accumulating in affected neurons, as well as modifying enzymes and interacting partners and to silence the expression of the above proteins using RNA interference.

**Recipient or parental organism**

*E. coli - K12 or B derivatives (e.g. SURE 2, Stratagene and DB3.1 ccdB gene tolerant cells). Human HEK 293T cells for packaging, NIH3T3 cells, HT1 080 cells or equivalent for virus titration. Experiments will be conducted in nonneuronal (e.g. COS-7 and CHO cells) of neuronal (e.g SH-SY5Y and N2a neuroblastoma cell lines as well as in primary rat or mouse neuronal cultures (cortical neurons, motor neurons, dorsal root ganglion neurons, Purkinje cells), including neurons derived from transgenic mice*

**Host/vector system**

The inserted genetic material will be cloned into the plasmids: pAMICBA-pl-WPRE-BGH for adeno-associated virus construction or into the self-inactivating lentiviral plasmids: pLenti-DEST1TOPO or p LentilOx3.7. Genes encoding the components required for packaging the viral genome are separated onto three plasmids for the

02/03/2022
lentiviral vectors (pLP1, pLP2, pLPNSVG). The lentiviral plasmids do not contain any regions of homology with each other to prevent undesirable recombination events that could lead to the generation of a replication-competent virus.

**Origin & function**

Full-length and truncated cDNA (Homo sapiens and rodents) or cloned genomic fragments encoding the protein known to be mutated or accumulating and aggregating in neurodegenerative diseases as well as sequences designed to silence these proteins by RNA interference. Some examples are listed below.

- Tau, a neuronal microtubule-associated protein that stabilises axonal microtubules. Mutations in tau cause a form of fronto-temporal degeneration.
- Sodium calcium exchanger, NCX2, Sodium calcium exchanger, calpain cleaved, NCX3
- Kinases: GSK3alpha and beta, Casein kinase 1, CdkS and its activators, CPRK family
- ALS2/alsin, a protein that contains several domains characteristic of GTP exchange factors. Mutations of the ALS2 gene are linked to juvenile familial forms of amyotrophic lateral sclerosis (ALS).
- VAPB (vesicle associated protein B —mutated in familial ALS) and its interacting partners.
- Standard reporter genes (e.g. GFP, Luciferase, β-galactosidase) will also be already present or cloned into these vectors.
- Superoxide dismutase 1 (SOD1) mutations in which cause familial ALS

**Evaluation of foreseeable effects**

Transformed E.coli: No significant hazards have been identified. Insertion of the foreign sequences into E coli is not expected to result in harmful physiological or pharmacological properties or to affect the pathogenicity of the host or normal human defence mechanisms. The resulting GMM’s are not expected to carry any additional risks compared to that of the un-modified recipients.

Virtually transfected HEK293FTIT cells could pose a risk to human health associated with the production of recombinant infectious lentiviral particles. However, as they are self-inactivating replication deficient vectors the risk is only from the insertion of the genetic material, described above. None of the genetic inserts are likely to cause significant effect on an individual as their potential toxic effect is limited to neurons have no known oncogenic properties.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware e.g. pipettes, flasks, tubes) — soaked in hypochlorite solution before autoclaving using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids placed in a clinical waste bag for incineration by external contractors.

Liquids (e.g. samples, culture supernatants, tissue culture media) — Disinfectant - Trigene left overnight, then dispose of to drain with running water

Safety cabinet - will be washed down with Trigene solution after use.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids in a clinical waste bag for incineration by external contractors.

Sharps (e.g. needles, syringes, scalpels) - dispose via clinical waste stream for incineration.

Degree of kill

Autoclaving, effectively 100% kill (annual validation)

Incineration, effectively 100% kill (licensed incinerator)

Chemical disinfection with Trigene, used according to manufacturers instructions under standard conditions,
manufacturers validation (e.g. 99.998 % kill).

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The assessment was reviewed by the Institute of Psychiatry Biological and GM Safety Committee in their September 2007 meeting. No concerns were raised and it was approved for notification to HSE.

Project Containment
The project involves the construction of replication incompetent viruses containing DNA sequences that encode four human transcription factors. These transcription factors will be introduced into primary human somatic cells with the objective of reprogramming them into induced pluripotent stem cells (iPSC). The resulting iPSC lines will be subjected to various differentiation protocols to convert them into desired somatic cell lineages. Of particular interest will be iPSC lines made from primary cells obtained from patients suffering from a range of monogenic and polygenic diseases. The research is expected to shed light on the pathophysiology of early human disease development as well as providing cellular reagents for drug screening and discovery. Two viral delivery systems will be used: lentiviral and retroviral vectors. The transcription factors in the lentiviral vectors will be under the control of doxycycline-inducible promotors.

Recipient or parental organism

Human embryonic kidney packaging cells for making infective lenti- or retro-viruses. A variety of human primary somatic cell cultures of which skin fibroblasts will make up
Host/vector system

Lenti-x Expression System (Clontech) In this lentiviral system, the final vector [assembled through independent transformation of packaging cells (HEK293T cells) with three plasmids] is a VSV-G pseudotyped, replication incompetent retrovirus derived from HIV-1. The virus does not encode Tat and the inserted transcription factor (Oct4 or sox2 or Klf4 or c-myc) is under the control of doxycycline. The presence of added doxycycline will be needed for activation of the inserted transcription factor (Oct4 or sox2 or Klf4 or c-myc). pLVX-Tight-Puro Vector from Clontech is needed to mediate the doxycycline control.

pCMV-VSVG are all retroviruses containing the inserted DNAs indicated. In order to assemble infectious retroviruses, these DNAs and two other plasmids are introduced into human 293T packaging cell lines to create a VSV-G pseudotyped, replication incompetent retrovirus derived from the Moloney Murine Leukemia Virus.

All assembled viruses can infect human and mouse cells. The pMX and pLVX retroviral constructs have ampicillin resistance for bacterial selection. pLVX also has puromycin resistance for mammalian cell line selection.

HEK293T cells will be used for packaging.

Origin & function

Full length human cDNAs encoding the transcription factors Oct4, Sox2, Klf4, c-myc, and Sall4 have been selected. The first four of these will be used to reprogram cells. Sall4 has been included because there are rumours that it alone can reprogramme cells. However this technology is moving very fast and it is eminently possible that fewer and different human gene inserts will be required in the future. New and even safer vector delivery systems are being developed and we would like to suggest that HSE permission, if granted, will also cover new vector systems and unspecified human sequences that can reprogram human somatic cells efficiently (subject of course to the caveat that any changes will receive the approval of the local risk assessment committee and will be notified to HSE).
The Committee had minor comments which have been covered in the signed risk assessment form.

02/03/2022
Prion protein is a normal component of many of our cells (especially neurons) that has the unusual ability to change its conformation, either spontaneously or in response to genetic mutation or to prion infectious agent, to an amyloidogenic form that resists proteolysis, accumulates in the brain and appears to be capable by itself of propagating infection. While recent studies have been increasingly successful in replicating elements of this conformational conversion using recombinant prion protein modified in the test tube, no one has produced an infectious agent except within a living cell, suggesting that the full conversion from normal to infectious protein requires the action of some cellular process. The trafficking of prion protein from the cell surface into endosomes is a candidate for such a cellular process since the acidification that occurs in endosomes is used by other proteins (e.g., diphtheria toxin) and viruses (e.g., flu) to change their conformation, enabling the latter types of agent to fuse with the membrane and enter the cell.

Curiously, there is not a strong correlation between the accumulation of this infectious form of protease-resistant prion protein, and neural degeneration. Recently it has become apparent that prion protein is capable, during its biosynthesis, of being incorporated into the membrane, not only by its major mechanism (linkage to the luminal surface of the endoplasmic reticulum by a glycosylphosphatidylinositol (GPI) anchor), but also by utilisation of an internal cryptic transmembrane sequence. The proportion of prion protein that is incorporated via this alternative route, which is increased by some mutations that in man predispose to familial CJD, has been found to correlate better with neurotoxicity than has the accumulation of amyloidogenic prion protein in fibrils.

The underlying cause of neuropathology and toxicity in each case is aberrant trafficking of prion protein. Similar faults in protein trafficking are increasingly becoming to
be seen to cause other amyloid diseases such as Alzheimer's.

The purpose of the contained use is to enable us to mutate residues (or groups of residues) within normal mouse prion protein to enable us to study particular aspects of the trafficking of this protein, and in particular its translocation into the endoplasmic reticulum and its recycling between the cell surface and endosomal compartments. The mutations will be assessed firstly for their effect on the trafficking of the protein, either in transfected cell lines (N2a cells) or in simplified cell-free systems (microsomal or endosomal preparations); mutations that change trafficking characteristics will then be evaluated for their interaction with added mouse scrapie agent (from non-BSE derived strains).

Recipient or parental organism

The parental organism (original source of inserted cDNA was normal (non-infected) mouse brain.

The recipient organisms are:
1. XL2-Blue, derived from XL1-Blue, multiple auxotroph, classified as disabled or non-colonising (ACGM Compendium of Guidance, Part 2A, Annex II, Section 11).
2. N2a mouse neural cell line, maintained without harm or escape in many labs since its derivation in 1969.

Host/vector system

XL2 Blue/pCDNA for construction of expression vectors with mutated PrP
Mouse N2a neural cell line/pCDNA3/4 for expression of above in mammalian cells.

Origin & function

Mouse cDNA encoding normal mouse prion protein was derived originally from mouse brain library. Fragments of it will be subjected to PCR-based directed mutagenesis, which when confirmed by sequence will be incorporated into expression vectors (CDNA 3/4) along with an epitope or fluorescent protein tag (normally inserted after the signal sequence (amino acids 1-22), either immediately before aa 23; Lee et al (2001) J. Neurochem. 79: 79-87) or slightly more distally (after aa 42; Negro et al (2001) Mol. Cell. Neurosci. 17:521-38) where it appears not to perturb prion protein trafficking), for the following purposes:

1. Translocation of prion protein: individual amino acids will be altered to one with an expected functionally neutral character primarily within the signal sequence (amino acids 1-22), or the surrogate transmembrane sequence (aa's 100-136) or the GPI anchor (aa 231 ff). These alterations will be incorporated into cell lines to allow cell fractionation followed by immunoaffinity purification to determine the chaperone associations of the proteins (Graham, C H Anderton, B A & Morris, R J (2001) submitted for publication) as they traffic between the biosynthetic compartments of the cells. Studies may also be done where these constructs are introduced into primary cultured neurons by microinjection or by chemically-assisted transfection (Ca 2+, Liptofectine etc), to allow comparison with real neurons. In addition, sense RNA may be transcribed using an RNA polymerase, capped and polyadenylated before being used in in vitro translation studies with microsomes (Kim et al (2001) J. Biol Chem 276: 26132-40).

2. Interaction of externally applied prion infectious agent with translocation of mutant prion protein at the endoplasmic reticulum. To determine whether and how exogenously applied prion infectious agent could alter the routing of prion protein as it is made on the ER, mouse scrapie-associated fibrils or whole homogenate of mouse scrapie-infected brains will be added to cells expressing normal or mutant forms of prion protein (from step 1), and the proportion of protein translocated in the transmembrane forms (and its subsequent fate) determined, with particular attention paid to any change in the chaperone proteins associated. It should be noted that here and in 4 below, long studied mouse strains of scrapie derived originally from sheep (ME7, Chandler) and not from bovine or human sources will be used.

3. Endocytic trafficking of mutant forms or prion protein. We have an existing CL2 approved project (GM295/01.2) for investigating the effect of mutations in the N-terminus (aa's 23-108) of prion protein upon the trafficking of prion protein from the cell surface to intracellular compartments; this application will extend this by using mutations within the C-terminal domain, primarily with the surrogate transmembrane domain and GPI anchor (as in 1 above).
4. Interaction of externally applied prion infectious agent with mutant prion protein. We have an existing CL2 approved project (GM295/01.3) for investigating the interaction of mouse scrapie agent with cells; this application will extend this by studying the interaction with cells bearing mutations in prion protein that affect the endocytic trafficking of this protein (as in 3 above).

**Evaluation of foreseeable effects**

It must be assumed that at least some of the mutations we produce will predispose the mouse prion protein to adopt an infectious or neurotoxic conformation. Regarding the infectious form, the amounts produced will be small, contained, and rigorously denatured by oxidants before disposal for incineration. Moreover, the point mutations involved will in no way break down the species barriers for transmission of the infection to either man or to cattle, so that any escape of the mutation should affect no more than any local mouse populations. Regarding the potential neurotoxicity of the transmembrane forms of prion protein, these are not protease resistant and will be broken down normally by our usual physiological barriers in the gut and skin (and by our containment and denaturation procedures). There is no reason to think there is any species barrier to the neurotoxicity, but equally the barriers to a foreign protein reaching a nerve in our body are formidable.

At the genetic level, in the regions that will be mutated the mouse sequence is either identical or very similar to the human sequence. CL3 level of containment, with accompanying SOPs (minimisation of aerosols, use of sharps etc) will ensure that escape of mutated sequences does not occur, but should, despite these precautions, cDNA encoding a mutant form of prion protein be injected into eg the finger of a researcher, and become translated into mutant protein, all the other prion protein in the body would remain human and non-mutated, so that any production of infectious prion should be restricted to the site of injection.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Given the work involves mutant prion protein, all work will be done under containment level 3 conditions with the additional safeguards appropriate for working with mouse scrapie itself. Of these the most important are those for waste disposal, outlined below.

Liquid waste will be disinfected in 20,000 ppm active chlorine (as sodium hypochlorite) overnight before being washed down the drains with copious water. Solid waste will be double bagged for autoclaving (135 1 degree C, 18 min) prior to incineration.

For treatment of liquid wastes 20,000 ppm active chlorine is considered to be a completely effective procedure for inactivation of TSE agent; for solid waste, incineration is completely effective, the autoclaving will substantially reduce the titre of any agent (should it be produced) adding an extra level of security during the transport to the incinerator.

Monitoring is only applicable to the autoclave step, where we use Brown tubes within a load, and have a printed readout of each cycle; the autoclave is serviced annually. The ultimate form of the prion protein will be fragmented and highly oxidised carbon derivatives with no biological activity.

**Is an emergency plan required according to regulation 20?**

N

If yes, tick to confirm that it is attached to this form

N
The Genetic Modifications Safety Committee of the MRC Centre for Developmental Neurobiology reviewed this application at its meeting of 13 December 2001. The Committee were satisfied that the steps taken to contain and dispose of the mutant mouse prion proteins and the constructs encoding it were sufficient and conformed fully to national guidelines and local needs. The staff involved have been fully consulted in drafting the Risk Assessment, and effective Standard Operating Procedures are in place. The Committee therefore accepted this application.

Tick if you are claiming exemption from disclosure for section of the risk assessment: N
**Project Additional Information**

**Purposes of the contained use**

The purpose of the contained use is to enable us to pursue studies of primate lentiviral replication (that is, HIV-1, -2, and SIV) and of murine leukemia virus (MLV) without exposure of personnel or of the external environment to these pathogens. In addition, contained use will enable proper decontamination of the laboratory space and large equipment used for these studies.

HIV is the causative agent of Acquired Immunodeficiency Syndrome (AIDS). HIV-2 and SIV are related viruses that cause less severe disease in human beings. MLV is a retrovirus with a tropism for a variety of mammalian cells.

**Recipient or parental organism**

A variety of immortalized cell lines will be utilized for these studies including:

- Human T lymphoid (Jurkat, CEM, SupT1, C8166, HUT78, H9)
- Human fibroblast (HeLa, 293T)
- African green monkey fibroblast (COS)
- Murine fibroblast (3T3, L)
- Murine Lymphoid (EL4, Timi)
- Quail fibroblast (QT6)

**Host/vector system**

HIV-1, -2, SIV or MLV viruses will be passaged in the immortalised cell lines mentioned above.

**Origin & function**

All immortalised cell lines and wildtype viral isolates are obtainable from the AIDS repository at the US National Institute of Health.

The genetic material involved is intended to aid in the investigation of viral protein function and the molecular mechanisms of viral assembly and infection. Generally, by removing regions of the viral genome, we can examine in what ways the virus life cycle is altered and thereby determine the role of the deleted region.

**Evaluation of foreseeable effects**

In comparison to wild type virus, all modified HIVs will have reduced pathogenicity as a consequence of disruption of essential viral sequences. Importantly, all such viruses will be maintained and used under category 3 conditions. All necessary precautions are being undertaken to prevent infection of workers or release from the containment 3 laboratory. Special attention has been paid to minimization of aerosols and sharps. In the unlikely event of exposure of a worker to the virus, prophylactics and emergency procedures are on hand.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Given the work involves primate lentiviruses, all work will be done under containment level 3 conditions. Of these the most important are those for waste disposal, outlined below.

Liquid waste will be disinfected in 10% active chlorine (as sodium hypochlorite) overnight before being washed down the drains with copious water. Solid waste will be double bagged for autoclaving (135 1 degree C, 18 min) prior to incineration.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid wastes: Double bag and autoclave at high vacuum, 135 1 degree C for a minimum of 18 minutes. After autoclaving, waste is bagged in designated yellow bags, offloaded from the site as clinical waste and, ultimately, incinerated.

Liquid waste: Inactivate with 10% active chlorine in the form of sodium hypochlorite overnight, wash down drains with copious amounts of water.

For treatment of liquid wastes 10% active chlorine is considered to be a completely effective procedure for inactivation of retroviruses. For solid waste, autoclaving is completely effective.

Monitoring is only applicable to the autoclave step, where we use Brown tubes within a load, and have a printed readout of each cycle; the autoclave is serviced biannually.

Project Ref  295/02.3

Date Ackn'd  CU2 Project Title  Class  CultureVolClass2  CultureVolumeClass3-4

02/03/2022  1532602/03/2022
The purpose of this activity is to study the intracellular signalling mechanisms that mediate the response of cells to growth factors and extracellular matrix molecules, including proliferation and migration, and thus play a role in the development of human cancers and in cellular differentiation.

**Recipient or parental organism**

(i) E. coli
(ii) murine cells (NIH3T3, and the NIH3T3 variants 293T, GP+E86, GP+EnvAm12)
(iii) human primary keratinocytes and carcinoma cell lines
(iv) monkey cells (COS-7)

**Host/vector system**

(i) Host: E.coli DH5a; Vector: pCEV27, pBABEneo/puro plasmid, pMSCVneo, pMSCVhygro, pLib, pRx-bsr, pRcCMV, pC1, pGET-T, pPCR-Script
(ii) Host: GP+E86 murine fibroblasts; Vector: pBABEneo/puro, pMSCVneo, pMSCVhygro, pLib, pRx-bsr plasmid
(iii) Host: GP+EnvAm12 murine fibroblasts; Vector: pBABEneo/puro, pMSCVneo, pMSCVhygro, pLib, pRx-bsr plasmid
(iv) Host: Murine and human mesenchymal cells (osteoblasts, chondrocytes, fibroblasts, and adipocytes) either as established cell lines or primary cultures, as well as osteoclasts, osteoclast precursors, haematopoetic stem cells, and embryonic stem cells. Vector: pBABEneo/puro plasmid, pMSCVneo, pMSCVhygro, pLib, pRx-bsr virus
(v) Host: NIH3T3 murine fibroblasts; Vector: pBABEneo/puro virus
(vi) Host: HNEK, H357, A431, HN12, HN4 & MCF7 human keratinocytes; Vector: pBABEneo/puro virus
(vii) Host: 293T cells; Vector: PINCO (modified from plasmid LZRSpBMN-Z).

**Origin & function**

Mouse and human cDNAs encoding signalling intermediates, cell cycle control genes, and AP-1 transcription factors, as well as novel cloned target genes, will be obtained by PCR, or excised from existing plasmid vectors, subcloned into viral plasmids, and used to produce amphotropic/ecotropic viruses as a means of expressing them in the target cells (see above).

The intended function is to investigate growth factor and extracellular matrix-dependent signalling pathways that regulate cellular differentiation, proliferation and motility, all
of which are key aspects of cancer development.

**Evaluation of foreseeable effects**

The vectors to be used in these studies are replication-defective recombinant retroviruses, and have been well characterised and extensively used (Morgenstern & Land, Nucl Acids Res 18: 3587, 1990; Gasperi et al., Journal of Leukocyte Biology 66: 263-267, 1999). They are non-mobilisable in mammalian cells, and are rapidly inactivated by serum. The cell lines (GP+E86 and GP+envAm12 are third generation packaging cell lines, and have been specifically constructed to prevent recombination events between introduced constructs and endogenous viral structural sequences. Investigators using this system have not observed production of any replication-competent virus (RCV) (Markowitz et al., Virology 167: 400, 1988). The recipient cell lines are free of helper virus, and transduction of these lines with replication-defective viruses will not generate RCV. In spite of these findings, assays to detect RCV will be carried out as a matter of course. Thus, although the vectors will be packaged with ecotropic and amphotropic envelopes, and could conceivably infect rodent (ecotropic) and human cells (amphotropic), such viruses would be incapable of replication. Furthermore, these viruses are unstable at ambient temperatures, with a half-life of around 2 hours. Some of the gene products encoded by cDNAs cloned into these vectors have oncogenic potential. Therefore, the assessment is that work with both ecotropic and amphotropic viruses will be carried out at level 2. The containment level and procedures proposed for the study, together with the inherent safety of the packaging systems, will make the environmental risk effectively zero.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Liquid waste from bacterial and vertebrate cell cultures will be aspirated and treated with bleach (Haztabs; 1 tablet per litre = 2,500 ppm chlorine) for 12 hours. The bleach will be made freshly on the day of use according to manufacturers instructions. This will result in at least 99.999% kill of bacteria and 100% kill of viral GMMs and cell lines which are extremely liable. In addition, the retroviruses and cell lines have a very short half life at room temperature. Inactivated culture supernatants will be discharged to the drainage system. Solid waste will be double bagged, sealed, and placed within and autoclaved in a closed metal container. This will prevent any accidental release of GMMs into the working environment. The waste will be autoclaved at 136 degrees C for 30 minutes. This will result in complete inactivation of GMMs. Autoclave function will be monitored by annual services, the use of autoclave indicator tape (which measures a temperature of 134 degrees C for 3 minutes) during every run. Autoclaved waste will then be incinerated by White Rose.

The GMSC accepted the risk assessments for these projects.

Class of Activity 2.

**Project Containment**
Purposes of the contained use

Mycobacterium tuberculosis (MTb) is a class 3 human pathogen and requires level 3 containment facilities for use. The recombinant MTb expressing luciferase gene would be used to significantly decrease the experimental times for bacterial determination in infected cultures and BCG expressing either luciferase or green fluorescent protein (GFP) would allow additional flexibility in substituting pathogenic MTb in certain types of assays. Luciferase and GFP are biologically harmless genes but as the recipient strain is pathogenic the containment level 3 would be required for the use of recombinant strains as for the wild type MTb. The same applies to Mycobacterium bovis (MB) expressing luciferase gene which would be used to uncover differences in pathogenesis between these two closely related species.

Recipient or parental organism

The recipient organism is bacterium Mycobacterium tuberculosis (MTb) or the attenuated strain of Mycobacterium bovis (MB) known as BCG (Bacillary of Calmette and Guerin). MTb and MB are class 3 organisms and BCG is Class 2.
Host/vector system

pSMT1 and pSMT3, both non-mobilisable vectors.

Origin & function

Luciferase gene is of bacterial origin and its function in the intended recombinant strains of Mycobacteria is to serve as reporter gene for quantitative determination of bacteria. The green fluorescent protein (GFP) is derived from jellyfish and is a fluorescent marker for tracking down the recombinant bacteria during infection of cells.

Evaluation of foreseeable effects

The recombinant Mycobacterium tuberculosis and Mycobacterium bovis expressing luciferase and BCG expressing luciferase or GFP are generated several years ago in the laboratory of Douglas Young at Imperial College London (Lab GM77). They have been used since then worldwide and several publications have quoted the use of these strains. Both genes are reporter constructs. Luciferase is an enzyme that converts certain type substrates into chemiluminescent products and GFP is a fluorescent protein that can be easily identified by fluorimetric techniques such as flow cytometry (FACS). These two genes have been used in numerous experimental systems with no biologically harmful effects ever being reported. The use of these two genes would normally require level 1 containment measures but as the recipient strains are class 3 (MTb and Mb) or class 2 (BCG) organisms, it is necessary to apply the class 3 or respectively, class 2 containment measures. There is no indication from the originator or from the others who have used these strains that they are in any way different in terms of virulence from the corresponding wild type strains. Therefore, the environmental or personal risk from using these strains is no different from that of wild type strain.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Re: APPLICATION FOR DEROGATION FOR AUTOCLAVE FACILITY FOR CONTAINMENT LEVEL 3 LABORATORY

During a recent inspection by HSE, it was pointed out to us that there had been a change in the regulations defining what constitutes a laboratory suite, and as a result our containment level 3 facility (room 311, floor 28 Guy's Tower) contravened the new interpretation under the Genetically Modified Organism (Contained Use) Regulations 2000 (CU2000). I therefore am applying for derogation from Schedule 8 of CU2000.

The relevant features, following the guidance attached to Newsletter 30 are:

a) Both the autoclave and the containment facility are located at the far end of the building remote from the main access to the floor. They are joined by a short corridor that is not used by students, non-scientific staff or members of the general public. There are no offices at this end of the building, only laboratories.

b) The infection with Mycobacterium tuberculosis and mycobacterium bovis occurs through respiratory route. The infectious dose has not been firmly established but it is thought that the size of aerosol-born droplets containing bacteria is critically important (ie several droplets containing 3-5 bacteria each, if inhaled by an immuno-susceptible person may establish an infection). Only 5% of infected individuals develop the disease.

c) The highest concentration of bacteria is present in the waste is 10^7/ml which is the remaining stock solution from the experiment (the stock solution is 1 ml, thus the amount of this waste is always less than 1 ml). The unused stock solution is cultured with hycolin for several hours prior to disposal. Typical concentration of bacteria in the experimental liquid waste is 10^5/ml or less.

d) The waste is in loosely tied autoclave bags contained in metal autoclave bins.

e) Following the inspection we have purchased autoclave tins with clip-on lids to replace the identical ones without clip-on lids.
f) as in (e) above.

g) The container will be placed on a trolley following an agreed procedure that has been in place for the last 2 years.

h) the removal of waste from the Containment Laboratory does not take place unless it is clear that the autoclave is available for use. After this waste has been loaded into the autoclave low level waste may also be added, but only by the staff loading the level 3 waste.

i) As in (h) above.

j) The container is placed directly in the autoclave and the tray that sits on the trolley is then also placed in the autoclave.

k) The only personnel that move the waste are trained for work at containment level 3.

l) The SOP (revised to include the use of clip-on lids) for use of the Containment facility is attached. This contains an emergency procedure to be followed in the event of a spillage during waste transport.

DECONTAMINATION

1. All glassware and plastics must be autoclaved on a cycle to reach 126 degrees C before removal from the laboratory suite. Autoclave bins with properly fitting clip on lids containing the waste in loosely tied autoclave bags must be taken from the CL3 laboratory to the autoclave immediately prior to autoclaving. The following procedures will be follows:

i) at least two trained staff must be available to carry out these procedures

ii) the autoclave is room 3245 must be available for use

iii) one member of staff will act to open doors; one will move the autoclave tins from the CL3 facility onto the transport trolley

iv) the autoclave tins will be removed from the CL3 facility and placed on a tray on a trolley outside the CL3 laboratory

v) autoclave bins from the CL3 laboratory will be taken directly to the autoclave and placed in the autoclave

vi) when all autoclave bins have been loaded into the autoclave, the tray will also be placed in the autoclave and the autoclave cycle will be started.

2. If a spillage of CL3 infectious material occurs during transport of waste, the area will be disinfected by treatment with Presept, and/or by swabbing with disinfectant.

i) Any contaminated clothing must be removed and any affected skin should be washed with soap and water. In the event of cuts, the First Aid Officer should be contacted.

ii) Notification of the Biological Safety Officer and the relevant Line Manager must then take place. They will decide if any further action is required.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The waste consisting of disposable plastics and liquid waste in volumes of 100 ml or less in plastic containers will be placed in plastic bags, sealed and transferred to metal tins with clip-on lids. The standard internal operating procedure for removal and autoclaving of waste will then be applied (for details please see above application for derogation of autoclave facility for CL3 room).

The autoclave will operate the cycle at 126 degrees C for 80 min at 2.5 bar. The waste will then be placed in bags and disposed to designated bins.

This procedure is effective for complete killing of Mycobacterium tuberculosis wild type as determined by re-plating of the autoclaved material on microbiological plates. Similar test will be conducted for GM strains of MTb and MB (ie following completion of the cycle the metal been containing the waste will be returned to CL3 room in a reverse of the removal of waste procedure and the waste placed in Microbiological Safety Cabinet. An aliquot of the liquid waste and a swab from the solid waste will be
tested for the presence of live bacteria by microbiological methods. Only following the negative result of the test will the remaining waste be removed from the room in a repeat of standard procedure and autoclaved prior disposal. This test-procedure will be repeated each time when the nature or the quantity of the waste significantly differs from the routine waste.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The proposal was looked at by two members of Safety Committee who were satisfied with risk assessments and proposed risk categorization.

The class of activity is 2/3 as detailed in the KCL GM RA.

Project Additional Information

**Purposes of the contained use**

The key objective is to bridge the gap between Imaging, Cancer Cell Biology and Medicine, particularly in the field of translational cancer research. The aims are summarised as follows:

1. Development of cancer cell imaging facilities which can measure biochemical changes in cancer patient-derived tumour samples, including fresh primary tumour cells.
2. Investigation of the function of specific gene products or proteins in a range of mammalian cell lines and primary cells, by gene expression or knockdown.
3. The cells for these gene expression or knockdown studies will include primary tumour cells, primary human T cells, human T-cell leukaemia cells, monocytes and endothelial cells, and primary cells derived from mouse tissues. For these studies, we use plasmid-based expression vectors, retroviruses, adenoviruses and lentiviruses.

Human T -cell line — .Turkati-luman embryonic kidney ccl line —2931, 293A, 293GPG
Mouse Fibroblast cell line — P167
Rat Breast Carcinoma cell line — MTLn3, MTLn3e
Human hepatocyte cell line — HepG2
Human B-cell line—721211, Raji
Human NK cell line — Y1, NK92, NKL
Human Myelogenous Leukaemia cell line — K562
Primary human tumour cells, primary human 1 cells and endothelial cells, and primary cells derived from mouse tissues.
Human, mouse, rat cDNA are obtained from existing eDNA libraries. Lentiviral vectors encoding shRNAs targeting human proteins, obtained from Sigma (Mission library)

The intended function is to investigate the regulation of cancer cell and leukocyte motility

Evaluation of foreseeable effects

Lentivirus:
The pLentilox lentiviral vector system is a so-called 3 generation lentiviral vector that has been extensively modified to prevent viral replication outside the packaging cells:
- pLentilox has a self-inactivating 3'tLTR (TATA box deletion) and large deletions result in absence of env, tat, rev, vpr, vpu, v(f and nef. Therefore, there are no viral gene products expressed from pLentilox.
- the gag, pot, and coy genes are supplied in trans from separate plasmids only in the packaging cell line.

References for packaging vectors:

References for self-inactivating LTR:

Adenovirus:
- The pCR220 (adenovirus serotype 5 backbone) is a plasmid containing most of the human adenovirus serotype 5 (AdS) genome, with deletions in the genes El and E3. This vector has been developed to infect but not replicate in non-permissive target cells. The El gene is provided in the packaging cell line (HEK293 cell line) in trans.

Exposure and risk to health of the researchers is reduced to negligible levels by performing the class 2 work in a class 2 microbiological safety cabinet in a dedicated area of a containment 2 laboratory. All personnel are fully trained to reduce the risk of accidental spill of virus to a minimum. For all these cell/retroviral studies, infected cells will be contained within dedicated incubators. All GM manipulated material will be destroyed on site.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste from bacterial and vertebrate cell cultures will be aspirated and treated with bleach (Haztabs; 1 tablet per litre 2,500 ppm chlorine) for 12 hours. The bleach will be made freshly on the day of use according to the manufacturers instructions. This will result in at least 99.999% kill of bacteria and 100% kill of viral GMMs and cell lines. In addition the cell lines and retroviruses have a very short half life at room temperature. Inactivated culture supernatants will be discharged to the drainage system.

Solid waste will be double bagged, sealed and autoclaved. This will prevent any accidental release of GMMs into the working environment. The waste will be autoclaved at 136 ºC for 30 minutes. This will result in complete inactivation of GMMs. Autoclave function will be monitored by annual services and the use of autoclave tape (which measures a temperature of 134 ºC for 3 minutes) in every autoclave run. Autoclaved waste will then be incinerated by White Rose.

Is an emergency plan required according to regulation 20?

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment
Please find attached the GM Proposal and Risk Assessment for - project entitled “Cancer cell and leukocyte motility and imaging”. I am satisfied that they have made the amendment requested b) the at its meeting on September 4th, and would be grateful if you could sign as appropriate. Below is the relevant section from the minutes of that meeting.

Randall Institute

introduced the project. had previous received approval at Level 1 for the project, but wished to incorporate work with primary cells using attenuated viral vectors (lenti and adeno), which is categorised as Class 2. This was now a joint submission with

2A, (ii) 4: Answer should be “No”, and subsequent explanation of “Yes” response should be removed.

Approved at CL2 subject to implementation of above amendment, completion of CU2 form, payment to HSE and provision of completed signatures page.

Letter from

School Safety Manager and representing the committee:

College Safety Officer.

Project Ref 295/10.1

Investigation of signalling pathways in human myometrial smooth muscle cells and epithelial cells of the reproductive tract

04/03/2014

Consent Granted

Project notified under transitional arrangements N
The overarching goal of this study is to gain greater functional insight into the physiological and pathophysiological regulation of the female reproductive tract during pregnancy. Our work focuses on:

i) The control of uterine smooth muscle growth and excitability and ii) the response of reproductive tract to infection and inflammation.

i) Ion channels and related proteins play a major role in regulating uterine excitability and rhythmic contraction.

We are interested in the contribution of potassium channels (alpha and beta subunits) which are hypothesised to promote uterine quiescence in early-mid pregnancy (Aaronson et al., 2006; McCallum et al., 2009; Ohya et al., 2009) and calcium channels (e.g. TrpCs; Dalrymple et al., 2004; 2007) and related proteins (e.g. Stim and Orai, caveolin and flotilin) which can control cell growth, excitability and responses to agonists.

ii) Toll-like receptors and related signaling pathway (e.g. MAPkinases, cytokines etc) on reproductive tract (e.g. cervical and vaginal cells and human myometrium) responses to infection.

In order to investigate their functional roles in regulation of parturition/contraction we intend to introduce a range of molecular tools which include:

1) Over expression and assessment of gene promoter regulation in well known model cell systems (eg HEKs) which may help to assess the role and significance of genes taking part in human pregnancy and parturition

2) Stable shRNA delivery (using commercially available plasmids and viral vector systems) which is a highly effective strategy for permanently disrupting the function of individual genes in order to study their role in signaling pathways in myometrial cells (primary cultures and hTERT HM cell line) and epithelial cells of the reproductive tract (VK2/E6E7cell line)

Recipient or parental organism

- Primary cultured and passage 1-6 pregnant human myometrial smooth muscle cells (HMSM)
- Human myometrial cells immortalised with retroviral hTERT vector (HTER-HM)
- Vaginal epithelial cell line (ATCC CRL-2616 ) (VK2/E6/E7)

Host/vector system

Host cells:
- Lenti-X 293T cells
- HEK 293
- E. Coli DH5alpha

The viral vectors which will be used in the study are listed below however we might use other vectors with similar properties without changing the containment level:
Lenti-X pLVX-shRNA1, SMARTvector® 2.0 Lentiviral shRNA Particles, GIPZ Lentiviral shRNAmir

All lentiviral constructs contain all the viral processing elements necessary for the production of replication-incompetent lentivirus and elements responsible for improved viral titer and overall vector function.

Genes encoding the structural and other components required for packaging the viral genome are separated onto mix of plasmids minimizing the threat of recombinant replication competent virus production. Lack of homology between the packaging mix of plasmids and Lenti-vectors also prevents transfer via homologous recombination. After transduction viruses cannot replicate autonomously in target cells (SIN vectors).

Non-mobilisable (Bom-, Mob-, Tra-) plasmid vectors which may be used in the study:

- **pIRES2-EGFP**: Expression vector which contains bacterial and mammalian promoter and internal ribosome entry site (IRES) that allows the co-expression of a marker gene and another gene from a single transcript.
- **pKD**: siRNA expression plasmid H1 promoter, Fl ori., PuC ori., Amp)
- **pGL3**: Basic plasmid which lacks a resident promoter. Encodes firefly luciferase which expression depends on insertion of the promoter sequence. SV40 promoter, Amp, ori, Luc+).

### Origin & function

**Stim (1-2):** Stim proteins have emerged as potential candidates underlying store-operated channels (SOCs). STIM1 is a calcium sensor integrated within endoplasmic reticulum. It has been shown to relocate to the plasma membrane on store depletion and activate store-operated calcium entry (SOCE). STIM2 may be a negative regulator of STIM1-induced SOCE and is thought to be involved in the regulation of basal/cytosolic and endoplasmic reticulum Ca2+.

**Orai**: Orai proteins are thought to form the plasma membrane channel regulated by STIM. There is compelling evidence that Orai1 encodes the Ca2+ selective SOC channel/ICRAC current in a range of non excitable cells, but as SOC currents display distinctly different characteristics in excitable cells, it has yet to be fully established whether Orai1 channels or STIM can also mediate this more non-selective cation current alone.

**KCNQs**: KCNQ (Kv7) genes encode a family of K+ channel α-subunits most extensively investigated in cardiomyocytes and the CNS where they contribute to action potential repolarisation and subthreshold excitability respectively. More recently a role for Kv7 channels in smooth muscle has emerged, with functional roles being seen in the vasculature, the GI tract and the uterus.

**KCNE(1-5)**: KCNE subunits modulate KCNQs and other voltage-gated channels in vitro and in vivo

**Caveolin(1-2)**: Caveolins serve a structural role, inducing and maintaining caveolae invaginations and can act as a scaffold proteins to sequester and modulate the activity of many signalling effector and receptor proteins.

**Flotillin(1-2)**: Flotillins are integral membrane proteins and constituents of lipid rafts. Flotillin-1 and -2 were originally discovered in neuronal cells as Reggie-2 and -1, respectively, and they are thought to be involved in signalling transduction and modulation.

**Toll–like receptors (2,4)**: Toll-like receptors (TLRs) are pattern recognition receptors and serve as the first line of defense in host immunity. Current data suggests that TLR2 and TLR4 may play a protective and/or regulatory role in an effort to limit a lethal inflammatory response.

**TrpC**: Transient receptor ‘canonical’ channel proteins are proposed to form store-operated (SOCE) and receptor operated (ROCE) calcium channel entry in a variety of tissues. We have shown that several TrpC proteins are gestationally regulated in myometrial tissue and that pregnancy associated stimuli (stretch, cytokines) induce differential expression off TrpC proteins in human myometrial smooth muscle cells.
None of the above-mentioned genes and their products are potentially hazardous, infectious, or oncogenic. Their overexpression will not have any influence on the environment.

**Evaluation of foreseeable effects**

The ability of retroviruses to integrate into the host cell chromosome raises the possibility of insertional mutagenesis and oncogene activation. Both these phenomena are well known in the interactions of certain types of wild-type retroviruses with their hosts.

In order to improve the risk-benefit ratio associated with retroviral-mediated techniques several approaches are currently developed, like the design of self-inactivating (SIN) vectors containing an internal promoter to drive transgene expression instead of the long terminal repeat-containing enhancer of standard retroviral and lentiviral vectors, reduced homology between retroviral vector and packaging components and split-genome conditional packaging systems. Probability of survival of host cells or viruses in environment is very unlikely and disable genomes of these vectors prevent events of replication and creating new strains of wild type viruses.

Contact with viral particles and infection of cells at the contact site could resist in transient immune response with local swelling and inflammation. This is unlikely to be more than a minor effect. Moreover 3rd and 4th generation lentiviral construct cannot replicate after infection so no virus could be passed on to other people.

Low to none if experimental work is done with all safety procedures maintained:

1. Personal protective clothing (gloves, lab coats)
2. MSC class 2, mechanical pipetting devices, safety centrifuge caps and rotors, autoclave, sharp containers, clinical waste yellow bags
3. All laboratories have lockable doors and sinks for hand washing and can be easily cleaned and decontaminated

Each researcher completes an individual risk assessment for their work and are aware of potential hazards.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Waste contaminated with GMOs will be inactivated so as to ensure that any contact between the GMOs and humans or the environment is limited to an extent commensurate with the risks identified in the risk assessment and to provide a high level of protection for humans and the environment.

**Is an emergency plan required according to regulation 20?**

N

**If yes, tick to confirm that it is attached to this form**

N

**Tick to confirm that you have attached a risk assessment to this form**

Y

**Tick if you are claiming exemption from disclosure for section of the risk assessment**

N
The project was discussed at the Joint GMSC of the Schools of Biomedical and Health Sciences and Dental Institute. The following comment was made: Approved at Class 2 subject to implementation of minor amendments and provision of completed signatures page to GMSC Secretary.

(Please note this department was formerly under the management of the School of Medicine, GM386, but is still under the overall management of King’s College London.)

**Purposes of the contained use**

(i) Propogation of small stocks and recombinant Vaccinia Virus (rVV) and recombinant Adeno Virus (rAd) .

(ii) Infection of simian and murine antigen presenting cells in vitro with rVV and rAd which will be used to restimulate in vivo primed cytotoxic T lymphocytes.
Recipient or parental organism

(i) Thymidine Kinase deficient vector WR strain vaccinia virus.
(ii) Adenovirus -5. (1.88kb E3 deletion).
Vaccinia virus deleted in the thymidine kinase (TK) gene from Strain WR Adenovirus 5 (1.88kb deletion in early region 3 (E3)).

Host/vector system

The hosts used in propagating recombinant vaccinia virus (or recombinant Adenovirus) are mammalian cell lines which cannot survive in the environment and this can be considered safe. The vector (WR strain of vaccinia virus) is Thymidine Kinase negative and thus attenuated in replication of virulence. Adenovirus 5 is replication competent in mammalian cells, but cannot survive outside the host used in its propagation.

Origin & function

rrVV SIVgag, rVV EBVgpH wild-type Vaccinia (WR strain) small scale propagation, infection of cell lines in vitro for immunological assays.
rrVV SIVgag-pol, rVV SIVgag, rVV SIVenv, rVV SIVnef*, rVV SIVrev, small scale propagation, infection of cell lines in vitro for immunological assays.
rAD-5-Luciferase, rAD-5-B-galactosidase, small scale propagation, infection of cell lines in vitro for immunological assays.
rVV SIVgag, rVV SIVenv, rVV SIVnef*, in vivo immunisation of rhesus macaques via the mucosal, Intra-dermal and Intra-muscular routes.

Evaluation of foreseeable effects

Although recombinant vaccinia and recombinant Adeno-5 viruses can persist in a non-replicating form (outside their host) for an unknown length of time, at Containment Level 2 where the material is handled in a Class 2 exhaust ducted Hepa filtered safety cabinet (MAT design), the risk of release to the environment is effectively zero. The products of genes expressed by the vectors used are not known to be toxic, oncogenic or mediate pharmacologic effects.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid and solid waste inactivated overnight in 10% chloros (14,000 ppm available chlorine). Hypochlorite level checked with starch iodine strips. Solid waste subsequently drained from chloros, autoclaved 121°C x 20 mins (in leakproof containers).
Solid animal waste collected for incineration.
Inactivated liquid waste to mains drainage. Inactivated solid waste for incineration

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
The committee have reviewed and approved this risk assessment and the facilities where this work will be conducted. The committee is satisfied that the personnel involved with work at Containment Level 2 have received the appropriate training.

02/03/2022
M-CSF is overproduced by a range of human tumours and contributes to the malignant phenotype by enhancing growth, invasive potential and contributing to an immunosuppressive environment in the vicinity of tumour deposits. In this study, it is proposed to engineer T cells to express the receptor for M-CSF. The underlying hypothesis is that such genetically modified T cells will acquire a growth/functional advantage in proximity to tumour deposits which produce M-CSF. In support of this, we have previously shown that the human M-CSFR is functionally active when expressed in immortalised CD4+ and CD8+ T cell lines. Addition of M-CSF to these cells co-stimulates IL-2 driven growth and activation of these cell lines (HSE centre No. for that project GMR 76-2).

Two questions are posed in the present study. First we wish to evaluate the functional activity of the human M-CSFR when ectopically expressed in primary human T cells. To achieve this, retrovirus-mediated gene transfer will be used to express this molecule in T cells derived from normal healthy donors. In vitro assays will be used to assess the ability of M-CSF to co-stimulate activation, growth and cytotoxic activity of these transduced T cell cultures.

The second phase of the project is designed to address the question of whether M-CSFR+ T cells would prove useful in targeting an in vivo established tumour. To test this, an animal model will be established using the ovalbumin-expressing tumour cell line, E.G7 which will be inoculated by intraperitoneal (IP) injection into syngeneic immunocompetent mice (C57/BL6). Tumour-bearing animals will be treated by IP injection with T cells derived from the OT1 transgenic mouse (which expresses a
transgenic T cell receptor specific for an epitope in Ovalbumin). This treatment is known to cause partial control but not eradication if IP-inoculated E.G7 tumour. Here OT1 T cells will be engineered to express the human M-CSFR (or mock transduced as control) and tumour cells will be transduced with retroviruses encoding for the secreted and membrane-associated isoforms of M-CSF. Using this approach it is hoped to determine whether the co-stimulatory activity of M-MCSF in T cells can be harnessed to improve tumour control in this model.

Recipient or parental organism

Recipient organisms are as listed below (hosts). No additional recipient organisms (eg animals, plants) will be used. Parental organisms are as follows: (i) Prokaryotic - DH5a are ultimately derived from E. coli. (ii) Viral - The replication-defective retroviral vectors for use in this study are all ultimately derived from the Moloney murine leukaemia virus. (iii) Eukaryotic - all fibroblasts cell lines including retrovirus packaging cell lines are ultimately derived from NIH3T3 cells.

Host/vector system

a. VECTORS - All viral vectors to be used have been mutated (by extensive deletion) to make them replication incompetent i.e. they do not produce infective virus though they do generate defective virus-like particles. The viral vectors (detailed below) do not have any inherent pathogenicity and are fully sensitive to human complement.

a. Host range and species specificity: vectors will be packaged by ecotropic (GP+env86) packaging cell lines, which have the capacity to infect murine cells. For retrovirus-infection of primary human T cells, vectors will also be packaged using PG13 (which imparts a Gibbon Ape leukaemia virus pseudotype).

b. Tissue specificity: No attempt will be made to generate tissue specific vectors.

c. Promoters and regulatory elements: Three expression vectors will be used for the purpose of the study (see attached figures for maps): (i) pBabe hygro (Morgenstern & Land (1990) Nucleic Acids Res. 18, 3587); (ii) pBabe puro (Morgenstern & Land (1990) Nucleic Acids Res. 18, 3587); (iii) MFG (Riviere et al (1995) PNAS 92, 6733-7. Promoter usage is as follows:

<table>
<thead>
<tr>
<th>Expression of insert DNA</th>
<th>Expression of selectable marker</th>
</tr>
</thead>
<tbody>
<tr>
<td>pBhygro</td>
<td>retroviral long terminal repeat (LTR)</td>
</tr>
<tr>
<td>pBpuro</td>
<td>retroviral LTR</td>
</tr>
<tr>
<td>MFG</td>
<td>retroviral LTR</td>
</tr>
</tbody>
</table>

b. Hosts

Eukaryotes

Retroviral packaging cell lines GP+env86, PG13
Primary human T cells (activated with the mitogenic lectin, PHA)
CD8+ T cells derived from the OT1 transgenic mouse (activated with the mitogenic lectin, Con A).
E.G7 (an OVA-transfected variant of the EL4 immortalised murine thymoma cell line)

Prokaryotes

All hosts are derived from the DH5a strain of E.coli.

Origin & function

The inserts to be expressed using the vectors described above are as follows:

A. Using MFG, an insert will be expressed which comprises three elements;
   1. cDNA encoding for the human M-CSFR. This was originally provided by Dr N Dibb (Dept of Obstetrics and Gynaecology, Imperial College, Hammersmith campus). The intention of this study is to generate T cells which are co-stimulated in an M-CSF-dependent manner. Preliminary studies using immortalised T cell lines indicate that the
M-CSFr is functionally active in T cells but only in the presence of ligand (M-CSF).

2. Internal ribosome entry site - derived from Encephalomyocarditis virus. The purpose of this element is to facilitate translation of the subsequent cDNA - purchased from Clontech.

B. Using the pBabe series of vectors, it is planned to express cDNAs encoding for the membrane-associated and secreted isoforms of human M-CSF, PUC-based plasmids containing these cDNAs have been supplied by Dr Kirsten Koths (Chiron). These plasmids will be expressed in the E.G7 tumour cell line in order to model the effects of an M-CSF-producing tumour in vivo. Once this has been achieved, it is planned to treat such mice with T cells engineered to express the human C-CSFr.

Evaluation of foreseeable effects

The principle potential hazard associated with the use of retroviral-mediated gene transfer is the possibility that recombination may occur between the expression vector and the complementary sequences found in the packaging cell line, leading to the generation of replication competent virus (RCR). Generation of RCR is rendered less likely by the use of the GP+env86, and PG13 packaging cell lines, in which at least 3 independent recombination events are required for PCR generation. In addition, the viral vectors for study are fully sensitive to human complement.

As detailed in the preceding section, it is highly unlikely that any of the recombinant retroviral constructs to be generated in this study will prove transforming. M-CSF exerts no effect in the absence of the M-CSFr and vice versa.

It is envisaged that there will be a negligible risk to human health or the environment associated with the use of the prokaryotic or eukaryotic hosts specified since these are unable to colonise human hosts.

In addition, any theoretical risks posed by the above are further reduced by the containment and waste disposal measures to be employed. Bacterial work will take place at containment level 1 while all work with retroviral vectors and T cells will operate at level 2.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

1. OT1 mice, transgenic for an Ovalbumin-specific T cell receptor, will be used as donors for gene transfer and adoptive immunotherapy. It is proposed that these animals will be housed and manipulated under class 1 conditions.

2. In the present proposal, it is planned to establish retrovirus-transduced tumours in C57/BL6 mice. Furthermore, it is additionally planned to treat these established tumours with retrovirus-transduced OT1-derived T cells. A risk assessment for this protocol is detailed in Section 6 of the accompanying risk assessment form. Although this assessment indicates that the risk associated with establishment of this model is "effectively zero". it is planned to house all animals harbouring retrovirus-transduced cells under class II conditions. Furthermore, all manipulations of such animals (eg IP injections) will be performed under class II conditions.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All materials that have been in contact with genetically modified material will be sterilised. All solid waste will be autoclaved at 121 degrees C for 90 minutes before removal from the building in double bags for incineration, thereby ensuring 100% kill. To achieve 100% kill of liquid material, waste will be treated with 10,000ppm hypochlorite and incubated overnight (in agreement with manufacturers recommendations) before disposal down a sink. We have opted not to autoclave liquid waste in light of concerns about delays prior to autoclave availability for this purpose, coupled with undesirability of autoclaving bleach-treated waste. Periodic in-house testing will be performed to assess the % kill of prokaryotic and eukaryotic hosts by the overnight bleaching approach as described. All animals carcasses will be incinerated.

### Purposes of the contained use

Adenoviral vectors provide the most efficient vehicles available for gene delivery, but because they integrate very inefficiently, the expression of incorporated transgenes is only transient. The aim of this proposal is to develop a modified adenovirus vector able to integrate into the host cell genome.

The long-term aim of this study is to use disabled adenovirus vectors (generated from Ad5 virus with deletions in the E1 region alone or with deletions in both E1 and E3 regions), for delivery of genes, the product of which will be useful either as cell markers (e.g., β-galactosidase, Green Fluorescence Protein, etc.) or will confer, either directly or indirectly, anti-tumour activity. Genes with anti-tumour activity can be grouped into the following categories:

- Anti-oncogenes such as wild-type p53 and p16;
- Immune stimulatory cytokines such as IL-2, IL-4, IL-6, IL-12, GM-CSF;
- Immune co-stimulatory factors such as B7.1, B7.2, CD40 Ligand;
- Antibodies and single-chain variable fragment of antibodies (scFv) against oncogenes such as c-erbB2, bcr-abl, etc.
- Prodrug convertases conferring greater susceptibility to the cytotoxic activity of prodrugs (e.g., HSV-tk and Gancyclovir).

The ultimate aim of these studies is to use the vectors for genetic modification of human tumour cells with the eventual aim of application of the vectors and modified cells to clinical trials for gene therapy of cancer.

### Recipient or parental organism

**Bacteria** -
Attenuated and mobilisation defective E.coli (K-12) derivatives such as DH5α and XL1 Blue, unable to survive in the absence of specialised growth conditions.

**Adenoviral packaging cells** -
Recombinant adenovirus vectors and plasmids needed for generation of new disabled vectors will be obtained from collaborating groups in the UK and USA. The vector will be propagated in mammalian cell lines with stable integrations of adenovirus genome with specific deletions. The presence of these deletions both in the packaging cells and in the vector will reduce the chances of recombination mediated generation of replication competent vectors. The 293 cell used for Ad vector production contains only the left 11% of AD5 genome, therefore providing E1a and E1b gene products in trans. The vectors will have at least the E1 region deleted, however, replication competent virus can be generated by recombination.

Events resulting in generation of recombinants with the E1 region replaced. However, such recombinants will have lost the inserted gene of the vector as a consequence of the recombination event.

The more recently developed vectors and packaging cells contain additional deletions, further reducing the chance of generation of replication competent vectors. Where possible we shall use these newer vector systems developed either by ourselves or obtained from other workers in the field.

**Established human and mouse tissue culture cell lines.**
Spontaneously immortalized, unable to colonize human hosts, unable to survive outside specialised tissue culture environs.

### Host/vector system

**Cloning vectors** -
pUC series, pBluescript and TOPO based, in bacterial (K-12) hosts such as DH5α and XL1 Blue, unable to replicate in non-bacterial cells.

**Disabled adenoviral vector** -

pJM17 based deleted in E1a and E1b and therefore unable to replicate. The E1a and E1b function are provided in trans by the commonly used packaging cell 293 which contains 5000 bp of the left end of the Ad5 genome. Homologous recombination can result in the release of replication competent adenovirus. This is unlikely to have deleterious effects in immun-competent hosts because of previous exposure and the presence of antibody titres in most humans. Recently developed packaging cell lines such as PerC5 contain no homologous sequences between packaging construct and vector and should in theory prevent the formation of replication competent virus. These types of packaging cells will be used if they become freely available but due to company ownership they are out of reach of most research institutions.

Human and mouse tissue culture cell lines -
Unable to colonise humans, spontaneously immortalised, no evidence of the ability to secrete transmissible agents, unable to supply helper functions to disabled adenoviral vectors.

Origin & function

The genetic material originates from Ad5 and is intended as efficient vector for the introduction of marker genes such as neomycin, puromycin, GFP etc from bacterial and other origin and are used to follow the efficiency of transduction and expression of these genes in established tissue culture cell lines.

Evaluation of foreseeable effects

Waste -
All waste material is dealt with as described under section 12 - This covers the deliberate removal of material from the laboratory environment.

Accidental escape into the environment -
All air is filtered (Hepa) before venting to the environment, the labs are provided with spill kits and SOP's for dealing with accidental spillage. All manipulations with bacteria take place at containment level 1. Bacterial hosts are attenuated for growth in the absence of special growth media, and the ability to adhere to the gut lining. All manipulations with adenoviral packaging cells, adenoviral vectors and established human tissue culture cell lines take place at containment level 2. Cell lines are unable to survive outside the laboratory environment. White coats and gloves are mandatory.

In the event of escape of disabled adenoviral vectors they are unable to replicate in the absence of helper function, are sensitive to desiccation, and have a short half life. In the event of infection the vast majority of the population have been pre-exposed to Ad5 and have active antibody titres.

Accidental contamination of workers in the suite -
Bacterial hosts are attenuated for growth in the absence of special growth media, and the ability to adhere to the gut lining. Established cell lines (mouse and human) are unable to colonise human hosts.

Security -
The building has 24 hour security, and swipe card only access, visitors must report to the security and be escorted whilst in the building.

The capacity of the vector to integrate into the genome carries the risk of insertional mutagenesis. However, this risk would be comparable to that of retroviral vectors which do integrate by nature.

Risk assessment
Expressible DNA is deliberately inserted in frame downstream of a strong promoter. Expression Factor 1.
A biologically active substance which might have a deleterious effect if delivered to a target tissue. Damage Factor 10.3
The vector is non-mobilisable and especially disabled. Access Factor 10-12.
Overall risk factor is 10-15

However, in view of the easy "access" of adeno vectors, all handling will be strictly under Containment Level 2.
This is based on advice from HSE and takes into account the fact that work with the wild-type vector requires containment at level 2. However, attention is drawn to the fact that in the presence of genes with immune stimulatory products, particularly in the vectors with E3 deletion, there is increased risk of induction of acute inflammatory responses in case of accidental exposure. However, by the same token, the increased immune stimulatory nature of these vectors will reduce the risk of a chronic infection.
and chronic adverse effects. Therefore despite the replication incompetence of these vectors, and the safe record of use in human trials, they will be handled with strict adherence to containment level 2 requirements and avoidance of aerosol generation, to reduce the risks of accidental respiratory infections.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Solid waste -
All contaminated waste is autoclaved in the departmental autoclave that is used only for waste. The moist heat autoclave is used at 121 degrees C for 60 minutes. Temperature validation provided by means of thermocouple probe. The autoclave is serviced annually by Meadowrose Scientific and documentary evidence of correct function stored on site. Under these conditions complete kill of organisms is guaranteed. The resultant sterile waste is double bagged in yellow bags and taken away and incinerated by Medical School contractors (White Rose).

Liquid waste -
All liquid waste is inactivated with 10,000 ppm of Chlorine for greater than 10 hours after which it is disposed of down the designated sink. Under these circumstance complete kill of organisms is guaranteed.

AN INVESTIGATION INTO THE MECHANISMS GOVERNING THE EXPRESSION OF HUMAN CD28

**Purposes of the contained use**

To determine the consequences of the expression full length and splice variant cDNA constructs of human and mouse CD28 in established human and mouse tissue culture cell lines.

**Recipient or parental organism**

Bacteria - Attenuated and mobilisation defective E. coli (K-12) derivatives such as DH5 and XL1 Blue, unable to survive in the absence of specialised growth conditions.

Retroviral packaging cells -

GP+E-86, murine fibroblast derived, split helper function, Ecotrophic for mouse, human complement sensitive

PG13, murine fibroblast derived, split helper function, restricted amphotrophic, human complement sensitive

Unable to colonise human hosts, unable to survive in the absence of specialised tissue culture environs

Established human and mouse tissue culture cell lines - NK, T-cell and myeloid cells - Spontaneously immortalised, unable to colonise human hosts, unable to survive outside specialised tissue culture environs.

**Host/vector system**

Cloning vectors - Puc 13 and TOPO, in bacterial (K-12) hosts such as DH5 and XL1 Blue, unable to replicate in nonbacterial cells.

Disabled retroviral expression vector - pBabe. Puro. In the plasmid form - Able to replicate only in bacterial cells and transiently in SV40 transformed cells. In the disabled retroviral vector form unable to replicate in the absence of helper virus. Attenuated by the removal of the pol and env genes and partial deletion and repression of gag translation, compliment sensitive when secreted from mouse derived GP+E86 and PG 13 packaging cells, absence of gag, pol and env sequences reduces recombination.
likelihood with helper virus sequences.

Retroviral packaging cell lines - The human complement sensitive (restricted amphotrophic) PG13 and the Ecotropic GP-E86. Split helper function increase the number of recombination events required to generate replication competent retrovirus. The presence of replication competent retroviral vectors is determined on cells banks by testing the ability of infected target cells to secrete infectious virus. Bank samples are cultured for limited (10) passages before destruction.

Human and mouse tissue culture cell lines - Unable to colonise humans, spontaneously immortalised, no evidence of the ability to secrete transmissible agents, unable to supply helper functions to disabled retroviral vectors.

Origin & function

The genetic material originates as mRNA from human and mouse T-cells. The intended function of the genetic materials is that the full length transcript cDNA and the splice variants should be expressed in human and mouse tissue culture cell lines to allow the determination of the ability of such transcripts to be detected by antibodies directed against CD28. In addition the function of these protein products will be tested for the ability to bind the counter-receptor B7 and activated downstream T cell activation events.

Evaluation of foreseeable effects

Waste - all waste material is dealt with as described under Section 12 - This covers the deliberate removal of material from the laboratory environment.

Accidental escape into the environment - All air is filtered (Hepa) before venting to the environment, the labs are provided with spill kits and SOPs for dealing with accidental spillage. All manipulations with bacteria take place at containment level 1. Bacterial hosts are attenuated for growth in the absence of special growth media, and the ability to the gut lining. All manipulations with retroviral packaging cells, retroviral vectors and established human tissue culture cell lines take place at containment level 2. Cell lines are unable to survive outside the laboratory environment. Retroviral vectors are unable to survive in the presence of human complement. White coats and gloves are mandatory.

In the event of escape of disabled retroviral vectors they are unable to replicate in the absence of helper function, are sensitive to desiccation, and have a half life of only 5-8 hours under optimum laboratory conditions. In addition PG13derived vectors are unable to infect recipient permissive cells in the presence of normal complement. GP+E86 derived vector are unable to infect cells other than mouse. In the event of infection the protein product of the cDNA that would be integrated reflects that found in normal tissue and has not been designed for high expression.

Accidental contamination of workers in the suite - Bacterial hosts are attenuated for growth in the absence of special growth media, and the ability to adhere to the gut lining. Established cell lines (mouse and human) are unable to colonize human hosts. Disabled retroviral vectors are sensitive to human complement and in the case of GP+E86 derived vectors unable to infect humans. In addition the retrovirus is unable to replicate in the absence of halper functions and the protein product of the cDNA that would be integrated reflects that found in the normal human and has not been designed for high expression.

Security - The building has 24 hour security, and swipe card only access, visitors must report to the security and be escorted whilst in the building.

Project Additional Information

Purposes of the contained use

T-cells secrete a wide variety of cytokines that mediate their different effector functions. We propose to study one possible mechanism by which T-cells execute their effector function, by knocking out their ability to produce IFN-y. Our strategy to achieve that is by expressing an intracellular antibody (intrabody) inside the endoplasmic reticulum (ER). This intrabody will bind to IFN-y in the ER and hopefully prevent it from being secreted. These cells will be used in our different models and systems which will help us elucidate effector functions of T-cell derived IFN-g.

Recipient or parental organism

Recipient organisms are as listed below (hosts). No additional recipient organisms will be used.

Bacteria - attenuated and mobilisation defective E. coli (K-12) derivatives such as DH5 and XL1 Blue, unable to survive in the absence of specialised growth conditions.

Retroviral packaging cells -
GP+E-86, murine fibroblast derived, split helper function, Ecotrophic for mouse, human complement sensitive
PG13, murine fibroblast derived, split helper function, restricted amphotrophic, human complement sensitive.

Unable to colonise human hosts, unable to survive in the absence of specialised tissue culture environs.

Established human and mouse tissue culture cell lines - NK, T-cell and myeloid cells - Spontaneously immortalised, unable to colonise human hosts, unable to survive outside specialised tissue culture environs.

Host/vector system

Cloning vectors - pAK-100, pUC-18 derivatives, in bacterial (K-12) hosts such as DH5 and XL1 Blue, unable to replicate in nonbacterial cells.

Mammalian expression vectors - pCDNA-3 (Invitrogen) - Able to replicate only in bacterial cells and transiently in SV40 transformed cells.

Disabled retroviral expression vector - pBabe. Puro. In the plasmid form - Able to replicate only in bacterial cells and transiently in SV40 transformed cells. In the disabled retroviral vector form unable to replicate in the absence of helper virus. Attenuated by the removal of the pol and env genes and partial deletion and repression of gag translation, compliment sensitive when secreted from mouse derived GP+E86 and PG13 packaging cells, absence of gag, pol and env sequences reduces recombination likelihood with helper virus sequences.

Retroviral packaging cell lines - The human complement sensitive (restricted amphotrophic) PG13 and the Ecotrophic GP+E86. Split helper function increase the number of recombination events required to generate replication competent retrovirus. The presence of replication competent retroviral vectors is determined on cells banks by
testing the ability of infected target cells to secrete infectious virus. Bank samples are cultured for limited (10) passages before destruction.

Human and mouse tissue culture cell lines. Unable to colonise humans, spontaneously immortalised, no evidence of the ability to secrete transmissible agents, unable to supply helper functions to disabled retroviral vectors.

Origin & function

The genetic material originates as mRNA from mouse hybridoma cell line. The intended function of the genetic materials is that the partial transcript cDNA should be expressed in rat and mouse tissue culture cell lines and primary T-cells. These cells will be tested for their ability to produce IFN-y in the presence of the intrabody. In case down regulation of IFN-y production is observed these cells will be further tested in assays to determine T-cell function.

Evaluation of foreseeable effects

Waste - All waste material is dealt with as described under section 12 - This covers the deliberate removal of material from the laboratory environment.

Accidental escape into the environment - All air is filtered (Hepa) before venting to the environment, the labs are provided with spill kits and SOP’s for dealing with accidental spillage. Project transferred to GM543 on 08/09/2003 PROJECT REOPENED AS T
Project Additional Information

Purposes of the contained use

To determine the effect of SV40 Large T antigen and tumour-suppressor genes such as Apoptin (VP3), p53, p16, p19ARF and pRB proteins on a range of cells, when added exogenously as fusions with the TAT protein transduction peptide.

Recipient or parental organism

SV40 Large T:
Bacteria - Attenuated and mobilization defective E. coli (K-12) derivatives such as ER 1647, DH5-a and XL1 Blue, unable to survive in the absence of specialised growth conditions.
Human fibroblasts - Detroit 551 cells, non-immortalized, limited replicative life span, unable to colonize human hosts, unable to survive outside specialized tissue culture environs.

Apoptin (VP3), p53, p19ARF and pRB proteins:
Retroviral packaging cells: GP+E86, murine fibroblast derived with split helper function, ecotrophic for mouse, sensitive to human complement. PG13 murine fibroblasts derived, split helper function, restricted amphotropic, sensitive to human complement.
Established and primary mouse and human tissue culture cell lines: epithelial, fibroblasts and myeloid types. These cell lines are spontaneously immortalised, unable to colonise in human hosts, unable to survive outside special tissue culture environments.

Host/vector system

SV40 Large T:
* Cloning vector - pET22b (Novagen Ltd), in bacterial host, unable to replicate in nonbacterial cells. No expression of specific gene products in the absence of exogenously provided T7 polymerase AND isopropyl-thiogalacto-pyranoside (IPTG).

Apoptin (VP3), p53, p16, p19ARF and PRB proteins:
* PBABE and MFG series of retroviral vectors with murine leukaemia virus derived LTR promoter. These vectors are produced by safe packaging cell lines such as GP+E68 and PG13. These vectors have an LTR promoter and infect only rodent cells (GP+E68) or a wide range of cells including human (PG13). No inherent pathogenicity other than low risk of insertional mutagenesis is associated with these viruses.
* Mobilisation defective pUC based vectors with large array of different promoters such as SV40, CMV. Bacterial expression vectors such as pTriEx-1, in disabled bacterial hosts such as E. coli K-12 auxotrophic mutants for propagation.
* Spontaneously immortalised human and mouse tissue culture cell lines, unable to colonise humans. There is no evidence of the ability of these cells to secrete transmissible agents. These cells are unable to supply helper functions to disabled retroviral vectors.

Origin & function

SV40 Large T
* The genetic material originates as mRNA from human and/or mouse cells. The indicated function of the genetic materials is growth stimulatory.

Apoptin (VP3), p53, p16, p19ARF and pRB proteins:
* The genetic material originates as mRNA from human and/or mouse cells. The indicated function of the genetic material is that the full length cDNA products are tumour suppressors, including FHIT, p16/INK4a, p19/ARF, p21/waf1 and p53. These are cloned into mobilisation defective plasmid vectors including bluescript pCDNA3.1, pTRE2, pSVNeo and/or pBABE replication incompetent retroviral vector and will be expressed in human and mouse tissue cancer cell lines to determine their ability to apoptose.
Evaluation of foreseeable effects

Waste - All waste material is dealt with as described under Section 12 - This covers the deliberate removal of material from the laboratory environment.

Accidental escape into the environment;
a) from bacteria: All manipulations with bacteria will take place at containment level 2. Bacterial hosts are attenuated for growth in the absence of special growth media, and the ability to adhere to the gut lining. In the absence of combination stimulation of induction, expression of the protein in bacteria will be virtually zero. Protein preparations from induced bacteria will be via detergent lysis, to avoid aerosol production.
b) From tissue culture - All air is filtered (Hepa) before venting to the environment, the labs are provided with spill kits and SOPs for dealing with accidental spillage. All manipulations with human tissue culture cell lines take place at containment level 2. Cell lines are unable to survive outside the laboratory environment. White coats and gloves are mandatory. In the event of escape of disabled retroviral vectors, hazard is unlikely because they are unable to replicate in the absence of helper function and are sensitive to dessication and have a half life of only 5-8 hours under optimum laboratory conditions. In addition, PG13 derived vectors are unable to infect recipient permissive cells in the presence of normal complement. GP+E86 derived vectors are unable to infect cells other than mouse. In the event of infection and integration, the protein products of the cDNA being examined in this way (e.g. apoptin(VP3), p53, p16, p19ARF and pRB proteins) do not have deleterious effects in normal animal cells.

Accidental contamination of workers in the suite - Bacterial hosts are attenuated for growth in the absence of special growth media, and the ability to adhere to the gut lining. The vector DNA is unable to propagate or express in human cells. Established cell lines used are unable to colonize human hosts.

Security - The building has 24 hour security, and swipe card only access, visitors must report to the security and be escorted whilst in the building.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste - all contaminated waste is autoclaved in the departmental autoclave that is used only for waste. The moist heat autoclave is used at 121 degrees C for 40 minutes. Temperature validation provided by means of thermocouple probe. The autoclave is serviced annually by Meadowrose Scientific and documentary evidence of correct function stored on site. Under these conditions complete kill of organisms is guaranteed. The resultant sterile waste is double bagged in yellow bags and taken away and incinerated by Medical School contractors (White Rose).

Liquid Waste - All liquid waste is inactivated with 10,000 ppm of Chlorine for greater than 10 hours, after which it is disposed of down the designated sink. Under these circumstances complete kill of organisms is guaranteed.

### Project Additional Information

**Purposes of the contained use**

The aim of this project is to inhibit HIV infection of CD4+ T cells by expression of cellular factors which are able to block one or more of the steps required for a productive virus infection.

**Recipient or parental organism**

Bacterial hosts:  E coli, K-12 DH5, XL1 blue, and similar DISABLED bacterial hosts. Unable to survive in the absence of specialised growth conditions.
Retroviral packaging cells: GP+E86, murine fibroblast derived, split helper function, ecotropic for mouse, human complement sensitive, PG13, murine fibroblast derived, split helper function, restricted amphotropic, human complement sensitive, unable to colonise human hosts, unable to survive outside specialised tissue culture conditions. Murine and Human primary and established cell lines: T cell, HeLa, murine fibroblasts - spontaneously immortalized unable to colonise human hosts, unable to survive outside specialised tissue culture conditions.

Cloning vectors: pUC13 and TOPO bacterial plasmids, in bacterial (K-12) hosts, unable to replicate in non-bacterial cells.
Disabled retroviral expression vector: pBabe.puro, in the plasmid from - able to replicate only in bacterial cells and transiently in SV40 transformed cells. In the disabled retroviral vector form, it is unable to replicate in the absence of helper virus. Attenuated by the removal of the pol and env genes and partial deletion and repression of gag translation. It is compliment sensitive when secreted from mouse derived GP+E86 and PG13 packaging cells. Absence of pol, env, and gag sequences reduces the likelihood of recombination with helper virus sequences.
Retroviral packaging cell lines: The human sensitive (restricted amphotropic) PG13 and the ecotropic GP+E86 cells will be employed to package recombinant retrovirus. Split helper function increases the number of recombination events required to generate replication competent retrovirus. The presence of replication competent retroviral vectors is determined on cell banks by testing the ability of infected target cells to secrete infectious virus. Bank samples are cultured for limited (10) passages before destruction.
Murine and Human primary and established tissue culture cell lines: Unable to colonize humans, spontaneously immortalised, no evidence of the ability to secrete transmissible agents, unable to supply helper functions to retroviral vectors.

Host/vector system

Cloning vectors: pUC13 and TOPO bacterial plasmids, in bacterial (K-12) hosts, unable to replicate in non-bacterial cells.

Disabled retroviral expression vector: pBabe.puro, in the plasmid from - able to replicate only in bacterial cells and transiently in SV40 transformed cells. In the disabled retroviral vector form, it is unable to replicate in the absence of helper virus. Attenuated by the removal of the pol and env genes and partial deletion and repression of gag translation. It is compliment sensitive when secreted from mouse derived GP+E86 and PG13 packaging cells. Absence of pol, env, and gag sequences reduces the likelihood of recombination with helper virus sequences.

Retroviral packaging cell lines: The human sensitive (restricted amphotropic) PG13 and the ecotropic GP+E86 cells will be employed to package recombinant retrovirus. Split helper function increases the number of recombination events required to generate replication competent retrovirus. The presence of replication competent retroviral vectors is determined on cell banks by testing the ability of infected target cells to secrete infectious virus. Bank samples are cultured for limited (10) passages before destruction.

Murine and Human primary and established tissue culture cell lines: Unable to colonize humans, spontaneously immortalised, no evidence of the ability to secrete transmissible agents, unable to supply helper functions to retroviral vectors.

Origin & function

The aim of this project is inhibition by expression of host cell and/or viral factors that can block the infection. Therefore the inserts are of mammalian or viral origin and their function in this context will be inhibition of different stages in the viral life cycle.

Evaluation of foreseeable effects

Waste - All waste material is dealt with as described under section 12. This covers the deliberate removal of material from the laboratory environment.
Accidental escape into the environment - all air is filtered (HEPA) before venting to the environment, the labs are provided with spill kits and SOP's for dealing with accidental spillage. All manipulations with bacteria take place at containment level 1. Bacterial hosts are attenuated for growth in the absence of special growth media, and the ability to adhere to gut lining. All manipulations with retroviral packaging cells, retroviral vectors, and established murine and human tissue culture cell lines take place containment level 2. Cell lines are unable to survive outside the laboratory environment. Retroviral vectors are unable to survive in the presence of human complement. White coats and gloves are mandatory. All work involving HIV will take place at containment level 3. Decontamination and destruction of all cultures and vectors at the end of each culture, without passage of any generated virus from one culture to another. The genetically modified cells will not be used for virus propagation.

In the event of escape of disabled retroviral vectors, they are unable to replicate in the absence of helper function, are sensitive to desiccation, and have a half-life of only 5-8 hours under optimum laboratory conditions. In addition PG13 derived vectors are unable to infect recipient permissive cells in the presence of normal complement. GP+E86 derived vectors are unable to infect cells other than mouse.

Accidental contamination of workers in the suite - Bacterial hosts are attenuated for growth in the absence of special growth media, and the ability to adhere to gut lining. Established cell lines (mouse and human) are unable to colonise human hosts. Disabled retroviral vectors are sensitive to human complement and in the case of GP+E86 derived vectors unable to infect human hosts. In addition, the retrovirus is unable to replicate in the absence of helper function and the cDNAs expressed do not contain oncogenic sequences nor pathogenic.

Security - The building has 24 hour security, and swipe card only access, visitors must report to the security and be escorted whilst in the building. Containment level 3 laboratory has restricted access to only named persons.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste - all contaminated waste is autoclaved in the departmental autoclave that is used only for waste. The moist heat autoclave is used at 121 degrees C for 20 minutes. Temperature validation provided by means of thermocouple probe. The autoclave is serviced by Meadowrose Scientific and documentary evidence of correct function is stored on site. Under these conditions complete killing of organisms is guaranteed. The resultant sterile waste is double bagged in yellow bags and taken away and incinerated by external contractors (White Rose). The containment 3 facility has an autoclave inside the laboratory.

Liquid waste - All liquid waste is inactivated with 10,000 ppm of Chlorine for greater than 10 hours after which it is disposed of down the designated sink. Under these circumstances complete kill of organisms is guaranteed.

CU2 Project Title UTILISATION OF GENE MEDIATED APPROACHES TO DESTROY RESIDUAL

Class 2

Culture Vol Class 2 1-50 litres

Culture Volume Class 3-4
**Project Additional Information**

**Purposes of the contained use**

Studies designed to find effective ways of destroying tumour cells that remain in the body after surgery that are resistant to conventional radiotherapy.

**Recipient or parental organism**

Human, rat and mouse cells maintained in vitro. The overall containment level that will be applied to these studies is 2.

**Host/vector system**

Host: human, murine or rat squamous cells.

Vector systems:

A. Adenovirus and selectively replicating adenovirus.
B. Salmonella species modified to carry either the cytosine deaminase gene or anti-angiogenic peptides.

**Origin & function**

The vectors all induce lysis of rodent and human tumour cells. In the case of the salmonella derived vectors tumour lysis occurs after exposure of the host to the prodrug 5-fluorocytosine. Treatment with vectors carrying anti-angiogenic peptides is designed to prevent outgrowth of blood vessel sprouts. It is anticipated that this treatment will prevent tumour outgrowth and spread.

**Evaluation of foreseeable effects**

Non-replicating adenoviruses or selectively-replicating adenoviruses and Salmonella species are all used with the intent of destroying tumour but not normal cells. There are no foreseeable hazards to human health or the environment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste. Solid waste will be double-bagged and autoclaved at 121 degrees C for 90 minutes followed by incineration. Sharps are discarded into designated sharps containers for incineration off site by White Rose Environmental.

Surgical instruments. Surgical instruments will be treated with a chlorine-releasing agent (for example HazTabs) and then scrubbed and autoclaved. All our autoclaves are on a service contract and are tested annually to ensure they meet the required specification for temperature and time holding.

Liquid waste. Decontamination with a chlorine-releasing solution at a concentration of greater than 10,000 ppm available chlorine for greater than 10 minutes prior to disposal down a designated sink.

The disinfectant to be used will be a chlorine-releasing cyanurate (Haz Tabs or PreSept), an agent that has good activity against Salmonella species and adenovirus.

The activity of HazTabs against Salmonella was demonstrated by Bloomfield and Miles (Journal of Applied Bacteriology 1979, 46:65-73) using a capacity test which demonstrated a 9log reduction following treatment of a test inoculum of 2.5 x 10 (to the power of 10) cfu/ml of Salmonella typhi. When 20% plasma (equivalent to serum) was included in the test 3,000mg/l of available chlorine was needed to kill Staphylococci. As HazTabs generate 10,000 ppm available chlorine (equivalent to 7,000 mg/l) and the concentration of serum in media will typically be less than 2%, this is a good disinfectant for the work to be carried out and is unlikely to become exhausted (Bloomfield and Uso 1985, Journal of Hospital Infection, 6@20-30).

The efficacy of HazTabs against viruses is shown by studies incorporating dried suspension of Polio virus and demonstrating a 5 log reduction following treatment with 9,200 ppm available chlorine after 1 minute, and at 5 and 10 minutes no virus was recovered, (Tyler R., Alylisse G.A.J., Bradley C. Virucidal activity of disinfectants: Studies with the Poliovirus, Journal of Hospital Infection, 15,339-45).

The work proposed will not generate "high-hazard" waste and we do not propose to test whether organisms can be grown from the waste. However, every care will be taken to ensure that the concentration of chlorine is appropriate and liquid waste is treated for a minimum of 10 minutes to compensate for the presence of serum.

02/03/2022
The use of RNA inhibition to assess gene function in primary cultured human myometrial cells. Myometrial cells will be transfected with plasmid vectors containing gene specific antisense gene fragments to inhibit gene translation.

The plasmid vectors and inserts to be used require containment level 1 conditions. The host cells to be transfected will be primary cultured human myometrial smooth muscle cells and passaged human myometrial smooth muscle cells. Primary cultured cells require containment level 2, thus all work will be performed at containment level 2.

The recipient cells will be primary cultured human myometrial smooth muscle cells and also passaged human myometrial smooth muscle cells.

The host cells will be primary cultured human myometrial smooth muscle cells and also passaged human myometrial smooth muscle cells. The vectors we plan to use are non-mobilisable plasmid vectors.
The non-mobilisable plasmid vectors will contain small gene fragments that will generate RNAs that will be processed to 23 mers. Inserts will be chemically synthesised and will be homologous to human genes. Transfection of the plasmid will inhibit gene translation and will enable physiological functions to be determined.

**Evaluation of foreseeable effects**

We plan to transfect myometrial cells with plasmid vectors containing short gene fragments, which will functionally knock out specific genes rather than add genes. Transfected and untransfected human myometrial cells are unable to survive outwith tissue culture facilities, so they will have minimal effect to the environment. Prior to disposal, cells will be inactivated using 50% Virkon. Cells and all culture materials will be incinerated with hospital waste. Cells are unable to colonize laboratory workers. The non-mobilisable plasmid vectors that we plan to use are unable to enter cells without mechanical or chemical manipulation and plasmids are unable to transcribe the inserted gene fragment out with the host cell, there will be minimal risk to the laboratory staff or the environment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Transfected cells and culture medium will be treated with 50% Virkon which will cause cell inactivation. In addition, cells will be unable to remain viable out of tissue culture facilities. Cells and tissue culture materials will be autoclaved in a vacuum cycle at 135 degrees C for 5 minutes and then incinerated with hospital clinical waste.

Purposes of the contained use

Lentiviral and adenoviral vectors for use in the transfection of isolated cardiovascular cells and tissues.

Recipient or parental organism

Human and eukaryotic cell lines for viral production and experimental work and prokaryotic cells for vector propagation.

Host/vector system

Lentiviral vectors: pCMV R8.2, pCMV R8.91, pMD.G, pHR'SinctwSV, pLVTHM, etc
Adenoviral vectors: pDC316-p^7m9, pDC316, pShuttle-M1(p47(W193T)), pShuttle-M1, etc
Prokaryotic host cell lines for molecular subcloning: TOP10F', TOP10F, DH5a, XL1-Blue, JM109, DH101, TG1
Eukaryotic host cell lines for testign constructs: COS-7 cells, etc
Eukaryotic host cell lines for producing virus particles: HEK-293 cells
Normal primary culture cells/tissues: primary human or rodent cardiomyocytes, vascular smooth muscle, fibroblasts, endothelial cells and/or aortae or muscle strips.

Lentiviral: Split-genome HIV-1 based lentiviral packaging system to produce replication disabled vectors (generation 2.5; self-inactivating lentiviral system). This includes a plasmid to express lentiviral functional (gag-pol) and/or accessory genes (vpr, vif, rev, tat, ref and nef) driven by a CMV promoter (plasmids pCMV R8.2 and pCMV R8.91 and variants thereof which don't alter the risk factor), attenuated by the removal of the packaging signal, , and the 5' and 3' LTR. The viral genes are prevented from
packaging into the infectious virion and can only apply their functions in trans from the packaging host. A second plasmid encodes a pseudotype envelope protein - Plasmid pMD.G encodes the Vesicular Stomatitis Virus G protein (VSV-G). The use of an envelope pseudotype instead of the HIV envelope minimises the risk of homologous recombination and the generation of wild-type and replication competent t virus. The lentivector will be similar to plasmid (pHR' series) encoding the packageable lentiviral vector to express a heterologous gene of interest transcribed from a strong mammalian promoter such as CMV. These vectors are attenuated by the removal of pol, env and accessory genes and partial deletion and repression of gag translation. All pHR'-derived vectors are self-inactivated by deletion within the U3 region of the 3' LTR, which results in the generation of an inactivated 5' LTR promoter following reverse transcription. Self-inactivated vectors are therefore unable to replicate following integration into target cells even in the presence of helper function, further minimising the risk of generating replication competent virus.

Adenoviral: Adenoviruses differ from lentiviruses in that they remain episomal (do not integrate into the host genome) and therefore are expressed transiently within the infected cells. Replication incompetent adenovirus particles are made via homologous recombination events in HEK 293 cells. The E1 and E3 deletions out of the wild-type adenoviral genome ensures that recombinant adenovirus is not replicative except in HEK 293 cells. The pShuttle system from Clontech is proven safe and efficient and will be the main system used for our adenovirus experiments.

Wherever possible we shall be inheriting vectors containing gene sequences of interest to us via collaboration with other labs. Although the vectors may not be based upon exactly the same parental backbone as presented here, they will be of essentially the same design and will not increase the risk factor.

The cDNA inserted into the vectors described above will be subcloned from gift plasmids or plasmids obtained through the HGMP resource centre. Some cDNAs may be cloned in house using RT-PCR of mRNA isolated from cells or tissues. Antibiotic resistance and other marker genes are from prokaryotic species, green fluorescent protein from Aequorea victoria (jellyfish), transcription factors, enzyme and signalling components are initially cloned from mammalian cells and tissues, including rat, mouse and human. Eukaryotic promoter/enhancer elements from commercially commonly available vectors.

The oxygen inserted in the vectors described above will be subcloned from gift plasmids or plasmids obtained through the HGMP resource centre. Some cDNAs may be cloned in house using RT-PCR of mRNA isolated from cells or tissues. Antibiotic resistance and other marker genes are from prokaryotic species, green fluorescent protein from Aequorea victoria (jellyfish), transcription factors, enzyme and signalling components are initially cloned from mammalian cells and tissues, including rat, mouse and human. Eukaryotic promoter/enhancer elements from commonly commercially available vectors.

The project will involve the overexpression of biological factors in cardiovascular cells and tissues in order to elucidate at a molecular level the signalling pathways that mediate pathophysiological effects. Cells such as primary cardiomyocytes, endothelial cells and vascular smooth muscle cells are difficult to transfer efficiently by standard non-viral approaches, thus gene transfer by viral delivery is necessary.

Our overall aim is to study the role of oxidative stress in the pathophysiology of cardiovascular disorders such as left ventricular hypertrophy, heart failure, endothelial dysfunction and atherosclerosis. Oxidative stress acts through (a) direct modification of cellular proteins and membranes; (b) inactivation of the potent signalling molecule nitric oxide (NO); and © modulation of redox-sensitive signal transduction pathways. A family of ROS-generating enzymes, the NADPH oxidases (Noxs), is recognised to be a major source of ROS involved in redox signalling. Work by our group and others has demonstrated an important role for NADPH oxidases in the development of endothelial dysfunction as well as components of the cardiac hypertrophic phenotype. Furthermore, separate Nox isoforms are activated by distinct stimuli and have divergent downstream effects both in the vasculature and the heart. This programme of work will use a combination of ex vivo preparations and cultured cell systems to investigate: (i) the mechanisms of activation of different Nox isoforms in cardiovascular cells; (ii) the relative roles of different Nox isoforms in cardiovascular cells; (iii) the mechanisms of ROS-mediated cardiac contractile dysfunction; (iv) therapeutic approaches to inhibiting NADPH oxidase activity.

Inserts will comprise components of the NADPH oxidase enzyme complex either as wild-type or dominant-negative versions and short hairpin cDNA complexes designed to disrupt the function of the NADPH oxidase complex. Infection of cell lines and the virus particles made with these inserts will be expected to have perturbed physiological responses and/or transcriptional profiles. The production of these altered cells lines will allow pathophysiological experiments to be done testing the function of each of the components of the NADPH oxidase complex. These studies will substantially increase our understanding of the roles of NADPH oxidase in the pathophysiology of left ventricular hypertrophy and endothelial dysfunction, and may provide the basis for the development of novel therapeutic strategies for human disease.

Expression of the cDNA moleculars described above are intended to produce biologically active products. The expressed products will have activity relevant to the experimental system being studied. Thus cDNA encoding NADPH oxidases, will be expected to perturb physiological responses of the eukaryotic cells that involve the
generation of reactive oxygen species (e.g., in redox signalling).

None of the genes or DNA fragments to be used encode a known oncogene. The materials and organisms to be used present little potential hazard since no known pathogens or oncogens are involved. The prokaryotic hosts and eukaryotic cells to be used are unlikely to survive outside of the culture conditions, colonise animals or humans or transfer genetic material to other hosts.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

The risk assessment for prokaryotic work indicates that it can safely be carried out at containment level 1.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste products, such as agar plates, plastics etc. contaminated with GM material will be disposed to autoclave bags (double bagged to prevent penetration) which will be sterilised by autoclaving at 121 degrees for 30 min. Bags of autoclaved waste will be placed in yellow bags for incineration.

Waste cell culture medium from cultures containing GM eukaryotic cells and growth medium from GM prokaryotic cell cultures will be sterilised by adding chlorine release tablets (e.g., Presept) or hypochlorite to provide a concentration of 10,000 ppm chlorine and standing in a Microbiological Safety Cabinet for at least 3h. The sterilised medium will be disposed of down the sink with copious amounts of water.

Sharps including pipette tips will be collected in designated sharps bins, which will then be autoclaved as above and incinerated.

These are standard procedures and are recognised to kill all GM organisms and brownning tubes are used to monitor the "kill"

Use of RNA inhibition to assess gene function

The plasmid vectors and inserts to be used require containment level 1 conditions. The host cells to be transfected will be primary cultured and passaged human cells, including T lymphocytes, dendritic cells and airways smooth muscle cells. Primary cultured cells require containment level 2, thus all work will be performed at containment level 2.

The recipient cells will be primary cultured and also passaged human cells detailed above.

The host cells will be primary cultured and also passaged human T lymphocyte cells. The vectors we plan to use are non-mobilisable plasmid vectors.

The non-mobilisable plasmid vectors will contain small gene fragments that will generate RNA’s that will be processed to 23 mers. Inserts will be chemically synthesised and will be homologous to human genes. Transfection of the plasmid will inhibit gene translation and will enable physiological functions to be determined. cDNA’s will be derived by pcr from pre-existing cDNA libraries.
**Evaluation of foreseeable effects**

We plan to transfect cells with plasmid siRNA vectors containing short gene fragments, which will functionally knock out specific genes. The duration of our transfection experiments will be 1-7 days. Secondly, we will overexpress certain cDNA's. Transfected and untransfected human cells are unable to survive out with tissue culture facilities, so they will have minimal effect on the environment. Prior to disposal, cells will be killed using 1% Virkon. Cells and all culture materials will be autoclaved. Cells are unable to colonise laboratory workers. The non-mobilisable plasmid vectors that we plan to use are unable to enter cells without mechanical or chemical manipulation and plasmids are unable to transcribe the inserted gene fragment out of the host cell, there will be minimal risk to the laboratory staff or the environment.

Date Ackn'd: 04/03/2005

CU2 Project Title: Regulation of T-cell differentiation & cytokine gene expression

Class: Class 2
CultureVol: Class 2 Culture Volume: < 1 Litre

Non-GMM Consent Granted

Project notified under transitional arrangements

Historical Significant Changes

Tick if notifying a connected programme of work

Project Additional Information

Purposes of the contained use

The plasmid vectors and inserts to be used require containment level 1 conditions. The host cells to be transfected will be primary cultured and passaged human cells, including 293 cells, T lymphocytes, dendritic cells and airways smooth muscle cells. Primary cultured cells and lentiviral transduction requires containment level 2, thus all work will be performed at containment level 2.

Recipient or parental organism

The recipient cells will be primary cultured and also passaged human cells detailed above.

Host/vector system

The host cells will be 293 cells and primary cultured and also passaged human cells detailed above. The vectors we plan to use are a lentivirus system LentiLox. The vector systems used a third generation packaging system and generates self-inactivating lentivirus. Viral particles will be generated by cotransfection into 293 cells.

Origin & function

The lentiviral vectors are pMDLg/pRRE, pMD.G, pRSV-Rev and pLentiLox 3.7 and have been described in detail: D.A. Rubinson et al. Nature Genetics vol. 33 pages 401-406 (2003).

The lentiviral vectors will contain small gene fragments that will generate RNA’s that will be processed to 23 mer duplexes. Inserts will be chemically synthesised and will be homologous to human genes. Transduction of the virus will inhibit gene translation and will enable physiological functions to be determined. cDNA’s will be derived by polymerase chain reaction from pre-existing cDNA libraries.
We plan to transduce cells with lentiviral siRNA vectors containing short gene fragments, which will functionally knock out specific genes. The total duration of these manipulation experiments will be up to 28 days. Transduced human cells are unable to survive tissue culture facilities, so they will have minimal effect to the environment. Prior to disposal, cells will be killed using 1% Virkon. Cells and all culture materials will be autoclaved. Cells are unable to colonize laboratory workers. The lentiviral vectors that we plan to use require cotransfection with three packaging vectors and are unable to enter cells without mechanical or chemical manipulation and plasmids are unable to transcribe the inserted gene fragment out of the host cell, there will be minimal risk to laboratory staff or the environment.

Evaluation of foreseeable effects

N/A

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Transduced cells and culture medium will be treated with 1% Virkon for more than 15 mins which will cause death. In addition, cells will be unable to remain viable out of tissue culture facilities. Cells and tissue culture material will be autoclaved in a vacuum cycle at 121 degrees for 20 mins and then incinerated with hospital clinical waste.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The assessment was approved by the local GMSC committee on 23rd June 2004, with some minor amendments. The class of activity is 2.

A safety audit of the laboratory where the work will be carried out has also been done.

Disabled retroviral vectors (including both murine and lentivirus based vectors) provide efficient vehicles for gene transfer and expression in both primary and established mammalian cells.

This project concerns the development of novel retroviral (and lentiviral) vector inserts, constructs, packaging cells and modes of 2 optimised transduction, for the, efficient delivery and expression of single and multiple genes to target cells.

We have previously developed strategies for the use of paramagnetic particle (PMP) for capture and concentration of retroviral and lentiviral vectors, resulting in increased vector titre and/or infectivity by several orders of magnitude. We now wish to continue this work for achievement of even greater vector titres and for targeted infection of specific cell types. These are both still major obstacles in the clinical application of gene therapy. As part of these studies we are developing new retrovirus/lentivirus producing cells and will test new vector concentration and targeting strategies. These vectors will also be used for the expression of immune modulatory factors, in order to induce immunological reactions (primarily cytotoxic T cell mediated responses) against solid tumours and leukaemia.

We have recently been awarded permission by Gene Therapy Advisory Committee (GTAC) of the Department of Health for a E Phase-I clinical study, to assess the effect of vaccination with genetically modified myeloid leukaemic cells that have been engineered to express B7.1 (an immune costimulatory molecule expressed on the surface of antigen presenting cells) and IL-2 (a T cell stimulatory cytokine). This is achieved by Infection of primary and established leukaemic cells with a replication defective, self-inactivating, lentivirus vector encoding B7.1 and IL-2. We are now in discussion with Medicines and Healthcare products Regulatory Agency (MHRA) for the production of clinical grade HIV based lentivirus vector (self inactivating vectors encoding B7.1 and IL-2), in the GMP facility in the Rayne Institute at Denmark Hill (Rayne Cell Therapy Suite).
Bacteria – K12 derived E. coli strains such as: DH5α (F−λ80d/acZΔM15 Δ(lacZYA-argF) U169 recA1 endA1 hsdR17(rl, Mh) supE44 thi-1 gyrA96 relA1), STBL2 (F−mcrA Δ(mcrBC-hsdRMS-mrr) recA1 endA1 lon gyrA96 thi-1 supE44 relA1 Δ(lac-proAB)), and other such disabled and/or non-colonising E.coli strains that are unable to survive in the absence of specialized growth conditions.

Retroviral packaging cells -
- GP+env E-86, murine fibroblast derived, split helper function, ecotropic for mouse, human complement sensitive.
- GP+env AM12, murine fibroblast derived, split helper function, amphotropic, human complement sensitive.
- PT67 murine fibroblast derived, split helper function, amphotropic, human complement sensitive.
- PG13 murine fibroblast derived, split helper function, restricted amphotropic, human complement sensitive.
- 293 GPG7-VSV-G, human 293 derived, split helper function, xenotropic, human complement sensitive.
- Tally (TELceB6-Ampho, TELceB6-RDII4)- human TE671 derived, split helper function, amphotropic, limited human complement sensitivity.
- FLYA13, FLY-RD114 - Human HT1080 derived, split helper function, amphotropic, minimal human complement sensitivity. Unable to colonize human hosts, unable to survive in the absence of specialized tissue culture environs.
- Phoenix-A and Phoenix-E - human 293 derived, split helper function, amphotropic (A) and ecotropic (E), human complement sensitive.

Lentiviral producer cells -
- STAR-Ampho, STAR-RDII4, 293T and modified derivatives as hosts for transient lentiviral vector production.

Recipient cells
Established human and mouse tissue culture cell lines such as 293T, TE671, HTI080, HeLa, K562, HL-60, NB4, U937, NIH3T3. Primary human cells, such as acute myeloid leukaemia blasts, peripheral blood T-cells, CD34+ myeloid cells, as well as other primary and established mammalian cells.

All cell types to be utilized will be unable to colonize human hosts and unable to survive outside specialized tissue culture environs.

Host/vector system
Cloning vectors - Puc 13 and Pcr 2.1-TOPO, in bacterial (K-12) hosts such as DH5α and XL1 Blue, unable to replicate in nonbacterial cells.

Plasmid eukaryotic expression vectors - such as pSecTag2A, pIRESPuro3

Disabled retroviral expression vector - pWzl.blast, pBabe.puro, pIL2B7.blast, pEGF.blast, pBMN-GFP, pBMN-Z pBabe. ΔLNGFR. In the plasmid form - able to replicate only in bacterial cells and (in some cases) transiently in SV40 transformed cells. In the disabled retroviral vector form unable to replicate in the absence of helper virus. Attenuated by the removal of the pol and env genes and partial deletion and repression of gag translation, compliment sensitivity conferred by packaging cell. Absence of gag, pot and env sequences in the vector, and the use of split function packaging cells, reduces likelihood of recombination-mediated generation of replication competent retrovirus.

Retroviral packaging cell lines -
- GP+env E-86, murine fibroblast derived, split helper function, ecotropic for mouse, human complement sensitive.
- GP+env AM12, murine fibroblast derived, split helper function, amphotropic, human complement sensitive.
- PT67 murine fibroblast derived, split helper function, amphotropic, human complement sensitive.
- PG13 murine fibroblast derived, split helper function, restricted amphotropic, human complement sensitive.
- 293 GPG7-VSV-G, human 293 derived, split helper function, xenotropic, human complement sensitive.
- FLYA13, FLY-RD114 - Human HT1080 derived, split helper function, amphotropic, minimal human complement sensitivity. Unable to colonize human hosts, unable to survive in the absence of specialized tissue culture environs.
- Phoenix-A and Phoenix-E - human 293 derived, split helper function, amphotropic (A) and ecotropic (E), human complement sensitive.
These vectors will be generated in split-genome packaging/producer cells in order to reduce the risk of recombination-mediated acquisition of the deleted genes in the vector. For the retroviral vectors this will be achieved by transfection of at least two plasmids one encoding gag and pol another the env gene. The split helper function increases the number of recombination events required to generate replication competent retrovirus. The absence of replication competent retrovirus is determined by testing the infected target cells for production of infectious virus.

Lentiviral helper plasmids and vectors

Helpers - pCMVΔR8.2, pCMVΔR8.91, pMDLg/pRRE, pRSV-rev, pMDG, pFBSALF,
- Vectors - Replication defective (helper dependent) HIV based lentiviral vectors (e.g. pLenti6N5-GW/lacZ, or vectors with the prefix HR' or RRL' in the list below). Other HIV based lentiviral vector will be both replication defective and self-inactivating due to the removal of a 400 base pair deletion in the U3 region of the 3'LTR (vectors with SIN in the their name).
- Non-exhaustive list of current vectors: pH'CMV/IacZ, pH'R'CMVGFP/SIN, pH'R'PGK/GFPWSIN, pH'R'SINcPPT-SEW, pLenti6N5-GW11acZ, pH'R'SINctwSVGFP, pH'R'SINctwSV71, pH'R'SINctwSV12L271, pH'R'SINctwSV12L2871, pH'R'SINctwSVGFP, pH'R'SINctwSVIL-2/87.1.

In the plasmid form - replication is restricted to bacterial cells and (in some cases - plasmids with SV40 origin of replication) in transiently in SV40 transformed cells. In the disabled vector form unable to replicate in the absence of helper functions.

Lentivirus production will involve the co-transfection of the vector plasmid together with at least two other plasmids encoding gag, pol, env and the accessory genes (vpr, vif, rev, tat and nef). The absence of packaging signal, \( \psi \), in the plasmids encoding the a structural or accessory proteins will prevent the packaging of these sequences into infectious virions, other than by recombination events. The generation of a replication competent lentivirus will require multiple recombination events, making this very unlikely. In any event the self-inactivating vectors, will have a substantially reduced chance of replication in target cells, even in the presence of helper functions, further minimising the risk of generation of replication competent virus.

No retroviral vectors and only some lentivirus vectors (the self inactivating lentivirus vectors) used in the study will contain an N enhancer of gene expression derived from woodchuck hepatitis virus (WHV) called the woodchuck post-transcriptional regulatory c element, WPRE. This element is capable of expressing part of the X protein from WHV. The truncated or full-length hepadna W virus X-proteins may have oncogenic properties. Although this has not been proven, we will treat this as a potential risk in accordance with the recommendations of SACGM.

Human and mouse tissue culture cell lines or primary cells - Unable to colonize humans, spontaneously immortalized, no evidence of the innate ability to secrete transmissible agents, unable to supply helper functions to disabled retroviral vectors.

Origin & function

Vectors: Expression plasmids containing eukaryotic promoters (of viral and eukaryotic origin). Plasmids encoding retroviral and lentivirus vectors, including HIV based lentivirus vectors. Retro- and lentivirus vectors.

Source of Inserts: Human and rodents (e.g. IL-2, B7.1, ALNGFR, etc.), Bacterial (LacZ, Biotin ligase, biotin synthase, blastcidin SR, PuromycinR) or Jelly Fish, Aequorea victoria (gfp).

Function:

Immunomodulatory Factors - The expression of factors such as IL-2 and B7.1 will promotes immune recognition and stimulate a immunological responses against the transduced cells expressing these factors, and also against non-transduced cells with similar antigenic properties. Therefore, a potential hazard is the induction of autoimmune disease, due to enhanced immunological reactions.

Marker genes - Drug resistance genes such as blastcidin SR, PuromycinR, etc., enable the drug mediated selection of the transduced cells, where as marker genes such as LacZ, GFP, ALNGFR, etc., allow the detection of the transduced cells either N by their inherent chomogenicity (GFP) or use of precursor agents converted to chomogenic products (LacZ) or the antibody mediated recognition of the transduced cells (ALNGFR). Other factors such as bacterial biotin synthase and biotin ligase promote the synthesis and transfer of biotin to target proteins, allowing targets for avidin mediated recognition (staining, concentration, etc.) of the biotin labeled proteins or...
viral particles containing such labeled proteins on their outer surface.

**Evaluation of foreseeable effects**

Accidental escape into the environment - EXTREMELY UNLIKELY: All air is filtered (Hepa) before venting to the environment, the labs are provided with spill kits and SOPs for dealing with accidental spillage. All manipulations with bacteria take place at containment level 1. Bacterial hosts are attenuated for growth in the absence of special growth media, and the ability to adhere to the gut lining. All manipulations with retro- and lenti-iviral vectors, their packaging cells, as well as their primary and established cell targets will take place at containment level 2. Cells are unable to survive outside the laboratory environment. White coats and gloves are mandatory. Disabled retroviral and lentiviral vectors are unable to replicate in the absence of helper function, are sensitive to desiccation, and have a half life of only 5-8 hours under optimum laboratory conditions.

All waste material is dealt with as described under section 12 - This covers the deliberate removal of material from the laboratory environment.

Accidental contamination of workers in the suite - VERY UNLIKELY: Bacterial hosts are attenuated for growth in the absence of special growth media, and the ability to adhere to the gut lining. Established and primary cells are extremely unlikely to colonize human hosts. Many (but not all) of the retroviral and lentiviral vectors to be used in this project will also have additional sensitivity to human compliment. In addition all retrovirus and lentivirus vectors used in this project have deletions in their genome to make them unable to replicate in the absence of helper functions. The absence of reversion to replication competent is very unlikely with the specific design of the retrovirus and lentivirus vectors used in this project. The lentivirus vectors have additional deletions in their 3’ LTR, making them self-inactivating vectors.

Possible effects of accidental exposure of laboratory workers: In a worse case scenario the vectors could infect the laboratory worker and integrate into the genome of the infected cells. In such cases the eukaryotic gene promoter and enhancer sequences could induce or stimulate expression of nearby genes including those with oncogenic potential. Insertional N mutagenesis could also result in the disruption of activation of tumour suppressor genes, thus increase the risk of oncogenesis. Furthermore, the presence of WPRE sequence present in some of the vectors may have an oncogenic potential. The other potential risk is the induction of immunological responses (stimulation or suppression) due to the expression of the immune regulatory factors. The consequence of this may be the induction of autoimmune or Immune suppression disease. Therefore the vectors to be used in this project will be amongst the most attenuated of the available retro and lentivirus vectors. They will have multiple deletions, will be dependent on the presence of helper functions, and will in addition contain 3’ LTR deletions resulting in the self-inactivation of the lentivirus vector in target cells (infected cells will not be able to produce new virus). All operators will be specifically trained for the safe handling of these vectors, use protective clothing (laboratory coat and gloves), and operate a no-sharps/no-aerosol policy in the containment level 2 laboratories in which the lenti and retroviral vectors are handled.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**NOT APPLICABLE**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

The handling of retro and lentivirus vectors that contain potentially hazardous sequences (such as WPRE) will be restricted to containment level 2. However, vectors that do not encode such potentially hazardous genes, or cells genetically modified by such vectors, may be used at containment level one. This will apply to all such studies including the proposed Phase-1 human clinical trial. These vectors will encode marker genes (e.g. EGFP, ΔNGFR, β-galactosidase, etc), and/or immune regulatory genes (for instance B7.1 alone or in combination with IL-2).

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Solid waste - All containment waste is autoclaved in a dedicated Department waste autoclave. The moist heat autoclave is used at 121°C for 30 minutes. Temperature validation provided by means of thermocouple probe. The autoclave is serviced every six months by Rodwell Scientific Instruments and documentary evidence of correct function stored on site. The resultant sterile waste is double bagged in yellow bags and taken away and incinerated by Medical School contractors.

Liquid waste - All liquid waste is inactivated with 10,000ppm of Chlorine for greater than 10 hours after which it is disposed of down the designated sink.

**Is an emergency plan required according to regulation 20?**

N

**If yes, tick to confirm that it is attached to this form**

N
The local GMSC considered the risk assessment for this project on 17 February 2005 and recommended a number of amendments. The enclosed copy of the risk assessment has been accordingly revised and incorporates these amendments.

- **Consent Granted**: Not Applicable
- **Project notified under transitional arrangements**: N

**Project Additional Information**
### Purposes of the contained use

This research will involve the generation of galectin-1, transfected primary human T cells, using retroviral transduction methods, to analyse the role of this lectin in T cell immunoregulation. On the basis of the results obtained, new strategies for generating tolerogenic T cells specific to allo- and self-antigens will be investigated that could be exploited in developing strategies for the induction of tolerance.

### Recipient or parental organism

Recipient cells - primary human T cells derived from buffy-coat purified peripheral blood mononuclear cells.

### Host/vector system

Vector: Replication defective retroviral vector constructed using amphotrophic barring packaging cell line.

### Origin & function

**Origin of inserts (genus, species, strain):** mammals - human placenta derived cDNA.

**Functions of insert:** Galectin-1, a lectin protein, also named in literature as B-galactoside-binding protein (B-GBP) is involved in cell cycle arrest and thus the negative proliferation of T cells. The purpose of this project is to determine exactly how galectin-1 mediates its suppressive effect of regulatory T cells and to dissect the molecular mechanism implicated in such an effect.

The specific aim of the project is:

* To generate and characterise panels of human CD4+ T cell clones expressing galectin-1 by performing retroviral transfection of T cells with human and mouse-derived Galectin-1 protein, respectively. Human galectin-1 is inserted in pCR3.1 vector murine galectin-1 is cloned in CDM8 vector. Retroviral constructs will be generated using the Phoenix ecotropic and amphotropic 293 packaging cell line.

### Evaluation of foreseeable effects

Cloned galectin-1 protein is unlikely to alter the pathogenicity of the recipient cells as we neither propose work with oncogenes nor genes derived from pathogens that might cause harm. Moreover, the plasmid and retroviral vectors planned for use and cloning sequences used are known to be devoid of any transposable elements from both literature available and our own experimental work, respectively.

In addition, the vectors used and viral constructs generated will be replication-incompetent with a very short half-life when exposed to environmental conditions different than the specific culture conditions required for maintaining their activity.

All vectors have previously been well used and characterised by several groups. No reports have shown them to be harmful in vitro or in vivo since they were first described. The vectors used will be replication-incompetent with a very short half-life when exposed to environmental conditions different than the specific culture conditions required for maintaining them active.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Non requested - full containment measures of Class II activity will be followed.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All waste materials, including cultures, will be made safe by autoclaving. Bulk liquid wastes will be disinfected and inactivated using an equivalent volume of 2% Virkon.

---

02/03/2022  
Page 6809 of 15326
solution (ie final concentration of Virkon is 1%). Fully deactivated liquid waste is then disposed of by draining down the sink with water.

The laboratory and work area using genetically modified microorganisms has an accidental spill kit available containing undiluted disinfectants for immediate use in case of spillage. Bench tops and equipment will be disinfected on a regular basis in accordance with good laboratory practice procedures.

Solid waste from GMO work will be treated by inactivation by incubating the materials for a minimum period of 30 minutes with 1% Virkon solution, then autoclaved (autoclave cycle: moist heat, 20 minutes at 121 degrees celcius). Inactivated solid material is then disposed of as clinical waste, by incineration at an off-site facility for Guys Hospital.

### Purposes of the contained use

The use of primary human cell lines (human endothelial cells and endothelial progenitor cells).

### Recipient or parental organism

Human microvessel endothelial and human endothelial progenitor cells and established cell lines of human and animal origin will be transfected with expression vectors and small interfering RNAs (siRNA's) to develop cells with specific genes belonging to the ADAMs family of disintegrin-metalloproteases targeted for overexpression/downregulation respectively.

### Host/vector system

**pCDNA3**

### Origin & function

Vector inserts were cloned from human carcinoma cell line MDA-MB-468 cDNA library and from canine smooth muscle cell cDNA library and supplied to us by collaborators.

### Evaluation of foreseeable effects

Risk assessment for this activity has placed the likelihood of GMM surviving outside of the tissue culture laboratory environment as zero and has placed an overall risk factor of 10-18 with a likelihood of hazard being effectively zero.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Project Additional Information

Purposes of the contained use
The analysis of function of gene targeted DNA methyltransferases, designed to methylate specific gene promoters and downregulate their expression in a heritable manner.

Recipient or parental organism
Bacterial: E. coli K-12 (Top10, ER1647) disabled bacterial hosts. Unable to survive in the absence of specialized growth conditions. Unable to survive in the gut.
Modified cell lines and primary cells should not be able to colonize other human or animal hosts and also will not be able to survive outside a class II microbiological safety cabinet.

Host/vector system
Cloning Vectors: pCDNA3.1 mammalian expression vector (standard commercial unmodified vector). Human primary and humane/murine established tissue culture cells: Unable to colonize humans, no evidence of the ability to generate transmissible agents.

Origin & function
The genetic material encodes a protein comprising artificial gene specific zinc finger proteins fused to bacterial cytosine DNA methyltransferases. The purpose of this enzyme is to target methylation to the cellular genome at regions predetermined by the zinc finger recognition specificity.

Evaluation of foreseeable effects
Waste: All solid waste material is dealt with as follows: Solid waste: All contaminated waste is autoclaved in the departmental autoclave that is used only for waste. The moist heat autoclave is used at 121°C for 40 minutes. Temperature validation provided by means of thermocouple probe. The autoclave is serviced by Meadowrose Scientific and documentary evidence of correct function is stored on site. Under these conditions complete killing of organisms is guaranteed. The resultant sterile waste is double bagged in yellow bags and taken away and incinerated by external contractors (White Rose).
Liquid waste: All liquid waste is inactivated with 10,000 ppm of Chlorine for greater than 10 hours after which it is disposed of down the designated sink. Under these circumstances complete killing of organisms is guaranteed.
Accidental escape into the environment: The work will be carried out under level-II containment laboratories, and generation of aerosols will be minimized (use of sealed tubes, handling of open containers in level - Class II Microbiological Safety cabinets, etc.). The labs are provided with spill kits and SOP's for dealing with accidental spillage. The bacterial hosts used in this study will be attenuated for growth in the absence of special growth media, and for the ability to adhere to the lining in the gut. All tissue culture manipulations will take place at containment level 2. Cell lines are unable to survive outside the laboratory environment. White coats and gloves are mandatory.
Accidental contamination of workers in the laboratory: Established and primary cell lines (mouse or human) are unlikely to colonize human hosts. Security: The building has 24 hour security, and swipe card only access, visitors must report to the security and be escorted whilst in the building. Only qualified personnel, or trainees under qualified supervision, have access to the level 2 containment laboratories.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Temperature validation provided by means of thermocouple probe. The autoclave is serviced by Meadowrose Scientific and documentary evidence of correct function is stored on site. Under these conditions complete killing of organisms is guaranteed. The resultant sterile waste is double bagged in yellow bags and taken away and incinerated by external contractors (White Rose).

Liquid waste: All liquid waste is inactivated with 10,000 ppm of Chlorine for greater than 10 hours after which it is disposed of down the deignayed sink. Under these circumstances complete killing of organisms is guaranteed.

This project was initially approved as a class 2 activity by the GMSC in August 2005.

### Project Additional Information

#### Purposes of the contained use

The plasmid vectors and inserts to be used require containment level 1 conditions. The host cells to be transfected will be primary cultured human and rodent smooth muscle cells and small vessels. Primary cultured cells require containment level 2, thus all work will be performed at containment level 2.

#### Recipient or parental organism

The recipient cells will be primary cells from human and mice and rats.

#### Host/vector system

The host cells will be primary cultured human and rodent smooth muscle cells and small vessels. The vectors we plan to use are non-mobilisable plasmid vectors.

#### Origin & function

The non-mobilisable plasmid vectors will contain small gene fragments that will generate RNA's that will be processed to 23 mers. Inserts will be chemically synthesised and will be homologous to human genes. Transfection of the plasmid will inhibit gene translation and will enable physiological functions to be determined. cDNA inserts used to overexpress full length proteins will be derived by rtPCR from human, mouse or rat reverse transcribed RNA pools.

#### Evaluation of foreseeable effects

We plan to transfect primary cultured human and rodent smooth muscle cells and small vessels with plasmid vectors containing short gene fragments, which will functionally knock out specific genes; and cDNA's encoding full length proteins. All cells and vessels in this study are unable to survive outside tissue culture facilities, so they will have minimal effect to the environment. Prior to disposal, cells will be inactivated using a 1% Virkon solution then autoclaved. Cells and all culture materials will be incinerated with hospital waste. Cells are unable to colonize laboratory workers. The non-mobilisable plasmid vectors that we plan to use are unable to enter cells without mechanical or chemical manipulation and plasmids are unable to transcribe the inserted gene fragment outside the host cell, there will be minimal risk to the laboratory staff or the environment.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Transfected cells will be autoclaved at 121°C for 20 mins and then incinerated with hospital clinical waste, culture medium will be treated with 1% Virkon for greater than 15 mins which will cause death of any cells therein. Media will be disposed to drain diluting with copious amounts of water. The cells used will be unable to remain viable out of tissue culture facilities.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form  

Tick to confirm that you have attached a risk assessment to this form  

Tick if you are claiming exemption from disclosure for section of the risk assessment

The assessment was approved by the local BSC committee on 2nd February 2006, with some minor amendments. The class of activity is 2. A safety audit of the laboratory where the work will be carried out has also been done.

Withdrawn N  

Tick if notifying a connected programme of work N
Huntington's disease (HD) is a late onset inherited neurodegenerative disease. In order to understand the molecular changes that occur in HD it is essential that cell models of this disease are available. Throughout the research community, many cell models have been established and although these have had many uses, they also all have limitations. In all cases, the HD mutation has been introduced into cells that are immortal, either because they have been transformed or because they have been established from a natural malignancy. Therefore, these cells divide, unlike the neurons that are affected in patient brains. Also these established cell models often contain abnormal numbers of chromosomes (polyploidy) which is a problem if one wishes to study the cellular pathways that have been abnormally affected in the disease.

Therefore we wish to introduce the HD mutation into human embryonic stem cells to produce a much better cell model of HD. These cells will not be immortalized and can be differentiated into any cell type. In the first instance we would choose to differentiate them into neurons and muscle cells.

The recipient cells are well characterized human embryonic stem cell lines (Pickering et al.2003. Reprod Biomed. Online 7.353-364). They can be maintained in a pluripotent non-differentiated state by culturing them in specialized cocktails of growth factors. They can be differentiated into different cell types, by changing the constituents of the culture medium.

The autosomal dominant mutation that causes Huntington's disease is the increase in the length of a CAG repeat in exon 1 from the normal range (CAG) 6-35 to the pathogenic range (CAG) 40-->200

The human embryonic stem cell lines contain two normal copies of the HD gene. We shall replace the CAG repeat in one of the HD genes with a longer repeat that is in the pathogenic range. This will be carried out by homologous recombination. Cell lines will be selected in which the only genetic modification has been a change in the length of this repeat. These cell lines will be characterised and cellular pathways associated with HD will be identified.

Once the cells have been established and characterized, we shall try to improve the HD phenotype by altering the expression of other genes in pathways predicted to modify HD. Potential modifiers will either be overexpressed by introducing the gene of question into the cell line, or their expression will be knocked down by introducing RNAi into the cell line. Modifying genes and RNAi sequences will be introduced by lentiviral infection.

The genomic DNA for homologous recombination at the HD gene locus will be constructed by cloning in bacterial non-expression plasmids. The constructs will be prepared by cloning in the bluescript vector (Stratagene) and propagation will in non-mobilisable/disabled E coli hosts. These manipulations are containment level 1 and there are no foreseeable adverse effects.
Gene sequences and RNAi sequences that have been predicted to modify the phenotype of the HD-embryonic cell line will be cloned into lentiviral vectors prior to introduction into the human HD cells. Either FIV or HIV-1 (Invitrogen) lentiviral vector systems will be used. The lentiviruses will be transiently transfected into 293T cells along with the packaging plasmids that allow production of the infectious particles. The coding sequences of the two packaging constructs cannot undergo recombination with the infectious virion which itself contains less than 5% of original wild type viral sequences. The probability of a replication competent vector being generated via homologous recombination with wild type virus or packaging construct rescue is therefore negligible. This would require multiple homologous recombination events including recombination with either wild type FIV or wild type HIV, which is never introduced in the production process. The lentiviral vector is also self-inactivating due to deletions being present in the 3'LTRs. Cloning into the lentiviruses and production of the infectious particles is containment level 1 and no adverse effects are anticipated.

The human DNA containing a long CAG repeat will be obtained from pre-existing cosmid and plasmid clones. This will be used to replace the CAG repeat in one of the HD genes in the human embryonic stem cells. The DNA containing the final long repeat will be purified away from vector sequences prior to electroporation.

The DNA for homologous recombination will be electroporated into humans ES stem cells. Cells containing recombination events will be identified through selectable markers that confer resistance to various antibiotics. Resistant colonies will be analysed by molecular techniques to ensure that the desired recombination at the HD locus is the only genetic manipulation that has occurred.

The expression level of other genes that have been predicted to modify the HD phenotype of the HD ES cells will be either over expressed by introducing the genes of interest or its expression will be knocked down by introducing RNAi sequences. The gene or the RNAi will be introduced as lentiviruses. The gene sequences will be isolated by RT-PCR from RNA that has been prepared from other non-primary, non-diseased human cell lines (e.g fibroblast or lymphoblastoid). RNAi sequences will be derived from oligonucleotides.

This project will be at containment level 2 because we are manipulating a human primary cell line.

Origin & function

The DNA for homologous recombination will be electroporated into humans ES stem cells. Cells containing recombination events will be identified through selectable markers that confer resistance to various antibiotics. Resistant colonies will be analysed by molecular techniques to ensure that the desired recombination at the HD locus is the only genetic manipulation that has occurred.

Introduction of genes and RNAi by lentiviruses:
The lentiviral vector is replication incompetent and therefore even though it will insert into the host genome of the HD ES cells it will not be able to replicate and become infectious.

The genes that we shall introduce in order to modify the HD phenotype or whose expression will be reduced will be of known function and will not be anticipated to have any adverse effects.

Insertional mutagenesis at the site of lentiviral integration is a possibility. In order to identify phenotypes arising from such events, the phenotypes of at least two independent cell clones will be compared after infection with lentiviruses. If two clones show the same phenotype, this is unlikely to arise from insertional mutagenesis as integration into the same genomic region is extremely unlikely to occur in two separate lines.

The woodchuck hepatitis virus post-transcriptional regulatory element will be present in some of our lentiviral vectors. As the oncogenic potential of this element is currently under scrutiny, vectors containing WPRE will be treated with the assumption that harmful sequences are present as recommended by the guidelines from GTAC and HSE.

Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Cell Culture:

All cell culture will be performed in a class II microbiological safety cabinet. Appropriate protective clothing (lab coats and latex gloves) will be used. Nitrile gloves and powder free gloves will be available for staff allergic to latex and powder. Pipettes and culture flasks will be disposed of directly into autoclave bags, sealed and autoclaved. Liquid waste will be removed directly into disinfectant. A biological spill kit will be at close hand.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste is first autoclaved at 134°C for 20 min and then sealed in biohazard containers and incinerated.
Liquid waste is disinfected with Vircon at 10g per litre overnight and washed down the laboratory sink.

Is an emergency plan required according to regulation 20? N

Project Ref 386/07.1

Date Ackn'd 17/08/2007
CU2 Project Title Modelling Gene Therapy Applications in Cell Lines and Primary Human Cells.

Class CultureVolClass2 CultureVolumeClass3-4
Class 2 < 1 Litre
Project Additional Information

Purposes of the contained use

The purpose of the contained use is to genetically modify cell lines and primary human somatic and stem cells with plasmid and lentiviral vectors with the aim of assessing efficacy of potential gene therapy applications. This will include the testing of therapeutic genes and the conditional immortalisation of primary human somatic and stem cells.

Recipient or parental organism

Human embryonic human cell line (293T) expressing the SV40 large T antigen will be used as the host for transient transfection with the lentiviral packaging system for the production of infectious lentiviral vector particles. Primary human somatic and stem cells (e.g. neuronal stem cells, pancreatic stem cells, hepatic stem cells, myoblasts, CD34+ haematopoietic stem cells) will be transduced with the lentiviral vectors or transfected with plasmids for functional analysis.

Host/vector system

PLASMID AND LENTIVIRAL VECTOR CONSTRUCTS

HIV-based lentiviral vector: pRRL_c_s3bglod.cadII: This vector has a self-inactivating (SIN-18) backbone. It contains no viral protein encoding genes and includes a short 3’ HBB cloned in reverse orientation to preserve intron and non-coding cis-acting regulatory sequences: central polyuridine tract (cPPT) and packaging domain ().

Origin & function

The protein coding genes within the lentiviral vectors will be either reporter (e.g. EGFP, galactosidase) or potentially therapeutic (e.g. human -globin, dystrophin) genes aof known function. These genes will be placed under the control of a number of either tissue specific (e.g. human beta-globin and dsemin locus control regions, promoters and enhancers) or ubiquitous (e.g human HNRPA2B1/CBX3 dual divergently-transcribing promoter region) transcriptional regulatory elements. All componenets are of known function and based on this are determined to be of negligible health risk.

Evaluation of foreseeable effects

The lentiviral vectors are devoid of their own genome and are self-inactivating. They are therefore incapable of replication and spread beyond the point of intial infection.

The therapeutic genes that will be incorporated into the lentiviral vectors are all of known function and are known not to be pathogenic.

The tissue culture cells that will be used to either generate the lentiviral vectors or to be transduced with the lentiviral vectors or transfected with plasmids are incapable of
survival outside of the laboratory environment. They therefore pose negligible health risks to individuals and environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

We have two methods of treating waste according to the nature of the material: solid waste will be autoclaved at 121C for 30 min, then transferred to yellow bins for incineration. Liquid waste is disinfected overnight with 10,000ppm chlorine (Precept) before disposal via the drainage system. The use of sharps such as needle, metal scalpel blades or glass Pasteur pipettes is prevented by using plastic alternatives. The formation of aerosols is prevented by mixing in capped tubes. Potential aerosol-releasing manipulation will be carried out in biological safety cabinets. When necessary, a formaldehyde bomb is used for fumigation in the microbiological safety cabinets. After an accident such as spills or release, the area will be cleared of personnel and have restricted access. The affected area will then be decontaminated with bleach followed by appropriate disposal of waste. A complete biological spill kit is present.

During work, lab coats, gloves (powdered and non-powdered nitrile), goggles will be worn and work will be performed in specified areas for easier containment.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment Y

Please enter comments on the GM safety committee on the risk assessment

The risk assessment was reviewed by the King's College London Biological Safety Committee (BSC) on the 7th June 2007. The BSC found the risk assessment to be (i) clearly presented, (ii) comprehensive, (iii) precise in detail regarding the nature of the GMO's and genes to be used, (iv) precise in detail of the nature of the work that will be conducted with the GMO's and (v) met the requirements of the local national safety regulations.

The risk assessment was approved pending the completion of minor modifications.

The goal of this project is the development of a genetic approach to re-target human T-lymphocytes to common solid tumours using chimeric antigen receptor (CAR) technology. In brief, CAR consist of a targeting moiety (most commonly a single chain antibody fragment (scFv) or modified ligand) coupled via a hinge and transmembrane module to an endodomain that elicits T-cell activation and effector function.

Recipient organisms are as listed below (hosts). No additional recipient organisms (eg animals, plants) will be used. Parental organisms are as follows: (i) Prokaryotic — DH5a are ultimately derived from E.coli. (ii) Viral - The replication-defective retroviral vectors for use in this study are all ultimately derived from the Moloney murine leukaemia virus. (iii) Eukaryotic — all fibroblasts cell lines including retrovirus packaging cell lines are ultimately derived from NIH3T3 cells.

Vectors: All viral vectors to be used have been mutated (by extensive deletion) to make them replication incompetent. Thus, viral vectors (detailed below) do not have any inherent pathogenicity and are fully sensitive to complement.

(i) CAR will be targeted to tumour cell surface molecules including prostate-specific membrane antigen (PSMA), carcinoembryonic antigen (CEA), ErbB2 (scFv-based),
MUC1, ErbB4 (ligand based), colony-stimulating factor-I receptor (CSF-I R; ligand based). Signalling domains will consist of CD3z +1- co-stimulatory modules (CD28, TNF receptor family members etc). In some cases two or more CAR will be co-expressed in T-cells in order to deliver complementary signals upon engagement of two tumour antigens.

(ii) Cytokine receptors - to enable the regulated expansion of gene-modified T-cells in a tumour- or drug-regulated fashion. An example of the former is the colony-stimulating factor-I receptor (CSF-I R) which is active when ectopically expressed in T-cells, conferring responsiveness to the tumour-associated cytokine, CSF-I.

(iii) To facilitate detection of gene-modified cells, (enhanced) red or green fluorescent protein may be expressed. In some cases, this may be joined in-frame to other cDNA inserts to engineer a fusion protein.

(iv) Internal ribosome entry sites (IRES) or 2A peptide cleavage systems may be used to enable expression of more than one open reading frame from a single transcript.

(v) Genetic resistance genes will facilitate selection of gene-modified cells (using puromycin, G418, blasticidin, zeocin etc).

(vi) To recreate the environment associated with cancer-associated cytokine overproduction, immortalized tumour cells may be genetically engineered to express tumour-associated cytokines such as CSF-I.

(vii) To eliminate gene-modified cells, suicide genes may be used (eg HSV-TK; caspase 9 fusion genes). (viii) To provide antigen-expressing tumour cells, targets may be expressed in immortalized tumour cells, eg Erb6i-4, CEA, PSMA, CSF-iR, MUC1

(ix) To facilitate imaging, bioluminescent imaging reporters (firefly or renilla luciferase) or PET reporter genes (eg HSV-TK, Na/I symporter) may be expressed. (x) Inactivated (mutated) controls will be generated for all inserts as appropriate.

**Evaluation of foreseeable effects**

The principle potential hazard associated with the use of retroviral-mediated gene transfer is the possibility that recombination may occur between the expression vector used and the complementary sequences found in the packaging cell line, leading to the generation of replication competent virus (RCR). Generation of RCR is rendered less likely by the use of the GP+env86, and PG13 packaging cell lines, in which at least 3 independent recombination events are required for RCR generation. In addition, the viral vectors for study are fully sensitive to human complement. It is envisaged that there will be a negligible risk to human health or the environment associated with the use of the prokaryotic or eukaryotic hosts specified since these are unable to colonize human hosts.

In addition, any theoretical risks posed by the above are further reduced by the containment and waste disposal measures to be employed. Bacterial work will take place at containment level 1 while all work with retroviral vectors and T cells will operate at level 2.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All materials that have been in contact with genetically modified material will be sterilised. All solid waste will be autoclaved at 121 degrees C for 90 minutes before removal from the building in double bags for incineration, thereby ensuring 100% kill. To achieve 100% kill of liquid material, waste will be treated with Virkon 1% and incubated overnight (in agreement with manufacturers recommendations) before disposal down a sink. We have opted not to autoclave liquid waste in light of concerns about delays prior to autoclave availability for this purpose, coupled with undesirability of autoclaving bleach-treated waste. Periodic in-house testing will be performed to assess the % kill of prokaryotic and eukaryotic hosts by the overnight bleaching approach as described. All animals carcasses will be incinerated.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

02/03/2022
The risk assessment was approved by the KCL School of Medicine Biological Safety Committee subject to minor amendments on 7-10-2007. All amendments have been made exactly as requested.

Project Additional Information

02/03/2022  Page 6824 of 15326
Chronic kidney diseases (CKD) are characterized by chronic inflammation and refractory fibrosis. We have 3 major focuses in our research aiming at developing new therapies: (i) Analogues of vitamins A and D; (ii) Ras and Rho; (iii) T-type channels.

1. Vitamin A and D analogues antagonises renal inflammation and fibrosis
The specific hypothesis is that vitamin A and 0 derivatives may have both anti-inflammatory and anti-fibrotic effects in the kidney. The specific aims are to test the above hypothesis by addressing their effects in vitro models of fibrosis, TGF-beta signaling, MAP kinase, AP-1 and NF-kappaB and MKP-1 activities in kidney mesenchymal and epithelial cells. Experiments involving gene modification procedures include: transfection of the cells with a Smad3 activity reporter plasmid, plasmids expressing Smad7, dominant negative mutants of RARs, RXRs, vitamin D receptor, and other nuclear receptors, MAP kinases ERK1/2, MEk5/ERK5, p38 and JNK, siRNAs of RXRalpha, beta, gamma and RARalpha, beta and gamma, vitamin D receptor, MKP-1, etc.

2. Roles for Ras and Rho in inflammation and fibrosis
The specific hypothesis is that Ras and Rho subtypes play different roles in inflammation and fibrosis in the kidney. The specific aims are to test the above hypothesis by addressing their roles in unilateral ureteral obstruction (UUO) and anti-Thyl.1 nephritis rodent models and kidney mesenchymal and epithelial cells. Experiments involving gene modification procedures include: Expression of H, K and N-Ras, Rho A, B, C and E and short hairpin siRNAs for each isoform. Also Ras binding domain of Raf-glutathione-s-transferase fusion protein, Rho binding domain Rhotekin-GST fusion protein and Rac binding domain of PAK-GST fusion protein.

3. Role for the T-type channels in inflammation and fibrosis
The specific hypothesis is that T-type channels play some roles in inflammation and fibrosis in the kidney. Ib pepific aims are to test the above hypothesis by addressing their roles in unilateral ureteral obstruction (UUO) and anti-Thyl.1 nephritis rodent models and in kidney mesenchymal and epithelial cells. Experiments involving gene modification procedures include: Transfection of cells with siRNAs to knockdown 3 T-type Calcium channel isoforms (Cav3.1, Cav3.2 and Cav3.3).

Recipient or parental organism
Identify the species and tissue origins of all the cell lines to be used and specify cell lines being used: Primary human mesangial cells provided by Prof. Lucio-Cazana (Spain), human (Saleem) and mouse (Mundel) podocyte cell lines, NRK49F rat renal fibroblasts, SM43 and FM14 rat mesangial cell lines, wild-type and Smad2 or Smad5 knockout mouse embryonk fibroblasts.

Describe the method(s) of immortalisation: The NRK49F rat renal fibroblasts, SM43 and FM14 rat mesangial cell lines, mouse embryonic fibroblasts are spontaneous cell lines. Human and mouse podocyte cell lines were immortalised by transfecting with a temperature- sensitive SV40-T gene. Establishment of transgenic mice: In some studies, Alb/TGF-betal and Ren-lcrrGF-betal transgenic mice will be used. No further gene modification will be done to these mice.

Host/vector system
1. Type of vector Plasmid, cosmicl, etc): Plasmid
2. Vector name: pcDNA3.1, pSG5, pMEP4, pBPSTRI, pRSh, CDM8, pCEP4, pRE, pmaxGFP, pEF-BOS.
3. Provide a map/www/scientific reference for each vector, has this been done:
   - pMEP4: http://lmcb.asm.org/cgi/reprint/25/4/1475
   - pBPSTRI: http://lmcb.asm.org/cgi/reprint/19/6/3212
   - pRSh: http://www.jbc.org/cgi/reprint/276/1 6/12697
   - CDM8: http://www.jbc.org/cgi/reprint/276/16/12697
   - pCEP4: http://www2.kumc.edu/solab/LabLinks/vectors/pcpep4.htm
   - pmaxGFP: http://www.amaxa.com/fileadmin/groups/marketing/Downloads/Protocols/RNAiOP_sIRNAlastKit. pdf
Origin & function

Genetic materials: Plasmids, siRNAs and antisenses of MKP-1, MKP-ICS, RARs, RXRs, dnRARs, dnRXRs, WT and dn ERK, WT and dn JNK, WT and dn p38, ADH5, RALDHs, Cyp26, ABCAI, AP1-SEAP, NFkappaB-SEAP, RARE-SEAP, wild-type, constitutive active and dominant negative mutants of Rho.

Origins: From academic collaborators or commercial suppliers.

Intended functions: These genetic materials are modulators of signal transduction. They will be used in in vitro studies to explore the roles for the MAP kinase, retinoid, Ras and Rho, AP-1 and NF-kappa B in cell biology.

Evaluation of foreseeable effects

These gene materials will change the expression of specific genes and change the phenotypes of the cells and thus might change the natural course of inflammation and fibrosis. None of these materials is carcinogenic.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

No GM plants will be used or created in this project. Well-established transgenic mice will be used but not further modified. The transgenic mice will be brought in from National Institutes of Health, University College London and other American or European collaborators. All the animals will be housed by the King's Biological Services and all procedures will be carried out according to the Animals (Scientific procedures) Act 1986, with appropriate personal and project licences in place.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Treat waste:
Solid: Autoclave and then sent for incineration. The length of sterilisation cycle will be more than 20 mm and the temperature is 121 degree centigrade. Indicator tapes will be used to indicate the wastes have been autoclaved.
(ii) Liquid: 1% Virkon. Contact time should be longer than 60 mm. At UCL, it has been confirmed that exposure longer than 10 mm will reduce micro-organisms to below detectable level, The Virkon-treated liquid will be poured down into sink with copious amounts of water

Project was approved by School of Medicine Biological Safety Committee (GM386) with minor amendments, which have now be made.
## Project Additional Information

### Purposes of the contained use

### Recipient or parental organism

Recipient organisms are listed as below (hosts):

### Host/vector system

Host E.coli JM101, JM109, DH5alpha, DH10B, DB 3.1, Invaf, JS4, XL1-Blue, BL21(DES), TOP10, INV110, K12 strains DH5a, BL21(DE3). Such hosts are naturally attenuated, known to be non-virulent and are fully sensitive to a wide range of antibiotics.
Origin & function

Evaluation of foreseeable effects

The vectors don't contain any potentially harmful sequences. They contain non-coding DNA sequences. There is a minimal risk that retroviral or lentiviral plasmid DNA could integrate into human genomic DNA.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All materials that have been in contact with genetically modified material will be sterilised. All solid waste will be autoclaved at 128 degrees C for 20 minutes before removal from the building in double bags for incineration, thereby ensuring 100% kill. To achieve 100% kill of liquid material, waste will be treated with virkon 1% and incubated overnight (in agreement with manufacturers recommendations) before disposal down a sink. We have opted not to autoclave liquid waste in the light of concerns about delays prior to autoclave availability for this purpose, coupled with undesirability of autoclaving bleach-treated waste. Period in-house testing will be performed to assess the %kill of prokaryotic and eukaryotic hosts by the overnight bleaching as described.

### Project Additional Information

#### Purposes of the contained use

The aims of the project are to define the key molecules involved in human and murine T-cell activation and differentiation. The understanding of these fundamental processes will allow a rational design of treatment for autoimmune, infection, allergic and neoplastic disease.

#### Recipient or parental organism

Recipient organism will be human or mouse T-cells. Parental organism will also be human or mouse. Parental and recipient will generally be identical.

#### Host/vector system

Genes of interest into PCR2.1 TOPO or Pbluescript in the first instance. Genes then sequenced and transferred to viral vectors such as MSCV-EGFP, PGC-IRES (retroviral vectors), Plentilox 3.7, pMDLg-gRRE (lentiviral vectors) using various packaging/helper plasmids such as pMD.g, pRSV-rev and VSV-G.

#### Origin & function

Genes involved will be various mouse/human genes controlling T-Cell activation and/or differentiation. Alternatively transduced genetic material may be ShRNAs designed specifically to knock down or silence these genes. Genes will originate in human or mouse primary T-Cells and will be cloned and then sub cloned into viral vectors following PCR. Genes of interest will be identified in the first instance by array analysis. ShRNAs are small 18-30 mers and are generated by a commercial company.

#### Evaluation of foreseeable effects

Forseeable results are that the inserted (or knocked down) genes will influence the process of differentiation or activation in the target T-cells. Examination of these cells
with a variety of techniques (ie ICC, RT-PCR) will yield a greater understanding of the molecular mechanisms of these processes. The virus produced during this project is potentially infective to humans if VSVG pseudotyped, however the virus is replication deficient and a multi vector system is used for maximum safety of handling. Further, SOP's are in place to prevent the information of aerosols and limit the use of sharps in the lab which should further cut down on any potential hazards. All procedures are performed in a designated area within a class 2 MSC. The modified target cells are not hazardous and are unable to survive outside lab conditions. All material transduce by virus or used in the production of virus is disposed of via methods listed in section 12.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid: All solid waste autoclaved, 20 minutes 121 degrees C and then transferred to yellow bag clinical waste route for incineration.

Liquid: All liquid waste is treated with a 1% virkon solution for at least 1 hour before being disposed of in a designated sink with copious running water. Autoclaving gives 100% kill rates. This can be tested every cycle and efficacy of the autoclave is routinely tested during servicing which is performed on an annual basis. Virkon also gives an effective 100% kill rate. Documentation is available from suppliers, see risk assessment for further details.

Project Ref 386/09.2
The analysis of the role of the complement regulator CD46 during cell/cell interactions (human T cells and human epithelial cells) using primary cells and cell lines in which CD46 or CD46-interacting proteins have been silenced via siRNA technique or mutated forms of these proteins introduced.

CD46 IN T CELL RESPONSES. We recently found that the activation of the complement regulator CD46 on human CD4+ T cells induces the de novo development of adaptive Tregs that can suppress the proliferation and function of effector T cells in the vicinity. The in vivo induction conditions of complement-induced cTregs, their tissue localization and mode of action as well as their impact on other participants in the immune response are poorly defined. Under this part of the project, we aim to understand the CD46-mediated signals leading to cTreg induction as well as identify a novel CD46 ligand that can induce these signals.

CD46 IN EPITHELIAL CELL LAYER INTEGRITY. E. coli infections are the most common complication after renal transplantation. CD46 expressed on uroepithelial cells functions as a receptor for C3b-opsonised E. coli. As in T cells, CD46 activation also triggers important signalling events in epithelial cells: CD46 signals are central in the uptake of pathogenic E. coli by uroepithelial cells and subsequent promotion of infection. We aim to identify the mechanism by which E. coli uses CD46 to gain cell entry and hypothesize that changes in the cell layer integrity/permeability induced via CD46-mediated signalling events support bacterial invasion.

HUMAN:
A. Primary human CD4+ T cells (isolated from blood of healthy volunteers or blood packs from the National Blood Supply). These cells are non-adherent (suspension) and have not been previously mutated or altered and therefore show the normal proliferation, cytokine secretion and life span behavior of freshly cultured human CD4+ T cells. We anticipate having these cells (without manipulation and after siRNA treatment) in culture for 5-10 days per experiment. More than 90% of the cells will by that time be exhausted and apoptotic/dead; remaining cells will be killed.
B. Jurkat, clone E6-1; human CD4+ T lymphocyte; acute T cell leukemia. The Jurkat suspension cell line was established from the peripheral blood of a 14-year old boy. Clone E6-1 cells produce large amounts of IL-2 after stimulation with phorbol esters and either lectins or monoclonal antibodies against the T3 antigen (both types of stimulants are needed to induce IL-2 production). This is a pseudodiploid human cell line. The modal chromosome number is 46, occurring in 74% with polyploidy at 5.3%. The karyotype is 46,XY,-2,-18,del(2). Cells were obtained from the ATCC, USA, and not further manipulated. As this line is immortalized, we do not expect an effect on cell proliferation/survival.

C. HEK293 (human fetal epithelial cell line, adenovirus 5-transformed). This is an adherent hypotriploid human cell line. The modal chromosome number was 64, occurring in 30% of cells. The rate of cells with higher ploidies was 4.2%. The der(1)t(1;15) (q42;q13), der(19)t(3;19) (q12;q13), der(12)t(8;12) (q22;p13), and four other marker chromosomes were common to most cells. The Ad5 insert was cloned and sequenced, and it was determined that a colinear segment from nts 1 to 4344 is integrated into chromosome 19 (19q13.2). Cells were obtained from the ATCC, USA, and not further manipulated.

D. A498 (human kidney epithelial cell line, clear cell renal cancer). A498 cells, established from a clear cell renal cell cancer of a 52 years old male patient. Cells were obtained from ATCC, USA, and not further manipulated.

BACTERIA:

A. DH5α (bacteria, E. coli strain, commercially available, generally used for plasmid transformation). This is a well characterised, commercially available E. coli strain that is used for plasmid transformation and cloning purposes. Genotype: F- supE44 hsdR17 recA1 gyrA96 endA1 thi-1 relA1 deoR lambda-. The strain was obtained from Invitrogen and not further manipulated.

B. BL21-CodonPlus-RIL (bacteria, E. coli derivative, commercially available, commonly used for protein expression). BL21-CodonPlus-RIL cells contain extra copies of the argU, ileY, and leuW tRNA genes, which recognize codons that are a problem predominantly in organisms with AT-rich genomes. BL21-CodonPlus-RP competent cells contain extra copies of the tRNA gene argU, which recognizes the AGA and AGG arginine codons, and the tRNA gene proL, which recognizes the proline codon, CCC. These codons appear frequently in GC-rich genomes, such as mammals. Genotype: E. coli B- ompT hsdS(rB– mB–) dcm+ Tetr gal λ(DE3) endA Hte [argU ileY leuW Camr. The strain was obtained from Stratagene and not further manipulated.

C. UT5600(DE3) (bacteria, E. coli K12 derivative used for protein expression). This is a E. coli K12 derivative, commercially available and purchased from New England Biolabs. Genotype: F- ara-14 leuB6 secA6 lacY1 proC14 tsx-67 Δ(ompT-fepC)266 entA403 trpE38 rfdD1 rpsL109 xyl-5 mtl-1 thi-1.

Host/vector system

A. pET-15b vector (host:bacteria). Protein expression vector designed and sold by Novagen. 5708 bp in size; pBR322 ORI; T7 Promoter; His-Tag; MCS; T7 Terminator; lacI gene. The vector was purchased from Novagen and not further modified (except for the insertion of cDNA coding for CCPs1-4 of human CD46 – see below).

B. pcDNA-3.1 vector (host:bacteria, mammalian cells). pcDNA™3.1 vector is commercially available, 5428 bp in size and designed for high-level stable and transient expression in mammalian hosts. The vectors contain the following elements: Human cytomegalovirus immediate-early (CMV) promoter, MCS, neomycin and ampicillin resistance genes, T7 promoter, f1 origin, pUC origin. The vector was purchased from Invitrogen.

C. pcDNA6.2-GFP pcDNA6.2-V5, pcDNA6.2-C-YFP vectors (host: bacteria, mammalian cells). These three vectors are all derived from the same 7500 bp sized protein expression vector developed and sold by Invitrogen. The Vivid Colors™ Fluorescent Protein Gateway® Destination Vectors allow fusion of a protein of interest (here CD46, SPAP, α-E-catenin) to the widely used and well-characterized fluorescent proteins from the jellyfish Aequore (i.e. Green Fluorescence Protein (GFP) and Yellow Fluorescence Protein (YFP) or with a V5 tag to which a number of Abs exist. The vectors contain the following elements: CMV promoter, options to fuse GFP, YFP or V5 to the N- and C-terminus of the selected protein, f1 origin, pUC origin, T7 promoter, ampicillin and blasticidin resistance genes.

Origin & function

cDNAs USED FOR PROTEIN EXPRESSION IN BACTERIA AND/OR MAMMALIAN CELLS:
A. CD46/CCP1-4; CD46/CCP1-4M. This cDNA codes for CCPs 1-4 of the human complement regulator CD46. CD46 is expressed on all cells and prevents complement deposition (opsonins C3b/C4b) on host cells. The cDNA has been derived from a healthy donor. The CD46/CCP1-4M contains a mutation in the C3b/C4b binding site and can therefore not regulate complement anymore. No potential hazards are currently linked to this gene product.

B. SPAK; SPAKM. This cDNA codes for the human serine/threonine kinase SPAK. SPAK is expressed in most cells and activated during cellular stress and regulates MAP kinases. The cDNA has been derived from a healthy donor. The SPAKM cDNA contains a mutation in the kinase site and lacks therefore MAP activation activity. No potential hazards are currently linked to this gene product.

C. α-E-catenin; α-E-cateninM. This cDNA codes for human α-E-catenin. This protein is ubiquitously expressed and involved in tight junction formation and may also function as tumor suppressor gene in epithelial cells. The cDNA has been derived from a healthy donor. The α-E-cateninM mutant contains a mutation in the F-actin binding site. Deficiency/mutations in this protein have been linked to colon cancer.

D. E-cadherin; E-cadherinM. This cDNA codes for human E-cadherin. E-cadherin is preferentially expressed in epithelial cells and involved in tight junction formation. It may also function as tumor suppressor gene in epithelial cells. The cDNA has been derived from a healthy donor. The E-cadherinM mutant contains a mutation in β/α-catenin binding site. Mutations or deficiencies in this protein are linked to colon cancer and metastasis.

siRNAs TO BE TRANFECTED/DELIVERED INTO MAMMALIAN CELLS:

A. siRNA CD46. 22 shRNA targeting human CD46.

B. siRNA SPAK. 22 shRNA targeting human SPAK.

C. siRNA α-E-catenin. 22 shRNA targeting human α-E-catenin.

D. siRNA E-cadherin. 22 shRNA targeting human E-cadherin.

The 4 listed siRNAs (targeting the RNAs of the genes described above) are synthetic RNAs and have all been purchased from AB Biosciences. These siRNAs are delivered via electroporation into target cells and have been shown to reduce target protein expression to about 20-30% compared to non-treated cells. Protein knockdown of all 4 listed proteins has been achieved and published previously by a number of groups including our laboratory. No potential hazards have been linked to these approaches/experiments.

Evaluation of foreseeable effects

FORSEEABLE EFFECT OF GENETIC MANIPULATION ON HOSTS:

Human CD46 and SPAK are ubiquitously expressed proteins. The full-length wild type as well as several mutant forms of these proteins have previously been over-expressed in human primary cells and cell lines by several investigators including the proposer (CK) of this GMO assessment application. These processes did not lead to any reported increase in toxicity, infectivity or other potentially hazardous features of these cells.

E-cadherin and α-E-catenin are proteins involved in tight junction formation and tumor suppression. Thus, the silencing of these proteins in the human HEK293 and A498 epithelial cell lines could potentially lead to higher/uncontrolled proliferation of these cells and pose most likely the most hazardous genetically modified organism within this work. However, these GMO are non-infectious in nature, risk of exposure for humans/environment is minimal and their survival in the environment is unlikely (see below).

The host range of the E. coli bacteria strains used in this work covers technically a variety of mammalian hosts. However, these strains are commercially available; they have been specifically designed for the safe laboratory use and contain no virulence factors. Even in the case of accidental transmission (which should be prevented by protective closing, working at appropriately equipped designated work spaces and waste disposal/disposal of used materials according to the Good Practice Code), the survival/proliferation of the GMO in mammals is unlikely. Also, CD46 has already been expressed in the bacteria strains that are used in this work and no unexpected/negative effects on the bacteria have been observed.
LIKELIHOOD OF HUMAN EXPOSURE AND ENVIRONMENTAL HARM:
The likelihood of human exposure to any of the GMOs listed in this assessment application is minimal. Researchers are all trained in laboratory SOP and COP, will wear protective clothing at all times (laboratory coats, gloves etc.) and all primary cells and cell/bacteria lines are cultured in tightly closed cell culture flasks or spill safe culture dishes. Cultures will only be opened under sterile conditions in a Microbiological Safety Cabinet (MSC). The MSC is a Class II, is on a service contract and was last serviced and KI tested (service and KI test result: pass and pass) on 17/04/08 by 'Environmental Validation Solutions'. Thus, any accidental spillage will be detected immediately and the affected area cleaned/disinfected using the appropriate measures that laid out in the laboratory COP, which is on file with each laboratory member and also displayed on the outside of the MSC. The MSC itself is located in a lockable room only accessible from the laboratory and this room is designated solely for cell culture work carried out by members of the laboratory. Potential aerosols from the E. coli bacteria strains used for sub cloning and protein expression as well as the uropathogenic bacteria will be prevented/kept to minimum by culturing these in closed flasks, handling them generally in leak and air-proof containers (i.e. centrifugation in buckets with a safety lid) and opening containers in MSCs.

In addition, likelihood of human exposure to the GMO is minimal as these GMO are 1. Non-infectious in nature and 2. Have been generated without an infectious agent (virus). In addition, they are unable to survive in the environment for longer than 3-4 hrs. Although the HEK293 cells line was originally generated via adenovirus 5-immortalization, the cells contain only residual virus sequences but are not producing/shedding infectious virus. In addition, none of the inserted/mutated DNA sequences is known to confer toxicity or infectivity.

We are NOT using animals or plants.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

We are NOT using animals or plants.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

We do not apply for any derogation from full containment for Class 2 activity.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Any biologically contaminated waste (i.e. cell/bacteria cultures, glassware [4 liter glass containers are used to grow bacteria cultures needed for tetramer production], materials and media used in cell/bacteria cultures will be treated with the disinfectant Virkon. Liquids: liquids will be treated with a Virkon solution such that 1% of final Virkon concentration is reached and incubated for at least 20 min. Waste fluid can then be poured down the laboratory sink with copious amounts of water. Materials will be fully immersed for at least 30 min in 1-2% Virkon solution, then double-bagged into autoclave bags and autoclaved for am minimum of 40 min at 120 oC using a designated waste autoclave in room G66-050-350. The autoclave is inspected every 6 month by ‘Priorclave’ and the last inspection was 29/08/2008; inspection result: pass. Autoclaved plastic ware will the be double bagged in a Clinical Waste Yellow bag, sealed with red tape and put into the Clinical Waste container in room G68-050-480. These measure reduce the likelihood of exposure to a minimum. The proposed experiments do not involve injections, thus, exposure due to usage of needles or scalpels is unlikely. Nonetheless, a sharps COP is in place and a designated approved container for sharps and for broken glassware are located in the laboratory. Full containers will be deposited in room G68-050-480 and picked up/handled by a professional waste disposal company.

**Purposes of the contained use**

The aim of this project is to assess the biological impact of the expression of human oncogenes and in particular those identified in association with specific cytogenetic abnormalities in human leukaemia. We wish to target tissues that closely mirror those affected in the naturally occurring disease. This procedure will involve gene transfer into human derived packaging cells and generation of a replication defective recombinant retrovirus and lentivirus capable of targeting human and murine cells. The recombinant virus will contain specific, potentially oncogenic gene products that are found in association with different subsets of leukaemia. The virus will be used to infect...
human and murine cells in vitro and the targeted cells will be assessed both in in vitro assays and in vivo.

Recipient or parental organism

Primary human cells purified from cord blood, bone marrow and peripheral blood or mouse primary bone marrow, foetal liver cells and embryonic cells. These cells will have a normal genotype or carry well defined genetic abnormalities ie will be immortalised with well defined genetic abnormalities – primary cells transformed with proto-oncogenes.

Human and murine cell lines eg. HL-60, NB4 cells, MV4;11, NIH3T3, commercially available from ATCC and ECACC. These are standard tissue culture cell lines. Human cell lines may be derived from patient material e.g. HL-60 is derived from a patient with acute promyelocytic leukemia. Murine cell lines may be derived from immortalised murine cells e.g. NIH3T3.

Escherichia coli K12 bacteria derivatives, e.g. DH10beta, DH5alpha. All are commercially available from eg Invitrogen or Promega. Disabled, non-colonising and non-pathogenic to humans and animals

DH5alpha: F- φ80lacZΔM15 Δ(lacZYA-argF)U169 recA1 endA1 hsdR17(k-, m+) phoA supE44 thi-1 gyrA96 relA1 λ-

DH10beta: F- mcrA Δ(mrr-hsdRMS-mcrBC) φ80lacZΔM15 ΔlacX74 recA1 endA1 araD139 Δ(ara, leu)7697 galU galK λ- rpsL nupG

Packaging cell lines eg HEK293 and NIH3T3 and their derivatives are commercially available from ATCC. HEK293 are transformed human embryonic kidney cell line. Cell line was derived from fetal kidney embryonic cells transformed with adenovirus 5 DNA. NIH3T3 are derived from mouse embryonic fibroblasts

Host/vector system

pRRL-X Plasmid used for generating lentivirus where X = gene of interest

Used to generate self-inactivating and replication incompetent lentivirus. The pRRL vector is a lentiviral (HIV)-based plasmid. It is safe to use due to its modified features (deletion of a number of accessory genes implicated in the virulence of HIV, minimal genome of the viral particles, non-replicating and self-inactivation features), making it incapable of producing virus once infected into the host cell.

pHR-X Plasmid used to generate lentivirus where X = gene of interest

Used to generate self-inactivating and replication incompetent lentivirus. The pHR vector is a lentiviral (HIV)-based plasmid. It is safe to use due to its modified features, making it incapable of producing virus once infected into the host cell.

pLKO-X Plasmid used to generate lentivirus where x = shRNA against protein of interest

Used to generate self-inactivating and replication incompetent lentivirus. The pLKO.1 vector is a lentiviral (HIV)-based plasmid. It is safe to use due to its modified features (deletion of a number of accessory genes implicated in the virulence of HIV, minimal genome of the viral particles, non-replicating and self-inactivation features), making it incapable of producing virus once infected into the host cell. The human U6 promoter (a pol III promoter) is used to drive expression of the shRNA hairpin.

pMSCV-X Plasmid used to generate retrovirus where X = gene of interest

Used to generate self-inactivating and replication incompetent retrovirus. Derived from the Murine embryonic stem cell virus and LN retrovirus. It is safe to use due to its modified features (deletion of a number of accessory genes) making it incapable of producing virus once transduced into the host cell.

All the above are plasmids which contain viral elements such as LTR and packaging signal and also elements necessary for propagation in E. coli e.g. DH10B. However there are elements missing e.g. gag, pol, env (e.g. VSV-G) which are only provided in trans (packaging plasmids) in the packaging cell line to create a functional, but replication incompetent viral particles. To further enhance biosafety these elements are split to at least 2 different packaging plasmids to minimise the chance of recombination and therefore production of a replication competent virus. Packaging plasmids encode genes (e.g. capsid, reverse transcriptase) essential for generating infectious viral particles.

Origin & function

The genetic material involved originated from chromosomal translocations found in leukaemia patients.

E2A-FP and MLL-FP Aberrant transcription factors and putative proto-oncogenes identified in patients and literature.

Nup 98-FP and FP-RAR Aberrant transcription factors that can potentially immortalise and transform cells.

RXR family Aberrant transcription factor and member of nuclear receptor family.

MN1-FP and AML1-FP Aberrant transcription factors and putative proto-oncogenes.

ZFN's Zinc finger nucleases with or without donor sequences cut dsDNA at predetermined sequence
Fusion of DNA binding protein (zinc finger) and DNA cleaving protein (nuclease)

FP (fusion proteins) are naturally occurring and derivatives of them are used for structure/function analysis.

**Evaluation of foreseeable effects**

The worst possible consequence of exposure to modified virus would be that operator’s cells could be infected by the virus and the virus integrated into the genome. This could theoretically result in insertional mutagenesis which may lead to the disruption of the function of an important gene which may cause cell death or cellular transformation. It may be theoretically possible that the experimental gene of interest or construct of interest encoded by the virus may be expressed. There may be a very small risk that expression of oncogenes may result in tumorigenesis. Viral vectors are engineered to transfer and integrate specific DNA sequences into the genomes of target cells and are designed to be replication-defective to avoid further spread after the initial transfer event. The likelihood of this happening is effectively zero. Exposure to skin, eyes and lungs would be minimal as gloves and protective clothing are used at all times, no sharps are used and all work will be carried out in a Containment Level 2 laboratory and cellular infections in a Class II Microbiological Safety Cabinet. The modified viruses should not pose a serious risk as they are inactivated by detergent, uv light and ethanol. The half life of the virus is 6-9hrs in tissue culture media at 37oC, it is unknown how long it would survive in the environment. They are also replication defective so will not be shed from the modified cells. Any residual virus on tissue culture plastics, solid waste and liquid waste is inactivated by use of appropriate disinfectants. MSCs are located in specified rooms designated as Containment Level 2 laboratories and only competent and trained operators would carry out these procedures. The modified virus is replication deficient and there is an extremely low risk of transfer of genetic material to wild-type organisms.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

All the measures specified as requirements for the containment level 2 procedures will be adhered to.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Disposable plastic contaminated with virus must be sprayed with disinfectant before placing into autoclave bag and autoclaving.
Plastic pipettes and tips are soaked for at least 12 hours in 1% Virkon solution before being sealed in autoclave bag and autoclaved.
All media must be treated with 1% Virkon solution for at least 12 hours.
All viruses and E.coli are stored at -80°C in designated area of freezer in sealed containers. E.coli grown on LB agar plates are sealed and stored in designated area of fridge for maximum of two week and disposed of by autoclaving.
Autoclaves are serviced and tested every 6-months (December 2009). All waste is autoclaved at 121oC for 30minutes.
MSCs are tested every 6-months and an annual operator protection (KI discus) test was performed in November 2009.

Purposes of the contained use

The major focus of the work is to identify the genes and delineate the biochemical pathways underlying a range of human genetic disorders using both established and novel technologies.

We plan to achieve these goals by carrying out a range of cell-based functional assays. These include the cloning and transfection of wild-type and mutagenised cDNA transcripts (e.g. from whole or partial disease causing genes such as Dymeclin) which may be transiently or stably expressed in cell lines. If necessary, gene regulatory
regions (e.g. promoter regions) will also be cloned in appropriate vectors. siRNAs will be cloned into appropriate vectors and stably expressed in cell lines to knock down expression of disease causing genes.

The majority of this work will be carried out using standard containment level 1 cloning procedures. However a small proportion of this work will involve the use of lentiviral based vectors to create stable knock down cell lines which will be carried out at containment level 2.

**Recipient or parental organism**

**Class 1 work**
- For generation of standard cloning vectors the recipient cells will be attenuated E.coli cell lines.
- For experimentation the recipient cells will be human and mouse cell lines.

**Class 2 work**
- For generation of virus particles the recipient cell line will be HEK293 cells.
- For experimentation the recipient cells will be human cell lines such as HeLa and HeCat

**Host/vector system**

**Class 1 work**
- For class 1 work the cDNA transcripts and / or regulatory regions will be cloned into a range of mammalian expression vectors (e.g. pcDNA) which will be selected by resistance antibiotics - e.g. Ampicillin, Zeocin, Kanamycin, Neomycin, Puromycin and may be designed to result in fusion of the transcript with tags (e.g. flag, myc), fluorescent proteins (e.g. GFP) or result in the expression of markers (e.g. B-Gal or Luciferase).

**Class 2 work**
- This will make use of the lentivirus vectors using 2nd and 3rd generation packaging systems (e.g. GIPZ lentivirus system). New generation Lentiviral Vectors have been modified to reduce cytoxicity and reduce their ability to replicate. Replication and vector functions are carried on separate, multiple plasmids allowing transfections and transductions to be carried out using replication competent virus and replacing coat with VSV-G reduces likely toxicity (although will broaden host cell range).

**Origin & function**

**Class 1 work**
- DNA sequences for cloning will be generated by PCR from human or rodent cDNA and / or genomic DNA Mutagenesis will be carried out using commercially available systems such as Quikchange (stratagene).

**Class 2 work**
- Vectors will be purchased with siRNA insert for each gene cloned, e.g. GIPZ vector systems (open biosystems)

**Intended functions**

**Class 1 work**
- The genetic material will be intended to either over-express or knock down the gene of interest or to study the effect on expression of regulatory regions. Genes of interest have a range of functions depending on the disease system under study e.g. Dymeclin, a peripheral golgi protein of unknown function in which we identified mutations in patients with Dyggve-Melchior-Clausen syndrome and now seek to determine its physiological role in normal and disease systems.

**Class 2 work**
- The lentiviral vector system will be used to knock down expression of genes of interest in order to study the functional consequences of down-regulated expression e.g. CDKAL1, a gene in which we have identified mutations associated with psoriasis.
Potential Hazard to Human Health

Class 1 work
Likelihood of exposure to humans is low.

E. coli - lines are attenuated and non-infectious.

Cell lines - due to immune rejection of non-self tissue, it is highly improbable that accidental exposure would result in survival and replication in normal healthy individuals. Mammalian cells have very stringent requirements for growth and are very susceptible to dehydration and to exposure to ultraviolet radiation. Outside of the animals from which they are derived, growth and survival requirements can only be met by using specialised media, the correct temperature range, optimum pH and an adequate oxygen concentration. These constraints mean that cell lines will pose risk minimal risk to both human and the environment.

Class 2 work

Likelihood of exposure to humans is low.

Work with Lentiviral vectors will be carried out at containment level 2 to protect against exposure. The modifications to the new generation viruses reduce cytoxicity and make it very unlikely that viruses will have the ability to replicate outside experimental conditions.

Potential hazard to the environment

Class 1 work

Organisms are unlikely to survive outside the laboratory.

E. coli - Attenuated strains are auxotrophic for nutrients that will be scarce except in specialised media. These transformants would not be expected to replicate and may not survive in the environment. However, disabled E. coli strains have been shown to persist for several days in the environment. Good microbiological practice will be sufficient to protect both human health and the environment.

Cell lines - Mammalian cells have very stringent requirements for growth and are very susceptible to dehydration and exposure to ultraviolet radiation. Outside of the animals from which they are derived, growth and survival requirements can only be met by using specialised media, the correct temperature range, optimum pH and an adequate oxygen concentration. These constraints mean that cell lines will pose minimal risk to both human health and the environment.

The likelihood of organisms passing GM material to wild type organisms is very low.

E. coli - Non mobilisable plasmids are used to prevent transfer between bacteria. Attenuation means that bacteria are unlikely to infect wild type organisms preventing transfer from occurring and low survivability in the environment for these strains reduces the opportunity for transfer.

Cell lines - Cell lines are unlikely to be able to survive in both the environment and host organisms preventing the opportunity for transfer to wild type organisms. In addition cell lines do not have the capability of genetic transfer without reproduction.

Class 2 work

Lentiviral vectors - Lentiviruses are rapidly inactivated outside the host, as illustrated by the fact that close contact is required for transmission. Therefore, the survivability of
lentiviruses is not thought to pose a risk to the environment.

Rapid inactivation of virus means that there is little likelihood of transfer of genetic material to wild type organisms.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Solid waste likely to be contaminated with GMOs is collected in autoclave bags and autoclaved prior to disposal. Autoclave cycle: 121 oC 20 minutes. This is above the standard kill time for decontamination of hazardous material. Following decontamination waste is disposed of by incineration.

Autoclaves are destruct tested every 3 months and insured by Sun Alliance.

Liquid waste is treated with Virkon, Precept, or Trigene or other appropriate commercially available biocide according to the manufacturers instructions for 100% kill.

The GM Risk Assessment for this project was discussed by the School of Medicine GMSC on 11/02/2010. The project was approved subject to minor amendments as a Class 2 activity.
Scientific aims: to investigate the molecular mechanisms regulating immunoglobulin heavy chain class switch recombination using primary human B cells isolated from patients undergoing routine tonsillectomies. To investigate this phenomenon certain genes thought to act upon the system will be overexpressed or knocked down and the effect of these manipulations investigated by the isolation of RNA and DNA followed by analysis by sequencing and PCR.

Genes of interest for manipulation include: Transcription factors (e.g. Helios and E-box binding factors), Chromatin remodeling enzymes (e.g. Histone methyl transferases SETDB2, G9a, SUV39H, MLL), factors involved in DNA recombination and repair (e.g. AID, UNG, RPA, PKA, MSH2, XRCC1 polb) and miRNAs (155, 21 and 29). DNA to be cloned for analysis purposes includes: Immunoglobulin heavy chain locus, BCL6, Pax5, myc, globin genes, b-actin.

This project involves the use of E. coli and lentiviral vectors exclusively for the purpose of cloning, sequencing and manipulating recombinant inserts. None of the vectors support the expression of those inserts in E. coli.

A number of previously genetically manipulated mammalian cell lines, which have been obtained from cell culture collections, and primary B cells isolated from the lung, nose, tonsils, and blood are detailed in this application. DNA and RNA is to be extracted from these cells, and either cloned or analysed directly by sequencing and PCR based methods.

In addition this project will undertake to transiently transfect primary human cells with short interfering RNAs and miRNAs to knock down the expression of genes of interest. Long term overexpression of cDNAs, shRNA and miRNA constructs will be carried out by delivery of mammalian expression vectors containing cloned cDNA/shRNA/miRNA by lentiviral mediated delivery mechanisms.

Recipient or parental organism

Escherichia coli: strains in common laboratory use e.g. DH 5 alpha, XL-1 blue, TOP10 will be used as cloning tools. These strains, which are derivatives of the K12 strain,
have a widespread and long history of safe use. They also contain numerous mutations eg thi-1 which render the strains auxotrophic and therefore unlikely to survive outside the laboratory environment.

Well characterised packaging cell lines, transformed human embryonic kidney (HEK) cell lines, will be used for the propagation of the recombinant viral vectors used to overexpress the genes of interest or deliver inhibitory si and shRNAs.

Primary human B cells and well characterised and authenticated tissue culture cell lines, RAMOS, BJAB, BL-2, CL-01 RPMI 8866 and 8226, A20, HeLa will be used as targets for the overexpression or inhibitory vectors. These lines will be transfected with recombinant viruses then analysed in various ways in order to investigate the function of the genes/proteins of interest. All primary human material will be treated as potentially hazardous and appropriate precautions will be taken to prevent infection. The cell lines used are all well characterised with a long history of safe use.

Host/vector system

Host:
Escherichia coli strains e.g. DH 5 alpha, XL-1 blue, TOP10 are derivatives of the K12 strain, recognised as non-colonising and disabled. They are expected to have limited survivability in the environment and often have auxotrophic requirements, which are unlikely to be satisfied outside of laboratory culture.

HEK packaging cell line and well characterised and authenticated tissue culture cell lines, RAMOS, BJAB, BL-2, CL-01 RPMI 8866 and 8226, A20, HeLa will be used. These cell lines are all well characterised with a long history of safe laboratory use.

Primary human B cells will be isolated from the tonsils of donors undergoing routine tonsillectomies. All primary human material will be treated as potentially hazardous and appropriate precautions will be taken to prevent infection. The cell lines used are all well characterised with a long history of safe use.

Vectors:
pUC based plasmid backbones (PUC 18, PUC 19, pGEM T-easy vectors and pCR2.1-and related TOPO vectors) are used for cloning vectors, these are non-mobilisable.

Lentiviral packaging vectors will be used to generate defective 3rd generation Lentivirus (HIV-1 based). The viral genes used to produce these vectors (gag, pol, rev and VSV-G envelope genes) are contained on discrete plasmids (pMDLg/pRRE, pC1-VSVG CMV-VSVG, pRSV-Rev). Packaging vectors lackLTRs and have no packaging signal, the packaged viral genome has self-inactivating LTRs. This system ensure minimal replication competence and recombination likelihood.

Mammalian expression vectors (pGIPZ, pLentiLox3.7, psPAX2, pMD2.G) Contain LTR or CMV/RSV promoter driving expression of transgene flanked by cis-acting elements necessary for its encapsidation, reverse transcription and integration. Packaged viral genome has self-inactivating LTR. This is the only genetic material transferred to target cells and contains the viral backbone and transgene cassette.

Origin & function

Non-coding gene products for Ig heavy chain fragments will be produced for propagation prior to downstream analysis (PCR & sequencing) – no potential hazards.

Non-coding gene products for a variety of “control gene” fragments will be produced for propagation prior to downstream analysis (PCR & sequencing), gene fragments will include: globin, BCL6, Pax5, myc, b-actin, – no potential hazards.

We will over-express and knock-down a variety of miRNAs in our mammalian cells; this will entail overexpression of the active gene product in a mammalian overexpression system. The function of these miRNAs is currently of unknown and they will therefore be treated as potentially oncogenic.

A number of histone modification enzymes and chromatin remodelers, including: SETDB2, G9a, SuV39H and MLL, will be studied by over-expression of the active gene product in a mammalian overexpression system and si/shRNA mediated knockdown some of these genes have been described as having oncogenic potential, all
constructs will therefore be treated as such.

A number of transcription factors including Helios, E box factors (Eno1, Id2, ARNTL), AP1 factors (ATF3, NFIL3) and NfkB factors (NFkB1/2, TRIB2,3) will be studied by over-expression of the active gene product in a mammalian overexpression system and si/shRNA mediated knockdown. The oncogenic potential of some of these genes is unknown; as such they will all be treated as potentially oncogenic.

A number of involved in the DNA repair/recombination pathways (e.g. AID, UNG, RPA, PKA, MSH2, XRCC1 polb) will be studied by over-expression of the active gene product in a mammalian overexpression system and si/shRNA mediated knockdown. The oncogenic potential of some of these genes is unknown; as such they will be treated as potentially oncogenic.

Evaluation of foreseeable effects

E. coli: - Likelihood of exposure to humans is low, lines are attenuated and non-infectious.

Cell lines - due to immune rejection of non-self tissue, it is highly improbable that accidental exposure would result in survival and replication in normal healthy individuals. Mammalian cells have very stringent requirements for growth and are very susceptible to dehydration and to exposure to ultraviolet radiation. Outside of the animals from which they are derived, growth and survival requirements can only be met by using specialised media, the correct temperature range, optimum pH and an adequate oxygen concentration. These constraints mean that cell lines will pose minimal risk to both human health and the environment.

Primary Human material: B cells will isolated from tonsils obtained from patients undergoing routine tonsillectomies. The use of any human material represents an infection hazard from unknown disease causing agents. All human derived material will be handled in a class II microbiological safety cabinet and standard good laboratory practice followed.

We aim to use lentivirus to transduce cell lines and primary human B cells with plasmids to either over express or inhibit the expression of a number of genes of interest. The risks from accidental infection by lentiviruses are insertional mutagenesis and over/under expression of cellular genes by random integration or uptake of expression vectors. The main risk is to the laboratory personal directly handling the lentivirus. The risk attached to using the replicative defective HIV vectors is minimised because these viruses are extremely susceptible to dessication and will only survive a few hours at room temperature. In addition, the replicative defective nature of the HIV vectors ensures that even in the case of a breach of containment and accidental injection, no virus can spread from individual to individual.

The DNA sequences used are capable of encoding biologically active proteins which have unknown oncogenic potential in humans. Sequences encoding biologically active oncogenic proteins are classified as carcinogens for which containment level 2 is appropriate. Neither the DNA, encoded protein, bacterial or mammalian transfectants are likely to have any deleterious effect on the environment. The GM microorganisms are incapable of surviving outside of the laboratory environment. All laboratory procedures will follow good microbiological practice. GM microorganisms will be manipulated in a Class II Microbiological safety cabinet.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All GMOs will be handled in Class II safety cabinets with air-circulation through double filters within a 'viral work only' laboratory. Work is carried out in such as way so as to minimize entry/exit to and from the room. All reagents used in these procedures are stored within the room. The surfaces of all Tubes/Flasks & centrifuge buckets taken from the room i.e. for centrifugation are wiped with disinfectant prior to removal. Spill kits are present within this lab. All waste materials are autoclaved immediately upon completion of experiments thereby minimizing escape of GMO into the environment. The GM microorganisms used are incapable of surviving outside of the laboratory environment. All laboratory procedures will follow good microbiological practice. Written records of staff training will be obtained and checked before commencement of work by individuals. Handling and manipulation of naked DNA micro-organisms and GMOs will require the wearing of lab coats and disposable gloves. Where possible, sharps will be avoided in all operations. Disposable plasticware will be used throughout. All laboratory procedures will follow good microbiological practice.

Waste handling procedures:
Solid: All waste autoclaved, 20 minutes 121oC (SOP-DRMA2) then to clinical waste and incineration.
Liquid: Treated with HAZTABLES (SOP-DRMA2 - 4.5g Haz-Tabs added to a litre of water will make a solution of 10,000 p.p.m. available chlorine) for greater than 15mins then
disposed via sink with copious amounts of water.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Project Ref 386/11.1

Date Ackn’d 23/09/2011  CU2 Project Title Study of skin Immunology, Biology and Pathology

Class 2  CultureVolClass2 < 1 litre  CultureVolumeClass3-4

02/03/2022
The objective of this programme is to dissect molecular, immune and genetic pathways of inflammatory skin disorders, such as psoriasis, and tissue malignancies such as melanoma.

The initial phase of our studies on psoriasis and tissue malignancies such as melanoma will employ in vitro disease-relevant models to determine the functional role of disease-associated genes such as HLAC, CD1d in psoriasis, and Fc receptor and tumour-associated antigens (e.g. HMW-MAA pathway) in melanoma. The experiments will focus on the interaction of these genes with their potential receptors at the protein level in vitro and at the whole system level in vivo.

Our in vitro studies will utilise human cells including tumour cells, lymphocytes or other immune cells, which will be isolated from healthy volunteer and/or patient blood, tissues or tumours, and immortalized using retroviral vectors.

The studies involve the use of standard containment level 1 cloning procedures, however, a portion of the studies will involve lentiviral expression into human primary cells and will be carried out at containment level 2.

### Recipient or parental organism

**Containment Level 1 activities**
- For vector generation the recipient cells will be E. coli strains which are unable to colonise.
- For experimentation the recipient cells will be human and murine cell lines.

**Containment Level 2 activities**
- For generation of virus particles the recipient cell line will be HEK293 cells.
- For experimentation the recipient cells will be cell lines such as HaCaT and BAF-3, primary murine and human cells such as hematopoietic stem cells (HSC), lymphocytes and keratinocytes.

### Host/vector system

**Containment Level 1 activities**
- cDNA transcripts and/or regulatory regions will be cloned into a range of mammalian expression vectors (e.g. pcDNA3) which will be selected by resistance to antibiotics.
and may be designed to result in fusion of the transcript with tags (e.g. flag, myc), fluorescent proteins (e.g. GFP) or result in the expression of markers (e.g B-Gal or Luciferase). The generated constructs will be used for transfection of standard murine or human cell lines such as HEK293T, HeLa or HaCaT.

**Containment Level 2 activities**
Will involve the use of lentiviral systems using 2nd and 3rd generation lentiviral vectors that have been modified to reduce cytotoxicity and reduce their ability to replicate. The supply of viral packaging from separate plasmids makes the associated risks of using the vector system low.

### Origin & function

All genetic material are of human or mouse origin, apart from GFP/eGFP (jellyfish Aequorea Victoria) and B-glactosidase, which is of bacterial origin. The genetic material will be used to determine their functional roles in psoriasis and melanoma.

Inserts for conventional expression (e.g in plasmids of the pcDNA3 series):

i) Reporter genes
   - LacZ, GFP, firefly luciferase: Reporter genes; Lac Z: encodes protein beta-galactosidase; GFP; encodes 'Green fluorescent Protein'; firefly luciferase; encodes enzyme luciferase, which catalyzes a reaction with luciferin to produce light; no known potential hazards.

ii) MHC and MHC-like genes.
   - HLA-C: MHC class 1. Capacity to interact with CD8 T cells and innate immune receptors (KIRs) on NK and NKT cells; candidate gene for psoriasis susceptibility; no known potential hazards.

iii) Cytokines and chemokines
   - IL-2: Cytokine instrumental in body's response to microbial infection; produced by antigen-activated T cells; facilitates production of immunoglobulines made by T cells and induces differentiation and proliferation of NK cells; use in treatment of cancer (malignant melanoma; renal cell cancer); no known potential hazards.
   - IL-22: Cytokine involved in innate immune response against viral infection; no known potential hazards.
   - IL-4, IL-10, IL-13: Anti-inflammatory cytokines produced by T-helper 2 (Th2) CD4+ T-cells; no known potential hazards.
   - IL-17A, IL-22: Pro-inflammatory cytokines produced by Th17 cells; no known potential hazards.
   - CXCL16, CX3CL1: Membrane-bound chemokines; can be proteolytically cleaved from cell surface to generate soluble molecules; role in cell adhesion and leukocyte migration; no known potential hazards.
   - TNF, IFN-γ: Pro-inflammatory cytokines; signal via NFκB (TNF) and STAT1 (IFN-γ); TNF: induces apoptosis and inflammation, inhibits tumorigenesis and viral replication; IFN-γ: activates lymphocytes to enhance anti-microbial and anti-tumour effects; no known potential hazards.

iv) Receptors
   - FR-α, FR-β: Genes encoding the folate receptor which binds folic acid (vitamin B9); no known potential hazards
   - KIRs: Killer Immunoglobulin-like receptors (innate immune receptors); expressed on Natural Killer (NK) and Natural Killer (NKT) cells; interact with MHC class I molecules;
interaction can be inhibitory or activating; dysregulation of KIR/class I interaction important in human disease (e.g. viral infections, cancer, autoimmunity); no known potential hazards.

NKG2C, NKG2D: NKG2C: activating receptor expressed by T cells, as well as by natural killer (NK) cells and macrophages; receptor for MHC class I like molecule MICA No known potential hazards; NKG2D: activating receptor expressed by T cells, as well as by natural killer (NK) cells, interacts with HLA-E; no known potential hazards.

FcγR, FcγRII, FcεRI, FcεRII (CD23): Fc Receptors; expressed e.g. on NK cells, macrophages, neutrophils and mast cells; involved in protective function of the immune system: bind to antibodies that are attached to infected cells or invading pathogens; function e.g. in antibody-mediated phagocytosis or antibody-dependent cell-mediated cytotoxicity; no known potential hazards.

IL-2R, IL-4R, IL-10R1, IL10R2, IL-12R, IL-29R, IL-23R: Cytokine receptors; no known potential hazards.

HMW-MAA: High molecular weight- melanoma associated antigen; potential role in tumour cell adhesion, spreading and invasion; no known potential hazards.

NY-ESO-1: Member of the cancer-tests family of tumour antigens; can be expressed in melanoma; elicits humoral immune responses; promising target for cancer vaccination; no known potential hazards.

v) Intracellular signalling molecules and peptides

Bcl-2, Bcl-xl: Bcl-2 abd Bcl-xl are inhibitors of apoptosis: no known potential hazards.

MMPs: Matrix-Metalloproteinases; zink-dependent endopeptidases; capable of degrading extracellular matrix proteins; involved in cleavage of cell surface receptors, role in cell proliferation, migration, differentiation angiogenesis, apoptosis and host defence; no known potential hazards.

LL37 (CAMP): Human cathelicidin; antimicrobial peptide; potent antibacterial and antiviral activity; no known potential hazards.

S100 proteins, e.g. S100A8: S100 calcium binding protein A8; antimicrobial peptide; also involved in regulation of cellular processes such as cell cycle progression and differentiation; no known potential hazards.

Raf, Raf, cdk, ERK, MEK, IRAK, IRAK4, TAK1: Intracellular signalling molecules; no known potential hazards.

SMAD2, SMAD3, SMAD4, SMAD7: TGF-beta signalling proteins; no known potential hazards.

vi) Viruses

TK39: Herpes simplex virus mutant; no known potential hazards.

vii) Telomerase for immortalisation (inserts for retro-/lentiviral expression)

hTERT: Human telomerase reverse transcriptase (hTERT), contained in pBABE-hTERT retroviral vectors; hTERT has immortalization and therefore oncogenic potential.

viii) Inserts for retro-/lentiviral expression

CD1d: See above

HLA-C: See above
Evaluation of foreseeable effects

The likelihood that exposure to GMOs would have consequences to the health of humans is low.

E. coli harbours the potential of causing infection to humans, however, E.coli lines are attenuated and non-infectious, therefore they are unlikely to cause any harm to human health.

Mammalian cell lines may have oncogenic potential, however these have very stringent requirements for growth and are very susceptible to dehydration and to exposure of ultraviolet light radiation. Outside the hosts from which they are derived, growth and survival requirements can only be met using specialised media, the correct temperature range, optimum pH and an adequate oxygen concentration. These contraints mean that the cell line as well as primary cells will pose minimal risk to both human health and environment.

Lentiviral vectors have been modified to reduce cytototoxicity and reduce their ability to replicate. The supply of viral packaging from separate plasmids makes the associated risks of using the vector system low. hTERT has oncogenic potential and so care must be taken to avoid exposure to this gene by working at containment level 2.

Inserts are not known to be hazardous although some may have oncogenic potential as they have a possible role in cell proliferation; therefore all inserts are cloned in non-mobilized vectors.

Lenti and retroviral preparations are checked for replication incompetence prior to use.

Any mammalian cells transduced by the above methods may harbour oncogenic potential, so all procedures will be carried out at containment level 2, and decontamination, autoclaving procedures will minimise any risk of transfer to humans or the environment. Safe working laboratory practices will be followed. Personal protection equipment e.g., lab coat and disposable nitril gloves will be worn.

In order to minimize exposure risk, use of sharps will not be used when there is a reasonable alternative.

The potential hazard to the environment is low as there are stringent containment procedures in place which include aseptic techniques, decontamination and autoclaving procedures. Such procedures will ensure that the risk of transfer of any genetic material to wild-type organisms will be effectively zero.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The likelihood of exposure to humans is low. There is a regulatory requirement for suitable protective clothing to be worn. Specified disinfection procedures are in place and effective disinfectants are available for use. All waste material containing viable GMO are inactivated by validated means before disposal before final disposal. Refer to Section 12.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste likely to be contaminated with GMO is collected in autoclavable bags, supported in rigid container and autoclaved prior to disposal. Autoclave cycle 121
degrees Celcius for 20 mins. Following decontamination, the waste is incinerated.

Autoclaves are validated annually and insured by Sun Alliance.

Liquid waste is treated with 2% Virkon (final concentration) or Presept (10,0000 pm) or other appropriate commercially available disinfectants may be used according to the manufacturer's instructions for 100% kill.

The GMRA reviewed on 7th April 2011 and approved as suitable and sufficient for Containment level 2 activity by the King's College London School of Medicine Biological Safety Committee.

Primary human keratinocytes

Host/vector system

GENOME NON-INTEGRATING VIRUSES We will use modified multi-attenuated self-inactivating (SIN) lentiviral vector pHR'SIN, devoid of all accessory and potentially pathogenic genes. The vectors encode either one (Oct4) or more (Klf4, Sox2, c-Myc and LIN28) reprogramming factors as well as either d2eGFP or mCherry. The vectors are synthesized by GeneArt AG, Germany (www.geneart.com).

GENOME INTEGRATING VIRUSES The Stemgent Lentivirus Set, distributed by Sigma Aldrich, which consists of four lentiviruses, each of which is capable of expressing one of the four (LIN28, Oct4, Sox2, Klf4) reprogramming transcription factors when transduced into mammalian cells.

Origin & function

The purpose is reprogramming of adult cells into pluripotent state. All genes that involved in induction of reprogramming (Klf4, Sox2, c-Myc, Lin28, Oct4) are of human origin. c-Myc and Klf4 proteins are reported to demonstrate oncogenic properties.

mCherry and d2eGFP are used to monitor transduction. mCherry is a modified gene from the marine anemone tetrameric Discosoma striata encoding red fluorescent protein. d2eGFP is a modified gene from the jellyfish Aequorea victoria encoding green fluorescent protein.

Evaluation of foreseeable effects

HR'SIN-cPPT-SEW lentiviral vectors will be of SIN configuration and thus replication defective and incapable of spreading.

Stemgent lentiviral vectors:
The platform used by Stemgent eliminates hazards of autonomous replication during the packaging process by combining a disabled viral genome with a unique manufacturing process. Also, gene functions that facilitate the enclosing of the silencing sequence in a viral capsid (e.g., Gag, Pol, Env) are distributed into multiple helper plasmids (which do not contain significant regions of homology) during packaging. This tactic further minimizes the probability of recombination events that might otherwise generate viruses capable of autonomous replication. With these safety measures in place, the Stemgent IPS cell Lentivirus particles are to be employed only in standard Containment Level 2 tissue culture facilities and should be treated with the same level of caution as with any other potentially infectious agent.

LIKELIHOOD OF EXPOSURE: Low. The work is done exclusively in a microbiological safety cabinet (MSC). Moreover, because of working in a CL2 lab, personnel will use labcoats and nitrile gloves at all times. Nitrile gloves are the most protective gloves when compared with vinyl and latex gloves as they have better barrier protection.
properties. Both the gloves and labcoats are disposable. Personal Protective Equipment (PPE) required: nitrile gloves and labcoat. Facemasks are required to protect sterility of the lab. Personal Protective Equipment and facemask to be used at all times. Aseptic technical work to be performed only within a MSC.

CONSEQUENCES OF EXPOSURE: If the worker becomes exposed to virus, the likely route would be a spill or splash onto exposed skin. Even if this were to happen, infection is extremely unlikely due to the protective layer of stratum corneum of epidermis.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All solid non-sharp material (gloves, cell cultures, plasticware) is disposed into yellow medical waste bags that will be incinerated.

All liquids are treated with 1% Virkon® S solution for 4 h before disposal.

Serological pipettes and pipette tips are placed in doubled thick plastic autoclave transparent bags and autoclaved before being incinerated. The autoclave decontamination cycle lasts a minimum of 45 min at 134°C (the time is increased according to the amount of waste to be treated). The autoclaved waste is then put in a yellow sharp bin, which is closed and tagged. This yellow bin is then disposed through the normal hospital waste stream.

Is an emergency plan required according to regulation 20?

02/03/2022
The objective of this programme is to investigate pathogenic mechanisms important in Huntington's Disease and to validate therapeutic targets by the following approaches:

1) The generation and characterization of cell culture models of HD (including primary cell lines)
2) The manipulation of the levels of genes of interest in cell culture models of HD (including primary cell lines).

The studies involve the use of standard containment level 1 molecular biology techniques using plasmid vectors with human or mouse genomic DNA or cDNA inserts in bacterial hosts and commercially available mammalian cell lines. We will also carry out gene silencing studies (siRNA or miRNA) using adenoviral, adenovirus associated (AAV), lentiviral or retroviral systems in the above hosts.

A proportion of these gene silencing studies, however, will be performed in primary human cell lines derived from HD patients / unaffected controls and will be carried out at containment level 2.
possibility of transduced cell lines colonising laboratory workers. The likelihood of any cell lines, primary or otherwise, existing outside the tissue culture environment is effectively zero. There is no potential for oncogenicity and likelihood of deleterious consequences is effectively zero.

Host/vector system

While all vector systems used are CL1, all experiments involving primary human cell lines will be at CL2. Lentiviral, adenoviral, AAV and retroviral work involving E.coli and commercially available mammalian cell lines, although assessed at CL1, will also be performed under CL2 conditions as an additional precaution. All vector handling (after suitable staff training) will be within a Biosafety cabinet and PPE worn. Efforts will be made to limit the use of needles and other sharps. Solid and liquid waste will be autoclaved prior to disposal, work surfaces regularly decontaminated e.g 10% bleach and disposable gloves regularly changed. Standard Operating Procedures and Risk Assessments will be in place and rigorously adhered to.

Gene silencing in cell lines (siRNA or miRNA) will be carried out using lentiviral, retroviral, adenoviral or adenovirus associated (AAV) vectors. These commercially available vectors are replication incompetent due to deletion of essential genes. The necessary genes are supplied in trans on helper plasmids and cell lines, making the associated risks of using these vectors extremely low as detailed below for each vector system:

Lentiviruses: Lentiviral vectors can transduce human cells, presenting a risk to investigators. This risk will be reduced to a minimum using the precautions outlined in the preceding paragraph. Furthermore, the commercial lentiviral vector is replication incompetent due to large deletions. The coding sequences of the two packaging constructs cannot undergo recombination with the infectious virion which itself contains less than 5% of original wild type viral sequences. The probability of a replication competent vector being generated via homologous recombination with wild type virus or packaging construct rescue is therefore negligible. This would require multiple homologous recombination events including recombination with wild type HIV, which is never introduced in the production process. Therefore, the lentiviral vectors are non-viable and there is no potential for the release of infectious virus from the cell line. Irrespective of the low risk, vectors are tested to ensure that they are not replication competent. Current lentiviral vectors have minimal effect on the mammalian immune system and there is no reason to expect that any of the inserts will increase an immune response.

Adenoviruses: The adenoviral vector plasmid pAdEasy-1, containing most of the human adenovirus serotype 5 (Ad5) genome, is deleted for the genes E1 and E3. The removal of these two viral genes creates space for foreign DNA and eliminates self replication capabilities. Therefore, the adenoviral vectors are non-viable and are there is no potential for the release of infectious virus from the cell line. Irrespective of the low risk, vectors are tested to ensure that they are not replication competent. AdEasy vector is non-insertional: Because the recombinant adenovirus remains epichromosomal in the human host cell, there is only a remote possibility of activation or inactivation of host cell genes resulting from interruption by the transfected gene(s). Current adenoviral vectors have minimal effect on the mammalian immune system and there is no reason to expect that any of the inserts will increase an immune response.

AAVs: Adeno-associated viruses (AAVs) are derived from defective paroviruses, which depend on essential helper functions provided by other viruses, such as adenovirus and herpes virus, for efficient viral replication and propagation. AAV has no etiologic association with any known diseases and has been successfully used to establish efficient and long-term gene expression in vivo in a variety of tissues without significant cellular immune responses or toxicity. The rep and cap genes have been removed from the viral vector that contains AAV-2 ITRs and are supplied in trans on the plasmid pAAV-RC. Remaining adenovirus gene products required for the production of infective AAV particles are supplied on the plasmid pHelper (i.e. E2A, E4, and VA RNA genes) that is co-transfected into cells with human AAV vector DNA. The remaining adenoviral gene product is supplied by the 293 host cells, which stably express the adenovirus E1 gene. Therefore, the AAV vectors are non-viable and there is no potential for the release
of infectious virus from the cell line. Irrespective of the low risk, vectors are tested to ensure that they are not replication competent.

Retroviruses: pLPCX does not contain the structural genes (gag, pol, and env) necessary for particle formation and replication; however, these genes are stably integrated into PT67. Subsequent introduction of pLPCX, containing Ψ+, transcription and processing elements, and the gene of interest produces high-titer, replication-incompetent infectious virus. These retroviral particles can infect target cells and transmit the gene of interest (which is cloned between the viral LTR sequences), but cannot replicate within these cells since the cells lack the viral structural genes. The separate introduction and integration of the structural genes into the packaging cell line minimizes the chances of producing replication-competent virus due to recombination events during cell proliferation. Therefore, the retroviral vectors are non-viable and there is no potential for the release of infectious virus from the cell line. Irrespective of the low risk, vectors are tested to ensure that they are not replication competent. Current retroviral vectors have minimal effect on the mammalian immune system and there is no reason to expect that any of the inserts will increase an immune response.

**Origin & function**

All genetic material is of mouse or human origin, apart from GFP/EGFP (jellyfish Aequorea victoria), luciferase (firefly Photinus pyralis) and B-galactosidase (bacterial origin).

The genetic material will be used to determine its functional role in the pathogenesis of Huntington’s disease, for example:

Human or mouse genomic DNA, for example Huntingtonin (Htt), a protein involved in cell signaling, transport and protection against apoptosis, which in HD, is mutated by a poly-glutamine triplet repeat expansion within the first exon, leading to protein mis-folding and subsequent disruption of protein/protein interactions. Other inserts encode genes which are dysregulated in HD such as Histone Deacetylase 4 (Hdac4), a regulator of gene expression and Heat Shock Factor 1 (Hsf1), a heat stress induced transcription factor. Inserts will come from pre-existing plasmid, cosmids or BAC clones, from mouse tissue or cell lines, or from human cell lines (not primary and not diseased). These genes are not oncogenes and have no oncogenic potential. They do not encode toxins, antagonists of tumour suppressors or other cell cycle genes. We will not prepare large volumes of vectors containing these genes. There is no potential hazard from these genes or their products.

**Evaluation of foreseeable effects**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Plasmids: Solid waste is autoclaved within the department, following which it is placed into griff bins and sent for incineration by licensed contractor. Autoclave and cycle time: 134°C, 20 min for 100% kill. The efficiency of autoclaving is monitored using autoclave instrumentation, chemical and biological indicators (B. stearothermophilis). Liquid waste is disinfected with 1% w/v Virkon overnight and washed down the laboratory sink.

Lab coats are worn in the laboratory at all times. Latex gloves are worn for bacteriological work. Nitrile gloves and
powder free gloves are available for staff allergic to latex and powder. SOPs are followed for microbiological and cell culture work as described in the Departmental codes of practice.

The project proposal was reviewed by the GMSC for KCL School of Medicine 4th August 2011. The project was approved subject to minor amendments.

### Project Additional Information

**Purposes of the contained use**

The purpose of this project is to study the effect of Retinoic Acid (RA), a metabolite of Vitamin A, on the immune system. Understanding how RA impacts on immunity has profound implications in global health as well as the management of immune related diseases, like Multiple Sclerosis, Rheumatoid arthritis and Lupus.

**Recipient or parental organism**

For experimentation recombinant Listeria monocytogenes (Lm) has previously been engineered by insertion of the gene encoding the 2W1S peptide.

**Host/vector system**

N/A

**Origin & function**

2W1S peptide

The 2W1S peptide is a variant of an I-Ab-binding peptide from the α chain of the murine I-Ed MHCII molecule. This petide will prime 2W1S specific T cells.

**Evaluation of foreseeable effects**

The likelihood that exposure to GMOs would have consequences to the health of humans is low.

In order to minimize exposure risk, use of sharps will not be used when there is a reasonable alternative.

The potential hazard to the environment is low as there are stringent containment procedures in place which include aseptic techniques, decontamination and autoclaving procedures. Such procedures will ensure that the risk of transfer of any genetic material to wild-type organisms will be effectively zero.

Listeria monocytogenes (Lm) ΔactA-2W1S has been attenuated by the targeted deletion of the actA locus (Lm ΔactA-2W1S). The listerial actA gene is required for polymerization of host actin into filaments, which allows cell-cell spread using components of the host cell’s actin cytoskeleton. Thus the Lm ΔactA strain is unable to spread from cell-cell, and displays a three order of magnitude decrease in virulence without interfering with immunogenicity.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The likelihood of exposure to humans is low. There is a regulatory requirement for suitable protective clothing, specifically side fastening lab coats and gloves, to be worn. All activity with Lm restricted to CL2 laboratories and Class II MSCs. Specified disinfection procedures are in place and effective disinfectants are available for use. All waste material containing viable GMO are inactivated by validated means before disposal before final disposal. Refer to Section 12.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste and cell suspensions to be treated with 1% w/v Virkon solution as directed by the manufacturers protocol and then poured to drain. All plastics that have come into contact with GMOs are to be treated with 1% w/v Virkon as directed by the manufacturers protocol and then bagged or placed in sharps bins (pipette tips and serological pipettes) for off-site incineration.

Project Ref 386/12.3
The remodelling of a variety of pathological vascular lesions such as venous thrombi, atherosclerotic plaques, intimal hyperplasia, aneurysms, other venous diseases and chronic venous ulcers may be characterised by similar processes. Inflammatory cells, neutrophils, lymphocytes & monocytes, invade the lesion and may release transcription factors, chemokines, growth factors and proteases, which orchestrate tissue remodelling. The roles of these molecules are largely undefined. The work outlined in our proposal includes creating vectors for increasing or decreasing the expression of various proteins in models of venous disease. These studies include introducing viral vectors into primary human blood cells.

Recipient will be macrophages isolated from human donors.

The vectors to be used are attenuated adenoviral, adeno-associated viral, retroviral or lentiviral vectors. These will be designed to express wild type proteins, constitutively active or inactive mutants, or to produce siRNA to knock-down native protein levels. We wish to characterise the effects of these alterations on macrophage function in in vitro experiments. The adenoviral vector to be used is serotype 5 with deletions of the E1 and E3 regions. The probability of reversion to wild type is very low, as the deletions are non-contiguous, making rescue by homologous recombination with wild type adenovirus very unlikely. The adenoassociated virus is serotype 2 containing woodchuck hepatitis post-transcriptional regulatory element sequences and is missing rep and cap genes, which are essential for replication and packaging. The retrovirus to be used carries a macrophage-specific promoter, is based on the Maloney murine leukemia virus, and has deletions of essential promoter and enhancer elements in the 3' long terminal repeat, making the vector self-inactivating (SIN). Packaging genes are deleted. The lentivirus is third generation VSV-G pseudotyped and is replication-incompetent.
| Human hypoxia factor 1alpha (HIF1α); wild type and protease-resistant mutant; transcription factor sensitive to low oxygen levels which promotes the formation of blood vessels. |
| Human tissue plasminogen activator (tPA); serine proteinase which converts plasminogen into plasmin, which breaks down fibrin clots. |
| Human urokinase-type plasminogen activator (uPA); serine proteinase which converts plasminogen into plasmin, which then breaks down fibrin clots. |
| Human vascular endothelial growth factor (VEGF); promotes the formation of blood vessels. |
| Human placental growth factor (PLGF); promotes the formation of blood vessels. |
| Human nuclear factor of activated T cells (NFAT); family of transcription factors involved in immune responses. |
| Human forkhead box protein C2 (FOX-C2); transcription factor involved in development of varicose veins. |
| Human GATA transcription factors; involved in regulation of gene expression in haematopoietic cells. |
| Human TIE2 receptor; tyrosine protein kinase which acts as a cell-surface receptor for angiopoietin1, 2 and 4, regulating angiogenesis, endothelial cell survival, proliferation, migration and adhesion. |

**Origin & function**

All of the viral vectors to be used are attenuated and unable to reproduce without laboratory-specific helper cells to provide essential deleted genes in trans. In the intended recipient cells, the vectors are expected to express the specific proteins cloned into the vector, sometimes together with marker proteins such as green fluorescent protein, or to suppress the expression of native proteins. The expression or loss of the various proteins is anticipated to modulate the response of macrophages to various added factors, which will be tested in in vitro experiments. The modification of human macrophages in a contained manner is not likely to present a hazard.

The accidental inoculation of personnel with modified macrophages should also not be a hazard, as the cells should be rapidly cleared by the immune system. Laboratory workers will not be allowed to work with their own modified macrophages.

Exposure of workers to viral vectors should also result in rapid clearance by the immune system. Any vectors which manage to infect cells will be unable to reproduce, so any effect of transgene expression should be minimal. There is a small risk of insertional mutagenesis if retroviral vectors integrate into a workers chromosome; however, this has never been documented in laboratory workers.

**Evaluation of foreseeable effects**

All of the viral vectors to be used are attenuated and unable to reproduce without laboratory-specific helper cells to provide essential deleted genes in trans. In the intended recipient cells, the vectors are expected to express the specific proteins cloned into the vector, sometimes together with marker proteins such as green fluorescent protein, or to suppress the expression of native proteins. There is a small risk of insertional mutagenesis if retroviral vectors integrate into a workers chromosome; however, this has never been documented in laboratory workers.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

None under the current project

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None requested

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All solid waste (tips, serological pipettes, tissue culture plastic, vials and other containers) disinfected by immersion in 10 % Microsol3+ overnight. After rinsing with water, plastic waste is disposed of via clinical waste stream (orange bags).

For liquid waste, Microsol3+ is added to 10 % and left overnight. Waste is then flushed down drain with lots of water. Surfaces are wiped down with 10 % Microsol3+.

Microsol3+ is effective against bacteria, fungi and viruses, and overnight incubation at the stated dilution should result in 100 % kill.

### Project Additional Information

#### Purposes of the contained use

The overall aim of this project is to study immune regulation in humans during steady state (health) and during inflammation, with a focus on rheumatic disease. More specifically, it aims to uncover cellular and molecular mechanisms via which the inflammatory processes is initiated and regulated and how this is altered by therapeutic agents.

The specific objectives of this project are:

1) To generate expression vectors for select candidate genes of interest for transient expression of proteins in mammalian cell lines and primary human cells. The vectors will co-express fluorescence marker proteins such as GFP.

2) To knock down or decrease expression of genes using siRNA/ microRNA approaches in mammalian cell lines and primary cells.

#### Recipient or parental organism

Recipient cells - Human mononuclear cells - primary and cell lines; bacterial cells - E. coli (DH10b strain) for vector propagation.

Source genes - Various human genes (detailed in the sections below), enhanced green fluorescent protein (eGFP) originally from jelly fish, as a marker of exogenous gene expression and specific antibiotic resistances genes (Ampicillin and Kanamycin) for vector propagation in E. coli.

#### Host/vector system

**HOSTS**

- **i. For vector generation**
  - E. coli DH10b - Standard lab strain, allows replication of large vectors at high copy number. Genotype: araD139 Δ ara-leu7697 fhuA lacX74 galK (Φ80 Δ lacZM15) mcrA galU recA1 endA1 nupG rpsL (StrR) Δ(mrr-hsdRMSmcrBC)
  - **ii. For experimentation**
    - Human peripheral blood T cells and monocytes - Isolated from peripheral blood of healthy donors and arthritis patients
    - Human synovial fluid T cells and monocytes - Isolated from synovial fluid collected from the inflamed joints of consenting arthritis patients
    - HeLa cell line - Well established human cervical carcinoma cell line (ATCC #: CCL-2)
    - HEK293T cell line - Human Embryonic Kidney cell line variant of the HEK293 cell line expressing the SV40 large Tantigen (ATCC #: CRL-11268)
    - HL-60 - Human promyelocytic cell line (ATCC #: CCL-240)
    - Jurkat - Human T-cell leukaemia cell line (ATCC #: TIB-152)
    - THP-1 - Human monocytic leukaemia cell line (ATCC #: TIB-202)
    - U937 - Human histiocytic lymphoma monocyte cell line (ATCC #: CRL-1593.2)
    - CEM - Human acute lymphoblastic leukaemia cell line (ATCC #: CCL-119)

**VECTORS**

- pCMV-SPORT6 - Mammalian expression vector with CMV promoter and Ampicillin resistance gene. Commercially available from Invitrogen.

    - CEM - Human acute lymphoblastic leukaemia cell line (ATCC #: CCL-119)

**VECTORS**

- pCMV-SPORT6 - Mammalian expression vector with CMV promoter and Ampicillin resistance gene. Commercially available from Invitrogen.
pCA-IRES-eGFP - Mammalian expression vector with CMV enhancer and chicken beta actin promoter with an IRES GFP reporter and Ampicillin resistance gene; kind gift of Dr L. Carlin, King's College London.

pEGFP-N1 Mammalian expression vector with CMV promoter eGFP reporter and Kanamycin resistance gene; kind gift of G. B, King's College London.

Origin & function

Except for the selection/marker genes (eGFP, ampicillin resistance), the sequences of the genes to be over-expressed are to originate from human cells. All vectors will be introduced into E. coli with the sole purpose of propagating the vector, and not for any expression studies. Expression of the genes/vectors in human cells will be for the sole purpose of studying the features and functions of the protein encoded by the genes in an entirely in vitro system; the vectors will not be introduced into living animals.

Evaluation of foreseeable effects

Genetic sequences to be inserted

Name: Human CADM1 gene
Function & potential hazards: Cell surface expressed adhesion molecule. CADM1 was originally identified as a tumour suppressor gene (TSLC1: Tumour suppressor in Lung Cancer 1), however this project aims to examine its role in chronic inflammatory conditions rather than in cancer. The gene is normally expressed in very rare populations of healthy blood cells (a DC subset, 0.05% of PBMC), and at very, very low levels in healthy monocytes, which is the cell type to be used for the experiments proposed here. Knockdown of this gene is intended to be carried out by transient siRNA transfection only; no stable knockdown experiments will be performed. As per routine practice in the laboratory, no staff member will perform these experiments on cells isolated from themselves, their close relatives or lab members closely involved in these experiments. With these precautions followed, the potential risk from this gene in the experiments proposed will be low.

Name: Human EGLN3 gene
Function & potential hazards: Intracellular protein involved in regulation of hypoxic responses of cells and activation of HIF-1/2 proteins. No known potential hazards expected on over-expression or knock down.

Name: Human IKZF3 gene
Function & potential hazards: A transcription factor involved in lymphocyte development. A member of the Ikaros family of transcription factors, IKZF3 (also known as Aiolos) plays an essential role in regulation of B-cell differentiation, proliferation and maturation. It is involved in regulating BCL2 expression and controlling apoptosis in T cells in an IL2-dependent manner. Aiolos expression may be dysregulated in chronic lymphocytic leukemia (CLL).
Over/underexpression of Aiolos in T/B cell lines could therefore form a potential hazard. As per routine practice in the laboratory, no staff member will perform these experiments on cells isolated from themselves, their close relatives or lab members closely involved in these experiments, and it is expected that only short-term cell culture experiments will be performed. With these precautions followed, the potential risk from this gene in the experiments proposed will be low.

Name: Human CRTAM gene
Function & potential hazards: Cell surface expressed on activated CD8 T cells and NK cells. No known potential hazards expected on over-expression or knock down.

Name: eGFP
Function & potential hazards: Commonly used fluorescent protein originally identified and cloned from jellyfish. No known potential hazards expected on over-expression.

Environment: No foreseeable effects on human health or the environment are anticipated provided that the safety precautions outlined below are followed.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

1. All GM work performed with human cells will be carried out in a certified microbiological safety cabinet, housed in a separate room (tissue culture room) in the main laboratory.
2. All GM materials will be thoroughly disinfected/de-activated prior to disposal as detailed in section 12 below.
3. Access to the laboratory where this work will be carried out is restricted to authorised, trained personnel only, who are allowed to work unsupervised. All users will be required to have read and signed the Laboratory Codes of Practice.
4. Spills - The following procedures will be followed in case of spills
   - Use biological spill kit
   - Allow aerosols to settle for 10 mins prior to clean up
   - De-activate/disinfect using 1% Virkon solution for 1h
   - Absorb the Virkon/spill with spill absorbent mats provided in the spill kit (located in Taams lab bay, window bench)
   - Dispose mats as follows:
     - For lab E.coli strains dispose off in biohazard bins
     - For human contaminated waste dispose mats off in specially marked biohazard bags (special bags for autoclaving human waste)
     - Place warning notice to indicate area of spillage
     - Dispose of plastic waste in biohazard waste bin

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste: All solid GM waste of human origin such as excess cells, or remaining unfixed cells after an experiment, as well as equipment/tubes contaminated with human waste, will be autoclaved (120°C for 20 min) on site first for full (100%) degradation before disposal for incineration with hospital waste.
Liquid waste: All liquid waste of GM human and microbial origin eg. culture supernatants will be decotaminated with Virkon at 10 g/L overnight for full (100%) killing/disinfection and disposed via the laboratory sink.
Sharps: All sharps and pipette tips contaminated with GM human waste will be collected in a yellow sharps bin clearly marked as containing human waste, autoclaved and disposed by incineration with hospital waste.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]
Tick to confirm that you have attached a risk assessment to this form [Y]
Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

Please enter comments on the GM safety committee on the risk assessment

The project was reviewed by the KCL School of Medicine Biological Safety Committee on 16th August 2012 and approved as Class 2 GM subject to minor amendments.

### Historical Significant Changes

- **Historical Date of Additional Info**
  - 

### Project Additional Information

#### Purposes of the contained use

- Production of retro and lentiviruses, transduction of cells with these viruses, plasmid amplification in bacteria, yeast 2-hybrid assays, transfection of mammalian cells.

#### Recipient or parental organism

- The E Coli host will be the multiply disabled K12 strain DH10b using a variety of well charaterised bacterial, mammalian and yeast expression vectors such as pCR3.1, pCAGGS, pGBKT7 and pBABE.
- The S cerevisiae (yeast) host will be Y190 using pGADT7 and pGBK7 vectors.
The mammalian recipients will be 293T, HeLa, BJ fibroblast and MCF10A cells and will be transfected with the above expression vectors purified from bacteria.

**Host/vector system**

The E Coli host will be the multiply disabled K12 strain DH10b using a variety of well charaterised bacterial, mammalian and yeast expression vectors such as pCR3.1, pCAGGS, pGBK7 and pBABE.

The S cerevisiae (yeast) host will be Y190 using pGADT7 and pGBK7 vectors

The mammalian host will be 293T cells and will be transfected with the above expresison vectors purified from bacteria.

**Origin & function**

cDNAs encoding numerous genes both wild type, point mutated and truncated forms. For the majority of these cloned inserts there is no evidence to suggest that any of the inserts have harmful effects.

To allow immortalisation of non-transformed cells, cells will be transduced with a plasmid allowing expression of human Telomerase and/or SV40 T-antigen (as for 293T cells described above). Positive controls such as H-Ras G12V will be used, with handling of H-Ras performed under CL2 conditions. No autologous cell lines will be used.

Individual viral genes that are important for virus assembly were provided from well characterised viral vector systems. There is no evidence that any single gene or protein has virulence potential in vitro. In addition, there is no documented risk associated with handling naked viral DNA under standard/controlled CL1 conditions. The lentiviral packaging system comprises some genes from HIV-1 but they do not constitute an infectious HIV-1. the retroviral packaging system comprises some genes from MLV. These inserts are introduced into cell lines under CL2 conditions, but vectors employed will always contain less than two-thirds of a provirus and cannot result in infectious virus production

**Evaluation of foreseeable effects**

All vectors, inserts and hosts described are not considered pathogenic. They are expected to have limited survivability in the environment and often have auxotrophic requirements, which are unlikely to be satisfied outside of laboratory culture.

The likelihood that any of the bacterial, yeast or eukaryotic cells could survive in a human host and/or transfer the inserted sequences to other organisms is effectively zero. All work with eukaryotic cells will be conducted in a microbiological safety cabinet, reducing the potential for aerosol transmission, and protective gloves, laboratory coat and safety goggles will be used.

In the majority of cases, vectors are simply being propagated using E.coli as the host, their encoded protein products are not expressed. The exception is the expression in yeast or bacterial expression vectors, however, there is no evidence that the expressed proteins presents toxicity.

The retro and lenti-viral vectors employed are multiply disabled and thus replication incompetent. Control measures for dealing with waste are detailed below.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

NA

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

NA

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
In all cases, GMOs will be inactivated by autoclaving (121 °C for 60 minutes for solid waste) or Virkon (1% v/v, overnight, for liquid waste, prior to disposal to the drains). Surfaces and instruments will be disinfected using 70% Ethanol. All disposables will be autoclaved prior to incineration. Autoclaves are serviced 6-monthly.

Historical Significant Changes

02/03/2022
Plasmids containing various gene constructs will be first amplified in bacteria and used to transiently transfect established mammalian cell lines. Amphototropic pseudotype lentiviruses will then be produced and used to deliver the gene constructs to other mammalian cells. The observed phenotypic changes in the recipient cells will be studied and recorded using routine molecular and cell biology laboratory techniques.

The recipient cell cultures will be of primary human epidermal cells, oral squamous cell carcinoma cells or established fibroblast cell lines. The expression of gene constructs which modify the regulation of cell differentiation or proliferation in the recipient cells is expected to produce an increase or decrease in cell division and altered differentiation states.

All epidermal cell cultures have been derived from clinical biopsies. The presence of adventitious pathogens would be more likely if cells were sourced from populations known to have an elevated prevalence of HepB, HepC, HIV, HPV or other pathogens. Therefore low risk patients are selected by interview prior to surgery at the time consent is given and those who have received blood transfusions or have a lifestyle likely to suggest a high risk infection with blood borne viruses, are excluded.

Genes encoding proteins involved in cell proliferation and differentiation will be cloned into plasmid vectors and used to transform bacteria. The E. coli host will be the multiply disabled K12 strain DH10b and a variety of well characterised bacterial, mammalian expression vectors such as pDONR221, pLX301 and pBABE will be used. The plasmid components of a lentiviral vector system will be purified from bacteria and used to transfect HEK293T cells resulting in the production of infectious pseudotyped amphotropic lentiviral particles.

The viral packaging plasmid, PsPAX2, contains genes for Gag, Pro, Pol, RRE and Ampicillin resistance. The envelope plasmid pMD2.G encodes VSV-G protein using a CMV promoter and Ampicillin resistance. pTRIPZ-shRNA plasmid is used for Tet-inducible shRNA constructs and also contains, IRES, tRFP, TRE, self-inactivating 3'SIN LTR and Puromycin resistance. pGIPZ-shRNA plasmid is used for constitutively active shRNA constructs and also contains CMV, RRE, tGFP, IRES, WPRE, self-inactivating 3'SIN LTR and Puromycin resistance.

Plasmids containing the genes of interest and viral assembly genes will be transfected into a mouse cell line and cultured for 24 to 48 hours. The virus will be collected in cell culture supernatants and transferred to other cultures of epithelial or fibroblast cells for the transfection process. The genes needed for packaging the construct into viral particles are present on three or more different plasmids that cannot by themselves be packaged into viral particles. This means that cells can be infected with viral particles made in packaging cell lines, but infectious viral particles cannot be made in the target cells. Exceptionally, the presence of adventitious "helper" retrovirus in a host cell could restore replication competence to the system. Although the components of virus production are present as individual genes in multiple vectors the process of stable integration into the host genome can not yet be predicted so the host and viral genes may be positioned to interact in a complimentary way which could cause cell proliferation. Many of the proposed gene constructs under study are themselves proto-oncogenes or components of mitogenic signalling pathways.

The VSV-G enveloped pseudotype particles have a wide host range which includes humans and expression of the cDNA gene constructs under study has the potential to...
give a proliferative growth advantage to the recipient or neighbouring cells, this can occur by the overexpression of modified proto-oncogenes (Myc, β-catenin, Tcf/Lef, MEK1, Ras, Raf, Rac, Rho, cdc42, PI3K) and pluripotency genes (Nanog, Sox2, Klf, Oct4) or by knocking down tumour suppressor genes. The constructs are modified to be constitutively active, inducibly activated, or have a dominant negative effect, e.g. Ephrins, and E-cadherin, components of the hedgehog signalling pathway (Delta, Notch, Sonic Hedgehog, Patched), TGF-signalling pathway (Smads), EGF-signalling pathway (LRIG) and α and β integrin subunits.

Commercially designed shRNA constructs will also be obtained which specifically target areas of interest within the human genome and prevent expression of individual genes. The recipient cells may acquire a growth advantage over normal or control infected cells as a result of subsequent direct or inadvertent modulation of cellular signalling pathways.

Evaluation of foreseeable effects

All vectors, inserts and host cells described are expected to have limited survivability in the environment and often have auxotrophic requirements, which are unlikely to be satisfied outside of laboratory culture.

The likelihood that any of the bacterial or eukaryotic cells could survive in a human host and/or transfer the inserted sequences to other organisms is effectively zero.

All work with eukaryotic cells will be conducted within a restricted laboratory area using a microbiological safety cabinet, reducing the potential for aerosol transmission, and personal protective equipment (gloves, laboratory coat) will be worn during all manipulations.

The lentiviral vectors employed are able to infect humans but are multiply disabled and thus replication incompetent so virus could not spread from cell to cell except in the presence of adventitious 'helper virus'. However accidental exposure resulting in infection and integration into the genome of lentiviral proto-oncogene inserts brings an increased risk due to the long term nature of the expression produced and the risk (albeit very low) of insertional mutagenesis producing tumorigenesis. Great care will therefore be taken to avoid the use of sharps, such as needles and scalpels, in the presence of infectious virus and any pre-existing skin lesions will be kept covered.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be inactivated by exposure to a final concentration of Virkon, 1% w/v solution for a minimum time of 10 minutes, according to the manufacturer’s instructions, prior to disposal to the drains. Surfaces and instruments will be disinfected using 1% Virkon followed by 70% ethanol.

Solid plastic waste will be exposed to Virkon, 2% w/v solution overnight and discarded into clinical waste bags or rigid plastic "Sharps" boxes which will be sealed before removal by a licensed contractor or incineration

Tick if you are claiming exemption from disclosure for section of the risk assessment N
The maternal and fetal disease group has a program of work that focuses on the aetiology of gestational metabolic disease. A particular focus of the research of the group is the mechanisms underlying Intrahepatic Cholestasis of Pregnancy (ICP), a relatively common (affecting 1 in 150 UK pregnancies) liver disease presenting with raised maternal serum bile acids; with potentially serious consequences for the fetus. To understand the molecular aetiology of this disease, a diverse research program is active. This includes genomic studies to identify susceptibility loci (SNP genotyping and sequencing (Sanger and NGS)) building on previous genetic studies. We are also...
performing in vitro and in vivo endocrine signalling experiments to determine the role of reproductive hormones in the disease. This is based on the group’s identification of cross-talk between bile acid and progesterone metabolite signalling pathways in the liver.

In addition the group have recently identified an in-utero “programming” effect of raised bile acids in a mouse model (offspring have a pre-diabetic phenotype) and this is being explored in further experiments, with analysis of the effect of circadian rhythms. Future work will expand from ICP to investigate gestational diabetes and gestational lipid derangements.

Clinical and translational studies (mostly at present at Imperial College London) are focused on the elucidation of mechanisms of adverse pregnancy outcomes and studies of the metabolic profile of women with ICP with an emphasis on analysis of gut-liver signalling (the FGF19 pathway).

Recipient or parental organism

Primary human cells:
- HUH7 cells (human hepatoma cell line - spontaneously immortal)
- HepG2 cells (human hepatome cell line - spontaneously immortal)
- BeQo cells (human coricarcinoma cell line - spontaneously immortal)
- HEK293 (human embryonic kidney cell line - adenviral transformation)
- HEK293T (human embryonic kidney cell line - adenviral transformation)
- HT29 (intestinal adenocarcinoma cells - spontaneously immortal)
- HT116 (intestinal adenocarcinoma cells - spontaneously immortal)
- CaCo 2 cells (intestinal adenocarcinoma cells - spontaneously immortal)
- NCI -H716 (colorectal adenocarcinoma cells - spontaneously immortal)

Host/vector system

E. coli TOP10
pcDNA3.1 (Life Technologies)
pBIND (Promega)
pGEX6P2 (GE Healthcare)
pGL3/4 (Promega)
pENTR1A (Life Technologies)
pAd/CMV/VS-dest from Invitrogen

Origin & function

mouse ppar-alpha - nuclear receptor which modulates cellular differentiation, metabolism and development. No known or expected hazard from expression
mouse ppar-gamma - Nuclear receptor which modulates cellular differentiation, metabolism and development. No known or expected hazard from expression.
mouse lxr-alpha - Nuclear receptor, controls cholesterol metabolism. No known or expected hazard from expression
mouse fxr - Nuclear receptor, sensor for bile acid levels. No known or expected hazard from expression
humsn lxr-alpha - Nuclear receptor, mediates the biological function of retinoids. No known or expected hazard from expression.
GFP - green fluorescent protein. No known or expected hazard from expression
2xLXR RE luc - Synthetic lxr response elements with luciferase gene. No known or expected hazard from expression
h ET-1 promoter sequence - The promoter sequence of endothelin-1 (vasoconstrictor) as cloned into a luciferase-expressing vector. No known or expected hazard from expression.

Evaluation of foreseeable effects

All of the cell lines and vector systems described above are commercial products that have a considerable history of safe use in laboratories around the world. The E. coli strains have a very little ability to survive in humans.

The gene products are not known to carry any specific risks. It is unlikely any significant hazard will occur as protein expression only happens in very small quantities.

All cells are performance assayed and test negative for HIV-1, mycoplasma, hepatitis-B, hepatitis-C, bacteria, yeast and fungi. Cell performance and characterization are
measured after recovery from cryopreservation. Clonetics™ Media are formulated for optimal growth of specific types of normal human cells. Certificates of analysis (COA) for each cell strain are shipped with each order.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste will be inactivated prior to disposal:
Solid waste will be autoclaved at 121°C for 30 minutes prior to incineration off-site by licenced contractor.
Liquid waste will be treated with Virkon (2% working solution) for 30 minutes then poured to drain.

02/03/2022

Page 6872 of 15326
The research group is interested in the function of a group of proteins that share a common protein domain, namely a zinc-binding motif. The proteins themselves are a diverse group with implication through mutation in leukaemia and breast cancer. The aim of this work is generally two fold:

1) To assess the biological impact of the expression of zinc finger proteins, in particular those identified to be targeted by the translocations in acute promyelocytic leukaemia (APL). We wish to target APL cell lines that closely mirror the naturally occurring disease. This procedure will involve inserting the gene of interest (e.g. SUMO1/2/3, PML-RARA, IRF2BP2-RARA) into a pMIG or pMSCVpuro retroviral vector and transfecting this construct into the Phoenix-Eco packaging cell line. We will use the pGIPZ lentiviral vector for RNAi studies in combination with pCMV-dR8.74 (gag, pol and rev) and pMD2.G (env) to produce lentivirus in 293T. The supernatant from these cells will be used to infect murine and human cell lines and murine primary cells (e.g. MEFs) in vitro.

2) To assess DNA damage repair and ubiquitin ligase activity in stem cells with BRCA1 mutations. The project aims to generate induced pluripotent stem (iPS) cells from a somatic cell line (keratinocytes). For the generation of iPS cells the CytoTune-iPS Sendai Reprogramming Kit (Invitrogen) will be used. Once the iPS cells are obtained, the work will be followed by irradiation of cells, Western blot and immunofluorescence analyses for DNA repair proteins and for ubiquitin ligase activity. The project also involves siRNA silencing of the BRCA1 gene.

Recipient or parental organism

HEK293T: Human embryonic kidney cells, derivative of the 293 cell line into which the temperature sensitive gene for SV40 T-antigen was inserted
Human hair keratinocyte cell lines: Somatic cell lines derived from patients with BRCA1 gene mutations
HeLa: Human cervical cancer cell line
COS-7: African Green Monkey SV40-transfected kidney fibroblast cell line
K562: Human immortalised myelogenous leukaemia cell line from a CML patient in blast crisis
NB4: Human acute promyelocytic leukemia cell line cytogenetically characterized by a t(15;17) (q22;q11-12)
translocation encoding the PML-RARA oncogene
NB4-LR2: Human acute promyelocytic leukemia cell line encoding a mutant form of the PML-RARA oncogene, retinoid maturation resistant
U937: Human monocytic cell line obtained from histiocytic lymphoma
U937-PR9: Human monocytic cell line obtained from histiocytic lymphoma with a Zn-inducible promoter which can switch on expression of the PML-RARA oncogene
KG1: Human acute myeloid leukaemia cell line, deficient in human p53
ME-1: Human acute myeloid leukaemia cell line characterized by an inv(16) (p13;q22) rearrangement encoding the CBF/MYH11 oncogene
Kasumi-1: Human acute myeloid leukemia cytogenetically characterized by a t(8;21) (q21;q22) translocation encoding the AML1-ETO oncogene
WI38: Human fibroblast-like fetal lung cell line

Common laboratory E. coli strains (DH5a, GeneHog, TOP10, XL1 Blue)

Mammalian cells
HEK293T cells: Human embryonic kidney cells, derivative of the 293 cell line into which the temperature sensitive gene for SV40 T-antigen was inserted
Phoenix-ECO: Derivative of HEK293T, second-generation retrovirus producer cell line for the generation of helperfree ecotropic and amphotropic retroviruses, contains constructs producing gag-pol and env

Non-viral vectors
DR-GFP (M. Jasin, Memorial Sloan-Kettering Cancer Center and Cornell University Graduate School of Medical Sciences, New York)
Vector to measure homologous recombination (HR), consists of direct repeats of mutated GFP genes: a full-length GFP mutated to contain an I-SceI site and a 5' and 3'-truncated GFP. Repair of the I-SceI-generated double-stranded break by HR results in GFP-positive cells; puromycin and ampicillin resistance gene
EJS-GFP (J. Stark, City of Hope Graduate School of Biological Sciences, Duarte, California)
Vector to measure non-homologous end-joining (NHEJ), contains a promoter that is separated from a GFP coding region by a puro gene that is separated by two I-SceI sites. Once double-stranded breaks are generated by I-SceI and the puro gene is excised by NHEJ repair, the promoter is joined to the rest of the expression region, leading to restoration of functional GFP; puromycin and ampicillin resistance gene
pGEMT-easy (Promega)
Linearised vector with a single 3'-terminal thymidine at both ends for ease of cloning, ampicillin resistance gene
pcDNA3.1 (Invitrogen, now Life Technologies)
High level stable and transient expression in mammalian hosts, CMV promoter, episomal replication in cell lines that are latently transfected with SV40 or express SV40 large T-antigen (e.g. COS-1 and COS-7), neomycin resistant
pBluescript (Stratagene, now Agilent)
For cloning and sequencing. Extensive polylinker with 21 unique restriction enzyme sites flanked by T7 and T3 RNA polymerase promoters that can be used to synthesize RNA in vitro, ampicillin resistance gene
pBluescript SK II+ (Stratagene, now Agilent)
For cloning and sequencing. PLac, lacZ, f1 (+) ori, pUC origin, ampicillin resistance gene
pEGFP-C2/N2 (Clontech)
Genes cloned into the multiple cloning site will be expressed as fusion proteins to the C- (C2) or N- (N2) terminus of EGFP (a red-shifted variant of wild-type GFP), SV40 origin of replication for expression in cells expressing SV40 Tantigen and a pUC origin, can make stable mammalian lines, Neomycin and kanamycin resistant, Herpes simplex
virus thymidine kinase allows G418 resistance.

pGL3 (Promega)
Luciferase reporter vector, SV40 promoter upstream of the luciferase gene, Col E1 and F1 origins, ampicillin resistant

pSG5 (Stratagene, now Agilent)
For expression, F1 origin, SV40 early promoter and polyadenylation signal, T7 promoter, β-globin intron II allows splicing of expressed transcripts, ampicillin resistant

pREP4-tk-luc (A. Zelent, Institute of Cancer Research, London)
Luciferase reporter vector, RSV LTV promoter, TK promoter, EBNA-1 gene, pUC origin, OriP, ampicillin resistant for expression in bacteria and hygromycin resistant for mammalian cell selection.

Viral vectors

pMSCVpuro (Clontech)
Retroviral vector, does not include gag, env or pol genes so is unable to replicate, has a CMV promoter, ampicillin resistant for bacterial expression, puromycin resistant for mammalian selection

pMIG (Addgene)
Retroviral vector MSCV 2.2 inserted with the internal ribosomal entry site (IRES)-GFP sequence, does not include gag, env or pol genes so is unable to replicate, has a CMV promoter, ampicillin resistant for bacterial expression, puromycin resistant for mammalian selection

pGIPZ (Thermo Scientific)
Lentiviral vector, tGFP, IRES, shRNA, WPRE, does not include gag, pol or env genes so is unable to replicate, has a CMV promoter, ampicillin resistant for bacterial expression, puromycin resistant for mammalian selection

pCMV-dR8.74 (Addgene)
Packaging vector, ColE1 Origin, GPT, CMV, Gag, Pol, RRE, ampicillin resistance

pVSV-G (Clontech)
Packaging vector, envelope plasmid, ColE1 Origin, CMV, IVS, VSV-G, ampicillin resistance

psPAX2 (Addgene)
Packaging vector, SV40 ori, CAG promoter, cPPT, RRE, HIV_Rev_NES, ampicillin resistance

pMD2.G (Addgene)
Packaging vector, envelope plasmid, CAG enhancer, CMV promoter, CMV2 promoter, Glob_int, VSV-G, pBR322 ori, ampicillin resistance

Sendai Virus Kit (Invitrogen, now Life Technologies)
Contains four SeV-based reprogramming vectors, each capable of expressing one of the four Yamanaka factors (i.e. Oct4, Sox2, Klf4 and c-Myc), 5 genes for viral proteins (starting from 3' end): Nucleocapsid protein, Phosphoprotein, Matrix protein, Hemagglutinin-Neuraminidase and Large protein. The gene encoding the Fusion (F) protein has been deleted, rendering the virus incapable of producing infectious particles from infected cells. In addition, the presence of functional mutations such as temperature sensitivity in the amino acid sequence of several SeV proteins (SeV/TSΔF, SeV/TS12ΔF, and SeV/TS15ΔF) renders the vectors easily removable from transduced cells.

Origin & function

P65: Human, wild-type, transcription factor, NFkB
SUMO1/2/3: Human, wild-type, protein modifier, will be inserted into viral vectors
BRCA1: Human, wild-type and mutant, oncogene involved in breast cancer, siRNA
Ubiquitin: Human and mouse wild type and mutant, protein modifier
OCT3/4: Human, wild-type, transcription factor, marker for undifferentiated cells, in SeV
SOX2: Human, wild-type, transcription factor, pluripotency marker, proto-oncogene, in SeV
KL4: Human, wild-type, transcription factor, pluripotency marker, proto-oncogene, in SeV
C-MYC: Human wild-type transcription factor, proto-oncogene, in SeV
PLZ: Human and mouse, wild type and mutant, can be pro-oncogenic when fused to RARA
PML: Human and mouse, wild type and mutant, can be pro-oncogenic when fused to RARA
RARA: Human, wild-type, transcription factor, fused to various partner genes in APL
PML-RARA: Human, wild-type and mutant, oncogene that can cause APL, will be inserted into viral vectors
PLZ-RARA: Human, wild type, oncogene that can cause APL
IRF2BP2-RARA: Human, wild type and mutant, oncogene that can cause APL, will be inserted into viral vectors
P50-RARA: Murine, mutant transgene, fusion protein that causes permanent dimerisation of retinoic acid receptor alpha (RARA)
elF4E: Murine, eukaryotic translation initiation factor that directs ribosomes to bind to the mRNA cap, also involved in mRNA transport from the nucleus
RFP: Red fluorescent protein
PRH: Human, involved in cell proliferation and differentiation
TRAP1: Human and mouse, wild-type, hsp90-related protein, molecular chaperone involved in cell signalling, protein folding and morphologic evolution
HSP90: Human, wild-type, molecular chaperone involved in cell signalling, protein folding and morphologic evolution
HGF promoter: Human, wild-type and mutant, paracrine cellular growth, motility and morphogenic factor
STAT3: Human, wild-type and mutant, transcription factor, proto-oncogene

Evaluation of foreseeable effects

Hazards to human health
Although the effects are ultimately unknown, the likelihood of transfected or primary cells surviving outside the tissue culture environment is effectively zero. No adventitious agents are known to be secreted from the cell lines used in this project.

The viral vectors used in this project are all replication defective. Therefore, they cannot undergo more than a single round of transduction and establish a productive infection in an individual. Most of the original viral genome of the retroviral/lentiviral vectors has been deleted such that disease-causing genes are absent and the pathogenicity of the vector markedly reduced compared to the parental strains. Infectivity of the resulting virus is only possible via packaging constructs/cell lines. Similarly, SeV vectors used in the Sendai virus kit are no longer capable of producing infectious particles from infected cells because the viral genome lacks the F-gene.

Second and third generation lentiviral vectors usually elicit a relatively low immune response compared to nonintegrating vectors. As well as having minimal effect on the mammalian immune system, there is no evidence to suggest that the gene products or any of the inserts will increase any immune response. Human is not a natural host for the SeV and this virus is not pathogenic to humans.

In case of accidental exposure, the use of retroviral/lentiviral vectors carries a risk of triggering oncogenic events in transduced cells by upregulation of cellular protooncogenes at the site of vector integration (insertional mutagenesis). The genotoxic risk is greatly reduced for the pGIPZ lentivector due to self-inactivating (SIN) 3’ LTR. Additionally, the retroviral vectors containing oncogenic inserts such as leukaemia-associated fusions (i.e. PML-RARA, IRF2BP2-RARA) are more likely to induce tumourigenesis. Other oncogenes (i.e. c-MYC, SOX2, KLF4) will only be delivered via SeV reprogramming vectors. Since SeV does not integrate into the host genome and remains in the cytoplasm there is no risk of insertional mutagenesis. Moreover, the host cell can be cleared of the vectors and reprogramming factor genes by exploiting the cytoplasmic nature of SeV and the functional temperature sensitivity mutations introduced into the key viral proteins. To minimise the likelihood of accidental exposure, only low volumes of viruses will be used and the work will be conducted following all safety rules for working in a Containment Level 2 (CL2) facility.
Hazards to the environment
The likelihood of the GMO surviving in the environment is effectively zero. The likelihood of transfected or primary cells surviving outside the culture environment is low. The viral vectors used in this project have a short half-life outside a host cell and are replication deficient so they would not be able to reproduce. Attenuated E. coli strains are dependent on nutrients supplied in specialized media and therefore do not persist in the environment. The risk of transfer of genetic material to wild-type organisms is effectively zero. The retroviral/lentiviral vectors used in this project are replication incompetent and therefore would not be able to reproduce and infect wild-type organisms. Wild-type SeV is highly contagious in host species (i.e. rodents), but the infection does not persist in immunocompetent animals. In addition, the SeV genome in the kit is missing its F-protein, rendering the virus incapable of producing infectious particles from infected cells

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be soaked in a disinfectant with a proven wide spectrum virucidal, bactericidal and fungicidal activity (1% Virkon, VWR) overnight to achieve greater than 99.999% kill prior to sink disposal. Solid waste, such as tissue culture flasks, tips, etc., will be soaked in 1% Virkon prior to autoclaving. Autoclave bags will be closed when ¾ full and autoclaved at 121°C for 30 minutes then transferred for incineration.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
The project was reviewed by the School of Medicine Biological Safety Committee on 11th April 2013 and approved the project at GM Class 2 subject to minor amendments

## Project Additional Information

### Purposes of the contained use

Lentiviral vectors pseudotyped with filoviral surface glycoproteins will be used to study the cell biology and immunology of filoviruses.

### Recipient or parental organism

1. Transformed human, primate or murine cell lines cultured by standard procedures.
2. Isolated human primary leukocytes subsets (macrophages, dendritic cells, T cells and B cells) used to assess the host range of the filoviruses and the response of these cells to lentiviral challenge. These cells will be isolated from healthy donors with informed consent.
3. Primary murine leukocyte subsets.

### Host/vector system

**HOSTS:**
1. E. coli DH5a or DH10b bacterial strains will be used as hosts for the propagation of the plasmids by standard methodologies.
2. Transformed human embryonic kidney cell line HEK293T will be used as mammalian cell hosts for the production
3. Yeast (S. cerevisiae) Y190 will be used for yeast-2 and 3-hybrid assays examining interaction of human and individual filovirus proteins.

VECTORS:
- Filoviral glycoprotein pseudotyping of lentiviral or retroviral vectors:
  The cellular biology of Ebola virus entry into a target cells will also be investigated using gammaretrovirus or lentivirus vectors pseudotyped with filoviral glycoproteins. These are regular replication defective MLV or HIV-based vectors produced from 3 plasmid transfections including the genome plasmid containing a reporter gene (eGFP, RFP, Firefly luciferase, Beta-galactosidase), a Gag-Pol packaging plasmid and an Ebolavirus glycoprotein expression vector instead of standardly used VSV-G expression vector. These will be used in experiments when only GP function is being assayed. The only filovirus protein expressed in this system is the glycoprotein. These vectors are well characterized in the literature and are non-hazardous.
- The plasmid vectors expressing genes under contained use:
  All individual filoviral proteins will be expressed from the mammalian expression vector pCR3.1, pCAGGS for transfection in 293T cells, or pGBK7 or pGADT7 for expression in Yeast 2 hybrid assays.

ORIGINS:
Glycoprotein genes cloned into pCAGGS will be used from the Ebolavirus strains Zaire, Sudan, Reston, Tai Forest and Budibungyo and from the related Marburg virus.

Plasmid propagation:
• All plasmids will be propagated in E coli DH5alpha, DH10b or STBL2 bacteria by standard methodologies. Plasmids will be purified by Qiagen kits or commercial equivalents. All bacterial strains are multiply attenuated and pose no risk to handlers.

Production of lentiviral vectors pseudotyped with filoviral envelopes:
• HEK293T cells will be transiently transfected with a lentiviral vector genome encoding a reporter gene (mainly eGFP or mCherry fluorescent proteins) along with a standard HIV-1-based vector packaging plasmid supplying the lentiviral structural proteins and enzymes, and expression vectors for various strains of filoviral GPs (see below). 48h post transfection, lentivectors will be harvested and target cells challenged, with read-out being fluorescent protein expression by FACS.

Yeast assays:
Yeast (S. cerevisiae):
Yeast are used for yeast-2-hybrid and yeast-3-hybrid assays to test for protein:protein interactions between selected EBOV proteins and human proteins. Plasmid expression vectors containing biosynthetic selectable markers and encoding genes of interest fused to GAL4 activation or DNA binding domains are transformed into exponentially growing Y190 cultures. Selected transformants are then tested for beta-galactosidase expression.
Evaluation of foreseeable effects

Retroviral/lentiviral vectors:
MLV-based oncoretroviral vectors and HIV-based lentiviral vectors. HIV naturally infects human cells whereas MLV infects cells of many mammalian species. Our work will use retroviral/lentiviral vectors pseudotyped with the G proteins of VSV, EBOV or MARV. VSV-G can mediate entry into any mammalian cell type. EBOV naturally infects myeloid cells and endothelial cells, and retroviral/lentiviral pseudotypes can infect a subset of human and primate cell lines. With respect to the laboratory research activities outlined here, transmission of could occur through the exposure of unprotected and broken skin to liquids containing VLPs or viral vectors, e.g. tissue culture supernatants from living cells producing with viral vectors or VLPs.

Most Hazardous component:
The most hazardous biological agents are the VSV-G pseudotyped lentiviral vectors as they have the ability to transduce an integrated vector genome into most mammalian cells with varying efficiencies. However all viral vectors used are replication incompetent. There is no evidence that any single gene or protein has virulence potential when expressed in bacteria. Finally, there is no documented risk associated with routine handling of naked filoviral or retroviral DNA under CL1/2 conditions.

Consequences of exposure to any of the above:
Bacteria/Yeast and mammalian cell lines: All bacteria, yeast and cell lines have demanding requirements for maintaining cell viability, which will not be met in the general environment. The E coli strains used for propagation are multiply attenuated and pose no hazard to users. There is no posibility of generating filoviral or lentiviral particles in bacterial strains propagating the plasmids.

Retrovirus: MLV-based oncoretroviral vectors and HIV-based lentiviral vectors. Our work often uses retroviral vector virions pseudotyped with the G protein of VSV, and therefore able to infect cells of many species. There is a potential risk of insertional mutagenesis, but as the vectors are replication-defective, this is a low risk. There are no documented cases of harmful consequences of accidental exposure to the MLV- based or HIV-based vectors discussed herein.

Exposure to skin, eyes, and lungs are minimal as gloves and protective clothing are used all the time, no sharp are used and all viral vector work is performed in a class 2 MSC.

Tissue culture plastics, solid waste and liquid waste is inactivated by use of 10% P3-Steril. It should be noted that when 10% P3-Steril is added to a tissue culture monolayer, the cells are completely lysed and therefore it will decontaminate all viruses. All solid waste is subsequently autoclaved and incinerated.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None applied for

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Tissue culture plastics, solid waste and liquid waste is inactivated by use of 10% P3-Steril (a quaternary ammonium compound). It should be noted that when 10% P3-Steril is added to a tissue culture monolayer, the cells are completely lysed and therefore it will decontaminate all enveloped viruses and viral like particles. All solid waste is subsequently autoclaved and incinerated. Inactivated liquid waste will be disposed of via the drainage. All bacterial culture waste is inactivated with 2% Virkon, which completely kills all viable E coli, before drainage disposal.
The project was reviewed by the KCL School of Medicine Biological Safety Committee on 4th December 2014 and was approved subject to minor amendments.

02/03/2022
The Catanese lab studies the molecular cell biology of Flaviviridae. This family of positive-sense, single-stranded RNA viruses includes hepatitis C virus (HCV), dengue virus (DENV); Zika virus (ZIKV); West Nile virus (WNV), Japanese encephalitis virus (JEV) and Yellow fever virus (YFV) among others. Their genome is translated into a single polyprotein that is subsequently cleaved into 10 proteins: 3 structural proteins (the capsid protein and two envelope glycoproteins), and 7 non-structural proteins (see figure 1 in appendix A).

Flaviviridae viruses produce a wide range of diseases including fever, arthralgia, rash, liver failure, haemorrhagic fever and encephalitis.

Initial research will primarily focus on HCV and ZIKV. At a later stage, we intend to expand these studies to include WNV, JEV, DENV and YFV. Through collaborations, we began comparative studies with other RNA positive-strand viruses, including the Alphaviruses Sindbis virus (SINV) and Semliki Forest virus (SFV), which led to discovering conserved exploitation strategies of cellular factors with HCV. We therefore would like to include SINV and SFV as part of our model systems.

Our goal is to gain insights into the subversion strategies devised by these viruses (i.e. cytoskeleton rearrangements, endomembrane remodeling during virus replication/assembly, vesicle trafficking and cell-to-cell spread) that promote successful viral dissemination. Furthermore, we will study the functions of virion-associated host proteins to investigate how these cellular factors contribute (either positively or negatively) to the propagation of infection. These studies will provide insights into the exploitation of physiological cellular processes by this related group of viruses. The research team will address these questions using a multidisciplinary experimental strategy that includes molecular genetics, cell biology, biochemistry and structural biology.

This risk assessment covers all work performed in our lab under CL2 and CL3 conditions, and therefore relates to procedures involving the introduction (and expression) of viral genomes into permissive cells. This includes work with replication-competent viruses. Both immortalized cell lines and primary human cells are used for this work. CL 2 will be used to study individual viral proteins of the Flaviviridae members (i.e. HCV, DENV, ZIKV), which are not infectious, and full length ZIKV, SFV and SINV. CL 3 will be used for experiments with full length infectious HCV.

Experiments outside the CL2 and CL3 facilities will be conducted on fixed (4% paraformaldehyde (PFA) or 100% methanol) cells/tissues/supernatants that are no longer infectious.

**Recipient or parental organism**

Our goal is to generate key tools and experimental systems to study the biology of Flaviviridae infection in cell culture and compare it to other RNA positive-strand viruses (SFV and SINV). Specifically:

Full length HCV, ZIKV, SFV and SINV genomes will be generated by in vitro transcription of molecular cDNA clones and electroporation/transfection of permissive cells.

Virus-containing supernatants will be inoculated onto naïve cells to propagate infection in cell culture. We will produce soluble Flaviviridae envelope proteins, pseudoparticles and subgenomic replicons. None of these system is infectious and can be safely used in CL2 laboratories. These constructs will be either generated by molecular cloning or synthesised by Origene and will be used to test host and cell permissiveness of various isolates, to understand aspects of the molecular biology of viral replication, and the potential impact of viral genetic changes on pathogenicity.

**Host/vector system**

Constructs encoding for viral genomes or individual viral proteins will be amplified in bacteria and expressed in permissive eukariotic cells (i.e. hepatocytes or hepatoma cells for HCV; skin, neuronal, placental cells for ZIKV; BHK, Hela, 293T and hepatoma cells among others for SINV and SFV).

**Origin & function**

1. Production of soluble Flaviviridae envelope glycoproteins.
   1.1. Soluble forms of viral envelope glycoproteins will be produced in 293T cells by transfecting constructs lacking the transmembrane domains, leading to their secretion. This approach was used successfully for several viruses of the Flaviviridae family, including HCV and DENV (8, 9).
   1.2. Tagged versions (6x-His, HA, FLAG) will be created to facilitate protein purification, and to enable biochemical studies to search for Flaviviridae cellular receptors/interacting partners.
1.3. These proteins will be used in cell culture to determine if they can compete with infectious particles and inhibit virus infection.

2.1. ZIKV pseudoparticles (ZIKVpp) and HCV pseudoparticles (HCVpp) will be produced as done previously with other Flaviviridae (10). 293T cells will be co-transfected with expression vectors encoding: (i) viral envelope proteins, (ii) gag-pol proteins of either murine leukemia virus (MLV) or human immunodeficiency virus (HIV) and (iii) a retroviral ge-name bearing a reporter gene such as luciferase or green fluorescent protein to allow quantitative measure of viral en-try into target cells.

2.2. This experimental system will help define the host-range and cellular tropism of ZIKV entry. We will screen the permissiveness of neuronal, placenta-derived, blood brain barrier, testis and prostate cells to ZIKVpp infection, using either flow cytometry or luciferase production as readout. Pseudoparticles constitute a very safe and versatile system to express any variant glycoproteins that may be identified in severe cases of ZIKV disease to study whether specific genetic alterations lead to changes in virus host and/or tissue tropism.

2.3. Using pseudoparticles, we will be able to express patient-derived viral glycoproteins to address the neutralization properties of virus-specific antibodies present in patient sera, and to identify cross-neutralizing epitopes.

3. Generation of Flaviviridae sub-genomic replicons

A sub-genomic replicon is a non-infectious, self-replicating RNA construct containing the viral non structural (NS) genes, where the regions encoding for the structural proteins have been deleted or replaced by foreign genes (11). As a result, no infectious particles can be produced with this system, making for a very safe cell culture experimental model.

3.1. ZIKV and HCV sub-genomic replicons will be constructed to define the minimal set of NS genes required for virus replication in a range of cells. Reporter (i.e. luciferase, GFP) or antibiotic resistance genes will replace the structural region of the genome, enabling rapid screening and quantification of virus replication and the generation of cell lines stably replicating ZIKV and HCV, respectively.

3.2. Cells from different hosts (i.e. mosquito, monkey, human) and tissues (including skin, placenta, brain and testis) will be screened for permissiveness to ZIKV replication upon transfection of in vitro-transcribed viral replicons. We also address how interferon treatment and expression of interferon-stimulated genes (ISGs) impact on ZIKV and HCV replication, using ISGs libraries available at KCL.

3.3. We will introduce a range of genetic variations found in the NS regions from different ZIKV and HCV isolates into sub-genomic replicons to determine the relative replication ability of geographically distinct strains/genotypes. It was recently shown that the current ZIKV Asian lineage spread is associated with significant NS1 codon usage adaptation to resemble more closely that of human genes, which could promote ZIKV replication and increase viral titers (12). Similarly, ZIKV isolated from a fetus with microcephaly revealed two amino acid substitutions in NS1 and NS4B (2). It is unclear whether these represent adaptations of the virus to enhance replication in the brain. We assess these muta-tions in our systems to determine the impact of these genetic changes on ZIKV replication and tropism.

3.4. We will study the ultrastructure of ZIKV- and HCV-infected tissues by transmission electron microscopy to gain a better understanding of the sites of viral replication and the resultant tissue damage. This aim will be applied to in vitro replication studies and biopsies obtained from the current epidemic.

4. Virus-host interaction studies with full length HCV (CL3), ZIKV, SFV and SINV (CL2) genomes. These will include down regulation (with siRNA/shRNA) and over-expression studies of cellular factors to determine their role on the propagation of HCV, ZIKV, SFV and SINV infections. The expression of both cellular and viral proteins will be as-sessed by biochemistry and flow citometry or visualised by fluorescence and electron microscopy.

Evaluation of foreseeable effects

Cell culture infectious HCV (HCVcc) is a HG3 virus capable of establishing chronic infections and causing progressive liver disease. However, it is possible to cure infected individuals with a combined regime of interferon and ribavirin, furthermore, a range of new anti-virals are dramatically improving treatment efficacy (>90% cure rate).

The original HCV clones were derived from human patients, specifically GenBank accession # AB237837.1 and derivatives thereof, originally described in Lindenbach, Science, 2005,309, p623-6.

HCVcc is transmitted exclusively by percutaneous inoculation and is not capable of transmission by air or ingestion. In a research setting, the primary risk comes from contaminated sharps or, potentially, eye-splash exposure. However, these risks are all but eliminated under containment level 3 (CL3). Gloves, eye shields and protective clothing are used all the time, no sharp are used and all viral work is performed in a class II MSC.

Modification of HCVcc clones by introduction of specific mutations and protein tags/fluorescent proteins that allow us to visualise and quantify viral infection is not expected to increase infectivity.

The ZIKV clones used in these studies are from either the Asian or African lineages and are described in Haddow et al., PLoS Negl Trop Dis. 2012;6(2):e1477. doi: 10.1371/journal.pntd.0001477.

Zika virus (ZIKV) is a HG2 mosquito-borne flavivirus distributed throughout much of Africa and Asia and recently spreading through the Americas. Infection with the virus
may cause acute febrile illness that clinically resembles dengue fever. It is thought to be transmitted by percutaneous inoculation. Possible consequences of ZIKV infection include: fever, rash, joint pain, or conjunctivitis, muscle pain and headache. SFV is spread mainly by mosquito bites. Both Wild-type SFV and fluorescently-tagged viral genomes (i.e. SFV_nsp3/GFP) will be used in these studies. SFV can cause infection but there is only one recorded incident of pathogenesis.

The prototype of the Alphaviruses, SINV has a broad host range, shuttling between an insect vector to a vertebrate host for its transmission cycle (Hernandez et al., Curr Protoc Microbiol. 2005 Oct;Chapter 15:Unit 15B.1. doi 10.1002/9780471729259.mc15b01s00). As a result, in tissue culture, SINV can replicate in several cells of both vertebrate and invertebrate origin.

Wild-type SINV utilized in these studies was generated from plasmid pToto1101 (Rice, C. M., et al. (1987) J. Virol. 61, 3809 –3819). Virus expressing GFP as an in-frame fusion within nsp3 was described previously (Liang, Z et al. (2005) GeneTher. Mol.Biol.9,317–324) and is here designated nsp3-GFP Sindbis. SINV can infect humans, producing a rash-arthritis syndrome. However, these Alphaviruses need an insect vector for human transmission and cannot spread directly from human to human.

The major risks to be considered for research with HIV-1 based lentivirus vectors are the potential for generation of replication-competent lentivirus (RCL). This risk has been removed with the later generation lentivirus vector systems that use a heterologous coat protein (in our case VSV-G) in place of the native HIV-1 envelope protein, thus reducing the risk of RCL generation. To improve safety, transfer vectors are all replication incompetent and in some cases additionally contain a deletion in the 3’LTR, rendering the virus “self-inactivating” (SIN) after integration.

The pseudotyping env gene is carried on a separate plasmid to other viral components/sequences and cannot be packaged, limiting infection by the pseudotyped virus to a single round only.

ZIKV, SFV, SINV and pseudotyped retroviral particles carrying VSV Env glycoprotein can infect an expanded number of cell types and cells from additional species. The most probable route of exposure for laboratory research activities involving these viruses would be dermal via sharps (needle-sticks), absorption through exposed scratches or abrasions on skin, or mucous membrane exposure of the eyes, nose, and mouth. Another route would be inhalation via aerosols depending on the use of equipment such as centrifuges or vortex mixers. Potential insertional mutagenesis through the use of lentiviral vector systems.

Viral sequences encoding specific proteins may be sub-cloned into other plasmids to allow production of virus proteins in isolation, however these will pose no risk to human health.

There are no identified risks to the environment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applied for.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

General procedures for working in the Department are outlined in the Departmental Code of Practice (CL1, CL2 & CL3). All work is covered by Departmental Standard Operating Procedures, which should be followed in conjunction with the relevant COSHH risk assessments and this Biological Risk Assessment. All staff must have a written training record

Solid: all solid waste will be soaked overnight in 20% P3-Steril (final concentration), a quaternary ammonium compound, and autoclaved (moist heat for 60 min at 121 oC). All solids will be place in yellow bags for subsequent incineration by licenced contractor.

Liquid: all liquid waste will be treated with 20% P3-Steril (for at least 1h) and then put down the sink and rinsed with copious quantities of water.

We have demonstrated effective virus inactivation after 1h incubation. In house validation of HCV inactivation by P3-Steril was successfully conducted and proved complete removal of infectivity from the sample (see detailed protocol and results in appendix of CoBRA file).

Similar testing with 20% P3-Steril will be conducted on SINV, SFV and ZIKV once these virus are on site to ascertain complete inactivation

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N
The project was reviewed by the Faculty of Life Sciences and Medicine Biological Safety Committee on 28th April 2016 and approved it as a Class 3 GM activity subject to a number of amendments.

Date of Significant Change

Project Additional Information
### Purposes of the contained use

To study the antimicrobial activities of anti-TB formulations, *Mycobacterium smegmatis* (Harzard Group 1) and severely attenuated *Mtb* (HG 2) strains will be used in in vitro studies. Monocyte cell line (ATCC TIB 202™) will be differentiated into macrophages using phorbol 12-myristate 13-acetate (PMA) for the study of intracellular antimicrobial activity. NMR and HR-MAS will be exploited to elucidate mechanism of actions of D-LAK peptides.

### Recipient or parental organism

Fully drug sensitive laboratory *Mycobacterium tuberculosis* strain H37Rv

### Host/vector system

N/A

### Origin & function

Genetic modification resulted in four double auxotrophs with deletions in designated positions in the genome involving Leucin, pantothenate, lysine and RD1 protein as well as the introduction of hygromycin resistance cassette.

| Bleupan ΔleuD ΔpanCD hygR | mc2 6020 ΔlysA ΔpanCD hygR |
| mc2 6030 ΔRD1 ΔpanCD hygR | mc2 7000 ΔRD1 ΔpanCD unmarked |
| lysA, leuD and panCD involve in the biosynthesis of lysine, leucine and pantothenate respectively. Corresponding deletions in strains lead to impairment of protein synthesis affecting normal metabolism and respiration. The *M. tuberculosis* ΔleuD ΔpanCD double auxotroph has two independent, attenuating, non-revertible mutations, which delete the essential leuD and panCD loci in *M. tuberculosis*. The resulting strain is highly attenuated in vivo and auxotrophic for both leucine and pantothenate (i.e. unable to grow without leucine and pantothenate supplemented growth medium). |
| Region of difference 1 (RD1) is the main genetic modification involved in the attenuation of the vaccine strain BCG. Deletion of RD1 completely removes 7 genes (Rv3872–Rv3878) and truncates 2 others (Rv3871 and Rv3879c). In which two of them encode the strong immunogenic antigens and virulence factors—the early secreted antigenic target (ESAT-6) and the culture filtrate protein (CFP-10). Studies have demonstrated RD1 is required for full virulence of *Mtbc*. (The Journal of Infectious Diseases (2003) 187:117–23, Scientific Reports (2015) 5:17078-91) |
| Hygromycin resistance (hygR) cassette is introduced as a selectable marker of strains. |
| Strains have previously been notified under GM Notifications GM 77/94.4 and GM 77/98.2. |

### Evaluation of foreseeable effects

There is no evidence that the severely attenuated strains are hazardous to human in contained use. Studies have also shown that the strains are effectively cleared by immunocomprised SCID or interferon gamma knock-out mice.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

There will be no larger GMOs in this study.

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

For sample preparation of NMR metabolomic studies, the *M. tuberculosis* strain will be fixed by 2% formaldehyde for...
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid GMM culture will be treated with 10% Surfanios, mycobactericidal agent based on amine and quaternary ammonium compounds, overnight before pouring to drain with plenty of running water. Containers will be dispatched as orange clinical waste for incineration by licensed contractor. Solid GMM contained waste such as plates and tips will be placed in autoclave bags for autoclaving at 121°C for at least 15 minutes. The autoclave is located on a different floor in the same building.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

The project was reviewed by the Former GM295 Biological Safety Committee (now incorporated into GM386) on 01/11/2016. It was approved subject to minor changes.

Project Ref 386/18.1

Date Ackn'd 09/02/2018

CU2 Project Title Understanding the mechanisms of EBV (Epstein-Barr virus) induced immune responses in human T lymphocytes

Class Class 2

CultureVolClass2 < 1 Litre

Consent Granted Not Applicable
We propose to investigate the effects of EBV on T cell functionality with a focus on the IL-12 pathway in human lymphocytes by use of a GM strain of EBV (delta-mir) and comparing it to WT strains. Wild type strains of EBV can suppress the release of IL-12 by the infected cells and thereby reduce the effector functions of CD4+ and CD8+ T-cells. While CD4 T cells require IL-12 for induction of the T helper 1 phenotype, which is vital in combatting viral infections, in CD8 T cells IL-12 functions as an important third signal cytokine, allowing full activation and cytotoxic functions as well as the development of T cell memory, again playing a vital role in anti-viral immunity. The suppression of IL-12 production by WT EBV is mediated via viral microRNA expression, whereas the delta-mir GM strain has been modified to produce no functional MicroRNAs and is therefore unable to interfere with IL-12 production in infected cells in addition to also showing loss of other immune suppressive mechanisms (like the down-modulation of HLA molecules).

**EBV Delta-mir**
Modified strain of EBV that has modifications to the BART and BHRF1 genes such that the virus produces no mature MicroRNAs. Wild type EBV produces over 40 different MicroRNAs.

**Host/vector system**
EBV Delta-mir BAC is transfected into HEK-239T cells via standard transfection methods (Calcium phosphate/lipofectamine or similar) and transfection efficiency assessed by GFP expression. Transfected cells can be selected for with hygromycin drug treatment. Viral stocks are subsequently generated by further transfection of vectors containing BZLF1, BRLF1 and BALF4 to initiate viral lytic cycle. WT EBV stocks to be generated via a similar approach. Viral stocks subsequently used to infect human CD19+ve cells for use in CD4/CD8 co-culture experiments. All vectors (EBV BACS as well as accessory vectors) are initially cultured in transformed bacteria under drug (ampicillin) selection.

**Origin & function**
Modifications to EBV present in DElta-Mir construct are modifications to the BART and BHRF1 genes such that Delta-Mir EBV produces no mature MicroRNAs. Genetic modifications in this case is a loss of function.
EBV BAC constructs (both WT and Delta-mir) contain GFP and Hygromycin resistance genes. Hygromycin resistance allows drug selection of transfected 293T cells when generating viral stocks and GFP allows flow cytometric assessment of transfection efficiency and also infection efficiency when using viral stocks. Both Wt and Delta-Mir have ampicillin resistance genes to allow selection in bacteria. Accessory vectors used when generating viral stocks contain BZLF1, BRLF1 and BALF4 genes. BZLF1 and BRLF1 genes trigger the EBV lytic cycle and are required to generate appreciable viral levels (293T cells transfected solely with EBV BAC produce little or no virus). BALF4 encodes the GP110 precursor an envelope protein that enhances the subsequent viral stocks ability to infect human cells. All vectors also have ampicillin resistance genes to allow selection in bacteria.

**Evaluation of foreseeable effects**

The GM EBV virus (Delta-Mir) will have no functional MicroRNAs whereas the WT EBV has over 40. The individual functions of these Mirs is unknown but they are thought to have a variety of functions in regulating viral and host cellular genes. These functions would include a number of pathways that aid the virus in establishing a latent infection, such as inhibiting apoptosis of the host cell, inhibiting expression of viral genes (thus avoiding immune response) as well as inhibiting the II-12 pathway.

We would envisage that the GM Delta-Mir EBV virus would be less able to regulate the immune response of CD4/CD8 cells.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Solid GM waste (plates, flasks etc) is disposed of into clear waste bags and then autoclaved at 121°C for 20 minutes. After inactivation by autoclave waste is disposed of in yellow waste bags in waste room. Waste bags from this point are collected by external contractor and ultimately incinerated. Serological pipettes are placed in a 7L yellow Biobin, when full this bin is loosely sealed (i.e. flap is folded over) and then autoclaved as above before disposal as above. Pipette tips are placed in a 1L yellow Biobin and loosely sealed when full before being autoclaved and disposed of as above. Biobin autoclaving , both for serological pipettes and pipette tips has been validated as effective using temperature indicators. Autoclave for waste disposal is serviced and maintained on a 6 monthly basis and function will be independently checked with temperature indicators during the proposed experimental work. Liquid waste (cell culture media, viral stocks) is treated with liquid Distel disinfectant (to a concentration of 1% Distel) and left for at least 1 hour before disposal down designated laboratory sink. Distel is EN14476 tested for this purpose (greater than 4-log reduction in virus with 1 hour contact at 1/100 dilution) and is also tested for Bacteriacidal and fungicidal activity.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N
The project was reviewed by the King's College London Biological Safety Committee for the Faculty of Life Science and Medicine on 5th October 2017.
The project was approved as a Class 2 GM activity requiring CL2 subject to minor amendments.

Project Ref 386/18.3

Molecular cloning, expression in Escherichia coli, and insertional mutagenesis of genes putatively involved in protease expression, post-translational modification, macromolecular biosynthesis and virulence in Porphyromonas and related organisms

Date Ackn'd 05/10/2018

CU2 Project Title

Molecular cloning, expression in Escherichia coli, and insertional mutagenesis of genes putatively involved in protease expression, post-translational modification, macromolecular biosynthesis and virulence in Porphyromonas and related organisms

Class 2

< 1 Litre

Non-GMM

Consent Granted

Project notified under transitional arrangements N

Tick if notifying a connected programme of work N

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

02/03/2022
## Project Additional Information

### Purposes of the contained use

Manipulation of Porphyromonas / Bacteroides DNA for expression in Escherichia coli and mutagenesis of Porphyromonas / Bacteroides genes, by homologous recombination.

### Recipient or parental organism

Recipient species: E. coli XL-1 Blue MRF', E. coli SURE , SCS110, E. coli XL-10 Gold and derivatives will be used. These strains are K12-derived, are attenuated and unable to survive in the gut - sensitivity to bile salts. Donor species: Porphyromonas gingivalis and Bacteroides sp. These organisms are sensitive to oxygen and requires specialised anaerobic conditions and media for growth and propagation.

### Host/vector system

- **E. coli** - pUC18not, pUC18/19-derivatives, JFQ301 (derivative of commercial pQE80, Qiagen)
- **P. gingivalis**- E.coli derived plasmids do not replicate in P. gingivalis:
  - Gel-purified fragments, from vectors propagated in E. coli will be used for electroporation. pNJR12 is autonomously replicating, low copy number shuttle plasmid, will be used to complement mutations in P. gingivalis.

### Origin & function

Intended genes are from Porphyromonas / Bacteroides and encode:
- Protease specific for arginine-peptide bonds
- Protease specific for lysine-peptide bonds
- Putative outer membrane proteins / biomolecular translocation
- Lipopolysaccharide (LPS) biosynthesis
- Glycan transferases and capsular polysaccharide biosynthesis

### Evaluation of foreseeable effects

E. coli – The scale is limited to < 1 litre and K12 strains are unable to survive in the gut. Cloned proteases are known not to retain enzymatic activities. In most cases, incomplete (internal fragments) and promoter-less P. gingivalis genes will be cloned, with no intention of expressing the gene product. When expression is necessary (e.g. to use products for antibody generation), the products are unlikely to have the post-translational processing and the level of maturation that is required in P. gingivalis. Thus, GMO is unlikely to be more harmful than P. gingivalis itself.

P. gingivalis - Mutated genes are unlikely to confer any advantage relative to the wild type strain; some of these genes are expected to be critical to the organism’s ability to grow and survive. There are no reports of mutated genes leading to improved virulence in the mouse subcutaneous model. Similarly, complemented strains are expected to restore wild type activities. The scale will be confined to < 500ml.

Both systems are unlikely to be detrimental to health.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

NOT APPLICABLE

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All relevant containments are in place to minimise the potential of significant risk. All materials that come in contact with DNA and or bacteria will be decontaminated either by thoroughly cleaning with 1% (v/v) ChemGen (Starlabs) or by autoclaving 136 °C for 55 minutes, and disposed of via incineration as yellow clinical waste by licenced contractor.

Spent media / culture will be autoclaved at 136 °C for 55 minutes or (liquid media only) treated with ChemGen (1% (v/v) final concentration) overnight. Autoclaved solid media will be disposed of via incineration as yellow clinical waste by licences contractor. Autoclaved or disinfected liquid media will be poured to drain with copious quantities of water.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

The project was reviewed by the Joint IoPPN/Dental Institute Biological Safety Committee on April 22nd 2018. It was approved with minor amendments.

### Project Additional Information

**Purposes of the contained use**

To identify the molecular and cellular processes that regulate the early steps of IAV infection, including the activities of interferon (IFN) regulated genes and investigate the molecular pathogenesis of Influenza A Virus using cultured cell models

**Recipient or parental organism**

**Bacteria - Attenuated and mobilization defective E. coli (DH5α, and DH10β), unable to survive in the absence of specialised growth factors, and unabe to colonize humans.**

Mammalian cell lines (such as MDCK, HEK 293T, HeLa, A549, U87-MG):
- MDCK cells will be infected with IAV for production of IAV stocks
- HEK 293T cells will be transfections with multi-component (non-replicative) systems based on the gamma-retroviral MLV or lentiviral HIV to produce viral vectors coding for single cellular genes or indicator genes.
- HeLa, A549 or U87-MG cells will be modified with viral vectors to express single cellular genes or indicator genes

**Retroviral vectors:** MIGR1 (gamma-retroviral expression vector), pRRL and pHR (lentiviral expression vectors)
- Single cellular genes or indicator genes will be inserted into retroviral expression plasmids for the generation of vectors

**IAV A/Victoria/3/75 (H3N2 strain) - Isolated clinical specimen in Australia, in 1975**

**Host/vector system**

To grow plasmids - E coli strains (DH5α, and DH10β).

To grow virus stock - MDCK (IAV) and HEK293T cells (retroviral vectors).

**IAV A/Victoria/3/75 NanoLuc reporter virus - Engineered influenza reporter virus where genome segment 3 expresses a polymerase acidic protein–2A–NanoLuc fusion protein**

**Tran et al, J.Virol (2013) 87, 13321.**

**MIGR1- MIGR1 (a retroviral expression vector for use in eukaryotic cells; refer to Pear et al., Blood vol 92, pp 3780. Non self-inactivating (Non-SIN). Amp resistance gene.**

**GFP expressing vector.**

**Can be used to insert single cellular genes cDNAs.**

**pHR (SIN-dE SFFV-Ctrl-P2A-SBP-dLNGFR-WPRE)- A retrovirus vector derived from HIV. Refer to PLoS One. 2014 Oct 31;9(10):e111437. doi:**

**10.1371/journal.pone.0111437. eCollection 2014. Self-inactivating (SIN). Amp resistance gene. Can be used to insert single cellular genes cDNAs.**

**pEasiLV (CG149 real)- A doxycycline-inducible lentiviral vector for expressing cDNAs, refer to Goujon, Nature vol 502, pp 559-562. Self-inactivating (SIN).**

pLenti-SIREN- A modified pCSGW containing the U6-promoter driven cassette for shRNA hairpin expression from pRetro-SIREN.

pLenti-CRISPR-Lentiviral vector encoding CRISPR guide RNA and the Cas9 nuclease for engineering specific gene knockouts. Encodes either Puromycin resistance of GFP

pCMVR8.91- pCAGGS encoding Mo-MLV Gag and Pol proteins for packaging retroviral vectors, such as pMIGR.

pCAGGS-MLVgagpol- pCAGGS encoding Mo-MLV Gag and Pol proteins for packaging retroviral vectors, such as pMIGR.

pMDG.2- Expression vector encoding the VSV-G envelope glycoprotein for pseudotyping retroviral and lentiviral vectors.

Origin & function

Segments of HIV, MLV or VSV- HIV (e.g. gag, pol, rev, vpr, vif, vpu and nef) or MLV (gag and pol) genes; will be used for the preparation of retrovirus or lentivirus vector stocks for gene transduction into mammalian cells.

VSV env is carried on a separate expression plasmid that is transiently transfected into cells producing retrovirus or lentivirus cores for the purpose of particle pseudotyping.

cDNAs corresponding to mammalian genes - Different mammalian genes (e.g., MX1, NUP214, other interferon-inducible genes, etc) will be analyzed to determine their biological function or effects on IAV replication.

cDNAs corresponding to non-mammalian genes - Marker/ reporter/ indicator genes are used widely (e.g., chloramphenicol acetyl transferase [CAT], β-galactosidase, luciferase, or naturally fluorescent proteins [GFP, YFP, etc.]).

Evaluation of foreseeable effects

There is no evidence that any of the above genes or proteins have virulence potential in vitro when expressed in mammalian cells. In addition, there is no documented risk associated with handling naked HIV DNA under standard/controlled CL1 conditions.

Inserts derived from retroviruses are introduced transiently into cell lines under CL1 conditions. They always contain less than two-thirds of a provirus and they cannot result in replicating infectious retroviruses. They will produce a viral vector that only has the capacity for a single-round infection.

The indicator virus A/Victoria/3/75 NanoLuc is a live virus able to infect humans, causing influenza, that additionally expresses the NanoLuc reporter protein upon infection.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

This project will not use larger GMOs, only cultured cell systems.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

NOT APPLICABLE

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

1) Solid: All solid waste will be rinsed in P3 Steril (10% in water; recommended and validated germicide for enveloped viruses and mammalian cell lines – (Refer to 1) Guideline for Disinfection and Sterilization in Healthcare Facilities, 2008, (CDC), 2) Conform to Regulation (EC) No 1907/2006 (REACH), and 3) Webber et al, 20, 12, Infection control and Hospital Epidemiology 2015), left overnight and then autoclaved (moist heat for 25 min at 1210C). The autoclave is serviced twice a year by Getinge. All autoclaved solids will be placed in yellow bags for subsequent incineration by KCL contractor.

2) Liquid: All liquid waste will be treated with P3 Steril (final concentration 10%), put down the sink and rinsed with copious quantities of water.

Spillage procedure: Wear laboratory coat and nitrile gloves. Use prepared solution P3 Steril (10% in water). If a spill occurs in a centrifuge, leave for 30 min for aerosols to settle. Cover spill with 10% P3 Steril solution starting from the outer edges of the spill. If any glass, needle or other sharp material is present, use a dustpan and brush or forceps to collect them; place in Sharps bin (yellow lid). Wipe up P3 Steril inactivated liquids with paper towels. Rinse surface with 10% P3 Steril and then water, wipe up with more paper towels. Place towels in yellow waste bag. All re-usable contaminated equipment (e.g. centrifuge following containment failure, the forceps or dustpan and brush used in the clean-up) should be carefully cleaned with 10% P3 Steril and then with water. Report all significant spills via KCL reporting system, AIRS.
The project was reviewed by the Faculty of Life Sciences and Medicine Biological Safety Committee on 7th February 2019 and approved it as a Class 2 GM activity subject to a number amendments.

# Project Additional Information

## Purposes of the contained use

To study neutralizing antibody responses in COVID-19 infected and recovered individuals. We aim to identify patients that have developed a robust neutralizing antibody response and use single B cell technologies to isolate the monoclonal antibodies (mAbs) with neutralizing activity that can be investigated as immunotherapeutics and be used to guide future vaccine design strategies. This work will also help identify recovered patients whose sera could be used for treatment of COVID-19 patients in ICU.

## Recipient or parental organism

| Bacteria - Attenuated and mobilization defective E. coli (STBL2, and DH10β), unable to survive in the absence of specialised growth factors, and unable to colonize humans. |
| Cells (including HEK-293T, HeLa, HeLa/TZM-bl, Vero-E6, A549, Caco2 and HEK-293F) |
| - HEK 293T cells will be transfected with multi-component (non-replicative) systems based on the gamma-retroviral MLV, lentiviral HIV or VSV-deltaG to produce SARS-CoV-2 pseudotyped virus for use in neutralization assays. |
| - HeLa, A549 or Vero-E6, and Caco2 cells will be used as reporter cell lines for neutralization assays |
| - HEK 293F cells will be used for antibody and glycoprotein expression. |

## Host/vector system

| To grow plasmids - E coli strains (STBL2 and DH10β). |
| To grow virus stock - HEK293T cells (retroviral vectors). |

## Origin & function

| Segments of HIV, MLV or VSV- HIV (e.g. gag, pol, rev, vpr, vif, vpu and nef) or MLV (gag and pol) genes; will be used for the preparation of retrovirus or lentivirus vector stocks for gene transduction into mammalian cells. |
| Viral surface glycoproteins include; SARS-CoV, SARS-CoV-2, MERS, VSV and will be used for the purpose of pseudotyping. |
| Rescued heavy and light chain variable genes will be cloned into IgG expression vectors containing the human heavy and light chain constant regions. |

## Evaluation of foreseeable effects

| There is no evidence that any of the above genes or proteins have virulence potential in vitro when expressed in mammalian cells. In addition, there is no documented risk associated with handling naked HIV DNA under standard/controlled CL1 conditions. Inserts derived from retroviruses are introduced transiently into cell lines under CL1 conditions. They always contain less than two-thirds of a provirus and they cannot result in replicating infectious retroviruses. They will produce a viral vector that only has the capacity for a single-round infection. |

The aim of our program is to understand the pathogenesis of myeloid neoplasms and leukemias using multiple approaches using primary patient tissues as well as patient derived cell-lines and cells derived from haematologically normal patients.

1. The first part of the project will study the genomics, transcriptomics and proteomics of the human primary cells. We will be studying the stem cells/progenitor like cell compartments isolated from blood or bone marrow aspirates of patients using in vitro assays.

2. The second part of the project will assess the biological impact of the expression of human oncogenes or other ‘mutated genes’, particularly those genes identified in association with myeloid neoplasms and leukaemias.

This procedure will involve either transfection of plasmids or generation of a replication defective recombinant lentivirus capable of targeting human cells to make genetic modifications. Genetic modifications will include gene editing using CRISPR-Cas systems, gene over-expression or shRNA knockdown of potential oncogenes. Plasmids will be generated using competent E. coli. Infective viral particles will be generated using HEK-293T ‘producer’ cells in vitro. Transfection of target cells (with plasmid) or infection (with lentiviral particles) will be carried out in vitro. The effects of modified target cells will be assessed using various in vitro assays, including cell proliferation and colony assays, flow cytometry and microscopy.

3. The third part of this project will use vector constructs with gene combinations for the creation of induced pluripotent stem cells (iPSCs).

Recipient or parental organism

E. coli: commercially-sourced, attenuated and mobilization defective E. coli (listed below), unable to survive in the absence of specialised growth factors, and unable to colonize humans.

- TOP10
- DH10B-T1
- BL21DES
- STBL3
- DH5alpha

Mammalian cell lines which may be genetically modified are listed below:

- NIH3T3
- Mouse embryonic fibroblast cell line
- U937
- Human Histiocyota cell line
- K562
- Human Myelogenous leukaemia cell line
- NB4

Cell lines used to produce viral particles: HEK293T, PG13 (Murine NIH-3T3-derived)

Host/vector system
Viable cells might be transduced with known or possibly oncogenic genes/sequences by transfection, lentiviral vector infection.

Viable cells: i) primary haematopoietic cells derived from donor bone marrow or blood
ii) human leukaemia cell lines: see list above; viral and plasmid producing cell types: see list above.

Viral and non-viral plasmids used are detailed below, including their target cells.

Non-viral Plasmids:
- pcDNA3.1+/Thermo Fisher
- E coli and eukaryotic cells
- Original TA cloning vector pCR2.1
- E coli TOP10
- pGEX4t-1 Sigma
- Bacteria
- pET22b pET30a Novagen

Origin & function

Viral origin genetic material:
Segments of HIV, MLV or VSV- HIV (e.g. gag, pol, rev, vpr, vif, vpu and nef) or MLV (gag and pol) genes; will be used for the preparation of retrovirus or lentivirus vector stocks for gene transduction into mammalian cells.
VSV env is carried on a separate expression plasmid that is transiently transfected into cells producing retrovirus or lentivirus cores for the purpose of particle pseudotyping.
Human origin genetic material is intended for the study of the involvement of these sequences in the induction/progression of haematological malignancies. These include oligonucleotides and cDNAs derived from human DNA sequences.
Marker/reporter/indicator genes are used widely (e.g., chloramphenicol acetyl transferase [CAT], β-galactosidase, luciferase, or naturally fluorescent proteins [GFP, YFP, etc.]).

Evaluation of foreseeable effects

7. Characteristics of the GMO(s) including the evaluation of foreseeable effects (cont'd)
   1. There is a risk that the researcher may inadvertently become infected with viral particles used to deliver genetic modifications. However, viruses used in these experiments are self-inactivating and replication incompetent once they infect the target cell and so their effects would be limited. Researchers will be suitably trained to handle viruses safely, and waste contaminated with viruses will be disposed of safely (see later section).
   2. There is a theoretical risk that a researcher may inadvertently contaminate themselves internally with genetically modified primary cells carrying oncogenic mutations. The risk that any experimental cells could be inadvertently administered parenterally (e.g. into the bloodstream) is small due to use of appropriate PPE and safe disposal of sharps. Furthermore, any experimental cells will be recognised as 'foreign' by a competent immune system and eliminated. To our knowledge, there have been no documented cases of researchers acquiring malignant disease through this route.
Exposure to skin, eyes and lungs would be minimal as gloves and protective clothing are used at all the times. All viral as well as human tissue experiments are performed in a Microbiological Safety Cabinet. Tissue culture plastics, solid waste and liquid waste is inactivated by use of appropriate disinfectants. Microbiological Safety Cabinets are located in specified rooms designated as CL2 laboratories and only competent and trained operators are allowed to perform these procedures.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Disposable plastic, plastic pipettes and tips contaminated with virus or human cells are soaked for at least 12 hours in 1% Virkon before placing into autoclave bag and autoclaving.

Autoclave 134°C, 5 minutes. 121°C, 20 minutes this will kill off 100% of any viable organism. Autoclave inspected and tested on a yearly basis.

Final disposal via incineration by an external licensed contractor.

All media must be treated with 1% Virkon solution for 12 hours to render inactive and then flushed into the drain with lots of water.

Is an emergency plan required according to regulation 20? \( \text{N} \)

### Project Additional Information

**Purposes of the contained use**

Blood samples will be collected by qualified clinicians and nurses from haematologically normal and sickle cell disease patients (Kings College Hospital) under NHS guidelines. Samples will be transported to the Rayne Institute where they will be processed and stored as either cell-pellets or viable cells. Requested samples will be transported on dry ice to the lab. Samples will be lysed in a Class II microbiological safety cabinet for preparation of DNA, RNA or protein for downstream applications such as protein analysis, PCR, Nextgen Sequencing, single cell sequencing etc. DNA, RNA and/or protein will be isolated from cell pellets which have been stored in liquid nitrogen and are therefore not viable. Viable cells will be prepared in dedicated Class II microbiological safety cabinet by staining with antibodies for FACS analysis, FACS Sorting, Cytof analysis or cytokine profiling of blood or cell supernatant.

Animal work will be performed at the Denmark Hill KCL BSU where primary haematopoietic cells from mice will be isolated mice and used for experiments to establish an in vitro model of erythropoiesis. Viable cells may be used for downstream applications as described above.

**Aims:**

The aim of our research program is to understand the development of erythropoiesis, globin gene regulation and the pathogenesis of red cell disorders via multiple approaches using primary patient tissues as well as patient derived cell-lines, established immortalised human cell-lines, mouse models and cells derived from haematologically normal patients. Using human or mouse erythroid cell lines or human and mouse primary haematopoietic stem and progenitor cells, we investigate how under/over-expression or mutation of our genes of interest influence the propagation, maturation and function (including globin gene expression) of erythroid cells. The experimental readouts of our work include data on transcription factor binding, chromatin looping, gene expression (mRNA and protein levels), red cell membrane physiology, growth and differentiation behaviour.

Our experimental pipelines include (CRISPR/Cas9) gene editing enabling us to decipher gene and protein function as well as the influence of human mutation and common human genetic variability on red blood cell formation and function. Our work is aimed at understanding human diseases affecting red blood cells, such as sickle cell disease and at identifying targets for novel therapeutic approaches.

**Recipient or parental organism**

Viable cells derived from blood from haematologically normal and sickle cell disease patients.

**Host/vector system**

Viable cells might be transduced with known or possibly oncogenic genes/sequences by transfection, retroviral or lentiviral vector transduction.

**Origin & function**

Genetic material is derived from human and murine sequences and is intended to study the involvement of these sequences in the induction/progression of haematological
and erythroid physiological development and disease.

Evaluation of foreseeable effects

The most hazardous biological agent most likely to impair human health will be from adventitious agents contaminating the primary human cells samples, and the most likely of these will be patient samples at presentation. Primary human cells (whether GM or otherwise) have the added possibility of contamination with adventitious agents. Human blood and bone marrow cells are treated as if it were infectious to lab workers. In addition, all the staff members are offered a Hepatitis B vaccination as a precautionary measure.

The most hazardous genetically modified constituent would be the MYB and BCL11A constructs regarding their oncogene status and modified virus (e.g. lentivirus pseudotyped with VSV-G) carrying putative oncogene(s). There is no reason to believe that the GMO may be more dangerous to man and the environment than the recipient strain. Any new gene target to be used is not expected to have oncogene activity exceeding that of MYB. Over-expression of both proto-oncogenes, BCL11A and MYB, have been found to increase malignant behaviour of human tumour and leukaemia cells (references, e.g., Jiang BY et al. Mol Cancer 2013 and Zhao L et al. Oncogene 2014).

The risk to researchers of developing cancer from our procedures is non-existent because modified viruses are replication incompetent and disabled/self-inactivating once target cells are infected.

Lentiviral vectors have become standard reagents for the genetic manipulation of mammalian cells. Viral vectors are engineered to transfer and integrate specific DNA sequences into the genomes of target cells and are designed to be replication-defective to avoid further spread after the initial transfer event. Any infected cells would normally be expected to be targeted by the immune system in all healthy individual(s) with a competent immune system such as any researcher in our lab. There have been no reported incidences of infection resulting in insertional mutagenesis or infection resulting in expression of vector insert resulting in unwanted cell proliferation.

CRISPR/Cas9 gene editing will use single-stranded DNA and ribonucleoprotein complexes to modify genomic sequences via nucleofection. They are not viral vectors, so the potential for integration into the operator's cells and result in an inherited modification is non-existent.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

**Project Additional Information**

**Purposes of the contained use**

The Malim lab investigates the molecular pathogenesis of human viruses using cultured cell models of infection. Broadly speaking, the group employs a multi-disciplinary strategy that includes molecular genetics, cell biology, biochemistry, structural biology, genomics, bioinformatics, and cohort-based analyses. These will be extended by applying them to induced pluripotent stem cell (iPSC) lines, which possess intrinsic/natural genetic variation and can be exploited as models to define proteins and networks that regulate the HIV-1 life cycle.

Primary peripheral blood mononuclear cells (PBMCs) obtained from consenting healthy individuals will be obtained via the Infectious Diseases Biobank, and used to generate iPSC cell lines. To achieve this, they will use the CytoTune-iPS 2.0 Sendai Reprogramming kit from ThermoFisher, which is composed of three Sendai virus (SeV)-derived vectors expressing Klf4, Oct3/4, Sox2 and c-Myc. These well-established vectors are based on Sendai virus (a mouse parainfluenza virus type I from the
paramyxoviridae family) that has had the gene that encodes the fusion protein (F) deleted. These vectors cannot replicate or produce virus particles, and the genome sequence of iPSCs is not changed by this process.

Recipient or parental organism

Primary cells (PBMCs) isolated from blood of consented healthy adult donors. Donor bloods will be obtained through the King’s College London Infectious Diseases Biobank.

Host/vector system

Sendai vectors (ThermoFisher): These vectors contain transgenes that express hOCT3/4, hSOX2, hKlf4, and hc-myc. The vectors are based on a modified, non-transmissible form of Sendai virus, which has the gene encoding for the fusion protein deleted.

Origin & function

The genetic sequences inserted in the Sendai vectors are hOCT3/4, hSOX2, hKlf4, and hc-myc. These transcription factors can reprogramme human cells into a pluripotent state. These genes include the oncogene hc-myc.

Evaluation of foreseeable effects

The Sendai vectors and PBMCs are both handled under CL2 conditions. Sendai vectors cannot replicate, but can alter the expression of genes in exposed cells.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

This project will not use larger GMOs, only cultured cell systems.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

1) Solid: All solid waste will be rinsed in P3 Steril (10% in water; recommended and validated germicide for enveloped viruses and mammalian cell lines – (Refer to 1) Guideline for Disinfection and Sterilization in Healthcare Facilities, 2008, (CDC), 2) Conform to Regulation (EC) No 1907/2006 (REACH), and 3) Webber et al, 20, 12, Infection control and Hospital Epidemiology 2015), left overnight and then autoclaved (moist heat for 25 min at 121°C). The autoclave is serviced twice a year by Getinge. 10% P3 Steril has been shown by our group to inactivate several viruses including HIV-1 and SARS-CoV-2. All autoclaved solids will be placed in yellow bags for subsequent incineration by KCL contractor.

2) Liquid: All liquid waste will be treated with P3 Steril (final concentration 10%), discarded down the sink and rinsed with copious quantities of water. Spillage procedure: Wear laboratory coat and nitrile gloves. Use prepared solution P3 Steril (10% in water). If a spill occurs in a centrifuge, leave for 30 min for aerosols to settle. Cover spill with 10% P3 Steril solution starting from the outer edges of the spill. If any glass, needle or other sharp material is present, use a dustpan and brush or forceps to collect them; place in Sharps bin (yellow lid). Wipe up P3 Steril inactivated liquids with paper towels. Rinse surface with 10% P3 Steril and then water, wipe up with more paper towels. Place towels in yellow waste bag. All re-usable contaminated equipment (e.g. centrifuge following containment failure, the forceps or dustpan and brush used in the clean-up) should be carefully cleaned with 10% P3 Steril and then with water. Report all significant spills via KCL reporting system, AIRS.

**Date Ackn'd** 05/05/2021

**CU2 Project Title** Characterisation of interferon mediated block to Hantavirus infection

**Class** 2

**Culture Volume** ≤ 1 Litre

**Non-GMM Consent Granted**

**Project notified under transitional arrangements** N

**Historical Significant Changes**

**Historical Date of Additional Info**

**Significant Change ID**

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

To identify interferon stimulated genes (ISGs) that decrease Hantavirus replication in cell culture. This will be done by knocking down individual ISGs in cells before treating...
them with interferon alpha, infecting them with Puumala virus (PUUV) or Tula virus (TULV) and assessing viral replication using focus forming unit assays, quantitative polymerase chain reaction (qPCR) and western blotting. The results will help explain the variation in severity of these infections in people.

Recipient or parental organism

Bacteria - Attenuated and mobilization defective E. coli (STBL2, and DH10β), unable to survive in the absence of specialised growth factors, and unable to colonize humans.

Cells (including HEK-293T, Vero-E6 and A549)
- HEK 293T cells will be transfected with multi-component (non-replicative) systems based on the gamma-retrovirus MLV or lentivirus HIV in order to generate viral vectors to knock down genes in other cell lines.
- A549 or Vero-E6 cells will be used for infection assays with PUUV and TULV.

Host/vector system

To grow plasmids - E. coli strains (STBL2 and DH10β).
To grow virus stock - HEK293T cells (retroviral vectors).

Origin & function

Segments of HIV (e.g. gag, pol, rev, vpr, vif, vpu and nef) or MLV (gag and pol) genes; will be used for the preparation of retrovirus or lentivirus vector stocks for gene transduction into mammalian cells. VSV env is carried on a separate expression plasmid that is transiently transfected into cells producing retrovirus cores for the purpose of particle pseudotyping.

Different mammalian genes (e.g., MX1, NUP214, other interferon-inducible genes, etc) will be cloned into the above expression vectors and used to determine their biological function or effects on PUUV and TULV replication.

Evaluation of foreseeable effects

There is no evidence that any of the above genes or proteins have virulence potential in vitro when expressed in mammalian cells. In addition, there is no documented risk associated with handling naked HIV DNA under standard/controlled CL1 conditions.

Inserts derived from retroviruses are introduced transiently into cell lines under CL1 conditions. They always contain less than two-thirds of a provirus and they cannot result in replicating infectious retroviruses. They will produce a viral vector that only has the capacity for a single-round infection.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

This project will not use larger GMOs, only cultured cell systems.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

### Project Additional Information

#### Purposes of the contained use

Our overarching aim is to understand the cell and molecular mechanisms underlying scarring. We have recently discovered a unique extracellular matrix composition and architecture in keloids and are now questioning the functional significance of this. We are also working to understand the importance of cell plasticity and differentiation (regulated by transcription factors and epigenetic modifying enzymes) to wound repair and normal versus pathological scar formation. Our main approach will be to manipulate expression of transcription factors, epigenetic proteins, and extracellular matrix components and receptors (a number of which are implicated in cancers) in our in vitro culture models (primary human cell isolations, some immortalised).

#### Recipient or parental organism

**Bacteria** - Attenuated and mobilization defective E. coli, unable to survive in the absence of specialised growth factors, and unable to colonize humans.

**Cells** - Including HEK-293T, primary human or mouse cells (dermal fibroblasts, keratinocytes or immune cells), or cell lines (BJ or HCA2 fibroblasts, HaCaT keratinocytes, 3T3, Kera-308)

#### Host/vector system

1) Production of lentiviral vectors by co-transfection of HEK293T cells with lentiviral transfer vectors, with 3rd generation self-inactivating lentiviral vectors that have been extensively modified to prevent viral replication outside the packaging cells (pLentilox system, pLX302, pLX304, pLenti-CMVtight-puro-DEST, pLenti-CMV-BLAST-DEST, pmD2.G, pRSV-REV, pMDLg/pRRE).

2) Transduction of cells (listed above) with viral particles produced from 1)

#### Origin & function

A number of the planned inserted genetic sequences can contribute to oncogenic transformation of cells (e.g. epigenetic modifying enzymes (e.g. HDACs), transcription factors (e.g. Sox9, Foxl2), cell-cell adhesion molecules (e.g. Ephrins), signalling receptors and intracellular signalling molecules (e.g. TLRs, integrins, ERK), and a cell line immortalisation strategy (hTERT). Although a 3rd generation lentivirus approach will be used to transduce cells with these genetic sequences, the nature of the genes deems this work is CL2.
This project will not use larger GMOs, only cultured cell systems.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

1) Solid: All solid waste will be rinsed in P3 Steril or equivalent (i.e. recommended and validated germicide for enveloped viruses and mammalian cell lines – (Refer to 1) Guideline for Disinfection and Sterilization in Healthcare Facilities, 2008, (CDC), 2) Conform to Regulation (EC) No 1907/2006 (REACH), and 3) Webber et al, 20, 12, Infection control and Hospital Epidemiology 2015), left overnight and then autoclaved (moist heat for 25 min at 121oC). The autoclave is serviced twice a year. All autoclaved solids will be placed in yellow bags for subsequent incineration by KCL contractor.

2) Liquid: All liquid waste will be treated with P3 Steril or equivalent, put down the sink and rinsed with copious quantities of water.

Spillage procedure: Wear laboratory coat and nitrile gloves. Use prepared solution P3 Steril or equivalent. If a spill occurs in a centrifuge, leave for 30 min for aerosols to settle. Cover spill with 10% P3 Steril solution starting from the outer edges of the spill. If any glass, needle or other sharp material is present, use a dustpan and brush or forceps to collect them; place in Sharps bin (yellow lid). Wipe up inactivated liquids with paper towels. Rinse surface with 10% P3 Steril and then water, wipe up with more paper towels. Place towels in yellow waste bag. Origin & function

Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

To make and use recombinant retroviral and lentiviral vectors, for the study of proteins involved in regulation of the cell cycle in mammalian cells.

Human diploid fibroblast cell line MRC5, human embryonic kidney cells (293T), H9C2 rat myoblast cells, U2OS and HeLa cancer cell lines, primary neonatal rat cardiac myocytes, human smooth muscle cells and human breast cancer cell line MCF7.

HPASMCs- Human pulmonary arterial smooth muscle cells (HPASMCs) are isolated from human pulmonary arteries. HPASMC are cryopreserved at passage one and delivered frozen. HPASMC are characterized by immunofluorescence with antibodies specific to α-smooth muscle actin. Cultured PASMC play an important role in vascular disease research and can be used to identify new therapeutic targets to treat pulmonary vascular disease.

1) Production of lentiviral vectors by co-transfection of HEK293T cells with lentiviral transfer vectors, with either 2nd generation packaging vectors (HIV-1 and VSV-G) or 3rd generation packaging vectors (pLP1, pLP2 and pLP/VSVG).
2) Transduction of cells (listed above) with viral particles produced from 1)
3) Transduction of human MRC5 fibroblasts, 293T, U2OS, HeLa, neonatal rat cardiomyocytes, H9C2 myoblasts, HAP1 cells, human smooth muscle cells or MCF7 breast cancer cells with viral particles produced from 2).

Cyclin D1 and Cdk4 are tumour promoters and can drive tumour progression, putting them into viruses would require CL2.
For only GMMs - application for any derogation from full containment for the Class of activity.  (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

- **Disinfection**: 1% Virkon overnight for both liquid and solid waste.
- **Autoclave**: Solid waste is autoclaved at 121°C for 30min prior to disposal in clinical waste stream.
- **Liquid waste**: Disinfected liquid waste is dispelled down the drain with copious amounts of water

Project Title: Pathogenesis and treatment of infections at mucosal surfaces

Mucosal surfaces of the oral cavity, gastrointestinal and genital tracts are the main routes of entry of infectious microorganisms as well as being the sites for mucosal infections that may also have systemic effects. This activity will investigate the mechanisms by which both pathogenic microorganisms and those that form part of the normal mucosal flora may cause disease. In addition novel approaches to treatment by using genetically engineered commensal bacteria to deliver microbicidal agents will be investigated.

Recipient or parental organism:
1. E.coli
2. Streptococcus mutants
3. Streptococcus pneumoniae
4. Streptococcus gordonii
5. Streptococcus mitis
6. Fusobacterium nucleatum
7. Tannerella forsythensis
8. Porphyromonas gingivalis
9. Enterococcus faecalis
10. Lactobacillus spp
11. Candida albicans

Host/vector system:
1. Fragments of genomic DNA derived either directly or by polymerase chain reaction amplification derived from Streptococcus spp., T. Forsythensis, F. nucleatum will be used for mutagenesis to generate microorganisms that are defective in gene function either as a result of random mutagenesis or targeted mutagenesis.

2. Gene fragments identified as having functions of interest as above, may be cloned and used for expression of the gene products in E.coli. To understand function of such gene products, mutagenesis may also be performed with expression in E.coli. Similarly, DNA encoding proteins with antimicrobial potential e.g. single domain antibodies, cyanovirin and derived from human, animal, plant or algae sources will be used for expression of the gene product in heterologous hosts. The aims are to identify genes that contribute to virulence of mucosal pathogens and to express proteins that may be used for treatment or prevention of mucosal infections.

The microorganisms that will be modified are part of the normal flora to be found at mucosal surfaces in healthy individuals. Mutagenised microorganisms, Streptococcus spp., T. Forsythensis, F. nucleatum, Candida albicans show or are expected to show loss of function compared with wild type organisms. Streptococcus pneumoniae is a class 2 pathogen and work with virulent strains (i.e. TIGR4 derivatives) will be carried out in a microbiological safety cabinet.

Engineered Streptococcus gordonii and Lactobacillus strains may have comparable colonizing activity to wild type strains but cannot transfer antibiotic resistance since the genes are stably integrated into the chromosome of the modified host and cannot be mobilised. To reduce exposure and risk for the researcher to negligible levels, liquid cultures will be handled in a microbiological safety cabinet.

In all studies, genetically modified material will be destroyed on site by autoclaving.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste from GMM cultures will be aspirated and treated with Haztabs (1 table/litre = 2,500 ppm chlorine) for 12 hours. Concentrated solutions will be made freshly on the day of use according to manufacturer’s instructions. Inactivated culture supernatents will be discharged to the drainage system. Solid waste will be double bagged, sealed and placed in a closed metal container. Waste will then be autoclaved in the closed metal container at 136°C for 30 minutes. This will result in complete inactivation of GMMs. Autoclave tape will be used to indicate that the material has been autoclaved. Autoclave function is monitored by services performed at 3 month intervals by Health Services Associates. Autoclaved waste will be placed in yellow bags for off-site incineration by White Rose.
The local GMSC approved the Risk Assessment for this project on and signed off the component activities on 11th March 2006 and 11th July 2006.

The class of activity is 2.

### Project Additional Information

**Purposes of the contained use**
Identification and study of the host contribution to bacterial infection and pathogenesis. This is done by infection of the fruitfly Drosophila melanogaster with the class 2 pathogen Mycobacterium marinum. Both host (Drosophila) and pathogen (M. Marinum) can be genetically modified.

**Recipient or parental organism**
- Mycobacterium marinum
- Drosophila melanogaster

**Host/vector system**
- M. marinum vectors: pVK173T, pFPV2, and equivalents/derivatives thereof.
- D melanogaster: crippled P-element-derived transposable elements (carried in vector pUAST and equivalents/derivatives thereof).

**Origin & function**
- M. marinum: transgenes encoding fluorescent proteins such as dsRed and GFP, from corals or jellyfish, used for tracking bacteria cells.
- D melanogaster: transgenes encode a variety of molecules (signal-transduction molecules, fluorescent proteins, etc.) of heterologous (human, mouse, jellyfish, coral, bacteria) or homologous origin; used to alter the course of infection and hence to be informative as to the genetic basis of susceptibility to infection or of pathogenesis.

**Evaluation of foreseeable effects**
- M. marinum: in our hands, fluorescent derivatives typically grow more slowly and are slightly less pathogenic than wild-type strains; they will also be resistant to some aminoglycoside antibiotics (apramycin or kanamycin), the net effect should be a mild decrease in pathogenicity for these strains, since primary treatment for M. marinum does not typically depend on aminoglycosides.
- D melanogaster: transgenic files should exhibit reduced fitness relative to other laboratory strains; since lab strains of drosophila are already poorly-adapted for life in the environment, these flies should present no environmental risk.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
We are very careful to prevent release of any pathogen-infected Drosophila.

1. Individual infected flies are tracked.
2. In most cases flies are infected, placed in culture vials and never again removed. Once the experiment is completed, the entire vial (including contained flies) is frozen to kill flies, then autoclaved to kill bacteria, and finally incinerated.
3. In cases where an experiment requires removal of live infected flies as samples, all flies within the vial are anesthetized before the vial is opened, preventing inadvertent escapes.
4. Fly-traps will be placed at frequent intervals in the fly room to attract and contain escaped flies.

Using these techniques, in the course of 6 years doing similar experiments at Stanford University, I observed fewer than 10 escapes of a total of more than 100,000.
Infected flies. All of these escapes were due to defective vial closures; I have now changed the type of vial-closure to one that is more secure, so fewer escapes are expected.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solids: Waste will be double-bagged and autoclaved at 124°C for 15 minutes. Appropriate autoclave indicator tape will be used to monitor autoclave function. After autoclaving, waste will be incinerated by White Rose. Waste containing live flies as well as pathogens will be frozen for at least 6 hours at -20°C before autoclaving.

Liquid: Addition of disinfectant (chlorine bleach to 5% or 1 haztab/litre) followed by pouring down designated sink.

Both procedures are expected to achieve 100% killing.

Monitoring will be done by attempting to culture M. marinum using standard techniques either after autoclaving or after addition of bleach, as appropriate.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Recipient or parental organism

1. E. coli
2. Streptococcus mutans
3. Streptococcus pneumoniae
4. Streptococcus gordonii
5. Streptococcus mitis
6. Fusobacterium nucleatum
7. Tannerella forsythensis
8. Porphyromonas gingivalis
9. Enterococcus faecalis
10. Lactobacillus spp
11. Candida albicans
12. Epithelial cells
13. T cells
14. Knockout mouse

Host/vector system

2. Host: Streptococcus spp.: Vector: pALH109, pALH122, pNE1gfp, pEVp3, pSMB55, pMHL120, pCMG8 or related plasmids
3. Host: T. forsythensis; Vector: pMUF. R II or related plasmids
4. Host: F. nucleatum; Vector: pKH90, pORI9, pHS19, pSH17 or related plasmids
5. Host: C. albicans SC5314 and CAI4 strains; Vector: Cip10
8. Host: Knockout Mouse (C57/BL6)
1. Fragments of genomic DNA derived either directly or by polymerase chain reaction amplification derived from Streptococcus spp., T. Forsythensis, F. nucleatum will be used for mutagenesis to generate microorganisms that are defective in gene function either as a result of random mutagenesis or targeted mutagenesis.

2. Gene fragments identified as having functions of interest as above, may be cloned and used for expression of the gene products in E. coli. To understand function of such gene products, mutagenesis may also be performed with expression in E.coli. Similarly, DNA encoding proteins with antimicrobial potential e.g. single domain antibodies, cyanovirin and derived from human, animal, plant or algae sources will be used for expression of the gene product in heterologous hosts.

3. DNA encoding partial or complete HIV-1 genome to be used for the production of pseudovirus (non-replicating) or intact HIV-1.

The aims are to identify genes that contribute to virulence of mucosal pathogens and to express proteins that may be used for treatment or prevention of mucosal infections.

**Evaluation of foreseeable effects**

The microorganisms that will be modified are part of the normal flora to be found at mucosal surfaces in healthy individuals. Mutagenised microorganisms, Streptococcus spp., T. Forsythensis, F. nucleatum, C. albicans show or are expected to show loss of function compared with wild type organisms. Streptococcus pneumoniae is a class 2 pathogen and work with virulent strains (i.e. TIGR4 derivatives) will be carried out in a microbiological safety cabinet.

Engineered Streptococcus gordonii and Lactobacillus strains may have comparable colonizing activity to wild type strains but cannot transfer antibiotic resistance since the genes are stably integrated into the chromosome of the modified host and cannot be mobilised. To reduce exposure and risk for the researcher to negligible levels, liquid cultures will be handled in a microbiological safety cabinet.

HIV-1 pseudovirus is non-replicating. Intact HIV-1 is infectious and therefore work will be carried out in microbiological safety cabinets in the class 3 laboratory.

In all these studies, genetically modified material will be destroyed on site by autoclaving.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

SOP for use of autoclave external to CL3 laboratory:

All material for disposal will be autoclaved outside of the Cat 3 facility on a cycle that reaches 126°C. Autoclave bins with properly fitted, locking lids containing the waste will be taken from the CL3 laboratory to the autoclave immediately prior to autoclaving. The following procedures will be followed:

i) two trained staff must be available to carry out the procedure

ii) the autoclave room must be available for use.

iii) one member of staff will act to open doors; one will move the autoclave bins from the CL3 facility onto the transport trolley.

iv) the autoclave bins will be sprayed with 70% alcohol before being removed from the CL3 facility and placed on a tray on a trolley outside the CL3 laboratory. Gloves used for transferring the bins must be placed on top of the closed bins

v) autoclave bins from the CL3 laboratory will be taken directly to the autoclave and placed in the autoclave, the lids are then unlocked & turned over to allow steam penetration
vi) when all autoclave bins have been loaded into the autoclave, the tray will also be placed in the autoclave and the autoclave cycle will be started.

vii) at the end of the cycle, the print-out should be kept as a record of adequate sterilisation.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Liquid waste from GMM cultures will be aspirated and treated with Haztabs (1 tablet/litre = 2,500 ppm chlorine) for 12 hours. Concentrated solutions will be made freshly on the day of use according to manufacturer’s instructions. Inactivated culture supernatants will be discharged to the drainage system. Solid waste will be double bagged, sealed and placed in a closed metal container. Waste will then be autoclaved in the closed metal container at 136°C for 30 minutes. This will result in complete inactivation of GMMs. Autoclave tape will be used to indicate that the material has been autoclaved. Autoclave function is monitored by services performed at 3 month intervals by Health Services Associates. Autoclaved waste will be placed in yellow bags for off-site incineration by White Rose.

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Give brief details of the genetic modification safety committee

02/03/2022
For activities involving GMMs, describe the waste management measures which will apply to the activity

Cultures up to 50 L volumes. Chloros (Sodium hypochlorite) at 2% v/v final concentration. Virkon (Potassium monopersulphate/anionic surfactant) at 1% w/v and 20 minutes contact time. Autoclaving for 35 minutes at 121 degrees C (1 bar pressure) is also available for solid waste and cell paste.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment
**Project Additional Information**

**Purposes of the contained use**

To obtain a stably transfected cell lines with a reporter gene constructs containing a transcription factor responsive element fused to a reporter gene. The binding of specific transcription factors to the reporter gene enhancer will provide a direct measurement of activation of the appropriate pathway. The reporter cell lines would be used for invitro cell-based assays that incorporate signal transduction through the required signalling pathway.

**Recipient or parental organism**

Cell lines to be used for transfection with reporter genes are human and of haemopoietic origin. Such cell lines include cells of erythroid origin (eg.TF-1), basophilic (eg.KU812), lymphocytic (eg.Jurkat, Ramos), monocytic (eg. THP-1, U937) and myeloid origin (eg. KG-1, HL-60). There is no evidence that these cells contain active viruses or blood-borne pathogens that represent an identifiable risk for human infection. These cells are unlikely to be oncogenic. The examples of cell lines given have been in continuous culture for > 20 years. In this time, no hazards associated with their use have been reported. However, these cells may contain as yet unidentified viruses or other pathogens and may acquire pathogens during culture as such these cells have been assessed as requiring handling under level 2 containment to minimise any potential risks to the operator. There is no identifiable potential for harm to the environment. Accidental release would not introduce anything into the environment that could easily be transferred to other hosts. The cells require specific nutrients not available outside of culture media and are sensitive to physical conditions present in the environment, thus would be unlikely to survive in the environment.

**Host/vector system**

AAV Helper-Free Systems - Details & Specifications

The first step is cloning the gene of interest into an appropriate plasmid vector. For most applications, the DNA of interest is cloned into one of the ITR vectors (pAAV-MCS). The inverted terminal repeat (ITR) sequences present in these vectors provide all of the cis-acting elements necessary for AAV-2 replication and packaging.
The recombinant expression plasmid is co-transfected into the AAV-293 cells with helper plasmids encoding adenovirus-derived genes and AAV-2 replication and capsid genes, which together supply all of the trans-acting factors required for AAV replication and packaging in the AAV-293 cells. Recombinant AAV-2 viral particles are prepared from infected AAV-293 cells and may then be used to infect a variety of mammalian cells.

**Origin & function**

The reporter vectors are commercially available.

Introduction of the NFκB pathway enables endogenous NFκB to bind to the kappa enhancer element located upstream of the reporter gene on the vector. Binding of NFκB enhances the association of the cell's general transcription machinery with the HSV-TK promoter fused downstream of the Kappa enhancer element. This results in high induction levels of reporter gene transcription.

The SRE responsive element is used to monitor the induction of the serum response element and the mitogen-activated protein (MAP) kinase signal transduction pathway. Addition of serum or growth factors to the cell culture medium induces the binding of transcription factors to the SRE, which activates the transcription of the appropriate reporter gene.

The CRE responsive element is used to monitor the activation of cAMP binding protein (CREB) and cAMP-mediated signal transduction pathways. Several signal transduction pathways are associated with the cAMP response element (CRE), including jun-N-terminal kinase (JNK), p38 and protein kinase A (PKA). Induction of these pathways enables endogenous transcription factors, such as CREB or ATF, to bind CRE, and in turn activate transcription of the appropriate reporter gene.

SEAP and luciferase are highly sensitive enzymic reporters that will be used to provide quantitative data on the absolute induction level of the appropriate signalling pathways. The SEAP gene encodes a truncated form of human placental alkaline phosphatase that lacks the membran-anchoring domain, thereby allowing the protein to be efficiently secreted from transfected cells. After transfection of the SEAP reporter vector into cells, the appropriate reporter pathway can be activated using an appropriate stimulus. The addition of a suitable substrate into the cell culture medium will lead to its dephosphorylation by SEAP and the generation of an appropriate signal.

The firefly luciferase (luc) gene was derived from Photinus pyralis. After transfection of the luciferase reporter vector into cells the appropriate reporter pathway can be activated using an appropriate stimulus, and this results in intracellular accumulation of the product. The addition of a suitable substrate and lysis agent or substrate solution into the cell culture will result in lysis of the cells and the generation of an appropriate signal.

The pcDNA3.1 vector from which the NEO gene was derived is also commercially available. The NEO gene is a bacterial aminoglycoside phosphotransferase (APH) that was derived from the transposon Tn5. Neomycin is an aminoglycoside that blocks protein synthesis in mammalian cells by interfering with ribosomal function. Expression of the NEO gene in mammalian cells results in detoxification of Neomycin. The reporter vectors have been modified with the NEO gene so that a stably transfected cell line could be generated.

**Evaluation of foreseeable effects**

Genetic modification of human cells of haemopoietic origin with the modified reporter gene vectors as described would not increase the potential hazards of these cells to either human health or the environment. Any unidentified risks to human health associated with these cells will be minimised by using good microbiological practice and handling the cells under level 2 containment conditions. The cells require specific nutrients not available outside of culture media and are sensitive to physical conditions present in the environment, thus would be unlikely to survive in the environment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste would be placed in a suitable container and autoclaved prior to disposal.
All liquid waste will be treated for at least 30 min with a chlorine-based disinfectant (2% Chloros v/v or 1% Virkon w/v) before being disposed of down the sink. Spills will be contained using absorbent material (such as paper towels), then Virkon powder added to the spill and left for 5 minutes. The used absorbent material would be disposed of by autoclaving. The area will then be wiped with a chlorine-based disinfectant (2% Chloros v/v or 1% Virkon w/v). Autoclaving or treatment with a chlorine-based disinfectant will be expected to kill 100% of the treated cells. Tests have shown that autoclaving or treatment with 1% Virkon w/v as described above reduced cell viability to 0%. 

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

Please enter comments on the GM safety committee on the risk assessment

The Genetic Modification Safety Committee of the 12th December 2003 found that the risk assessment covering this work identifies the potential risks. The committee agrees with the assessment of activity class 2 and that the use of level 2 containment measures are sufficient to protect human health and the environment. The committee approved this work. The company safety committee was informed of the intention to perform this work on 20/2/04 and made aware of the risks, containment and procedures associated with its completion. There were no additional concerns raised.

Project Additional Information

**Purposes of the contained use**

To use laboratory strains of E. coli, as a host for the expression of antibody single chain Fv (scFv) fragments fused to the truncated mutant form of Pseudomonas exotoxin A, known as PE38, to obtain sufficient material for purification and use of scFv-PE38 in assays for cell killing of malignant B-cells.

**Recipient or parental organism**

Containment level 1, laboratory strains of E. coli such as:
- E. coli TG1 F' traD36 lacI (lacZ)M15 proA+B+/supE (hsdM-mcrB)5 (rk-mk+McrB-) thi (lacproAB)
- E. coli HB2151 nai thi-1 ara (lac-proAB) [F' proAB+ lacIq lacZM15]
- E. coli ORIGAMI (ara-leu) 7697 lacX74 phoA pvull phoR araD139 ahpC galE galK rpsL
- F [lac+lacI pro] gor522::Tn10trxB (Kanr, StrR, TetR)
- E. coli BL21(DE3) F- ompT hsdSB(- mB-) gal dcm (DE3)

Laboratory strains of E. coli are disabled and unable to survive for long periods outside of laboratory culture conditions. Such strains lack any known virulence factors and are non-colonising.

**Host/vector system**

Name and description of vector(s) carrying the gene:
- pCantab6 phagemid, based on pUC119, containing the pMB1 and M13 replicons, LacZalpha and M13 intergenic regions, ampr, M13 leader sequence, scFv gene, 6 His and c-myc tags and M13 p3g.
- pUC119, containing the pMB1 and M13 replicons, LacZalpha and M13 intergenic regions, amp, M13 leader sequence, 6 His and c-myc tags.

**Origin & function**

Pseudomonas exotoxin A is a bacterial toxin composed of three domains: domain Ia (amino acids 1-252) is the cell binding domain; domain II (amino acids 253-364) is responsible for translocation into the cytosol; domain III (amino acids 400-613) ADP-ribosylates elongation factor 2, arresting protein synthesis and causing cell death in eukaryotic cells. Domain Ib (amino acids 365-399) is a minor domain and its function is unknown. PE38 is a modified form in which all of domain Ia and amino acids 365-380 of domain Ib have been deleted.

Antibody scFv domains that target B-cell cell surface proteins, such as CD22, or control scFv antibodies targeting non-human proteins, or haptens.

**Evaluation of foreseeable effects**

There is a potential for the transfer of the genetic material to other hosts. The host strains are F' positive and vectors contain the f1 origin of replication. As such in the presence of a helper phage such as M13K07, vector could be packaged can thus transfer the plasmid to other F' strains. These will be handled using good microbiological practice at containment level 2 and disposed of by a specified route and method potential for transfer is minimised.
Potential risk of transformed host transiently colonising staff through aerosols and low-level splashes. This could potentially result in delivery of B-cell targeted toxin to skin and mucous membranes. The fusion gene products have the potential to induce cytotoxic effects if delivered to the site of action in sufficient quantity. PE38 is only toxic once it has been transferred into the cell cytoplasm, this can only occur when binding is targeted to a cell surface epitope by the attached scFv. The risk of harm is reduced if the target antigen is elevated on malignant B-cells but present at low levels on non-malignant B-cells. The toxin is immunogenic and exposure is likely to generate neutralising antibodies to the drug. However, providing good microbiological practice at containment level 2 is followed and steps where the production of aerosols is likely are performed in a microbiological safety cabinet, the likelihood of the gene product reaching the site of action in sufficient quantity is minimal.

The anti-GITC PE38 fusion poses no identifiable risk as the target is not present in humans. However in practice it will be handled as above. The host E. coli strains used for this are disabled laboratory strains, provided the host carrying these genes is handled using good microbiological practice and disposed of or spills decontaminated by the specific route and method there is no identifiable risk of transfer or harm to the environment. Provided the hosts carrying these genes are handled using good microbiological practice the risk to human health should be minimal at containment level 2 as a precaution until more is known about the toxic effects of the fusion protein.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Solid waste will be placed in a suitable container and autoclaved (at >121 degrees C for longer than 15 min) in a validated autoclave prior to disposal.

All liquid waste will be treated for at least 30 min with a suitable, validated disinfectant (2% Chloros v/v or 1% Virkon w/v) before being disposed of to drains.

Spills will be contained using absorbent material (such as paper towels), then Virkon powder added to the spill and left for 5 minutes. The used absorbent material would be disposed of by autoclaving. The area will then be wiped with a suitable disinfectant (2% Chloros v/v or 1% Virkon w/v).

Autoclaving at >121 degrees C for longer than 15 min or treatment with a chlorine-based disinfectant will be expected to kill 100% of the bacterial cells. In house tests have shown that autoclaving or treatment with 1% Virkon w/v as described above reduced cell viability to 0%.

N

**Please enter comments on the GM safety committee on the risk assessment**

The GMSC held on 8th March 2006 found that the risk assessment identified potential hazards and that the control measures described are sufficient to protect human health and the environment. The committee agreed with the activity class 2 rating and approved the work, subject to HSE notification and consent, to be undertaken only in a designated containment level 2 laboratory. Work to be undertaken only by staff authorised by the manager responsible for this work.

**Project Containment**
Project Additional Information

**Purposes of the contained use**

Primary cells reach senescence after a limited number of population doublings, to use the same consistent cells throughout a research project, primary cells with extended replicative capacity, or immortalised cells are required. This risk assessment describes the use of modified lentiviral particles expressing sequence encoding either human telomerase (hTERT) or simian virus 40 (SV40) T antigen for the generation of stable immortalised primary cell lines to overcome senescence of these cells and to extend their use for subsequent in vitro studies.

**Recipient or parental organism**

Hazard Group 2 mammalian and primary human cells isolated from human tumours or normal tissue and covered by appropriate COSHH risk assessments.
The use of commercially available lentiviral particles expressing hTert or SV40 T antigen:

SV40 large T antigen (Simian Vacuolating Virus 40 Tag) is an oncogene derived from the polyomavirus SV40 which is capable of transforming a variety of cell types. The transforming activity of TAg is due in large part to its perturbation of the retinoblastoma (pRB) and p53 tumor suppressor proteins. In addition, TAg binds to several other cellular factors, including the transcriptional co-activators p300 and CBP, which may contribute to its transformation function.

3rd generation lentiviral vectors will be generated by a commercial source. All vectors used in this type of technology are self inactivating which minimises any risk. Lentiviral vectors fused to generate lentiviral particles from commercial sources have been designed to maximise their biosafety features. The envelope of HIV-1 has been completely removed from the vector and replaced with the VSV-G gene from Vesicular Stomatis Virus to pseudotype (envelope) the particles. Only five genes from HIV-1 are used in the system (gag, pol, rev, tat and vpr). These genes are required for packaging the virus particles. To minimise the threat of producing recombinant and new replication-competent virus, the genes are separated on to five different plasmids and contain no significant areas of homology. The expression vector contains a deletion in the 3’ LTR that results in self-inactivation of the virus after transduction of the target cell. Additionally, the four packaging plasmids may allow expression in trans of the proteins required to produce virus but none of the plasmids contain LTRs or the Ψ packaging sequence. This means that none of the HIV-1 structural genes are present in the packaged virus and therefore, are not expressed in the transduced target cell. It also minimises the chance of new replication-competent virus being produced. Virus will be produced by commercial sources and not on site.

Human Telomerase Reverse Transcriptase (hTERT for short) maintains telomere ends by addition of the telomere repeat TTAGGG. Without telomerase and TERT in humans DNA is unable to replicate ultimately causing cellular senescence, otherwise known as cell death. This is the basis for the aging process in humans. As cells die they are no longer able to replicate newer, fresher cells, hence causing aging. Hence when telomeres shorten cells die. Using methods to enhance hTERT in humans we can increase the health of telomeres and hence maintain replicative capacity of cells.

**Origin & function**

Human Telomerase Reverse Transcriptase (hTERT for short) maintains telomere ends by addition of the telomere repeat TTAGGG. Without telomerase and TERT in humans DNA is unable to replicate ultimately causing cellular senescence, otherwise known as cell death. This is the basis for the aging process in humans. As cells die they are no longer able to replicate newer, fresher cells, hence causing aging. Hence when telomeres shorten cells die. Using methods to enhance hTERT in humans we can increase the health of telomeres and hence maintain replicative capacity of cells.

**Evaluation of foreseeable effects**

What are the potential hazards associated with the recipient host?
Primary cells are derived from unfixed human tissue, although some there is a potential risk of human infection from agents they may harbour and will be treated as Hazard Group 2.

What are the potential hazards arising from the gene product?
The expression of SV40Tag or hTERT are both oncogenic and will transform and/or immortalise cells allowing them to overcome replicative senescence. This is a property that we want to take advantage of to increase the lifespan of these primary cells.

What are the additional potential hazards arising from the combination of gene and host?
No additional hazards these are self inactivating viruses and pose no risk following integration into the host genome.

What is the potential for the transfer of the gene to other hosts? i.e. with no controls in place
Lentiviral particles can infect almost all human cells (including non-dividing cells), however, the recombinant retroviral vectors used to generate viral particles are self inactivating, replication deficient in that they are unable to replicate and do not express any of their endogenous genes. Once within the mammalian cell no viral particles would be produced. The virus could not therefore be transferred to another host.

What is the potential for harm to human health (in the event of exposure)? i.e. with no controls in place
The only realistic route of exposure likely to lead to engraftment is via a sharps injury and even in such a scenario the likelihood of that outcome is still low given that the cells are non-syngeneic with those handling them, although this may be more likely with tumour cells (whether recombinant or not).

What is the potential to disseminate and harm the environment (in the event of accidental release)? i.e. with no controls in place
These do not pose any identifiable risk to the environment because the reagent containing lentivirus is unable to replicate unless supplied with helper plasmids hence they cannot replicate outside of laboratory conditions.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All GMO waste must be inactivated prior to disposal as Non-hazardous Biological waste (EWC 18 01 04) or where inactivation is not possible as Hazardous Biological waste (EWC 18 01 03). Inactivation should be by autoclaving or by chemical treatment with 1% final Virkon for at least 30 minutes (or other validated method).

Note: Occasions where inactivation is impossible due to the high volume of material, e.g. from robotic systems or due to the inability to prove inactivation, as is the case with large sealed filtration units. In such cases we use a registered waste contractor to remove as hazardous biological waste for incineration.

Both non-hazardous and hazardous biological waste are sent for incineration.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

This work should be classified at Activity Class 2, because of the potential for adventitious agents to be present in the primary cells. There is a slight chance that recombinant cells could be able to divide more quickly or disseminate more widely in the event of accidental engraftment; however, this would not affect the risk control measures requirement. The only realistic route of exposure likely to lead to engraftment is via a sharps injury and even in such a scenario the likelihood of that outcome is still low given that the cells are non-syngeneic with those handling them, although this may be more likely with tumour cells (whether recombinant or not).

The generation and use of lentiviral particles for mediating gene modulation in Hazard Group 1 & 2 and Activity Class 1 & 2 cells and their subsequent use in vitro and in vivo.

To enable the generation of lentiviral particles encoding Open Reading Frames (ORFs), cDNAs or specific gene sequences and their subsequent use in vitro and / or in vivo. The goals of this body of work are to enable the generation and use of third generation, recombinant lentiviral vectors expressing ORFs, cDNAs, specific gene sequences and / or shRNAs and their subsequent use to: 1) Efficiently generate cell and disease relevant models lines for assessment of target biology 2) To validate literature data 3) To create new models for use in the oncology and other therapeutic areas and 4) To identify and / or validate ORFs / cDNAs or specific gene sequences as potential drug targets.

Mammalian cell lines including Hazard Group 1 and 2 and Activity Class 1 and 2 genetically modified cells all of which are covered by appropriate risk assessments.

Third generation (or greater) lentiviral vectors will be used (ref: SACGM compendium of guidance part 2-11 P119 sections 8- 30).
“Third Generation” lentiviral vectors have several of the lentiviral accessory genes (required for pathogenesis only) deleted to increase biosafety. These include the vif, vpr, vpu and nef accessory genes which are not required for in vitro replication. The tat gene is also deleted and the Tat-responsive promoter present in the 5’ LTR is replaced with heterologous promoters, for example with the Rous sarcoma virus U3 region. An additional biosafety feature is achieved by deletion of the rev gene from the viral transfer vector. Viral packaging is achieved by providing three
helper constructs in trans containing gag, pol and rev sequences. An additional biosafety feature is that these vectors are self-inactivating (SIN), whereby the U3 region of the 3’ LTR (which contains the major viral promoters and enhancers) is copied to the 5’ end of the provirus during reverse transcription. Deletion of enhancer and promoter elements from the 3’ U3 region in the vector construct will result in a provirus that is entirely devoid of U3 enhancer sequences, therefore reducing the potential for transactivation of cellular genes as a result of insertion. Furthermore, such vectors are not easily mobilisable as a result of a superinfection with wild-type virus.

**Origin & function**

Open reading frames, cDNAs and gene sequences encoding potential drug targets or therapeutic proteins and/or shRNAs (designed to knockdown the expression of Open reading frames, cDNAs and gene sequences encoding potential drug targets or therapeutic proteins) will be expressed in self inactivating lentiviral expression vectors. Guidance on inserts that may have greater risk of adverse effects on human health can be found in SACGM compendium of guidance part 2-2 p37-46.

Of particular note:

**Oncogenes** (ref: SACGM compendium of guidance part 2-2 p38 sections 6-9)

Genes encoding known proto-oncogenes or genes with known oncogenic mutations which can contribute to cellular transformation. Full length cDNA encoding wild type and disease relevant mutants of these types of genes will be expressed in third generation SIN lentiviral vectors. Any use of lentiviral particles encoding oncogenic inserts will require appropriate controls and operator training.

Examples of genes that may be categorised as oncogenes include:

- Growth factors, or mitogens,
- receptor tyrosine kinases,
- cytoplasmic tyrosine kinases,
- cytoplasmic serine/threonine kinases and their regulatory subunits,
- regulatory GTPases
- transcription factors.

**Knockdown of tumour suppressors** (ref: SACGM compendium of guidance part 2-2, p42, paragraph 24).

Knockdown of genes encoding known tumour suppressors can contribute to cellular transformation. However, shRNA expression systems rarely completely silence the targeted gene. shRNAs targeting these types of genes or gene sequences with tumour suppressive functions will only be expressed in third generation SIN lentiviral vectors. Any use of lentiviral particles capable of reducing tumour suppressor expression will require appropriate controls and operator training.

Examples of genes that may be categorised as tumour suppressors include:

- p53 Nuclear, transcription factor
- RB1 Nuclear, transcription modifier
- APC Cytoplasmic, function unknown
- ATM Unknown location, kinase
- WT1 Nuclear, transcription factor
- NF1 Cytoplasmic, GTPase activating protein
- NF2 Cytoplasmic/cytoskeletal, membrane linkage
- P16 INK4 Nuclear, cyclin dependant kinase inhibitor
- VHL Nuclear, adaptor

Selectable markers – examples (but not restricted to):

- Ampicillin resistance: E.coli derived
Evaluation of foreseeable effects

Open reading frames, cDNAs and gene sequences encoding potential drug targets or therapeutic proteins and/or shRNAs (designed to knockdown the expression of Open reading frames, cDNAs and gene sequences encoding potential drug targets or therapeutic proteins) will be expressed in self inactivating lentiviral expression vectors. Guidance on inserts that may have greater risk of adverse effects on human health can be found in SACGM compendium of guidance part 2-2 p37-46.

Of particular note:
- Oncogenes (ref: SACGM compendium of guidance part 2-2 p38 sections 6-9).
  Genes encoding known proto-oncogenes or genes with known oncogenic mutations which can contribute to cellular transformation. Full length cDNA encoding wild type and disease relevant mutants of these types of genes will be expressed in third generation SIN lentiviral vectors. - Selectable markers – examples (but not restricted to);
  • Ampicillin resistance: E.coli derived
  • Neomycin resistance: bacteria derived aminoglycoside phosphotransferase gene
  • Puromycin resistance (PAC): Puromycin acetyl transferase is derived from Streptomyces alboniger

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All GMO waste must be inactivated prior to disposal as Non-hazardous Biological waste (EWC 18 01 04) or where inactivation is not possible as Hazardous Biological waste (EWC 18 01 03). Inactivation should be by autoclaving or by chemical treatment with 1% final Virkon for at least 30 minutes (or other validated method).

Note: Occasions where inactivation is impossible due to the high volume of material, e.g. from robotic systems or due to the inability to prove inactivation, as is the case with large sealed filtration units. In such cases we use a registered waste contractor to remove as hazardous biological waste for incineration.

Both non-hazardous and hazardous biological waste are sent for incineration.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

Please enter comments on the GM safety committee on the risk assessment

The BioSafety Committee classified this work at Activity Class 2 because of the use of HG/AC2 hosts and also the potential and/or unknown hazard of the inserted gene sequences rather than the use of the proposed lentiviral vectors. They were prepared to approve the work at AC2, since they saw no likelihood for the introduction of any Containment Level 3 requirements due to changes in infectivity.

They recommended that a note was included to allow reclassification to AC1 for some resultant cell lines, e.g. "Note: Where there is an opportunity to reclassify the culture and use of resulting cell lines as Activity Class 1, i.e. HG/AC1 hosts with non-hazardous sequences, a further GM risk assessment should be completed."

Project Ref 387/11.1
To use plasmids encoding:

1) Open Reading Frames (ORFs), cDNAs or specific gene sequences
2) silencing RNAs (e.g. siRNAs for the knockdown of Open Reading Frames (ORFs), cDNAs or specific gene sequences by RNA Interference (RNAi)

To create stable or transient recombinant hazard group or Activity Class 1 or 2 cell lines, and their subsequent use in vitro and/or in vivo.

This Risk assessment covers work where either the parental cell already requires Containment Level 2, or where the genetic insert is considered to have the potential to be hazardous, or increases the hazard of the parental cell.

Recipient or parental organism

The experimental work proposed here involves the generation of engineered plasmids and the transfection into mammalian or insect cell lines in vitro. Transfections may be transient or undergo selection to establish stable pools and/or clonal lines.

Following the transfection of the cell lines with gene specific plasmids;

- RNA and protein may be extracted from the cells to determine expression levels of target gene/product
- supernatants may be harvested for purification
- other function/cell based assays may be performed.
- Cell lines may be used for antibody selections in phage display
- Cell lines may be used in vivo for antibody generation, or for animal models

Host/vector system

The plasmid vectors to be used are derived form commercially available pUC or pBR322/pBR325 derived vectors, hence are high copy number, non-mobilisation deficient, contain ColE1 origin, with strong or moderate cellular or viral promoters (beta-actin, MV, SV40, EF1a) and one or more selectable marker (G418, zeocin, hygromycin resistance).
Examples of these vectors are given below.

pcDNA family:
Contains SV40 origin and early promoter expressing the neomycin resistance gene. pUC origin of replication, an F1 intergenic region and ampicillin resistance marker. Heterologous expression under control of CMV promoter.

pEE family:
Mammalian expression vectors containing the glutamine synthetase (GS) gene downstream of the SV40-early promoter. The gene of interest sequence is cloned downstream of the cytomegalovirus (CMV) immediate early promoter and upstream of the SV40 poly A terminator. The ampicillin resistance gene (beta-lactamase) is also present for propagation and selection in E.coli.

pDEST family (may contain oriP):
Mammalian expression vectors containing the ampicillin resistance (beta-lactamase) gene for propagation and selection in E.coli. An antibiotic resistance gene is also present downstream of the SV40-early promoter and upstream of the SV40 poly A terminator. The pUC origin of replication is present for propagation in E. coli and the EBV origin of replication (oriP) may be present for episomal replication in EBNA expressing cells. The gene of interest sequence is cloned downstream of the cytomegalovirus immediate early (CMVIE) promoter and upstream of the SV40 poly A terminator. The vector also contains the SV40 origin and an F1 intergenic region.

plEx insect cell vectors (Novagen):
The plEx vectors are designed for cloning and high-level expression of proteins in transiently transfected Spodoptera-derived insect cells. To drive target gene expression, the vectors employ an optimal combination of two transcription elements derived from AcNPV baculovirus, the hr5 enhancer and the IE1 immediate early promoter. This promoter/enhancer combination recruits endogenous insect cell transcription machinery, thereby avoiding the need for using baculovirus.

In this risk assessment both "non-hazardous" and "hazardous" inserts are covered.

Open reading frames, cDNAs and gene sequences encoding potential drug targets or therapeutic proteins and/or siRNAs (designed to knockdown the expression of Open reading frames, cDNAs and gene sequences encoding potential drug targets or therapeutic proteins) will be expressed.

Guidance on inserts that may have greater risk of adverse effects on human health can be found in SACGM Compendium of Guidance part 2-2 p37-46.

Of particular note:
Over-expression of Oncogenes (ref: SACGM compendium of guidance part 2-2 p38 sections 6-9).

Genes encoding known proto-oncogenes or genes with known oncogenic mutations which can contribute to cellular transformation. Examples of genes that may be categorised as oncogens include:

- p53 Nuclear, transcription factor
- RB1 Nuclear, transcription modifier
- APC Cytoplasmic, function unknown
- ATM Unknown location, kinase
- WT1 Nuclear, transcription factor
- NF1 Cytoplasmic, GTPase activating protein
- NF2 Cytoplasmic/cytoskeletal, membrane linkage
- P16 INK4 Nuclear, cyclin dependant kinase inhibitor
- VHL Nuclear, adaptor
- Selectable markers - examples (but not restricted to);
  - Ampicillin resistance; E coli derived
### Evaluation of foreseeable effects

**What are the potential hazards associated with the recipient host?**

Hazard Group and Activity Class 1 mammalian cell lines in continuous culture have been found unable to establish colonies in immuno-competent human adults following intradermal inoculation, ingestion or inhalation. Not known to be allergenic or toxic. Sf9 and Sf21 insect cells are non-pathogenic and there is no evidence that these cells contain active viruses or pathogens that represent an identifiable risk for human infection.

Hazard group 2 mammalian cells, primary human cells isolated from human tumours or normal tissue and covered by appropriate risk assessments. These may harbour viruses or other pathogens.

**What are the potential hazards arising from the gene product?**

The expression of the majority of genes is predicted to generally have little or no adverse effect. However, the precise outcome is difficult to predict. Expression of proto-oncogenes and oncogenic derivatives of these genes may transform normal epithelial and fibroblast cells and potentially enhance proliferation and tumourgenesis of cancer cell lines. Many Hazard Group 1 cancer cell lines in use already harbour mutations within these genes.

Knockdown of tumour suppressor genes may contribute to cellular transformation of normal epithelial and fibroblast cells and potentially enhance proliferation and tumourgenesis of cancer cell lines. Multiple cancer cell lines many of which already harbour mutations within one or more of these genes.

**What are the additional potential hazards arising from the combination of gene and host?**

The expression of the majority of genes is predicted to generally have little or no adverse effect. However, the potential outcomes of down regulating particular targeted genes should be carefully assessed. For example, knocking down the expression of a tumour suppressor gene in a mammalian cell could contribute to cellular transformation.

However, one of the features of RNAi knockdown systems is that the targeted gene is rarely completely silenced. Indeed, it is not unusual for there to be varying degrees of target gene down-regulation within an experimental population and therefore it is important to consider the ramifications of heterogeneous expression of the targeted genes.

**What is the potential for the transfer of the gene to other hosts? i.e. with no controls in place.**

Once within the host cell the plasmids are either stably integrated or transiently expressed and are not mobilisable.

**What is the potential for harm to human health (in the event of exposure)? i.e. with no controls in place.**

Genetically modified cells could have the potential to impair normal biological pathways and systems. However, the immune system would quickly recognise these cells as foreign and mount an immune defensive response. Recipient strains that are able to infect or colonise human hosts should be avoided i.e work should not be performed on ones own cells or those of other laboratory staff.

**What is the potential to disseminate and harm the environment (in the event of accidental release)? i.e. with no controls in place.**

There is no evidence to suggest that the host or genetically modified cell line will be able to propagate outside of a controlled laboratory environment without defined growth media and temperature requirements. There are no gene products that are known to be harmful to humans or to the environment.
In Vivo Waste Management

We would be doing the cell-based genetic modifications in our main laboratories and some of the resulting cells may be transferred over to our animal facility to administer into animals.

We would only send untreated GM waste off site from our main laboratories and only in two situations, which relate solely to medium to high scale cell culture, not in vivo work. These are:

• where the high volume of waste demands it, i.e. where we have robotic systems generating high volumes of plastic ware that we are unable to autoclave and;
• where we have large sealed filter housing units that we are unable to validate that inactivation has been successful without breaking open the unit and creating an increased risk of contamination.

Our animal facility is quite separate from the main laboratories and has its own set of waste handling procedures. In fact, no untreated GM waste, either solid or liquid, is transported off-site from our animal facilities; it will always be treated on-site prior to off-site incineration.

Treatment would be by autoclaving to 121°C for 45 minutes as a minimum (or 131°C for liquids).

Containment

We have separate isolation cages for our GM in vivo work, which is completely sealed with separate negative pressure air supply and a HEPA filter inlet and outlet. Our building is a designated building, regulated under the Animal (Scientific Procedures) Act 1986 and is therefore designed to prevent escape and to ensure complete containment of animals. We are also an AAALAC accredited establishment.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

There are occasional requirements to transfer untreated waste off site for incineration with a waste contractor approved to carry hazardous biological waste. This situation would only occur if a project was scaled up and would be when we did not have the onsite facilities to deal with the volume or type of consumables.

I request a derogation for to transfer untreated waste off site for incineration.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All GMO waste is inactivated prior to disposal as Non-hazardous Biological waste (EWC 18 01 04) or where inactivation is not possible as Hazardous Biological waste (EWC 18 01 03). Inactivation should be by autoclaving or chemical treatment with 1% final Virkon for at least 30 minutes (or other validated method).

Note: Occasions where inactivation is impossible due to the high volume of material, e.g. from robotic systems or due to the inability to prove inactivation, as is the case with large sealed filtration units. In such cases we use a registered waste contractor to remove a s hazardous biological waste for incineration.

Both non-hazardous and hazardous biological waste are sent for incineration.

**Project Additional Information**

**Purposes of the contained use**

To enable the generation and subsequent use of adenoviral particles encoding Open Reading Frames (ORFs), cDNAs, or shRNAs directed to specific gene sequences both in vitro and/or in vivo.

The goals of this body of work are to enable the generation and use of third generation ‘gutless’ adenoviral vectors expressing ORFs, cDNAs, shRNAs or specific gene sequences and their subsequent use to: 1) Efficiently generate cell and disease relevant models lines for assessment of target biology 2) To validate literature data 3) To create new models for use in the oncology and other therapeutic areas and 4) To identify and/or validate ORFs/cDNAs or specific gene sequences as potential drug targets.

**Recipient or parental organism**

Adenoviral vectors are viral-based gene delivery systems that can efficiently transduce a wide range of target cells resulting in high-level gene expression. They are non-integrating vectors so expression in dividing cells is progressively lost.

The experimental work proposed here involves the generation of adenoviral particles and the addition of adenovirus particles encoding gene sequences to mammalian cell lines (Hazard group 1 and 2 and Activity class 1 and 2 cells) in vitro and the direct administration in vivo. Following the transduction of the mammalian cell lines with adenovirus, RNA and protein will be extracted from the cells to determine expression levels of target gene or gene product and functional assays will be performed.

Following the direct administration of adenoviral vectors in vivo, animals will undergo behavioural analysis (as detailed in project licence) and/or tissues/cells will be harvested and used in downstream functional assays.

**Host/vector system**

Mammalian cell lines including Hazard Group 1 and 2 and Activity Class 2 genetically modified cells all of which are covered by appropriate risk assessments.

**Vector**

Third Generation "Gutless" Adenoviral Vectors will be used (ref: SACGM compendium of guidance part 2-7 p 80 sections 5).

Third Generation vectors have been constructed by deleting the majority of the viral genes (E1, 2 and 3 genes) and retain only packaging sequences (Amalfitano et al., 1998) and the latest vectors have all or nearly all of the virus genes removed. These so-called 'gutless' vectors (Hardy et al., 1997; Kumar-Singh & Chaberlain, 1996; Leiber et al., 1999, Morsy et al., 1998; Steinwaerder et al., 1999) originally retained only the ITR and packaging sequences and required helper virus and appropriate complementing cells for propagation, followed by careful purification to remove helper virions. This design was based on finding that all adenoviral packaging proteins could be supplied in trans (Morsey et al., 1998). The vectors are transfected into a cell line like HEK293 that is able to supply the proteins required for replication in trans along with a helper virus that has deletions in its genome.

The psi (packaging) sequence is often flanked by LoxP sequences which results in the deletion of the psi sequence from the adenovirus helper genome following the expression of cre recombinase in the packaging cell line which substantially reduce the packaging of the helper genome into the virion.

**Origin & function**

In this risk assessment both "non-hazardous" and "hazardous" inserts are covered.

Open reading frames, cDNAs, and gene sequences encoding potential drug targets or therapeutic proteins or shRNAs designed to knockdown the expression of specific gene sequences will be expressed in adenoviral expression vectors.
Guidance on expression of inserts that may have greater risk of adverse effects on human health can be found in SACGM compendium of guidance part 2-2 p 37-46.

Of particular note:

Oncogenes (ref: SACGM compendium of guidance part 2-2 p 38 sections 6-9).

Genes encoding known proto-oncogenes or genes with known oncogenic mutations which can contribute to cellular transformation. Full length cDNA encoding wild types and disease relevant mutants of these types of genes will be expressed in adenoviral vectors.

Knockdown of tumour suppressors (ref: SACGM compendium of guidance part 2-2, p42 paragraph 24).

Knockdown of genes encoding known tumour suppressors can contribute to cellular transformation. However, shRNA expression systems rarely completely silence the targeted gene.

Any use of adenoviral particles capable of increasing expression of potential oncogens or reducing tumour suppressor expression will require appropriate controls and operator training.

Evaluation of foreseeable effects

What are the potential hazards associated with the recipient host?

These will vary depending on the cell type and can be known or unknown. Primary human samples are screened for the presence of the high risk human pathogens hepatitis virus and HIV by the supplier. Samples containing such pathogens should not be used.

In general, Hazard Group 2 cells and Activity class 2 cells present a greater risk than Hazard Group 1 cells, usually due to their potential to harbour human pathogens.

What are the potential hazards arising from the gene product?

The knockdown of or increased expression of the majority of genes is predicted to generally have little or no adverse effect. However, the precise outcome is difficult to predict. Knockdown of tumour suppressor genes may contribute to cellular transformation normal epithelial and fibroblast cells and potentially enhance proliferation and tumourigenesis of cancer cell lines and expression of proto-oncogenes and oncogenic derivatives of these genes will transfrom normal epithelial and fibroblast cells and potentially enhance proliferation and tumourigenesis of cancer cell lines. Cells expressing these gene products pose no greater risk than Hazard Group 1 or 2 cancer cell lines many ofwhich harbour mutations within these genes.

What are the additional potential hazards arising from the combination of gene and host?

Adenoviral gene transfer is one of the most reliable methods for introducing genes into mammalian cells. Because infection by adenovirus is no cell-cycle dependent, you can deliver your gene to primary as well as transformed cell lines. Following infection, your target gene is transiently expressed at high levels since many cells receive multiple copies of the recombinant genome. Expression is transient because adenoviral DNA normally does not integrate into the cellular genome so expression in dividing cells is progressively lost. However persistent expression in non-dividing cells has been observed in vivo (Chen, H. H. et al., (1999) Human Gene Ther. 10:365-373).

Adenoviruses are capable of infecting a wide variety of proliferating and quiescent cell types from many different animal species including humans, non-human primates, pigs, rodents, mice, and rabbits. Published reports suggest that nearly all human cell types - including skin, muscle, bone, nerve and liver cells - are susceptible to infection by adenovirus. Replication-deficient adenovirus may theoretically recombine with the wild-type virus to result in a replication - competent virus. However with third generation or gutless vector systems this risk is minimal. Several recombination events would be required and this is unlikley to occur.

The following 3 boxes look at the theoretical potential for harm to human health. Do not refer to ways risks are minimised.

What is the potential for the transfer of the gene to other hosts? i.e. with no controls in place.

Adenovirus can infect almost all human cells (including non-dividing cells). Adenoviruses are unusually stable to chemical or physical agents and adverse pH or...
temperature conditions, allowing for prolonged survival outside of the body of water. However, the recombinant vectors used to generate viral particles are replication
deficient in that they are unable to replicate and do not express any of their endogenous genes and require packaging components to be provided in trans.

What is the potential for harm to human health (in the event of exposure)? i.e. with no controls in place.

Wild-type adenoviruses are respiratory pathogens and in vivo infections are generally limited to the epithelial cells lining the respiratory tract, they most commonly cause respiratory illness, but may also cause other illnesses such as gastroenteritis and conjunctivitis. Patients with compromised immune systems are especially susceptible to severe complications of adenovirus infection. Wild type Adenovirus is generally associated with mild respiratory infections in children, and it is thought that the majority of the population is likely to have antibodies to the wild type virus.

Adenoviruses are highly stable in even adverse conditions, allowing prolonged survival outside the body. Adenoviruses are most commonly transmitted by direct contact, such as a handshake. Persons who are infected may shed the virus for months or years, without experiencing any symptoms. Many people have been exposed to adenoviral infections throughout their lives and have anti adenoviral immunity.

However, Adenoviral vectors (Third generation) are rendered replication-deficient by removal of the majority of viral genes including the E1a gene, which is essential for the virus to replicate. If the virus cannot reproduce, it cannot sustain the illnesses listed above. The only potential for harm to human health could be through direct exposure to or injection of the recombinant adenoviral particles. However, even with injection the immune system would most likely recognise this as foreign and would mount an immune defensive response. Recipient strains that are able to infect or colonise human hosts should be avoided i.e. work should not be performed on one's own cells or those of other laboratory staff. The particles are unable to penetrate through gloves and would be unlikely to penetrate the dead layers of skin cells.

What is the potential to disseminate and harm the environment (in the event of accidental release)? i.e. with no controls in place.

Adenoviral vectors do not pose any identifiable risk to the environment because the reagent is unable to replicate unless supplied with helper plasmids and hence they cannot replicate outside of laboratory conditions.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**In vivo Waste Management**

We would be doing the cell-based genetic modifications in our main laboratories and some of the resulting cells may be transferred over to our animal facility to administer into animals.

We would only send untreated GM waste off site from our main laboratories and only in two situations, which relate solely to medium to high scale cell culture, not in vivo work. These are:
- Where the high volume of waste demands it i.e. where we have robotic systems generating high volumes of plasticware that we are unable to autoclave and;
- Where we have large sealed filter housing units that we are unable to validate that inactivation has been successful without breaking open the unit and creating an increased risk of contamination.

Our animal facility is quite separate from the main laboratories and has its own set of waste handling procedures. In fact, no untreated GM waste, either solid or liquid, is transported off-site from our animal facilities; it will always be treated on-site prior to off-site incineration.

Treatment would be by autoclaving for 121°C for 45 minutes as a minimum (or 131°C for liquids).

**Containment**

We have separate isolation cages for our GM in vivo work, which is completely sealed with separate negative pressure air supply and a HEPA filter inlet and outlet. Our building is a designated building, regulated under the Animal (Scientific Procedures) Act 1986 and is therefore designed to prevent escape and to ensure complete containment of animals. We are also an AAALAC accredited establishment.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

There are occasional requirements to transfer untreated waste off site for incineration with a waste contractor approved to carry hazardous biological waste. The situation would only occur if a project was scaled up and would be when we did not have the onsite facilities to deal with the volume or type of consumables.

I request a derogation for to transfer untreated waste off site for incineration.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All GMO waste is inactivated prior to disposal as Non-hazardous Biological waste (EWC 18 01 04) or where inactivation is not possible as Haardous Biological Waste (EWC 18 01 03). Inactivation should be by autoclaving or by chemical treatment with 1% final Virkon for at least 30 minutes (or other validated method).

Note: Occasions where inactivation is impossible due to the high volume of material, e.g. from robotic systems or due to the inability to prove inactivation, as is the case with large sealed filtration units. In such cases we use a registered waste contractor to remove as hazardous biological waste for incineration.

Both non-hazardous and hazardous biological waste are sent for incineration

Please enter comments on the GM safety committee on the risk assessment

The BioSafety Committee classified this work as Activity Class 2 by reference to the following:

(ref: SACGM compendium of guidance part 2 p84 sections 23). "Many adenovirus vectors will be considered low risk GM activity class 1 and can be handled at Containment Level 1. This means that virus preparations could be handled on the open bench. However, adenoviruses are robust and transmitted effectively in aerosols and droplets, even if disabled or attenuated. Therefore, measures might be required to control aerosol generation and airborne dissemination."

However since Activity Class 2 and Hazard Group 2 will be used and the inserts pose additional risk this work should be classified as 2.

There was some discussion about the ability of the virus for prolonged survival outside the body and the committee felt that there should be some mention of the means of surface decontamination and if a dedicated hood was advisable.

They were also prepared to approve the work at AC2, since they saw no likelihood for the introduction of any Containment Level 3 requirements due to changes in infectivity.

They recommended that a note was included to allow reclassification to AC1 for some resultant cell lines, e.g. "Note: Where there is an opportunity to reclassify the culture and use of resulting cell lines at Activity Class 1 i.e. HG/AC1 hosts with non-hazardous sequences, a further GM risk assessment should be completed."

---

Project Containment
Project Additional Information

**Purposes of the contained use**

The keratinocyte cell line (ATCC, CCD KERTr) will provide a continual cell source for in vitro experiments to explore the biology around inflammatory skin disease.

**Recipient or parental organism**

Cells are primary human skin epithelial cells, keratinocytes (immortalized). Human keratinocyte cell line (CCD 1106 KERTr) will be cultured using standard tissue culture techniques. Cells may be used in antibody selections and in several in vitro cell based assays. Human keratinocyte cell line is available from ATCC (CRL-2309 ). These calls should be assigned a Containment Level 2 category.

**Host/vector system**

**Vector:**
The pLXSN16E6E7 vector contains the human papilloma virus (HPV) type 16 E6 and E7 genes under control of the Moloney murine leukemia virus (MoMuLV) promoter-enhancer sequences. The vector also contains a gene controlling resistance to neomycin transcribed from the SV40 promoter. This line produces the amphotropic retrovirus LXSN16E6E7 which encodes the HPV16 E6 and E7 open reading frames, and which can be used to stably infect and immortalize many cell types. Therefore, this RA could potentially cover any human cell line that has been immortalized with this retroviral system.

**Origin & function**
The pLXSN16E6E7 vector contains the human papilloma virus (HPV) type 16 E6 and E7 oncogenes under control of the Moloney murine leukemia virus (MoMuLV) promoter-enhancer sequences. The E6 & E7 oncogene products will immortalize the recipient cell.

**Evaluation of foreseeable effects**

Potential hazards associated with the recipient host:
These will vary depending on the cell type and can be known or unknown. Potential common pathogens might be human pathogens such as Epstein Barr virus or rhinovirus. Primary human samples are screened for the presence of the high risk human pathogens hepatitis virus and HIV by the supplier. Samples containing such pathogens should not be used.

Potential hazards arising from the gene product:
The expression of the majority of genes is predicted to generally have little or no adverse effect. However, the precise outcome is difficult to predict. The work outlined in this assessment covers therapeutic transgenes and gene sequences expressed by the recombinant OV by their very nature these will have a therapeutic effect. Cells expressing these gene products pose no greater risk than Hazard Group 1 or 2 cancer cell lines and expression of a therapeutic transgene will often result in cancer cell death or arrest and render the cells more immunogenic in vivo which would result in greater clearance.

Potential hazards arising from the combination of gene and host:
The knockdown of or increased expression of the majority of genes is predicted to generally have little or no adverse effect. Gene products will only ever be expressed in cells that are able to support viral replication (tumour cells) and the greater the expression levels the more likely the cell is permissive to viral replication and will ultimately die due to this property. Cells expressing these gene products pose no greater risk than Hazard Group 1 or 2 cancer cell lines many of which harbour mutations within these genes or expressing these genes through other delivery vectors (adeno- or lentiviral transduction). Enhanced tumour cell killing is a beneficial additional effect of combination of host and gene.

Potential for transfer of gene to other hosts:
The recombinant OV agent can infect most human cells (including non-dividing cells). However, normal cells will not support viral replication and the virus will be inactivated. In cancer cells where replication is permissible the virus will be propagated and will result in cell lysis and death and release of virus which will go on to infect other surrounding cells. By their very nature, the replication component virus cells that support viral replication will ultimately die due to viral replication, and the level of viral replication will drive the level of the therapeutic transgene which will also enhance immune clearance in vivo or cell killing.

Potential for harm to human health in the event of exposure:
The recombinant OV agent has very low pathogenicity and is not considered a human pathogen. Human infection following acute exposure to large quantities of virus causes at most mild symptoms. No human-to-human
Transmission has ever been observed.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None required

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All GMO waste is inactivated prior to disposal as Non-hazardous Biological waste (EWC 18 01 04) or where inactivation is not possible as Hazardous Biological waste (EWC 18 01 03). Inactivation will be by autoclaving or by chemical treatment with 1% final Virkon for at least 30 minutes (or other validated method).

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The committee were happy in principle with this GMO RA at AC2 but further information is needed regarding any virus testing done on the line, initial isolation reference etc etc. If the host cell has been in use for a long period, and there is subsequent testing for virus production available there may be the possibility to down grade to AC1.

Project Ref 387/13.1

Date Ackn'd 02/03/2022
The use of a recombinant replicative Oncolytic Virus (OV), as a novel cancer therapeutic agent in vitro (in Hazard Group 1 & 2 cells), in vivo use and ex vivo analysis

Recombinant Oncolytic Virus strains (the production of which are described in Medimmune's GMO risk assessment G398) will be used to infect tumour cells. This work is described in MedImmune's GMO risk assessment G400.

The recombinant OV is a replication competent virus that can efficiently infect a wide range of target cells. In normal cells however, viral replication is inhibited and effectively shut down due to an intact intrinsic anti-viral response and intact interferon response pathway. In tumour cells with defects in the anti-viral response and interferon pathways, the recombinant OV is able to replicate, resulting in expression of viral genes and transgenes and production of viral progeny. They are non-integrative viruses so expression in dividing cells is progressively lost in cells that do not support viral replication. The GMO in this instance would be the virally infected tumour cells.

The experimental work proposed here involves the addition of recombinant OV particles encoding therapeutic gene sequences to mammalian cell lines (Hazard Group 1 and 2 and Activity Class 1 and 2 cells) in vitro and the direct administration (intra-tumoral or intravenous) in vivo using rodents. Following the transduction of the mammalian cell lines with recombinant OV, RNA and protein will be extracted from the cells to determine expression levels of viral RNA, target gene RNA or gene product and functional assays will be performed.

Following the direct administration of recombinant OV in vivo, animals will undergo monitoring and tumour measurements (as detailed in project licence) and / or tissues / cells will be harvested and used in downstream functional assays.

Recipient or parental organism

Recombinant Oncolytic Virus strains (the production of which are described in Medimmune's GMO risk assessment G398) will be used to infect tumour cells. This work is described in MedImmune's GMO risk assessment G400.

The recombinant OV is a replication competent virus that can efficiently infect a wide range of target cells. Host/vector system

Vector: An attenuated recombinant Oncolytic Virus is the vector system (please see details in section 17).

Origin & function

Specific Open Reading Frames, cDNAs and gene sequences encoding therapeutic gene sequences or therapeutic proteins (e.g. cytokines) and / or si/shRNAs or miRNAs
(designed to knockdown the expression of cancer causing genes) and reporter genes can be inserted into recombinant Oncolytic Virus. Examples of transgene inserts include immune-modulating cytokines which would augment the anti-tumour and anti-viral immune response. Inserts will generally have a neutral or therapeutic effect.

**Evaluation of foreseeable effects**

Potential hazards associated with the recipient host:
These will vary depending on the cell type and can be known or unknown. Potential common pathogens might be human pathogens such as Epstein Barr virus or rhinovirus. Primary human samples are screened for the presence of the high risk human pathogens hepatitis virus and HIV by the supplier. Samples containing such pathogens will not be used.

Potential hazards arising from the gene product:
The expression of the majority of genes is predicted to generally have little or no adverse effect. However, the precise outcome is difficult to predict. The work outlined in this assessment covers therapeutic transgenes; gene sequences expressed by the recombinant OV, by their very nature, will have a therapeutic effect. Cells expressing these gene products pose no greater risk than Hazard Group 1 or 2 cancer cell lines and expression of a therapeutic transgene will often result in cancer cell death or arrest and render the cells more immunogenic in vivo which would also result in greater clearance.

Potential hazards arising from the combination of gene and host:
The knockdown of or increased expression of the majority of genes is predicted to generally have little or no adverse effect. Cells expressing these gene products will be able to support viral replication (tumour cells) and the greater the expression levels the more likely the cell is permissive to viral replication and will ultimately die due to this property. Cells expressing these gene products pose no greater risk than Hazard Group 1 or 2 cancer cell lines many of which harbour mutations within these genes or expressing these genes through other delivery vectors (adeno- or lentiviral transduction). Enhanced tumour cell killing is a beneficial additional effect of combination of host and gene.

Potential for transfer of gene to other hosts:
The recombinant OV agent can infect most human cells (including non-dividing cells). However, normal cells will not support viral replication and the virus will be inactivated. In cancer cells where replication is permissible the virus will be propagated and will result in cell lysis and death and release of virus which will go on to infect other surrounding cells. By their very nature, the replication competent virus cells that support viral replication will ultimately die due to viral replication, and the level of viral replication will drive the level of the therapeutic transgene, which will also enhance immune clearance in vivo or cell killing.

Potential for harm to human health in the event of exposure:
The recombinant OV agent has very low pathogenicity and is not considered a human pathogen. Human infection following acute exposure to large quantities of virus causes at most mild symptoms. No human-to-human transmission has ever been observed.

Potential to disseminate and harm the environment in the event of accidental release:
Only attenuated recOV will be used and this poses minimal risk to the environment. (Please see Section 17 for further details)

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Note: Rodents will be used for the in vivo work.
All in vivo work will be carried out under Containment Level 2 conditions using rodents. All handling of recOV agents will be in Class II safety cabinets and all treated animals will be kept in separate red-line isolation cages, which are completely sealed with separate negative pressure air supply and HEPA filters on the inlet and outlet. Our building is a designated building, regulated under the Animal (Scientific Procedures) Act 1986 and is therefore designed to prevent escape and to ensure complete containment of animals. We are also an AAALAC accredited establishment.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

We require a derogation to send untreated GM waste off site from our main laboratories in two situations, which relate solely to medium to high scale cell culture, not in vivo work. These are:
- Where the high volume of waste demands it i.e. where we have robotic systems generating high volumes of plasticware that we are unable to autoclave and;
- Where we have large sealed filter housing units that we are unable to validate that inactivation has been successful without breaking open the unit and creating an increased risk of contamination.
We will treat all other waste as described in Section 12.
All GMO waste is inactivated prior to disposal as Non-hazardous Biological waste (EWC 18 01 04) or where inactivation is not possible as Hazardous Biological waste (EWC 18 01 03) under an HSE derogation, see Section 11. Inactivation will be by autoclaving (121°C for 45 minutes as a minimum, or 131°C for liquids) or by chemical treatment (1% final Virkon for at least 30 minutes or other validated method).

In vivo Waste Management

We would be doing the cell-based genetic modifications in our main laboratories and some of the resulting cells may be transferred over to our animal facility to administer into animals (rodents).

Our animal facility is quite separate from the main laboratories and has its own set of waste handling procedures. In fact, no untreated GM waste, either solid or liquid, is transported off-site from our animal facilities; it will always be treated on-site prior to off-site incineration.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Is an emergency plan required according to regulation 20? [N]
If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [Y]

Please enter comments on the GM safety committee on the risk assessment

The BioSafety Committee agreed with the risk assessments in principle, i.e. as a classification of Activity Class 2, subject to some minor modifications. They acknowledged the need for further discussions with the author on potential intellectual property and commercial confidentiality concerns for the preparation of the CU2 form.

Note: The BioSafety Committee were advised by the BSO of subsequent changes prior to the risk assessments being sent for signatures.

CU2 Project Title The generation and subsequent use of AC1 or AC2 cell lines by retroviral transduction

Class 2  Consent Granted

CultureVolClass2 < 1 Litre  CultureVolumeClass3-4
Project Additional Information

Purposes of the contained use

1) To generate genetically modified cell lines via retroviral delivery systems (e.g., MMLV-based, MSCV-based) or to purchase cell lines from external sources that have been generated using such retroviral delivery systems, and to culture these cells for use in vitro and in vivo experiments.
2) To perform subsequent genetic modification of these cell lines via further retroviral transduction.

Overview of different types of GMOs that will be produced:
Retroviral vectors (RV) are viral-based gene delivery systems that can stably deliver genes or shRNA into cells with up to 100% efficiency. RV particles bind to target cells using an envelope protein that allows for release of the RV RNA containing the gene or gene silencing sequence into the cell. The RVs RNA is then converted into DNA using an enzyme called reverse transcriptase by a process called reverse transcription. The DNA pre-integration complex enters the nucleus and integrates into the target cell's chromosomal DNA. Gene delivery is stable because the target gene is integrated in the chromosome and is copied along with the DNA of the cell every time the cell divides.

The experimental work proposed here involves the generation of retroviral particles and the addition of retrovirus particles encoding gene sequences to mammalian cell lines in vitro and the direct administration in vivo. Following the transduction of the mammalian cells with recombinant retrovirus, RNA and protein will be extracted from the cells to determine expression levels of target gene or gene product and functional assays will be performed. Extracellular vesicles may also be removed from the conditioned media and used to assess delivery of the vesicle content to other mammalian cells and in vivo models. These vesicles may also be analysed biophysically, proteomically and genetically. Following the direct administration of retroviral vectors in vivo, animals will undergo behavioural analysis (as detailed in project licence) and/or tissues/cells will be harvested and used in downstream functional assays.

Recipient or parental organism

Mammalian cells including Hazard Group 1 and 2 and Activity Class 1 and 2 genetically modified cells all of which are covered by appropriate risk assessments.

Host/vector system

Taken from the SACGM compendium of guidance part 2.11 p116-126:

To date most genetic modification work involving retroviruses has involved the development of transduction vectors derived from competent oncogenic retroviruses and lentiviruses. Many such retroviral transduction systems are manipulated in cDNA form and give rise to defective vectors. It is important to consider the hazards posed by the virus from which these vector systems are derived in order to make an accurate assessment of the risks posed to human health.

Wild-type retroviruses fall into a range of ACDP hazard groups (see Table 2.11.2). The appropriate containment level should be adopted as a minimum requirement when handling wild-type viruses. Please note that this risk assessment only covers vectors derived from the HG1 and HG2 wild-type retroviruses. The Hazard Groups of some retroviruses is shown in Table 3 (see in accompanying documentation).
Oncogenic retroviral vector systems generally consist of two main components – a transfer vector and a packaging system. The transfer vector is usually a proviral cDNA in which viral coding sequences have been deleted and foreign DNA inserted. The packaging system commonly consists of one or more helper constructs that express viral genes needed to generate infectious viral particles.

The generation of replication competent virus (RCV) and insertional mutagenesis as a result of proviral integration poses major safety issues when handling retroviral vectors. RCV can be generated by recombination events between the vector and the components of the packaging system (including both the packaging constructs themselves and endogenous proviruses present in the cell line used). Proviral integration can result in the activation of cellular genes adjacent to the integration site or insertional disruption of tumour-suppressor functions (features central to oncogenesis by retroviruses not carrying a cellular oncogene). Retroviral vector systems have therefore been developed and refined in order to reduce the likelihood of RCV generation and proviral transactivation. Consequently, there is a range of systems that vary in their safety profile.

Oncogenic Retroviral Vectors.

The majority of these vectors have been derived from competent oncogenic retroviruses, such as ALV, MoMLV and FeLV, that efficiently infect actively dividing cells. “First Generation” retroviral vectors contain a packaging system that is essentially a retroviral cDNA itself, encoding viral gag, pol and env genes but with its packaging sequence deleted. This construct is either cotransfected with the transfer vector, or is stably incorporated into the host-cell chromosomes generating a helper cell line. Such systems are inherently the most hazardous since a single recombination event would be sufficient to generate RCV. The 3' LTR is deleted in “Second Generation” packaging systems, improving biosafety by reducing the possibility that the packaging construct will be mobilised as well as reducing the likelihood of RCV generation, as two recombination events are required. With “Third Generation” systems, the 5’ LTR is also deleted and the packaging sequences are divided between two constructs, with gag/pol encoded by one construct and env by the second. This significantly reduces the likelihood of RCV generation, by increasing the number of recombination events that are required to reconstitute a competent viral genome. Two component packaging systems of this type should be used wherever possible. Additional biosafety can theoretically also be achieved by using self-inactivating (SIN) transfer vectors, although there are some publications suggesting that the use of SIN vectors confers no advantages with respect to cellular transformation (http://www.ncbi.nlm.nih.gov/pmc/articles/PMC2835037/).

Open reading frames, cDNAs and gene sequences encoding potential drug targets or therapeutic proteins and/or shRNAs or microRNAs (designed to knockdown the expression of open reading frames, cDNAs and gene sequences encoding potential drug targets or therapeutic proteins) will be expressed in retroviral expression vectors.

Guidance on inserts that may have greater risk of adverse effects on human health can be found in SACGM Compendium of Guidance part 2-2 p37-46.

Examples of such inserts include: "exogenous sequences that may have harmful biological activity (for example toxins, cytokines and growth factors, genes that may alter the growth status of cells (such as oncogenes, cytokines and growth factors), sequences which may be involved in the control of expression of such inserts (for example promoters and control regions) and other products that may have no inherent harmful activity but may have other adverse effects (such as allergens or antigenic proteins)"

Of particular note:

Overexpression of Oncogenes (ref: SACGM Compendium of Guidance part 2-2 p38 sections 6-9).

Genes encoding known proto-oncogenes or genes with known oncogenic mutations which can contribute to cellular transformation. Full length cDNA encoding wild type and disease relevant mutants of these types of genes will be expressed in retroviral vectors. Any use of retroviral particles encoding oncogenic inserts will require appropriate controls and operator training.

Examples of genes that may be categorised as oncogenes include:

See Table 1 in accompanying documentation

Knockdown of genes encoding known tumour suppressors can contribute to cellular transformation. However, shRNA expression systems rarely completely silence the targeted gene. shRNAs targeting these types of genes or gene sequences with tumour suppressive functions will be expressed in retroviral vectors. Any use of retroviral particles capable of reducing tumour suppressor expression will require appropriate controls and operator training.

Examples of genes that may be categorised as tumour suppressors include:

See Table 2 in accompanying documentation

Any use of retroviral particles encoding such increased risk inserts will be classed as an AC2 activity, and the appropriate controls should be adhered to. Use of retroviral particles encoding "non-harmful inserts" will be classed as an AC1 activity.
Evaluation of foreseeable effects

Potential hazards associated with the recipient host:

These will vary depending on the cell type and can be known or unknown. Potential common pathogens might be human pathogens such as Epstein Barr virus or rhinovirus. Primary human samples are screened for the presence of the high risk human pathogens hepatitis virus and HIV by the supplier. Samples containing such pathogens should not be used.

Note: Hazard Group 2 cells and Activity class 2 cells present a greater risk than Hazard Group 1 cells, usually due to their potential to harbour human pathogens.

Potential hazards arising from the gene product:

The expression of the majority of genes is predicted to generally have little or no adverse effect. However, the precise outcome is difficult to predict. Expression of proto-oncogenic derivatives of these genes will transform normal epithelial and fibroblast cells and potentially enhance proliferation and tumourigenesis of cancer cell lines. Cells expressing these gene products pose no greater risk than Hazard Group 1 or 2 cancer cell lines many of which harbour mutations are present in human colon carcinoma cell lines DLD-1, LoVo and HCT116; human prostate cancer cell lines LNCaP and PC-3; human lung cancer cell lines Calu-6 and SKLU-1; and human pancreatic cancer cell line MIAPaCa2, A549 lung cancer cells, SW480. Knockdown of tumour suppressor genes may contribute to cellular transformation of normal epithelial and fibroblast cells and potentially enhance proliferation and tumourigenesis of cancer cell lines. Multiple cancer cell lines already in culture have mutations or are null for tumour suppressor genes (esp. TP53, PTEN and TSC1 and 2). Cells expressing shRNA against these gene products pose no greater risk than Hazard group 1 or 2 cancer cell lines many of which already harbour mutations within one or more of these genes. For example, LnCAP, PC3, 87Mg all have PTEN mutations or are pten null.

Potential hazards arising from the combination of gene and host:

Guidance from SACGM compendium of guidance: Viruses and viral vectors with a human host-range carrying potentially oncogenic sequeces or shRNAs targeting tumour suppressor genes may pose risks to human health and safety over and above those hazards associated with the recipient strain itself. The potential outcomes of downregulating particular targeted genes should be carefully assessed. For example, knocking down the expression of a tumour suppressor gene in a mamalian cell could contribute to cellular transformation. However, one of the features of RNAi knockdown systems is that the targeted gene is rarely completely silenced. Indeed, it is not unusual for there to be varying degrees of target gene downregulation within an experimental population and therefore it is important to consider the ramifications of heterogeneous expression of the targeted genes. In particular, the use of virus vector strains that are capable of modifying host chromatin (eg retroviruses and lentiviruses) represent a hazard to the operator and appropriate controls will be required.

Potential for transfer of gene to other hosts:

Retroviral particles can infect almost all human cells (except non-dividing cells). However, the recombinant retroviral vectors used to generate viral particles are replication-deficient in that they are unable to replicate and do not express any of their endogenous genes. Once within the mammalian cell no viral particles would be produced. The virus could not therefore be transferred to another host. Once exception to this could be where an individual's genome contains endogenous viral genes through a previous retroviral infection that then recombine with the genes delivered by the retrovirus to produce replicative-competent virus. This scenario is very unlikely, especially with the separation of viral genes as exploited in 2nd generation and above systems.

One risk that should be considered is the subsequent addition of a retroviral packaging mix to cell lines that have already been manipulated though retroviral transduction, which has the potential to mobilise the integrated genes. This includes the use of the MembranePro reagent for the generation of virus-like particles. The risk is that the cells will produce infectious (but replication-deficient) retrovirus particles, so these cell lines (and the conditioned media) would need to be handled with the considerations afforded to the conditions/cell lines used to generate retroviral vectors, and retroviral particles.

Potential for harm to human health in the event of exposure:
The only potential for harm to human health could be through direct exposure to or injection of the recombinant retroviral particles. However, even with injection the immune system would most likely recognise this as foreign and would mount an immune defensive response. Recipient strains that are able to infect or colonise human hosts should be avoided i.e. work should not be performed on one's own cells or those of other laboratory staff. The particles are unable to penetrate through gloves and would be unlikely to penetrate the dead layers of skin cells.

Potential to disseminate and harm the environment in the event of accidental release:

Retroviral vectors do not pose any identifiable risk to the environment because the reagent is unable to replicate unless supplied with helper plasmids and hence they cannot replicate outside of laboratory conditions.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None at this stage, although waste derogations may be sought should we intend to scale up in the future.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All GMO waste is inactivated prior to disposal as Non-hazardous Biological waste (EWC 18 01 04) or where inactivation is not possible as Hazardous Biological waste (EWC 18 01 03). Inactivation will be by autoclaving or by chemical treatment with 1% final Virkon for at least 30 minutes (or other validated method).

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The committee agreed that retroviral transduction of cell lines was unlikely to result in a classification above AC2, providing the host cell lines did not contain HG3/4 adventitious agents. The AC2 classification was accepted. Note: Host cells are always checked by individual risk assessments to establish whether HG/AC 1/2.

Purposes of the contained use

Generation and use of isogenic cell lines generated with replication-incompetent adeno-associated viruses (AAV) containing human genomic DNA as a method of altering endogenous gene expression in human cell lines.

Cell lines, containing endogenous exons of the gene of interest will be replaced by exons encoded in the designed pAAV vector resulting in changes at the endogenous locus causing either:

1. Exon loss to knock-out gene function
2. Point mutations (coding/noncoding)
3. Introduction of a SNP/small deletion/small insertion into the endogenous gene
4. Complex modifications e.g translocations and amplifications
5. Tagged version of the endogenous gene using a reporter gene e.g. luciferase/SNAP Tag

The goals of this work will allow assessment of target biology and creation of new models for use in oncology and other therapeutic areas.

Adeno-associated viruses (AAVs) are replication-deficient paroviruses, which have traditionally required co-infection with a helper adenovirus or herpes virus for productive infection. The AAV Helper-Free System allows the production of infectious recombinant human adeno-associated virus (AAV) virions without the use of a helper virus. The AAV Helper-Free System takes advantage of the identification of the specific adenovirus gene products that mediate AAV replication and the demonstration that these gene products can be introduced into the host cell by transfection.

In the AAV Helper-Free System, most of the adenovirus gene products required for the production of infective AAV particles are supplied on the helper plasmid, pHelper (i.e. E2A, E4, and VA RNA genes), that is co-transfected into cells with human AAV vector DNA. The remaining adenoviral gene product is supplied by the AAV-293 host cells, which stably express the adenovirus E1 gene.2

By eliminating the requirement for live helper virus the AAV Helper-Free System provides a safer, purer and more convenient alternative to retroviral and adenoviral gene delivery systems. In the targeting vector the sequence between the ITR's can be customised to create specific genetic modifications.

There will be 3 main types of GMO created:
• GMO's containing knock-out of gene function by exon loss/modification - genomic DNA surrounding the region to be deleted and insertion of a selection cassette to knock-out gene function
• GMO's containing insertion of a SNP/small deletion/small insertion into the endogenous gene - genomic DNA encompassing the region containing the SNP/small deletion/small insertion of interest and a selection cassette
• GMO's containing a tagged version of the endogenous gene using a reporter gene e.g. luciferase-genomic DNA encompassing the region to be targeted, a reporter gene and a selection cassette.

In every case, the complete gene from the endogenous locus is not overexpressed or contained in the targeting vector. The technology specifically targets the endogenous gene locus and therefore we only the region of interest is targeted. For example, if we want to create a point mutation in exon 1 of a gene we do not need to insert a complete cDNA with the exon 1 mutation; we just need to insert the mutated version of exon 1 with surrounding genomic DNA.

Recipient or parental organism

Mammalian cell lines including Hazard Group 1 and 2 and Activity Class 1 and 2 genetically modified cells all of which are covered by appropriate risk assessments.

Host/vector system

AAV Helper-Free Systems - Details & Specifications

The first step is cloning the gene of interest into an appropriate plasmid vector. For most applications, the DNA of interest is cloned into one of the ITR vectors (pAAV-MCS). The inverted terminal repeat (ITR) sequences present in these vectors provide all of the cis-acting elements necessary for AAV-2 replication and packaging. The recombinant expression plasmid is co-transfected into the AAV-293 cells with helper plasmids encoding adenovirus-derived genes and AAV-2 replication and capsid genes, which together supply all of the trans-acting factors required for AAV replication and packaging in the AAV-293 cells. Recombinant AAV-2 viral particles are prepared from infected AAV-293 cells and may then be used to infect a variety of mammalian cells.

Origin & function

Guidance on expression of inserts that may have greater risk of adverse effects on human health can be found in SACGM compendium of guidance part 2-2 p37-46

Of particular note:

Oncogenes (ref: SACGM compendium of guidance part 2-2 p38 sections 6-9).
Genes encoding known proto-oncogenes or genes with known oncogenic mutations which can contribute to cellular transformation. Exons encoding wild type and disease relevant mutants of these types of genes will be expressed in AAV vectors, but not over-expressed.
Knockout of tumour suppressors (ref: SACGM compendium of guidance part 2-2, p42, paragraph 24).
Knockout of genes encoding known tumour suppressors can contribute to cellular transformation. The level of knockout of tumour suppressor will be specific to each cell line.

Any use of AAV capable of increasing expression of potential oncogenes or reducing tumour suppressor expression will require appropriate controls, operator training and a separate risk assessment.

Evaluation of foreseeable effects

Potential hazards associated with the recipient host:
These will vary depending on the cell type and can be known or unknown. Primary human samples are usually screened for the presence of high risk human pathogens such as hepatitis virus and HIV by the supplier although this may not always be the case. Unscreeded samples can be safely used at CL2 as long as they are not high risk samples or have been tested and shown to contain human pathogens.

Potential hazards arising from the gene product:
The knockdown of or increased expression of the majority of genes is predicted to generally have little or no adverse effect. However, the precise outcome is difficult to predict. Knockdown of tumour suppressor genes may contribute to cellular transformation of normal epithelial and fibroblast cells and potentially enhance proliferation and tumourigenesis of cancer cell lines. Cells expressing these gene products pose no greater risk than Hazard Group 1 or 2 cancer cell lines many of which harbour mutations within these genes.

Potential hazards arising from the combination of gene and host:
AAV gene transfer is one of the most reliable methods for introducing genes into mammalian cells. Following infection, there may be transient expression of the partial gene
product at high levels since many cells receive multiple copies of the recombinant genome, but this will not be full length cDNA. This transient expression is rapidly lost and in most cases there is not a promoter to drive expression of the gene fragment. AAV are capable of infecting a wide variety of proliferating and quiescent cell types from many different animal species including humans, non-human primates, pigs, rodents, mice, and rabbits. Published reports suggest that nearly all human cell types—including skin, muscle, bone, nerve, and liver cells—are susceptible to infection by AAV but it is limited to dividing cells. Recombinant AAV cannot recombine to form replication competent AAV. There are few risks that arise from the combination of gene and host that are not already present in the host cell line. Potential for transfer of gene to other hosts: There is no evidence that when the inserted genetic material recombines with the host cell lines genomic DNA that any sequences of the AAV viral genome are incorporated. In the recombinant AAV viral particles, the only AAV genomic sequences present are the ITR’s and there is no evidence that these are incorporated into the host genome during homologous recombination. There are very few hazards associated with removing gene function, e.g. tumour suppressors, since only one allele of the gene would be targeted rendering the infected cell heterozygous. The tumorigenic effect is only seen when both alleles have been removed. There is low risk associated with producing a tagged version of the endogenous gene using a reporter gene. The highest level of risk comes from introducing SNP/small deletion/small insertion of interest. The introduction of a single mutation in the inserted genetic material provides a low risk of transforming any cell line, potentially becoming oncogenic when recombined into a genes endogenous locus. However, the expression levels of this altered version of the gene will generally be lower as it is expressed under the control of its endogenous promoter. Even if an end-user were to be infected, there is a very low risk of the infected cells being correctly targeted due to the low efficiency of the targeting process without the use of a selection marker. If the cells are correctly targeted, only one allele of the gene would be targeted making the infected cell heterozygous. These cells are very unlikely to be cancerous – at worst they will be one step along the path to transformation of the cells. Potential for harm to human health in the event of exposure: Wild type AAVs are not categorised by ACDP and so are Hazard Group 1. AAVs are defective by nature and are not associated with human illnesses so the hazards to human health can be expected to be low. The AAV system being used (Stratagene Helper-Free AAV system) is a ‘gutless’ system which does NOT require wild-type adenovirus to supply helper functions. The main hazard associated with AAV vectors arises from the inserted genetic material. Potential to disseminate and harm the environment in the event of accidental release: AAV vectors do not pose any identifiable risk to the environment because the reagent is unable to replicate unless supplied with helper plasmids and hence they cannot replicate outside of laboratory conditions. If the project is successful, it would result in in vivo work, in mouse models. All in vivo work will be carried out under Containment Level 2 conditions using rodents. All handling of AAV agents will be in Class II safety cabinets and all treated animals will be kept in separate red-line isolation cages, which are completely sealed with separate negative pressure air supply and HEPA filters on the inlet and outlet. Our building is a designated building, regulated under the Animal (Scientific Procedures) Act 1986 and is therefore designed to prevent escape and to ensure complete containment of animals. Only Home Office-approved operatives, trained in safe handling, will be used to undertake in vivo work, to minimise the risk of infection from potentially infectious adventitious agents from the host cell lines. Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All GMO waste is inactivated prior to disposal as Non-hazardous Biological waste (EWC 18 01 04). Inactivation will be by autoclaving or by chemical treatment with 1% final Virkon for at least 30 minutes (or other validated method).

No non-inactivated waste will be sent off site.

---

Since some of the inserts are potentially hazardous and may be inserted into infectious hosts, the committee decided that this should be classified as AC2.

Project notified under transitional arrangements N
The cells will be used in a range of in vitro assays to characterise the target and investigate the activity of potential drugs.

No new GMOs will be created. Human foetal pancreatic buds were transduced with a lentiviral vector that expressed SV40LT under the control of the insulin promoter. SV40LT-expressing beta cells proliferated, formed insulinomas, and were then transduced with human telomerase reverse transcriptase (hTERT). "A genetically engineered human pancreatic beta cell line exhibiting glucose-inducible insulin secretion. Ravassard et al., J Clin Invest. 2011; 121(9):3589–3597 doi:10.1172/JCI58447".

Active protein is required to give the transformed phenotype of the cells. The virus stocks used to generate cell lines have all tested negative for the presence of replication competent particles hence the cell lines cannot release lentiviral particles. The lines have been passaged numerous times since their generation and would therefore be expected not to expressing vector particles themselves. No work with the lentivirus itself will be carried out at MedImmune.

In 2013 it was discovered by the collaborator that the EndoC-betaH1 cell line was contaminated with Murine Xenotropic retrovirus BXV1. Bxv1 endogenous MLV is produced as an active virus and is prevalent in the most common mouse lines e.g. C57/B16, BALB/C & DBA but also found in some cell lines e.g. RAW 264, hybridomas & VCAP. Bxv1 virus is on the HSE approved list of biological agents as a human pathogen hazard group 2 agent and therefore procedures must be performed at containment level 2.

<tr>
<td>SV40 large T antigen under control of the rat insulin II promotor. The cells will be used in a range of in vitro assays to characterise the target and investigate the activity of potential drugs</td>
<td></td>
</tr>
</tbody>
</table>
Potential hazards arising from the gene product:
SV40 Large T antigen originates from the SV40 virus. SV40 large T antigen is a multifunctional protein, essential for viral DNA replication and for regulation of viral gene expression. Reported functions of this protein include ATPase and helicase activities. p53s binding by the SV40 large T antigen may be involved in mediating the oncogenic action of this virus. In order to interact with p53, it would need to be delivered to the nucleus. If expressed however, the SV40 fragment may be a biologically active substance, and is potentially oncogenic which might have a deleterious effect if delivered to a target tissue. The SV40 large T antigen is under the control of the rat insulin II promoter to restrict expression to the beta cell. The hTERT is the human Telomerase Reverse Transcriptase. This gene has been extensively used in association with SV40LT to immortalise human cells. It will prevent shortening of human telomeres and therefore will be useful to prevent senescence of the cell line and thus can be crucial for establishment of stable cell lines.

Potential hazards arising from the combination of gene and host:
Host cells are human derived cells and should be cleared by normal immune response however the contaminating mouse Bxv1 virus is on the HSE approved list of biological agents and is therefore classified as human pathogen Hazard Group 2 agent.

Potential for transfer of gene to other hosts:
The lentivirus stocks used to generate cell lines have all tested negative for the presence of replication competent particles hence the cell lines cannot release lentiviral particles. The lines have been passaged numerous times since their generation and would therefore be expected not to be expressing lentivirus vector particles themselves. No work with the lentivirus itself will be carried out at MedImmune

Potential for harm to human health in the event of exposure:
The lentivirus stocks used to generate cell lines have all tested negative for the presence of replication competent particles hence the cell lines cannot release lentiviral particles. The lines have been passaged numerous times since their generation and would therefore be expected not to be expressing lentivirus vector particles themselves. No work with the lentivirus itself will be carried out at MedImmune

The contaminating component Bxv1 endogenous MLV is classified as Hazard Group 2 therefore can cause human disease and may be a hazard to employees; it is unlikely to spread to the community and there is usually effective prophylaxis or treatment available. It also has the potential to infect other cell lines.

Potential to disseminate and harm the environment in the event of accidental release:
Accidental spill of the contaminating component Bxv1 endogenous MLV would not harm the environment as viral particles could not survive outside of the lab environment. Correct disposal of treated cell waste will kill host cells and therefore destroy associated viral particles.

To prevent contamination of other cell lines by Bxv1 endogenous MLV we suggest a 24 hour exclusion from labs working on drug product expressing cell lines for those who have handled EndoC-BetaH1 cell line as a precaution.

8.

Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All GMO waste is inactivated prior to disposal as Non-hazardous Biological waste (EWC 18 01 04) or where inactivation is not possible as Hazardous Biological waste (EWC 18 01 03). Inactivation will be by autoclaving or by chemical treatment with 1% final Virkon for at least 30 minutes (or other validated method).

In addition: Correct disposal of treated cell waste will kill host cells and thus destroy associated viral particles.

CU2 Project Title

The culture and use of recombinant strains of Vaccinia Virus (VACV), an orthopoxvirus, generated by reverse engineering for in vitro cell-based assays, in vivo use and ex vivo analysis

Date Project Ceased 02/03/2022

Class CultureVolClass2 CultureVolumeClass3-4

Class 2 < 1 Litre

Non-GMM Consent Granted

02/03/2022 Page 6979 of 15326
Project Additional Information

Purposes of the contained use

To use recombinant vaccinia, an oncolytic virus, to selectively infect mammalian cells in vitro and/or in vivo to assess oncolytic potency in tumour and normal cells and to analyse levels of viral replication, selectivity of infection, oncolytic potency, viral cell viability and mechanisms of tumour cell lysis.

Recipient or parental organism

Recombinant oncolytic VACV will be used to infect tumour and normal cells.
VACV is a replication competent oncolytic virus that can efficiently infect a wide range of target cells, however viral engineering has rendered some of the rVACV variants tumour selective. The experimental work proposed here involves the addition of VACV particles encoding therapeutic gene sequences to mammalian cell lines (Hazard Group 1 and 2 and Activity Class 1 and 2 cells) in vitro and the direct administration in vivo. Following the transduction of the mammalian cell lines with rVACV, RNA and protein will be extracted from the cells to determine expression levels of viral RNA, target gene RNA or gene product and functional assays will be performed.
Following the direct administration of rVACV in vivo, animals will undergo monitoring and tumour measurements (as detailed in the project licence) and/or tissues/cells will be harvested and used in downstream functional assays.

Host/vector system

Hosts: The host organism would be normal and cancer cell lines of human and mouse origin. These would include Hazard Group 1 and 2 cell lines and Activity Class 1 and 2 genetically modified cells all of which are covered by appropriate risk assessments.
Vectors: Recombinant attenuated Western Reserve (WR) or Lister strains of Vaccinia are the backbone vectors for carrying the genes and are covered by appropriate risk assessments. Attenuation mechanisms are outlined briefly below and fall under the categories of Disabled and attenuated vectors and Conditionally replicative vectors (outlined in SACGM Compendium of Guidance, Section 2.10, p106-107). Various permutations of VACV have been created and attenuated for virulence by the deletion of the following genes, alone or in combination:
o Thymidine Kinase (TK): TK deletion from VACV engenders enhanced specificity for tumour cells. TK-deleted VACV is highly attenuated in non-dividing cells but is able to replicate robustly in transformed cells.
o Vaccinia Growth Factor (VGF): VGF is a viral ortholog of EGF that encourages increased metabolic activity in cells and promotes viral replication and spread. Deletion of VGF from vaccinia virus severely attenuated viral replication in vivo, and increases the LD50 of the virus by over 2 logs. VACV that are deleted for both VGF and TK appear to replicate specifically in tumour cells.
B18R: B18R is a Type I IFN decoy receptor encoded by VACV. Deletion of the B18R gene enables infected cells to generate a stronger type I IFN response in response to VACV infection and protects surrounding nontransformed cells from viral-mediated cell killing by eliciting the antiviral state. Tumour cells often have defects in the type I IFN response, rendering them still susceptible to oncolysis by B18R deleted VACV.

Origin & function

Specific Open reading frames, cDNAs and gene sequences encoding therapeutic gene sequences or therapeutic proteins (e.g. cytokines and antibodies) and/or si/shRNAs or miRNAs (designed to knockdown the expression of cancer causing genes) and reporter genes can be inserted into rVACV. An example of a transgene insert includes (but is not limited to) immune modulating cytokines such as human or mouse granulocyte-macrophage colony-stimulation factor (GM-CSF), a cytokine for stimulating proliferation of haematopoietic stem cells which would augment the anti-tumour and anti-viral immune response.

Guidance on inserts that may have a greater risk of adverse effects on human health can be found in SACGM compendium of guidance, Part 2-2, p37-46. Inserts will generally have a therapeutic effect.

Evaluation of foreseeable effects

Potential hazards associated with the recipient host:
These will vary depending on the cell type used and can be known or unknown. Potential common pathogens might be human pathogens such as Epstein Barr virus or rhinovirus. Primary human samples are screened for the presence of the high risk human pathogens: hepatitis virus and HIV by the supplier. Samples containing such pathogens should not be used.

Note: Hazard Group 2 cells and Activity Class 2 cells present a greater risk than Hazard Group 1 cells, usually due to their potential to harbour human pathogens.

Potential hazards arising from the gene product:
The expression of the majority of genes is predicted to generally have little or no adverse effect. However, the precise outcome is difficult to predict. The work outlined in this assessment covers therapeutic transgenes and gene sequences expressed by rVACV. By their very nature these will have a therapeutic effect. Cells expressing these gene products pose no greater risk than Hazard Group 1 or 2 cancer cell lines and expression of a therapeutic transgene will often result in cancer cell death or arrest and render the cells more immunogenic in vivo which would result in greater clearance.

Potential hazards arising from the combination of gene and host:
The knockdown of, or increased expression of, the majority of genes is predicted to generally have little or no adverse effect. Gene products will only ever be expressed in cells that are able to support viral replication (tumour cells) and the greater the expression levels, the more likely the cell is permissive to viral replication and will ultimately die due to this property. Cells expressing these gene products pose no greater risk than Hazard Group 1 or 2 cancer cell lines, many of which harbour mutations within these genes or expressing these genes through other delivery vectors (adeno- or lentiviral transduction). Enhanced tumour cell killing is a beneficial additional effect of combination of host and gene.

Potential for transfer of gene to other hosts:
Vaccinia can infect many cells, although the majority of variants used here are disabled/attenuated and conditionally replicative vectors, i.e. replicate selectively in tumour cells. Normal cells will not support viral replication and the virus will be inactivated. In cancer cells where replication is permissible the virus will be propagated and will result in cell lysis and death and release of virus which will go on to infect other surrounding cells. By their very nature, the replication component virus cells that support viral replication will ultimately die due to viral replication and the level of viral replication will drive the level of the therapeutic transgene which will also enhance immune clearance in vivo or cell killing. Vaccinia replication takes place in the
cytosol so there is no chance of stable integration or recombination with the host genome. Additionally many of the variants that will be used are disabled and attenuated vectors. Poxviruses have a large number of genes, many of which are dispensable for growth in vitro and cause attenuation when disrupted.

Potential for harm to human health in the event of exposure:

Typical characteristics of the poxvirus family include a large dsDNA viral genome (varying from 130 to 300kb in size) which is enclosed in a multi-membrane virion, making them some of the largest known viruses. Replication takes place within the cytoplasm of permissive cells and all the enzymes required to initiate viral gene transcription are carried within the virion. Other general features include the induction of virus containing pustular, epidermal lesions, although the severity of the disease is dependent on the host organism and poxvirus species. (Ref: SACGM, Table 2.10. Host range of poxviruses and the typical symptomatic consequences of infection. *Less common adverse reactions to Vaccinia virus inoculation in humans, p104).

VACV normally has no serious health effects in humans, although it can cause disease of the skin when used as a vaccine vector. Vaccinia virus is usually injected in the dermis where a localised lesion appears (a “take”) and then scabs over and heals in about 10-14 days. The vaccination is accompanied by fever, rash, lymphadenopathy, fatigue, myalgia and headaches in some patients. Accidental infection with the virus can occur through contact between the vaccination lesion and broken skin (inadvertent inoculation). Serious complications such as ocular vaccinia, myopericarditis, eczema vaccinatum (a papular, vesicular and pustular rash that is very infectious, 38 cases per million doses), progressive vaccinia (progressive necrosis at the vaccination site, 3 cases per million doses), postvaccinal CNS disease (headache, lethargy, seizures and coma, 12 cases per million doses), foetus malformations and abortion (very rare) sometimes occur after vaccination. Complications are more serious in immunosuppressed individuals and the smallpox vaccine usually causes one death for every million doses.

Contraindications to vaccine are their use in immunocompromised individuals, individuals with certain skin (e.g. eczema) and cardiac diseases and pregnant women. However it must be noted that VACV is a poxvirus that has an extensive safety record and has been used widely as a vaccine vector in vaccination campaign for the irradication of smallpox and is therefore considered to pose minimal risk to human health.

Vaccinia virus may cause disease in situations whereby immunity may be reduced, i.e. during pregnancy, in people with active skin disorders such as eczema or psoriasis, or in immuno-compromised individuals such as those infected with HIV, those individuals who have undergone splenectomy or are on high dose steroid treatment or immune suppressive chemotherapy. It is well documented that vaccinia can be passed to close contacts of vaccine recipients generally with little adverse consequence. Therefore, although an individual with a laboratory-acquired infection is unlikely to receive the virus dose given for vaccination purposes, close contacts, particularly those with contraindications for vaccination, may also be at risk.

The viruses that will be used in this assessment do not cause full blown Vaccinia infection but tend to cause more localised infections such as a pustule or blister (with or without necrosis and scarring) particularly on the hands, mouth or around the eyes. It is possible for one infected area to contaminate and infect another (e.g. finger to eye). A wide range of photographs of Vaccinia virus infections are available at: www.bt.cdc.gov/training/smallpoxvaccine/reactions/default.htm and by searching for “smallpox vaccine” or Vaccinia virus on the internet. SHE should maintain a list of people who work with Vaccinia and all people that work with Vaccinia will be given a letter for their family doctor to be kept with their general practice notes, to prompt their general practitioner to consider Vaccinia if they develop such a blister or sore.

Potential to disseminate and harm the environment in the event of accidental release:

Poxviruses are highly stable and resistant to dehydration; infectious virus can be stored in dried powder form. Transmission is usually via aerosol or direct contact and infectious virus can survive for protracted periods in dried scab material shed from epidermal lesions. In the event of any release into the environment, genetically modified poxviruses might persist and could be transmitted to other humans or animal species.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All in vivo work will be carried out under Containment Level 2 conditions using rodents. All handling of rVACV agents will be in Class II safety cabinets and all treated animals will be kept in separate red-line isolation cages, which are completely sealed with separate negative pressure air supply and HEPA filters on the inlet and outlet. Our building is a designated building, regulated under the Animal (Scientific Procedures) Act 1986 and is therefore designed to prevent escape and to ensure complete containment of animals. Only Home Office-approved operatives, trained in safe handling, will be used to undertake in vivo work, to minimise the risk of infection from potentially infectious adventitious agents from the host cell lines.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All GMO waste is inactivated prior to disposal as Non-hazardous Biological waste (EWC 18 01 04) or where inactivation is not possible as Hazardous Biological waste (EWC 18 01 03). Inactivation will be by autoclaving or by chemical treatment with 1% final Virkon for at least 30 minutes (or other validated method).

It is well known that Vaccinia and other poxviruses have the capacity to survive for considerable periods in dried material such as detached vaccination scabs, but it is less well appreciated that survival in aqueous solutions can be for several weeks. Live virus can also be isolated from solid surfaces and fabric for as long as two weeks after contamination. For laboratory workers, ingestion, inoculation via needles or sharps, and droplet or aerosol exposure of mucous membranes or broken skin are possible routes of infection. Laboratories working with Vaccinia and other poxviruses should have suitable local rules to control these potential sources of infection, including suitable procedures for decontamination of equipment and surfaces.

It is imperative that strict hygiene is adhered to, including hand-washing after work and the use of an alcohol gel to limit transfer. All door handles and equipment must be wiped down with 20% Trigene Advance as a precautionary measure.

Laboratory coats should be disposable or will require to be washed at a high temperature (at least 60°C) or autoclaved frequently as VV is relatively heat resistant, can survive for long periods on fabrics, and has been shown to transfer from fabrics to other objects by direct contact.

Other information

SUSCEPTIBILITY TO DISINFECTANTS: Susceptible to 0.02% sodium hypochlorite, 30% isopropanol, 40% ethanol, 0.02% glutaraldehyde, 0.01% benzalkonium chloride, 0.0075% iodine, 30% Sanytex and 0.0075% ortho phenylphenol.

The virus is resistant to solvent/detergent combinations (TNBP/Triton X-100 and TNBP/ Tween 80) and longer incubation periods (between 10 minutes and 24h depending on the solvent/detergent used) are necessary to inactivate the virus.

PHYSICAL INACTIVATION: The virus is inactivated by dry heat at 95 ºC for 2 hours. The heat-sensitive fraction of the virus is inactivated by moist heat at 60 ºC while the heat-resistant fraction may take higher temperatures to fully inactivate it. The virus in its aerosol form is also sensitive to UV light (254 nm).

SURVIVAL OUTSIDE HOST: The dried virus can survive up to 39 weeks at 6.7% moisture and 4°C

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N
The Biosafety Committee asked the author to expand on the goals, give an explanation as to why they were doing this work, is it oncolytic, and is it being used for tumour cell lines. The Committee agreed this would be AC2 and therefore require an HSE notification.

Please enter comments on the GM safety committee on the risk assessment

Project Ref 387/16.1

Date Ackn’d 14/01/2016

CU2 Project Title Culture and use of Klebsiella pneumoniae genetic knockout and reporter strains for in vitro assays

Class 2

CultureVolume Class 3-4 < 1 Litre

Non-GMM Consent Granted

Date Project Ceased

Withdrawn N

Tick if notifying a connected programme of work N

Project notified under transitional arrangements N
Project Additional Information

Purposes of the contained use

Klebsiella pneumoniae strains, including genetic knockout strains, will be cultured for use in phage display cell selections to isolate antibodies or antibody mimetics to cell surface antigens. Candidate antibodies and/or mimetics will subsequently be tested in in vitro screens, including phage ELISA, in vitro cell binding assays and opsonophagocytic killing assays.

K. pneumoniae, including capsular polysaccharide knockout (e.g. deltapCpSB) and lipopolysaccharide (LPS) O-antigen knockout (e.g. deltaWaaL) strains (allelic replacement with an antibiotic resistance gene), will be cultured with and without antibiotics for use in phage display cell selections to isolate antibodies or antibody mimetics to cell surface antigens. It is proposed that capsular polysaccharide and LPS O-antigen knockout strains will improve access to cell surface antigens by depleting cell surface carbohydrates. Candidate antibodies and/or mimetics will be tested in in vitro cell binding assays for cross-reactivity to wild-type K. pneumoniae strains.

Subsequently, candidate antibodies and/or mimetics will be further characterised in in vitro assays and assayed in an opsonophagocytic killing assay, utilizing K. pneumoniae reporter strains, e.g. luciferase.

Recipient or parental organism

K. pneumoniae is listed on the HSE’s Approved List of Biological Agents as a Hazard Group 2 bacteria, hence it has also been assessed as Hazard Group 2 in biologic risk assessment B605. It primarily poses a risk to immunocompromised individuals. Many strains have the ability to produce extended-spectrum beta lactamases (ESBL) and are resistant to many classes of antibiotics such as aminoglycosides, fluoroquinolones, tetracyclines, chloramphenicol, and trimethoprim/sulfamethoxazole. This work proposes to use GMOs derived from cultured strains available from American Type Culture Collection (ATCC) and National Collection of Type Cultures (NCTC). Examples include but are not restricted to: K. pneumoniae ATCC 43816, K. pneumoniae NCTC 9135, K. pneumoniae NCTC 9181, K. pneumoniae NCTC 9187 and K. pneumonia NCTC 11357.

Host/vector system

Vector:

pDMS 197 - a non-mobilisable suicide vector containing an R6K origin of replication, an antibiotic resistance gene (e.g. Gentamicin) and a sacB gene (Edwards et al., 1998, Gene: 207:2, 149-157). It integrates into the host chromosome and subsequent removal of the vector DNA, including the R6K origin of replication and the sacB gene, results in replacement of the wide-type allele with a mutant allele, such as the Gentamicin resistance gene.

Origin & function

Selectable antibiotic resistance markers - examples (but not restricted to):

- Gentamicin resistance: bacterial derived aminoglycoside phosphotransferase gene.
- Blasticidin resistance: bsd or bsr (blasticidin S deaminase) gene isolated from Aspergillus.
- Hygromycin B resistance: acts as an aminocyclitol to inhibit protein synthesis by disrupting translocation and promoting mistranslation.
- Puromycin resistance (PAC): Puromycin acetyl transferase is derived from Streptomyces alboniger.
- Luciferase reporter gene: bacterial derived luxCDABE operon. The bacterial luciferin-luciferase system is encoded by a set of genes labelled the Lux operon. Five genes (LuxCDABE) are active in the emission of visible light.
Evaluation of foreseeable effects

Potential hazards associated with the recipient host:
K. pneumoniae is categorized as a Hazard Group 2 bacteria, by the HSE, and predominantly poses a risk to immunocompromised individuals and those that are hospitalised. Drug resistant isolates are increasing with current evidence implicating plasmids as the primary source of the resistance genes (Hudson et al., 2014, PLoS One, 9:6, e99209). There is the potential but very low risk of drug-resistance genes from K. pneumoniae being transferred to laboratory strains of E. coli. K. pneumoniae is commonly present within environmental flora and fauna and poses limited risk to healthy individuals (Podschun & Ullmann, 1998, Clin Microbiol Rev: 11:4, 589-603).

Potential hazards arising from the gene product:
The luciferase reporter gene does not pose a risk to human health or the environment. It has been successfully used for over 10 years without report of adverse events.
The antibiotic resistance gene product does not pose a risk to human health or the environment. However, if the gene was transferred from K. pneumoniae to another human pathogen it could compromise the clinical use of that antibiotic. This transfer is extremely unlikely as the resistance gene is stably integrated into the host chromosome.

Potential hazards arising from the combination of gene and host:
There are no additional hazards identifiable from the combination of these genes (antibiotic resistance and luciferase reporter) and K. pneumoniae. With regard to the knockout antibiotic resistant strains, these have been created to knockout capsular polysaccharide and LPS O-antigen. It has been reported that capsular polysaccharide knockout mutants are severely attenuated and unable to cause pneumonia or urinary tract infections (Tomas et al., 2015, JBC, 290:27, 16678-16697). LPS O-antigen knockout mutants also have reduced virulence (Hsieh et al., 2012, PLoS One, 7:3, e33155).

Potential for transfer of gene to other hosts:
There is the potential but very low risk of genes from K. pneumoniae being transferred to other hosts. However, this risk is extremely low for the antibiotic and luciferase reporter genes due to their non-mobilisable nature and integration into the host chromosome.

Potential for harm to human health in the event of exposure:
K. pneumoniae is primarily an opportunistic pathogen and infections are predominantly seen in immunocompromised individuals, particularly those with impaired respiratory defenses, i.e. diabetics, alcoholics and those suffering from malignant and obstructive pulmonary diseases. Infections are primarily hospital acquired (nosocomial) but outside hospital the most common conditions caused by K. pneumoniae are pneumonia, typically in the form of bronchopneumonia and bronchitis, and urinary tract infections. For the luciferase reporter strains this risk remains. For the knockout antibiotic resistant strains, these have been created to knockout capsular polysaccharide and LPS O-antigen. It has been reported that capsular polysaccharide knockout mutants are severely attenuated and unable to cause pneumonia or urinary tract infections (Tomas et al., 2015, JBC, 290:27, 16678-16697). LPS O-antigen knockout mutants also have reduced virulence (Hsieh et al., 2012, PLoS One, 7:3, e33155).

Potential to disseminate and harm the environment in the event of accidental release:
K. pneumoniae is commonly present within environmental flora and fauna and poses limited risk to healthy individuals (Podschun & Ullmann, 1998). It can persist in the environment and also has the potential to infect the majority of mammalian species.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All Class 2 GMO waste must be inactivated prior to disposal as Non-Infectious Healthcare Waste (EWC 18 01 04) or where inactivation is not possible as Infectious Healthcare Waste (EWC 18 01 03). Inactivation should be by autoclaving or by chemical treatment with 1% final Virkon for at least 30 minutes (or other validated method).

Note: Where inactivation is not possible, the HSE will be contacted for derogation. It is not anticipated that this would be likely.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

K. pneumoniae is listed on the HSE’s Approved List of Biological Agents as a Hazard Group 2 bacteria, hence it has also been assessed as Hazard Group 2 in biologic risk assessment B605. The genetic modification of K. pneumoniae to express either antibiotic resistance or a luciferase reporter gene does not alter the risk associated with the recipient host.

02/03/2022
Salmonella enterica subsp. enterica serovar typhimurium (S. typhimurium), including genetic knockout strains, will be cultured for use in phage display cell selections to isolate antibodies or antibody mimetics to cell surface antigens. Candidate antibodies and/or mimetics will subsequently be tested in in vitro screens, including phage ELISA, in vitro cell binding assays and opsonophagocytic killing assays. 

S. typhimurium, including capsular polysaccharide knockout (e.g. deltaYih) and lipopolysaccharide (LPS) O-antigen knockout (e.g. deltaWaaL) strains (allelic replacement with an antibiotic resistance gene), will be cultured with and without antibiotics for use in phage display cell selections to isolate antibodies or antibody mimetics to cell surface antigens. It is proposed that capsular polysaccharide and LPS O-antigen knockout strains will improve access to cell surface antigens by depleting cell surface carbohydrates. Candidate antibodies and/or mimetics will be tested in in vitro cell binding assays for cross-reactivity to wild-type S. typhimurium. Subsequently, candidate antibodies and/or mimetics will be further characterised in in vitro assays and assayed in an opsonophagocytic killing assay, utilizing S. typhimurium reporter strains, e.g. luciferase.

Recipient or parental organism

S. typhimurium is listed on the HSE's Approved List of Biological Agents as a Hazard Group 2 bacteria and has been assessed as a Hazard Group 2 bacteria in B607v1.

S. typhimurium causes diarrhea and paediatric blood stream infections (bacteremia). Infections are especially common in a hospital setting; many of which can be severe. Patients with severe onset HIV are at the highest risk of infection while malnourished children are the next most susceptible group. Along with these susceptible groups, other links have been found between those suffering from malaria, sickle cell anemia, and people recently treated with gastric acid suppression. It poses limited risk to healthy individuals. This work proposes to use GMOs derived from cultured strains available from (but not limited to) American Type Culture Collection (ATCC) and National Collection of Type Cultures (NCTC).

Host/vector system

pACYC177 - a non-mobilisable plasmid vector containing the p15A origin of replication, an ampicillin antibiotic resistance gene and a kanamycin resistance gene. It integrates into the host chromosome and results in allelic replacement.
Selectable antibiotic resistance markers - examples (but not restricted to):
- Gentamicin resistance: bacterial derived aminoglycoside phosphotransferase gene.
- Blasticidin resistance: bsd or bsr (blasticidin S deaminase) gene isolated from Aspergillus.
- Hygromycin B resistance: acts as an aminocyclitol to inhibit protein synthesis by disrupting translocation and promoting mistranslation.
- Puromycin resistance (PAC): Puromycin acetyl transferase is derived from Streptomyces alboniger.

Luciferase reporter gene: bacterial derived luxCDABE operon. The bacterial luciferin-luciferase system is encoded by a set of genes labelled the Lux operon. Five genes (LuxCDABE) are active in the emission of visible light.

Potential hazards associated with the recipient host:
S. typhimurium is categorized as a Hazard Group 2 bacteria, by the HSE. It is a rod-shaped, Gram-negative, flagellated facultative anaerobe that is mostly present in the mammalian GI tract. It is a Non-Typhoidal Salmonella serotype that causes diarrhea and paediatric blood stream infections (bacteremia). Acute gastroenteritis is the most common symptom in infected patients. Patients with severe onset HIV are at the highest risk of infection while malnourished children are the next most susceptible group. Along with these susceptible groups, other links have been found between those suffering from malaria, sickle cell anemia, and people recently treated with gastric acid suppression.

Drug resistant isolates are increasing with current evidence implicating plasmids as the primary source of the resistance genes (Garcia et al., 2014, DOI: 10.1371/journal.pone.0089635). There is the potential but very low risk of drug-resistance genes from S. typhimurium being transferred to other laboratory bacterial strains. typhimurium is commonly present within environmental flora and fauna and poses limited risk to healthy individuals.

Potential hazards arising from the gene product:
The luciferase reporter gene does not pose a risk to human health or the environment. It has been successfully used for over 10 years without report of adverse events. The antibiotic resistance gene products do not pose a risk to human health or the environment. However, if the genes were transferred from S. typhimurium to another human pathogen it could compromise the clinical use of those antibiotics. This transfer is extremely unlikely as the resistance gene is stably integrated into the host chromosome.

Potential hazards arising from the combination of gene and host:
There are no additional hazards identifiable from the combination of these genes (antibiotic resistance and luciferase reporter) and S. typhimurium. With regard to the knockout antibiotic resistant strains, these have been created to knockout capsular polysaccharide and LPS O-antigen. It has been reported that capsular polysaccharide knockout mutants have reduced resistance to killing by human serum (Marshall et al., 2015, DOI: 10.1128/IAI.00634). LPS O-antigen knockout mutants also have reduced virulence (Bender et al., 2013, DOI: 10.1371/journal.pone.0073287).

Potential for transfer of gene to other hosts:
There is the potential but very low risk of genes from S. typhimurium being transferred to other hosts. However, this risk is extremely low for the antibiotic and luciferase reporter genes due to their non-mobilisable nature and integration into the host chromosome.

Potential for harm to human health in the event of exposure:
S. typhimurium is a Non-Typhoidal Salmonella serotype that causes diarrhea and paediatric blood stream infections (bacteremia). Acute gastroenteritis is the most common symptom in infected patients. Patients with severe onset HIV are at the highest risk of infection while malnourished children are the next most susceptible group. Along with these susceptible groups, other links have been found between those suffering from malaria, sickle cell anemia, and people recently treated with gastric acid suppression. There is limited risk to healthy individuals.

For the luciferase reporter strains this risk remains. For the knockout antibiotic resistant strains, these have been created to knockout capsular polysaccharide and LPS O-antigen. It has been reported that capsular polysaccharide knockout mutants have reduced resistance to killing by human serum (Marshall et al., 2015, DOI: 10.1128/IAI.00634). LPS O-antigen knockout mutants also have reduced virulence (Bender et al., 2013, DOI: 10.1371/journal.pone.0073287).

Potential to disseminate and harm the environment in the event of accidental release:
S. typhimurium is commonly present within environmental flora and fauna and poses limited risk to healthy individuals. It can persist in the environment and also has the potential to infect the many common mammalian species (cattle, pigs, sheep, horses, rodents and galliformes).

Evaluation of foreseeable effects

Potential hazards associated with the recipient host:
S. typhimurium is categorized as a Hazard Group 2 bacteria, by the HSE. It is a rod-shaped, Gram-negative, flagellated facultative anaerobe that is mostly present in the mammalian GI tract. Please enter comments on the GM safety committee on the risk assessment

S. typhimurium is listed on the HSE's Approved List of Biological Agents as a Hazard Group 2 bacteria. The genetic modification of S. typhimurium to express either antibiotic resistance or a luciferase reporter gene does not alter the risk associated with the recipient host.

Note: All work with HG2/AC2 infectious agents at our MedImmune Cambridge facilities is undertaken at Containment Level 2, following standard procedures including our Laboratory Code of Practice.

Working with infectious agents takes place in full compliance with Containment Level 2 requirements, including use of Class II safety cabinets to minimise the risk from aerosols and mandatory wearing of PPE (lab coat, safety glasses, gloves) for working with infectious agents.

Project Ref 387/17.2

Date Ackn'd CU2 Project Title  Class CultureVolClass2 CultureVolumeClass3-4

02/03/2022
The generation and use of recombinant adeno associated virus (rAAV) particles for mediating gene modulation in Hazard Group 1 & 2 and Activity Group 1 & 2 cells and their subsequent use in vitro and in vivo.

Project Additional Information

**Purposes of the contained use**

To enable the generation and use of recombinant adeno associated virus (rAAV) particles encoding 1) open reading frames (ORFs), cDNAs or specific gene sequences and 2) short hairpin RNAs (shRNAs) for the knockdown of ORFs, cDNAs or specific gene sequences by RNA Interference (RNAi) and their subsequent use in vitro and in vivo. RNAi is a phenomenon whereby small fragments of double stranded RNA trigger the sequence specific degradation of homologous mRNAs (see http://www.nature.com/focus/rnai for further reading). These vectors will be used to validate literature data and to identify and/or validate ORFs/cDNAs or specific gene sequences as potential therapeutics.

Gene products, cDNAs, ORFs, specific sequences and/or shRNAs will be cloned into available rAAV plasmids, or obtained commercially or from within the broader MedImmune/AZ organisation. These will be packaged into rAAV particles by commercial CROs or packaged in-house using commercially available helper-free systems (e.g., http://www.clontech.com/ES/ProductsNiral_TransductionAAV_Vector_Systems/ibcGetAttachment.jsp?dtemId=93546&fileId=6846850&siteex=10023:22372:US)

rAAV particles encoding genes of interest or shRNAs will then be used to transduce mammalian cells (Hazard Group 1 & 2 and Activity Class 1 & 2) for further studies or administered directly in vivo.

**Recipient or parental organism**

Mammalian and insect cells limited to Hazard Group 1 & 2 and/or Activity Class 1 & 2 genetically modified cells, all of which are covered by appropriate risk assessments. Wild-type AAV are not categorised by the ACDP therefore Containment Level 1 is sufficient.

**Host/vector system**

Wild-type AAV are not categorised by the ACDP therefore Containment Level 1 is sufficient. Wild type AAV have no known link to any human illness. rAAV have a long history of safe use and at the time of writing are being used in 173 clinical trials as gene delivery vectors in man http://www.abedia.com/wiley/vectors.php.
AAV are dependoviruses i.e. are not capable of replication without the presence of a helper infection, such as coinfection with adenovirus or herpes simplex virus. In this work rAAV particles will be prepared using a "helper-free" system in which the genes required for rAAV production are provided in plasmid form rather than from co-infection with another virus.

Wild-type AAV is able to integrate into human chromosome 19 at a specific site. However rAAV encoding genes of interest will be prepared by engineering of a "gutless" AAV vector in which the AAV replication and capsid genes are replaced by the coding sequence of interest, with the replication and capsid genes needed for AAV production being provided by plasmids. This means that the resulting rAAV particles do not possess AAV replication genes themselves and no longer have the ability to integrate into chromosomal DNA. Note that integration into DNA may occur in a passive way at chromosome break points but overall the risk of insertional mutagenesis is low.

To date, 13 natural AAV serotypes have been identified from human and non-human primate sources [Srivastava, A. (2016). In vivo tissue-tropism of adeno-associated viral vectors. Current Opinion in Virology, 21: 75-80.]

http://www.sciencedirect.com/science/article/pii/S1879625716300992]. This work will include the use of all natural AAV serotypes. Given the low pathogenicity of AAV, the major potential hazards posed by rAAV depend on the inserted genetic material.

Open reading frames, cDNAs and gene sequences encoding potential drug targets or therapeutic proteins and/or shRNAs (designed to knockdown the expression of open reading frames, cDNAs and gene sequences encoding potential drug targets or therapeutic proteins) will be expressed using rAAV vectors.

Guidance on inserts that may have greater risk of adverse effects on human health can be found in SACGM compendium of guidance part 2-2 p37-46.

Of particular note:

Overexpression of Oncogenes (ref: SACGM compendium of guidance part 2-2 p38 sections 6-9). Genes encoding known proto-oncogenes or genes with known oncogenic mutations which can contribute to cellular transformation.

Full length cDNA encoding wild-type and mutants of these types of genes will be expressed in rAAV. Any use of rAAV particles encoding oncogenic inserts will require appropriate controls and operator training. Examples of genes that may be categorised as oncogenes includes growth factors or mitogens (e.g. c-Sis), receptor tyrosine kinases (e.g. EGFR, PDGFR), cytoplasmic tyrosine kinases (e.g. Src-family), cytoplasmic serine/threonine kinases (e.g. Raf kinase) and their regulatory subunits, regulatory GTPases (e.g. Ras protein), transcription factors (e.g. myc gene) and telomerase complex components (e.g. TR, TERT).

Knockdown of tumour suppressors (ref: SACGM compendium of guidance part 2-2, p42, paragraph 24). Knockdown of genes encoding known tumour suppressors (e.g. TERT, TR).

Potential hazards associated with the recipient host:

Health and Safety
Executive

These will vary depending on the cell type and can be known or unknown. Potential common pathogens might be human pathogens such as Epstein Barr virus or rhinovirus. Primary human samples are screened for the presence of the high risk human pathogens hepatitis virus and HIV by the supplier. Samples containing such pathogens should
not be used. Note: Hazard Group 2 cells and Activity class 2 cells present a greater risk than Hazard Group 1 cells, usually due to their potential to harbour human pathogens.

Potential hazards arising from the gene product:
The expression of the majority of genes is predicted to generally have little or no adverse effect. However, the precise outcome is difficult to predict. Expression of proto-oncogenes and oncogenic derivatives of these genes will transform normal epithelial and fibroblast cells and potentially enhance proliferation and tumourigenesis of cancer cell lines. Cells expressing these gene products pose no greater risk than Hazard group 1 or 2 cancer cell lines many of which harbour mutations within these genes. For example, the T24 bladder cancer cell line has a H-Ras mutation, or K-ras mutations are present in human colon carcinoma cell lines DLD-1, LoVo and HCT116; human prostate cancer cell lines LNCaP and PC-3; human lung cancer cell lines Calu-6 and SKLU-1; and human pancreatic cancer cell line MIAPaCa2, A549 lung cancer cells, SW480. Similarly, expression of telomerase components may immortalise cells, however many cell lines in culture are already immortalised and by over expression of telomerase. Knockdown of tumour suppressor genes may contribute to cellular transformation of normal epithelial and fibroblast cells and potentially enhance proliferation and tumourigenesis of cancer cell lines. Multiple cancer cell lines already in culture have mutations or are null for tumour suppressor genes (esp. TP53, PTEN and TSC1 and 2). Cells expressing shRNA against these gene products pose no greater risk than Hazard group 1 or 2 cancer cell lines many of which already harbour mutations within one or more of these genes. For example, LnCAP, PC3, U87Mg all have PTEN mutations or are pten null.

Potential hazards arising from the combination of gene and host:
Guidance from SACGM compendium of guidance: Viruses and viral vectors with a human host-range carrying potentially oncogenic sequences or shRNAs targeting tumour suppressor genes may pose risks to human health and safety over and above those hazards associated with the recipient strain itself. The potential outcomes of downregulating particular targeted genes should be carefully assessed. For example, knocking down the expression of a tumour suppressor gene in a mammalian cell could contribute to cellular transformation. However, one of the features of RNAi knockdown systems is that the targeted gene is rarely completely silenced. Indeed, it is not unusual for there to be varying degrees of target gene downregulation within an experimental population and therefore it is important to consider the ramifications of heterogeneous expression of the targeted genes.

Potential for transfer of gene to other hosts:
rAAV are relatively stable and resistant to dehydration. They can infect many cell types, including most human cells, however the rAAV vectors are replication deficient so after transduction there would be no further production of virus particles.

Potential for harm to human health in the event of exposure:
The only potential for harm to human health could be through direct exposure to or injection of the rAAV. However, even with injection the immune system would most likely recognise the rAAV as foreign and would mount an immune defensive response. Recipient strains that are able to infect or colonise human hosts should be avoided i.e. work should not be performed on ones own cells or those of other laboratory staff. The rAAV particles are unable to penetrate through gloves and would be unlikely to penetrate the dead layers of skin cells. Most humans have had prior AAV infection and possess neutralising antibodies to AAV (e.g. 80% of individuals are seropositive for AAV-2).

Potential to disseminate and harm the environment in the event of accidental release:
AAV vectors are non-enveloped DNA viruses that are relatively stable and resistant to dehydration. They could potentially survive in the environment for long periods, however they are defective by nature and unable to establish an infection or replicate in the absence of a helper virus or helper functions.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All Class 2 GMO waste must be inactivated prior to disposal as Non-Infectious Healthcare Waste (EWC 1801 04) or where inactivation is not possible as Infectious Healthcare Waste (EWC 1801 03). Inactivation should be by autoclaving or by chemical treatment with 1 % final Virkon for at least 30 minutes (or other validated method). Note: Where inactivation is not possible, the HSE will be contacted for derogation. It is not anticipated that this would be likely. Both non-hazardous and inactivated hazardous waste is sent for incineration.

Is an emergency plan required according to regulation 20?  

 Tick if you are claiming exemption from disclosure for section of the risk assessment

Draft

Please enter comments on the GM safety committee on the risk assessment

The BioSafety Committee agreed that this work is classified as Activity Class 2. Work can only be performed at Containment Level 2 due to the nature of gene sequences and host cell lines (Hazard Group 2 or Activity Class 2). Note: All work with HG2/AC2 infectious agents at our MedImmune Cambridge facilities is undertaken at Containment Level 2, following standard procedures including our Laboratory Code of Practice. Working with infectious agents takes place in full compliance with Containment Level 2 requirements, including use of Class II safety cabinets to minimise the risk from aerosols and mandatory wearing of PPE (lab coat, safety glasses, gloves) for working with infectious agents.

Project Ref 387/18.2
Use of lentiviral systems to overexpress prion-like proteins: amyloid-beta, Tau, alpha-synuclein, TDP-43 and Huntingtin, in mammalian primary cells and cell lines.

The goals of this body of work are to enable the generation and use of third (and later) generation, recombinant lentiviral vectors to modulate gene expression by either over-expressing ORFs, cDNAs or specific gene sequences. These vectors will be used to: 1) efficiently generate cell and disease relevant models lines for assessment of target biology; 2) validate literature data; 3) create new models for use in the oncology and other therapeutic areas and 4) to identify and/or validate ORFs/cDNAs or specific gene sequences as potential drug targets. Specifically, this assessment covers the generation and use of recombinant lentiviral particles expressing ORFs/cDNAs/gene specific sequences for in vitro use and for the generation of stable cell lines (and subsequent use of such stable lines both in vitro).

Gene products, cDNAs, ORFs/specific sequences will be cloned into available lentiviral transfer plasmids or obtained commercially or from within the broader MedImmune/AZ organisation. These will be packaged into self-inactivating third generation lentiviral particles by commercial CROs or in house using commercially available 3rd generation packaging systems (e.g. http://tools.invitrogen.com/contentlisfs/manualsvirapoweUentiviral_system_man.pdf). Lentiviral particles encoding genes of interest will then be used to transduce mammalian cells (Hazard group 1 and Activity class 1 cells only) for further studies.

Prion-like proteins are proteins which exhibit some of the characteristics of prion proteins (e.g. are able to cause the transmission of aggregate forms of prion-like protein between cells) but are not prion proteins. The critical factor for a protein to be considered a prion is infectivity, which necessarily means inter-individual transmissibility. Infectivity has only been demonstrated for prion diseases and not to other diseases showing prion-like propagation mechanisms in experimental models.
The cells that we want to use may be generated in-house, bought in from commercial sources or brought in from collaborators. The prion-like proteins that we want to include in this assessment are based in the current ongoing projects and are: amyloid-beta, Tau, alpha-synuclein, TDP-43 and Huntingtin.

### Recipient or parental organism

Cell lines and primary rodent cell cultures including Hazard Group 1 and Activity Class 1 genetically modified cells all of which are covered by appropriate risk assessments, e.g. HEK, CHO and SHSY5Y cells.

### Host/vector system

Third generation (or greater) lentiviral vectors will be used (ref: SACGM compendium of guidance part 2-11 P119 sections 8-30).

"Third Generation" lentiviral vectors have several of the lentiviral accessory genes (required for pathogenesis only) deleted to increase biosafety. These include the vif, vpr, vpu and nef accessory genes which are not required for in vitro replication. The tat gene is also deleted and the Tat-responsive promoter present in the 5' L TR is replaced with heterologous promoters, for example with the Rous sarcoma virus U3 region. An additional biosafety feature is achieved by deletion of the rev gene from the viral transfer vector. Viral packaging is achieved by providing three helper constructs in trans containing gag, pol and rev sequences (figure 1).

An additional biosafety feature is that these vectors are self-inactivating (SIN), whereby the U3 region of the 3' L TR (which contains the major viral promoters and enhancers) is copied to the 5' end of the provirus during reverse transcription. Deletion of enhancer and promoter elements from the 3' U3 region in the vector construct will result in a provirus that is entirely devoid of U3 enhancer sequences, therefore reducing the potential for transactivation of cellular genes as a result of insertion. Furthermore, such vectors are not easily mobilisable as a result of a superinfection with wild-type virus.

The 3rd generation Lentiviral Expression Systems includes the following key safety features:

- The Lenti expression vectors contain a deletion in the 3' L TR (~U3) that does not affect generation of the viral genome in the producer cell line, but results in "self-inactivation" of the lentivirus after transduction of the target cell (Yee et al., 1987; Yu et al., 1986; Zufferey et al., 1998). Once integrated into the transduced target cell, the lentiviral genome is no longer capable of producing packageable viral genome.

- The number of genes from HIV-1 that are used in the system has been reduced to three (i.e. gag, pol, and rev).

- The VSV-G gene from Vesicular Stomatitiis Virus is used in place of the HIV-1 envelope (Burns et al., 1993; Emi et al., 1991; Vee et al., 1994). Alternative envelope proteins (eg. Rabies g protein) that provide different transduction profiles may also be used. Envelope proteins other than VSVG generally decrease the overall permissive transduction profile (compared to VSVG) and are therefore generally considered of no increased risk.

- Genes encoding the structural and other components required for packaging the viral genome are separated onto four plasmids. All four plasmids have been engineered not to contain any regions of homology with each other to prevent undesirable recombination events that could lead to the generation of a replication-competent virus (Dull et al., 1998).

- Although the three packaging plasmids allow expression in trans of proteins required to produce viral progeny (e.g. gal, pol, rev, env) in the 293FT producer cell line, none of them contain L TRs or the 4J packaging sequence. This means that none of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. No new replicationcompetent virus can be produced.
The lentiviral particles produced using these systems are replication-incompetent and only carry the gene of interest. No other viral species are produced.

Expression of the gag and pol genes from helper plasmids are Rev dependent by virtue of the HIV-1 RRE in the gag/pol mRNA transcript. Addition of the RRE prevents gag and pol expression in the absence of Rev (Dull et al., 1998).

A constitutive promoter (RSV promoter) has been placed upstream of the 5' LTR in the Lenti expression vectors to offset the requirement for Tat in the efficient production of viral RNA (Dull et al., 1998). The TransLenti Viral Packaging System is based on lentiviral vectors developed by Kappes and Wu (Kappes et al. 2001; Kappes et al. 2003; Wu et al. 2000; Wu et al. 2001). This newest (4th) generation lentiviral system includes a significant number of safety features designed to enhance its biosafety and to minimize its relation to the wild-type, human HIV-1 virus. More significantly, the reverse transcriptase (RT) and integrase (IN) proteins are split from the native Gag-Pol polypeptide structure and are provided in trans from a separate plasmid producing a novel class of HIV-based vectors. Instead of expressing Gag-Pol, the TransLenti Viral system contains a plasmid that expresses Gag/Gag-Pro and one that expresses Pol (RT & IN) fused to Vpr. Removing the RT & IN from the packaging construct prevents the lentiviral replication machinery from functioning. This system, in contrast to the standard third generation vectors, prevents the generation of recombinant viral particles that possess the required functional Gag-Pol structure for DNA mobilization and the emergence of replication competent lentivirus.

The TransLenti Viral Packaging System includes the following key safety features:

- The expression vectors contain a deletion in the 3' LTR (~U3) that does not affect generation of the viral genome in the producer cell line, but results in "self-inactivation" of the lentivirus after transduction of the target cell (Shimada et al. 1995 and Zufferey et al. 1998).
- The number of genes from HIV-1 that are used in the system has been reduced (Le. gag, pol, rev, tat and vpr).
- The VSV-G gene from Vesicular Stomatitis Virus is used to pseudotype the vector particles (Yee et al. 1994). The HIV-1 envelope has been completely removed from the vector.
- Genes encoding the structural and other components required for packaging the viral genome are separated onto four plasmids.
- Although the packaging plasmids allow expression in trans of genes required to produce viral progeny (e.g. gag, pol, rev, tat, env) in the TLA-HEK293T producer cell line, none of them contain LTRs or the I.jJ packaging sequence. This means that none of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. No new replicationcompetent virus has been shown to be produced.

3rd generation packaging systems for lentiviral production are based on those originally published by Dull T et al (J Virol. 1998 Nov; 72(11):8463-71.). There are several sources of these vectors. The lentiviral vectors vary depending on source but all have 3rd Generation or greater safety features built in.

**Origin & function**

Open reading frames, cDNAs and gene sequences encoding prion-like proteins amyloid-beta, Tau, alpha-synuclein, TDP-43 and Huntingtin will be expressed in self inactivating lentiviral expression vectors. Only inserts that have minimal risk those that will not increase the risk of the resulting cell lines above Cat1 Activity class 1 will be covered by this risk assessment. Inserts will be cloned into pCDH lenti packaging vectors. Guidance on inserts that may have greater risk of adverse effects on human health can be found in SACGM compendium of guidance part 2-2 p37-46. use of these types inserts will be covered by G345.
Potential hazards associated with the recipient host: These will vary depending on the cell type and can be known or unknown. All cells are considered minimal risk and are Hazard Group 1/2 or Activity Class 1/2.

Potential hazards arising from the gene product: The five proteins that are studied under this risk assessment are classified as prion-like proteins. Prion-like proteins are self-propagating proteins which have the transmission feature of prion proteins, this results in pathologic species being taken up by cells and normal protein within that cell being converted into the pathologic form. Prion-like proteins are not prion proteins. A detailed review of the five proteins has been made for a proper evaluation of the risks.

Amyloid-beta (AD): Is a fragment of 39-42 amino acids resulting from the cleavage of Amyloid precursor protein by several secretases [1]. The role of AD is not well understood but animal models lacking its expression don't show any loss of physiological function. There are several forms of AD, AD-40 which is soluble and AD-42 which has high in vitro propensity to misfold and aggregates, both soluble and insoluble forms have been associated with Alzheimer's disease (AD) and cognitive decline [2, 3]. AD-42 is present in AD patient's brains in the form of plaques but its presence has been also shown outside of the brain, in the cerebrospinal fluid (CSF). It is considered a prion-like protein as misfolded aggregates of AD can seed a chain reaction of misfolding and those aggregates shown the biochemical characteristics of prions (e.g., insoluble and proteinase partial resistance)[4, 5]. Furthermore, transmission from cell to cell has been achieved [6] and so has been the spreading of pathology and the replication of the cognitive decline in animal models after injection of AD [7-9]. Despite that, there is no evidence of AD being naturally transmitted between individuals or iatrogenic transmission of the disease and we estimate that the risk of "infection" is extremely small.

Tau is primarily a cytoskeletal stabilising protein abundantly expressed in the central nervous system (CNS) and much less abundantly expressed in the peripheral nervous system [10]. Inclusions of detergent insoluble tau protein are the pathological hallmark of several neurodegenerative diseases (Tauopathies). It has been shown by several groups that misfolded, insoluble tau can enter a cell and "corrupt" the soluble intracellular tau in a prion-like manner causing aggregation of the intracellular tau in a so called "seeding" reaction [11-13]. Species of tau shown to be capable of seeding have been derived from recombinant protein [11, 13], transgenic mice over expressing human tau [11], and from human tauopathy brain samples [13]. In all published work this seeding effect has relied on over expression of human tau in the recipient cells. Seeding is induced by using concentrations of exogenous tau much higher than is physiologically relevant. Indeed, exogenous aggregates must be injected directly into the brain of transgenic mice before any seeding effect is seen. Cell death has never been observed in cells which have undergone tau seeding either in vivo or in vitro. There is no direct evidence of a person ever having been "infected" with tau pathology, so we estimate that the risk of "infection" is extremely small.

Alpha-synuclein is a small protein of 140 amino acids highly expressed in the brain, with a pre-synaptic localization [14, 15]. The alpha-synuclein protein is considered to be a natively unfolded protein that can become misfolded and aggregates forming D-sheet structures [16, 17]. The presence of insoluble alphasyneuclein aggregates in Lewy bodies are indeed a hallmark of Parkinson's disease (PD) [18]. Aggregated material from a recombinant source can be taken up by cells, however, sustained persistence and seeding in the culture required over expression of the alpha-synuclein in the host cells [19]. Similarly, material from diseased brains and recombinant aggregates have been transmitted into transgenic mouse models accelerating the transgene generated pathology [20, 21]. Although the same pathology spread was reported in wild type animals, those results have been now disproved [22]. There is no direct evidence of a person ever having developed PD iatrogenically or due to exposure to contaminated material, so we estimate that the risk of "infection" is extremely small.

TDP-43 is an RNA binding protein of 414 amino acids localized in the cell nucleus in normal conditions.
Misfolded and aggregated TDP-43, accompanied by a mislocalization to the cytoplasm, has been described in a wide range of neurodegenerative diseases including tauopathies and synucleinopathies but mostly in Amyotrophic lateral sclerosis and Frontotemporal lobar degeneration [23]. Both wild type and dominantly inherited mutations of TDP-43 are associated with disease and in vitro experiments with recombinant protein have demonstrated a higher propensity to aggregate when mutations are present [24, 25]. Furthermore, either synthetically produced or brain purified TDP-43 aggregates have been transduced into cells have shown cellular uptake of TDP-43 [26]. Importantly, no evidence has been reported so far that prove transmission of any type of TDP-43 aggregates into animal models. Therefore, we estimate that the risk of “infection” by exposure to TDP-43 is negligible.

Huntingtin is a protein of unknown function which is highly expressed in the CNS and also expressed in several tissues throughout the body [27]. Wild-type Huntingtin contains a polyglutamine tract in the N-terminal of 6-35 glutamine residues. However, in individuals affected by Huntington's disease (an autosomal dominant genetic disorder), it contains more than 36 glutamine residues (highest reported repeat length is about 250) [28, 29]. This expansion leads to spontaneous aggregation of the Huntingtin protein, massive cell death in the CNS and the clinicopathological features of Huntington's disease. Although a genetically inherited condition, recent literature has pointed towards a "prion-like" spread of pathology within the brains of HD patients, whereby aggregated, pathogenic Huntingtin can leave a cell, enter a neighbouring cell and induce further aggregation. It has been shown that aggregated mutant Huntingtin derived from cell culture and from patient samples can induce seeding in a cell model over-expressing wild-type Huntingtin. Seeding models have all relied on high levels of over-expression of the wild-type protein in recipient cells [30, 31]. Seeding is induced by using concentrations of exogenous Huntingtin much higher than is physiologically relevant. There is no direct evidence of a person ever having been "infected" with Huntington's pathology and Huntington's disease has never been reported in an individual with less than 36 polyglutamine residues. Cell lines expressing wild-type Huntingtin pose no risk to the user as they are expressing a non-pathogenic protein, so we estimate the risk as negligible.

For all of the named prion-like proteins above, it is important noticing that the published cell to cell and animal propagation models for prion-like proteins require high concentration of misfolded protein combined with high levels of host protein over-expression to occur, so accidental transmission to normal expressing individuals are extremely unlikely [32,33]. Additionally, transmission to any in vivo model requires injection of the material, which makes the risk almost negligible under a no-sharp restriction.

Antibiotic Resistance Genes and Tags

There are thought to be no associated risks with these gene products. However, the clinical use of similar antibiotics could be compromised if the genes were transferred to a human pathogen. This is thought to be very unlikely because the plasmid vectors used are non-mobilisable. As for the tags, these are not known to be allergenic or toxic.

Potential hazards arising from the combination of gene and host

None, it is not thought to alter the resulting cell line classification.

Potential for transfer of gene to other hosts:

Lentiviral particles can infect almost all human cells (including non-dividing cells). However, the recombinant retroviral vectors used to generate viral particles are self-inactivating, replication deficient in that they are unable to replicate and do not express any of their endogenous genes. Once within the mammalian cell no viral particles would be produced. The virus could not therefore be transferred to another host.

Potential for harm to human health in the event of exposure:

The only potential for harm to human health could be through direct exposure to or injection of the recombinant lentiviral particles. However, even with injection the immune system would most likely recognise this as foreign and would mount an immune defensive response. Recipient strains
that are able to infect or colonise human hosts should be avoided i.e. work should not be performed on ones own cells or those of other laboratory staff. The particles are unable to penetrate through gloves and would be unlikely to penetrate the dead layers of skin cells.
Potential to disseminate and harm the environment in the event of accidental release: Lentiviral vectors do not pose any identifiable risk to the environment because the reagent is unable to replicate unless supplied with helper plasmids and hence they cannot replicate outside of laboratory conditions.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All Class 2 GMO waste must be inactivated prior to disposal as Non-Infectious Healthcare Waste (EWC 1801 04) or where inactivation is not possible as Infectious Healthcare Waste (EWC 18 01 03). Inactivation should be by autoclaving or by chemical treatment with 1% final Virkon for at least 30 minutes (or other validated method).
Note: Where inactivation is not possible, the HSE will be contacted for derogation. It is not anticipated that this would be likely.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y

Please enter comments on the GM safety committee on the risk assessment

Upon discussion with the BioSafety Committee it was decided to assign AC2 due to the potential health risks from prion-like agents.
Note: All work with HG2/AC2 infectious agents at our Medimmune Cambridge facilities is undertaken at Containment Level 2, following standard procedures including our Laboratory Code of Practice.
Working with infectious agents takes place in full compliance with Containment Level 2 requirements, including use of Class II safety cabinets to minimise the risk from aerosols and mandatory wearing of PPE (lab coat, safety glasses, gloves) for working with infectious agents.

### Project Additional Information

**Purposes of the contained use**

This risk assessment is to cover genetically modified cell lines that have been received or bought from third parties - where the method used for introducing the genetic modification cannot be established, when every effort has been made to elucidate the technology used in the cell line generation.

As the facts around generation of the GMO cell line cannot be established, it should be assumed that the most risky methods have been used (i.e. early Oncogenic gamma Retroviral Vectors systems) and worked on at Activity Class 2.

- This RA covers Hazard group 1 and 2, or activity class 1 and 2 parental cell lines that have been genetically modified by a third party using a process that cannot be traced or verified.
- Cells can be stored, resuscitated and undergo routine subculture.
- Use is limited to in vitro assays (no in vivo).
- The user should think through the potential risks and repercussions carefully when planning experimental work - specifically around the possibility of re-generating replication competent virus in processes such as Invitrogen Membrane Pro.
- When the intended use carries increased risk due to the unknown nature, then the scientist should evaluate if remaking the cell line inhouse is the preferred option.
Recipient or parental organism

Host: Hazard group 1 and 2, or activity class 1 and 2 parental cell lines covered by existing Biological or GMO RA.

Host/vector system

Vector: As the methods of genetic modification are unknown for the cell lines being assessed, the most hazardous scenario should be assumed, e.g. early "first generation" y-retroviral systems derived from Moloney Monkey Leukaemia Virus (MMLV); Murine Stem Cell Virus (MSCV); Feline Leukaemia Virus (FeLV) and Avian Leukosis Virus (ALV) that are packaged with <3 plasmids and are not self-inactivating (SIN).

Taken from the SACGM compendium of guidance part 2.11 p116-126:

To date, most genetic modification work involving retroviruses has involved the development of transduction vectors derived from competent oncogenic retroviruses and lentiviruses. Many such retroviral transduction systems are manipulated in cDNA form and give rise to defective vectors. It is important to consider the hazards posed by the virus from which these vector systems are derived, in order to make an accurate assessment of the risks posed to human health.

Vector Systems and their design:

These vector systems generally consist of two main components - a transfer vector and a packaging system.
- The transfer vector is usually a proviral cDNA in which viral coding sequences have been deleted and foreign DNA inserted.
- The packaging system commonly consists of one or more helper constructs that express viral genes needed to generate infectious viral particles.

The generation of replication competent virus (RCV) and insertional mutagenesis as a result of proviral integration poses major safety issues when handling retroviral vectors. RCV can be generated by recombination events between the vector and the components of the packaging system (including both the packaging constructs themselves and endogenous proviruses present in the cell line used). Proviral integration can result in the activation of cellular genes adjacent to the integration site or insertional disruption of tumour-suppressor functions (features central to oncogenesis by retroviruses not carrying a cellular oncogene). Retroviral vector systems have therefore been developed and refined in order to reduce the likelihood of RCV generation and proviral transactivation. Consequently, there is a range of systems that vary in their safety profile.

Oncogenic Retroviral Vectors

The majority of these vectors have been derived from competent oncogenic retroviruses, such as AIV, MoMlV and Fe IV, that efficiently infect actively dividing cells.

"First Generation" retroviral vectors contain a packaging system that is essentially a retroviral cDNA itself, encoding viral gag, pol and env genes but with its packaging sequence deleted. This construct is either cotransfected with the transfer vector, or is stably incorporated into the host-cell chromosomes generating a helper cell line.

Such systems are inherently the most hazardous since a single recombination event would be sufficient to generate RCV.

Origin & function

Inserts may be:
- Open reading frames
- cDNAs and gene sequences encoding potential drug targets or therapeutic proteins
- shRNAs or microRNAs designed to knockdown the expression of proteins
- those caused by use of CRISP/Cas9, TAIENs etc. where insertions or deletions in genes may arise due to genetic engineering
non-coding DNA elements such as response elements, promoters, enhancers etc. Guidance on inserts that may have greater risk of adverse effects on human health can be found in SACGM compendium of guidance part 2-2 p37-46.

Examples of such inserts include: "exogenous sequences that may have harmful biological activity (for example toxins, cytokines and growth factors, genes that may alter the growth status of cells (such as oncogenes, cytokines and growth factors), sequences which may be involved in the control of expression of such inserts (for example promoters and control regions) and other products that may have no inherent harmful activity but may have other adverse effects (such as allergens or antigenic proteins))."

Of particular note:
Overexpression of Oncogenes (ref: SACGM compendium of guidance part 2-2 p38 sections 6-9).

Genes encoding known proto-oncogenes or genes with known oncogenic mutations which can contribute to cellular transformation. Full length cDNA encoding wild type and disease relevant mutants of these types of genes will be expressed in retroviral vectors. Any use of retroviral particles encoding oncogenic inserts will require appropriate controls and operator training.

Examples of genes that may be categorised as oncogenes include:
- growth factors/mitogens eg C-Sis
- receptor tyrosine kinases eg EGFR, PGFR, VEGFR, HER2/neu
- cytoplasmic tyrosine kinases eg Src family, Syk-ZPA-70 family, BTK family and the Abl gene in CML
- cytoplasmic serine threonine kinases and their regulatory subunits eg Raf kinase and cyclin dependant kinase
- Regulatory GTPases eg Ras protein
- transcription factors eg myc gene

Knockdown of tumour suppressors (ref: SACGM compendium of guidance part 2-2, p42, paragraph 24).

Knockdown of genes encoding known tumour suppressors can contribute to cellular transformation. However, shRNA expression systems rarely completely silence the targeted gene. shRNAs targeting these types of genes or gene sequences with tumour suppressive functions will be expressed in retroviral vectors. Any use of retroviral particles capable of reducing tumour suppressor expression will require appropriate controls and operator training.

Examples of genes that may be categorised as tumour suppressors include:
- Cellular tumor antigen p53 P53
- Retinoblastoma-associated protein RB1
- Adenomatous polyposis coli protein APC
- Serine-protein kinase ATM ATM
- Wilms tumor protein WT1
- Neurofibromin NF1
- Merlin NF2/SCH

Health and Safety Executive
- Cyclin-dependent kinase inhibitor 2a CDK4/1/Multipple tumor suppressor 1/MTS-1/p16-INK4a
- von Hippel-Lindau disease tumor suppressor VHL

Please note that:
Even if the insert is considered "non-hazardous" due to unknown nature of the generation method used - the cell lines will be worked on at containment level 2.

Work using infectious protein type inserts (tau, alpha synucleon etc) are specifically excluded from this risk assessment and should be considered under a new GMO RA.

Evaluation of foreseeable effects

Retroviral vectors do not pose any identifiable risk to the environment because the reagent is unable to replicate.
unless supplied with helper plasmids and hence they cannot replicate outside of laboratory conditions. The genetically modified cells are no more risk than hazard group 2 cell lines and would rapidly die off outside of a sterile, warm, humid and enriched environment. These will vary depending on the cell type and can be unknown. Potential common pathogens might be human pathogens such as Epstein Barr virus or rhinovirus. Note: Hazard Group 2 cells and Activity class 2 cells present a greater risk than Hazard Group 1 cells, usually due to their potential to harbour human pathogens.

The expression or abrogation of the majority of genes is predicted to generally have little or no adverse effect. However, the precise outcome is difficult to predict. Expression of proto-oncogenes and oncogenic derivatives of these genes will transform normal epithelial and fibroblast cells and potentially enhance proliferation and tumourigenesis of cancer cell lines. Cells expressing these gene products pose no greater risk than Hazard group 2 cancer cell lines many of which harbour mutations within these genes. For example, the T24 bladder cancer cell line has a H-Ras mutation, or K-ras mutations are present in human colon carcinoma cell lines DLD-1, LoVo and HCT116; human prostate cancer cell lines LNCaP and PC-3; human lung cancer cell lines Calu-6 and SKLU-1; and human pancreatic cancer cell line MIAPaCa2, A549 lung cancer cells, SW480.

Knockdown of tumour suppressor genes may contribute to cellular transformation of normal epithelial and fibroblast cells and potentially enhance proliferation and tumourigenesis of cancer cell lines. Multiple cancer cell lines already in culture have mutations or are null for tumour suppressor genes (esp. TP53, PTEN and TSC1 and 2). Cells expressing shRNA against these gene products pose no greater risk than Hazard group 2 cancer cell lines many of which already harbour mutations within one or more of these genes. For example, LnCAP, PC3, 87Mg all have PTEN mutations or are pten null.

Guidance from SACGM compendium of guidance:
The potential outcomes of downregulating particular targeted genes in host cells should be carefully assessed. For example, knocking down the expression of a tumour suppressor gene in a mammalian cell could contribute to cellular transformation. However, one of the features of RNAi knockdown systems is that the targeted gene is rarely completely silenced. Indeed, it is not unusual for there to be varying degrees of target gene downregulation within an experimental population and therefore it is important to consider the ramifications of heterogeneous expression of the targeted genes.

Even the oldest recombinant retroviral vector systems used to generate viral particles are replication-deficient in that they are thought unable to replicate and do not express all of their endogenous genes. Once within the mammalian cell no viral particles would be produced therefore the insert could not therefore be transferred to another host. One exception to this could be where the host cells genome contains endogenous viral genes through a previous retroviral infection that then recombine with the genes delivered by the retrovirus to produce replicative-competent virus. This scenario is very unlikely, but theoretically possible.

Another risk that should be considered is the subsequent addition of a retroviral packaging mix to cell lines that have already been manipulated through retroviral transduction, which has the potential to mobilise the integrated genes. This includes the use of the MembranePro reagent for the generation of virus-like particles. The risk is that the cells will produce infectious (but replication-deficient) retrovirus particles, so these cell lines (and the conditioned media) would need to be handled with the considerations afforded to the conditions/cell lines used to generate retroviral vectors, and retroviral particles.

Under no circumstances should cells genetically manipulated by unknown methods be used with membrane-pro reagent or have retroviral packaging plasmids added to them. The user should think through the potential risks and repercussions carefully when planning experimental work. When the intended use carries increased risk due to the unknown nature then the scientist should evaluate if remaking the cell line in-house is the preferred option.

Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N

Upon discussion with the BioSafety Committee it was decided that work could be proceed at Activity class 2, only after every effort has been made to investigate the technologies used to generate the cell line. Wherever possible and practical cell lines should be re-made in-house so the technology and risks posed are clear and understood.

Note: All work with HG2/AC2 infectious agents at our Medimmune Cambridge facilities is undertaken at Containment Level 2, following standard procedures including our Laboratory Code of Practice.

Working with infectious agents takes place in full compliance with Containment Level 2 requirements, including use of Class II safety cabinets to minimise the risk from aerosols and mandatory wearing of PPE (lab coat, safety glasses, gloves) for working with infectious agents.

Project Additional Information

Purposes of the contained use
To use genetically-modified human Rhinovirus (HRV) in the infection of mammalian cells in vitro, to enable in vitro assays to be performed, such as (but not limited to):

- HTRF, Mirrorball assays, flow cytometry, western blotting, staining, proliferation assays.
- Cells may hazard group 1 or 2; or genetically modified activity class 1 or 2
- Cells may also be cultured with or without stimulating factors e.g. cytokines or growth factors
- Cell populations may be sorted using, for example, magnetic beads or flow-cytometry
- Protein or RNA may be extracted and used in assays such as RT-PCR, ELISAs
- Once isolated, cells, lysates or supernatants may be frozen and stored for culture or used in assays at a later date.

Recipient or parental organism
Human rhinovirus with non-hazardous genetic modifications, such as the insert of a fluorescent protein (e.g. GFP) will be covered. For hazardous inserts a further risk assessment will need to be undertaken.

Human rhinovirus is on the HSE approved list of biological agents and is classified as a human pathogen Hazard Group 2 agent (http://www.hse.gov.uk/pubns/misc208.pdf). Hazard Group 2 reflects the infectious nature of human rhinovirus, and the need for appropriate containment to minimise risk to operator health when performing the procedures outlined herein. There are >100 serotypes of HRV.

Human rhinoviruses (HRV) are a major cause of colds in humans. In healthy individuals, the symptoms are upper respiratory tract symptoms such as runny or blocked
nose, runny eyes and a general feeling of lethargy. Most individuals will recover within a few days. Viral shedding will occur a few days before symptoms appear and may continue for 3-4 weeks after infection.

HRV are able to survive outside mammalian cells on non-porous surfaces for several days and hands for several hours and still remain viable and infectious, especially when humidity is high (Gwaltney 1982). There is evidence that hands are a very important method of transmission of rhinoviruses (Ansari 1991) and that as few as 10 viral particles is sufficient to cause an infection (D’Alessio 1984).

Host/vector system

Human rhinovirus (HRV) is both the vector and the organism. An example of a GM insert to be covered by this risk assessment is the HRV-C15-GFP virus. This was made at MedImmune, Gaithersburg, Maryland, US. In brief, DNA encoding eGFP flanked by the viral protease recognition sites (to allow for the cleavage of free GFP from the viral polyprotein) was inserted into the wild-type virus DNA and subsequently generated as per wild-type rhinovirus.

Origin & function

In this risk assessment only inserts expected to be non-hazardous are covered, including: open reading frames (ORFs), cDNAs or specific gene sequences, e.g. Emerald green fluorescent protein (EmGFP) is an example of a non-hazardous protein. EmGFP has been isolated from the jellyfish Aequorea victoria.

Guidance on inserts that may have greater risk of adverse effects on human health can be found in SACGM compendium of guidance part 2-2 p37-46.

Evaluation of foreseeable effects

Potential hazards associated with the recipient host:

Potential hazards arising from the gene product:

The gene products covered are non-hazardous, and not anticipated to increase the hazard or risk posed by the recipient host virus.

Potential hazards arising from the combination of gene and host:

There are no additional hazards anticipated from the genetically modified rhinovirus over wild-type virus, and inclusion of a foreign gene may negatively impact growth and reproduction kinetics.

Potential for transfer of gene to other hosts:

The reporter viruses remain replication competent, and can produce progeny virus. However they are likely to have reduced growth kinetics given that they are encoding a foreign gene. HRV reporter virus (such as HRV-C15-GFP) do not tolerate the foreign genes well and lose the encoded gene insert within two passages, reverting to wild-type virus.

Therefore while recombination with rhinovirus serotypes is theoretically possible in the unlikely event of co-infection, it is unlikely that the gene modification would successfully spread or be maintained.

Potential for harm to human health in the event of exposure:
Human rhinoviruses (HRV) are a major cause of colds in humans. Transmission is airborne, via nasal passages, although hands and possibly eyes have been implicated too. However, to a small subset of the population, the common cold can present a serious health risk; especially in the very young or old, or in people with respiratory problems such as asthma and COPD. Although HRV itself is usually self-limiting, those suffering from asthma and COPD are 70% and 50% more likely to be hospitalised due to exacerbations as a result of HRV infection. HRV infection is also associated with pro-inflammatory cytokine production and enhanced mucous production from airway epithelial cells.

The addition of non-hazardous genetic modifications is not expected to increase the risk of infection or alter the natural history of the virus.

As vulnerable persons are more likely to have problems associated with viral infection, it is important that medical/occupational health advice is taken to ensure that careful consideration of the situation and potential implications is taken when any persons responsible for caring for neonates, the elderly or immuno-compromised persons, is thinking of working with rhinovirus. There is a risk of generating aerosols through processes such as, but not limited to centrifugation, plate washing and pipetting.

Potential to disseminate and harm the environment in the event of accidental release:
GM rhinovirus are likely to have reduced growth kinetics with respect to wild-type virus, given that they are encoding a foreign gene. HRV reporter virus (such as HRV-C15-GFP) do not tolerate the foreign genes well and lose the encoded gene insert within two passages, reverting to wild-type virus. Therefore while recombination with rhinovirus serotypes is theoretically possible in the unlikely event of co-infection, it is unlikely that the gene modification would successfully spread or be maintained.

Rhinovirus is rapidly degraded at room temperature and cannot survive on surfaces for longer than 1 week, therefore contact with receptor/host would have to occur within this timeframe for infection to be spread. All rhinovirus covered by this risk assessment are lab strains, although no disabling mutations have been introduced. Rhinovirus growth and replication are optimal at 33°C so are unlikely to survive outside of this temperature. Based on this, there is potential to disseminate and harm the environment (in the absence of control measures), however this is thought extremely unlikely.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All Class 2 GMO waste must be inactivated prior to disposal as Non-Infectious Healthcare Waste (EWC 18 01 04) or where inactivation is not possible as Infectious Healthcare Waste (EWC 18 01 03). Inactivation should be by autoclaving or by chemical treatment with 1% final Virkon for at least 30 minutes (or other validated method).

Note:Where inactivation is not possible, the HSE will be contacted for derogation. It is not anticipated that this would be likely.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N
The Biosafety committee agreed that this work should be undertaken at Containment Level 2.

Note: All work with HG2/AC2 infectious agents at our MedImmune Cambridge facilities is undertaken at Containment Level 2, following standard procedures including our Laboratory Code of Practice.

Working with infectious agents takes place in full compliance with Containment Level 2 requirements, including use of Class II safety cabinets to minimise the risk from aerosols and mandatory wearing of PPE (lab coat, safety glasses, gloves) for working with infectious agents.

Activity Class 2 as the host organism is assigned AC2 by the ACDP approved list of biological agents, and the genetic modification is not known to be disabling or attenuating.

Purposes of the contained use

The goals of this body of work are to enable the generation and use of recombinant AAV vectors to modulate gene expression by either over-expressing ORFs, cDNAs or specific gene sequences related to the already stipulated prion-like proteins. Specifically, this assessment covers the generation and use of recombinant AAV particles expressing ORFs / cDNAs / gene specific sequences for in vitro use and for the generation of stable cell lines (and subsequent use of such stable lines both in vitro). Gene products, cDNAs, ORFs, specific sequences will be cloned into available rAAV plasmids, or obtained commercially or from within the broader MedImmune/AZ organisation. These will be packaged into rAAV particles by commercial CROs or packaged in-house using commercially available helper-free systems.

Recipient or parental organism

Cell lines and primary rodent cell cultures including Hazard Group 1/2 and Activity Class 1/2 genetically modified cells all of which are covered by appropriate risk assessments, e.g. HEK, CHO and SHSY5Y cells.

Several different natural AAV serotypes have been described and these differ in their capsid structure, leading to different cell transduction profiles and specificities.

In this body of work, the particular AAV serotype chosen for the preparation of a particular rAAV will depend on the tropism of the natural AAV serotypes and the specific aims of the experiment, therefore this risk assessment will cover rAAV using all natural AAV serotypes. There is no difference in risk associated with any particular AAV serotype.

Host/vector system

Wild type AAV have no known link to any human illness therefore Containment Level 1 is sufficient. AAV are dependoviruses i.e. are not capable of replication without the presence of a helper infection, such as co-infection with adenovirus or herpes simplex virus. Wild-type AAV is able to integrate into human chromosome 19 at a specific site but with very low efficiency.

In this work rAAV particles will be prepared using a "helper-free" system in which the genes required for rAAV production are provided in plasmid form rather than from co-infection with another virus. The rAAV encoding genes of interest will be prepared by engineering of a "gutless" AAV vector in which the AAV replication and capsid genes are replaced by the coding sequence of interest, with the replication and capsid genes needed for AAV production being provided by plasmids. This means that the resulting rAAV particles do not possess AAV replication genes themselves and no longer have the ability to integrate into chromosomal DNA. Note that integration into DNA may occur in a passive way at chromosome break points but overall the risk of insertional mutagenesis is low. To date, 13 natural AAV serotypes have been identified from human and non-human primate sources [Srivastava, A. (2016). In vivo tissue-tropism of adeno-associated viral vectors. Current Opinion in Virology, 21: 75-80. http://www.sciencedirect.com/science/article/pii/S1879625716300992]. This work will include the use of all natural AAV serotypes. Given the low pathogenicity of AAV, the major potential hazards posed by rAAV depend on the inserted genetic material.

rAAV have a long history of safe use and at the time of writing are being used in 173 clinical trials as gene delivery vectors in man http://www.abedia.com/wiley/vectors.php.

Origin & function

The five proteins encoded by the genetic material being studied under this risk assessment are classified as prion-like proteins. Prion-like proteins are self-propagating proteins which have the transmission feature of prion proteins, this results in pathologic species being taken up by cells and normal protein within that cell being converted into the pathologic form. Prion-like proteins are not prion proteins. A detailed review of the five proteins has been made for a proper evaluation of the risks.

Amyloid-beta (AB): Is a fragment of 39-42 amino acids resulting from the cleavage of Amyloid precursor protein by several secretases [1]. The role of AB is not well understood but animal models lacking its expression don’t show any loss of physiological function. There are several forms of AB, AB-40 which is soluble and AB-42 which has high in vitro propensity to misfold and aggregates, both soluble and insoluble forms have been associated with Alzheimer’s disease (AD) and cognitive decline [2, 3].
AB-42 is present in AD patient's brains in the form of plaques but its presence has been also shown outside of the brain, in the cerebrospinal fluid (CSF). It is considered a prion-like protein as misfolded aggregates of AB can seed a chain reaction of misfolding and those aggregates shown the biochemical characteristics of prions (e.g., insoluble and protease resistant [4, 5]). Furthermore, transmission from cell to cell has been achieved [6] and so has been the spreading of pathology and the replication of the cognitive decline in animal models after injection of AB [7-9]. Despite that, there is no evidence of AB being naturally transmitted between individuals or iatrogenic transmission of the disease and we estimate that the risk of "infection" is extremely small.

Tau is primarily a cytoskeletal stabilising protein abundantly expressed in the central nervous system (CNS) and much less abundantly expressed in the peripheral nervous system [10]. Inclusions of detergent insoluble tau protein are the pathological hallmark of several neurodegenerative diseases (Tauopathies). It has been shown by several groups that mis-folded, insoluble tau can enter a cell and corrupt the soluble intracellular tau in a prion-like manner causing aggregation of the intracellular tau in a so-called seeding reaction [11-13].

Species of tau shown to be capable of seeding have been derived from recombinant protein [11, 13], transgenic mice over expressing human tau [11], and from human tauopathy brain samples [13]. In all published work this seeding effect has relied on over expression of human tau in the recipient cells. Seeding is induced by using concentrations of exogenous tau much higher than is physiologically relevant. Indeed, exogenous aggregates must be injected directly into the brain of transgenic mice before any seeding effect is seen. Cell death has never been observed in cells which have undergone tau seeding either in vivo or in vitro. There is no direct evidence of a person ever having been infected with tau pathology, so we estimate that the risk of infection is extremely small.

Alpha-synuclein is a small protein of 140 amino acids highly expressed in the brain, with a pre-synaptic localization [14, 15]. The alpha-synuclein protein is considered to be a natively unfolded protein that can become misfolded and aggregates forming B-sheet structures [16, 17]. The presence of insoluble alpha-synuclein aggregates in Lewy bodies are indeed a hallmark of Parkinson's disease (PD) [18]. Aggregated material from a recombinant source can be taken up by cells, however, sustained persistence and seeding in the culture required over expression of the alpha-synuclein in the host cells [19]. Similarly, material from diseased brains and recombinant aggregates have been transmitted into transgenic mouse models accelerating the transgene generated pathology [20, 21]. Although the same pathology spread was reported in wild type animals, those results have been now disproved [22]. There is no direct evidence of a person ever having developed PD iatrogenically or due to exposure to contaminated material, so we estimate that the risk of infection is extremely small.

TDP-43 is an RNA binding protein of 414 amino acids localized in the cell nucleus in normal conditions. Misfolded and aggregated TDP-43, accompanied by a mislocalization to the cytoplasm, has been described in a wide range of neurodegenerative diseases including tauopathies and synucleinopathies but mostly in Amyotrophic lateral sclerosis and Frontotemporal lobar degeneration [23]. Both wild type and dominantly inherited mutations of TDP-43 are associated with disease and in vitro experiments with recombinant protein have demonstrated a higher propensity to aggregate when mutations are present [24, 25]. Furthermore, either synthetically produced or brain purified TDP-43 aggregates have been transduced into cells have shown cellular uptake of TDP-43 [26]. Importantly, no evidence has been reported so far that prove transmission of any type of TDP-43 aggregates into animal models. Therefore, we estimate that the risk of infection by exposure to TDP-43 is negligible.

Huntingtin is a protein of unknown function which is highly expressed in the CNS and also expressed in several tissues throughout the body [27]. Wild-type Huntingtin contains a polyglutamine tract in the N-terminal of 6-35 glutamine residues. However, in individuals affected by Huntington's disease (an autosomal dominant genetic disorder), it contains more than 36 glutamine residues (highest reported repeat length is about 250) [28, 29]. This expansion leads to spontaneous aggregation of the Huntingtin protein, massive cell death in the CNS and the clinicopathological features of Huntington's disease. Although a genetically inherited condition, recent literature has pointed towards a prion-like spread of pathology within the brains of HD patients, whereby aggregated, pathogenic Huntingtin can leave a cell, enter a neighbouring cell and induce further aggregation. It has been shown that aggregated mutant Huntingtin derived from cell culture and from patient samples can induce seeding in a cell model over-expressing wild-type Huntingtin. Seeding models have all relied on high levels of over-expression of the wild-type protein in recipient cells [30, 31]. Seeding is induced by using concentrations of exogenous Huntingtin much higher than is physiologically relevant. There is no direct evidence of a person ever having been infected with Huntington's pathology and Huntington's disease has never been reported in an individual with less than 36 polyglutamine residues. Cell lines expressing wild-type Huntingtin pose no risk to the user as they are expressing a non-pathogenic protein, so we estimate the risk as negligible.
For all of the named prion-like proteins above, it is important noticing that the published cell to cell and animal propagation models for prion-like proteins require high concentration of misfolded protein combined with high levels of host protein over-expression to occur, so accidental transmission to normal expressing individuals are extremely unlikely [32, 33]. Additionally, transmission to any in vivo model requires injection of the material, which makes the risk almost negligible under a no-sharp restriction.

Antibiotic Resistance Genes and Tags
There are thought to be no associated risks with these gene products. However, the clinical use of similar antibiotics could be compromised if the genes were transferred to a human pathogen. This is thought to be very unlikely because the plasmid vectors used are non-mobilisable. As for the tags, these are not known to be allergenic or toxic.

16. Fauvet, B., et al., Characterization of semisynthetic and naturally Nalpha-acetylated alpha-synuclein in vitro and in intact cells: implications for aggregation and cellular...

**Evaluation of foreseeable effects**

All cell lines transduced by rAAV and so expressing prion-like protein will potentially become more hazardous.
rAAV are relatively stable and resistant to dehydration, therefore there is potential for persistence on contaminated surfaces. The rAAV can infect many cell types, including most human cells, however the rAAV vectors are replication deficient so after transduction there would be no further production of virus particles. Integration into the host genome is extremely unlikely. The only potential for harm to human health would be through direct exposure to or injection of the rAAV. However, even with injection the immune system would most likely recognise the rAAV as foreign and would mount an immune defensive response. Most humans have had prior AAV infection and possess neutralising antibodies to AAV (e.g. 80% of individuals are seropositive for AAV-2). The rAAV particles are unable to penetrate through gloves and would be unlikely to penetrate the dead layers of skin cells. Mammalian cells are unable to infect or colonise human hosts due to normal immune clearance.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

rAAVs generated will not be used to transduce larger GMOs

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be solidified with VernaGel 100 (a super absorbent powder) and disposed directly into a sharps bin (contained in the class 2 microbiological safety cabinet), autoclaved on site, and sent for specialist incineration as mentioned above. Solid waste e.g. plasticware, shall also be disposed via a sharps bin, autoclaved on site, and sent for specialist incineration. This is to avoid prion-like protein entering the water system and ensuring full deactivation. All waste material will be double contained during transfer to the on site autoclave facility.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

The maximum culture volume that could be released at any one time is 15 litres. Disposal of small quantities of solid and liquid waste is by autoclaving at 121 degrees C for at least 20 minutes. Autoclaves have temperature probes and automated air bleeds. Alternatively, small quantities of solid waste (e.g., biomass samples) are dried in a static oven (no internal fan) at 100 degrees C.

Disposal of 15 litre vessel wastes at the end of fermentations is by neat phenolic type disinfectant. The vessel is then emptied through the sample point into stainless steel buckets. The buckets are then autoclaved at 121 degrees C for 45 minutes as the second stage of waste inactivation.

No organisms that are especially tolerant of heat or disinfectants are used.

For activities involving GMMs, describe the waste management measures which will apply to the activity

For the GM work, currently performed on this site, the maximum culture volume that could be released at any one time would be 2000 litres once every two years. This waste, as with all other potentially active waste, is transferred to a kill tank where it is deactivated by steam sterilisation at 126 degrees C for 60 minutes. This deactivation method was validated by: control system validation (checking for correct functioning of all inputs and outputs of the system; pressure hold testing of the vessel; Twelve point thermocouple temperature mapping on a full vessel. The deactivation is monitored both physically and microbiologically. Correct execution of the temperature/time cycle acts as a failsafe for allowing the discharge valve to be opened. In addition, every time the effluent tank has gone through a sterilisation cycle (approximately once a week) a sample is taken and checked for microbiological sterility.

Project Additional Information
### Purposes of the contained use

Cultivation of GMMs to produce inactivated vaccines for livestock and/or poultry. Laboratory scale culture for process development and vaccine development. Larger scale growth for production of commercial product.

### Recipient or parental organism

**E. coli K12 and its derivatives:** strains DH10B, DH5alpha, XL1Blue, XL10, SURE, TG1, JM109, MC4100, or equivalent.

### Host/vector system

**pBR322 and its derivates:** pGEMT, pGEX series, pET series, pQE series, pMAL series, pACYC177, p15A or equivalent

**pUC and its derivates:** pBluescript, pBC, pACYC184 or equivalent.

### Origin & function

Gene(s) for antigenic proteins of Escherichia coli, Salmonella spp, Pasteurella spp, Clostridium spp. Mannheimia spp, Haemophilus spp, Brachyspira spp and Actinobacillus spp, EXCLUDING known toxins (except where genetically wholly and irreversibly detoxified on another HSE notified centre), cytokines, superantigens and hyperallergens.

### Evaluation of foreseeable effects

The GMOs compared to the parent E. coli K12 strains should have:

- (a) no increase in infectivity or pathogenicity;
- (b) no reversal of disabling mutation; and
- (c) in the event of inadvertent release, no increase in fitness for environmental survival or spread.

Consequently, overall there is a negligible likelihood that the insert in the GMOs could arise in harm with negligible consequences for the ecosystem, rare species, ubiquitous species or spread and persistence.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid culture waste from small scale and solid waste from laboratory experiments and production areas will be decontaminated by autoclaving using a validated decontamination cycle giving 100% kill.

Liquid waste from production areas is transferred to a kill tank where it is deactivated by steam sterilisation at 126 degrees C for 60 minutes. This deactivation method is validated by control system validation with correct execution of the temperature/time cycle as a failsafe for allowing opening of the discharge valve.

Solid waste is decontaminated by autoclave (commissioned with TST test and 12 point thermocouple tests followed by monthly TST test and 6 monthly review with 12 point thermocouple tests) ultimately disposed of by incineration (contract disposal) and decontaminated liquid waste is discharged to the sewer system.

### Is an emergency plan required according to regulation 20?

N

### If yes, tick to confirm that it is attached to this form

N
The risk assessments were discussed by the genetic modification committee on 9 November 2001. Some minor comments were made and the risk assessments modified slightly to the versions attached. The committee considered the risk assessments and considered that Class 2 categorisation under "the contained use (2000) regulations" was appropriate given the nature of the GMMs involved and the level of containment appropriate to the work.

CU2 Project Title

Project noted under transitional arrangements N

Inactivation by Homologous Recombination of Salmonella spp genes

Class 2

Consent Granted not applicable

> 500 litres

Tick if notifying a connected programme of work N
Project Additional Information

Purposes of the contained use

Cultivation of GMMs to produce inactivated vaccines for livestock and/or poultry. Laboratory scale culture for process development and vaccine development. Larger scale growth for production of commercial product.

Recipient or parental organism

Salmonella enterica serovars Enteritidis, Typhimurium, Hadar, Anatum, and derivatives thereof in which genes have been inactivated by internal deletion, multiple point mutation or antibiotic cassette insertion.

The genetic modifications are not expected to enhance either the existing pathogenic traits of the parent organism, or the fitness of the GMM. It is expected that pathogenicity and fitness will be reduced or at most unaffected by the proposed alterations. It is not expected that the potential for environmental harm will be increased by the genetic alterations proposed.

Host/vector system

Salmonella enterica spp described above with the following non-replicating or conditionally replicating (eg. thermoawbaurucw) suicide vectors: pSC101-ts, R6K, pLD55, pKD20, pKD46, pMB1, ColE1, RP4, p15A, oriV or derivatives thereof.

Origin & function

Gene(s) for antigenic proteins of Salmonella spp. EXCLUDING known toxins, cytokines, superantigens and hyperallergens.

Evaluation of foreseeable effects

The GMMs compared to the parent Salmonella strains should have:-
(a) no increase in infectivity or pathogenicity;
(b) no reversal of disabling mutations; and
(c) in the event of inadvertent release, no increase in fitness for environmental survival or spread.

Consequently, overall there is a negligible likelihood that the genetic modification in the GMMs could result in harm with negligible consequences for the ecosystem, rare species, ubiquitous species or spread and persistence.

Project Ref 391/03.1

EVALUATE THE UTILITY OF A BACULOVIRUS EXPRESSION SYSTEM FOR THE PRODUCTION OF IRREVERSIBLY GENETICALLY INACTIVATED CLOSTRIDIAL TOXINS.

Class 2 > 500 litres

Non-GMM Consent Granted: not applicable

Project notified under transitional arrangements: N
### Project Additional Information

**Purposes of the contained use**

| Cultivation of GMMs to produce vaccines for livestock and/or poultry. Laboratory scale culture for process development and vaccine development. Larger scale growth for production of commercial product. |

**Recipient or parental organism**

| Recombinant baculovirus engineered to express genetically inactivated clostridial toxins in cultured Sf9 or Sf21 insect cells. |

**Host/vector system**

| Recombinant baculovirus engineered to express genetically inactivated clostridial toxins in cultured Sf9 or Sf21 insect cells. |

**Origin & function**

| Genes for toxins of clostridial species supplied, by others, as detoxified by deletion or multiple point mutation. |

**Evaluation of foreseeable effects**

| The baculovirus used contains mutations that render it sensitive to conditions within its normal lepidoptera host and which greatly reduce the infectivity of the baculovirus for insect cells. Neither of these attenuating lesions is likely to be affected by the expression of inactivated clostridial toxins. The GMO therefore presents no foreseeable adverse effect. |

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

| N/A |

**For only GMMS - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Project Ref 391/05.1

Date Ackn'd 16/09/2005

CU2 Project Title Inactivation, by homologous recombination, of Campylobacter jejuni genes.

Class 2

Culture Vol Class 2 > 500 Litres

Class Volume Class 3-4

02/03/2022
**Project Additional Information**

**Purposes of the contained use**

The *C.jejuni* strains developed during this programme of work may be used as a live vaccine for use in chickens under high containment to reduce colonisation by wild type *C.jejuni*.

**Recipient or parental organism**

*C.jejuni*  
*E.coli* K12 and derivatives

**Host/vector system**

*C.jejuni* - non-replicating or conditionally replicating (e.g. thermosensitive) suicide vectors e.g. pGEMT  
*E.coli* - non-mobilisable e.g. pGEMT.

**Origin & function**

Gene(s) for: proteins of *C.jejuni* excluding known toxins, cytokines, superantigens, hyperallergens. These genes being inactivated by internal deletion, multiple point mutation or antibiotic cassette insertion.

**Evaluation of foreseeable effects**

- Is there an increase in infectivity or pathogenicity? - No  
- Could any disabling mutation within the recipient be overcome due to the insertion of a foreign gene? - No  
- Does the foreign gene encode a virulence determinant from a related organism? - No  
- If the foreign gene is a virulence determinant could it contribute to the pathogenicity of the GMM? - No  
- Is treatment available? - Yes  
- Will the genetic modification affect susceptibility of the GMM to treatment? - No [Any change in susceptibility will not be clinically significant. The antibiotic resistance in this instance is kanamycin from *C.jejuni* and so is a naturally occurring combination. Furthermore the treatments of choice are either erythromycin or ciprofloxacin and there is no implication from kanamycin resistance for treatment.]

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

02/03/2022
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste up to 5L or small scale solid laboratory waste are decontaminated by autoclave using a validated decontamination cycle (commission with TST test and 12 point thermocouple tests; ongoing monitoring by monthly TST test and 6 monthly review with 12 point thermocouple tests) giving 100% kill.

Liquid waste from production areas is transferred to a kill tank where it is decontaminated by steam sterilisation at 1260C for 60 minutes. This method is validated by control system validation with correct execution of the temperature/time cycle as a failsafe for allowing opening of the discharge valve.

Autoclaved solid waste is collected by a licensed clinical waste disposal agent for final destruction by incineration. Decontaminated liquid waste is discharged to the sewer system.

Animal carcass:- Contained in leak proof packaging as clinical waste and collected by a licensed clinical waste disposal agent for final destruction by incineration.

Bedding and semi-liquid animal waste from the bottom of the isolator:- Fumigated in isolator and then contained in leak proof packaging as clinical waste and collected by a licensed clinical waste disposal agent for final destruction by incineration.

The isolator:- Soaked in disinfectant (currently Virkon) and then washed. The washings are discharged to sewer.

Non-GMM Consent Granted

Project notified under transitional arrangements

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

**Project Additional Information**

**Purposes of the contained use**

A B. subtilis recombinant has been created that expresses the C-terminal domain of the alpha toxin (cpa 247-370) from Clostridium perfringens type A on the surface of the spore. This recombinant was constructed by the group of Prof S C using genetic technology developed at Royal Holloway College, University if London. This recombinant needs to be evaluated in chicken to demonstrate any potential for raising immune responses against alpha toxin in this species.
Recipient or parental organism

B. subtilis strain PY79, a derivative of the type strain 168. It is non-pathogenic and has GRAS (US FDA) status.

Host/vector system

Not relevant as the scope of experiments is limited to animal trials with the GMM that has been establishments previously by Professor C at the University of London. For the animal trials no genetic manipulations will be performed and vectors are therefore not involved.

Origin & function

The inserted gene codes for the C-terminal domain of the alpha toxin (cpa 247-370) from C. perfringens type A. This portion of the alpha toxin has no haemolytic or toxic activities (Titball et al. 1993, FEMS Microbiology Letters, 110, 45-50). However, antibodies raised to this non-toxic portion of the alpha toxin have been shown to protect mice against challenge with active whole alpha toxin (Stevens et al, 2004, Journal of Infectious Diseases, 190, 767-773).

Evaluation of foreseeable effects

B. subtilis is non-pathogenic and has GRAS (US FDA) status. It has no pathogenic traits and offers no risk to humans or animals. The inserted gene codes for the C-terminal domain of the alpha toxin (cpa 247-370) from C. perfringens type A. This portion of the alpha toxin has no haemolytic or toxic activities (Titball et al. 1993, FEMS Microbiology Letters, 110, 45-50), however it is responsible for the binding of the toxin to cell membranes (Naylor et al. 1999, Journal of Molecular Biology, 294, 757-770). There is therefore a very minor possibility that the expression of this protein could alter the tissue tropism of the recipient microorganism. However, the identical GMM described here has already been administered to mice with no detectable adverse effects on their health (Hoang et al. 2008, Infection and Immunity, 76, 5257-5265).

DNA transfer from B. subtilis to related micro-organisms has been described under a selection pressure (antibiotics). This would occur by transformation to similar species. Genetic transfer of this kind is recognised in most bacteria and is not unique to B. subtilis. Normally, transfer of genes is enhanced if the clone is carried on a plasmid vector since plasmid-borne transfer is exponentially more frequent. In this construct the recombinant DNA sequence is stably maintained within the chromosome and not on a plasmid thus the probability of genetic transfer is minimal.

Should recombinant spores be released accidentally, then as a soil organism it might be expected to survive indefinitely, in contrast to other species such as E. coli which would have limited long-term survival. While spores can survive 100s-1000s of years (Nicholson. 2002, Cellular and Molecular Life Sciences, 59, 410-416) it must be emphasized that the soil is rich in other bacteria and this GM B. subtilis would have to compete to survive. The type of strain used is a derivative of strain 168, a laboratory strain that has been routinely pasaged for over 60 years (Piggot and Coote. 1976, Bacteriology Reviews, 40, 908-962). It will have lost many of its original properties found in the soil-form. Thus, it is highly unlikely that the lab strain, even if released, would be able to compete with resident soil organisms. The C-terminal domain of the alpha toxin has no known environmentally hazardous properties

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Disposable and reusable labware and laboratory waste are autoclaved at 134°C for 20 minutes. For non-autoclavable labware and surfaces a 70% alcohol, 1% Nuevo, 1% Virkon or a 1% Bioceleanse solution with a contact time of at least 10 minutes will be used.

Animal containment isolators are cleaned by removal of the solid waste, which is disposed of as clinical waste gassing with formaldehyde to a minimum concentration of 3000 ppm for a minimum of 8 hours, washing with hot water and a final gassing with formaldehyde as above. The clinical waste is disposed of by a licensed contractor. Animal carcasses are disposed of by incineration by an approved specialist company.
The GM safety committee have reviewed the risk assessment and agree with the assignment of this project to class 2.

**Project notified under transitional arrangements**: N
### Project Additional Information

#### Purposes of the contained use

To evaluate safety and immunogenicity in chickens under controlled laboratory conditions

#### Recipient or parental organism

**Parental Strains:**
Avian meta pneumovirus from the UK and Germany

#### Host/vector system

Not relevant since the scope of experiments is limited to animal trials with GMM that have been established previously by Dr N at the University of Liverpool. For the animal trials no genetic manipulations will be performed and vectors are therefore not involved

#### Origin & function

The genes inserted code for the major protective antigen of the model virus

#### Evaluation of foreseeable effects

**Hazards associated with the recipient microorganism**

AMPV does not infect humans. After 20 years of animal experiments, humans have been exposed to high aerosol doses, yet there has been no evidence of human infection. Also personnel exposed to high levels of virus during AMPV outbreaks on commercial poultry farms have not displayed any evidence of infection or disease. The AMPV #8544 strain causes mild to moderate clinical disease in turkeys for up to 10 days after which there is full recovery. In chickens, #8544 causes little disease. LAH strain is completely attenuated in chickens and turkeys. Commercial poultry are the most susceptible species hence any escape into the general environment would be highly unlikely to lead to infection in the much less susceptible wild bird population. As confirmed by field surveys, one very extensive in Italy, AMPVs of subtype A and B has never been detected in wild bird populations.

**Hazards arising directly from the inserted gene product (e.g. cloning of a toxin or oncogene)**

The protein expressed from the inserted gene is involved in tropism and host range, effects on these traits with AMPV as a vector can not be excluded with 100% certainty but the protein as such has never been associated with causing harmful effects to humans. Further, any effect on tropism or host range of the recipient microorganism due to this protein is considered very unlikely since mononegavirales such as AMPV and NDV are not able to incorporate the protein into the virion. Related genes have been expressed in numerous viral vector systems including adeno, herpes, pox and paramyxovirus species such as Newcastle Disease Virus (NDV). In none of these cases altered pathogenic properties were observed.

The potential hazards of sequences within the GMM being transferred to related microorganisms.

Very unlikely, indications for genetic transfer between AMPV strains or between AMPV and other members within the family of paramyxoviridae have never been observed.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**Not Applicable**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Laboratory waste will be autoclaved using a validated discard cycle (134°C for 20 mins) prior to incineration off site by an approved licensed contractor.

Animal containment isolators will be cleaned by removal of the solid waste, which is disposed of as clinical waste (see below), gassing with formaldehyde to a minimum concentration of 3000ppm for a minimum of 8 hours, washing with hot water and a final gassing with formaldehyde as above. Animal carcases and waste are disposed of by incineration by an approved licensed specialist company. Animal waste and carcases will be placed in sealed bins prior to incineration off site by an approved contractor. Bins will be either surface disinfected with 1% Virkon or fumigated with formaldehyde (see above) prior to release to the contractor for incineration.

**Project Additional Information**

**Purposes of the contained use**
The purpose of this activity is to produce vials of freeze dried working seed in GMP environment for subsequent use in process transfer validation batches.

**Recipient or parental organism**
The GMM is Rhodococcus equi which has been modified to delete four genes, ipdA, ipdB, ipdA2 and ipdB2, involved in the cholesterol catabolic pathway. The resulting ΔipdABA2B2 double deletion mutant (=strain RG2837) was impaired in growth on the steroid catabolic pathway intermediate 3αo-H-4A (3'-propionic acid)-5α-o-hydroxy-7αß-methylhexahydro-1-indanone (5OH-HIP). In addition, strain RG2837 appeared hampered for macrophage survival and could be safely administered intratracheally to foals at a dose at which the parent strain induced pneumonia (van der Geize et al, 2011, PLoS Pathogens 7 (8) e1102181).

**Host/vector system**
Not Applicable

**Origin & function**
The bacteria is an unmarked gene deletion mutant

**Evaluation of foreseeable effects**
The vaccine strain is an unmarked deletion mutant which is attenuated for macrophage survival and therefore unable to colonise the lungs of foals and to cause pneumonia.

Genes, encoding for enzymes that are involved in the cholesterol catabolic pathway were deleted. As a consequence these enzymes are absent and the intermediate 3αo-H-4A (3'-propionic acid)-5α-o-hydroxy-7αß-methylhexahydro-1-indanone (5OH-HIP) cannot be catabolised. This results in attenuation of its most important virulence trait i.e. survival in macrophages and as a consequence in its ability to cause pneumonia.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
Not Applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**
None applicable

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**
All waste materials, consumable items and contaminated equipment will be autoclaved on transfer from the contained facility using a validated cycle of 126°C for 30 minutes, providing complete inactivation. The autoclave is validated in accordance with BS EN 285 and is subject to annual requalification. Temperature within the
autoclave load and chamber drain, and chamber pressure are continuously monitored and recorded using calibrated equipment for each autoclave run.

Historical Date of Additional Info

Significant Change ID

02/03/2022
**Project Additional Information**

**Purposes of the contained use**

To evaluate various previously created microbiological vectors, expressing one or more of a range of Campylobacter jejuni genes, as potential vaccines in chickens. The evaluation will involve the administration of the constructs, by the oral route, to the chickens and may include the assessment of induction of appropriate immune responses and effects on subsequent colonisation of the birds by C. jejuni in a challenge model.

**Recipient or parental organism**

A range of previously created microbiological vectors including bacteria and protozoa.

**Host/vector system**

Not relevant as the scope of the experiments is limited to animal trials with GMMs that have been previously created by other research teams in other facilities. For the animal trials no genetic manipulations will be performed and vectors are therefore not involved.

**Origin & function**

- **pal**: Peptidoglycan associated lipoprotein
- **jlpA**: Surface-exposed lipoprotein that actuates pro-inflammatory response via NF-kB and p38 MAP kinase
- **ciaA**: Putative amino acid transporter periplasmic solute-binding protein
- **fiaA**: Flagellin protein
- **pglE**: UDP-4keto-6-deoxy-GlcNAc c4 amino transferase - knockout mutant abolishes flagella function and inhibits invasion of epithelial cells therefore affecting C. jejuni ability to colonise the intestine
- **cadF**: Outer membrane fibronectin-binding protein which promotes bacteria-host interaction and facilitates colonisation in the intestine
- **flpA**: Adhesin
- **laj1**: colonisation associated proteins
- **laj2**: colonisation associated proteins
- **laj3**: colonisation associated proteins
- **laj4**: colonisation associated proteins

**Evaluation of foreseeable effects**

All of the microbiological vectors are non-pathogenic to humans and animals and have GRAS (US FDA) status or are not recognised to be human pathogens and infection occurs exclusively in chickens or are suicide vectors that are believed to be non-pathogenic in humans. The inserted genes code for adhesins and/or colonisation factors of C. jejuni. The products of these genes appear to contribute to the ability of C. jejuni to persist in the chicken gut for long periods. None of them appear to have any direct pathogenic effects, however, these factors may be responsible for the attachment of C. jejuni to cell membranes. There is therefore a very minor possibility that the expression of these proteins could alter the tissue tropism of the recipient microorganisms.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable
Disposable and reusable labware and laboratory waste are autoclaved at 134°C for 20 minutes. For non-autoclavable labware and surfaces a 70% alcohol, 1% Nuevo, 1% Virkon or a 1% Biocleanse solution with a contact time of at least 10 minutes will be used. 3% Kilcox, with a contact time of 3 hours, will also be used as appropriate.

Animal containment isolators are cleaned by removal of the solid waste, which is disposed of as clinical waste, gassing with formaldehyde to a minimum concentration of 3000 ppm for a minimum of 8 hours, washing with hot water and a final gassing with formaldehyde as above. The clinical waste is disposed of by a licensed contractor.

Animal carcasses are disposed of by incineration by an approved specialist company.

The GM safety Committee, having reviewed the risk assessment agrees with the assignment of this project to class 2.

CU2 Project Title Eimeria vector project

Class 2 CultureVolClass2 < 1 Litre

Consent Granted

Non-GMM

Project notified under transitional arrangements N
### Project Additional Information

#### Purposes of the contained use

- Evaluation of the safety and efficacy of Eimeria as a vector for the expression of heterologous coding sequences

#### Recipient or parental organism

- Chicken Eimeria species including
  - Eimeria tenella
  - Eimeria acervulina

#### Host/vector system

- Not applicable, work will only be carried out with transformed parasites

#### Origin & function

- VP2 from infectious bursal disease virus (IBDV). This constitutes the major outer component of the virus capsid. gB, gD and gI from infectious laryngotracheitis virus (ILT).
- These are all vital envelope glycoproteins.

#### Evaluation of foreseeable effects

- The chicken Eimeria species are globally endemic parasites currently not rated by the Advisory Committee on Dangerous Pathogens (ACDP), but regarded as hazard group 1 by DEFRA. Chicken Eimeria are completely host and tissue specific and consequently pose no risk to human health or risk of spread in the environment other than through contact with chickens.
- Further, Eimeria spp are antigenically complex micro-organisms and their interaction with the host is mediated by a diverse series of proteins expressed in a sequential manner. Whilst it is considered possible that the expression of VP2 might increase the potential for modification of the host pathogen relationship, most likely related to an immunosuppressive effect, any risk to human health is considered minimal because of the exquisite host specificity of the recipient. Expression of any inserted genetic material is controlled by stage specific promoters, restricting expression to defined stages of the life cycle of the parasite. Thus completion of the full life cycle is unlikely in the event of any effect on host range.
- Genetic transfer of traits between different strains of the same species but not between different species has been recorded for Eimeria. It is therefore possible that heterologous sequences could be transferred to wild type strains of the same species, in the worst case this might involve transfer of the sequence from an attenuated (precocious) strain to a non attenuated strain.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

- Not applicable

---

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Solid laboratory waste will be autoclaved using a validated discard cycle (134°C for a minimum of 10 minutes) prior to incineration off site by a licensed contractor.

Processed faecal suspensions will be sealed in plastic containers which will be surface disinfected using 3% Kilcox Extra prior to being sent off site for incineration by a licensed contractor.

Animal carcasses and isolator waste will be removed from the isolator in sealed plastic bags, sealed into plastic containers which will be surface disinfected using 3% Kilcox Extra prior to being sent off site for incineration by a licensed contractor.

Significant Change ID

Date of Significant Change

Project Additional Information

Purposes of the contained use

To evaluate safety and efficacy in chickens under controlled laboratory conditions

Recipient or parental organism

Parental Strains:
The HVT parent strain is FC-126

Host/vector system

Not relevant since the scope of experiments is limited to animal trials with GMM that have been established previously. For the animal trials no genetic manipulations will be performed and vectors are therfore not involved.

Origin & function

Three of the foreign genes are viral envelope glycoproteins thought to play roles in the attachment of the virus to host cell receptors prior to fusion with the cell membrane and in the envelopment of the virus during egress form the cell. The final protein is a major structural protein and host protective immunogen.

Evaluation of foreseeable effects

HVT is currently classified in the subfamily of alphaherpesvirinae, and is also known as Meleagrid herpesvirus 1, turkey herpesvirus, or Marek's disease virus serotype 3. The virus was first described around 1970 as a herpesvirus infecting turkeys and sharing antigenic features in common with Marek's disease virus (MDV). Whilst MDV is highly pathogenic for chickens, HVT is non-pathogenic and could therefore be used for effective vaccination against infection and disease caused by MDV (Okazaki et al., 1970, Avian Diseases, vol. 14, p. 413-429). Since then, vaccination of chickens against MDV by using HVT has become part of the standard vaccination program of billions of chickens produced worldwide every year.

The HVT virion has all the features of a typical herpesvirus, and is about 160nm in size in its enveloped form. It possesses a large genome (approximately 159 kb) comprising linear double stranded DNA. The HVT genome has a long history of manipulation; in particular its non-pathogenic properties have lead to research into the use of HVT as a viral vector for expression and delivery of various proteins to the chicken. Examples are the expression of genes coding not only for antigens from other poultry pathogens such as: Infectious bursal disease virus (IBDV) (Darteil et al., 1995, Virology, vol. 211, p. 481-490), and Newcastle disease virus (NDV) (Sondermeijer et al., 2993, Vaccine, vol. 11, p. 349-358). But also the expression has been described of a parasite antigen (Cronenberg et al., 1999, Acta et al., 2007, Vaccine, vol. 25, p. 8529-8535) Such work has led to the development of commercial vaccines using such technology, including the Vaxxitech product range (Merial), the Vectormune HVT product range (Ceva) and the Innovax product range (Merck Animal Health), thus providing convincing data in a large number of birds of the safety of HVT vectored IBD, ND and ILT vaccines.
There are no perceived hazards associated with the recipient microorganism.

Hazards arising directly from the inserted gene product (eg cloning of a toxin or oncogene)
The gene products are involved in attachment and entry into host cells, replication and release. There are no reports in the literature indicating that these gene products have a direct influence on virulence. Overall the risk of hazards arising directly from the inserted gene products is considered low.

Hazards arising from the alteration of existing traits (eg alteration of pathogenicity, host range, tissue tropism, mode of transmission or host immune response)
HVT is a non-pathogenic alpha herpesvirus with a host range restricted to chickens and turkeys. Whilst it is considered unlikely that the introduction of coding sequences for two of the genes into HVT would significantly modify the existing host restriction because they originate from a virus causing an acute, highly contagious, infection limited to chickens and pheasants. For the remaining gene it is possible that the presence of the protein in the virus envelope could result in transmission to man. HVT however is typically cell associated and does not generate enveloped viral particles in the supernatant of infected cultures such as is seen with most other herpesviruses, although infectious cell-free virus has been detected in the feather dust of chickens vaccinated with HVT. Therefore the risk of hazards arising from alteration of the existing traits of the HVT vector is considered low.

The potential hazards of sequences within the GMM being transferred to related microorganisms. The HVT backbone of recombinant construct has been modified by the insertion of a fragment containing the heterologous gene and promoter sequence. There have been no gene deletions. The phenotype of the recombinant strains is therefore the same as that of the HVT backbone. If the inserted fragment with the heterologous gene would be lost, this would result in the wild type HVT, which is also avirulent.

There have never been reports of the recombination of HVT with other related herpesviruses of poultry, e.g. virulent (serotype 1) MDV or serotype 2, and the possibility of recombination with a virus capable of infecting humans is therefore considered extremely small. Genetic transfer to other organisms in the environment has never been described for herpesviruses, and is therefore considered to be unlikely.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

### Project Ref 391/15.1

- **Date Ackn'd**: 11/11/2015
- **CU2 Project Title**: Development of a N-glycan based vaccine for use in chickens to aid in preventing infection and colonisation by Campylobacter jejuni
- **Class**: Class 2
- **Culture Volume**: 1-50 Litres

### Project Additional Information

- **Purposes of the contained use**: Proof of concept for the safety and efficacy of a N-glycan based vaccine and if successful the generation of safety, quality and efficacy data to be used for product registration
- **Recipient or parental organism**: Non-GMM

Project notified under transitional arrangements **N**
1. E. coli K12 W3110 laboratory strain (or other recognised non-pathogenic strains), which contains disabling mutations and is known to have a restricted ability to colonise the intestine and limited persistence in the environment. It has a history of safe commercial use and is not known to have adverse effects on micro-organisms or plants. The K12 strain used has a kanamycin cassette replacing the O-antigen polymerase (wzy) gene on the chromosome.

2. Avian pathogenic E. coli strains.

3. Avian 'commensal' E. coli strains

**Host/vector system**

E. coli vector pACYC 184: a commercially available cloning vector, origin of replication p15A, containing chloramphenicol (cat) and tetracycline resistance (tet) genes, which is mobilisation deficient.

**Origin & function**

The functional genes (pgl gene cluster of C. jejuni 81116): gne, pglK, pglH, pgll, pglJ, pgIB (with mutation in the WWDYG motif), pglA, pglC, pglDEFG and the waaC from the LOS locus upstream of gne transcribed in opposite direction) code for enzymes involved in polysaccharide biosynthesis and assembly. The mutation in pgIB (the oligosaccharyl transferase responsible for the transfer of glycan to the final protein) ensures that N-linked protein glycosylation does not occur. Instead the glycans are transferred to the E. coli lipid A to enable surface display on the outer membrane of E. coli.

The pgl gene cluster has been inserted into the tetracycline resistance gene on the parent plasmid and is constitutively expressed from the tetracycline resistance gene promoter. The tet gene was inactivated during the cloning process.

Functional operons with a reduced number of genes (including deletion of pgIB) within the cluster will also be evaluated.

**Evaluation of foreseeable effects**

i) Hazards associated with the recipient microorganism (eg bacterial host or viral vector)

Health and Safety

Executive

Contained Use Notification

E. coli K12 W3110 laboratory strain (or other recognised non-pathogenic strains), contain disabling mutations and is known to have a restricted ability to colonise the intestine and limited persistence in the environment. It has a history of safe commercial use and is not known to have adverse effects on micro-organisms or plants. The K12 strain used has a kanamycin cassette replacing the a-antigen polymerase (wzy) gene on the chromosome.

Avian pathogenic Escherichia coli. APEC is considered as both a primary and a secondary pathogen in the chicken and is a member of the extra-intestinal pathogenic E. coli (exPEC) pathotype along with human uropathogenic (UPEC) and neonatal meningitis-associated E. coli (NMEC). Data suggests that APEC strains can be readily transmitted to humans and there is evidence that some APEC strains are closely related to human exPEC strains.

Further, whole genome sequence analysis has revealed a high degree of similarity between APEC and exPEC (Zhu Ge et al (2014), Comparative genomic analysis shows that avian pathogenic Escherichia coli isolate IMTS5155 (02:K1:H5; ST complex 95; ST140) shares close relationship with ST95 APEC 01:K1 and human exPEC 018:K1 strains. PLoS ONE 9:11: e112048. DOI:10.1371/journal.pone0112048). PCR based phylotyping and multi-locus sequence typing have also revealed a link between APEC and human exPEC. Overall it is therefore considered that APEC possess zoonotic potential. (reviewed by Dziva and Stevens (2008), Coli bacillosis in poultry: unravelling the molecular basis of virulence of avian pathogenic Escherichia coli in their natural hosts. Avian Pathology, 37:4, 355-366.)
(ii) Hazards arising directly from the inserted gene product (eg cloning of a toxin or oncogene)

The inserted genes code for enzymes involved in the N-linked general protein glycosylation pathway of Campylobacter jejuni, resulting in the synthesis and transfer of a heptasaccharide glycan to lipid A which is surface expressed on the outer core lipooligosaccharide of the recipient E. coli. There is no indication of toxicity associated with the novel glycan.

(iii) Hazards arising from the alteration of existing traits (eg alteration of pathogenicity, host range, tissue tropism, mode of transmission or host immune response)

The biological significance of protein glycosylation in C. jejuni is unclear, however mutants with disrupted glycosylation have been constructed and shown to have both reduced capacity for attachment and invasion of human epithelial cell lines and impaired colonization of mouse and chicken intestinal tracts (Szymanski, Burr and Guerry (2002) Campylobacter protein glycosylation affects host cell interactions. J. Bacteriol. 70, 2242-2244; Hendrixson and DiRita (2004) Identification of Campylobacter jejuni genes involved in commensal colonization of the chick gastrointestinal tract. Mol. Microbiol. 52,471-484; Jones et al (2004) Adaptation of Campylobacter jejuni NCTC1168 to high-level colonization of the avian gastrointestinal tract. Infect. Immun. 72, 3769-3776; Karlyshev et al (2004) The Campylobacter jejuni general glycosylation system is important for attachment to human epithelial cells and in the colonization of chicks. Microbiology, 150, 1957-1964). Overall however these results are difficult to interpret due to alterations in the glycosylation of multiple C. jejuni proteins which could result in many variable effects including protection against proteolytic cleavage, solubility, protein assembly and antigenic variation as well as adhesion. Since the oligosaccharyl transferase gene pglB is either mutated or deleted from the inserted biosynthetic pathway Nglycosylation of E. coli proteins cannot occur, so the likelihood of any significant effect on colonisation potential through the modification of recognised E. coli adhesins is extremely low. Surface expressed recombinant glycan however could interact with lectin-like receptors on the host cell surface which has the potential to enhance bacterial adhesion. Even in the presence of an adhesin, specific virulence in E. coli is further associated with a combination of toxins and functional genetic elements which enable the strain to cause disease (Kaper, Nataro and Mobley (2004) Pathogenic Escherichia coli Nature Reviews: Microbiology 2, 123-140). It is thus unlikely that the presence of the recombinant glycan alone would be sufficient to enhance its virulence over that of the parental strain.

(iv) The potential hazards of sequences within the GMM being transferred to related microorganisms

Transfer of the operon to related microorganisms provides the potential for the introduction of a functional Nglycosylation pathway which whilst unable to glycosylate proteins could result in surface expression of recombinant glycan. The use of a non-mobilisable plasmid or the chromosomal integration of the operon minimise the likelihood of the successful transfer of the entire pathway. This pathway whilst highly conserved within Campylobacter sp. does not exist within other bacteria. It is therefore unlikely that this will provide any fitness advantage to the bacterium.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Laboratory waste materials will be subjected to autoclaving using an approved discard cycle (e.g. 134°C for 10 minutes) prior to disposal as clinical waste by an approved contractor. Re-usable glassware will be decontaminated by autoclaving using a validated cycle (e.g. 121°C for 20 minutes) before cleaning.
Small scale fermenters will be decontaminated using 1% Virkon. The vessel and associated connectors and tubing will be filled with freshly prepared 1% Virkon and left for a minimum of 12 hours. The condenser cannot easily be filled with Virkon and will therefore be removed and decontaminated by autoclaving or using Virkon separately. Animal carcasses and bedding will be placed into sealed bins, which will be surface disinfected or fumigated prior to removal from the animal room and sent for incineration by an approved contractor.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

### Project Additional Information

#### Purposes of the contained use

Evaluation of poxvirus vectored feline viral antigens for vaccination of cats.

#### Recipient or parental organism

- Non-modified poxvirus with no markers or attenuations prior to use. Biological Hazard and MAFF hazard group 1.
- Only produces disease in its natural host. Is not known to produce disease in humans.

#### Host/vector system

Host is poxvirus as described above.

#### Origin & function

- Inserted gene sequences derived from a feline virus, feline genes from feline peripheral blood mononuclear cells and marker genes derived from E. coli. The genes and their regulatory elements are not known to affect virulence, survival in the host, survival in the environment or increase resistance to therapeutic agents. The donor genes are not known to be involved in host range, virulence or expansion of tissue tropism.

- Insertion of the genes into the parental viruses confers an attenuated plaque phenotype.

- The inserted genes are intended to induce protection against the parental organism following vaccination of cats with the GMM.

#### Evaluation of foreseeable effects

The GMM is only known to cause disease in its natural host. The inserted sequences are not expected in increase the survivability of the GMM in the environment or increase its host range of tissue tropism. The use of category 2 containment reduces any risk to the environment and therefore exposing the natural host to effectively zero. The GMM is not known to cause disease in humans and category 2 containment reduces any risk of exposure to effectively zero.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste will be decontaminated by autoclaving using a validated temperature cycle designed to achieve 100% killing.

Liquid waste will be heat treated using a validated temperature cycle designed to achieve 100% killing.

No waste will be disposed off containing any live organisms.

The risk assessment and notification form was reviewed by the GMM Safety Committee on 15/12/00. All elements were debated and the committee found that the information provided was in accordance with the 2000 regulations. The containment level applied was deemed to be appropriate for the activities and scale in order to reduce all risk to effectively zero.

Please enter comments on the GM safety committee on the risk assessment

Date Ackn’d 29/04/2005

CU2 Project Title Storage of seed materials and associated laboratory work targeted at formulating an experimental vaccine.

Date Project Ceased

Class CultureVolClass2 CultureVolumeClass3-4

Non-GMM Consent Granted

Not Applicable
Project Additional Information

Purposes of the contained use

To provide vaccine for potential evaluation in controlled laboratory studies or in the field.

Recipient or parental organism

a) The parental Mannheimia haemolytica is a field isolate originally cultured from bovine pneumonic lung tissues.

B) The parental Pasteurella multocida is a field isolate originally cultured from pneumonic lung tissue. This strain is highly virulent and is capable of replication in the bovine lung.

These are both classified as ACDP hazard group 2 and had no genetic modifications carried out prior to the production of the deletant strains.

Host/vector system

Not applicable.

Origin & function

Attenuation of the virulence of Mannheimia haemolytica and Pasteurella multocida by virtue of gene deletions, whilst maintaining a suitable immune response in the host animal.

Evaluation of foreseeable effects

The deletant strains are likely to retain the features of the parental organism with respect to host range, tissue tropism and mode of transmission. They will however be significantly attenuated with respect to virulence.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

The level of attenuation of these organisms is such that the measures applicable to containment level 1 are appropriate. However, since the mode of transmission is unlikely to have been affected, work with open vessels where there is a risk of aerosol generation will be carried out within a microbiological safety cabinet.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
The risk assessment and notification form were reviewed by the GMSC on 31 January 2005. All elements were debated and the committee found that the information provided was in accordance with the 2000 regulations. The containment level applied was deemed to be appropriate for the activities and scale in order to reduce all risk effectively to zero.

Historical Significant Changes

Withdrawn N

Tick if notifying a connected programme of work N
**Significant Change ID**

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

Evaluation of immunogenicity, potency and safety in chickens.

**Recipient or parental organism**

The construct is a novel avian herpesvirus, consisting of regions of herpesvirus of turkeys (HVT) and of Marek's disease virus (MDV).

A. The parental HVT is ubiquitous in domestic turkeys and widespread in chicken populations where vaccination with HVT has been practiced since the early 1970s. It is not considered to be pathogenic for turkeys or chickens (Cainek BW HW Jr. Iowa State University Press, Ames, Iowa pp342-385).

B. The parental MDV causes a lymphoproliferative disease that affects the peripheral nervous system and other organs.

**Host/vector system**

Not applicable.

**Origin & function**

The construct contains MDV genes which are not known to affect virulence in and of themselves. Deletion of these genes has been shown to have no affect on the transforming potential of the virus. Further, these genes do not include the viral genes and regions known to be associated with virulence and oncogenicity in MDV. In the construct these have been replaced by the equivalent regions of HVT genome.

**Evaluation of foreseeable effects**

Neither of the parental strains are known to be human pathogens. The construct is expected to have similar traits to that of an approved avirulent vaccine strain of HVT.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Although the GMM has been shown to be avirulent, full evaluation of the potential for shed and spread is incomplete. In consequence, any animal work will be carried out in a facility with HEPA filtered extract air in order to provide enhanced protection of the environment. For studies involving subcutaneous or intramuscular vaccination of animals, syringes will be filled in a safety cabinet, but to reduce the risk of needlestick injury, injection of the animals will take place on the open bench.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All solid waste will be decontaminated by autoclaving using a validated temperature cycle designed to achieve 100% killing.

Liquid waste will be heat treated using a validated temperature cycle designed to achieve 100% killing.

No waste will be disposed of containing any live organisms.

Significant Change ID

Date of Significant Change

Project Additional Information
Purposes of the contained use

Evaluation of potential constructs for the expression of the gene of interest, process development and scale up to 40L.

Recipient or parental organism

The recipient E. coli strain is a weakened laboratory adapted mutant and is regarded as non pathogenic. It is expected that the survivability of the bacterial host in the environment will be poor.

Host/vector system

The plasmid comprises a heat-inducible expression plasmid with a pUC origin of replication and tetracycline resistance gene plus the coding sequence for the gene of interest. The plasmid is non conjugative and there is therefore minimal risk of transfet to other micro-organisms.

Origin & function

The gene sequence has been obtained from Cryptosporidium parvum and codes for a structural protein. It is not a known virulence determinant.

Evaluation of foreseeable effects

Not applicable.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

**Historical Significant Changes**

**Historical Date of Additional Info**

02/03/2022
## Purposes of the contained use

1. **ANTI-CANCER DRUGS**
   Lentivirus will be used to help identify targets for the development of novel anticancer drugs and to understand the mechanism of action of the drugs.

2. **SOMATIC CELL REPROGRAMMING**
   'Replication-incompetent' 'genome-integrating' viral vectors (using Lentivirus or LeV) or 'replication-incompetent' 'non-integrating' viral particles (using Sendai virus or SeV) will be used to reprogramme human somatic cells to induced pluripotent stem cells.

## Recipient or parental organism

1. **ANTI-CANCER DRUGS**
   Third generation lentiviruses will be modified to encode constructs that either increase (cDNA) or decrease (shRNA) the expression of genes involved in the activity of cancer drugs. This may include both oncogenes and tumour suppressors. The lentiviruses will then be used to transduce cultured normal or cancer cell lines.

2. **SOMATIC CELL REPROGRAMMING**
   Primary human fibroblasts and primary blood cells (Peripheral blood mononuclear cells). Primary cells from patients will be screened through a rigorous ethical screening process that will exclude patients with risk of infection. Uncharacterised cell lines may still be associated with endogenous biological agents (e.g., blood borne viruses). HEK293FT cell line will be used to package the Lentivirus.

## Host/vector system

1. **ANTI-CANCER DRUGS**
   3rd generation Lentivirus particles from commercial vendors (e.g. Thermofisher or Origene) will be generated in a packaging cell line (eg HEK293T) following transfection with plasmids encoding the viral proteins. The viral particles will be used to transduce cultured established cancer cell lines including Ovcar4, COV-362, COV318, MDAMB-231, MDAMB468 cells.

2. **SOMATIC CELL REPROGRAMMING**
   ViraPower™ Lentiviral Expression System, (Thermofisher), is a third-generation system consisting of the following components: (1) A pLenti-based expression vector into which the reprogramming genes (Oct4, Sox2, Klf4, c-Myc/l-Myc) will be cloned, (2) the ViraPower™ Packaging Mix that contains an optimized mixture of the three packaging plasmids, pLP1, pLP2, and pLP/VSVG, and (3) an optimized HEK 293FT producer cell line (called BL-15) that stably expresses the SV40 large T antigen under the control of the human CMV promoter and facilitates optimal production of virus.
   Sendai Virus kit is supplied by Thermofisher (Cat. No. A16517, A16518). SeV vectors used in this kit consist of viral proteins NP, P, M, F (activated), HN, and L, and the SeV genome RNA, from which the F gene is deleted.

## Origin & function

1. **ANTI-CANCER DRUGS**
   The genetic material will be purchased from commercial sources, for example Thermofisher ("ViraPower") or Origene ("LentiORF, lenti shRNA"). Standard molecular biology techniques will be used to incorporate the desired genetic material into a plasmid encoding the relevant part of the lentivirus where this is not already commercially available.
The intended function is to either identify and validate potential novel drug targets or to analyse the mechanism of action of candidate drug molecules.

2. SOMATIC CELL REPROGRAMMING
LeV kit (ViraPower™ Lentiviral Expression System) is supplied by Thermofisher (Cat. No. K4950-00). The procedure is designed to produce ‘replication-incompetent’ ‘genome-integrating’ viral vectors.
SeV kit (Sendai Virus kit) is supplied by Invitrogen (Cat. No. A16517, A16518). The procedure is designed to produce ‘replication-incompetent’ ‘non-integrating’ viral particles.
Both procedures to achieve reprogramming of human somatic cells to induced pluripotent stem cells. Somatic cells such as patient blood cells or patient fibroblasts (post surgical tissues or from pre-screened commercial cell banks) will be used for this reprogramming.

Evaluation of foreseeable effects

1. ANTI-CANCER DRUGS
There is not anticipated to be any effect on the virus of introducing the genetic constructs into the viral genome. The virus is replication-defective and this is not expected to change. The infectivity of the virus is also not expected to change.
The effect of the genetic modification on the cultured cells transduced with the virus will be assessed with a range of cancer cell biology techniques. These will include cell growth assays, immunoblotting, microscopy, QPCR, assays measuring cell death, apoptosis, autophagy and metabolic changes (eg changes in branched chain amino acids). The anticipated changes in the transduced cells include changes in the growth characteristics, for example altering the ability of the cells to grow in an anchorage independent manner or independently of growth factors. The sensitivity of the cells to other anti-cancer drugs may be altered. This may increase the ability of these cells to form tumours in immunocompromised individuals.
If personnel are inadvertently exposed to lentivirus, it is possible that the cells infected by the virus become predisposed to cancer because the cells may acquire the deregulated growth characteristics described above. The virus is not able to replicate, so the infection is not expected to spread beyond the directly infectly cells. The risk assessment has identified that the proposed work should be considered class 2.

2. SOMATIC CELL REPROGRAMMING
The nature of the vector (both LeV and SeV being replication-incompetent) is such that they do not endow the genetically modified micro-organism with a phenotype likely to cause toxicity to humans, animals or plants, or likely to cause deleterious effects on the environment. There is a possibility that DNA could become integrated into genomic DNA of personnel if accidentally introduced although this is likely to occur with a very low frequency and not more than the standard mutation rate in cells. Bearing in mind that some of the targeted sequences are implicated in carcinogenesis, there is, therefore, a very small risk of the personnel incorporating cancer promoting factors into a small number of cells. Despite the inclusion of the safety features associated with the two types of systems, the virus produced with these systems can still pose some biohazardous risk since it can transduce primary human cells. Therefore, an SOP for containment level 2, class 2 GMMs will be in operation as outlined in Risk Assessment.

Characterisation of GMO from reprogramming will include
1. Identification of reprogrammed colonies - by live/imunostaining
2. Assessing growth rate and morphology for abnormalities
3. Absence of viral genome using PCR after >10 passages
4. Pluritest to confirm pluripotency of GMO

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not applicable
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation is requested

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

1. Liquid waste containing high titre virus (viral stocks and from cells up to 1 passage after infection) will be collected into sealable polypropylene container containing 1/10 maximum volume of 10% Sodium dodecyl sulfate (final concentration at least 1% SDS) and left for at least 1 hour. Used tips and other small plasticware items will be placed in the same container. The liquid container will be closed and placed in a clinical waste bag for transport to the autoclave. At the autoclave, the bagged bottle will be placed inside the autoclave and the lid of the container will be loosened without opening the waste bag. After autoclaving, the liquid will be poured down a dedicated sink with copious amounts of water and solid items collected through a sieve transferred to normal clinical waste using gloves.

2. Liquid waste expected to contain a low titre of virus (eg from cells 2 passages after infection) will be collected into container containing 1/10 maximum volume of 10% Distel (final concentration at least 1%). After 24 hours, the liquid will be poured down the dedicated sink in the containment lab with copious amounts of water.

3. For large plastic solid wastes in contact with virus (eg. pipettes, culture flasks, pots, etc), the waste will be first soaked in 1% Distel in a sharps bin for 24hrs to inactivate the virus. After 24hrs, the lid will be attached but the seal left open to allow the liquid to be poured down the dedicated sink in the containment lab with copious amounts of water. The sharps bins will be sealed completely, placed in a clinical waste bag and sent for incineration unless it has come into contact with high titre virus (as defined above) in which case it will be placed inside an autoclave bag, with tissues to collect drips, then a further bag and inactivated by autoclaving and then sent for incineration.

4. Inactivation of waste by autoclave as indicted above will be for 60 min at 135°C. A Crossmark stick is included in every autoclave cycle to ensure correct operation. The autoclave is routinely calibrated to ensure it reaches the desired operating temperature and is in the same building as the containment laboratory.

5. The degree of virus inactivation is expected to be >4 log unit reduction by Distel alone and > 9 log unit reduction by disinfectant followed by autoclaving. Other methods may be necessary to inactivate virus before removing samples from the containment laboratory for analytical procedures. These will include treatment with 4% paraformaldehyde (eg prior to microscopy) or boiling in SDS (eg prior to electrophoresis). These methods will be validated by measuring the virus titre in the treated samples.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
1. Is autoclaving necessary?
Response - this is planned for high titre waste only. Because the virus may predispose anyone infected with it to cancer, a greater degree of cell kill than achieved by disinfection alone (4 log units) is desirable.

2. How will inactivation of the virus be confirmed before removing samples from the laboratory?
Response - for every experiment a point in the experimental protocol has been identified where it is anticipated the virus will be inactivated. These will be formally demonstrated to inactivate the virus before the samples are removed from the laboratory. Examples include treatment with 4% paraformaldehyde or 10% trichloroacetic acid or heating to 95 degrees C in 0.1% SDS.

3. How will viral stocks be stored?
Response - a dedicated space in a -80 freezer has been identified. Access to this will be restricted by a lock and samples will be clearly labelled to indicate the presence of viable virus. The laboratory door will also be labelled. Access to the laboratory area is restricted by card control.

The maximum culture volume to be released at any one time is estimated to be two litres.

The deactivation method of preference is to autoclave. The autoclave is subject to a recorded system of routine maintenance and testing. The deactivation method by autoclave for particular waste streams will be validated by trial and analysis.

The ongoing monitoring will cover verification of autoclave service and performance records, verification of method compliance by staff, and spot analysis of deactivated waste. Heat sensitive tape will be used to designate autoclavable waste and indicate heat treatment.

Should experience or risk assessment indicate that deactivation by autoclave will not be suitable, other methods such as chemical destruction or sterilisation will be considered.

Date of Significant Change
Farming of trout and salmon is an important commercial activity in the UK and is a sustainable means of ensuring an adequate supply of essential nutrients in the human diet. However, farmed fish are particularly susceptible to disease as they are stocked at high density and may be kept in less than optimal conditions. One particular disease of trout and salmon is called enteric redmouth (ERM) and is caused by the gram-negative bacterium Yersinia ruckeri. This bacterium occurs as a number of different strains, the most common of which is known as serovar O1, or the Hagermann strain. The disease has been largely controlled by application of an oral vaccine but in recent years, a novel strain called EX5 which is not controlled by the vaccine has made an appearance and is causing problems in fish farms. We have been analysing the difference between the O1 and EX5 strains by a proteomic-based approach and have noted a number of proteins that differ between the strains. For example, one of these is identified as the outer membrane protein OMPA, which appears to be greatly over-expressed in the EX5 strain relative to O1. We are interested in analysing the properties of the OMPA gene from EX5. We will also investigate those EX5 genes encoding other proteins (as yet unidentified) found to differ substantially in expression between O1 and EX5.

The sequence encoding the promoter and coding region of OMPA (and other proteins) from Yersinis ruckeri strain EX5 will be amplified by PCR methods and cloned into the vector pBluescript KS and replicated in the K12 E.coli strain XL1-Blue (Stratagene). This plasmid will then be recovered and introduced into Yersinia ruckeri strain O1. We will then monitor the effect of phagocytes and serum from vaccinated and unvaccinated fish (trout, Orynchus mykiss) on the genetically modified O1 strain, wildtype O1 and also EX5 Yersinia ruckeri. In addition we will introduce the modified O1 strain (and wildtype control strains) into vaccinated and unvaccinated trout by intraperitoneal injection, and monitor for signs of enteric redmouth disease.

Recipient or parental organism

Recipient organisms: Escherichia coli K12 XL1-Blue (Stratagene), Yersinia ruckeri O1 (Hagermann strain)
Parental organism: Yersinia ruckeri strain EX5

Host/vector system

Host system Escherichia coli K12 XL1-Blue (Stratagene), Yersinia ruckeri O1 (Hagermann strain)
Plasmid vector pBlueprint KS (Stratagene)

Origin & function

Initially we will concentrate on the gene encoding OMPA from Yersinia Ruckeri. OMPA is an outer membrane protein found in all gram-negative bacteria, required for outer membrane stability and may be involved in attachment of bacteria to host cells. Genes encoding other proteins that differ between the O1 and EX5 strains (as yet unidentified) will also be cloned and analysed in the same way. It is anticipated that these genes might encode, for example, elicitors of defense responses (so-called pathogen-associated molecular patterns) or secreted elicitors of pathogenicity. We may also isolate and characterise genes encoding homologous proteins from related bacteria (for example, Yersinia enterolitica).

Evaluation of foreseeable effects

The most potentially hazardous GMM to be produced will be Yersinia ruckeri strain O1 carrying plasmids bearing the OMPA gene (or other pathogenicity determining genes) from Yersinia ruckeri strain EX5. If OMPA (or other proteins) play a major role in the virulence of strain EX5, this GMM should resemble strain EX5 in its properties when fish are challenged with it; that is fish vaccinated against Yersinia ruckeri O1 will be susceptible to the recombinant line. The GMM will thus be as pathogenic (but no more than) the EX5 strain. Should an EX5-derived pathogenicity factor be transferred to related pathogenic microorganism, there is the possibility that virulence of these organisms could be enhanced. The genes in question will be plasmid-borne, so although the potential for gene transfer is relatively high under particular circumstances, there would have to be selection pressure for such plasmids to be retained in the environment. It is not considered probable that one single factor will convert a non-pathogenic organisms into a pathogenic one. Yersinia ruckeri is not a pathogen of humans or mammals, there are no risks to humans from any engineered strains of Yersinia ruckeri planned in this work.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
No non-microbial GM work is planned, however the GMO's may be tested against (non-GM) fish. This will be done in our contained fish facilities, all materials (including water) will be autoclaved or disinfected prior to disposal.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Manipulations that might cause aerosols will be undertaken in a safety cabinet. Solid waste, fish and bacterial cultures on plates will be autoclaved at 121 degrees C for 20 minutes. Autoclaved waste will be disposed of together with other waste from the School of Life Sciences. Liquid waste and water from infected fish tanks will be treated with Chloros before disposal in an appropriate drain. This disinfectant is routinely used for treatment of potentially infected liquids in our laboratories; microbiological safety is routinely monitored in the fish laboratories.

<td>Expression and RNA based knockdown of components of intracellular signal transduction pathways in mammalian cells using retroviral vectors</td>
<td>Class 2</td>
<td>&lt; 1 Litre</td>
<td></td>
<td>02/03/2022</td>
</tr>
</tbody>
</table>
We plan to use retroviruses to express, or knock down the expression of, intracellular signalling molecules in cultured mammalian cells and investigate the effects of these interventions on signal transduction pathways and assayable cellular processes, such as gene expression, migration, proliferation etc. Our core area of research is the class I PI3K signal transduction network and its significance in cancer.

The retroviruses will be previously developed laboratory vectors that have been modified, according to the originators designs, to express, or knock down the expression of, intracellular signalling molecules, including protein and lipid kinases and derived mutants (e.g. PI3K, AKT, InsR), lipid and protein phosphatases (e.g. PTEN, SHIP2) and associated proteins (e.g. adaptor, scaffolding proteins, substrates).

We aim to generate the retroviruses by packaging in cultured mammalian cell lines (often HEK293T cells). We will then use these prepared retroviruses to infect commonly used tissue culture cell lines (eg HEK293, HeLa, L6, 3T3-L1, U87MG, 1321N1, MCF10A and MDCK cells) or embryonic stem cells, hepatocytes, fibroblast and myoblast cells derived from rodents, with the purpose of modifying gene expression in these target cells.

Viral vectors and viruses

Viral vectors will either be engineered expression vectors, containing cDNAs encoding signalling molecules to be transcribed and translated, or be 'knock-down' vectors, encoding specific short hairpin RNA molecules for RNA interference. Examples of the vectors that will be used include:

Lentiviral/Retroviral expression vectors

pHR-SIN-CSGW, derived from human immunodeficiency virus 1 (HIV) genome but with viral genes deleted (Ikeda et al, Nature Biotechnology, 2003). This vector contains the viral long terminal repeat (LTR) but with the U3 region deleted in the 3’ LTR to prevent viral enhancer and promoter transfer into target cells, thus rendering it a so-called ‘self inactivated vector’. Derivatives of this plasmid with altered restriction sites for cDNA insertion will be used. The vector also contains the Rev Response Element (RRE) to enhance expression, packaging signals, the HIV central polypurine tract (cPPT) to increase viral titre and a WPRE (Woodchuck hepatitis virus post-transcriptional regulatory element) to enhance mRNA stability. Expression of the inserted gene comes from a SFFV (spleen focus forming virus) promoter. This vector is routinely packaged as a 3 component system to avoid the production through recombination of replication competent viruses.
The retroviral vector pWZL hygro (Serrano et al, 1996, Cell, 88, p593), based upon Murine Moloney sarcoma virus, contains long terminal repeats, the viral gag gene and an inserted hygromycin resistance cassette, within a bacterial plasmid vector. To produce infective virus particles, the virus requires pol and env sequences provided by co-transfection or a packaging cell line.

 Lentiviral/Retroviral RNAi vectors

pLKO.1 (Addgene) is a replication incompetent self inactivating lentiviral vector for siRNA expression, encoding a puromycin resistance gene.

pMKO.1puro (Addgene) is a modification of the pQCXIN vector (Clontech) in which the puromycin resistance gene was introduced and the human U6 promoter to drive the expression of inserted cDNAs.

Origin & function

The expressed cargo in these lentiviruses will be either cDNAs encoding proteins of scientific interest, or short complementary hairpin sequences, designed to knockdown endogenous expression of such proteins by RNA interference. The expressed proteins of interest will be those involved in intracellular signalling and regulatory mechanisms, including protein and lipid kinases and derived mutants (e.g. PI3K, AKT, InsR), lipid and protein phosphatases (e.g. PTEN, SHIP2) and associated proteins (e.g. adaptor, scaffolding proteins and substrates).

Evaluation of foreseeable effects

The most hazardous GMM to be produced appear to be pantropic expression lentiviruses encoding active oncogenes and pantropic lentiviruses expressing interfering RNA to knock down the expression of tumour suppressor proteins. Accidental exposure to these viruses in a form that could be internalised by the user or others would carry a significant risk of viral integration into cellular DNA and disruption of the normal mechanisms regulating cell proliferation, with an increased risk of cancer development. Other unforeseen effects of modified cellular gene expression, unrelated to tumour formation, could also stem from accidental personal contamination with lentiviruses encoding poorly characterised proteins.

Thorough measures must be taken to avoid personal contamination. However, it should be considered that retroviral particles and infected cultured cells would not survive outside culture medium, viruses would be harmless unless internalised and even if viral gene expression were to occur in cells, tumour development would be unlikely.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

No non-microbial GM work is planned.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid and liquid waste will be sterilised by same day autoclaving (121°C, twenty minutes), with some additional precautions.

Liquid waste, including culture medium that contains high titres of lentivirus, will be immediately mixed with disinfectant (Terminex) prior to autoclaving. Only disposable plastic culture ware and pipettes should be used. Solid waste will include disposable pipette tips contaminated with virus. These will be fully immersed in disinfectant for several hours before autoclaving. A treated waste sample will be included in each RT-PCR based contamination screen.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N
The GM risk assessment for this project was circulated to the Heriot-Watt Genetic Modification Safety Committee for review, and the Committee is content that the work as described falls under class 2, and that correct levels of containment and disposal are described. Dr Leslie has the appropriate experience to safely carry out this work and the laboratory where the work will be carried out is appropriate for category 2 work.

Project Additional Information

Purposes of the contained use

The overarching goal is to advance knowledge of bacterial factors which promote survival, persistence, resistance and infectivity of these bacteria and hence identify potential targets to take forward towards disease control.

To achieve this overall goal, specific targets include bacterial genes and genomic loci which are incorporates investigation of Hazard Group 1 (non-pathogenic) and Hazard Group 2 E. coli strains mainly of animal origin but also includes isolates from human and environmental sources. This panel of isolates includes pathogenic, opportunistic and antibiotic-resistant E. coli plus – for comparative purposes – related Enterobacteriaceae in which phenotypic or genomic characteristics (e.g. genome islands, plasmids, resistance determinants) exhibit similarities.

In order to adequately characterise E. coli strains a broad range of approaches will be employed:

i) Cloning of specific PCR- or restriction enzyme-derived fragments or synthetic oligonucleotides into cloning vectors for the purposes of producing reference standards for gene expression analyses by quantitative RT-PCR and for recombinant protein production.

ii) Cloning of specific PCR- or restriction enzyme-derived fragments or synthetic nucleotides into plasmid vectors to produce reporter constructs to monitor gene expression in response to environmental conditions.

iii) Mutation and (where required) complementation of selected genes, genome islands and plasmids to fulfil “molecular Koch’s postulates” for which the purpose is to demonstrate the contribution of gene products to fitness and/or pathogenicity.

iv) Introduction of selected genes, operons, genome islands, or plasmids into recipient E. coli strains to fulfil “molecular Koch’s postulates”.

v) Random transposon mutagenesis (e.g. Tn-Seq) as a “global” screen for fitness, colonisation and pathogenesis-associated factors and phenotypes.

Recipient or parental organism

For routine cloning and vector construction purposes, E. coli K12 strains (e.g. DH5alpha, TOP10 and TOP10F, XL1-Blue) will be used. These strains are multiple auxotrophs and lack abilities which permit their survival except under defined culture conditions in the laboratory.

Selected wild-type E. coli strains – mainly originating from agricultural species – will be targeted for loss- or gain-of-function investigations via mutagenesis & complementation and for expression analyses through introduction of reporter constructs. Genome sequence is available for >6000 E. coli and generally, cognate sequence is available for all strains to be subjected to genetic manipulation thus potential virulence and antibiotic resistance can be predicted.

We stock a panel of >200 E. coli isolates from which wild-type strains selected for genetic manipulation will include, for example:

- E. coli P4 (phylogroup A), 1303 (phylogroup A), P4-NR (phylogroup B1) which were originally isolated from bovine mastitis and are widely-employed in experimental infection studies;
- E. coli K71 (phylogroup B1) which was originally isolated from a bovine farm environment and is a non-pathogenic strain used for comparative purposes; widely-employed as in experimental infection studies;
- E. coli 26561 (phylogroup A) which is a multidrug resistant (MDR) strain.

Host/vector system

Vectors used will vary according to purpose and all vectors employed have been routinely used for genetic modification of many different E. coli strains as well as related bacterial species.

Examples of vectors for specific purposes include:

1. Cloning for recombinant protein production and for generating constructs: pBluescript II; pGEM; pGEX; pUC; pRSET.
2. Cloning large constructs such as genome islands: cosmids/BACs such as pBeloBAC
3. Mutagenesis: conditionally-replicating vectors such as pAJR
4. Complementation and monitoring Expression: low to moderate copy number vectors such as pACYC184

Origin & function

Genes inserted will be inserted for one or more of the following purposes:
a) express and purify relevant proteins for further study with an N- or C-terminal tag;
b) inactivation of genes targeted for mutagenesis using antibiotic resistance as a selective marker;
c) complementation a mutant strain.
d) monitoring expression/localisation of a promoter or protein sequence using enzymatic, fluorescent or luminescent protein reporter;
e) introduction of contiguous genomic regions for gain-of-function study in non-pathogenic strains.

Target genes will cover a range of functions such as sensors, regulators, transporters, adhesins, genome islands (e.g. secretion system or capsular polysaccharide). None of the genes we target are known to be involved in promoting human pathogenicity or persistence in the environment. Mutants are expected to create attenuated strains and reporter constructs are not expected to confer any increased risk. Complementation is intended to restore native, wild-type phenotype and cloning of genome islands will be carried out in highly auxotrophic laboratory strains.

Evaluation of foreseeable effects

Much of the work involves loss of function (mutagenesis), restoring native function (complementation) or production of individual recombinants none of which are expected to pose hazard.

Selected investigations may introduce a gene/locus into disabled strain. The targeted E. coli pathotypes are ACDP Hazard Group 1 (HG1) and HG2 and genes selected for cloning may represent any of a range of functional classes including metabolism, regulation, adhesion and toxicity thus cloned genes may confer function on recipient strains. However, pathogenicity of E. coli strains under investigation is typically conferred by multiple factors all of which are required co-ordinately to result in ability to cause disease – since recipient strains lack the combination of determinants required to confer pathogenicity, insertion of a single gene or of an operon encoding multiple components required for a single function has a very low possibility of increasing hazard in the recipient strain.

The greatest potential hazard is likely to be through introduction of antibiotic resistance gene(s) into wild-type strains. This is a necessary element of this work to be able to select for the appropriately modified organisms. All resistance determinants in use are naturally evolved genes which have become widely disseminated in a broad range of pathogenic, opportunistic and non-pathogenic (including commensal) strains and are widely distributed in global ecosystems.

The wild-type strains to be used represent pathotypes for which multiple determinants are typically required to confer pathogenicity. Inserted gene(s) and other genetic elements to be targeted are present in the natural “pan-genome” of E. coli and related bacteria hence novel factors are unlikely to be introduced with result of additional risk.

Vectors are not self-replicating and are all widely used in microbiology and molecular biology laboratories without harmful consequence.

The risks of the inserted materials are minimal with the application of routine safe working procedures.

E. coli strains are recognised as host-associated although some environmentally-adapted strains can survive outside warm-blooded hosts – this phenotype cannot yet be predicted for individual strains hence it is assumed that all E. coli will survive to some extent under ambient conditions. The strains targeted are animal pathogenic, commensal or environmental strains of no known human pathogenic potential; in some instances, human pathogenic E. coli strains will be used for comparative purposes.

All handling is carried out in a Containment Level 2 microbiology laboratory. Containment procedures will limit exposure to negligible levels and minimise any potential risk for human or environmental exposure. If exposure were to occur, strains pose no risk over and above natural strains of E. coli.

Evaluation of foreseeable effects

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Manipulations that might cause aerosols will be undertaken in a safety cabinet. Solid and liquid waste contaminated with microorganisms will be sterilised by autoclaving. Some liquid waste will be treated with hypochlorite disinfectant prior to disposal and surface decontamination will be done using Distel.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N
The Heriot-Watt Genetic Modification Safety Committee has reviewed the risk assessment for this project and there were no comments of note made.

Project Additional Information
Purposes of the contained use

Rapid blight is a newly emerging disease of amenity grasses in many parts of the world including the UK. A better understanding of the plant-pathogen interactions between monocotyledonous host plants such as Poa annua and this protist pathogen is required in order to design strategies to control this disease. The aims of this project are to generate transgenic lines of Labyrinthula terrestris, the causal organism of rapid blight in turf grasses, with constitutively expressed marker genes such as Green Fluorescent Protein, in order to understand the mechanisms by which L. terrestris and related species infect monocotyledonous plants, and how plants might defend themselves against L. terrestris. We will study plant-pathogen interactions during the infection process and in further physiological and biochemical studies, identify L. terrestris virulence factors and effectors. Subsequently, plant-pathogen interactions will be further explored by modulating gene expression of L. terrestris virulence factors, PAMPS and effectors in order to discover how grasses (for example Poa annua) defend themselves against this pathogen. DNA constructs will be generated either in generic E.coli cloning vectors (for example pBluescript KS) for transformation into Labyrinthula by electroporation or biolistics, or alternatively in binary vectors such as the pCambia series for transformation into Labyrinthula using disarmed non-pathogenic Agrobacterium tumefaciens (EHA 105 for example). For examples of methods to transform straminopiles, see Sakaguchi et al., Applied and Environmental Biology (2012), 78, 3193-3202; Cheng et al., Microbial Research (2012), 167, 179-186.

Recipient or parental organism

Initial recipient organisms are Escherichia coli K12 XL 1 blue (Stratagene), and Agrobacterium tumefaciens EHA 105. The final recipient organism will be the protist Labyrinthula terrestris and very closely related UK environmental strains and isolates. These environmental strains may possibly be new species but are not so far sufficiently characterised to establish this; examples of this are the groups Laby 10 and Laby 31, described by Chitrampalan et al., (European Journal of Plant Pathology, 001 10.1 007/s1 0658-015-0701-0).

Host/vector system

The host system will be Escherichia coli bearing pBluescript derived plasmids, and Agrobacterium tumefaciens bearing derivatives of the binary vector series pCambia.

Origin & function

Initially we will focus on commonly used marker genes; uidA encoding Beta glucuronidase, derived from E. coli, or the GFP gene encoding green florescent protein from Aequoria victoria, in order to monitor the growth and development of L. terrestris when invading plant tissue. The UidA and GFP genes will be expressed using the CaMV 35S promoter from the Cauliflower Mosaic Virus, or alternatively from the L. terrestris native ubiquitin promoter. Subsequently we will clone and analyse L. terrestris genes encoding PAMPS, virulence factors and effectors (as identified by biochemical and physiological studies on L. terrestris UK environmental accessions with different levels of virulence) by expressing these in L. terrestris and monitoring the plant-pathogen interaction in order to elucidate the role of specific L. terrestris genes in plant defense against L. terrestris.

Evaluation of foreseeable effects

The most potentially hazardous GMM to be produced may be an L. terrestris strain that is normally only weakly pathogenic towards grasses such as Poa annua bearing expressed genes for a pathogenicity factor from an aggressive donor strain of L. terrestris, which may convert the weak pathogen into a stronger pathogen, but no more virulent than the original donor strain of L. terrestris. Since these straminopile protists are not thought to have a high potential for gene transfer (they do not have plasmids, nor as far as known do they reproduce sexually, only clonally),
the risk for transfer to other organisms is not high. In addition, L. terrestris is not a pathogen of humans or animals, and will only infect certain monocotyledonous plants under specific conditions such as enhanced environmental salt concentrations.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

No non-microbial GM work is planned, however GMOs will be tested against (non-GM) plants such as the grass Poa annua. This will be done in contained facilities and all materials (including plants and soil) will be autoclaved prior to disposal.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Manipulations that might cause aerosols will undertaken in a safety cabinet. Solid waste, plants and soil and bacterial cultures on plates will be autoclaved at 121 degrees C for 20 minutes. Autoclaved waste will be disposed of together with other waste from the Institute of Life and Earth Sciences. Liquid waste and water from infected plants in bags will be treated with Chloros before disposal in an appropriate drain. This disinfectant is routinely used for treatment of potentially infected liquids in our laboratories.

TO DEFINE THE EFFECT OF ADENOVIRAL OR ADENO-ASSOCIATED VIRAL (AAV) GENE TRANSFER OF CANDIDATE GENES ON BLOOD PRESSURE AND ORGAN DAMAGE IN THE STROKE PRONE SPONTANEOUSLY HYPERTENSIVE RAT

**Date Project Ceased** 26/10/2007

**Class** Class 2

**Culture Volume Class 2** < 1 litre

**Consent Granted** Non-GMM

**Project notified under transitional arrangements** N

**Historical Significant Changes**

PROJECT TRANSFERRED TO GM 318 (26/10/07)

**Project Additional Information**
The aim of the project is to assess the ability of a number of biological active genes to reduce blood pressure, cardiac hypertrophy and other phenotypic changes associated with hypertension in the SHRSP animal model.

Recipient or parental organism

All adenovectors to be used in this study are E1-deleted first generation adenoviral vectors based on the pJM17 system (McGrory, WJ Bautista, DS and Graham, FL: A simple technique for the rescue of early region 1 mutations into infectious human adenovirus type 5. Virology 163: 614-617, 1988). In brief, adenoviruses are generated by recombination resulting in the deletion of the E1 region of the viral genome and replacement with the expression cassette. This renders the adenoviruses replication defective. However, with these first generation viruses there is still a small risk of recombination with the E1 region in 293 helper cells used to propagate the viruses. All stocks are therefore routinely tested for the presence of replication-competent adenovirus (RCA) and will be negative. All stocks will also be purified on caesium chloride gradients. E1-deleted adenoviruses cannot replicate unless the E1 function is complemented in trans. Therefore the disabled vector is considered a biologically agent unlikely to cause human disease and is assigned to hazard group 1 with containment level 1 as the minimum requirement. However, all the inserted genes are biologically active. None of the transgenes are proto-oncogenes. All transgenes will be under the control of the CMV promoter. There will be a minimal risk of harmful effect of these genes in organs/tissues. If the replication-defective adenovirus is inadvertently released into the general environment, immune cells will target any infected cells. It is generally accepted that the Ad will be inactivated almost immediately by the immune surveillance cells located in the peripheral system. The recombinant adenovirus will pose less of a threat once in the cell than most expression vectors as they will definitely not replicate or integrate into the host genome. Furthermore the natural topism of the adenoviral vectors are not altered from wild type adenoviruses in the viruses proposed for use. AAV vectors have received increasing attention for molecular interventions in vivo and for gene therapy applications due to their low level of immunogenicity in vivo and their ability to integrate into the genome, thus producing sustained expression of transgenes for prolonged periods of time. They also have the ability to infect both dividing and non-dividing cells. AAV vectors used in this study are serotype 2 and replication-defective through deletion of the rep and cap genes and insertion of the recombinant gene expression cassette within the AAV inverted terminal repeats (ITRs). The AAV vectors are generated by co-transfection of the AAV vector (carrying the expression cassette) and a helper plasmid carrying the helper functions necessary for AAV packaging in trans. The cells are then infected with a replication-defective herpes simplex virus (HSV) to provide helper function for AAV replication (in place of helper adenovirus). Upon a cytopathic effect in the cells, AAV and HSV particles are harvested. The HSV is removed completely by filter sterilisation to leave recombinant replication-defective AAV particles capable of expressing the transgene. This sytem is published (Zhang, X, de Alwesh, M, et al. High-tier rAAV production from replicating amplicons and gH-herpes vectors) and has been used for AAV preparation in Glasgow and elsewhere (Institute of Child Health, London). All stocks of AAV vectors will be generated at the Western Infirmary, University of Glasgow. AAV vectors are replication defective.

Host/vector system

The adenoviral vectors are generated by homologous recombination between pJM17 and shuttle vectors containing transgene expression cassette and flanking E1 sequences. Following homologous recombination in helper 293 cells (which express the helper E1 function in trans, replication-defective first generation adenoviruses are produced. This methodology has been used for many years for the development of recombinant adenoviruses. AAV vectors used in this study are serotype 2 and replication-defective through deletion of the rep and cap genes and insertion of the recombinant gene expression cassette within the AAV inverted terminal repeats (ITRs). The AAV vectors are generated by go-transfection of the AAV vector (carrying the expression cassette) and a helper plasmid carrying the helper functions necessary for AAV packaging in trans. The cells are then infected with a replication-defective herpes simplex virus (HSV) to provide helper function for AAV replication (in place of helper adenovirus). Upon a cytopathic effect in the cells, AAV and HSV particles are harvested. The HSV is removed completely by filter sterilisation to leave recombinant replication-defective AAV particles capable of expressing the transgene. This system is published (Zhang, X, de Alwesh, M, et al. High-tier rAAV production from replicating amplicons and gH-herpes vectors) and has been used for AAV preparation in Glasgow and elsewhere (Institute of Child Health, London). All stocks of AAV vectors will be generated at the Western Infirmary, University of Glasgow. AAV vectors are replication defective.
The adenoviral vector DNAs are standard and originated from the laboratory of Dr Frank Graham (McGrory, W J Bautista, DS and Graham FL: A simple technique for the rescue of early region I mutations into infectious human adenovirus type 5. Virology 163: 614-617, 1988). The cytomegalovirus immediate early promoter is a standard viral promoter used for gene expression studies in vivo to generate high-level gene expression in all cells transduced by the adenovirus. The AAV system is published (Zhang, X, de Alwesh, M., et al. High titer rAAV production from replicating amplicons and gH-herpes vectors) and has been used for AAV preparation in Glasgow and elsewhere (Institute of Child Health, London). All transgenes will be constructed from full length cDNAs obtained from other research institutes and verified in our own laboratory prior to subcloning into the relevant vectors.

**Origin & function**

There will be a minimal risk of harmful effect of these genes in organs/tissues. If the replication-defective adenovirus is inadvertently released into the general environment, immune cells will target any infected cells. It is generally accepted that the Ad will be inactivated almost immediately by the immune surveillance cells located in the peripheral system. The recombinant adenovirus will pose less of a threat once in the cell than most expression vectors as they will definitely not replicate or integrate into the host genome. AAV vectors are replication defective. There is some recombination between plasmids that may result in wild type like virus (not fully functional as they contain deletions). However, this is usually minimal (less than 0.01% of stocks). Furthermore, wild type AAV has no known pathogenicity and therefore no harmful consequences of generating even fully wildtype virus is anticipated. None of the sequences are likely to be harmful if expressed. If, by accident, they were introduced in humans via the recombinant vector, they are unlikely to be harmful since they are either reporter genes or a functional gene which would have no effect unless expressed at very high levels. Since we are only using small quantities of replication deficient vector (below 10e9 particles) accidental exposure to the vector is extremely unlikely to result in high levels of protein being produced. Consequence of environmental exposure - 'effectively zero'.

**Evaluation of foreseeable effects**

All measures as per HSE containment level 2 for both production of recombinant adenoviruses and AAV in the laboratory and animal experimentation.

Laboratory-based experiments: during the production of replication-defective adenoviruses, all solid waste (plastics etc.) are autoclaved prior to disposal. All liquid waste from tissue culture is treated with chlorine-based disinfectants for at least 24 hours prior to disposal. The use of sharps is avoided.

Animal experiments: All instruments used in the preparation of animals for GM work will be sterilised by autoclaving. Solutions exposed to the viable GMOs will be disinfected with chlorine-based disinfectant. All plastic ware will be autoclaved prior to disposal. Animals receiving the GMO will be housed in separate cages during the procedure-kill time period. All animal carcasses will be disposed of by incineration. Animal bedding will be autoclaved prior to disposal and cages disinfected prior to being re-used.

Purposes of the contained use

The aim of this project is to restrict the tropism of adenoviral and AAV vectors. Currently, both these vector types poorly transduced vascular cells in vitro and in vivo, but are highly permissive for transduction of non-vascular cells. We will use small targeting ligands (peptides) to develop tropism modified adenoviral and AAV vectors and test the ability of these modified viruses to provide cell selective gene transfer in vitro and in vivo. All adenoviral vectors will express reporter genes.

Recipient or parental organism
All adenovectors to be used in this study are E1-deleted first generation adenoviral vectors based on the AdEASY system (He, T-C., Zhou, S., de Costa, LT., Kinzler, KW, Vogelstein, B. A simplified system for generating recombinant adenoviruses. PNAS. 95:2509-2514, 1998). In brief, adenoviruses are generated by recombination resulting in the deletion of the E1 region of the viral genome and recombination with the expression cassette. Targeting ligands will be incorporated into fiber-deleted vectors as described by vonSeegern (Von Seegern DJ, Huang S, Fleck SK, Stevenson SC, Nemerow GR. Adenoviruses vector pseudotyping in fiber-expressing cell lines: Improved transduction of Epstein-Barr virus-transformed B cells. JOURNAL OF VIROLOGY 74; (1) 354-362 JAN 2000). E1 deletion renders the adenoviruses replication defective. However, with these first generation viruses there is still a small risk of recombination with the E1 region in 293 helper cells used to propagate the viruses. All stocks are therefore routinely tested for the presence of replication-competent adenovirus (RCA) and will be negative. All stocks will also be purified on cesium chloride gradients. E1-deleted adenoviruses cannot replicate unless the E1 function is complemented in trans. Therefore the disabled vector is considered a biological agent unlikely to cause human disease and is assigned to hazard group 1 with containment level 1 as the minimum requirement. There will be a minimal risk of harmful effect of these viruses in organs/tissues. If the replication-defective adenovirus is inadvertently released into the general environment, immune cells will target any infected cells. It is generally accepted that the Ad will be inactivated almost immediately by the immune surveillance cells located in the peripheral system. The recombinant adenovirus will pose less of a threat once in the cell than most expression vectors as they will definitely not replicate or integrate into the host genome. Furthermore, the natural tropism of the adenoviral vectors are not altered from wild type adenoviruses in the viruses proposed for use.

AAV vectors have received increasing attention for molecular interventions in vivo and for gene therapy applications due to their low level of immunogenicity in vivo and their ability to integrate into the genome, thus producing sustained expression of transgenes for prolonged periods of time. They also have the ability to infect both dividing and non-dividing cells. AAV vectors used in this study are serotype 2 and replication-defective through deletion of the rep and cap genes and insertion by co-transfection of the AAV vector (carrying the expression cassette) and a helper plasmid carrying the helper functions necessary for AAV packaging in trans. The cells are then infected with a replication-defective herpes simplex virus (HSV) to provide helper function for AAV replication (in place of helper adenovirus). Upon a cytopathic effect in the cells, AAV and HSV particles are harvested. The HSV is removed completely by filter sterilisation to leave recombinant replication-defective AAV particles capable of expressing the transgene. This system is published (Zhang, X, de Alwesh, M., et al. High-titer rAAV production from replicating amplicons and gH-herpes vectors) and has been used for AAV preparation in Glasgow and elsewhere (Institute of Child Health, London). Targeted AAV vectors will be prepared using published methods are produce replication-defective AAV vector particles (Girod A, Ried M, Wobus C, Lahm H, Leike K, Kleinschmidt J, Deleage G, Hallek M. Genetic capsid modifications allow efficient re-targeting of aden-associated virus type 2. Nature Medicine. 1999;5:1052-1056). All stocks of AAV vectors will be generated at the Western Infirmary, University of Glasgow. AAV vectors are replication defective. There is some recombination between plasmids that may result in wild type like virus (not fully functional as they contain deletions). However, this is usually minimal (less than 0.01% of stocks). Furthermore, wild type AAV has no known pathogenicity and therefore no harmful consequences of generating even fully wildtype virus is anticipated. None of the sequences are likely to be harmful if expressed. If, by accident, they were introduced in humans via the recombinant vector, they are unlikely to be harmful since they are either reporter genes or a functional gene which would have no effect unless expressed at very high levels. Since we are only using small quantities of replication deficient vector (below 10e9 particles) accidental exposure to the vector is extremely unlikely to result in high levels of protein being produced.

In addition, we are restricting the tropism of AAV and Ad vectors not expanding it. There will be no foreseeable deleterious effect of enhanced gene transfer to endothelial cells.

**Host/vector system**

The adenoviral vectors are generated by recombination in vitro and shuttle vectors containing transgene expression cassette and flanking E1 sequences (He, T-C., Zhou, S., de Costa, LT., Kinzler, KW, Vogelstein, B. A simplified system for generating recombinant adenoviruses. PNAS. 95:2509-2514, 1998). Following transfection into helper 293 cells (which express the helper E1 function in trans, replication-defective first generation adenoviruses are produced. This methodology has been used for many years for the development of recombinant adenoviruses.

AAV vectors used in this study are serotype 2 and replication-defective through deletion of the rep and cap genes and insertion of the recombinant gene expression cassette within the AAV inverted terminal repeats (ITRs). The AAV vectors are generated by co-transfection of the AAV vector (carrying the expression cassette) and a helper plasmid carrying the helper functions necessary for AAV packaging in trans. The cells are then infected with a replication-defective herpes simplex virus (HSV) to provide helper function for AAV replication (in place of helper adenovirus). Upon a cytopathic effect in the cells, AAV and HSV particles are harvested. The HSV is removed completely by filter sterilisation to leave recombinant replication-defective AAV particles capable of expressing the transgene. This system is published (Zhang, X,
de Alwesh, M., et al. High-titer rAAV production from replicating amplicons and gH- herpes vectors) and has been used for AAV preparation in Glasgow and elsewhere (Institute of Child Health, London). All stocks of AAV vectors will be generated at the Western Infirmary University of Glasgow. AAV vectors are replication defective.

Origin & function

The adenoviral vector DNAs are standard and originated from the laboratory of Dr Bert Vogelstein (He, T-C., Zhou, S., de Costa, L.T., Kinzler, KW, Vovelstein, B. A simplified system for generating recombinant adenoviruses. PNAS. 95:2509-2514, 1998). The cytomegalovirus immediate early promoter is a standard viral promoter used for gene expression studies in vitro and in vivo to generate high-level gene expression in all cells transduced by the adenovirus.

The targeting ligands (small peptides) have been isolated by phage display technology for their ability to bind vascular endothelial cells in vitro and in vivo. These peptides are selected for incorporation into the Ad and AAV vectors for tropism modification of viral vectors.

Evaluation of foreseeable effects

There will be a minimal risk of harmful effect of these genes in organs/tissues. If the replication-defective adenovirus is inadvertently released into the general environment, immune cells will target any infected cells. It is generally accepted that the Ad will be inactivated almost immediately by the immune surveillance cells located in the peripheral system. The recombinant adenovirus will pose less of a threat once in the cell than most expression vectors as they will definitely not replicate or integrate into the host genome.

AAV vectors are replication defective. There is some recombination between plasmids that may result in wild type like virus (not fully functional as they contain deletions). However, this is usually minimal (less than 0.01 of stocks). Furthermore, wild type AAV has no known pathogenicity and therefore no harmful consequences of generating even fully wildtype virus is anticipated. None of the sequences are likely to be harmful if expressed. If, by accident, they were introduced in humans via the recombinant vector, they are unlikely to be harmful since they are either reporter genes or a functional gene which would have no effect unless expressed at very high levels. Since we are only using small quantities of replication deficient vector (below 10e9 particles) accidental exposure to the vector is extremely unlikely to result in high levels of protein being produced. In addition, we are restricting the tropism of AAV and Ad vectors not expanding it. There will be no foreseeable deleterious effect of enhanced gene transfer to endothelial cells.

Consequence of environmental exposure - 'effectively zero'.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

All measures as per HSE containment level 2 for both production of recombinant adenoviruses and AAV in the laboratory and animal experimentation.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Laboratory-based experiments: during the production of replication-defective adenoviruses, all solid waste (plastics etc.) are autoclaved prior to disposal. All liquid waste from tissue culture is treated with chlorine-based disinfectants for at least 24 hours prior to disposal. The use of sharps is avoided.

Animal experiments: All instruments used in the preparation of animals for GM work will be sterilised by autoclaving. Solutions exposed to the viable GMOs will be disinfected with chlorine-based disinfectant. All plastic ware will be autoclaved prior to disposal. Animals receiving the GMO will be housed in separate cages during the procedure-kill time period. All animal carcasses will be disposed of by incineration. Animal bedding will be autoclaved prior to disposal and cages disinfected prior to being re-used.
Passed with amendments by local GMSC 1.2.2001

Historical Significant Changes

PROJECT TRANSFERRED TO GM 318 (26/10/07)
Project Additional Information

Purposes of the contained use

The aim of this project is to restrict the tropism of adenoviral and AAV vectors. Currently, both these vector types poorly transduced vascular cells in vitro and vivo, but are highly permissive for transduction of non-vascular cells. We will use small targeting ligands (peptides) to develop tropism modified adenoviral and AAV vectors and test the ability of these modified viruses to provide cell selective gene transfer in vitro and in vivo. All adenoviral vectors will express reporter genes.

Recipient or parental organism

All adenovectors to be used in this study are E1-deleted first generation adenoviral vectors based on the AdEASY system (He, T-C., Zhou, S., de Costa, T., Kinzler, KW, Vogelstein, B.A. simplified system for generating recombinant adenoviruses. PNAS. 95:2509-2514, 1998). In brief, adenoviruses are generated by recombination resulting in the deletion of the E1 region of the viral genome and replacement with the expression cassette. Targeting ligands will be incorporated into fiber-deleted vectors as described by von Seggern (von Seggern DJ, Huang S, Fleck SK, Stevenson SC, Nemereow GR. Adenovirus vector pseudotyping in fiber-expressing cell lines: Improved transduction of Epstein-Barr virus-transformed B cells. JOURNAL OF VIROLOGY 74: (1) 354-362 JAN 2000). E1 deletion renders the adenoviruses replication defective. However, with these first generation viruses there is still a small risk of recombination with the E1 region in 293 helper cells used to propagate the viruses. All stocks are therefore routinely tested for the presence of replication-competent adenovirus (RCA) and will be negative. All stocks will also purified on caesium chloride gradients. E1-deleted adenoviruses cannot replicate unless the E1 function is complemented in trans. Therefore the disabled vector is considered a biological agent unlikely to cause human disease and is assigned to hazard group 1 with containment level 1 as the minimum requirement. There will be a minimal risk of harmful effect of these genes in organs/tissues. If the replication-defective adenovirus is inadvertently released into the general environment, immune cells will target any infected cells. It is generally accepted that the Ad will be inactivated almost immediately by the immune surveillance cells located in the peripheral system. The recombinant adenovirus will pose less of a threat once in the cell than most expression vectors as they will definitely not replicate or integrate into the host genome. Furthermore, the natural tropism of the adenoviral vectors are not altered from wild type adenoviruses in the viruses proposed for use. AAV vectors have received increasing attention for molecular interventions in vivo and for gene therapy applications due to their low level of immunogenicity in vivo and their ability to integrate into the genome, thus producing sustained expression of transgenes for prolonged periods of time. They also have the ability to infect both dividing and non-dividing cells. AAV vectors used in this study are serotype 2 and replication-defective through deletion of the rep and cap genes and insertion of the recombinant gene expression cassette within the AAV inverted terminal repeats (ITRs). The AAV vectors are generated by co-transfection of the AAV vector (carrying the expression cassette) and a helper plasmid carrying the helper functions necessary for AAV packaging in trans. The cells are then infected with a replication-defective simplex virus (HSV) to provide helper function for AAV replication (in place of helper adenovirus). Upon a cytopathic effect in the cells, AAV and HSV particles are harvested. The HSV is removed completely by filter sterilisation to leave recombinant replication-defective AAV particles capable of expressing the transgene. This system is published (Zhang, X, de Alwesh, M., et al. High-titer rAAV production from replicating amplicons and gH-herpes vectors) and has been used for AAV preparation in Glasgow and elsewhere (Institute of Child Health, London). Targeted AAV vectors will be prepared using published methods are produce replication-defective AAV vector particles (Girod A, Ried M, Wobus C, Lahm H, Leike K, Kleinschmidt J, Deleage G. Hallek M. Genetic capsid modifications allow efficient re-targeting of adeno-associated virus type 2. Nature Medicine, 1999:5 1052-1056). All stocks of AAV vectors will be generated at the Western Infirmary, University of Glasgow. AAV vectors are replication defective. There is some recombination between plasmids that may result in wild type like virus (not fully functional as they contain deletions). However, this is usually minimal (less than 0.01% of stocks). Furthermore, wild type AAV has no known pathogenicity and therefore no harmful consequences of generating even fully wildtype virus is anticipated. None of the sequences are likely to be harmful if expressed. If, by accident, they were introduced in humans via the recombinant vector, they are unlikely to be harmful since they are either reporter genes or a functional gene which would have no effect unless expressed at very high levels. Since we are only using small quantities of replication deficient vector (below 10⁶⁹ particles) accidental exposure to the vector is extremely unlikely to result in high levels of protein being produced. In addition, we are restricting the tropism of AAV and Ad vectors not expanding it. There will be no foreseeable deleterious effect of enhanced gene transfer to endothelial cells.

Host/vector system

The adenoviral vectors are generated by recombination in vitro and shuttle vectors containing transgene expression cassette and flanking E1 sequences (He, T-C., Zious, S., de Costa, LT., Kinzler KW Vogelstein, B. A simplified system for generating recombinant adenoviruses PNAS. 95:2509-2514, 1998). Following transfection into helper 293 cells (which express the helper E1 function in trans, replication-defective first generation adenoviruses are produced. This methodology has been used for many years
for the development of recombinant adenoviruses. AAV vectors used in this study are serotype 2 and replication-defective through deletion of the rep and cap genes and insertion of the recombinant gene expression cassette within the AAV inverted terminal repeats (ITRs). The AAV vectors are generated by co-transfection of the AAV vector (carrying the expression cassette) and a helper plasmid carrying the helper function necessary for AAV packaging in trans. The cells are then infected with a replication-defective herpes simplex virus (HSV) to provide helper function for AAV replication (in place of helper adenovirus). Upon a cytopathic effect in the cells, AAV and HSV particles are harvested. The HSV is removed completely by filter sterilisation to leave recombinant replication-defective AAV particles capable of expressing the transgene. This system is published (Zhang, X, de Alwesh, M., et al. High-titer rAAV production from replicating amplicons and gH-herpes vectors) and has been used for AAV preparation in Glasgow and elsewhere (Institute of Child Health, London). All stocks of AAV vectors will be generated at the Western Infirmary, University of Glasgow, AAV vectors are replication defective.

Origin & function

The adenoviral vector DNAs are standard and originated from the laboratory of Dr Bert Vogelstein (He, T-C, Zhou, S., de Costa LT., Kinzler, KW, Vogelstein, BA simplified system for generating recombinant adenoviruses. PNAS. 95:2509-2514, 1998). The cytomegalovirus immediate early promoter is a standard viral promoter used for gene expression studies in vitro and in vivo to generate high level gene expression in all cells transduced by the adenovirus. The AAV system is published (Zhang, X, de Alwesh, M., et al. High-titer rAAV production from replicating amplicons and gH-herpes vectors; Girod A, Ried M, Wobus C, Lahm H, Leike K, Kleinenschmidt, Deleage G, Hallek M. Genetic capsid modifications allow efficient re-targeting and of adeno-associated virus type 2. Nature Medicine. 1999;5: 1052-1056) and has been used for AAV preparation in Glasgow and elsewhere (Institute of Child Health, London). The targeting ligands (small peptides) have been isolated by phage display technology for their ability to bind vascular endothelial cells in vitro and in vivo. These peptides are selected for incorporation into the Ad and AAV vectors for tropism modification of viral vectors.

Evaluation of foreseeable effects

There will be a minimal risk of harmful effect of these genes in organs/tissues. If the replication-defective adenovirus is inadvertently released into the general environment, immune cells will target any infected cells. It is generally accepted that the Ad will be inactivated almost immediately by the immune surveillance cells located in the peripheral system. The recombinant adenovirus will pose less of a threat once in the cell than most expression vectors as they will definitely not replicate or integrate into the host genome. AAV vectors are replication defective. There is some recombination between plasmids that may result in wild type like virus (not fully functional as they contain deletions). However, this is usually minimal (less than 0.01% of stocks). Furthermore, wild type AAV has no known pathogenicity and therefore no harmful consequences of generating even fully wildtype virus is anticipated. None of the sequences are likely to be harmful if expressed. If, by accident, they were introduced in humans via the recombinant vector, they are unlikely to be harmful since they are either reporter genes or a functional gene which would have no effect unless expressed at very high levels. Since we are only using small quantities of replication deficient factor (below 10e9 particles) accidental exposure to the vector is extremely unlikely to result in high levels of protein being produced. In addition, we are restricting the tropism of AAV and Ad vectors not expanding it. There will be no foreseeable deleterious effect of enhanced gene transfer to endothelial cells. Consequence of environmental exposure - 'effectively zero'.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

All measures as per HSE containment level 2 for both production of recombinant adenoviruses and AAV in the laboratory and animal experimentation.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Laboratory-based experiments: during the production of replication-defective adenoviruses, all solid waste (plastics etc) are autoclaved prior to disposal. All liquid waste from tissue culture is treated with chlorine-based disinfectants for at least 24 hours prior to disposal. The use of sharps is avoided.

Animal experiments: All instruments used in the preparation of animals for GM work will be sterilised by autoclaving. Solutions exposed to the viable GMOs will be disinfected with chlorine-based disinfectant. All plastic ware will be autoclaved prior to disposal. Animals receiving the GMO will be housed in separate cages during the procedure-kill time period. All animal carcasses will be disposed of by incineration. Animal bedding will be autoclaved prior to disposal and cages disinfected prior to being re-used.
Passed with amendments by local GMSC 1.2.2001.

The maximum volume of material that could be released at any one time is less than 10 litres. Solid waste is inactivated by on-site incineration using temperatures in excess of 1000 degrees centigrade. The progress of the material through the incinerator is automatically monitored until the 'slag' is collected for removal. Liquid waste is inactivated by autoclaving through a cycle that kills all microorganisms. Again, this is electrically monitored to ensure the procedure has taken place correctly.

## Purposes of the contained use

Terlings Park is a basic research site for Merck Sharp & Dohme specialising in neuroscience. Lentivirus will be used to transduce cells in vitro to identify those cells, to potentially knock-down specific gene expression, to express reporter genes or to express proteins thought to play a role in neurological diseases.

## Recipient or parental organism

293FT cells (Invitrogen) will be used to propagate virus (hazard group 2 cell line)

## Origin & function

Fluorescent reporter genes such as GFPO or DSred (Invitrogen)

Tetracyclin-regulated suppressor protein (tet- off or Tet-on) (Clontech)

Ecdysone induction system (Clontech)

Any gene whose expression is to be decreased by the use of DNAs encoding small hairpin RNA (shRNA) structures from the lentiviruses (obtained from Human or mouse whole genome clone collections as part of a global Merck & Co. effort on RNAi methodology).

Reporter genes such as beta lactamase or aequorin with the promiscuous G protein, Galpha 15 (Aurora Biosciences and NIH).

## Evaluation of foreseeable effects

Cells would only be hazardous to human health if they gain entry to the body and are histocompatible with the individual or the individual is immunosuppressed.

Virus is infectious at high titre and should be treated with caution. Routes of transmission are broken skin, exposure to mucus membranes and self inoculation. Viral particles are replication incompetent and therefore infection should not spread from infected area. If an individual is immunologically compromised (for example, taking immunosuppressant drugs) then their risk of infection from lower titre virus is increased. If individuals who are already infected with a wild type lentivirus such as HIV are infected there is an increased risk of a recombination event resulting in the HIV expressing the recombinant gene.

Genes and their products

Reporter genes such as beta lactamase or GFP would not have a detrimental affect on human health and, as stated above, would be confined to the local area of infection. The effect of other genes studies is unknown and, for the majority of cases, is likely to be minimal. However the risk of an adverse effect occurring, for example cell proliferation, is still possible.
No foreseeable environmental harm (see attached Risk Assessment).

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Control measures:
Only scientists with at least 6 months experience of working with Hazard group 1 biological agents and who have had specific training are allowed to work in the virus culture facility.
Laboratory is designed and operates to Containment Level 2 standards.
PPE: Double gloves (outer gloved changed regularly); disposable, one use, lab coats and safety glasses.
Any cuts or grazes are covered by a waterproof dressing prior to entry into the laboratory.
All solid waste is disinfected prior to placing in waterproof, waste containers (‘sharps bins’) which are wiped with disinfectant before removal from the lab for transport to the incinerator.
Any item that cannot be incinerated (equipment that has a high metal content) will be disinfected by either fumigation (Hydrogen peroxide) or liquid disinfectant.
All liquid waste is disinfected prior to disposal down the laboratory sink.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

- Liquid disinfectant, Trigene (Medichem International Ltd), used for surfaces and liquid waste
- On-site clinical incinerator (as governed by The Environment Agency) used for solid waste. Hydrogen Peroxide fumigation (Validated and performed by Bioquell) for Biological safety cabinets prior to annual K1 test or repair.

**Purposes of the contained use**

This project focuses on understanding the relationship between shape, form and the biochemistry of parasite cells and their pathogenicity ie how they cause disease. We work with the parasites (Trypanosoma brucei) that cause African Sleeping Sickness in humans and the disease Nagana in domestic cattle; and Leishmania species, the causative agents of Leishmaniasis. There is no effective vaccines against these diseases and only a meagre armoury of toxic drugs.

Genes encoding proteins that are important in controlling cell shape and motility will be modified, expressed or manipulated in cultured forms of these parasites. We anticipate that a greater understanding of the basic molecular and cellular biology of these parasites may afford new opportunities for vaccine and/or drug development. We are also interested in using these flagellated protozoan cells as model organisms to study the assembly of the eukaryotic flagellum.

In order to carry out this work we need to:

1. Grow Leishmania species and T. brucei in liquid culture media for extraction of nucleic acids and proteins.
2. Generate genetically modified Leishmania and T. brucei to study gene function.

**Recipient or parental organism**

The species of trypanosome we use in the laboratory, Trypanosoma brucei brucei, is not pathogenic to man but causes the disease Nagana in domestic cattle.

Leishmania major causes Old World cutaneous leishmaniasis whilst Leishmania mexicana causes New World cutaneous leishmaniasis in humans.

These parasites do not produce spores. They are rapidly killed outside the culture vessel by dessication, osmotic shock, washing with water, detergents and cannot penetrate unbroken skin. Tsetse flies are the vectors for trypanosomes and sand-flies the vector for Leishmania spp. We do not maintain insectories with either vector and they are not endemic in the UK. Thus these parasites are effectively deficient in mobilisation capacity.

The parasites can potentially cause disease in UK animals. However this would have to be by direct inoculation into the host animal with no likelihood of infection via feed, contaminated surfaces or by inhalation. Given that these protozoan parasites are spread by vectors not endemic in the UK and that they are rapidly killed outside of culture vessels the overall risk is effectively zero.
The main hazard to human health is by direct inoculation of the laboratory worker. We control this by establishing a set of Good Working Practices and Procedures.

### Host/vector system

**TRYPANOSOMA BRUCEI BRUCEI STRAINS**

Use is mainly made of strains that have been engineered to express T7 RNA polymerase and tet repressor to facilitate inducible expression of transfected genes. Engineered genes are effectively silent in the absence of inducer.

**TRYPANOSOMA VECTORS**

Trypanosome vectors are based on a series of vectors constructed to provide prokaryotic tetracycline mediated inducible expression of either epitope tagged proteins or double stranded RNA molecules capable of down regulating expression of genes of interest via an RNAi mediated mechanism.

**LEISHMANIA STRAINS**

- Leishmania major
- Leishmania mexicana

**LEISHMANIA VECTORS**

Leishmania vectors are based on a series of plasmid based or integrative vectors that enable the deletion of genes by homologous recombination of expression of epitope tagged proteins.

### Origin & function

Recombinant DNA inserts will be derived by PCR amplification of T. brucei and Leishmania spp. genomic DNA.

The main types of inserts to be used are:

i) Cytoskeletal and other housekeeping genes involved in the construction of the cytoskeleton, mitotic spindle and flagellum of the protozoa. Usually these genes will be tagged to allow visualisation of the expressed proteins.

ii) Portions of genes arranged to produce double stranded RNA copies that will down regulate endogenous gene expression by means of RNA interference.

iii) Gene flanking sequences to engineer gene knockouts.

### Evaluation of foreseeable effects

The final GMOs are likely to be generally reduced in fitness compared to wild type organisms.

Therefore the risks of the genetically modified organism is likely to be equivalent to, or usually lower than that of the ‘wild-type’ strain.

The rationale for these conclusions are as follows:

- Sequences transferred to the GMO are parasite gene sequences.

- The mutants are genetically stable and the potential for transfer of genetic material between these and other organisms is negligible.

- Antibiotic markers will be used that are not related to the primary therapeutic agents for these parasites. The reporter genes and counter-selectable markers will be either neutral or lead to a reduction in fitness.
We consider that none of these manipulations will effect the vector or host range, enhance or broaden tissue tropism, or decrease susceptibility to host defence mechanisms.

The genes that are of interest to us are housekeeping genes and are not known virulence genes. Moreover, these parasites do not produce toxic products that are linked to human or animal pathogenicity.

It is highly unlikely that transfer of even cryptic genes could result in enhanced virulence or endow extended host range on any recipient species. The complex and necessary life cycle changes also mitigate against such a likelihood for any of these organisms.

There is no intention to release genetically modified organisms into the environment as part of this programme of work.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste is treated with disinfectant (2% Trigene) or autoclaved for complete sterilisation prior to disposal according to procedures established by the University for the safe disposal of clinical waste. The autoclaves are routinely checked to verify the effectiveness of autoclaving.

Lancaster University has established procedures for the disposal of clinical waste. Briefly these are as follows:

Microbiological waste and viable genetically modified organisms are categorized as Group C waste. Such material must be autoclaved prior to disposal. After autoclaving waste material is placed into a yellow clinical waste sack (conforming to BS 6642:1985) labelled with the Departmental name, lab number and date of disposal and placed in the locked storage container situated outside the Biological Sciences building. Removal and disposal of waste from this storage facility is currently contracted to the Lancashire Ambulance Service who dispose of waste via the incinerator facility at the Royal Preston Hospital, Lancashire.

Given the class 2 containment and control measures it is unlikely that the GMMs will reach the environment and cause harm to humans or animals outside the laboratory.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
The committee met to consider the risk assessment submitted by Dr McKean entitled "Molecular cell biology of parasitic protozoa II", on April 25, 2003.

A number of minor criticisms were made pertaining to the level of detail and justification made for some statements within the assessment, and these were conveyed to Dr McKean who subsequently acted to improve the assessment to our satisfaction.

The committee noted that the assignment of the work to Class 2 was based solely on the classification of the host organisms at ACDP category 2, rather than on any specific risk posed by the proposed genetic modification activity. We were satisfied that the proposed genetic manipulation would not create any additional risk associated with these organisms and that the containment procedures in place to satisfy their ACDP category 2 status were sufficient for assignment to GM class 2.

Purposes of the contained use

1. Transgene expressing lentogenic Newcastle disease virus:

Newcastle disease virus (NDV) is an avian paramyxovirus serotype 1 (APMV-1) belonging to the Avulavirus genus within the Paramyxoviridae family that causes an acute, highly contagious disease responsible for severe economic losses in domestic poultry, especially chickens. In this project, we will use the NDV vaccine strain LaSota to investigate virus-host interactions in avian cell lines.

The molecular biology of NDV has extensively been studied and reverse genetics tools to examine the gene functions have been developed. In this proposal, we aim to make use of the reverse genetics tools to express following genes individually in the backbone of LaSota strains of Newcastle disease virus (NDV) pre-expressing green fluorescence protein (GFP) gene:

- S gene of infectious bronchitis virus
- VP2 protein of infectious bursal disease virus
- HA gene of low pathogenic avian influenza virus
- gD and gB genes of infectious laryngeotracheitis virus

Purpose and Predicted Outcome: We aim to understand the potential of NDV to effectively express these genes and to investigate if recombinant NDV expressing these genes can be used as vaccine candidates in chicken. Based on previous studies (Shirvani, et al., 2018; Huang et al., 2004, Hu et al., 2017, Kanabagatt et al., 2014), it is predicted that such expression of genes will not enhance the pathogenicity of pre-attenuated LaSota-NDV strain and these genes may attenuate it further.

2. The generation of reporter gene expressing low pathogenic influenza viruses.

Influenza viruses are member of orthomyxoviruses and carry broad host spectrum, which span from multiple animal species (chicken, pigs) to humans. We will use a laboratory adapted vaccine strain of Influenza A virus PR8/33/H1N1, which is a low pathogenicity virus with known genetic characteristics and an intravenous pathogenicity index = 0.0. In this project, we will construct reporter viruses expressing green fluorescent protein (maxGFP), red fluorescent protein (turboRFP) and Gaussia Luciferase. No modification in the virus sequence will be made or no alternation in the cleavage site of the HA gene is sought that change virus tropism and virulence.

Purpose and Predicted Outcome: The purpose of these reporter viruses is to evaluate the effects of innate immune genes on virus replication kinetics. Experimentally, cell lines including chicken embryo fibroblast (DF-1), Madin-Darby Canine Kidney (MDCK) and chicken kidney cells (CKC) will be transfected with expression plasmids to express innate immune genes. These cells will then be infected with the reporter influenza viruses. The replication of these viruses will be monitored either by conventional plaque assay, flow cytometry or by high throughout image screening of fixed cells.

Recipient or parental organism

GMOs of following viruses are intended in this application. These viruses are either vaccine strains or low pathogenic.

Newcastle disease virus

Over 250 species of birds have been reported to be susceptible to natural or experimental infection with NDV (Capua and Alexander, 2004). ND is normally absent in poultry in the UK, but 20 or more cases of "pigeon paramyxovirus" have been reported every year since 1983. NDV does not appear to naturally infect cattle, and vaccine strains of NDV are highly attenuated in experimentally infected calves (Subbiah, M., et al., 2008). Although, NDV has been isolated from pigs with an influenza-like illness (Ding, Z., et al., 2010), experimental inoculation of piglets with a strain of NDV did not produce any clinical signs of disease (Malik et al., 1969). The NDV has a tendency to replicate in the cancerous tissue of several animals including humans. The disease is not lethal for human and only cause mild and self-limiting flu-like illness and conjunctivitis.

Low Pathogenicity Influenza Viruses
Influenza A viruses (IAV) are zoonotic pathogens with a natural reservoir almost entirely in birds but can be transmitted to human and other animals. ACDP proposes that: (a) highly pathogenic e.g. H5N1 and H7N7 and uncharacterised avian influenza viruses and (b) animal viruses closely related to novel viruses capable of infecting humans should be handled at Containment Level 3 (CL3). Work with these viruses is not intended at Lancaster in this application. Only GFP/RFP/Luciferase expressing low pathogenicity viruses such as strain PR8/33/H1N1 will be used which are further attenuated due to insertion of the reporter genes.

Foreseeable effects:
The reporter genes (GFP/RFP/Luciferase) are non-viral components and are not reported to increase the pathogenicity of viruses. Expression of viral genes in NDV have attenuated LaSota strains which is already a selected attenuated strain of NDV. Since wild type NDV can infect all birds, expression of additional genes from any other avian viruses will not enhance host-spectrum. The generated reassortment viruses will remain low pathogenicity viruses and the proposed gene modifications would not be expected to alter the virulence and therefore the risk is still at CL2. The reporter genes are not reported to be carcinogenic or toxic when exogenously expressed and no harmful consequences are envisaged from their expression in cell cultures.

Transfected cells producing the recombinant influenza and NDV must be maintained in tissue culture and cannot replicate outside the laboratory. NDV and low pathogenicity AIV can cause mild infections in human if accidentally exposed to the virus. GM viruses are cultured only inside CL3 facilities within routine handling within Class II Microbiological Safety Cabinets. The main hazard to human health is by direct inoculation of the laboratory worker. We control this by establishing a set of Good Working Practices and Procedures, and avoiding the use of sharps. As all culture media and cells will be decontaminated in 1% Virkon or Distel for overnight before disposal, no harm to human health or the environment is envisaged.

The GM and parental viruses can potentially cause disease in UK animals; however, this would have to be by direct inoculation into the host animal with no likelihood of infection via feed, contaminated surfaces or aerosol. This programme of work does not include deliberate infection of animal species with these viruses. Although experimentally NDV would be able to infect other animal species such as ruminants, rodents or birds, the likelihood of this occurring accidentally is very small due to laboratory confinements. In the event that this did occur, the recombinant virus would be unable to propagate (Subbiah, M., et al., 2008). Also, since infected ruminants and pigs are unlikely to excrete virus, the risk that the virus will disseminate or cause disease is low. Accidental release of virus could result in infection of birds, including poultry. However, the GMO is produced from a licensed vaccine strain of NDV and low pathogenicity influenza virus, which are non-pathogenic in poultry and expression of a marker gene is likely to attenuate the virus further. The bird population, particularly pigeons, are exposed to the avian paramyxovirus APMV-1 (a virus similar to NDV) and are likely to be immune to NDV.

1.) Transgene expression in Newcastle Disease Virus (NDV) LaSota Strain
The NDV vaccine strain LaSota will be used to investigate the expression of these genes (Fig. 1) and their subsequent roles in virus biology. The recombinant viruses will then be used to infect the avian or duck cell lines. Two proteins (HN and F) are well characterized and are major immunogenic proteins of NDV. Most of the neutralizing antibodies are derived against these proteins and no modification will be made in these proteins that determine the viral tropism. The pathogenicity of NDV is controlled by the sequence in cleavage site of the F protein, which remains the same (GRQGR - nonpathogenic) for all recombinant viruses proposed in this application. Since an individual protein of other viruses will be expressed as transgene, no recombination is expected. These genes have previously been cloned in the NDV backbone and no adverse effects have been reported and the NDV has either retained the infectivity or was further attenuated (Shirvani, et al., 2018; Huang et al., 2004, Hu et al., 2017, Kanabagatt et al., 2014). Using reverse genetics initially constructed by Ben Peeters at Central Veterinary Institute, The Netherlands (Ben et al., 1999), rescue of the virus will be performed as described before (Ayllon et al., 2013). Modification includes expression of viral genes (Fig. 1) in the junction of M and P genes. Infectious viruses will be produced only in complementing cell lines that contain three supportive plasmids, pNP, pP, and pL, as a source of replication complex. Therefore, the virus can only be rescued in specific cell lines where all the required components are present.

Fig. 1: Schematic presentation of insertion of transgenes in the genome of LaSota NDV through restriction digestion of intergenic regions between P and M genes.
References:

2.) Reporter genes expression by low pathogenic influenza virus

Reporter genes (GFP, RFP and Gaussia Luciferase) will be cloned into the segment 8 (NS gene) of the low pathogenicity AIV strain PR8/33/H1N1. The reporter NS segment will be generated by mutating the splice acceptor site in the NS1 protein gene to prevent splicing (Fig. 2). The reporter protein will be fused to the C-terminus of the NS1 protein coding region. A self-cleaving protease (2A) from porcine teschovirus-1 will be inserted in the C-terminus of the reporter genes. This 2A self-cleavage will allow the release of NS2 protein (also known as NEP, nuclear export protein) during influenza virus infections. The reporter genes named as maxGFP, turboRFP and Gaussia Luciferase have been used to generate three reporter plasmids. These reporter genes will only be incorporated in the NS gene segment as illustrated in the figure 2. The generated reassortment viruses will remain low pathogenicity viruses and the proposed gene modifications will not alter the virulence and therefore the risk is still at CL2 (Breen M, et al., 2016, and Perez et al., 2013; Eckert et al, 2014).

Using reverse genetics a recombinant influenza virus will be rescued from DNA copies of the negative sense RNA influenza genome. Each of the 12 plasmids (8 expressing viral genomes and 4 expressing viral polymerase) will be transfected in 293T cells (human embryonic kidney cells) and then the co-culture with permissive MDCK (Martin Darby Canine Kidney) cells (as shown by Neumann et al., 1999). The AIV level 2 influenza viruses will be rescued in CL3 laboratory. All tube labels of plasmids for the rescue of new viruses must checked by a second member of the lab before use in the virus rescue.

Fig. 2: Schematic representation of reporter gene insertion in the NS gene segment of low pathogenicity IAV

- Gabriele Neumann, Tokiko Watanabe, Hiroshi Ito, Shinji Watanabe, Hideo Goto, Peng Gao, Mark Hughes, Daniel R. Perez, Ruben Donis, Erich Hoffmann, Gerd Hobom, and Yoshiihoro Kawoaka Generation of influenza A viruses entirely from cloned cDNAs. PNAS August 3, 1999 96 (16) 9345-9350; https://doi.org/10.1073/pnas.96.16.9345
DNA inserts will be derived by PCR amplification of reporter genes (GFP/RFP/Luciferase) or viral genes (VP2, S, gD, gB, HA) of from cDNA (as described in Purpose of the contained use). The reporter genes will be amplified from plasmid DNA whereas the cDNA from viral RNA/DNA will be prepared from non-infectious extracted genetic material of the virus or by a synthetic approach. The reporter genes will allow visualization and detection of viruses. The viral genes, to be studied in this application, are surface proteins in their respective viruses. The primary function of these proteins is immunogenicity in susceptible hosts and most of the virus neutralization antibodies are raised against these proteins.

**Origin & function**

The final GMOs are likely to be of comparable or reduced fitness compared to wild type organisms. Therefore, the risk posed by the GMO is likely to be equivalent to, or usually lower than that of the ‘wild-type’ strain.

The rationale for these conclusions are as follows:

- The sequences transferred to the GMO are reporter gene sequences or genes from other viruses that will not increase virulence.
- The mutants are genetically stable and the potential for transfer of genetic material between these and other organisms is negligible.
- The reporter genes markers will be either neutral or lead to a reduction in fitness.
- We consider that none of these manipulations will affect the host range, enhance or broaden tissue tropism, or decrease susceptibility to host defence mechanisms.
- The genes that are of interest to us are not known virulence genes. Moreover, these GMOs will not produce toxic products that are linked to human or animal pathogenicity.
- It is highly unlikely that transfer of viral genes could result in enhanced virulence or endow extended host range on any recipient species.
- There is no intention to release genetically modified organisms into the environment as part of this programme of work or to use them in live animals.

**Evaluation of foreseeable effects**

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**All waste will be chemically treated (1% Distel or 1% Virkon for 16h), autoclaved for complete sterilisation prior to sterilization (triple lock system) according to procedures established by the University for the safe disposal of clinical waste. The autoclaves are routinely checked to verify the effectiveness of autoclaving.**

Lancaster University has established procedures for the disposal of clinical waste. Briefly these are as follows:

Microbiological waste and viable genetically modified organisms must be autoclaved prior to disposal. After autoclaving waste material is placed into a yellow clinical waste sack (conforming to BS 6642:1985) labeled with the Departmental name, lab number and date of disposal and placed in a locked storage container. Removal and disposal of waste from this storage facility for incineration off-site is via a licensed contractor.

Given the Class 3 containment level and control measures in place it is very unlikely that the GMMs will reach the environment and cause harm to humans or animals outside the laboratory.
The proposed work is limited to low pathogenicity viral strains and will introduce genetic material that is unlikely to increase the virus pathogenicity or host range. The activities are to be conducted in a dedicated room within an ACDP Containment level 3 compliant lab, which exceeds the required level 2 containment and will minimise the risk of accidental release.

Maximum culture volume that can be released is less than one litre.

Autoclaving: Autoclaves are calibrated annually. Brownes tubes/indicator tape used for routine monitoring. Waste may also be incinerated if the risk assessment requires it. Disinfectants: Commercial disinfectants such as Virkon or Chloros are used at concentrations recommended by manufacturer. Working stocks replenished on a routine basis. Animal waste ultimately being destroyed by incineration. Incineration. Sealed containers are taken for incineration. Waste may have been autoclaved or treated with disinfectant beforehand. Records are kept of material sent for incineration.

For activities involving GMMs, describe the waste management measures which will apply to the activity

The maximum amount of fermentation culture fluid produced at any time is 100 litres. Waste is deactivated by two methods:

* adding amounts of a commercial disinfectant powder (Virkon) to give the concentration recommended by the manufacturer;
* steam sterilising (121°C, 1 bar) the fermenter contents in situ for 20 or 45 minutes as required.

Monitoring the deactivation method is carried out either by weighing and recording details of the amount of disinfectant powder added or by recording the time and temperature of the steam sterilisation process with a calibrated thermocouple.

When necessary, the deactivation process is validated using standard microbiological techniques and spreading a known volume of deactivated culture fluid on rich nutrient agar and checking for no growth.

The maximum culture volume for any single activity involving genetically modified bacteria or yeast will be 2 litres. For insect or mammalian cell lines a maximum culture volume of 3 litres will be used for any one activity. Waste in flasks or beakers is inactivated by addition of Presept (sodium dichloroisocyanurate) tablets. 5g tablet per 550 ml, for a minimum of one hour. Alternatively waste is aspirated into flasks containing Trigene II disinfectant concentrate at 1:100 dilution. Use of Presept tablets and Trigene II disinfectant have been validated by the manufacturers and relevant literature has been obtained. Monitoring of deactivation methods. No routine monitoring of the deactivating methods is considered necessary by our GMCS as the methods used are in excess of the minimum recommended by the manufacturers and the micro-organisms are all disabled and cannot survive outside of the laboratory environment.

For activities involving GMMs, describe the waste management measures which will apply to the activity

02/03/2022
The maximum culture volume handled on the premises is 6000 litres. Under normal working practices, no live organisms are released to the environment and the fermentation system is designed for containment, including exit gas streams and in process sampling. Any waste is heat inactivated via a contaminated waste heat treatment vessel, prior to discharge into the drain; this includes steam condensate which has been in contact with the process equipment. This vessel has been validated as suitable for assuring the thermal destruction of E. coli, and the temperatures of the vessel contents and the exit stream are monitored. If the release of a large quantity of cold material should occur into this vessel, the exit valve will close until the temperature of the contents rise to the required temperature for release.

The maximum volume of live culture, which could theoretically be released at any one time, is 6000 litres. However the likelihood of this event is extremely low, given that for this to occur, the fermenter vessel would have to fail, and the safety devices on the waste heat treatment vessel would also have to fail, simultaneously.

**Project Ref**  407/01.1

Date Ackn’d: 16/05/2001

**CU2 Project Title**

IMMORTALISATION OF PRIMARY CELL CULTURES BY EXPRESSION OF TRANSFORMING GENES USING RETROVIRAL VECTOR MEDIATED GENE DELIVERY

Date Project Ceased

Class: Class 3

CultureVolClass2: 100 ml

Consent Granted: yes

Non-GMM

Project notified under transitional arrangements: N

Withdrawn: N

**Historical Significant Changes**

**Historical Date of Additional Info**

**Significant Change ID**

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

To generate immortal cell lines by causing them to express one or more transforming/immortalising genes. Gene delivery will be achieved using pan-tropic (amphotropic) retroviral vectors containing one or more transforming/immortalising genes under a strong constitutive promoter. A non-origin binding, ts mutant (U19-tsa58) of SV40 T-Ag
and the human telomerase (hTERT) gene will be used in the first instance, but other transforming genes may be used in future.

Primary equine or ovine bone marrow cells will be used in the first instance, but other cell types may be used in future (eg rat neuronal cell progenitors).

Initially, the retroviral vectors will be provided by a collaborator and thus will not be prepared on this site. However, future use may require the production of the vectors in our own cat 3 laboratory.

Future work may involve the transformation and immortalisation of non-dividing cell types, necessitating the use of lentiviral (eg HIV or EIAV) based vectors.

**Recipient or parental organism**

Primary cell cultures from a variety of animal sources (eg Human, mouse, rat, cow, sheep). Finite lifespans. Not knowingly infected with any organism likely to pose a human or environmental hazard. Human cells will only be used from screened sources.

**Host/vector system**

| Moloney murine leukaemia virus derived vectors packaged in Ecotropic, amphotrophic or pan-tropic (VSV-G) envelope glycoprotein. |
| HIV or EIAV based vectors (non-replication competent, with all viral structural genes deleted) packaged in VSV-G protein. |

**Origin & function**

| Vector backbone: Retroviral LTR, packaging signal, selective marker (Hgr or Neo genes), polyadenylation site. |
| Purpose: Propagation, delivery and expression of genes contained within the vector. |
| Origin: Commonly used MLV vectors pBABE and pZIP derivatives. HIV and EIAV derived vectors. |

| Inserted genes: SV40 T-Ag (U19-tsa58 mutant), human telomerase gene (hTERT). |
| Purpose: Transformation and immortalisation of recipient cell lines. |

**Evaluation of foreseeable effects**

Possible deleterious effects include:

1. the accidental infection of the operator with the transforming viral vector;
2. the propagation of replication competent mutant viruses generated by recombination in the producer cell lines or by recombination with endogenous/adventitious agents present in the recipient lines. These viruses could conceivably infect and transfer the transforming genes to the operator in the event of a containment breach. This could conceivably lead to oncogenesis.

Evaluation 1: Handling the viruses at containment level 3 makes the likelihood of such an event effectively zero. The consequences of the event are unlikely to be severe as multiple events are required to cause oncogenesis in an immunocompetent individual. The vectors are not replication competent and cannot therefore establish a productive infection capable of perpetuating itself.

Evaluation 2: The vectors are generated using a multicomponent packaging line and are therefore unlikely to recombine to produce replication competent mutant (RCM) viruses. Multiple recombination events would be required to generate a replication competent virus containing the transforming genes. Since only one round of infection is possible and the titres of vector are fairly low (10^{4}/ml) there is very limited opportunity for such an event to occur in the recipient cell lines. It is highly unlikely that RCMs would be capable of replicating in the non-murine cell lines. After the vectors have been used to infect the recipient cell lines, the culture supernatants will be tested (by serial passage and gene specific PCR) to confirm that no RCMs have been generated. Resultant cell lines will be handled at containment level 2 for the duration of the studies.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Standard operating procedures for disposal of category 2 and 3 waste have been provided previously.

Solid waste: (Category 1, 2 and 3)
Sterilised by autoclaving in unsealed biohazard bags contained within stainless steel containers with loose fitting lids. Final disposal: landfill.

Liquid waste: (Category 2 and 3)
Collected in 1 litre polypropylene bottles containing 1 ml of QC Clear/D(superscript TM) broad-spectrum disinfectant. Volume not to exceed 800 ml per bottle. Autoclaved under standard conditions. Final disposal: Down the drain.

Glassware:
Contaminated bottles, etc are sterilised by autoclaving. Glass pipettes are completely submerged for at least 1 hour with 1% Virkon before being machine washed. The Virkon solution is changed once a week, or twice a week during hot weather or periods of heavy usage. Activity indicator colour is checked daily. Workers are expressly forbidden to discard pipettes containing growth medium because it will inactivate the Virkon. The conditions are compliant with manufacturers recommendations. Only disposable plastic pipettes are used for cat 3 work.

Autoclaving:
All autoclaves are serviced annually by an authorised agent using an 'in load' thermocouple monitor. Browne TST Control Integrators for steam autoclaves (complete colour change indicates that the strip was exposed to steam at 121C for at least 15 mins or 134C for 5.3 mins. Order code 2342) are included with all runs of category 3 waste. Steam exposure indicators are included in the centre of all category 1 and 2 waste runs. All three autoclaves are operated using the standard conditions of 30 min @ 128C. 100% kill is anticipated under these conditions.

02/03/2022
- The committee agree with Containment already assigned for these vectors at University College London and consider that Laboratory Level 3 Containment is appropriate for the generation of cell lines proposed in the present proposal.
- The use of glassware and sharps must be avoided at all stages of these Level 3 procedures.
- When it is confirmed that the transfected cell lines do not produce replication-competent virus, these lines may then be handled at Laboratory Level 2 Containment.

**Project Additional Information**

**Purposes of the contained use**

The purpose of the contained use is to express normal and modified sequences of PrP protein from assorted species, from plasmid vectors in which the sequences are inserted, via both prokaryotic and eukaryotic expression systems.
### Recipient or parental organism

Eukaryotic transfection and expression will be carried out using standard laboratory cell lines or dissociated primary cell cultures.

Prokaryotic transformation and expression will be conducted using disabled laboratory strains of E. coli E.g. XL1-Blue, DH5-Alpha, BL21 (DE3).

### Host/vector system

The vectors used in these procedures will be E. coli compatible plasmids of non-mobilisable or mobilisation defective phenotype.

### Origin & function

The PrP sequences to be used will be derived from genomic material or existing plasmids, and subsequent modifications will be carried out using standard molecular biology techniques. The PrP DNA sequences will be expressed as protein that will be detected on cell surfaces, in cell preparations or harvested as a source of recombinant protein for laboratory use. The attached RAs indicate that the primary species of interest will be murine, ovine, cervid and bovine. However, this work may expand to include PrP genes from any other species.

The function of PrP is not fully understood. It is a copper binding protein with a super-oxide dismutase activity. It is expressed in cells of the CNS and PNSD and lymphoid system. PrP is associated with transmissible spongiform encephalopathies, and it is currently believed that a modified form of the protein may itself constitute the infectious agent involved.

### Evaluation of foreseeable effects

Recombinant PrP is not a toxic substance and the vectors to be used do not encode toxic material. This has been established by use of similar reagents in a number of other laboratories generating similar protein. Therefore, it is reasonable to assume that there will be no toxicity or hazardous effect associated with the use of these reagents. In addition, recombinant PrP has not been shown to be infectious (Hill, Antoniou and Collinge, 1999).

The eukaryotic cell lines to be used cannot survive in the normal environment. As such, they would not be able to act as a vector as they cannot survive and colonise an external host effectively.

There is an extremely remote possibility that a host bacterium strain, even if disabled, could colonise the gut through ingestion and produce protein in situ, or pass on the plasmid of interest. The work is classified as Class 2 and the containment procedures required should eliminate any such risk. In addition, in the unlikely event that colonisation does occur, there is negligible risk as recombinant PrP protein is considered non-hazardous.

There is a theoretical risk that altering the PrP DNA sequence, or the context in which it is expressed, could alter the conformation of the protein to a disease specific form that may be regarded as hazardous. An example of this would be the generation of recombinant sequences that are analogous to mutations associated with human prion disease. The escape of a bacterial strain containing such a hazardous protein and the colonisation of an operator would be the worst-case scenario of this type of work.

The risk associated with this theoretical possibility is considered to be negligible because of the following:

- the infectivity of prion disease is subject to a species barrier that for some cases cannot be overcome.
- requires specific routes of infection that are unlikely to occur within the given working practices of the laboratory.
- the materials in use are subject to levels of containment and methods of disposal suitable for reducing to a minimum any chance of contact by the operator.

All these factors indicate that the risks to operator health and to the environment are negligible from this course of work.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
We would like to derogate the requirement of restricted access to laboratories to allow this work to proceed within a designated area of our Category 1 laboratory for particular parts of the proposed work, specifically the use of naked DNA and prokaryotic organisms. Furthermore, this derogation is sought only for GMMs based on sequences considered particularly low risk such as murine and ovine PrP DNA sequences. The Category 1 laboratories in our Department meet Category 2 criteria for all aspects of equipment, waste handling/disposal and other safety aspects except for the issue of limited physical access to the laboratory. Limited access to the GMMs (and hence the associated risks) can be provided by continuous supervision of the materials by the operator, by use of additional rooms that are lockable for certain phases of the work where supervision is impractical (eg overnight culture in a lockable hot-room) and storage of materials in areas with restricted access. This form of supervisory restriction of access at the point of work, combined with restricted access to storage areas, is sufficient to provide the necessary protection intended for Category 2, as outlined in the HSE Guidance documents. The low risk of the GMMs being handled, the limited opportunity for operator risks to occur, the non-pathogenic nature of recombinant proteins and species source for the DNA of these specific forms of PrP, means that this aspect of containment can be justifiably derogated for the prokaryotic usage described in this project.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste that contains PrP related material listed under the genetic manipulation regulations will be decontaminated and/or disposed of in an appropriate manner.

Specifically:
Solid waste will be placed into a clinical waste bag for incineration.

Spent bacterial or eukaryotic cell culture waste will be inactivated by autoclaving before disposal by normal drains.

Solutions of recombinant PrP, together with buffers and solutions from techniques such as SDS-PAGE and dialysis, that have been exposed to recombinant PrP, will be disposed of in accordance with COSHH regulations.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Decision:
Class 2, with derogation of physical access restrictions to allow work to be carried out in the CVS N lab subject to tightened access control measures.

Category:
Class 2, Notification required.

Comments:
Summary - this work assessed as Class 2 and should be notified to the HSE. The purification of recombinant ovine and mouse PrP may be performed in the CVS N lab, subject to the production of a written procedure based COSHH assessment detailing how the material is to be handled, processed, stored and disposed of. Spill response, personal protection and access control should also be specified. A specific area of the lab should be designated for this work. The bovine and cervid PrP work should be performed in the dedicated TSE lab where possible. Use of facilities outside this lab should comply with the relevant parts of the COSHH assessment described above.

Project Additional Information

Purposes of the contained use

This program of work has the objective of identifying genes from a range of hazard group 2 pathogens that are associated with virulence using mutagenic techniques and animal infection studies. Mutants will be investigated to determine the mechanisms behind any associated phenotypic change and assessed for their suitability as vaccine vectors.

Recipient or parental organism

- Salmonella enterica (HG 1 + 2 strains only), Bordetella pertussis, B.parapertussis, B. bronchiseptica, Streptococcus equi, S.suis, S.pneumoniae, Staphylococcus aureus, Listeria monocytogenes, Campylobacter jejuni and Rhodococcus equi. Many of the mutants made will be attenuated for virulence, as the mutations will be in metabolic...
genes, genes involved in the protection of bacteria from host defence mechanisms or genes that encode mechanisms for signalling to the host. However, some mutants will be as virulent as the parent.

Host/vector system

Animal hosts: Mice and possibly chickens in future.

Bacterial hosts: Salmonella enterica (HG 1 + 2 strains only), Bordetella pertussis, Bordetella parapertussis, Bordetella bronchiseptica, Streptococcus equi, Streptococcus suis, Streptococcus pneumoniae, Staphylococcus aureus, Listeria monocytogenes, Campylobacter jejuni and Rhodococcus equi. Vectors: Non-mobilisable or mob-defective plasmids appropriate for each species of bacteria.

Origin & function

This program of work has the objective of identifying genes from a range of hazard group 2 pathogens that are associated with virulence. The genes will be identified using library generating gene knockout technologists (such as transposon mutagensis) followed by screening individual mutants or pools of mutants for pathogenicity in a suitable animal model (e.g. mouse infection models). The genes identified in these screens will then be specifically knocked out in the original wild-type organism using defined allelic replacement techniques and complemented using chromosomal or plasmid-expressed copies of the gene in question to confirm that no other spurious mutations are responsible for any new phenotype. The precise identities of these genes cannot be specified in advance of the screening procedure. However, each gene that is identified will be risk assessed to ensure that the subsequent manipulations will not pose a substantially higher risk or require reclassification of the activity to a higher category (i.e. Class 3) or alter the host organism in a way that may increase it pathogenic potential (e.g. environmental stability as vaccine vectors. They will be transformed with expression plasmids containing prokaryotic or eukaryotic promoters (e.g. CMV promoters) to express recombinant proteins (as potential antigens and/or immunomodulatory proteins) and selectable markers (e.g. antibiotic resistance genes). To study the contribution of the different arms of the immune system to the response to these mutants, they will be used individually or in pools, to infect conventional, gene-targeted and transgenic mice, by various routes of infection (e.g. intravenous, intraperitoneal, oral or intranasal routes). This work is covered by a Home Office Project Licence. At various time points post-infection, mice will be killed and organs will be examined for bacterial counts and parameters such as gene expression in the bacteria and host immunological response to the bacteria. These experiments will use the parent strains of the mutants as controls.

Evaluation of foreseeable effects

It is expected that many of the mutants made will be attenuated for virulence, as the mutations will be in metabolic genes required for growth of the bacteria in vivo; genes involved in the protection of bacteria from host defence mechanisms; or genes that encode mechanisms for signalling to the host. However, some mutations may not affect the ability of the bacteria to grow and cause disease in vivo and hence those mutants will be as virulent as the parent strain. All of the proposed work will be performed at laboratory and animal containment level 2, unless there is deemed sufficient cause to raise or lower the containment level. Where this is the case, approval from the HSE will be sought in advance.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None requested

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Detailed standard operating procedures for disposal of category 2 laboratory waste have been provided previously.

To summarise:

Solid Waste: (Category 2)
Laboratory waste is sterilised by autoclaving in unsealed biohazard bags contained within stainless steel containers with loose fitting lids. Final disposal: Landfill, double bagged in plain black polythene outer bag.
Liquid waste: (Category 2)
Collected in 1 litre polypropylene bottles containing 1ml of QC Clear/D™ broad-spectrum (Quat-NH4) disinfectant. Volume not to exceed 800 ml per bottle. Autoclaved under standard conditions. Final disposal: Down the drain.

Autoclaving:
All autoclaves are serviced annually by an authorised agent using an "in load" thermocouple monitor. Browne TST Control Integrators for steam autoclaves (complete colour change indicates that the strip was exposed to steam at 121°C for at least 15 min or 134°C for 5.3 min: Order code 2342). Steam exposure indicators are included in the centre of all category 1 and 2 waste runs. All autoclaves are operated using the standard conditions of 30 min @ 128°C. 100% kill is anticipated under these conditions.

Animal containment Lab waste:
Animal waste (faeces, bedding, carcasses) is double bagged in yellow clinical waste bags. These bags are stored in a large locked clinical waste bin or cold storage room and collected regularly by a commercial company (Vetspeed) licenced for GM waste disposal by incineration. Cages are sprayed with 3% Virkon and then processed at 70°C with acidified wash solution in a commercial cage washer. More details and justification for these conditions being sufficient to ensure effectively 100% kill are provided as a separate attachment.

Please enter comments on the GM safety committee on the risk assessment

Two risk assessments are attached, with comments at the ends. Here is a representative set of comments for one of the Ras (GM2006/08)

Decision: Class 2. Notification required for subsequent animal work.

Comments:
BAB: insert description - I thought pTECH used the tetC fragment to act as an adjuvant so the proteins are expressed as fusions with this. So not sure if 'under the control of the pTECH promoter element' is correct. TetC fragment is bigger than amp.
Happy with the rest as she has acknowledged there may be some risk of increased pathogenicity and given reasons for why this is unlikely to happen.

DT: I have no major issues with this assessment. However, re Q23 (impact of immunosuppression) there is good evidence that Campylobacter-associated disease, at least, is much more prevalent in the immunosuppressed population (I suspect this will also be true of Salmonella).

LT: The work as described here is OK at CL2 and would be covered under GM407/97.2, however, I assume it is intended to introduce these GMOs into an animal at some point. On checking the detail of GM407/97.2 and its subsequent notification updates, I find that such work will require notification.

02/03/2022
**Project Additional Information**

**Purposes of the contained use**

This notification is intended to cover the use of lentiviral vectors as gene delivery vectors for making transgenic cell lines and animals. Lentiviral vectors will be used to introduce a variety of transgenes into a variety of cell lines (including human cell lines); tissues and germ line cells from a range of animal model systems, e.g: mice, rats, chickens. These transgenes will include: 1. micro RNAs and short hairpin RNAs designed to knock down gene expression within the recipient host cell line; 2. Functional gene products (e.g. Fluorescent markers, reporter genes, growth factors, interferon related genes, pro-apoptotic genes, ion channels and receptors) under a range of constitutive or inducible expression control. 3. innate immune receptors (such Toll-like or Nod-like receptors) and proteins from the Nuclear Factor Kappa B family. Although most targets/proteins would be innocuous, some of these targets/products may result in a phenotypic change in the recipient cell that might have deleterious effects should the vector be accidentally administered to the operators' own tissues. Thus, the lentivectors would be considered class 2 GMMOs, but once used for transgene delivery, the resultant GM cell line/animal etc would be considered a class 1 GMO unless risk assessment suggested otherwise. Each transgene will be individually assessed by the local GM safety committee to determine whether its use constitutes a Class 1 or Class 2 activity that falls under this current “umbrella” notification. Those deemed to be Class 3 activities will be notified individually to the HSE.

**Recipient or parental organism**

Lentivector particles will be produced by transfection of a eukaryotic cell line such as HEK 293T (a derivative of the 293 cell line containing the temperature sensitive gene for SV40 T-antigen and adenovirus type 5 E1A (a colinear segment from nt 1 to 4344, integrated into chromosome 19). The lentivectors will then be used to transduce mouse or rat neuronal cells (in cell culture and in individual animals), mouse cells (in cell culture), horse cells (in cell culture) and chicken cells (in cell culture and in ovo).
The anticipated effect is that the transgenes will be integrated into the cell genome, will be expressed and will produce a phenotypic change in the transduced cells/tissues. Typical phenotypic effects would be activation of the cells, resulting in enhanced repair capability in neuronal tissues; and expression of transgene products that suppress the replication of avian viruses.

Host/vector system

The lentivectors will be based upon (or similar to) the commercial vector systems pLentilox and Lenti 6 vectors in widespread use as gene delivery vectors. These consist of a vector plasmid into which the transgene cassette is inserted. Transfection of this plasmid into 293T cells results in the production of the lentivector RNA that contains the signals necessary for packaging into virion-like particles and integration into subsequently transduced cells. They contain no other lentiviral gene products (and some of our derivatives have had the potentially oncogenic WRE element deleted or modified as described in Schambach Gene Therapy (2006) 13, 641–645). These vectors are classified as HG1 while those that contain the entire WRE are classified as HG2. Packaging into virion-like particles is achieved by cotransfection of separate plasmids that express the gag/pol genes of HIV-1, the HIV rev gene and the VSV G envelope protein (or other the envelope protein from another virus such as influenza. The vectors lack extensive regions of homology and are unlikely to undergo homologous recombination. The likelihood of replication competent virus being regenerated by recombination is negligible. The recipient hosts would not be expected to propagate any such virus even if it did occur.

Origin & function

The genetic material to be included in the transgene cassette includes:

1. Mammalian genes encoding selected transcription factors or growth factors under the control of tissue specific or ubiquitous promotors (e.g. Sox2, NOGGIN)
2. Diphtheria toxin receptor gene under tissue specific promotor (e.g. P0 for Schwann Cell and olfactory ensheathing cells.
3. Micro RNA expression cassettes driven by the chicken, mouse or horse U6 promoter and targeting a variety of viral and host gene products.
4. Constructs designed to inducibly express the transgene contingent on the presence of the influenza virus RNA polymerase. In the absence of polymerase/virus infection, the transgene should not be expressed. The transgenes will consist of fluorescent markers, interferon response genes (e.g. Mx) and genes intended to cause the cell to rapidly initiate apoptosis in response to virus infection (eg. See section 17 for details).
5. Mammalian genes encoding selected proteins from the NIKB signalling pathway (p65, IKBa) or innate immune receptors under the control of tissue specific or ubiquitous promotors.
6. Channel rhodopsin 2, NMDA receptors and sodium channels.

The examples listed above correspond to those for which RAs have been submitted to our GMSC for approval. Since this is a standard gene delivery methodology, we anticipate that others will be submitted in future. These will be assessed individually by our GMSC and overall monitoring of the various projects will be the responsibility of the BSO.

Evaluation of foreseeable effects

The lentivectors will integrate their transgene payload into the target cells and the transgene RNA will be transcribed. This will result in a phenotypic change in the recipient cell/tissue/animal. The likelihood of this posing any risk to human, animal or environmental health is extremely low/negligible.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Some of the vectors are intended to be introduced into the germ-line of mice and chickens to produce transgenic animals. These would pose no environmental, human or animal health risk and would be maintained under standard animal laboratory containment level 1 conditions after administration of the lentivector.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None requested.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste: Biologically contaminated laboratory waste is collected in biohazard bags contained within a stainless steel container. Used plastic pipettes and pipette tips
are flushed with 5% Virkon and then discarded into disposable plastic containers that are autoclaved when full or weekly, whichever is sooner. All solid waste is autoclaved under standard validated conditions before exiting the premises.

Liquid waste: Collected in 1 litre polypropylene bottles containing 1 ml of QC Clear/D™ broad-spectrum (Quat-NH4) disinfectant. Volume not to exceed 800 ml per bottle. All liquid waste autoclaved under standard conditions.

Autoclaving: The premises have extensive autoclave facilities that are serviced annually by an authorised agent using an “in load” thermocouple monitor. Two Browne TST Control Integrators for steam autoclaves (complete colour change indicates that the strip was exposed to steam at 121 °C for at least 15 min or 134 °C for 5.3 min. Order code 2342) are included in loads periodically (one in the centre and one visible from the top). The autoclave is operated using the standard conditions of 60 min @121°C or 30 min @ 134°C. 100% kill is anticipated under these conditions.

Final disposal:
Solid waste: Landfill, double bagged in plain black polythene outer bag.
Clinical waste: Such waste is not routinely inactivated by a validated means prior to removal for incineration. Incineration is performed by external contractor licensed for GM waste transport and disposal of Class 2 GM waste.
Liquid waste: Post-inactivation, down the wash-up room sluice.
5% Virkon used for pipette tip rinsing is refreshed regularly and disposed of down the drain after minimum of 15 min from last use.
Animal carcasses and bedding: Incineration as described above.

Please enter comments on the GM safety committee on the risk assessment

Proposal 2008/03. Transgenic strategies to generate influenza virus resistant chickens.
BAB: I am happy with this.
RB: As discussed, I suggest including text that states the potential functional elements (see Q13) will be / could be from different species.
AG: I am happy with GM2008/3 (there is a spelling mistake in the answer to Q13 - it should read caspases not casases).
LT: No comment – its my proposal. Will be notified when candidate gene products have been tested in vitro before lentivector construction is done. GM chicken transgenesis is to be done by collaborators at the Roslin institute not here at Cambridge.

LT: Class 2 because of use of 293T cells and wpre in lentivector.
Inserts not hazardous. Include in umbrella notification to HSE.
AG: I have no major issues.
BAB: I am not up with the room designations in the Innes - is the surgery at category 2? I am happy once the injection is done that the animals are containment level 1 but probably with the possibility of aerosols and injecting the operator and animal handlers this procedure should still be containment level 2.
D.T: where she appears to refer to the host (mouse primary cells, or HEK cells) as ACDP class 2. May be I am out of touch but I didn’t think ACDP applied to mammalian cells? Other than that I didn’t have any issues.

Proposal 2011/11. Recognition of infectious agents by Pattern Recognition Receptors
LT: This is very similar to a number of proposals that have been considered by the GMSC in recent months and only falls into class 2 because of the use of the lentivector delivery system. I will include it with the umbrella notification for lentiviral vectors that is to be submitted shortly.

02/03/2022
Project Additional Information

Purposes of the contained use

This work will make use of Lactobacillus lactis subsp. cremoris for the cloning and expression of genes of interest (including potentially / known virulence and antibiotic resistance proteins) from Staphylococcus spp. (including the human pathogen: Staphylococcus aureus). The L. lactis subsp. cremoris cells will be electroporated with pOri23: a plasmid with the gene of interest under control of a lactococcal promoter (P23) following standard laboratory procedures. The resulting recombinant L. lactis subsp. cremoris strain expressing the protein of interest will then be tested in a range of in vitro phenotypic assays in order to evaluate the function of the expressed protein.

Recipient or parental organism
This work will make use of Lactobacillus lactis subsp. cremoris as a recipient.

**Host/vector system**

The vector is pOri23: ermAM - macrolide-lincosamide streptogramin resistance gene (erythromycin resistant in E. coli and Lactobacillus), P23 L. lactis promoter, oriColE1 – E. coli replicon, repD/E lactobacillus replicon.

**Origin & function**

The origin of the genetic material will be from Staphylococcus spp. (including S. aureus). A range of different coding sequences (CDS) will be cloned in order to investigate their biological function. CDS to be cloned include potential adhesins, coagulases proteins, other virulence factors and CDS encoding antibiotic resistance.

**Evaluation of foreseeable effects**

Lactobacillus lactis subsp. cremoris is a common bacterium used in the production of cheese and other dairy products. As a genetically tractable organism of very low pathogenic potential it has been used for the cloning and expression of genes from a range of more pathogenic bacteria. Its low pathogenic potential also has enabled its use as the first genetically modified organism in human clinical studies. In particular this Gram-positive bacterium is not known to carry adhesins to mammalian matrix proteins and has a well-characterized genetic background. It is highly unlikely that the transfer and expression of a single staphylococcal protein would generate a Lactobacillus lactis subsp. cremoris strain with pathogenic potential towards humans. Furthermore any such GMO would be unlikely to be any more pathogenic that the original Staphylococcus spp. strain from which the gene originated.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All bacterial liquid cultures will be autoclaved in an suitable autoclavable container. All other bacterial cultures and contaminated materials will be autoclaved following standard Departmental practice for handling Category 2 pathogens (see below). Routine cleaning of surfaces and areas of work are carried out using 70% Ethanol solution. Thus all waste leaving the department will be completely inactivated.

Solid waste: General laboratory waste is collected in biohazard bags contained within a stainless steel container. All solid waste is autoclaved under standard conditions before exiting the premises.

Liquid waste: Collected in 1 litre polypropylene or glass bottles containing 1 ml of QC Clear/D™ broad-spectrum (Quat-NH4) disinfectant. Volume not to exceed 800 ml per bottle. All liquid waste autoclaved under standard conditions.

Autoclaving: The premises have extensive autoclave facilities that are serviced annually by an authorised agent using an “in load” thermocouple monitor. Two Browne TST Control Integrators for steam autoclaves (complete colour change indicates that the strip was exposed to steam at 121 °C for at least 15 min or 134 °C for 5.3 min) are included in loads periodically (one in the centre and one visible from the top). The autoclave is operated using the standard conditions of 60 min @121°C or 30 min @ 134°C. 100% kill is anticipated under these conditions.

Final disposal:

Solid waste: Landfill, double bagged in plain black polythene outer bag.

Liquid waste: Post-inactivation, down the wash-up room sluice.

**Is an emergency plan required according to regulation 20?**

N

**If yes, tick to confirm that it is attached to this form**

N
Decision: Approved conditionally. Initial work in E.coli can be done under existing notifications. However, transfer to Lactobacilli will require HSE notification.

Category: Class 2, Notification required.

Comments:
A.G. I have a couple of minor points.
Summary: gram should start with 'G'; mammal should be mammalian; lactocococcal should be lactococcal
Q17: Is this not yes? especially with relation to the antibiotic resistance determinants
Q31: What about the antibiotic resistance
I agree with a class 2 designation

BAB: I think Ewan is confused about what should go in the Insert description box - he has described what is in the plasmid vector, which for me should be in the box above. From his summary text what should be here is genes of interest (potentially known virulence and antibiotic resistance proteins) from Staph species which he has put in Q14. Apart from that I am happy with the classification to take it to containment level 2.

C.C: It should be made clear whether intermediate cloning steps will be performed in E. coli.
The E.coli<>L.lactis shuttle vector pOri23 is given as being non-mobilizable. It is in fact mobilization-defective (it is a derivative of pIL253, a L.lactis plasmid that can be mobilized by pIL205). This isn't likely to happen in the lab of course.
Class 2 activity fine (depending on the genes to be cloned, Class 1 activity could be justified)
P.M. looks fine to me

L.T: The only concern I have is whether the plasmid carrying the genes has the potential to enable them to be transferred to another less innocuous host species. I assume this is the reason that it has been moved up to Class 2. We have not notified Lactobacillus for Class 2 GM work, so this will need to be done.

**Tick to confirm that you have attached a risk assessment to this form** Y

**Tick if you are claiming exemption from disclosure for section of the risk assessment** N
**Project Additional Information**

**Purposes of the contained use**

To use plasmid transfection methods to generate recombinant influenza viruses to study the effect of mutations in the influenza A virus genome on antigenicity, replicative fitness, host species tropism and transmission dynamics in cell culture and animal model systems.

**Recipient or parental organism**

Influenza A virus generated from plasmid clones corresponding to each of the 8 segments of naturally occurring wild-type strains, specifically: A/PR/8/34 (Cambridge) and A/WSN/33 vaccine strains; A/Duck/Netherlands/10/99 (H1N1); A/swine/Eng/1353 (H1N1)). Other low pathogenicity avian influenza strains and strains of equine influenza may also have virus rescue systems developed for them. This notification only applies to HG2 strains and class 2 genetically modified versions of these.

**Host/vector system**

pDual reverse genetics plasmids or derivatives thereof capable of producing:
A/PR/8/34 (Cambridge); A/WSN/33
A/Duck/Netherlands/10/99 (H1N1);
A/swine/Eng/1353/09 (H1N1);
A/England/195/09(H1N1)
**Origin & function**

The pDual reverse genetics plasmids (e.g. pRF483) are comprised of the pCDNA3 backbone carrying human or avian PolI promoter upstream of the negative sense full genome sequence from 1 of each of the 8 segments of the viruses named above. Downstream of these is the mouse RNA PolI terminator or HDV self-cleaving ribozyme sequence positioned to facilitate precise termination at the 3' end of the influenza genome sequence. This sequence is then followed by the CMV IE promoter in the reverse orientation to drive expression of a mRNA encoding the influenza gene product. Transfection of 8 plasmids (1 for each gene segment) allows the rescue of infectious virus with the genetic content dictated by the plasmids used. Substitution of one or more plasmids with those obtained from different strains, or carrying defined mutations allows the production of defined genetic variants that can then be studied to determine the effects of the sequence variation on antigenicity, replicative fitness, host range and transmission dynamics.

**Origin of viral sequences:** Wild-type sequences of the strains listed above. Sequence variants occurring in response to antigenic selective pressure, or selection by passage of virus strains in cells or tissues from non-cognate host-species (e.g. pig, horse, chicken, but excluding human) are amplified by PCR and sequenced (or generated commercially by gene synthesis). These are then cloned into the reverse genetics plasmid (e.g. pRF483) and used to generate viruses with defined mutations (either individually or in combination). These studies are restricted to HG2/Class2 influenza viruses e.g. low pathogenicity avian influenza viruses (excluding H5 and H7), swine influenza viruses, equine influenza viruses and human influenza viruses.

**Evaluation of foreseeable effects**

The virus rescue systems allow the production of as near as technically possible homogenous population of viruses from a defined set of plasmid encoded genes. The expectation is that such rescued viruses will behave like the viruses they were derived from. However, it is not uncommon for the rescued viruses to show decreased replicative fitness as their homogeneity limits their adaptive and interactive potential when compared to the quasispecies behavior of the original virus population. The application of virus rescue for reverse genetics allows the effects of mutations (such as those that occur naturally during virus growth) to be tested individually in a defined genetic background to determine their effect on antigenicity, replicative fitness and host-range. The foreseeable effects are: 1. No effect (synonymous mutations); 2. reduced susceptibility to neutralization by sera specific for the original strain; 3. increased replicative fitness in the cell lines from the species in which they have been passaged; 4. increased or decreased replicative fitness when propagated at different temperatures. The possibility of generating viruses that gain the ability to infect humans...
more efficiently than the parental virus is unlikely but possible (note: A/Swine/Eng/1353 is a close descendant of the pdm2009 strain A/England/195 and is already human tropic). The proposed work does not involve the deliberate introduction of mutations associated with human tropism into non-human tropic strains. All virus genes used will be sequenced prior to performing virus rescue experiments. The virus rescue system uses the HEK293 cell line which is of human origin. It is now generally considered to be necessary to verify the sequences of rescued viruses to confirm that no unintended mutations have occurred during the rescue process. This has the added benefit of confirming that mutations confirming human tropism are absent. Any unexpectedly showing signature sequences for human tropism (i.e ability to use alpha 2-6 sialic acid receptors) will not be cultured. Should it be decided in future to analyse such variants we deem this would require renotification to the HSE.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None requested

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste is pretreated with QC-Clear D prior to autoclaving. All waste is autoclaved (25 min@134°C for mixed solid waste; 25min@121°C for liquid waste, using appropriate "in load" probe location. 100% kill expected) using the main department autoclave. Disposal is to landfill or down the sluice to the drain. The autoclave waste cycle is validated annually by 12 point in-load thermocouple. Each waste run is verified by visual inspection of the data print-out showing temperature and duration for each stage of the sterilization cycle. Each load contains a TST control strip* to verify the load has undergone the process. Success or failure is recorded in the autoclave logbook, along with action where relevant.

*Browne TST Control Integrators for steam autoclaves. Re-order code 2342. Complete color change indicates that the strip was exposed to steam at 121degC for at least 15 min (or 134degC for 5.3 min).

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick if you are claiming exemption from disclosure for section of the risk assessment N
GM4014_01 Rescue of recombinant influenza viruses. (Part 1 of 2). Barcoded influenza viruses.
BAB: This looks good to me. I did wonder if the 7 day restriction for contact with pigs was too long - is it
not usually a 48h restriction (eg people from Pirbright etc).
Response from LT: As there is the potential for infection of the worker rather than simple passive
carriage, 7 days seems more appropriate. This would be extended if the worker showed flu-like
symptoms to 7 days post recovery. Workers will also be vaccinated using the current trivalent vaccine
C.C: This seems fine, given that the only modifications are in the wobble position and are unlikely to
cause any phenotypic changes.
C.B: These look OK to me.
A.G: Assuming that all operators have received the appropriate training and are familiar with the
techniques and SOPs then I am happy with the risk assessments. I am not sure that anybody else
using the hoods that you refer to will come into contact with swine, however if they do then it might be
worth notifying them in advance of them using the hoods.
Response from LT: There will be a hood dedicated to working with influenza virus for the duration of
this project.
GM4014_02 Rescue of recombinant influenza viruses. (Part 2 of 2) Characterisation of cell culture
adapted influenza viruses.
BAB: This looks good to me. I did wonder if the 7 day restriction for contact with pigs was too long - is it
not usually a 48h restriction (e.g. people from Pirbright etc).
Response from LT: As there is the potential for infection of the worker rather than simple passive
carriage, 7 days seems more appropriate. This would be extended if the worker showed flu-like
symptoms to 7 days post recovery.
C.C: This also seems fine. I was concerned at the possibility that the adaptations may increase
virulence, but this is expected to be unlikely given the nature of the lab passaging. Has there been any
published work reporting this type of approach to generate attenuated strains? If so it'd be useful to
include a reference.
C.B: These look OK to me.
A.G: Assuming that all operators have received the appropriate training and are familiar with the
techniques and SOPs then I am happy with the risk assessments. I am not sure that anybody else
using the hoods that you refer to will come into contact with swine, however if they do then it might be
worth notifying them in advance of them using the hoods.
Response from LT: There will be a hood dedicated to working with influenza virus for the duration of
this project.
GM4014_04 Rescue of recombinant influenza viruses: Production of A/PR/8/34 virus carrying segment
4 (HA) from A/mallard/10-Nmkt/1999 or A/mallard/10-Cam/1999
BAB: On Q28b can you definitely say it would not disseminate or would this be a limited transmission
chain. This sort of goes with Q30 answer - unknown.
Response from LT: Changed to "unlikely" and now addressed in Q35.
You need to complete the Q36 justification.
Response from LT: Now completed.
Apart from that I am happy with CL2
CB: Looks fine to me.
DT: I am fine with the revised version.
A.G: I have looked over the application and it all looks fine to me.

### Historical Significant Changes
- N

### Project Additional Information

**Purposes of the contained use**:  
The purpose of the contained use is to express normal and modified sequences of DNA encoding the prion protein (PrP) within invertebrate and mammalian hosts to study prion pathogenesis in laboratory animal models.

**Recipient or parental organism**
- **Invertebrate hosts**:  
  Drosophila melanogaster are small flies (about 3 mm in length and 2 mm in width) and belong to the order Diptera. Drosophila mature through complete metamorphosis.
with the mature female being slightly larger than the male. Similar to all insects Drosophila are covered in a chitinous exoskeleton, they have three main body segments and they have three pairs of segmented legs. They have one pair of wings and can walk and fly (excluding wingless mutants). Caenorhabditis elegans (C. elegans) are free-living (non-parasitic), transparent nematodes (roundworms), about 1 mm in length and were the first animal whose relatively small genome was completely sequenced. C. elegans is an unsegmented, vermiform, pseudocoelomate, that lacks a respiratory and a circulatory system. The majority of these nematodes are female hermaphrodites. Males have specialised tails for mating that include spicules. C. elegans is bilaterally symmetrical, has a cuticle (a tough outer covering), four main epidermal cords, and a fluid-filled pseudocoelom, (body cavity). The basic anatomy of C. elegans includes a mouth, pharynx, intestine, gonad, and collagenous cuticle. The four bands of muscles that run the length of the body are connected to a neural system that allows the muscles to move the animal's body only in the forward direction, (from the back to the front), so that any living, moving individual is always on either its left side or its right side when observed crossing a horizontal surface.

Vertebrate hosts
Laboratory mice are small mammals of the order rodentia, usually of the species Mus musculus. They are the most commonly used mammalian research model in areas such as bio-medicine, immunology, genetics, and infectious disease. Mice belong to the Euarchontoglires clade, which includes humans. The laboratory mouse genome has been sequenced and many mouse genes have human homologues. This relatively high homology with humans at the genetic level, their ease of maintenance and handling, and their high reproduction rate, make mice particularly suitable models for human-oriented research. Mice have sharp teeth and can bite if provoked.

Laboratory hamsters are typically stout-bodied, with tails shorter than body length, and have small, furry ears, short, stocky legs, and wide feet. They have thick, silky fur, which can be long or short. Hamsters have sharp incisors; they have an upper pair and lower pair that grow continuously throughout life. Hamsters are very flexible, but their bones are somewhat fragile. Hamsters have poor eyesight.

Host/vector system
Selected hosts will be made transgenic for PrP by appropriate transgenesis vector systems that give stable integration of DNA encoding the prion protein in the recipient’s genome. We will use currently available vectors that allow efficient transgenesis of the species in question, as well as any new vectors or transgenesis systems that may emerge in the future.

Origin & function
The normal form of the prion protein is expressed in hosts ubiquitously but principally by cells of the central and peripheral nervous system, and the lymphoreticular system. The physiological function of the normal form of the prion protein PrPC is not fully understood although it can function as a copper binding protein. PrP is associated with prion diseases, or transmissible spongiform encephalopathies. It is currently believed that PrPSc, a conformationally modified form of PrPC, may itself constitute the infectious prion agent.

The species forms of PrP to be studied here will include: ovine, murine, hamster, bank vole, porcine, cervid, bovine and human. However, the work may expand to include PrP genes from any other species. The PrP DNA sequences will be obtained by PCR cloning from the genomic DNA or mRNA from the species in question or from plasmids carrying the previously cloned genes or by direct DNA synthesis by a commercial gene synthesis company. The genes will be expressed as protein in the new invertebrate and mammalian host and will be detected on cell surfaces, in the cytosol, or secreted from cells, or in cultured cell preparations or harvested as a source of protein for laboratory use.

Evaluation of foreseeable effects
Drosophila melanogaster
In the unlikely event that PrP transgenic flies that express the prion protein manage to escape from our fly containment laboratory, there is a possibility that they will be able to survive for a limited amount of time and potentially breed with non-transgenic flies. However, only 25% of the resultant progeny could express the prion protein since expression requires the presence of the PrP transgene and the driver gene, which are encoded on different chromosomes in our transgenic flies. Escapees that express wild-type PrP are considered to present an extremely low level of risk. There is no evidence that wild-type PrP expression in the fly spontaneously mis-folds into an
infectious form. Furthermore, it is considered to be extremely unlikely that such flies would come into contact with a prion-infected animal and acquire exogenous prions un-aided. Escapees that express a mutant allele of PrP associated with spontaneous formation of prion disease (e.g. alleles associated with CJD, GSS and site directed mutants that knowingly disrupt the stability of the native conformation of the protein) and their progeny could potentially spontaneously generate infectious prions. However, the ability of such flies to generate infectivity that can infect a mammalian host has not yet been demonstrated experimentally. Escapees could be those that express wild-type or mutant forms of PrP that have knowingly been exposed to exogenous prions in the laboratory and such flies could potentially infect other hosts that express PrP. For this to occur the infection would be expected to occur by the oral route. However, it would be very unlikely that a prion-infected fly would escape from our fly containment laboratory and subsequently be eaten by another animal or human. Even if it did, the amount of prion infectivity in one fly would be considered to be relatively low and therefore present an extremely low risk by peripheral exposure.

**Caenorhabditis elegans**

In the wild, C. elegans are found in the soil and feed upon decomposing plant matter. In the laboratory, C. elegans are maintained in liquid culture or on agar plates supplemented with bacteria, using very specific methods. It is not likely that experimental C. elegans could survive for any appreciable time if they were to escape from such laboratory cultures or if they are removed unwittingly. As such, in the highly unlikely event that PrP transgenic C. elegans, with or without exposure to infectious prions, could escape from a worm containment laboratory, it is considered that this would pose little, if any, risk to the operator or the surroundings.

**Rodents**

Any prion infectivity work to be carried out in laboratory mice or hamsters will be in collaboration with groups already working with these animals and these infectious agents so that discussions on current ‘best practice’ can take place prior to commencement of the work. All prion-infected vertebrate hosts will be housed in CL-2 / CL-3 purpose-built animal containment facilities (for example, the APHA at Weybridge) that have been specifically designated as suitable for prion infectivity experiments. These types of experiments have been on-going for many years at the APHA CL-2 / CL-3 purpose-built animal containment facilities where prion-infected rodents are suitably maintained, controlled and monitored by experienced animal staff. The chances of a prion-infected vertebrate host escaping from such a facility is considered to be negligible.

---

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Two GMO classification levels and corresponding containment levels apply as follows: Low level (CL-2) applies to hosts carrying PrP genes with no history or expectation of causing spontaneous prion disease in the natural host. These will include, but will not be limited to, wild-type (normal alleles) of ovine, murine, hamster, bank vole, porcine, cervid, bovine and human PrP. Higher risk level (CL-3) applies where mutant alleles of PrP associated with spontaneous formation of prion disease (e.g alleles associated with inherited prion diseases of humans such as familial CJD, GSS, FFI, and site-directed mutants) that knowingly disrupt the stability of the native conformation of the protein that may induce a prion disease-specific form.

The intention is to expose these two classes of GMOs to infectious prion material from a variety of sources. Use of prion inocula from hosts not known to produce prions capable of causing disease in humans (e.g. ovine and murine PrPSc) will not result in alteration of the containment class used for the experiment. However, where the prion inocula is derived from human, bovine or cervid prion disease, or any species infected with bovine prion material, the activity will be deemed as Class 3, irrespective of the origin of the PrP gene in the host GMO.

This work will be carried out in CL-2 / CL-3 prion-dedicated containment laboratories with suitable control measures in place for use of invertebrate (e.g. Drosophila or C. elegans) or vertebrate hosts (e.g. rodents) of experimental prion disease.

With particular reference to the use of Drosophila, the fly laboratory (room 313) will contain 2 types of fly-trap (hanging sticky paper and bright yellow liquid traps) to trap any flies that escape from their containment vials. In addition, the fly containment facilities will have a double door arrangement with an internal fly screen to prevent the escape from the room of any flies that can fly. The PrP transgenic Drosophila used for Class 3 experiments will be first crossed with a wingless diver fly line to produce flightless flies that express PrP. The use of flightless Drosophila will significantly reduce the possibility of escape from the containment laboratory of flies potentially carrying prion agents that have a remote possibility of causing human disease. The fly containment laboratory will have sticky paper mats placed on the ground in the doorway area (on the inside) so that any flightless flies will be trapped as they attempt to cross this area in the unlikely event of escape from their containment vials. Only suitably experienced
research personnel will perform experiments with Drosophila inoculated with Category 3 prion material.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

1. Plasmid preparation: There is an extremely remote possibility that a PrP DNA transformed host bacterium strain, even if disabled, could colonise the gut through ingestion and produce protein in situ, or pass on the plasmid of interest. The molecular biology component involving murine and ovine PrP genes has been risk assessed to require Containment Level (CL) CL-2 and notified as such previously (with derogation see GM407/03.1). The PrP genes from human and bovine sources were specifically excluded from that derogation. They will therefore be manipulated in our CL2/3 prion laboratories for all procedures. However, we request permission to perform plasmid preparative procedures requiring centrifugation in the CL1 laboratory on the condition that to ensure restricted access, the centrifuge will not be left unattended. Sealed buckets will be used and opened in the class 2 MSC in room 313.

There is a theoretical risk that altering the PrP DNA sequence, or the context in which it is expressed, could alter the conformation of the protein to a disease specific form that may be regarded as hazardous. An example of this would be the generation of recombinant sequences that are, or are analogous to, mutations associated with human prion disease. The escape of a bacterial strain containing such a hazardous protein and the colonisation of an operator would be the worst-case scenario for this type of work.

The risk associated with this theoretical possibility is considered to be negligible because of the following:

a) the infectivity of prion disease is subject to a transmission, or species barrier, that for some cases cannot be overcome.

b) requires specific routes of infection that are unlikely to occur within the given working practices of the laboratory.

c) the materials in use are subject to levels of containment and methods of disposal suitable for reducing to a minimum any chance of contact by the operator.

2. Fly manipulation. All this work will be carried out in CL-2 / CL-3 prion-dedicated containment laboratories with suitable control measures in place. We would like to be permitted to house our Class 3 fly cultures in the incubators in our prion-dedicated CL-2 laboratory (rooms 309 and 310. See facility plan). The flies will not me manipulated in these labs and so there is an extremely low likelihood of accidental escape. Access will be restricted by locking the incubators (in addition to the CL2 PIN code access controls already in place). Although possible, we would prefer not to have to designate these rooms as CL3(TSE) because of the limitations this would place on their use by inexperienced students and future re-designation for other non-TSE purposes.

See Appendix I: Standard Practices for Arthropod Research at Containment Level 3

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste that contains prion-infected material (either CL-2 or CL-3 material) will be decontaminated and/or disposed of in an appropriate manner.

All solid waste will ultimately be placed into clinical waste bags for incineration. The items for disposal will be double bagged and fully sealed and clearly labelled before being taken to an appropriate clinical waste bin for removal from site and incineration.

Solutions of prion-infected material or samples of brain homogenate, together with buffers and solutions from techniques such as SDS-PAGE and ELISA that have been exposed to prion samples, will be disposed of in accordance with COSHH regulations. Specifically, all liquid waste will be de-contaminated in a solution of 2M NaOH for one hour or 1M NaOH overnight followed by suitable neutralisation [ie. addition of an equal volume of 2M or 1M HCl, respectively (NaOH + HCl = NaCl + H2O)] prior to disposal in a designated sink using copious amounts of water.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N
ATTACHMENTS: GM2015_02_decision.doc, GMA2015_01_decision.dot, Prion facility.ppt, Appendix 1 Standard Practices, Appendix 2
Local ACGM use Proposal no: GM2015/02
Decision: Approved
Category: Class 2 GM. Significant change from previous notification. Notification required.
Comments:
BAB: GM2015_02 Q40 do they want to derogate from CL2 for all this work or only non-human that is not bovine??
They are proposing to work in room 309 which does not have a CL2 cabinet for the Ecoli work I think. Where they produce final high concentrations of bacteria in suspension and/or plasmids/proteins how are they proposing to limit aerosol formation and inhalation?
Where they work with human genotypes or mutants that are more likely to spontaneously cause PrPsc I think this needs to be done in a CL2 hood. Presumably all waste from this would need to either be chemically inactivated if liquid or incinerated if solid ie not the usual CL2 autoclave route that they have said they will use in Q28.
Response from LT. No derogation is requested (see comment below). A class 2 MSC is required for the components likely to generate an aerosol. The class 2 hood in room 313 is to be used for this purpose. This RA refers to the plasmid preparation. Solid waste disposal is by incineration (this has now been indicated as the final route of disposal). Chemical inactivation (2M NaOH or 20K ppm hypochlorite) for liquid as specified in TSE SOP.
LT. This is basically an update of a previously approved RA dealing with recombinant PrP purification. It revises the containment up to full Class 2 (or possibly CL3) from a previous derogated CL2 standard because they now intend to purify human PrP sequences. The preparation of the plasmids and proteins for the expression component requires full CL2 (including use of a class 2 MSC for any steps likely to generate an aerosol). The production of the drosophila transfer vectors arguably does not require CL2, as the plasmids will not be able to express protein except when crossed into the appropriate drosophila driver-line background. However, it makes sense to do all this work in the dedicated CL2 and CL3 TSE labs. Room 313 is to be designated as CL3(TSE) and its access controls upgraded. It is an ex-CL3 lab and already up to standard.
Rm 313 is where the Class 3 TSE infection experiments in drosophila will be performed (see GMA2015/01). I am uncertain whether the E.coli expression of human and bovine PrP is class 2 or class 3 (Class 3 seems excessive for WT proteins.) The modified versions that might have the propensity to spontaneously adopt the prion form might be viewed as Class 3. If so, the general derogation for TSEs pertaining to negative pressure and fumigation sealability would enable rooms 309 and/or 310 to also be designated CL3(TSE) simply by upgrading the access control. Ideally room 313 will be sufficient and this wont be necessary as it may pose problems in the future should we ever wish to re-task these rooms if there is reason to believe the rooms themselves have been contaminated. I will request clarification from the HSE regarding the classification of the E.coli expression of human PrP mutants in the CU2 notification.
DT: I have been through the documents and I agree that the this risk assessments appear to be appropriate. I don’t have any questions or points for consideration.
A.G. I have reviewed all of the documents that you have provided and I am happy that sufficient consideration has been made to the work that will be conducted and that sufficient security measures are in place. One minor point, the documents state that prions from other species may be used. For records and in case of an accidental release the group should inform you of the species if other species are used.
C.Can. I have gone through the documents and it all looks in place to me.
S.S. I am happy with the risk assessment, although I agree with Andrew that if prions from other species not currently mentioned are brought in then it would be a good idea to inform you/update the document accordingly.

Local ACGM use Proposal no: GMA2015/01
Decision: Approved
Category: Class 3 GMA. HSE notification required.
Comments:
BAB: GMA2015_01
Do the cabling ingresses into room 313 need to go through Roxtec gland plates or is the trunking sufficient?
Can they add in Section B that wingless flies are unlikely to breed with wild-types?
I am not sure which bits of the project they want derogated - all of it? Surely not the ones with forms of PrP that can spontaneously form human infectious PrP. Just thinking this through I am not sure it will make a difference to what they are going to do in practice anyway.
Response from LT: The trunking has been thoroughly sealed and will not allow flies to escape via any cable penetrations to other rooms in the suite. The comment regarding wingless flies mating habits could be included, but this is a post escape event and escape is already adequately prevented by other measures. The reference to derogation was a hangover from an earlier version and has been deleted.
C.Can. I have gone through the documents and it all looks in place to me.
L.T. I think Drs Bujdoso and Thackray have done a thorough job of their risk assessment and supporting documentation. The measures taken to reduce the hazard posed by the PrP transgenic flies (whether infected or uninfected) are proportionate to the risks. The facility (room 313) requires some upgrading before the Level 3 work can commence (double access door and covering vents with mesh).
DT: I have been through the documents and I agree that the this risk assessments appear to be appropriate. I don’t have any questions or points for consideration.
A.G. I have reviewed all of the documents that you have provided and I am happy that sufficient consideration has been made to the work that will be conducted and that sufficient security measures are in place. One minor point, the documents state that prions from other species may be used. For records and incase of an accidental release the group should inform you of the species if other species are used.
S.S. I am happy with the risk assessment, although I agree with Andrew that if prions from other species not currently mentioned are brought in then it would be a good idea to inform you/update the document accordingly.

Project Ref 407/20.2

Date Ackn’d 04/09/2020

CU2 Project Title
Host interactions and motility of Klebsiella pneumoniae and Pseudomonas aeruginosa

Class 2
CultureVolClass2 < 1 Litre
CultureVolumeClass3-4

Non-GMM Consent Granted

Project notified under transitional arrangements N
**Project Additional Information**

**Purposes of the contained use**

| The motility and interaction of the opportunistic pathogens Klebsiella pneumoniae and Pseudomonas aeruginosa with the eukaryotic host will be studied by infection assays, FACS and microscopy. Therefore, plasmids carrying antibiotic resistance markers for selection and expressing fluorescent proteins will be electroporated into strains of Klebsiella pneumoniae. Genes of interest will be deleted by allelic exchange mutagenesis. Genes will be inactivated by insertion of antibiotic resistance markers (e.g. tetracycline, chloramphenicol) by using a suicide plasmid. Mutants will be confirmed by PCR and DNA sequencing. Commercially available transposon mutants of Klebsiella pneumoniae (Ramage et al. 2017) and Pseudomonas aeruginosa (Liberati et al 2006) will be used. Functional genes and their natural promoters from Klebsiella pneumoniae or Pseudomonas aeruginosa will be cloned into plasmid vectors to allow complementation of the mutant strain. |

**Recipient or parental organism**

| Klebsiella pneumoniae and Pseudomonas aeruginosa are ACDP hazard group 2 pathogens. Both species are opportunistic pathogens and primarily only pose a risk to immunocompromised individuals and those that are hospitalised. Both are commonly present within the environmental flora and fauna and pose limited risk to individuals if correct sanitation procedures are followed. Klebsiella species rarely cause disease in healthy humans and most Klebsiella pneumoniae infections are self-limiting with symptoms relating to pneumonia (bronchitis) and urinary tract infections. Pseudomonas aeruginosa is able to infect the airway, urinary tract, burns, and wounds, and other blood infections. |

**Host/vector system**

| Escherichia coli |

**Origin & function**

| Plasmids carrying fluorescent proteins and antibiotic resistance markers for selection. Plasmids do not increase pathogenicity of Klebsiella pneumoniae or Pseudomonas aeruginosa and antibiotic resistance markers are chosen so that at least two different classes of antibiotics remain usable. The vast majority of the transposon mutants are expected to have reduced virulence when compared to the respective wildtype because most of the mutations result in loss of function, and there are no examples of mutants that substantially increase its virulence in such a way that the mutant strains would have to be considered as HG3 or above. |
Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid and liquid waste will be deactivated by QC clear treatment followed by autoclaving using a validated waste cycle. The expected degree of kill is effectively 100% according to preliminary tests. This procedure is in accordance with the University policy, according to which all GMM must be inactivated before disposal.

In case the autoclave might be down or is unavailable, samples will be treated with 1 % final Virkon for at least 30 min.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form  

Tick if you have attached a risk assessment to this form  

Tick if you are claiming exemption from disclosure for section of the risk assessment

Please enter comments on the GM safety committee on the risk assessment

The project and the risk assessments have been viewed and approved by the Department of Veterinary Medicine Biological and Genetic Modification Committee.

Minor comments from members of the Biological and Genetic Committee were included in the final version. e.g.

RB - In case of power cut/failure, samples will be moved to a different freezer in the same containment level two laboratory. In the unlikely event that the freezer defrosts, as all the contents are sealed in cryo-vials inside freezer boxes, the biological material will be kept contained.

02/03/2022
Project Additional Information

**Purposes of the contained use**
Identification of vaccine targets to prevent respiratory disease in racehorses. Respiratory disease affects 10% of all Thoroughbreds each month during their first two-years of life. The disease reduces performance and is an important cause of lost days in training, leading to significant cost to the racing industry. *Streptococcus zooepidemicus* is the pathogen most strongly linked to this disease, but there are currently no vaccines against it. We have studied the genomes of *S. zooepidemicus* and its close relative, *S. equi*, which causes strangles in horses. Recently, we developed a novel method, transposon directed insertion site sequencing (TraDIS), to identify genes important to *S. equi*, which has informed the design of better strangles vaccines. In this project, we will use this new method to identify key genes required for *S. zooepidemicus* to resist the equine immune response and attach to the equine trachea, prerequisites for this organism to cause respiratory disease. Our results will direct vaccine design to improve the health of young Thoroughbred racehorses.

**Recipient or parental organism**
*Streptococcus zooepidemicus* (wild type)

**Host/vector system**

**Origin & function**
Conferring erythromycin antibiotic resistance for selection carried on ISS1. Generating mutants by transposon mutagenesis. Allelic replacement mutagenesis using sections of *S. zooepidemicus* DNA for homologous recombination.
The transposon libraries generated will contain strains with an insertion in every gene of S. zooepidemicus (apart from essential genes, which will be lost in the process of generating the libraries), generating a knockout in the gene where the transposon has inserted, these strains express erythromycin resistance as part of the integration process. Allelic replacement mutants will have the gene of interest deleted from the genome and will lose the function of that particular gene these strains will be antibiotic sensitive.

### Evaluation of foreseeable effects

Not applicable

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid and liquid waste will be deactivated by autoclaving using a validated waste cycle. Liquid waste will be treated with QC clear D followed by autoclaving. The autoclave cycle for waste disposal will be run at 121°C for 15 minutes. This procedure is in accordance with the University policy, according to which all GMM must be inactivated before disposal. All waste will be ultimately incinerated as clinical waste. Spillages/leaks will be decontaminated with 70% ethanol or 1% virkon for 30 min, Swabs will be taken from spillage area, plated onto Strep select agar plates and incubated overnight at 37°C to confirm complete killing.

### Tick to confirm that you have attached a risk assessment to this form

Y

### Tick if you are claiming exemption from disclosure for section of the risk assessment

N

The project and risk assessments have been viewed and approved by the Department of Veterinary Medicine Biological and Genetic Modification Committee. Comments from the committee include:

Although not on the ACDP list of biological agents, other Streptococci are Hazard Group 2 pathogens. HSE website for occupational risk of infection supports information given in RA. Disease similar to eg Streptococcus pyogenes, a group 2 pathogen. Experiments planned interrupt gene expression and do not introduce new expressed genetic material apart from erythromycin, thus I agree with the hazard group and containment level (2) specified in the RA. As the bacteria are penicillin resistant the erythromycin resistance does not interfere with treatment options if infection occurs.

**Historical Significant Changes**

**Historical Date of Additional Info**

**Significant Change ID**

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

To study the function of human proteins in cell culture by reducing their levels using siRNA.

**Recipient or parental organism**

Recipient/vector

- Amphotropic retroviruses
  - murine embryonic stem cell virus
  - extensively modified human lentivirus (commercial vector system)

Inserted material

- 21 nucleotide fragments of human cDNA.

**Host/vector system**

- Eukaryotic viruses/mammalian
Replication incompetent retroviruses

Cell Lines
HeLa
Ltert
Phoenix Packaging cell line
293T Packaging cell line

Origin & function

Origins:
Hairpin repeat of 21 nt human exon. Sequences that should stimulate siRNA in human cell lines. Hairpins derived from human cDNA library generated in Amsterdam and distributed by Cancer Research UK.

Intended function: To reduce the level of endogenous protein in cell culture in siRNA screens and generating stable cell lines.

Evaluation of foreseeable effects

The insertion of siRNA sequences into the recipient virus is not expected to alter its tropism, host range or virulence. They should not allow generation of replication-competent viruses. The siRNA sequences are expected to reduce but not eliminate the amount of endogenous protein.

The viruses to be packaged are extensively modified to prevent the generation of replication competent virus. The human lentivirus has only the gag, pol and rev proteins of the parental virus (see risk assessment).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

-

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Standard methods will be used.

Liquids: Treat with virkon according to manufacturers instructions. 100% kill expected. Dispose via drains.
Solid and mixed waste: Autoclave 121 degrees C, 100% kill expected. Disposed as standard waste.

Project Additional Information

Purposes of the contained use

By using retrovirus expression vectors containing cDNA5 from mammalian cells, we would like to screen for reprogramming factors that can affect cell fate and proliferation.

Recipient or parental organism

Differentiated mouse cell lines
### Host/vector system
- pMX retroviral expression vector
- Phoenix Eco Cells (Murine-ecotropic)

pMX vector lacks gal-pol and envelope sequence. The pMX vector amplifies and produces retrovirus protein only in Phoenix Eco Cells. These cells produce gal-pol and envelope protein that can only infect mouse or rat cells.

### Origin & function
**Origins of the genetic materials involved:**
Expression library contains cDNA5 from mouse oocytes, primordial germ cells and embryonic germ cells. Embryonic germ cells are derived from primordial germ cells of mid-gestation embryos. The library contains all gene sequence expressed in these tissues and the cell line.

**Intended functions of the genetic material involved:**
Since all gene sequences expressed in the original tissues can be expressed in recipient cell lines, there would be various types of functions. However, only recipient cells that express a certain gene product will survive in vitro culture by virtue of de-differentiation and re-programming. These gene products presumably have a role in cell differentiation and proliferation.

### Evaluation of foreseeable effects
Some recipient cells transfected with the gene products are expected to acquire pluripotency by being reprogrammed. The reprogrammed cells are expected to be able to differentiate all kinds of tissues including germ U cells, neuronal cells and muscle cells, etc. The foreseeable effects can be evaluated by expression of pluripotent U cell-specific genes, such as Stella/Dppa3, Oct4 and Nanog.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**n/a**

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

To prevent the retrovirus into human, we have chosen the Phoenix Eco cells that produce envelope that can only infect mouse or rat cells. Retrovirus-encoding vector lacks sequences for its gag-pol and envelope, therefore the virus cannot replicate in any cells except the Phoenix cells.

All culture medium containing active retrovirus particle will be autoclaved after use.

All other liquids will be treated with 2% Virkon solution for 30 mm.

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The type (form): Phoenix Eco cells and transfected recipient cells (cells)

Treatment: Autoclave (126 degrees, 25 mm)

Degree of Kill: 100%

Autoclave is tested and certified annually

All other liquids: 2% Virkon solution for 30mm according to manufacture’s guidelines.

Ultimate form and fate: Incineration

Project Ref 408/11.1

Date Ackn'd
17/06/2011

CU2 Project Title
Cell fate determination in lung/stem progenitor cells and lentiviral RNAi-mediated gene silencing to study cell competition in mammalian cells

Date Project Ceased

Class Culture Vol Class 2 Culture Volume Class 3-4

Class 2 < 1 Litre

Non-GMM Consent Granted

Withdrawn N

Tick if notifying a connected programme of work N

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

Project Additional Information

Purposes of the contained use

1. Manipulation of gene expression in lung stem and progenitor cells growing in culture. The aim of the project is to identify signalling pathways and transcription factors which mediate the switch between proliferation and differentiation of the stem/progenitor cells.
2. To study the process of cell competition in mammalian cells growing in culture using Lentiviruses as a tool for manipulating gene expression.

Recipient or parental organism

The recipient cells will be:
1. Human, mouse or canine cell lines including HEK 293T (human embryonic kidney); MDCL cells (Madine-Durby Canine Kidney) or other human or mouse polarized epithelial cells.
2. Mouse wildtype lung progenitor cells in primary cultures.
3. Embryonic or adult wildtype mouse lungs and trachea primary cultures.

Host/vector system

Third generation lentivirus used for ectopic expression or knock-down (siRNA) of gene expression. Replication-incompetent. Self-inactivating (SIN). Gag, pol, env and rev are encoded on three additional plasmids to minimize the risk of replication-competent virus formation by homologous recombination. Replication-incompetent. Self-inactivating (SIN). Gag, pol, env and rev are encoded on three additional plasmids to minimize the risk of replication-competent virus formation by homologous recombination. VSV G coat protein. E1-deleted adenovirus used for ectopic expression or knock-down (siRNA) of gene expression.

Origin & function

Origins:
Mouse and human DNA. Commercially available Lentiviral shRNA Pooled Libraries (pre-assembled lentiviral particles) such as:
- MISSION LentiPlex Pooled Libraries (SIGMA or Open Biosystem, based on TRC shRNA collection);
- TRIPZ Lentiviral Inducible shRNAmir Library (Open Biosystems collection).
Well characterized reporter genes, such as the jellyfish enhanced Green Fluorescent Protein (eGFP) and bacterial β-galactosidase.

Intended Functions:
1) Silencing of specific genes e.g. the Wnt inhibitor Notum expression in target cells to characterize its role in cell competition.
2) Systematic genome-wide knockdown of target genes in target cells in order to screen for novel cell competition genes.
3) Control of cell fate specification, differentiation and self-renewal of progenitor cells.

Evaluation of foreseeable effects

Potential human health hazard of the GMO (virus-modified cells growing in culture):
There is no evidence that mammalian cells in culture per se can affect the operator. In addition to the cell lines used for most of these experiments, we will be obtaining patient samples which, by their nature, will not be completely characterized. There is a very small chance that the primary human cells will be infected with a transmissible virus which was not screened for in the hospital. The consequences of a researcher contracting such an infection could be very severe. We will only grow these cells in microbiological safety cabinet in a containment level 2 laboratory to ensure that the chance of this occurring is very low. The viruses that the cells will be infected with will be self-inactivating and contain no sequences for packaging proteins. Consequently it is highly unlikely that they become infectious even in human cells.

Potential human health hazard of the inserted genetic material.
It is possible that the manipulations could increase the oncogenic potential of target cells. There is a low risk that the researcher will accidently infect themselves with the virus particles (see risk assessment).

Potential human health hazard of the vectors
The lentivirus and the adenovirus can infect human cells. They are both replication-incompetent and will not result in a transmissible infection. There is a low risk that the researcher will accidentally infect themselves with the viral vector. This could result in the researcher being exposed to the inserted genetic material (potentially oncogenic), or the lentivirus incorporating into their DNA (random insertion).
Potential human health hazard of the resulting genetically modified micro-organism. The likelihood of these genetic modifications making mammalian cells growing in culture hazardous to humans is negligible. Even if this somehow occurred, the cells are killed after completion of the experiment and do not survive out of the culture conditions.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Partially-characterized human primary cells will be used in some experiments. These will always be treated as containment level 2.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste will be inactivated by autoclave (degree of kill effectively 100% and liquid waste treated with virkon according to the manufacturer's guidelines. Autoclave is tested and certified annually, and during each run is shown to hold temperature correctly. All carcasses of mice injected with genetically-manipulated cells will be incinerated.

Project Ref 408/12.1

Date Ackn'd 02/03/2022
Silencing of specific non coding RNA or chromatin reader/modifier e.g. down regulation of the expression of the PCR2 components in target cells to characterize their role in gene regulation

Purposes of the contained use
Chromatin readers or effectors, and more recently non coding RNA, have been shown to modify the activation of certain genes, but not the sequence of DNA. Additionally, the chromatin proteins associated with DNA may be activated or silenced. This is why the differentiated cells in a multi-cellular organism express only the genes that are necessary for their own activity. Replication incompetent viruses will be used to ectopically express, or knock-down, candidate proteins or long non coding RNAs to test their ability to regulate gene expression.

Recipient or parental organism
The recipient cells will be:
Human or mouse cell lines e.g. mouse embryonic stem cells (E14, J1); colorectal carcinoma cell line (HCT116); HEK 293T (human embryonic kidney); mouse embryonic fibroblasts (MEF, NIH3T3, MRCS, WI38); mouse myoblast cell line (C2C12); breast cancer cell lines (MCF7, MDA-MB415, MDA-MB231, BT474, MCF10A, T47D); osteosarcoma lines (U2OS); lung cancer cell lines (HuH7, H1299, A549), human and mouse erythroid leukaemia cells (HEL, MEL, K562); human promyelocytic leukemia cells (HL60); Human Burkitt’s lymphoma cell line (P493-6)

Host/vector system
Lentiviral inducible shRNA silencing will use third generation lentivirus. Replication-incompetent. Self-inactivating (SIN). Gag, pol, env and rev are encoded on three additional plasmids to minimize the risk of replication-competent virus formation by homologous recombination.
Retroviral vector, based on Moloney murine leukemia virus (MMLV), will provide the viral package signal, transcription and processing elements. The viral env gene is produced by the package cell line. Transfection into a package cell line produces high-titer, replication-incompetent viruses.
Commercially available Lentiviral shRNA Pooled Libraries (pre-assembled lentiviral particles) such as:
- MISSION LentiPlex Pooled Libraries (SIGMA or Open Biosystem, based on TRC shRNA collection);
- TRIPZ Lentiviral Inducible shRNA mim Library (Open Biosystems collection).
- pMX Retroviral vector (Cell Biolabs)
- pLKO Tet On inducible vector (Addgene)

Origin & function
Origins:
Mouse and human DNA. Commercially available Lentiviral shRNA Pooled Libraries (pre-assembled lentiviral particles) such as:
- MISSION LentiPlex Pooled Libraries (SIGMA or Open Biosystem, based on TRC shRNA collection);
- TRIPZ Lentiviral Inducible shRNAmir Library (Open Biosystems collection).
- pMX Retroviral vector (Cell biolabs)
- pLKO Tet On inducible vector (Addgene)

Intended Functions:
Silencing of specific non-coding RNA or chromatin reader/modifier e.g. down regulation of the expression of the PCR2 components in target cells to characterize their role in gene regulation

Evaluation of foreseeable effects

Human health hazard identification - Identify any potentially harmful properties of:

i) The recipient micro-organism (for micro-organisms also give ACDP hazard group)
There is no evidence that mammalian cells in culture per se can affect the operator.
Also, the Replication-defective Lentiviruses that the cells will be infected with will be self-inactivating and contain no sequences for packaging proteins. Consequently it is highly unlikely that they become infectious even in human cells.
Overall Risk: Low

ii) The inserted (donated) genetic material
The inserted genetic material will knock-down the whole genome, one gene at a time. In addition in separate experiments we will knock-down specific inhibitors and modulators of Wnt signalling e.g. Notum, a Wnt signalling inhibitor expressed at high levels in some cancer cell lines. It is possible that such manipulations could be increasing the oncogenic potential of target cells.
Overall Risk: Medium

iii) The donor micro-organisms (where used/appropriate)
Not used.

iv) The vector* (see additional section below for viruses or viral vectors)
The Lentiviral transfer vector is replication incompetent. We use self-inactivating transfer vectors (with SIN 3’LTR, reducing the likelihood of RCV generation) and additionally we use 3rd generation packaging system (where the packaging sequences are divided in two separated constructs, also reducing the likelihood of RCV generation).
The Replication-defective Lentiviruses can infect human cells. However the event of operator infection is not likely. In particular no sharps will be used when handling lentiviruses so there is no risk that the researcher will accidently inject themselves with the viral vector.
Overall Risk: Low

v) The resulting genetically modified micro-organism
The likelihood of genetic modifications generating cell lines in culture that are hazardous to humans is negligible. In addition cells do not survive out of the liquid culture media.
Overall Risk: Effectively Zero
i) The recipient micro-organism
The cells are not hazardous and they will not survive outside the culture conditions.
Overall Risk: Effectively Zero

ii) The inserted (donated) genetic material
Since the viruses are replication defective they cannot spread between cells and animals and the consequence is therefore low.
Overall Risk: Effectively Zero

iii) The donor micro-organisms (where used/appropriate)
Not used.

iv) The vector* (see additional section below for viruses or viral vectors)
There is the risk that one of the genes silenced can result in an oncogenic effect for the target cell. If they escaped into the environment, the viruses would not survive for more than a matter of minutes. In principle, the viruses could infect mammalian cells and cause a cancer. However, no live animals are within the immediate environment of the experiments. Therefore, the probability of this occurring is incredibly low. The viruses cannot replicate and spread to other cells and they are therefore unlikely to cause any noticeable adverse effect for the environment.
Overall Risk: Effectively Zero

v) The resulting genetically modified micro-organism
The likelihood of genetic modification that make tumour cell lines in culture hazardous for environment is negligible, and even if this happened the cells are killed after completion of the experiment and they do not survive out of the culture media.
Overall Risk: Effectively Zero

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Every cell line will always be treated as containment level 2

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All waste that has been in contact with the Lentiviruses/Retroviruses or modified cells will be inactivated using standard laboratory measures (autoclaving material, using virkon inactivation for liquid). No sharps will be used when handling lentiviruses/retroviruses. Each researcher will receive individual training and this will be documented.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

The recipient cells will be:
1. Mouse, human and monkey, including HEK 293T (human embryonic kidney); MDCK cells (Madine-Durby Canine Kidney) or other human or mouse germ cells
2. Mouse or human embryonic stem cells or progenitor cells, including neuronal progenitor cells and primary embryonic fibroblasts.

**Host/vector system**

expression. Replication-incompetent. Self-inactivating (SIN). Gag, pol, env and rev are encoded on three additional plasmids to minimize the risk of replication-competent virus formation by homologous recombination. Self-inactivating (SIN).

Retroviral vector used for ectopic expression of transcription factors. The vector, based on Moloney murine leukemia virus (MMLV), will provide the viral package signal, transcription and processing elements. The viral Gag, pol, env gene is produced by the package cell line. Transfection into a package cell line produces high-titer, replication-incompetent viruses.

**Origin & function**

Origins:
Mouse and human DNA. Commercially available Lentiviral shRNA Pooled Libraries (pre-assembled lentiviral particles) such as:
- MISSION LentiPlex Pooled Libraries (SIGMA or Open Biosystem, based on TRC shRNA collection);
- TRIPZ Lentiviral Inducible shRNAmir Library (Open Biosystems collection).

Well-characterized reporter genes, such as the jellyfish enhanced Green Fluorescent Protein (eGFP) and bacterial β-galactosidase.

Intended Functions:
1) Expression or silencing of specific genes, for example of the key determinants of PGC specification, Prdm1, Tcfap2c, Prdm14 and Oct4 to induce PGC fate.
2) Systematic genome-wide knockdown of target genes in target cells in order to screen for novel genes regulating germ cell specification and their properties.
3) Control of cell fate specification, differentiation and self-renewal of progenitor cells.

**Evaluation of foreseeable effects**

Potential human health hazard of the GMO (virus-modified cells growing in culture):
There is no evidence that mammalian cells in culture per se can affect the operator. In addition to the cell lines used for most of these experiments, we may use established human progenitor cells and human induced pluripotent cells. There is a very small chance that the human cells will be infected with a transmissible virus which was not screened for in the human cells. The viruses that the cells will be infected with will be self-inactivating and contain no sequences for packaging proteins. Consequently it is highly unlikely that they become infectious even in human cells.

Potential human health hazard of the inserted genetic material.
It is possible that the manipulations could increase the oncogenic potential of target cells. There is a very low risk that the researcher will accidentally infect themselves with the virus particles (see risk assessment).

Potential human health hazard of the vectors
The lentivirus, retrovirus and adenovirus can infect human cells. They are replication-incompetent and will not result in a transmissible infection. There is a low risk that the researcher will accidentally infect themselves with the viral vector. This could result in the researcher being exposed to the inserted genetic material (potentially oncogenic), or the lentivirus incorporating into their DNA (random insertion).

Potential human health hazard of the resulting genetically modified micro-organism.
The likelihood of these genetic modifications making mammalian cells growing in culture hazardous to humans is negligible. Even if this somehow occurred, the cells are killed after completion of the experiment and do not survive out of the culture conditions.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
Partially-characterized human induced pluripotent cells and established progenitor cells will be used in some experiments. Primary cells if included in the experiments will be treated as containment level 2.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste will be inactivated by autoclave (degree of kill effectively 100%) and liquid waste treated with virkon according to the manufacturer’s guidelines. Autoclave is tested and certified annually, and during each run is shown to hold temperature correctly.

All carcasses of mice injected with genetically-manipulated cells will be incinerated.

Project Ref 408/15.1

Date Ackn’d 01/04/2015

CU2 Project Title Expansion, genetic modification and generation of stable knockout human-derived cell lines

Date Project Ceased 02/03/2022

Class 2

Consent Granted
**Project Additional Information**

**Purposes of the contained use**

1- Generation of human cell lines and mouse embryonic stem cells stably expressing the Cas9 nuclease to allow the generation of single-knockout cells clones. The aim of the project is to identify novel genes involved in DNA damage response and repair, and the prevention of chromosomal translocation, a hallmark of many cancers.

2- Generation of 3D-cultures for epithelial-derived cancers and epithelial-derived diseases, and generation of mutation, knockout and knock-in alleles. The aim of the project is to investigate further the function of genes involved in cancer formation and development.

**Recipient or parental organism**

The recipient cells will be:

1- Human and mouse cell lines including HEK 293T (human embryonic kidney); HepG2 (human hepatocellular carcinoma), HeLa cells, U2OS (Human osteosarcoma cells), RPE-1 (human immortalised epithelial retina cells), HAP1 (human near-haploid cells), E14TG2a (mouse embryonic stem cells)

2- Human cells in primary cultures expanded in culture

**Host/vector system**

1- CRISPR plasmids (such as pSpCas9n-2A-GFP and pSpCas9-2A-GFP)

2- Second and third generation adenovirus, E1- and E3-deleted; E2 gene inactivated, further reducing the possibility of RCA generation

5- Second generation retrovirus. Replication incompetent. Self-inactivating
(SIN). 5'-LTR deleted. Gag, pol, env and rev are encoded on two additional plasmids to minimise the risk of replication-competent virus formation by homologous recombination. VSV-G coat protein
6- Adeno-associated virus
7- Sendai virus

Origin & function

Origins:
- bacterial Cas9 nuclease
- human and murine single-guide RNA (sgRNA)
- human DNA
- I-SceI (yeast endonuclease)
- Well-characterised reporter genes such as eGFP (jellyfish enhanced Green Fluorescent Protein), HA-tag (Human influenza hemagglutinin tag) or LacZ (bacterial ß-galactosidase)

Intended functions:
- Knocking down specific genes involved in cancer formation or tissue regeneration
- Systematic genome-wide knockdown of target genes in target cells in order to screen for novel interactors
- Systematic genome-wide knockdown and knock-out of target genes involved in preventing chromosomal translocation

Evaluation of foreseeable effects

Potential human health hazard of the GMO (genetically modified cells growing in cultures)
There is no evidence that mammalian cells in culture per se can affect the operator. However, in addition to cell lines of known safe history, human cells from patients will be used. Transplant donors will be screened for (at least) hepatitis B and C, HIV, Cytomegalovirus, Epstein-Barr virus, Toxoplasma and Syphilis. However patient samples will not be fully characterised and there is a very small chance that the primary human cells will be infected with a transmissible virus. The consequence of a researcher contracting such infection could be very severe. Such cells will only be grown at containment level 2 to ensure that the chance of this occurring is very low.

Potential human health hazard of the inserted genetic material
It is possible that the genetic manipulation could increase the oncogenic potential of target cells. There is a low risk that the researcher will accidently infect themselves with the virus particles (see risk assessment).

Potential human health hazard of vectors
Lentivirus and adenovirus can infect human cells. They are both replication-incompetent and will not result in transmissible infection. There is a very low risk that the researcher will accidently infect themselves with the viral vector. This could result in the researcher being exposed to the inserted genetic material (potentially oncogenic) or the lentivirus incorporating into their DNA
Also, one of the lentiviral vector used (pRRL sEF1a HA.NLS.Sce(opt).T2A.IFP) contains Woodchuck hepatitis Post-transcriptional Regulatory Element (WPRE) to enhance transgene expression. This element may be capable of expressing part of the X protein of WHV, which has potential oncogenic properties.

Potential human health hazard of the resulting GMO
The viruses that the cells will be infected with will be self-inactivating and contain no sequences for packaging proteins. Consequently it is highly unlikely that they become infectious even in human cells.

The likelihood of the genetic modifications making mammalian cells growing in culture more hazardous is negligible. Even if this somehow occurred, the cells are killed after completion of the experiment and do not survive outside the culture conditions.

Partially characterised human tissues and primary cells will be used in some experiments. These will always been handled at containment level 2.

Date of Significant Change
# Project Additional Information

## Purposes of the contained use

1) Reprogram somatic patient-derived cell lines for study using our cortical differentiation model
2) Human stem cell models of cerebral cortex development and disease. The aims of this project are to:
   1. Carry out lineage analysis and live imaging of single human and non-human primate neural progenitor cells, using GFP-expressing lentiviruses
   2. Express, using lentiviruses, different gene products to study their effects on neurogenesis and neurodegeneration.
   3. Express, using a single lentivirus construct, the Cas9 nuclease together with libraries of genespecific guide RNAs

## Recipient or parental organism

The recipient cells will be:
1) human fibroblast cell lines generated from patient skin biopsies
2) human and mouse cell lines: HEK 293T, human fibroblasts, human pluripotent stem cells, human neural stem cells, neurons and glial cells derived from pluripotent stem cells

## Host/vector system

1) modified, non-transmissible forms of mouse Sendai Virus (SeV) with Fusion protein deleted rendering the virus incapable of producing infectious particles (such as CytoTune-IPS 2.0 kit from ThermoFisher)
2) 3rd generation, replication-incompetent, self-inactivating lentiviruses, containing different promoter sequences and wild-type WPRE: pBOB and pLenti backbones, with CMV, synapsin1, EF1-alpha or PGK promoters; lentiCRISPRv2, with the human U6 promoter, the EFS-NS promoter and wild-type WPRE

## Origin & function

- Origins:
  - human genes (transcription factors Oct4, Sox2, Klf4 and c-Myc and genes involved in neurogenesis and neurodegeneration)
  - bacterial Cas9 nuclease
  - human and murine single-guide RNA (sgRNA)
  - Well-characterised reporter genes such as GFP (jellyfish Green Fluorescent Protein)
- Intended functions:
  - Expressing the transcription factors Oct4, Sox2, Klf4 and c-Myc in differentiated cell types, resulting in the effected cell reverting to an embryonic stem cell-like pluripotent state.
  - Expressing and/or knocking down specific genes involved in neurogenesis
Evaluation of foreseeable effects

Hazards to human health:
1) Sendai virus is ACDP class 1 organism and is a murine parainfluenza virus that is non-pathogenic to humans, yet genetically modified sendai viral vectors can transduce human and animal cells.

The Sendai virus in the CytoTune 2.0 kit is non transmittable, replication incompetent, and will not integrate into the genome: since Sendai virus is an RNA virus, it does not need to enter the nucleus for transcription. Sendai virus requires no integration for viral proteins to be made in the host cell. This eliminates the possibility of integration of the transgenes into the host genome and alteration of the host genome. As it is replication-incompetent, the virus is cleared from the reprogrammed cells by proliferation/passaging. The host cell can be cleared of the vectors and encoded genes thanks to the cytoplasmic nature of SeV: also functional temperature sensitive mutations have been introduced into the key viral proteins to aid clearance of the virus from the cytoplasm in culture.

Although the virus is replication incompetent, the encoded transgenes (Yamanaka reprogramming factors, c-Myc, Klf4, Oct3/4 and Sox2) could result in a short term expression of a potentially oncogenic gene within the infected cell. However only cells that come in direct contact with the packaged virus could become infected.

2) The lentiviral transfer vectors pBOB and lentiCRISPR v2 are replication incompetent and self-inactivating. The use of a 3rd generation packaging system (where the packaging sequences are divided in two separated constructs, reducing the likelihood of RCV generation), which obviates the need to include the Tat gene/protein, increases the safety of this system yet further. pBOB contains wild-type WPRE which is suspected to express part of the X protein which may have oncogenic properties; it is used due to necessity for robust expression in neural cells.

The replication-defective lentiviruses can infect human cells. However the event of operator infection is not likely. In particular no sharps will be used when handling lentiviruses so there is no risk that the researcher will accidently inject themselves with the viral vector.

Hazard to the environment:
1) Wild-type SeV is highly contagious in host species (i.e. rodents), but the infection does not persist in immunocompetent animals. However, as the virus does not survive for more than 3 hours outside of the host cells and culture conditions, the risk of infecting and causing disease in animals is negligible. In addition, in the extremely improbable event that an animal was infected with modified, non-transmissible SeV, it would not be able to spread beyond the infected cell as the virus lacks the Fusion protein.

The likelihood of genetic modifications generating cell lines in culture that are
hazardous to the environment is negligible. In addition cells do not survive out of the liquid culture media. Since SeV does not integrate into the host genome and remains in the cytoplasm, there is no risk of insertional mutagenesis. Also, the host cell can be cleared of the vectors and encoded genes thanks to the cytoplasmic nature of SeV; plus functional temperature sensitive mutations introduced into the key viral proteins.

2) The viruses cannot replicate and spread to other cells and are therefore very unlikely to cause any adverse effects. The likelihood of genetic modifications generating cell lines in culture that are hazardous to humans is negligible. In addition cells do not survive out of the liquid culture media.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

To minimize any possible aerosol effects of the viral stocks, appropriately capped centrifuge bottles and screw-capped tubes will be used. Tubes will be centrifuged in capped buckets and the buckets will be opened in a MSC Class II.

Solid waste will be inactivated in Anistel (or other approved disinfectant) before autoclaving (degree of kill effectively 100%). Autoclave is tested and certified annually, and during each run is shown to hold temperature correctly.

Liquid waste will be treated with Anistel, Virkon or other approved disinfectant, according to the manufacturer's guidelines.

No sharps will be used when handling viruses. Virus will be used at containment Level 2 in a Class II biological safety cabinet, and with appropriate personal safety equipment to prevent mucosal exposure/splash (gloves, lab coat and safety specs).

All work surfaces will be wiped with Anistel 1% (or other approved disinfectant, according to the manufacturer guidelines).

Project Ref 408/17.1

Date Ackn’d: 16/03/2017

CU2 Project Title

Investigating the molecular function of RNA-modifying enzymes in normal regulatory processes and in cancer

Class: Class 2

CultureVolClass2: < 1 Litre

CultureVolumeClass3-4

Non-GMM: Consent Granted

Project notified under transitional arrangements: N

Withdrawn: N

Tick if notifying a connected programme of work: N

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

Project Additional Information

Purposes of the contained use

To use the CRISPR-Cas9 system in human cell lines in order to investigate the molecular function of RNA-modifying enzymes, especially terminal uridyl transferases, such as TUT4 and TUT7.

Recipient or parental organism

Mammalian cell lines (such as OV-90, PA-1, DU-145, H1299, A549, MCF-7, ...
### Host/vector system

3rd generation lentivirus, replication-incompetent, self-inactivating such as lentiCRISPRv2
helper vectors such as pMD2.G and psPAX2

### Origin & function

**Origins:**
- bacterial Cas9 nuclease
- human single-guide RNA (sgRNA)
- Well-characterised reporter genes such as GFP (jellyfish Green Fluorescent Protein)
- involved Fluorescent Protein)

**Intended functions:**
- Knocking down specific genes encoding for RNA-modifying enzymes

### Evaluation of foreseeable effects

**Hazard to human health:**
The lentiviral vector lentiCRISPR v2 is a 3rd generation system, where the packaging system is split into two plasmids (one encodes Rev and the other encodes Gag and Pol). Tat is eliminated in the 3rd generation system that makes it safer. lentiCRISPR v2 is replication incompetent and self-inactivating as it incorporates a SIN system. Replication-incompetent lentiviruses can infect human cells, however the risk is very low as no sharps will be used when handling lentiviruses.
lentiCRISPR v2 contains a mutated version of WPRE (mut6, see Zanta-Boussif et al, 2009, Gene Therapy 16, 605-619). mut6-WPRE cannot express part of the protein X, therefore doesn't present a risk to human health.
The inserted genetic material is in itself harmless. However, the Cas9 nuclease and the sgRNAs are both carried by the lentiviral vector and the targeted genes may have oncogenic properties. In the unlikely event of infection, there is a small risk of harm.
The likelihood of genetic modifications generating cell lines in culture that are hazardous to human health is negligible. In addition cells do not survive out of the liquid culture media.

**Hazard to the environment:**
The lentivirus cannot replicate and spread to other cells and is therefore very unlikely to cause any adverse effects.
The likelihood of genetic modifications generating cell lines in culture that are hazardous to the environment is negligible. In addition cells do not survive out of the liquid culture media.

02/03/2022
We can generate human and non-human primate cerebral organoids containing cortical neurons from pluripotent stem cells (PSCs). This process consists of a number of distinct steps, including the directed differentiation of PSCs to form a complex population of cortical stem and progenitor cells and an extended period of cortical neurogenesis. Importantly, this system reproduces the diversity of cortical projection neurons found in vivo. The two aims of this project are to:

1. Carry out lineage analysis in organoids of single human and non-human primate neural progenitor cells, using GFP-expressing lentiviruses
2. Express or knock down/out, using lentiviruses, different gene products to study their effects on neurogenesis and neurodegeneration.

Wild-type cerebral organoids generated from well-characterised ESCs and iPSCs lines (Human, Chimp, Bonobo, Gorilla, Macaque) – e.g. already used in published work (Shi et al., 2012; Otani et al., 2016)

Third generation, replication-incompetent, self-inactivating lentiviruses, containing different promoter sequences and wild-type WPRE. Backbones: pBOB, pLB, pLKO.1, lentiCRISPRv2 and pLenti backbones

Promoters: CMV, synapsin1, EF1-alpha, U6, PGK, or EFS-NS
Expression of fluorescent protein (FPs) such as GFP or combination of several FPs, such as BFP, GFP, mRuby2. FPs may be fused to genes encoding factors affecting neural progenitor temporal identity or proliferation. Alternatively FPs might be expressed in combination with siRNAs or gRNAs and Cas9 protein aiming to knock down or knock out genes involved in neural progenitor and neuronal biology.

Origin & function

Hazard to human health:
Lentiviral transfer vectors such as pBOB and lentiCRISPR v2 are replication incompetent and self-inactivating. They are 3rd generation systems where the packaging system is split so to limit the risk of RCV generation. They contain wild-type WPRE which is suspected to express part of the X protein which may have oncogenic properties; it is used due to necessity for robust expression in neural cells. The replication-defective lentiviruses can infect human cells. However the event of operator infection is not likely. A small volume (1-2ul) of diluted suspension of lentivirus (estimated 7x10^4 TU/ml) is loaded in a glass micropipette for the injection of organoids. These glass micropipettes are extremely fragile and cannot easily puncture gloves. The risk of infection is therefore negligible.

Hazard to the environment:
The viruses cannot replicate and spread to other cells and are therefore very unlikely to cause any adverse effects. The likelihood of genetic modifications generating organoids in culture that are hazardous to the environment is negligible. In addition they do not survive out of the liquid culture media.

Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste will be inactivated in Anistel (or other approved disinfectant according to manufacturer's instructions) before autoclaving (degree of kill effectively 100%). Autoclave is tested and certified annually, and during each run is shown to hold temperature correctly.
Liquid waste will be treated with Anistel, Virkon or other approved disinfectant, according to the manufacturer's guidelines.
No sharps else than the glass micropipettes will be used when handling viruses. Virus will be used at containment Level 2 in a Class II biological safety cabinet, and with appropriate personal safety equipment to prevent mucosal exposure/splash (gloves, lab coat and safety specs).
All work surfaces will be wiped with Anistel 1%.

### Project Additional Information

#### Purposes of the contained use

During replication, the RNA-genome of Zika virus undergoes cyclisation by base pairing regions in the 5'UTR with corresponding regions in the 3'UTR. One of these regions is called Cyclisation sequence (5'CS and 3'CS). We have recently identified a few candidate host genes involved in the life cycle of Zika virus possibly by affecting the virus genomic cyclisation process. We wish to further characterise the role of these candidate genes by:

1. Deleting these genes in the host cells by CRISPR, and testing the ability of Zika virus to replicate in the knockout cells.
2. Introducing mutations in the genomic-RNA of Zika virus and testing the virus interaction with the candidate host genes.

#### Recipient or parental organism

- Commercial human cell lines such as JEG3, RPE1, Vero
- Commercial Aedes mosquito cell lines such as C6/36 or Aag-2
- Commercial human and mosquito cell lines such as JEG3, RPE1 or Aag2 modified using the CRISPR-Cas9 technology

#### Host/vector system

- Plasmids and 3rd generation lentiviral vectors for CRISPR-Cas9 editing of cells
- pACNR-based plasmids for modified positive strand Zika RNA

#### Origin & function

1. CRISPR-Cas9 is expected to knock-out selected genes in the target cells. In most cases, gene editing will have minimal effect on the biology of the cells or it may negatively impact their growth in culture.
2. Modified positive strand RNA Zika genome capable of infecting tissue culture cells; they will not be more pathogenic than the wild-type virus.
   - 5'-CS-M: A strain with 3 point mutations in the 5'CS that attenuate the basepairing ability of the 5'UTR and 3'UTR of the virus and hence severely reduces the ability of the Zika virus to replicate inside cells (relative replication efficiency 0.02 +/- 0.002)
   - 5'-CS-M + 3'-CS-M: A strain that contain the 3 point mutations mentioned above, plus 3 point mutations in the 3'CS that rescue the base-pairing ability of the 5'UTR and 3'UTR of the virus and hence partially-rescues the ability of the virus to replicate inside cells (relative replication efficiency 40.15 +/- 1.67) (see Liu et al, 2017, J. Virol. doi: 10.1128/JVI.00484-17)
   - Additional Zika strains with point mutations that are expected to reduce the pathogenicity of the virus
The Zika virus strain that contains a luciferase reporter gene. This strain is not more pathogenic than the wildtype virus.

- Zika virus with a mutated non-functional RNA polymerase. This strain cannot replicate inside its host and its pathogenicity is severely reduced.

**Evaluation of foreseeable effects**

**Hazard to human health:**
recipient and resulting GM micro-organisms and cells:
E.coli ACDP 1 and well-characterised commercial cell lines with a long history of safe use are not hazardous. Resulting cells are not fitter nor pathogenic than the recipient cells.

inserted (donated) genetic material:
1) CRISPR-Cas9: the inserted genetic material is in itself harmless. However the Cas9 nuclease and the sgRNAs are both carried by the lentiviral vector and the targeted genes may have oncogenic properties. In the unlikely event of infection, there is a small risk of harm.

2) Mutated Zika viruses have a similar or decreased pathogenicity.

vectors:
The lentiviral vector lentiCRISPR v2 is a 3rd generation system where the packaging is split into two plasmids (one encode Rev and the other encodes Gag and Pol). Tat is eliminated in the 3rd generation system that makes it safer. lentiCRISPR v2 is replication incompetent and self-inactivating as it incorporates a SIN system. Replication-incompetent lentiviruses can infect human cells however the risk is very low as no sharps will be used.

lentiCRISPR v2 contains a mutated version of WPRE (mut6, see Zanta-Boussif et al, 2009, Gene Therapy 16, 605-619); it has been suggested that WT WPRE (Woodchuck Hepatitis Post-transcriptional Regulatory Element) expresses a truncated X-protein that may have oncogenic properties. Mut6-WPRE cannot express part of the protein X, therefore doesn't present a risk to human health.

pACNR-based plasmids are not mobilisable. They carry modified positive strand Zika RNA genomes; Zika virus is ACDP 2. The plasmids are not infectious as they require in vitro transcription. Also they cannot cross cell membranes and will not produce any viruses. The replication of the modified Zika viruses is reduced and the pathogenicity is not greater than the pathogenicity of WT Zika virus.

No sharps will be used.

**Hazard to the environment:**
The cells and E. coli strains (recipients and resulting GMs) cannot survive outside lab culture conditions. Also, disinfection procedures prevent them to reach the environment.

The products of the inserted genetic material will not be detrimental to fauna or flora.

The lentiviral vectors cannot replicate and spread to other cells and are therefore very unlikely to cause any adverse effects.

There is a potential for Zika virus to infect mosquitoes Aedes aegypti and...
Aedes albopictus, but these are not native species in the UK.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste is inactivated using either chemical treatment (Anistel or approved disinfectant) according to the manufacturer’s validated conditions. Solid waste is inactivated by autoclaving using validated and recorded temperature cycles.

Project Ref  408/19.1

Date Ackn’d  16/01/2019  
CU2 Project Title  Applying CRISPR/Cas9 genome editing and lentiviral gene delivery to study cancer  
Class  2  
CultureVol  ≤ 1 litre
Bacteria-derived CRISPR/Cas systems have recently been applied as novel tools to introduce site-specific double strand breaks (DSBs) in mammalian cells. When the DSB sites are repaired by nonhomologous end joining, small insertions/deletions are often introduced into the sites: hence, null mutations can be introduced into target genes. The CRISPR/Cas system consists of two components: Cas9 endonuclease and guide RNA (gRNA) molecules. Both elements can be expressed from separate transgenes transiently or constitutively. In this project, we use retro/lentivirus as a vector for delivering Cas9 and gRNA expression cassettes to target cells. The goal is to develop and utilize retro/lentiviral vectors for CRISPR/Cas9-based genome editing including the performance of genomewide genetic screens and the targeted disruption of genes of interest for mechanistic and translational studies.

In addition, we will use retro/lentiviral vectors for delivery of putative oncogenes or tumour suppressors (TS) into mammalian cells under the control of constitutive or inducible promoters. This will allow us to assess their oncogenic/TS potential in desirable cellular and genetic context.

**Recipient or parental organism**

- Mouse ES cells: AB1, AB2.2, JM8, R1, v6.5, KY1.1 and their derivative lines.
- Human ES cells: H1, H9, Shef lines and their derivative lines.
- Human iPS cells: Pathogen-negative hiPSC lines derived from various donor/somatic cells.
- Primary mouse cells from transgenic or wild type mice.
- Mouse and human cell lines and their derivative lines.
- Cell lines for virus production (PlatE for ecotropic retrovirus production, 293T for amphotropic retrovirus and lentivirus production)

**Host/vector system**

Specify plasmids, viral and cellular vectors etc to be used for delivery into
host (remember, these can also be genetically modified and be considered as resultant GMMs)

<Retroviral vector>
Mouse Moloney leukaemia virus-derived retroviral vector (e.g., pRetrox, pBabe, pMSCV)
Packaging plasmid mix for amphotropic retrovirus production (Clontech Retro-X system or equivalent)

<Lentiviral vector>
3rd generation lentiviral vectors (Invitrogen pLenti 7) and its derivatives (pLenti-CMV/TO Hygro DEST, Addgene #17291) and pHIV-ZsGreen (derivative of pSico, Addgene #11586).
4th generation lentiviral vectors (Clontech pLVX).
Packaging Mix for 3rd generation vectors such as Invitrogen ViraPower Lentiviral Packaging Mix)
Packaging Mix for 4th generation vectors such as Clontech Lenti-X packaging mix or Invitrogen ViraPower.

Origin & function

drug resistant markers (neo, puro, puro-lk, hyg, zeo, bsd)
fluorescent proteins (GFP, zsGreen, mCherry, dsRed, mRFP, mTagBFP, CFP, Venus, YFP, tagRFP657)
Cas9 endonuclease
CRISPR guide RNAs: 20-nt sequences fused with guide RNA scaffold sequences
Integration and expression (constitutive or inducible) of ORFs (wild type or tagged) of putative oncogenes and tumour suppressors.

Evaluation of foreseeable effects

Hazard to health:
Fluorescent proteins and Drug selection markers are active in humans. Transgenic animals (including monkeys) expressing fluorescent proteins and/or drug selection markers have been generated and appear to be healthy. There is no evidence to suggest a harmful effect.
CRISPR guide-RNA and Cas9 endonuclease: When both elements are coexpressed in the same cells, they form complexes and induce double strand breaks at the genomic sites that match 20-nt guiding sequences – active in humans. CRISPR guide RNAs and the Cas9 protein themselves are not harmful. Moreover, mouse guide RNAs are designed not to match the human genome to avoid targeting in the very unlikely case of researcher infection with the viral vectors.
Any of these genes are not directly oncogenic. However, when guide RNAs target, for example, tumour suppressor genes, the genes can be inactivated and this may eventually cause tumour formation.
Similarly, when human ORFs are overexpressed they might potentially have oncogenic or tumour suppressive function based on the genetic and cellular
context. These might eventually cause tumour formation however, since
development of fully blown tumour requires acquisition of multiple genetic
lesions this is highly unlikely.

Hazard to environment:
Any inserts are not directly hazardous. However, when guide RNA and Cas9
proteins are co-expressed in the same cells, they form complexes and can
induce double strand breaks at target sites. This may be hazardous to the
recipient cells/organism but not to the environment (as onward infection
cannot occur). Same applies for overexpression of genes with potentially
oncogenic or tumour suppressive function that could be potentially deleterious
for the recipient cells/organism.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid wastewill be inactivated by autoclaving (degree of kill effectively 100%) and liquid waste will be
treated with Distel or other approved disinfectant according to the manufacturer's instructions.
Autoclave is tested and certified annually and during each run is shown to hold temperature correctly.
Contingency plan: Backup autoclave in the building and in the adjacent department.

### Purposes of the contained use

**Specific Objectives**

1. Modify recipient mammalian cell lines (including previously generated OCRL KO Lowe syndrome disease models) to carry Cas9 using a lentiviral expression system
2. Screen target genes of interest using commercially available gRNA vectors that will be transduced into the Cas9 modified cells using the lentiviral expression system

**Recipient or parental organism**

To generate the Lentivirus - HEK293T-LentiX
To be transfected with Cas9 and gRNA vectors - Mammalian cell lines, including:
- Unmodified immortalised RPE-1 (Human retinal pigmented epithelial) cells
- These RPE-1 cells modified for OCRL KO
- Unmodified immortalised HK2 (Human Kidney) cells
- These HK2 cells modified for OCRL KO

**Host/vector system**

For viral packaging in HEK293-T-LentiX:
- Third generation lentivirus (self-inactivating, replication incompetent)
- Packaging Vectors: pRSV-Rev (rev element), pRRE (gag/pol elements)
- Envelope vector: pMD2.G

Expression Vectors (packaged in HEK293-T-LentiX, delivered to model cell lines by lentiviral infection)
- Cas9
- Commercially available gRNA target plasmids for each gene of interest (e.g., Dharmacon Edit-R sgRNA or Transomic transEDIT-dual CRISPR)

**Origin & function**

Transfection of HEK293T-LentiX cells with viral packaging and Cas9 or gRNA expression vectors will allow the HEK293T-LentiX cells to generate Lentivirus for later use in target model cell lines. Viral infection of model cell lines with Cas9 will allow gRNA plasmids later transfected in to be processed and KO target genes of interest, while infection of model cell lines with gRNA target vectors will allow KO of specified target genes of interest in each Cas9 modified model system via the CRISPR/Cas9 pathway. They will also allow resistance to puromycin, geneticin or blasticidin, for the purpose of positively screening integrations. The inserted sequences themselves will integrate randomly and thus not target specific sequences in the genome. None of these inserted sequences have any potential oncogenic activity.

**Evaluation of foreseeable effects**

**Hazard to health:**
Recipient cells: The mammalian cell lines to be used are non-hazardous and will not survive outside of cell culture conditions.

Inserted genetic material: There is a small chance a researcher may be exposed and accidently infect themselves with the viral vector, however the genetic material is harmless. Neither the Cas9 nor sgRNAs would cause harm separately as editing only occurs in lines which have both at the same time. Additionally, given genome integration is not targeted, but random, there is a low risk of any insertional mutagenesis in tumour suppressor genes. However, as some of the genes targeted for knock-out are oncogenes, in the unlikely event of infection, there is a small risk of harm.

**Vector:**
The lentivirus that will be used to infect cells are replication incompetent, and contain no sequences for packaging or envelope proteins, therefore making them incapable of infected a recipient cell more than once. Thus, they will not be able to cause a transmissible infection. As they are using a 3rd generation system, four plasmids (rather than three) are required to be co-transfected into the same cell to generate viral particles, and the tat protein, which is essential for wild type retroviruses to replicate is completely absent from the system, making the protocol even safer. This makes the risk of infection to the user or colleagues extremely low, even during the production of the lentivirus when working according to biosafety conditions. Though there is a low risk that a researcher could accidently infect themselves, it is unlikely that they will be exposed to the inserted genetic material or the lentiviruses; no sharps will be used, so the risk of the researcher accidently injecting themselves with viral particles is negligible.

The commercial gRNAs, including those from Dharmacon and Transomic contain the Woodchuck hepatitis posttranslational regulatory element (WPRE), and so may be able to express part of protein X from the WHV. Several publications have suggested that truncated forms of these X proteins may have oncogenic properties, which while the virus could not replicate, could be inserted and result in a potentially oncogenic mutation. The Cas9 construct contains the mutated mut6 version of WPRE that cannot express part of protein X and thus presents no risk to public health.

**Resulting GM cells:**
Any risk that the resulting modified human cell lines would be hazardous to humans is negligible, and in the
extremely unlikely event that it happened, they would be unable to survive outside of culture conditions.

Hazard to the environment:
The mammalian cell lines to be used are non-hazardous and will not survive outside of cell culture conditions.
The inserted genetic material is not hazardous to the environment.
The vector viruses are replication incompetent and thus extremely unlikely to cause any adverse effects, they cannot spread to animals.
The resulting genetically modified cells: there is negligible risk that the genetic modifications would make the human model cell lines hazardous to the environment, and even if so they could not survive outside of culture conditions.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

02/03/2022
RNA-modifying enzymes might play important roles in maintaining structure and stability of mitochondria RNAs, enabling efficient, accurate and dynamic protein synthesis in mitochondria. Defects in mitochondrial RNA modifications, arising from either mt-DNA mutations or mutations in nuclear-encoded mitochondrial modification enzymes, are associated with multiple mitochondrial diseases, the molecular mechanisms of action still remain poorly understood.

In this study, we propose to characterise NSUN2-mitochondria interdependence and investigate the biology of NSUN2 mediated m5C RNA modifications in mitochondrial translation and crucial mitochondrial functions for cell survival by utilizing CRISPR-Cas9 system and generating stable knockouts. We will also generate rescue mutants by using lentiviral based integration of the gene in KO mutants to further characterize the role of NSUN2. We will be studying the loss-of-function mutants (knockouts) and rescue of these mutants to understand its biological functions in mitochondrial physiology and human cancers.

Human tissue culture cells (such as U-2OS, lung cancer cell line such as PC_14, NCI-H358 etc.)

3rd generation lentivirus system
VB190206-1038ate (Vector builder)
**lentiCRISPRv2** (Addgene #52961)  
**pMD2.G** (Addgene #12259)  
**psPAX2** (Addgene #12260)

### Origin & function

Loss of function of the targeted gene – The gene is involved in regulating stress response which could be mediated via mitochondria. Mutation in this gene is not lethal but renders the cell sensitive to stress.

### Evaluation of foreseeable effects

**Hazard to Health:**
The cell lines are commercial cell lines with a long history of safe use. They cannot survive outside lab culture conditions. The GM cells are not fitter and/or more pathogenic than the recipient cell lines. In addition they cannot survive outside lab culture conditions.  
There is a low risk of accidental infection with the viral vector however the inserted gene (CRISPR-Cas9) doesn’t encode for a product with potentially harmful biological activity. Cas9 and the sgRNA are carried on the same plasmid however the targeted genes do not have harmful effects.  
The system is a 3rd generation system, the packaging system is split so to limit the risk of replication-competent virus; there is no requirement for Tat, which is essential for WT viruses. The lentivirus is replication-incompetent and self-inactivating, they cannot infect more than one cell. Any accidental infection would not be a transmissible infection.  
The vector is pseudotyped and the envelope plasmid encodes for VSV-G, giving the lentiviral vector a broad host-cell range rather than limiting the infection to cells expressing CD4 on their surface (as would be the case with wild-type HIV).  
The vector VB190206-1038ate used for the rescue experiment contains the WT WPRE that is capable of expressing part of the X protein of the Woodchuck Hepatitis Virus, which may have oncogenic properties, work using this vector must be done at CL2.  
The lentiCRISPRv2 vector contains the mut-6 mutated version of WPRE, that cannot express part of the protein X of the Woodchuck Hepatitis Virus, therefore doesn’t present a risk to human health. Work using this vector can be assigned to Class 1 and can be done at Containment Level 1.  
The fact that lab coat, gloves and safety specs are worn, and that no sharps are used when handling lentiviral vectors reduces further the risk of accidental injection. Also, only small amounts of lentivirus are handled at a time.  
**Hazard to Environment:**
WT and GM mammalian cells cannot infect or colonise animals and plants and they cannot survive outside lab culture conditions.  
The product of the inserted gene is not detrimental for natural flora and fauna.
The viruses are replication-incompetent and therefore unlikely to cause any harm to the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste will be inactivated by autoclave (degree of kill effectively 100%) and liquid waste treated with 1% Distel for 30 minutes (or other approved disinfectant according to manufacturer’s guidelines). Autoclave is tested and certified annually, and each run is shown to reach and hold temperature correctly (134 degrees C for 3 minutes). Contingency plan: waste autoclave available in the adjacent building.

Project Ref 408/20.1
Work in the lab will be split across two areas: (1) characterisation of the mechanism of Human Silencing Hub (HUSH)-mediated repression of endogenous target genes and repetitive elements; and (2) exploiting fluorescent reporter lines for different types of chromatin to characterise epigenetic pathways.

(1) HUSH: We will (i) clone individual genes encoding HUSH complex subunits into expression vectors, and deliver them to relevant cultured host cells; (ii) knockout HUSH complex components using CRISPR/Cas9 in host cells, and (iii) re-introduce either wild-type or mutant versions of HUSH subunits in these knockout cell lines using lentiviral delivery vectors. We will then characterise the effects of these modifications on the host cell. In addition, we will assess the requirement for additional cellular components in HUSH complex function by performing genome-wide CRISPR/Cas9 screens in fluorescent reporter lines previously used to characterise HUSH.

(2) Chromatin reporters: We will generate fluorescent reporter lines for epigenetic pathways other than the HUSH complex. This will be achieved either through CRISPR-mediated knock-in into a target genomic locus, or through lentiviral expression of a fluorescent protein (e.g. GFP). Resulting reporter lines will be interrogated through genome-wide CRISPR/Cas9 screens, and any resulting hits will be characterised in the same way as HUSH components (described above).

Recipient or parental organism

Mammalian tissue culture cell lines (e.g. HeLa, 293T, KBM7, HAP1, Jurkat, HuT78, SUPT1, CEMT4, Molt3, Molt4, HL-60, LCL, Daudi, U87, THP1, Ramos, U373, KG1, DG75, AKBM, Kasumi-3, NK-92, SH-SY5Y, SK-N-SH, hTERT RPE-1).

Human and murine embryonic stem cells
Established human and mouse organoids (e.g. intestinal organoids)
Bacteria: E. coli K-12 and derivatives (e.g. Top10, Sure 2, NEB Stable, DH5-alpha, DH10-beta, ElectroMAX DH10B, XL1-Blue).

Host/vector system

Non-mobilizable standard cloning vectors (e.g. TOPO, pMAX-GFP and pcDNA3), along with replication incompetent retroviral (e.g. pBABE, pGT0-GFP-pA and pMKO) and lentiviral vectors (e.g. pHIR-SIN, pSIREN and pTRIPZ), will be used to clone genes (including endogenous retroelements) encoding fluorescent proteins and epigenetic regulators.

2nd rather than 3rd generation lentiviral vectors will be used for most experiments involving exogenous gene expression. While 3rd generation systems are generally considered safer than 2nd generation systems because the packaging vector has been divided into two separate plasmids, the majority of lentiviral transfer plasmids available in the laboratory are 2nd generation, and therefore extensive time and work would be required to subclone all of these into 3rd generation transfer plasmids.

2nd and 3rd generation lentiviral vectors harbouring shRNAs or CRISPR sgRNAs or a CRISPR-associated protein (e.g. Cas9) will be used for gene knockout or modulation of expression of individual cellular genes, as well as for genetic screens. While both 2nd and 3rd generation lentiviral systems are used, 3rd generation systems will be used exclusively where delivery of both Cas9 and sgRNA in a single vector is required.

Retroviral vectors will also be used for gene disruption in gene-trap genetic screens (pGT0-GFP-pA), modulation of expression of individual genes (pMKO), or exogenous expression of fluorescent proteins or epigenetic factors (pBABE).

Origin & function

Inserts will be used to (i) express fluorescent proteins (e.g. GFP, mCherry, mScarlet, iRFP or HaloTag), (ii) introduce shRNAs or CRISPR sgRNAs or a CRISPR-associated protein (e.g. Cas9) for gene knockout or modulation of expression of individual cellular genes, as well as for genetic screens, (iii) encode mammalian proteins involved in epigenetic modulation, and (iv) express labelled mammalian genes to enable their visualisation, using fluorescent tags as well as antibiotic resistance genes for positive/negative selection (e.g. Puromycin, Blasticidin, Hygromycin or thymidine kinase), or to simplify biochemical analyses using tags such as HA, Strep, Myc, Flag, luciferase or a biotin ligase (e.g. BirA, BioID2 or BASU).

Genes encoding fluorescent proteins, Cas9 or sgRNAs have no known oncogenic activity. Genes encoding mammalian proteins or mutant versions of these proteins may have oncogenic activity. The inserted DNA will integrate randomly and therefore not target specific sequences in the genome. Inserts will be used to (i) express fluorescent proteins (e.g. GFP, mCherry, mScarlet, iRFP or HaloTag), (ii) introduce shRNAs or CRISPR sgRNAs or a
CRISPR-associated protein (e.g. Cas9) for gene knockout or modulation of expression of individual cellular genes, as well as for genetic screens, (iii) encode mammalian proteins involved in epigenetic modulation, and (iv) express labelled mammalian genes to enable their visualisation, using fluorescent tags as well as antibiotic resistance genes for positive/negative selection (e.g. Puromycin, Blasticidin, Hygromycin or thymidine kinase), or to simplify biochemical analyses using tags such as HA, Strep, Myc, Flag, luciferase or a biotin ligase (e.g. BirA, BioID2 or BASU). Genes encoding fluorescent proteins, Cas9 or sgRNAs have no known oncogenic activity. Genes encoding mammalian proteins or mutant versions of these proteins may have oncogenic activity. The inserted DNA will integrate randomly and therefore not target specific sequences in the genome.

Evaluation of foreseeable effects

Hazard to health:
Recipients will be various mammalian cells in culture. They are well characterised, have a long history of safe use, and are not hazardous to human health. They are unlikely to survive outside lab culture conditions. Bacteria: the bacterial strains we use are highly disabled and unable to replicate to any extent outside the lab, and are therefore considered ACDP hazard group 1.
There is a low risk that the researchers could accidently infect themselves with the viral vector, but the inserted genetic material is in itself harmless. Fluorescent proteins are not toxic, nor reported to have deleterious effects on exposure. The Cas9 nuclease or the sgRNAs can cause no harm separately as genome editing only occurs in cells expressing both simultaneously. Moreover, given that the integration in the genome will be random, there is a very low risk of insertional mutagenesis in tumour suppressor genes. Even though the following is not required, we will follow, as common sense suggests, all the standard safety procedures in our lab, which are: i) wearing gloves, labcoats and glasses; ii) handle viruses inside safety cabinets; iii) treat all the working surfaces within the cabinets with disinfectant and 70% ethanol after finishing work with viruses.
Viral gene delivery vectors (retroviruses, lentiviruses) to be used are those typically considered class 1 GMMs, and will all be self-inactivating, and therefore once packaged, are unable to propagate. A three-plasmid transient transfection system will be used to generate the recombinant retroviruses and lentiviruses, thereby decreasing the likelihood of recombination within the packaging cell lines to generate replication competent virus. The retroviral vectors are based on the Moloney murine leukaemia virus in which the gag, pol and env genes have been deleted. Gag and pol are supplied in trans on a packaging plasmid. We will generate VSV-G pseudotyped virus in order to deliver the virus particles to human cells. The lentiviral vectors are based on an HIV-1 self-inactivating vector (SIN) containing a deletion in the U3 region of the 3' LTR of the virus. In addition, the gag, pol, env, nef, vif,
vpu and vpr genes have been deleted. Again, a second packaging plasmid encoding gag, pol, rev and tat will be used along with the plasmid encoding VSV-G to make pseudotyped viruses that will enter human cells.

Lentiviral vectors contain the wild-type version of WPRE (Woodchuck hepatitis post-transcriptional regulatory element); it has been suggested that wild-type WPRE expresses a truncated X-protein that may have oncogenic properties.

There is a very low risk that the researchers will accidentally infect themselves with the viral particles. It is very unlikely that the researchers will be exposed to the inserted genetic material or the viruses and, therefore, incorporating foreign DNA into their genome. No sharps will be used when handling lentiviruses or retroviruses so there is no risk that the researcher will accidently inject themselves with the viral vectors.

The disabled nature of the bacterial hosts will not be altered by the plasmids used – no expression is anticipated and would not in any case be compatible with bacterial systems.

Expression of genes encoding epigenetic modifiers in cultured mammalian cells may alter the expression of cellular genes but these changes will not override the especially disabled nature of the cells.

As lentiviral and retroviral vectors containing are disabled, any accidental infection of the epithelial cells of the researcher would be localised. Transduced cells would not be able to produce viral particles. Due to the high turnover rate of epithelial cells, any localised infection would not be expected to be long lasting.

Expression of the genes described above is not expected to be detrimental to human health.

Hazard to environment:
Mammalian stem cells or cell lines are especially disabled and unable to survive or propagate outside of laboratory culture. They are not hazardous to fauna or flora.

Bacteria: the bacterial strains we use are highly disabled and unable to replicate to any extent outside the lab. Nevertheless, appropriate control measures, including disinfection of liquid cultures and autoclaving of bacterial plates, will be taken.

Fluorescent proteins are not toxic, nor reported to have deleterious effects on exposure.

Non-viral mammalian expression vectors are easily destroyed in the environment and therefore pose no risk on their own.

The viral vectors are all replication-disabled so will be unable to disseminate in the wider animal or human populations.

None of the inserts or deletions in cells, vectors or viruses will be able to alter the non-hazardous status of the recipients with respect to environmental risk.

None of the gene products used have hazardous properties and will therefore not pose an environmental risk.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste will be inactivated by autoclave (degree of kill effectively 100%) and liquid waste treated with 1% Distel for 30 minutes (or other approved disinfectant according to manufacturer’s guidelines). Autoclave is tested and certified annually, and each run is shown to reach and hold temperature correctly (134 degrees C for 3 minutes). Contingency plan: waste autoclave available in the adjacent building.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

Please enter comments on the GM safety committee on the risk assessment

The Biological and Genetic Modifications Safety Committee approved the risk assessment after a comment was added (justifying the use of 2nd generation lentivirus vector)

Project Ref  408/21.1

Date Ackn'd  02/12/2021  CU2 Project Title  Gene editing of intestinal cells using viral vector loaded with shRNA or dCas9 and

Class  CultureVolClass2  CultureVolumeClass3-4

Class 2  < 1 Litre
The function of epithelia depends on the apical-basal polarisation of each cell. It is generally assumed that polarity complex proteins govern epithelial polarisation. These proteins, which were discovered in Drosophila, are evolutionarily conserved in organisms as diverse as worms and mammals. The recent discovery that the Drosophila adult midgut polarises in the absence of these conserved polarity proteins provides evidence for an alternative pathway in epithelial polarisation. Together with increasing evidence of the lack of defects in mammalian epithelia when polarity proteins are knocked out, this raises the question of whether the mammalian intestinal epithelium polarises independently of these conserved polarity factor proteins. To test this hypothesis, I plan to employ CRISPR Interference (CRISPRi) to silence polarity factors and their paralogues in mouse intestinal organoids to investigate whether the canonical polarity proteins are required for cell polarisation in the mouse intestinal epithelium. The efficiency of gene silencing will be measured by qRT-PCR and western blotting. Cell morphology, the localisation of polarity proteins and cell junction proteins will be characterised. This project will elucidate whether polarity in the mammalian intestinal epithelium depends on these conserved polarity proteins or whether it resembles that in the Drosophila intestine.

We plan to manipulate gene expression in intestinal organoids in vitro to understand the mechanisms that control intestinal cell polarity. We are targeting genes that modulate cell polarity in the intestinal cells. We will knock down Myo5b and polarity factor proteins (aPKC, Par3 and Par6) in wild type mouse intestinal organoids and study their role in mammalian intestinal epithelium polarity.

We plan to induce CRISPRi and gRNA to cells through lentiviral infection, which allows for stable integration. The workflow of CRISPRi starts with 1) sgRNA design& clone sgRNA into an expression vector, 2) double-transfect cells with dCas9 and sgRNA containing vectors and 3) induce dCas9 expression in transfected cells and assay gene of interest's transcript levels. Once validated in mouse intestinal organoids we will knockdown mammalian organoids or epithelial tissues that derived from wild type mouse embryonic cells, lung, bladder, and mammary tissue to determine whether these mammalian epithelia also require these polarity proteins to polarise.

If CRISPRi is ineffective, I plan to employ Lenti-X Tet-On 3G CRISPR/Cas9 System (632633, Takara Bio) to generate knockout cells by co-expressing an endonuclease Cas9 and a gRNA specific to the targeted gene. The Tet-On 3G system enables doxycycline (dox)-inducible Cas9 expression. Fully functional CRISPR/Cas enzymes will introduce a double-strand break (DSB) at a specific location based on a gRNA-defined target sequence. DSBs are preferentially repaired in the cell by non-homologous end joining (NHEJ), a mechanism which frequently causes insertions or deletions (indels) in the DNA. Indels often lead to frameshifts, creating loss of function alleles. CRISPR plasmids are listed in the below vectors section.

Recipient or parental organism

- HEK 293T cells
- Mouse primary cell lines:
  - Mouse intestinal organoids derived from wild type mouse intestinal stem cells
Wild type mouse embryonic cell lines and its derives
Wild type mouse mammary cell lines (EPH4 cell)
Wild type mouse primary mouse bladder epithelial Cells
Wild type mouse primary alveolar epithelial

**Host/vector system**

**CRISPRi plasmid vectors:**
1. pLenti-gRNA opti_EF1a-EGFP-CAAX (Addgene: 167936)
2. pLenti-Krab-dCas9 (1.1)-ecDHFR-EF1a-tagRFP-2A-tet3G (Addgene: 167935)

**CRISPR plasmid vectors:**
1. Lenti-X™ Tet-On® 3G CRISPR/Cas9 System, with Cas express under CMV Promotor (632633, Takara)
2. pLVX-hyg-sgRNA1 Vector System and with gRNA express under U6 Promotor (632630, Takara)
3. Third generation, replication- incompetent, self- activating lentiviruses, containing different promoter sequence and wild-type WPRE
4. Promotors: minimal CMV promoter, PGK promoter, EF1-alpha and tetON
5. 3rd generation transfer vector : pInducer20 (Addgene# 44012), Tet-pLKO-neo(Addgene# 21916) and pHIV-EGFP (Addgene# 21373)

**Helper vectors:** pMDLg/pRRE (Addgene 12251) contains Gag and Pol; pRSV-Rev (Addgene#12253) and pMD2.G. (Addgene#12259)

**Origin & function**

**Hazard to Health:**
The recipient microorganism(s) (standard bacterial strains, E/coli k-12 derivatives, which are commonly used for plasmid expansion) are not pathogenic to humans and unlikely to survive outside laboratory culture. The hosts can be assigned to ACDP hazard group 1. HEK293T cells and EPH4 cells, and wildtype intestinal organoid, embryonic cell lines and primary cells, are safe to use and cannot survive outside the lab culture conditions.

We do not anticipate any genes we tested will be oncogenic or have a distinguish effect on the progression of cancer when knockdown. There is a low risk that the researcher will accidentally infect herself/himself with the viral vector. The consequences of this are low. The plasmid vectors are all derivatives of standard lab vectors. They are not mobilizable.

The method of genetic modification involves the transduction of mammalian intestinal organoids in culture with lentivirus containing dCas9 and sgRNA. They are pseudotyped with VSVG and Rev and are capable of transducing many, possibly all, human and mouse cells types, including those of the researchers. No human gRNAs and Cas9 will be used, and introduction of dCas9 will not result in the production of double strand DNA break putting them at risk of later cancer development. So the risk is low. However, to expose the researcher to dCas9 and mouse sgRNA would have penetrate the skin, or eyes, or be swallowed.

The gene transfer vector contains a woodchuck hepatitis virus posttranscriptional regulatory element (WPRE) which contains an open-reading frame (ORF) encoding a truncated peptide of the woodchuck hepatitis virus X protein. It has been suggested that the X protein is pivotal to the generation of liver cancers, which are a very common consequence of infection with HBV in man. Many studies have suggested that the X protein is nonfunctional in the absence of a second enhancer, We2/En2 (WHV/HBV), which is not present in the PRe, and this has been confirmed recently in the context of a lentiviral vector. The expression of the X protein does not appear to be directly oncogenic, but there are studies that show that under some circumstances it can act as a weak cofactor for oncogenesis; for example, in combination with cellular oncogenes. Researchers must know the potential safety issues surrounding the use of an unmodified WPRE in their vectors.

**Evaluation of foreseeable effects**

The recipient microorganism(s) (standard bacterial strains, E/coli k-12 derivatives, which are commonly used for plasmid expansion) are not pathogenic to humans and unlikely to survive outside laboratory culture. The hosts can be assigned to ACDP hazard group 1. HEK293T cells and EPH4 cells, and wildtype intestinal organoid, embryonic cell lines and primary cells, are safe to use and cannot survive outside the lab culture conditions.
The genetically modified microorganisms are not more hazardous to health than the recipient microorganisms.

Hazard to the Environment:
The recipient cell lines and organoids would not survive and become established in the environment, they are unlikely to survive outside laboratory culture. The plasmid vectors are all derivatives of standard lab vectors. Neither the sgRNA, encoded dCas9, bacterial or mammalian transfectants are likely to have any deleterious effect on the environment. Also, lentivirus particles are relatively fragile, being easily inactivated by 0.1% detergent, chloroform, phenol, 1% bleach, 70% ethanol, 65°C for 30 min, pH <6.5 or >9.0, UV light, or autoclaving.

In a case of disposal of plasmid directly to the environment, the plasmid will get degraded. Plasmid on their own has no effect to a host as it can only be delivered to a host via transfection or viral transduction. Lentiviral particles are pseudotyped with VSVG and are capable of transducing many, possibly all, mammalian cells types.

In the very unlikely event of the release of virus from the Level 2 Containment facility, it could survive in the environment for a similar period of time to the wild-type virus. If the virus infected a susceptible host, then expression of the plasmid would occur in the infected cells.

Since the virus cannot replicate under normal circumstances, expression would be limited to the infected cell and once this cell divides to one of its daughter cells. The potential hazard to environment e.g. mouse live in wild, is also low. In order to cause hazard lentiviral vector with CRISPRi and gRNA have to be delivered to the same mouse. To induce the gene knockdown, the mouse expresses CRISPRi and gRNA needs to be treated with both TMP and DOX for a period of time. The probability of such occurrence is extremely low.

Therefore, no foreseeable adverse environmental effects are expected and risk to the environment is negligible.

The genetically modified microorganisms are not more hazardous to the environment than the recipient microorganisms.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste will be killed effectively 100% by autoclave (134°C for 3 minutes). Autoclave tested and certified annually and each run shown to reach and hold temperature correctly. Liquid waste material will be treated with Distel 1% for 30 minutes prior to sink disposal.

Two waste autoclaves on site.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The committee recommended the use of PEG-based solution for smaller lentiviruses as this has proven to be an effective alternative to centrifugation, with a lower risk associated to it.

The committee recommended making the risk assessment more concise as key information was sometimes diluted in the text.

The committee unanimously approved the RA pending the changes expressed above.
Project Additional Information

Purposes of the contained use

Bacteria-derived CRISPR/Cas systems have recently been applied as novel tools to introduce site specific double strand break (DSBs) in mammalian cells. When the DSB sites are repaired by non-homologous end joining, small insertions/deletions are often introduced into the sites, hence, null mutations can be introduced into target genes. The CRISPR/Cas9 system consists of two components: Cas9 endonuclease and guide RNA (gRNA) molecules. Both elements can be expressed from separate transgenes transiently or constitutively. In this project, we use retro/lentivirus as a vectors for delivering Cas9 and gRNA expression cassettes to target cells. The goal is to develop and utilize retro/lentivirus vectors for CRISPR/Cas9-based genome editing including the performance of genome-wide
genetic screens and the targeted disruption of genes of interest for mechanistic and translational studies. In addition, we will use retro/lentiviral vectors for delivery of putative oncogenes or tumour suppressors (TS) into mammalian cells under the control of constitutive or inducible promoters. This will allow us to assess their oncogenic/TS potential in desirable cellular and genetic context.

**Recipient or parental organism**

1. Mouse ES cells: AB1, AB2.2, JM8, R1, v6.5, KY1.1 and their derivative lines.
2. Human ES cells: H1, H9, Shef lines and their derivative lines.
3. Human iPS cells: Pathogen-negative hiPSC lines derived from various donor/somatic cells.
4. Cell lines for virus production (PlatE for ecotropic retrovirus production, 293T for amphotropic retrovirus and lentivirus production)
5. Human cell lines (cancer and non-cancer cells) with long history of safe use, such as A549, H1975, OE21, Kasumi, MV411, Panc-1, MCF10A

**Host/vector system**

- **Retroviral vector**
  - Mouse Moloney leukemia virus-derived retroviral vector (eg. pRetrox, pBabe, pMSCV)
  - Packaging plasmid mix for amphotropic retrovirus production (Clontech Retro-X system or equivalent)

- **Lentiviral vector**
  - 3rd generation lentiviral vectors (Invitrogen pLenti 7) and its derivatives (pLenti-CMV/TO Hygro DEST, Addgene 17291), pHIV-ZsGreen (derivative of pSico, Addgene 11586) and lentiCRISPR v2 (Addgene #52961), CRISPRi and CRISPRa system.
  - 4th generation lentiviral vectors (Clontech pLVX).
  - Packaging mix for 3rd generation vectors such as Invitrogen ViraPower Lentiviral Packaging Mix)
  - Packaging Mix for 4th generation vectors such as Clontech Lenti-X packaging mix or Invitrogen ViraPower

**Origin & function**

1. Drug resistant markers (neo, puro, puro-tk, hyg, zeo, bsd)
2. Fluorescent proteins (GFP, zsGreen, mCherry, dsRed, mRFP, mTagBFP, CFP, Venus YFP, tagRFP657)
3. Cas9 endonuclease
4. CRISPR guide RNAs: 20-nt sequences fused with guide RNA scaffold sequences
5. Integration and expression (constitutive or inducible) of ORFs (wild type or tagged) of putative oncogenes and tumour suppressors.

**Evaluation of foreseeable effects**

- Hazard to health:
  1. The recipient cell lines used here are not pathogenic and cannot survive outside culture conditions.
  2. Altered genetic material: Fluorescent proteins and drug selection markers are active in humans. Transgenic animals (including monkeys) expressing fluorescent proteins and/or drug selection markers have been generated and appear to be healthy. There is no evidence to suggest a harmful effect.
  3. CRISPR guide-RNA and Cas9 endonuclease: When both elements are co-expressed in the same cells, they form complexes and induce double strand breaks at the genomic sites that match 20-nt guiding sequences-active in humans. CRISPR guide RNAs and the Cas9 protein themselves are not harmful. Moreover, mouse guide RNAs are designed not to match the human genome to avoid targeting in the very unlikely case of researcher infection with the viral vectors.
Any of these genes are not directly oncogenic. However, when guide RNAs target, for example, tumour suppressor genes, the genes can be inactivated and this may eventually cause tumour formation. Similarly, when human ORFs are overexpressed they might potentially have oncogenic or tumour suppressive function based on the genetic and cellular context. These might eventually cause tumour formation however, since development of fully blown tumour requires acquisition of multiple genetic lesions this is unlikely.

3. Vectors: Both the retrovirus and lentivirus systems that will be used here are replication-incompetent; therefore, there is no risk of diseases associated with these viruses. However, they integrate into the genomes of infected cells and can cause insertional mutagenesis. There are generally two concerns associated with insertion of vectors: oncogene activation and tumour suppressor inactivation. Both viruses have been engineered to lack enhancer elements in LTR, which significantly reduce the risk of oncogenic activation. Tumour suppressor inactivation, which can theoretically lead to tumour formation. To our knowledge, this has never been observed in human operators. Note that retro-and lenti-viruses that lack the U3 enhancer element have been used in clinical trials of gene therapy of hematopoietic disorders and no leukaemia has been thus far observed. The lentiviral vectors contain WT WPRE. This element is capable of expressing part of the X protein from WHV and it is suggested that truncated hepadna virus Xproteins may have oncogenic properties. A vector containing wild type WPRE would be handled at CL2.

4. The GM cell lines are not fitter than the recipient strain and they are not pathogenic.

Hazard to the environment:
1. The recipient cell lines used here do not present a hazard to fauna or flora and cannot survive outside culture conditions.
2. Altered genetic material: Any inserts are not directly hazardous. However, when guide RNA and Cas9 proteins are co-expressed in the same cells, they form complexes and can induce double strand breaks at target sites. This may be hazardous to the recipient cells/organism but not to the environment (as onwards infection cannot occur). Same applies for overexpression of genes with potentially oncogenic or tumour suppressive function that could be potentially deleterious for the recipient cells/organism.
3. Vectors: The viral vectors are replication-disabled and couldn’t spread in animals.
4. The modified cell lines do not present a hazard to the environment.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste will be inactivated by autoclaving (degree of kill effectively 100%) and liquid waste will be treated with Distel or other approved disinfectant according to the manufacturer’s instructions. Autoclave is tested and certified annually and during each run is shown to hold temperature correctly (134°C for 3 minutes).

**Historical Significant Changes**
Appropriate control measures will be employed to restrict the GMM to designated containment locations in order to minimise potential for exposure to staff and prevent escape into the environment.

Information included in this form takes into account the following considerations:
- □ Donor organism: genetic sequences obtained from human genome (Homo sapiens) and synthetic origin that have been inserted into human adenovirus type 5 (HAd5) genome to act as genetic expression modulators and induce selective replication of VCN-01 in tumor cells.
- □ Recipient (parental organism): Human Adenovirus type 5
- □ Final GMO: VCN-01

Wild-type human adenovirus (HAd) serotype 5 belongs to the C-subgroup type (Mastadenovirus, Adenoviridae). HAd consists of an icosahedral protein capsid of about 80nm in diameter with no lipid envelope. The faces of the icosahedron are formed by a structural protein called hexon. In each of the twelve vertices of the capsid there is a protein known as fiber, which binds to the virus’ primary cellular receptor, the Coxsackle-Adenovirus Receptor (CAR). For the virus to enter the cell, in addition to the fiber-CAR binding, it is also necessary that a protein attached to the virus fibers called penton base binds to the cell surface integrins. The viral genome is packaged within the capsid, and it is a linear double stranded DNA of 36 Kb which is released into the core after the capsid reaches the nuclear membrane.

Once in the nucleus, adenoviruses express regulatory genes responsible for the activation of cell cycle and subsequent transcription of other viral genes. The former are known as early gene 1 (Early 1). The E1 region is divided into E1A and E1B which encode E1A proteins (12S and 13S) and E1B, E1A protein binds to and inactivates proteins of the retinoblastoma (Rb) family, and thus the E2F transcription factor is released from the E2F-Rb complex, inducing cell cycle progression. E1A-13S protein in conjunction with E2F activates the transcription of E2 (DNA replication proteins), E3 (proteins that evade immune response) and E4 (proteins which functions are similar to the ones of E1, and that also control the transport and RNAs viral transcription). Most adenoviral vectors used in gene therapy are based on HAd5.

HAd Host-range

The host range of HAd5 is restricted to humans. It is also described that chimpanzees, swine, cotton rats (Sigmodon hispidus) and some kinds of hamsters (Mesocricetus aurata), are semi-permissive species for the replication of human adenovirus.
**HAd pathogenicity**

In terms of biosafety, HAdV5 are human adenoviruses classified as class 2 biological agents. HAd infections are mostly asymptomatic but may cause diseases of the respiratory, ocular and gastro-intestinal system, especially in children. Clinical studies using healthy human volunteers have also shown that infection with natural non-attenuated isolates of group C and other adenovirus serotypes does no cause severe disease, with self-limiting, profile and rarely requiring medical intervention. The incubation period for getting disease is 1-10 days, being lymphoid organs considered as natural repositories for the virus. Most of the human population is sero-positive for adenovirus, and HAd-C is a widespread species, which implies that any adenoviral infection is easily neutralized. Biosafety level 2 practices and containment facilities are recommended for all activities involving the virus and potentially infectious body fluids or tissues.

**Host/vector system**

Not applicable.

**Origin & function**

VCN-01 is an oncolytic adenovirus which is able to replicate and lyse selectively tumor cells.

VCN-01 is derived from wild-type human adenovirus (Had) serotype 5 (HAd5), whereby HAd5 backbone has been genetically altered to incorporate distinct modifications that confer tumour selectivity and anti-tumour activity: 1) Insertion of a tumour-specific promoter in E1A; 2) Partial deletion of the E1A gene; 3) Amino acid change in a adenovirus fiber protein; and 4) Insertion of the coding region of the human sperm hyaluronidase gene.

The genetic modifications in VCN-01 are the following:

1. Insertion of a tumour-specific synthetic promoter composed have been inserted at the E1A endogenous promoter region of the human adenovirus type 5 genome.
2. Partial deletion of the E1A gene (delta-24 mutation). Such deletion corresponds to a 24 base pairs sequence in the HAd5 ARM genomein the E1A protein sequence.
3. Mutation of the sequence that codes for amino acids in the adenovirus fiber protein that interact with heparan sulfate in eucariothic cells.
4. Insertion of an expression cassette for the human sperm hyaluronidase (PH20) cDNA.

Role of deleted or mutated genes/sequences:

- Role of the partial deletion of the E1A gene: The delta-24 mutation generates a truncated E1A viral protein unable to bind to cellular pRb. In normal cells, this binding is required for effective virus replication. Deregulation of the retinoblastoma pathway is a hallmark of tumour cells. Under these conditions E1A function is unnecessary. Therefore, VCN-01 is unable to activate viral replication in normal cells.

- Role of the adenovirus fiber protein modification: Different HAd5 capsid proteins binds to cellular membrane to promote internalization. VCN-01 capsid includes genetic modifications that benefit simultaneously from liver de-targeting properties and the tumour-targeting properties of the integrin-binding RGD peptide.

Role of inserted transgenes/sequences:

- Role of the tumour-specific synthetic promoter: E1A modified promoter has been inserted to confer selectively of viral replication only in tumour cells, where E2F pathway is constitutively over-activated. It restricts the expression of key master proteins in adenovirus to cancer cells and inhibits its expression in normal cells.

- Role of the human sperm hyaluronidase (PH20) cDNA: Hyaluronan (HA) is the major structural component of extracellular matrix (ECM). High levels of this compound are found in several types of cancer, including pancreatic cancer and are often correlated with invasive and metastatic behaviour. PH20 expression from VCN-01 facilitates spread of the agent during treatment and improves antitumour activity.

**Evaluation of foreseeable effects**

Wild-type adenoviruses are able to replicate in epithelial tissues whereas VCN-01 replication is restricted to tumour cells. Several in vitro studies have been conducted with...
VCN-01 to assess the selectivity of replication and of cytotoxicity in non-tumour cells. Its selectivity has been evaluated in terms of replication using human primary biopsies. Contrary to the non-selective wild-type, VCN-01 was not able to replicate and behaved as the non-replicating control virus. Additionally, some in vitro studies were conducted to determine VCN-01 selectivity using cytotoxicity assays in human normal cells. In these studies VCN-01 cytotoxicity has demonstrated to be significantly lower than wild-type adenovirus toxicity.

IDENTIFICATION OF CHARACTERISTICS AND MECHANISMS THAT MAY DIRECTLY OR INDIRECTLY LEAD TO ADVERSE ENVIRONMENTAL EFFECTS.

a) Possibility of recombination and mutation of VCN-01 in the subject (human host):

The likelihood that VCN-01 is genetically unstable is negligible. Reasoning:

- Possibility of GMO recombination: HAd5 and other adenoviruses have humans as their natural host. However, most of the human population is sero-positive for adenovirus, which implies that any adenoviral infection is easily neutralized. Moreover, such infections are mostly asymptomatic, auto-limiting and restricted to several permissive tissues. Studies have shown that for recombination between different adenoviruses genomes occur they need to be present in the same cell at very high number of copies. It is a highly unlikely event that a single cell of an infected animal contains high amounts of VCN-01 together with pre-existing forms of HAd5 or other adenoviruses, due to the differential target cell populations of the intended use by the proposed route of administration for VCN-01 compared to the one of native HAd5 infections (oral/respiratory tract).

- Possibility of GMO complementation: Transcomplementation between the genomes of VCN-01 and wild-type adenoviruses from subgroup C could take place in case of co-infection at a cellular level. In that situation, wild-type genomes could provide missing functions in a temporal and self-limiting way. However, co-infection of VCN-01 and an HAd5 at a cellular level is not expected, since the target cells of Adwt serotype subgroup C would be the broncoepithelial cells (the typical route for HAd subgroup C is the oral/respiratory), and VCN-01 would not be able to reach this cell type in preclinical models. Confirming this assumption, this phenomenon has never been described during the extensive preclinical experience with different oncolytic adenovirus.

- Possibility of GMO mutation: The genomic stability of VCN-01 has been thoroughly assessed. Data obtained in a bioamplification assay demonstrates that VCN-01 genome is stable even at high selective pressure.

b) Modifications in the GMOs that affect the viral life cycle by changes in virus structure or by non-structural changes in the context of the intended use for human host.

- Changes in binding and entry compared to the parental virus: VCN-01 contains a genomic modification in the adenovirus fiber protein. Nevertheless, such a modification only induces increased bioavailability at short time-points after infection. Overall, capsid modifications in VCN-01 have demonstrated not to increase its tropism for normal organs or modify its host range.

- Changes in transcription and translation compared to the parental virus: Because of its genetic modifications viral transcription and translation will be not possible in normal cells. Other viral proteins involved in transcription and/or translation are normally present in VCN-01. The likelihood that the modifications in VCN-01 will result in an increased transcription pace or decreased transcription specificity compared to wild-type adenovirus is negligible.

- Changes in assembly compared to the parental virus: The role of the modified genes contained in VCN-01 has been studied. None of these genes encode structural proteins or play a role in adenovirus genome packaging. The genes encoding structural proteins are not expressed by VCN-01 in normal (non-tumor) cells but packaging sequences are normally present and structural proteins expressed at normal levels in VCN-01 infected tumor (permissive) cells. The likelihood that the genetic modifications will result in a more effective assembly is negligible. An influence on viral assembly due to more efficient transcription and translation is also unlikely.

- Changes in replication compared to the parental virus: Because of the insertion of its genetic modifications, VCN-01 is not able to replicate in normal cells and its cytotoxicity is significantly reduced. In tumour cells, however, the proteins involved in viral replication are present and expressed by VCN-01 at levels equivalent to wild-type
(permissive) cells are equivalent to non-modified adenovirus.

- Changes in release and cell to cell spreading compared to the parental virus: Several adenoviral proteins are known to be involved in release spreading. These proteins are normally present in permissive (tumor) cells infected with VCN-01, whereas not expressed in normal (non-tumour) cells. The function of the genetic modifications does not include a known direct role in release and spreading in normal cells. The likelihood that deletion or insertions of these genes will enhance virus release and spreading of VCN-01 compared to wild-type HAd is negligible.

- Changes in cell, tissue and host tropism compared to the parental virus: VCN-01 includes a modification in the fiber sequence that provokes that the mechanisms of adenovirus entry in organs after in vivo administration change. However, tissue biodistribution of VCN-01 has been evaluated in mice and hamster, and after extensive analysis in different organs it has been concluded that biodistribution profile of VCN-01 at short time-points after systemic administration is very similar to that reported for wild-type adenovirus and other oncolytic adenovirus previously tested in clinical trials. In addition, the analysis of VCN-01 genome content at different time-points clearly indicates a fast kinetics of degradation of the virus in normal tissues where VCN-01 is not able to replicate. By contrast, the analysis of VCN-01 genome content in tumors demonstrates that virus reaches efficiently tumours and its levels increase significantly with time after both intratumour or intravenous administration. Therefore, although VCN-01 displays capsid modifications affecting its infectivity in RGD-expressing cells and tumour accessibility in vivo, these changes do not broaden the tropism for normal cells compared to wild-type adenovirus.

- Changes in route of transmission compared to the parental virus: All structural proteins that determine transmission capabilities of adenoviruses are normally present in VCN-01 genome and the proteins deleted in VCN-01 do not play a direct roles in transmission. Therefore the likelihood that the route of transmission of VCN-01 is altered compared to wild-type HAdV-C viruses is negligible.

c) Effects of the GMO compared to wild-type virus on the subject (human host)

- Changes in immuno-modulation compared to the parental virus: Any adenoviral gene implicated in immune-modulation has not been ablated or affected by the genetic modifications introduced in VCN-01. In addition, genetic modifications in VCN-01 are not expected to introduce new immunogenic domains in the virus that could rest in a modified immune response against the virus, and these assumptions have been further validated in preclinical studies using the relevant animal models.

- Changes in induction of cell death (apoptosis and necrosis) compared to the parental virus: Adenoviral genes implicated in apoptosis induction have not been manipulated in VCN-01.

- Changes in growth factor, cyto-/chemokine signalling compared to the parental virus: Host recognition of adenovirus occurs via different elements including the capsid components and the nucleic acids. VCN-01 does not contain any modification that could result in a modulation of such pathways.

- Changes in cell intrinsic signalling and intracellular homeostasis compared to the parental virus: Although VCN-01 uses a different entry pathway compared to wild-type HAd5, after the initial attachment step, VCN-01 induces identical pathways for internalization, endosomal maturation, endosomal escape and trafficking to the nuclear pore with respect to HAd5.

Pathogenesis compared to the parental virus in the subjects: Interactions of VCN-01 with host have been previously analyzed and, overall, experimental data demonstrate that the immune response induced by VCN-01 only undergoes productive replication in tumour cells, which results in significantly reduced toxicity after in vivo administration. As a consequence, the modifications contained in VCN-01 significantly reduce its pathogenesis compared to HAd5.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste associated with dosing of the GMM, residual GMM dose and disposable blood sampling equipment will be autoclaved at 121°C/20 minutes prior to disposal and secured in clinical waste bins and disposed of through the Company’s clinical waste incineration route. Monitoring for residual viable GMM will not be performed.

Animal wastes (both treated animal carcasses and used bedding) will be autoclaved as required. All animal wastes will be secured in clinical waste medibins and disposed of through the Company's clinical waste incineration route.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

**Purposes of the contained use**

The GMO is a potential cancer treatment. These studies are required prior to clinical evaluation.

**Recipient or parental organism**

Human adenovirus type 5

**Host/vector system**

Not applicable

**Origin & function**

The adenovirus has 4 genetic inserts:
- Survivin promoter: regulates adenoviral Ela gene expression in a cancer-specific manner
- El a: transactivating the viral and cellular genes; critical for producing infective adenoviruses.
- CMV promoter: capable of significantly increasing the expression of a wide variety of genes, which cover a broad eukaryotic host range
- El El 9k: prevents early onset of cell death, providing extended periods for efficient adenoviral replication

**Evaluation of foreseeable effects**

Wild type Adenovirus serotype 5 (Ad5) is commonly contracted in childhood and causes mild respiratory symptoms conferring lifelong immunity (estimated 90%+ adults are seropositive for Ad5). Adenovirus does not have to be replication-competent to cause corneal and conjunctival damage. Surv.m-CRA-1 is conditionally replication competent virus with survivin promoter in its construct, which enables the vector to replicate only in tumour cells and to reduce the risk of infection to normal cells. Survivin is expressed highly in many tumours and in foetal tissue, it is also expressed during the G2-M phase of the cell cycle. Therefore replication may be possible in healthy individuals as well as in tumours.

Project Ref 410/17.1

Date Ackn'd 09/03/2017

CU2 Project Title Pre-clinical testing programme for PT3.9 and the contained use of 3 strains of modified pseudomonas aeruginosa bacteria (identified as Strain 3524, Strain 5538 and Strain 3633), susceptible to the phage.

Date Project Ceased

Class 2

< 1 Litre

Consent Granted

Non-GMM

Tick if notifying a connected programme of work N

Withdrawn N

Historical Significant Changes
### Project Additional Information

**Purposes of the contained use**

PT3.9 is in development for treatment of antibiotic resistant pseudomonas aeruginosa infection. The notification consists of the pre-clinical testing programme for PT3.9.

**Recipient or parental organism**

1) Phi33, which is a bacteriophage belonging to the PB1-like family of phage
2) *Pseudomonas aeruginosa*

**Host/vector system**

*Pseudomonas aeruginosa*

**Origin & function**

1) PT3.9 has been modified to improve its efficacy  
2) the 3 strains of *Pseudomonas aeruginosa* in use have been modified to increase their susceptibility to PT3.9

**Evaluation of foreseeable effects**

The 3 bacteriophages making up PT3.9 and the 3 strains of pseudomonas aeruginosa are considered to be equivalent, in terms of potential effects and overall risks. They are therefore considered together in the risk assessment

1) The PT3.9 bacteriophage is not anticipated to pose a risk to human health. It has the potential to replicate and infect pseudomonas aeruginosa, which is widespread in the environment. The sponsor indicates that the modified bacteriophage will not have any significant advantage over the wildtype bacteriophage, based on in-vitro data. Since there is a potential for the phage to persist, and since the work involve significant aerosolisation to perform the inhalation toxicology study, biosafety level 2 measures are
required to prevent the potential for adverse effects on the environment.

2) P. aeruginosa is a hazard group 2 pathogen. The modifications made to the strains in use are not indicated to affect the potential or scope of adverse effects on humans or in the environment.

Biosafety level 2 control measures will be employed throughout the programme of work.

Project Ref 410/17.2
Development of influenza vaccines. The candidate influenza vaccine must be assessed for retroviral purity prior to release by the client. This work does not require use of the vaccine strain as such, but assessment of bulk virus seed containing the virus for presence of retroviral contamination.

Wild-type animal origin low pathogenic influenza viruses do not have the multi-basic amino acid peptide insertion at the HA cleavage site (PENPKTR*GLF), are not pathogenic to chickens and are not therefore designated a SAPO agent by DEFRA. As such the wildtype viruses are handled at CL2.

Virus to be generated by client and sent to Envigo within study samples.

HOST Wild-type animal origin low pathogenic influenza viruses do not have the multi-basic amino acid peptide insertion at the HA cleavage site (PENPKTR*GLF), are not pathogenic to chickens and are not therefore designated a SAPO agent by DEFRA. As such the wildtype viruses are handled at CL2.

VECTOR E. Coli (strains NEB 5-alpha F’Iq competent E.coli, Veggie NovaBlue Singles Competent Cells or Invitrogen Top 10 Cells) - Disabled non-pathogenic, ACDP category 1

pAD 3000 plasmid - non-mobilisable
The virus contains the hemagglutinin (HA) and neuraminidase (NA) genes reasserted influenza virus strain B/Indiana/25/2015 and the internal genes from the cold adapted, temperature sensitive, attenuated master donor virus (MDV) backbone A/Ann Arbor/6/60

Origin & function

Wild-type animal origin low pathogenic influenza viruses do not have the multi-basic amino acid peptide insertion at the HA cleavage site (PENPKTR*GLF), are not pathogenic to chickens. Hemagglutinin (HA) and neuraminidase (NA) genes reasserted influenza virus strain B/Indiana/25/2015. The HA protein on the surface of the virus is responsible for virus/cell attachment and fusion. The HA protein does NOT contain the 7 amino acid multi-basic peptide insertion at the HA cleavage site (PENPKTR*GLF), characteristic of highly pathogenic influenza viruses. The NA of influenza viruses has enzymatic activity and is responsible for cleaving the HA from the cell receptor thus releasing new virus particles budding from the cell surface. There are no known regions or sequences that have been shown to be solely responsible for a highly pathogenic phenotype. Internal genes PB2, PB1, PA, NP, M or NS from Influenza A/Ann Arbor/6/60 - these are all well characterised genes that are used in the commercial vaccine and have been shown to be safe. E. Coli (strains NEB 5-alpha F'Iq competent E.coli, Veggie NovaBlue Singles Competent Cells or Invitrogen Top 10 Cells) - Disabled non-pathogenic, ACDP category 1

pAD 3000 plasmid - non-mobilisable

Influenza A/Ann Arbor/6/60 - attenuated, cold adapted and temperature sensitive ACDP category 1

Evaluation of foreseeable effects

The wildtype virus is designated CL2 by HSE and DEFRA based on the following:
• presence of a HA cleavage site consistent with low pathogenic influenza viruses
• shown in assays not to cause pathogenicity in the chickens
Combination of the wildtype HA and NA genes with the internal genes of A/Ann Arbor/6/60 is known to result in highly attenuated cold adapted temperature sensitive viruses.
Potential for harm to human in the event of exposure - Potential for limited and mild upper respiratory tract infection
Potential to harm and disseminate to the environment - The HA and NA genes are from low pathogenic animal origin influenza strain that is NOT currently circulating in the UK. In this case there is a low risk to the environment if the 6:2 virus was accidently released because the HA and NA genes could potentially reassort with genes from currently circulating wild type influenza to generate an influenza virus with a novel HA that is not currently in the UK
Environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Surfaces will be deactivated using Virkon spray. All samples and waste materials will be inactivated by autoclaving or chemical treatment (e.g. Virkon) prior to disposal as clinical waste.

Project Ref 410/17.3

Date Ackn'd 15/12/2017

CU2 Project Title Pre-clinical testing programme for HB-201, consisting of toxicology studies and

Class 2

Culture Volume Class 2 Not Applicable

20/02/2022
**Project Additional Information**

**Purposes of the contained use**
The GMO is a potential cancer treatment. These studies are required as part of its approval process.

**Recipient or parental organism**
Lymphocytic choriomeningitis virus (LCMV), Armstrong strain (i.e. hazard group 2).

**Host/vector system**
Not applicable

**Origin & function**
Human papillomavirus 16 (HPV16) E6 and E7, expressed as a nonfunctional, non-oncogenic fusion protein E7E6. This acts as an antigen to provide cancer immunotherapy.

Additionally, HB-201 has been modified to contain three genome segments, i.e. one L and two S segments of which each is altered to carry either the viral GP protein plus one vaccine antigen or the viral NP protein plus one vaccine antigen. Consequently, HB-201 encodes for the full genomic information of LCMV (NP, GP, L and Z proteins) of three genome segments (instead of the naturally occurring two Segments) and are therefore infectious. However, due to the fact that only a small percentage of viral progeny packages (10%) all three genome segments, vector spread is severely compromised (i.e. attenuated) compared to bi-segmented wildtype LCMV and can be easily controlled by the host’s immune system.

**Evaluation of foreseeable effects**
The house mouse (Mus musculus) is the primary reservoir host of LCMV. Peripheral (IV, SC, IM) infection of most laboratory mouse strains is
asymptomatic. Conversely, direct intracerebral (IC) inoculation causes immuno-pathological T cell-mediated choriomeningitis and death within 6 - 9 days (Cole et al., 1972). In mice, besides vertical transmission, virus ingestion via the gastric route is the probable natural route of infection (virus is shed in urine and feces) and there are to our best knowledge no documented cases of human to human transmission with the only exception of human vertical transmission from infected mother to fetus (causing congenital hydrocephalus, chorioretinitis, mental retardation, and even more rarely, through organ transplantation. Human seroprevalence ranges from 3 - 5% in most industrialized countries (Welsh et al 2008) LCMV infections of humans can occur after exposure to fresh urine, droppings, saliva, or nesting materials from infected rodents. Transmission may also occur when these materials are directly introduced into broken skin, the nose, the eyes, or the mouth, or presumably, via the bite of an infected rodent. Post-natal acquired LCMV infection of immunocompetent human adults may be even asymptomatic or limited to a non-specific, self-limited viral syndrome with symptoms such as fever, cough, malaise, myalgia, headache, photophobia, nausea, vomiting, adenopathy, and sore throat.

The client's vaccine vectors code for Human papilloma virus-16 (HPV-16) proteins E7 and E6 (Genbank K02718). HPVs are restricted in their host range to human stratified epithelia at either cutaneous or mucosal sites. The HPV-16 proteins E7 and E6 are artificially expressed as a fusion protein that is rendered non-functional due to several mutations as described in Cassetti M et al, 2004. Thereby, the original activity of the individual proteins (Wieking et al., 2012) is abrogated which renders the expressed fusion protein E7E6 non-oncogenic. Thus, in contrast to functional individual HPV E6 and E7 proteins, E7E6 fusion proteins expressed from HB-201 is unable to interfere with cellular functions of p53, Rb (retinoblastoma protein) and PTPN13 (protein tyrosine phosphatase, non-receptor type 13) while still maintaining its immunogenicity.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste will either be autoclaved or chemically deactivated (e.g. immersion in Virkon solution) within the work room. All waste materials will then be disposed of via our clinical waste route.
Members of the GMSC were involved in the development of the risk assessment, and the comments and recommendations of all GMSC members were incorporated into the final version of the risk assessment.

**Project Additional Information**

**Purposes of the contained use**
The GMO is a potential skin cancer treatment. These studies are required as part of its approval process.

**Recipient or parental organism**
Parapox (Orf) virus strain D1701-V. This is apathogenic and avirulent in-vivo, it has been classified as S1 by the ZKBS (Az: 6790-01-1627).

**Host/vector system**
Not applicable

**Origin & function**
The inserted genetic material codes for human Melan-A, which is involved in melanosome biogenesis by ensuring the stability of GPR143. It plays a vital role in the expression, stability, trafficking, and processing of melanocyte protein PMEL, which is critical to the formation of stage II melanosomes.

**Evaluation of foreseeable effects**
ORFV-MELAN-A is not anticipated to reproduce in vivo, however the client has indicated that there is a possibility that the inserted genetic material could induce adverse autoimmune effects in the event of exposure.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
High titre waste will either be autoclaved or chemically deactivated (e.g. immersion in Virkon solution) within the work room. All waste materials will be disposed of via our clinical waste route.

Project Additional Information

Purposes of the contained use
The GMO is a potential cancer treatment. These studies are required as part of its approval process.

Recipient or parental organism
HB-202 consists of 2 GMOs; TheraT(Pic)-E7E6 and TheraT(LCMV)-E7E6. TheraT(Pic) is based on the Pichinde virus, TheraT(LCMV) is based on Lymphocytic choriomeningitis virus (LCMV), Armstrong strain (i.e. both hazard group 2).

**Host/vector system**
Not applicable

**Origin & function**
Human papillomavirus 16 (HPV16) E6 and E7, expressed as a nonfunctional, non-oncogenic fusion protein E7E6. This acts as an antigen to provide cancer immunotherapy.

**Evaluation of foreseeable effects**
The risk of causing disease in man and/or potential toxicity cannot be formally excluded. However, based on all available information we believe that TheraT vectors carry a minimal risk of causing disease in man, consistent with their intended use as cancer immunotherapies in humans. In the unexpected event that an accidental infection of staff occurred, the course of infection would most likely be clinically unapparent and without risk of human to human transmission. There are no anticipated adverse effects from the donated genetic material (HPV E7E6).

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste will either be autoclaved or chemically deactivated (e.g. immersion in Virkon solution) within the work room as necessary. All waste materials will then be disposed of via our clinical waste route.

### Project Additional Information

**Purposes of the contained use**

The GMM is a potential cancer treatment. These studies are required as part of its approval process.

**Recipient or parental organism**
### Host/vector system

Not applicable

### Origin & function

VCN-11 is an oncolytic adenovirus that is unable to replicate in normal cells but has been genetically altered to selectively replicate in and lyse tumour cells. VCN-11 is derived from wild-type human adenovirus serotype 5 (HAd5) where the HAd5 backbone has been genetically altered to incorporate five distinct modifications that confer tumour selectivity and anti-tumour activity as follows:

1. Insertion of a tumour-specific promoter (415 promoter) to confer selectivity of viral replication only in tumour cells and inhibit expression of viral proteins in normal cells.
2. Partial deletion of the E1A gene such that VCN-11 is unable to activate viral replication in normal cells.
3. Mutation of the sequence that codes for amino acids in the adenovirus fibre protein resulting in improved tumour infectivity and reduced infection of liver cells.
4. Insertion of the coding region of the human sperm hyaluronidase gene enhances dissociation of the Hyaluronan extracellular matrix in tumour cells, thus enhancing the intra-tumoral distribution of the oncolytic adenovirus and improving its therapeutic activity.
5. An albumin binding domain (ABD) inserted in the hypervariable region 1 of the hexon that enables the virus to bind to blood albumin of human, mouse and hamster origin, resulting in the evasion of pre-existing neutralizing antibodies against human adenovirus serotype 5.

Ad5WT-PH20 is a modified version of wild-type human adenovirus serotype 5 (HAd5) that has been genetically altered to incorporate a single change as follows:

1. Insertion of the coding region of the human sperm hyaluronidase gene (PH20) enhances dissociation of the Hyaluronan extracellular matrix in tumour cells, thus enhancing the intratumoural distribution of the oncolytic adenovirus and improving its therapeutic activity. PH20 is expressed only when the Ad5 is able to replicate, as PH20 expression is linked to the major late promoter via de splice acceptor IIIa after the fiber viral gene.

### Evaluation of foreseeable effects

Wild type Adenovirus serotype 5 (Ad5) is commonly contracted in childhood and causes mild respiratory symptoms conferring lifelong immunity (estimated 90%+ adults are seropositive for Ad5). Wild-type adenoviruses are able to infect and replicate in normal epithelial tissues, whereas following VCN-11 infection replication is restricted to tumour cells indicating that the overall risk from infection is low in healthy individuals. The expression
products of the inserted genes result in selective enhancement of antitumour activity. In vitro cytotoxicity studies with the related virus VCN-01 have demonstrated significantly lower cytotoxicity than wild-type adenovirus toxicity, therefore the same is expected to be true of VCN-11. The likelihood that deletion or insertions of these genes will enhance virus release and spreading of VCN-11 compared to wild-type HAd is considered to be negligible.

Although VCN-11 is not able to replicate in normal cells, the replication competency of VCN-11 in tumour cells was considered sufficient justification to assign this work to activity Class 2 and therefore we conclude that it can be safely used at laboratory and animal containment level 2.

Ad5WT-PH20 is modified version of wild-type human adenovirus serotype 5 (HAd5) that is fully replication competent and is therefore assigned to activity Class 2.

Wild-type human adenovirus serotype 5 (HAd5), while not a GMM, is fully replication competent and is therefore assigned to activity Class 2.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste associated with dose preparation and dosing of the GMM, residual GMM dose and disposable blood sampling equipment will be autoclaved at 121°C/20 minutes prior to disposal and secured in clinical waste bins and disposed of through the Company’s clinical waste incineration route. Monitoring for residual viable GMM will not be performed.

Disinfection of dissecting instruments following completion of post-mortem procedures can be made by chemical disinfection (eg. immersion in 2% Virkon for 30 minutes) followed by autoclaving. Animal wastes (both treated animal carcasses and used bedding) will be disposed directly into medibins and sealed. The outsides of clinical waste bins will be disinfected using 2% Virkon solution prior to disposal through the Company’s clinical waste incineration route. Monitoring for residual viable GMM will not be performed.

Immunoassay wastes will be autoclaved at 121°C/20 minutes prior to disposal and secured in clinical waste bins and disposed of through the Company’s clinical waste incineration route. Monitoring for residual viable GMM will not be performed.

**Significant Change ID**

**Date of Significant Change**

**Project Additional Information**

02/03/2022
Purposes of the contained use

The GMM is a potential cancer treatment. These studies are required as part of its approval process.

Recipient or parental organism

Adenovirus type 5 (Ad5)

Host/vector system

Not applicable

Origin & function

AdsVEGF-R2 and AdsVEGF-R3 are replication defective recombinant Adenovirus type 5 (Ad5 serotype) based gene transfer vectors with partial deletions of the E3 region and deletions of the E1A and E1B genes. They have expression cassettes for human soluble vascular endothelial growth factor receptors 2 and 3 respectively (sVEGFR2 and sVEGFR3 respectively). In addition to the sVEGFR coding DNA (cDNA) the expression cassette contains human cytomegalovirus (CMV) enhancer and promoter elements. In addition to the common characteristics AdsVEGF-R2 additionally contains simian virus 40 polyadenylation signal. In addition to the common characteristics AdsVEGF-R3 additionally contains bovine growth hormone polyadenylation signal (BGH pA). Both organisms were constructed using standard DNA manipulation techniques. The sVEGFR fusion protein constructs for both organisms were created by fusing cDNA’s of Ig domains 1 – 3 of hVEGFR2 and VEGFR3 respectively into the Fc-region of human IgG1. Initial virus stocks for both organisms were generated in HEK293 cells by cotransfection and plated plaques were further purified and amplified to generate the initial stocks.

Evaluation of foreseeable effects

The recombinant viruses are replication deficient due to the loss of the E1 and part of the E3 gene. However, the viral particles are themselves capable of transduction and will elicit an immune response should it enter a human. If a human is infected with either recombinant virus the transgene will be constitutively expressed in any infected cells however the infected cells should be rapidly cleared such that expression is only transient. Neither virus will integrate into the cellular genome and so the transgene will be gradually diluted from the cell population. VEGF-R2 is a human gene considered to be the main mediator of angiogenesis, vasculogenesis and vascular permeability. VEGF-R3 is a human gene involved in lymphangiogenesis.

The sponsor has indicated that the AdsVEGF-R2 material retains some degree of replication competence despite modification. Therefore containment level 2 is required.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

- **Significant Change ID**
- **Date of Significant Change**

### Project Additional Information

**Purposes of the contained use**  
Both GMM's are potential cancer treatments. These studies are required as part of the approval process.

**Recipient or parental organism**  
Copenhagen Recombinant Vaccinia Virus (VV)

**Host/vector system**  
Not applicable

**Origin & function**  
TG6010:  
TG6010 is a recombinant vaccinia virus (Copenhagen strain) deleted in the thymidine kinase (J2R) and ribonucleotide reductase (I4L) genes.  
The following genetic material was inserted:  
- human cytidine deaminase (hCD) DNA in the thymidine kinase locus of the VV genome.
Replicative and propagative characteristics of VV have been attenuated in TG6010 with the disruption of the thymidine kinase (J2R) and ribonucleotide reductase (I4L) genes which renders the modified organism dependent of highly dividing cells such as cancer cells (Parato K.A. et al., 2011). Deletion of thymidine kinase (TK) J2R gene to attenuate the virus and restrict its replication to actively dividing cells (i.e. tumour cells). Deletion of the I4L gene, the large regulating subunit of the ribonucleotide reductase (RR) gene to decrease the virus replication by acting on the viral deoxyribonucleic acid (DNA) synthesis in order to reduce toxicity and dissemination. Generation of TG6010 was performed by homologous recombination. The hCD gene was inserted into the thymidine kinase locus. Modification was conducted using plasmid vector pTG18657. The VV transfer plasmid pTG18657 contains an expression cassette encoding for the human hCD gene under the control of the p11K7.5 promoter flanking by sequences (BRG and BRD) surrounding the TK (J2R) gene. It was generated by cloning of the sequence encoding hCD in the plasmid pTG18495.

TG6030 is a recombinant vaccinia virus (Copenhagen strain) deleted in the thymidine kinase (J2R) and ribonucleotide reductase (I4L) genes. The following genetic material was inserted:

• the coding sequences for the light chain of a monoclonal antibody (4E03) blocking human CTLA4 immune checkpoint protein and for the human GMCSF glycoprotein in the ribonucleotide reductase (RR) locus of the VV genome.
• the coding sequence for the heavy chain of a monoclonal antibody (4E03) blocking human CTLA4 immune checkpoint protein in the thymidine kinase (TK) locus of the VV genome.

Replicative and propagative characteristics of VV have been attenuated in TG6030 with the disruption of the thymidine kinase (J2R) and ribonucleotide reductase (I4L) genes which renders the modified organism dependent of highly dividing cells such as cancer cells (Parato K.A. et al., 2011). Deletion of thymidine kinase (TK) J2R gene to attenuate the virus and restrict its replication to actively dividing cells (i.e. tumour cells). Deletion of the I4L gene, the large regulating subunit of the ribonucleotide reductase (RR) gene to decrease the virus replication by acting on the viral deoxyribonucleic acid (DNA) synthesis in order to reduce toxicity and dissemination. Generation of TG6030 was performed by homologous recombination. The coding sequence for the heavy chain of a monoclonal antibody (4E03) blocking hCTLA4 immune checkpoint protein was inserted in the thymidine kinase (TK) locus of the VV genome. Then, the coding sequences for the light chain of a monoclonal antibody (4E03) blocking hCTLA4 immune checkpoint protein and for the hGM-CSF glycoprotein were inserted in the
Modification was conducted using plasmid vectors pTG19348 and pTG19367. The VV transfer plasmid pTG19367 contains an expression cassette encoding for the heavy chain of the 4-E03 monoclonal antibody gene under the control of the p7.5 promoter flanking by sequences (BRG and BRD) surrounding the TK (J2R) gene. The VV transfer plasmid pTG19384 contains two expression cassettes encoding for the light chain of the 4-E03 monoclonal antibody and the human GM-CSF genes under the control of the p7.5 short promoter and pSE/L respectively. The cassettes are flanking by sequences (BRG and BRD) surrounding the TK (J2R) gene.

Evaluation of foreseeable effects

The deletion of the TK and RR activities in the vaccinia virus (VV), which restricts its replication to highly dividing cells such as tumour cells, should considerably reduce the pathogenicity and the dissemination of the virus compared to the wild type VV.

TG6010:
The hCD gene inserted in the VV has no harmful properties by itself. The hCD enzyme is ubiquitously and constitutively expressed in normal tissues. Variable levels of expression are reported in organs and fluids. As the enzyme is derived from human polymorphonuclear neutrophils, high concentration of hCD is found in mature neutrophils, with levels many times greater than in other blood elements such as lymphocytes. hCD is not suspected to induce toxicity. The in vivo effect of hCD was tested by injecting 20 mg (1 mg/kg) of hCD subcutaneously in female C57BL mice daily for 1 day or 4 days. Blood samples were then collected, and platelet numbers and cell counts, including differential counts, were obtained. No immediate harmful effect was observed.

The transfer plasmids used to generate the GMM have no harmful properties.

TG6030:
The coding sequences for the hGM-CSF cytokine inserted in the VV has no harmful properties by itself. The hGM-CSF cytokine is routinely used clinically by subcutaneous injection, primarily for bone marrow stimulation to reduce the complications of neutropenia and/or bone marrow transplantation. It was chosen as a potent stimulator of systemic anti-tumour immunity. It is well-tolerated in patients. The result is a transient stimulation of neutrophil and eosinophil cells. Clinical trials of hGM-CSF demonstrated this protein was well-tolerated at very high doses that increased white blood cell counts to over 50,000 cells/mL. The most common toxicity is mild bone pain.

The coding sequences for the light and the heavy chains of monoclonal antibody (4E03) blocking human CTLA4 immune checkpoint protein inserted in the VV have no harmful properties by themselves. Human monoclonal antibody blocking CTLA4 immune checkpoint inhibitor is a medicinal product already commercialised as ipilimumab through a non-viral vector based vectorized form. Then, pre-clinical and clinical experiments experience cumulated inform on potential harmful potential of human monoclonal
antibodies blocking CTLA4 immune checkpoint inhibitor. In its pre-clinical development, 66 cynomolgus monkeys were treated for ≥ 3months with ipilimumab for toxicology studies. Most pre-clinical studies were conducted at 3 or 10 mg/Kg and toxicities associated with ipilimumab in cynomolgus monkey were minimal, and included slight increases in circulating T cells, slight to moderate lymphocyte administration of multiple organs, lymph node hyperplasia, and some evidence of decreased spleen weight. In clinical trials, ipilimumab is most commonly associated with adverse reactions resulting from increased or excessive immune activity. The transfer plasmids used to generate the GMM have no harmful properties.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste associated with dosing of the GMM, residual GMM dose and disposable blood sampling equipment will be autoclaved at 121°C/20 minutes prior to disposal and secured in clinical waste bins and disposed of through the Company’s clinical waste incineration route. Monitoring for residual viable GMM will not be performed.

Disinfection of dissecting instruments following completion of post-mortem procedures can be made by chemical disinfection (e.g. immersion in 2% Virkon or 0.45% active chlorine bleach solution for 30 minutes) followed by autoclaving.

Animal wastes (both treated animal carcasses and used bedding) will be disposed directly into medibins and sealed. The outsides of clinical waste bins will be disinfected using 2% Virkon or 0.45% active chlorine bleach solution prior to disposal through the Company’s clinical waste incineration route.

Monitoring for residual viable GMM will not be performed.

Immunoassay wastes will be autoclaved at 121°C/20 minutes prior to disposal and secured in clinical waste bins and disposed of through the Company’s clinical waste incineration route. Monitoring for residual viable GMM will not be performed.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste associated with dosing of the GMM, residual GMM dose and disposable blood sampling equipment will be chemically inactivated by soaking in 2% Virkon solution for a minimum of 30 minutes. The outsides of any dosing waste containers (e.g. designated sharps bins) will be sealed and chemically disinfected with 2% Virkon solution prior to removal from the treatment area then secured in clinical waste bins and disposed through the Company's clinical waste incineration route. Monitoring for residual viable GMM will not be performed.

Disinfection of dissecting instruments following completion of post-mortem procedures can be made by chemical disinfection (e.g. immersion in 2% Virkon or 0.45% active chlorine bleach solution for 30 minutes) followed by autoclaving.

Animal wastes (both treated animal carcasses and used bedding) will be disposed directly into medibins and sealed. The outsides of clinical waste bins will be disinfected using 2% Virkon or 0.45% active chlorine bleach solution prior to disposal through the Company's clinical waste incineration route. Monitoring for residual viable GMM will not be performed.

Animals rooms will be cleaned using 2% Virkon solution at the end of the animal housing phase of the studies.

Immunoassay wastes will be autoclaved at 121°C/20 minutes prior to disposal and secured in clinical waste bins and disposed through the Company's clinical waste incineration route. Monitoring for residual viable GMM will not be performed.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y
Members of the GMSC were involved in the development of the risk assessment, and the comments and recommendations of all GMSC members were incorporated into the final version of the risk assessment.

CU2 Project Title GENERATION OF EQUINE INFLUENZA VIRUS BY A REVERSE GENETICS SYSTEM

Date Project Ceased

Class Class 2

CultureVol Class 2 < 1 litre

Consent Granted not applicable

Project notified under transitional arrangements N

Tick if notifying a connected programme of work Y

Historical Significant Changes

02/03/2022 Page 7268 of 15326
The project aim is to establish a plasmid-based reverse genetics system to generate equine influenza viruses entirely from cloned cDNA. This technique enables the relevance of amino acid changes in influenza virus proteins to be directly assessed. The system will be established for a well-characterised strain of the H3N8 subtype of equine influenza virus (A/eq/Newmarket/2/93). The plasmid-based reverse genetics system has been established for human influenza virus, and the plasmids for the rescue of A/Victoria/3/75 (H3N2) are available from Dr Thomas Zrcher (GiaoxSmithKline, Stevenage, UK) for use in this project. In this system, mammalian cells are transfected with 4 protein expression plasmids in which the influenza virus replication genes are expressed under the control of human cytomegalovirus (CMV) promoter and viral RNA transcription plasmids expressing all 8 influenza genes under the control of the human polymerase I (Poll) promoter. Assuming functional compatibility between the human influenza replication proteins and equine influenza virus genes (equine-human influenza reassortants have been generated by traditional methods), the human influenza system will be used as the basis for establishing the equine influenza system. Individual genes of the human influenza system will be generated de novo. Chloramphenicol acetyltransferase (CAT) and/or green fluorescent protein (GFP) reporter genes flanked by the non-coding sequences of an influenza gene will be used as a model RNA to demonstrate that protein expression plasmids expressing the viral replication genes NP, PB1, PB2 and PA are functional and to determine transfection efficiency. Transfection of mammalian cells with protein-expression plasmids encoding cDNA for each of the equine influenza proteins will be used to check expression of full-length proteins prior to subcloning into the vRNA-coding transcription plasmid. The T7 expression system may also be used to confirm expression of full-length proteins if this cannot be achieved by expression under the control of the CMV promoter.

If successful in generating recombinant virus, the relevance of specific amino acid mutations in the influenza virus proteins for the phenotype of equine influenza viruses will be assessed. Mutations will be introduced into the haemagglutinin (HA) gene and any effect on antigenicity examined in vitro. The mutations that will be introduced will be those observed in wild-type viruses, the aim being to compare the effects of different mutations in a common background to remove the influence of concomitant changes in other genes or other regions of the same gene.

Recipient or parental organism

Recombinant human and equine influenza A viruses. Human influenza A virus is an ACDP Hazard Group 2 agent; therefore the recombinant viruses will be handled at ACDP Containment Level 2

Host/vector system

Host/Vector systems are standard, well-defined systems including standard cloning strains of Escherichia coli, attenuated vaccinia virus, modified vaccinia Ankara T7 virus and non-human mammalian cells.

Origin & function

02/03/2022

Page 7269 of 1532
Genetic material obtained from influenza virus isolates. To be used in in vitro research only.

Evaluation of foreseeable effects

Mutations in the HA may potentially alter virus binding to, or entry into cells by changing the structure of the receptor binding site, which is well-defined for influenza HA. Only mutations observed in naturally arising variants of equine influenza will be introduced into the HA, and it is considered unlikely that natural variants occurring as a result of antigen drift will have alterations to tissue tropism or host range. Introduction of equine influenza HA and/or NA into a genetic background of human influenza virus is expected to alter the host range as equine influenza has a different receptor specificity to human influenza. It is expected that an equine-human reassortant will have reduced infectivity for humans. Such reassortants have been generated in vitro without the use of genetic manipulation techniques. Traditional equine influenza vaccines should provide susceptible species with adequate protection against an equine-human reassortant, as the major component of protective immunity is antibody to the (equine) HA.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

02/03/2022
Purposes of the contained use

Viral vectors will be used to express genes which are associated with pluripotency in equine and canine cells to induce the formation of pluripotent stem cells. These cells will be used for in vitro modelling of inherited diseases in these species and for investigations into the therapeutic potential of these cells or their derivatives in the treatment of injuries and diseases.

Recipient or parental organism

Equine and canine cell lines

Host/vector system

Replication defective retroviral and/or lentiviral vectors

Origin & function

The viral vectors will express multiple genes which are associated with pluripotency. These will include oncogenes such as c-myc

Evaluation of foreseeable effects

The viral vectors to be used will be capable of infecting human cells. The vectors to be used will all be replication defective to minimise their risk and would be unable to spread if released to the environment. However, some of the vectors may contain oncogenes (e.g., c-ymyc) and would therefore have the potential to promote tumour formation if they came into direct contact with human cells during handling. To minimise this risk, the viral vectors containing oncogenes will be handled in class 2 microbiological safety cabinets. The use of sharps will not be required during the handling of the viral vectors.
The viral vectors will be used to genetically modify animal cells to induce pluripotency. The resulting cells will pose no risk to human health or the environment should they be released. Therefore they will be handled in containment level 1 facilities.

The induced pluripotent stem cells (or cells derived there from) may be transplanted into experimental animal models of injury or disease to assess the therapeutic potential of the cells. No additional genetic modifications will be made to the cells which would make them more likely to undergo uncontrolled growth. Therefore any animal models receiving these cells will pose no risk to human health or the environment and will not require special containment facilities.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

| Not applicable |

Describe the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

| The viral vectors containing oncogenes may pose a risk to human health and so all material which comes into contact with these lenti/retroviruses will be treated to ensure that all virus is killed |
| Surfaces will be cleaned with a 1% solution of virkon followed by 70% alcohol. |
| Liquid waste containing viral vectors will be inactivated by treatment with disinfectant for 1h. |
| Contaminated laboratory glassware will be immersed in disinfectant for 1h prior to washing and sterilisation by autoclaving |
| Contaminated plasticware including pipettes will be immersed in disinfectant for 1h prior to washing and sterilisation by autoclaving |
| Contaminated plasticware including pipettes will be immersed in disinfectant prior to being double bagged and autoclaved to ensure complete inactivation of any hazardous material |
| Either a 3% solution of virkon (peroxygen compound or a 10% solution of chloros will be used as a disinfectant. |
| Inactivation will be monitored regularly by the direct plating of treated liquids onto permissive cell lines and PCR analysis for viral sequences being performed or monitoring viral reporter gene (e.g green fluorescent protein) expression directly where applicable. |

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
The GMO committee reviewed the application on the 7th February 2011 and agreed the work involved expression of an oncogene, and therefore has an increased risk to human health, then the work should be carried out at level 2. This is in agreement with the discussions at the 16th meeting of the scientific advisory committee on genetic modification on the 18th March 2009. An area at the AHT currently used for level 2 work was identified (room 70 within the centre for preventive medicine) in which the work would be performed.

**Historical Significant Changes**

**Historical Date of Additional Info**

**Significant Change ID**

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

The plasmids containing phospholipase A2 genes will be used to express recombinant proteins in E. coli. These proteins will be used in vitro to stimulate different subsets of equine immune cells, and the effects will be studied.

02/03/2022
will allow for the furthering of our knowledge of the pathogenic factors produced by S. equi and the immune response in the horse.

**Recipient or parental organism**

Competent E. coli K-12 derivatives such as DHSa-like and Bl21-DE3

**Host/vector system**

The plasmids will be produced and protein expressed in competent E coli (DHSa-like and Bl21-DE3). The vectors used will be pGEX, pET, or pMAL

**Origin & function**

The plasmids transformed into E coli will express phospholipase A2. proteins from S. equi and S. zooepidemicus.

**Evaluation of foreseeable effects**

The plasmid produced will be transformed into E. coli. The risk of transfer to other bacteria is low. The recipient E. coli strains are not considered pathogenic to humans or animals. They are expected to have limited survivability in the environment and often have auxotrophic requirements, which are unlikely to be satisfied outside of laboratory culture. E. coli K-12 derivatives are recognised as non-colonising and disabled, and may be considered to be equivalent to hazard group 1. The vectors are considered to be non-mobilisable. Gene transfer is thus a remote possibility. Phospholipases are a group of enzymes that bring about changes in host cell membrane composition through the hydrolysis of fatty acids. This causes release of arachidonic acid, a precursor of eicosanoids (e.g prostaglandin, leukotrienes) leading to activation of inflammatory cascades. Therefore, the protein is likely to be toxic and cause an inflammatory response, and so if the recombinant protein breached the skin it is possible that this would be detrimental to humans, and so poses a risk. To minimise this risk, the bacteria expressing the plasmid will be cultured in plastic rather than glass flasks, and no sharps will be used during the handling of either the bacteria ~ expressing the protein, or the protein itself. The bacteria will be handled in class 2 microbiological cabinets at containment level 2.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

No derogation required

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

The E. coli expressing the phospholipase A2 proteins may pose a risk to health, therefore all material that comes into contact with these bacteria will be treated to ensure all bacteria are killed. Surfaces will be cleaned with a 1% solution of virkon, followed by 70% alcohol. Liquid waste will be inactivated by treatment with disinfectant for 24 hours. Contaminated laboratory culture flasks will be immersed in disinfectant for 24 hours prior to washing and sterilisation by autoclaving. Should pipettes or other laboratory equipment become contaminated, where possible, they will be immersed in disinfectant prior to being double bagged and autoclaved to ensure all bacteria are killed. Where this is not possible (e.g. the non-removable interior of an incubator), the contaminated area will be sectioned off and thoroughly cleansed with a 1% solution of virkon, followed by 70% alcohol.
Either a 10% solution of chloros, or a 1:50 ANIGene HLV4D solution (previous name TriGene) will be used as disinfectant. Inactivation will be monitored by direct plating of treated liquids on to agar plates and incubated at 37°C for 24 hours. Where no growth is observed after 24 hours in culture, decontamination will be deemed complete.

The risk assessment covers the expression of phospholipase A2 toxins derived from Streptococcus equi and Streptococcus zooepidemicus in E. coli. The committee reviewed the application on the 13th November 2014 and agreed that because of the nature of the toxins the application was correctly considered to be a class 2 activity. The committee also agreed that it was prudent that no sharps would be used when handling the bacteria and the expressed proteins.

Maximum culture volume which would be released is 12 L per day. Waste is deactivated by autoclaving at 126 degrees C for 30 minutes. The autoclave receives regular servicing at which time all instrumentation is recalibrated. In addition TTS and Spore Strips are used periodically to ensure continued effectiveness of the system.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Historical Significant Changes

Historical Date of Additional Info

02/03/2022
**Significant Change ID**

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

**Aim:** This project aims to utilise genetically altered bacterial strains, typically associated with nosocomial infections (Staphylococcus and Enterococcus species), to investigate the cellular responses to situations that pose a stress condition (e.g., antibiotic-induced stress and stresses encountered within the host during colonisation or infection, for example pH).

**Methods:** Global regulatory genes and virulence genes of candidate Staphylococcus and Enterococcus species will be inactivated by targeted gene deletion or disruption, using for example TargeTron Gene Knockout System (Sigma). Initially the Enterococcus faecalis virulence gene efA will be deleted using, for example, the TargeTron Gene Knockout system (Sigma). Other deletion mutants targeting specific global regulatory genes will be acquired from other laboratories for use in this project and not constructed within the laboratory.

Resistance to the antibiotic linezolid will be generated in the reference strain of Staphylococcus aureus ATCC 29213 using a naturally occurring linezolid resistance plasmid. This GMM will be acquired from another laboratory and not constructed within the laboratory.

**Recipient or parental organism**

**Parental strains:**

i) Enterococcus faecalis ATCC 47077 / OG1RF (complete genome GenBank: CP002621.1). This strain is a rifampicin and fusidic acid resistant derivative of OG1, which is widely used by the research community. Hazard Group 2 organism.

ii) Staphylococcus aureus ATCC 29213. Staphylococcus aureus subsp. aureus ATCC 29213 is one of the most commonly used strains in drug discovery research and for quality control (Soni et al., 2015). It is sensitive to a large variety of antimicrobials, including methicillin. Hazard Group 2 organism.

**Host/vector system**

Enterococcus faecalis ATCC 47077 / OG1RF – no vector, deletion mutant. Targetted gene deletion to be generated using a commercially available system, eg TargeTron Gene Knockout System (Sigma) or equivalent.

Staphylococcus aureus ATCC 29213 will be given the plasmid cfr (a naturally occurring resistance plasmid of S. aureus), which codes for linezolid resistance.

**Origin & function**

GMM which will be generated using the host strains listed above:

1) Enterococcus faecalis ATCC 47077 / OG1RF; deletion of relA or relA/relQ (GTP diphosphokinase genes) (Abranches et al., 2009). RelA/RelQ are involved in the synthesis/hydrolysis of ppGpp (guanosine 3’-diphosphate 5’-diphosphate), which is a mediator of the stringent response (bacterial stress response) that coordinates a variety of cellular activities in response to changes in nutritional abundance. This GMM will be acquired from another laboratory and not constructed within Dr Lang’s laboratory.

Enterococcus faecalis. Journal of Bacteriology 191(7);2248-2256.

2) Enterococcus faecalis ATCC 47077 / OG1RF; deletion of the virulence factor gene efaA (Enterococcus faecalis endocarditis specific antigen). Enterococcus faecalis endocarditis specific antigen (EfaA), a well-known virulence factor of E. faecalis originally detected in connection with studies of endocarditis (Lowe et al., 1995). Using a mouse model system, it has been shown that an EfaA mutant of E. faecalis OG1RF is less virulent than the wild-type strain (Singh et al., 1998). This GMM will be constructed in Dr Lang's laboratory at Glasgow Caledonian University.

3) Staphylococcus aureus ATCC 29213; insertion of the naturally occuring plasmid cfr (Locke et al., 2014).
The plasmid cfr is a naturally occurring plasmid of S. aureus that conveys resistance to the antibiotic linezolid. Plasmid DNA isolated from strain 1128105 was previously transformed into the strain S. aureus ATCC 29213. This GMM will be acquired from another laboratory and not constructed within Dr Lang's laboratory.

Evaluation of foreseeable effects

1) Enterococcus faecalis ATCC 47077 / OG1RF; deletion of relA and relQ; these mutants are defective in the regulatory pathways associated with a stringent (stress) response. There is no known increase to the innate hazard/risk of these mutants relative to the parental strain (Enterococcus faecalis ATCC 47077 / OG1RF; Hazard Group 2 organism).

2) Enterococcus faecalis ATCC 47077 / OG1RF; deletion of efaA; using a mouse model system, it has been shown that an EfaA mutant of E. faecalis OG1RF is less virulent than the wild-type strain (Enterococcus faecalis ATCC 47077 / OG1RF; Hazard Group 2 organism) (Singh et al., 1998). References: Singh KV, Coque TM, Weinstock GM, Murray BE (1998). In vivo testing of an Enterococcus faecalis efaA mutant and use of efaA homologs for species identification. FEMS Immunol Med Microbiol. 21(4):323–31.

3) Staphylococcus aureus ATCC 29213 cfr+; isolate will be resistant to the antibiotic linezolid, but virulence will not be altered. There is no known increase to the innate hazard/risk of this mutant relative to the parental strain. The parental strain, S. aureus ATCC 29213 (Hazard Group 2), is one of the most commonly used strains in drug discovery research and for quality control. To limit the potential for horizontal gene transmission of the resistance plasmid, the GMM will be cultivated in pure culture only and all discard will be isolated from other biological waste. The organism is sensitive to a large range of clinically used antibacterials, including methicillin, therefore, despite the acquisition of resistance to the antibacterial linezolid other treatment options are available.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None requested

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Working environment: To reduce the hazard posed to the workers and environment, all manipulations will be undertaken in the Micro-Containment Suite (MCS) C122 using Class II Microbial Safety Cabinet (MSC II) and cultures incubated in a bacterial cell incubator, also located in the MCS.
Access to the MCS is restricted via keycard entry to users who are carrying out the work described in the specific Risk Assessments and a training log is retained within C122 alongside the Risk Assessments.
Waste disposal: Solid media cultures (agar plates) will remain within the MCS in sealed containers and separate from other biological waste prior to autoclave destruction. The solid waste will be transported in sealed and labelled containers to the autoclave (located on the floor above the Micro-Containment Suite), using a hoist system, and destruction recorded using a biological waste destruction log system.
Liquid cultures (broth cultures) will only leave the MCS once inactivated using an appropriate disinfectant, eg 10% Anistel for 24 hours. Once inactivated, the waste will be sent for autoclave disposal, as outlined above. Contaminated materials decontaminated by immersion in appropriate disinfectant, eg 10% Anistel for 24 hours then bagged and autoclaved.
Discard is undertaken according to GMM Risk Assessment and MCS guidelines. All discards will be labelled GMM for disposal purposes. Waste is removed daily from the MCS for autoclaving using a hoist system (autoclave located the floor above the Micro-Containment Suite), autoclaved and discarded following a strict and traceable protocol. Only trained and registered personnel are permitted access to the MCS, domestic staff are not permitted access and are not allowed to dispose of any waste from this area.

Accidental spillages: Small spillages: contaminated surfaces will be treated with an appropriate disinfectant; eg 10% Anistel. Contaminated materials decontaminated by immersion in appropriate disinfectant, eg 10% Anistel for minimum 60 minutes or bagged and autoclaved.

Large spills: Anyone working in the MCS will be alerted to the spill. A Microbial Spill Kit (available in MCS) will be used to cover the area twice the size of the spill with disinfectant soaked tissue or surrounded with dry disinfectant. The contaminated tissue will be bagged for autoclave destruction and the area re-cleaned with disinfectant solution (2% Anistel or equivalent). If broken glass is involved, forceps or a brush will be used to transfer the glass to a sealable autoclavable discard pot. The pot will be labelled and discard technicians notified. (PI and Biological Safety Advisor) and (GMO officer) will be notified and the incident recorded through the accident recording system.

Is an emergency plan required according to regulation 20?  
If yes, tick to confirm that it is attached to this form  
Tick to confirm that you have attached a risk assessment to this form  
Tick if you are claiming exemption from disclosure for section of the risk assessment

Please enter comments on the GM safety committee on the risk assessment

Your application to GCU GMSC has been approved for submission to HSE as a Class 2 project with some minor amendments indicated in the document

Project Ref: 419/16.2

Date Ackn’d: 22/12/2016

CU2 Project Title: The generation of human induced pluripotent stem cells (and targeted cell lineages derived by differentiation from these cells) through the delivery of episomal vectors into human primary cells by non-viral transfection methods

Class: Class 2

Culture Volume: Class 2 < 1 Litre

Consent Granted: Non-GMM

Date Project: 02/03/2022

Page 7288 of 15326
Project Additional Information

Purposes of the contained use

To reprogram human skin fibroblasts, derived from skin biopsies from patients undergoing elective surgery, or from diabetic and non-diabetic individuals, and from involved (diseased) and uninvolved regions of skin. The patients are not tested for HBV, HCV or HIV, requiring Class 2 categorisation. The IPS cells will then be differentiated to target cell lineages, as required, using modified serum, specific substrata and combinations of growth factors and cytokines, and used in numerous studies requiring difficult or impossible to source human cell types.

Recipient or parental organism

Human skin fibroblasts, derived from skin biopsies from patients undergoing elective surgery for breast cancer, or from diabetic and non-diabetic individuals, and from involved (diseased) and uninvolved regions of skin from diabetic patients. The anonymised patients are not tested for HBV, HCV or HIV, although their clinical background is available on request.

Host/vector system

The system uses episomal DNA plasmid vectors, as described in Risk Assessment 24/15/AG/LS. There is no integration of the genetic material into the host cell genome. The non-viral DNA plasmid vectors contain the EBNA 1 (Epstein-Barr virus nuclear antigen 1) expression cassette and the OriP origin of replication. Though EBNA 1 is a viral protein, the vectors themselves are DNA plasmids which enter the cell via lipid-based transfection, or Amaxa electroporation, and do not act as viruses or retroviruses.

Epi5 Reprogramming Vectors
These are oriP/EBNA1 vectors containing 5 reprogramming factors (Oct4, Sox2, Lin28, Klf4, and L-Myc) which replicate extra-chromosomally only once per cell cycle.

- pCE- hOCT3/4: Oct 4
- pCE-hSK: Sox2, KLF4
- pCE-hUL: L-Myc, Lin28

Epi5 p53 & EBNA Vectors
Vectors expressing mp53DD (a dominant negative mutation of p53) and EBNA1, which together improve the reprogramming efficiency of the system.

- pCE-mP53DD: mp53DD
- pCXB-EBNA 1: EBNA 1
The vectors will be delivered to the recipient cells, using either Lipofectamine 3000 (ThermoFisher Cat No L3000 - please see MSDS appendices 5 and 6 to risk assessment, 24/15/LS/AG), or using Amaxa II electroporation and kit VAPD-1001 as described in the amendment (dated 18/05/16; received and approved 23/05/16) to the same.

Origin & function

The episomal vectors are of commercial origin (ThermoFisher C-004-SC, MSDS Appendix 7, 24/1S/AG/LS) and contain the reprogramming factors Oct4, Lk4, Sox2, L-Myc and Lin28, as well as mpS3DD and EBNA1.

Oct3/4 is encoded by POUSF-1, and is a transcription factor associated with maintenance and self-renewal of pluripotent stem cells.

Sox2 is encoded by SOX2, and is a transcription factor associated with maintenance and self-renewal of pluripotent stem cells.

Klf4, encoded by KLF4, is a transcription factor regulating proliferation, apoptosis, differentiation and pluripotent reprogramming.

L-Myc, encoded by MYCL 1, is a transcription factor implicated in pluripotent reprogramming and lung cancer. Full function is unknown.

Lin28, encoded by LIN28, enhances translation of IGF-2 (insulin-like growth factor 2) mRNA

MpS3DD, encoded by MpS3DD, is a dominant negative mutation of pS3 protein, providing temporary high efficiency pS3 knockdown for improved reprogramming.

EBNA1, encoded by EBNA1, is involved in gene regulation, extrachromosomal replication and episome genome maintenance.

Evaluation of foreseeable effects

The oncogenic potential of the genes to be introduced to achieve reprogramming:

POUSF1: Aberrant expression of this gene in adult tissues is associated with tumorigenesis.

SOX2: Implicated in proliferation and tumorigenicity in melanoma and lung cancer.

KLF4: Oncogene involved in cell migration and invasion, also implicated as a tumour suppressor.

MYCL 1: Implicated in lung cancer.

LIN28: Associated with chemoresistance and oncogenesis.

Hsu KF, Shen MR, Huang YF, Cheng YM, Lin SH, Chow NH, Cheng SW, Chou CY, Ho CL. Overexpression of the RNA-binding proteins Lin28B and IGF2BP3 (IMP3) is associated with chemoresistance and poor disease outcome in ovarian cancer. Br J Cancer. 2015 Jul 28;113(3)

EBNA1: Increases cell survival and proliferation. Implicated in cancers included B-ceillymphoma and epithelial tumours.

Frappier L. Contributions of Epstein-Barr nuclear antigen 1 (EBNA 1) to cell immortalization and survival. Viruses. 2012 Sep;4(9):1537-47.

The introduction of the genes is intended to induce a state of pluripotency in the recipient cells, which will increase their proliferative and tumorigenic capabilities. Pluripotent cells are also able to generate teratomas when injected into immunedeficient mice, and may pose a similar risk with humans. The modified cells therefore pose a greater risk to human health than the original host cells.

The cells only pose a teratoma risk when injected or ingested, so needles or sharps will not be used for any aspect of pluripotent cell culture. It is highly unlikely that the the procedures followed post-transfection will create significant aerosols. If good laboratory practice and the recommendations listed in the risk assessment are followed, ingestion or inhalation of the material is highly unlikely. Further, the plasm ids used to re-programme the cells are essentially eliminated on subsequent culture due to their episomal nature, as indicated in Appendices 1 and 2 of the current risk assessment (24/15/AG/LS). The cells are highly unlikely to survive outside of a specified tissue culture environment and should not pose an increased risk compared with the original (unmodified) primary cells if good laboratory practice and the recommendations for decontamination listed in the risk assessment are followed.

The use of primary human cells which have not been tested for viral contamination leads to containment requirements (Class 2). It is not possible to predict how the reprogramming factors used may interact or impact on such contaminants. Culture work is to be performed at low scale and in low volumes, reducing the overall risk from handling the cells.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Colonies should be picked using pipette tips and not needles or sharps. Adherence to good laboratory practice and correct disposal as detailed in the risk assessment (Appendix 8) and relevant COSHH forms. Spent tissue culture media, reagents and plastics are treated overnight with Presept inside fume hood, as is done with all cultures from any source. Presept is a chlorine releasing agents which operates with a complete biocidal spectrum. Liquids are then disposed of in a standard sink with plenty of water, and culture plastics are disposed of as standard laboratory plastic. Class II safety cabinet should be utilised for transfection and maintenance of cells, and PPE (laboratory coat and latex/nitrile gloves) should be worn. Correct decontamination procedures are essential, together with adherence to the protocols set out in the risk assessment and COSHH forms to inactivate the cells. Culture work is to be performed at
low scale and in small volumes which further reduces the risk associated with the material.

The cells will undergo a morphological change and acquire new characteristics upon being successfully modified. Visual confirmation of pluripotent cell morphology is the first indicator of this, which will be followed by characterisation techniques such as alkaline phosphatase staining, flow cytometry (SSEA3, SSEA4, TRA-1-60, TRA-1-81), immunocytochemistry (Oct4, Sox2, Nanog), RT-qPCR (tools such as pluripotency array cards), and differentiation to cells representing the three germ layers. Given the culture protocol and usage, and adherence to good laboratory practice for Class II organisms, the modified cells are not seen as presenting a greater risk to the user than the starting material. The ultimate form of the iPSCells will, of course, depend upon their directed differentiation to targeted cell lineages, which is achieved using modified media, specific substratum and defined combinations of cytokines and/or growth factors delivered at key stages of differentiation (see amendment 02 dated 24/10/16; receipted and approved 26/10/16).

These cells will also be subject to Class II containment (above), none of the iPSCells, or their targeted cell lineages, will be employed as human therapeutics.

Working environment: To reduce the hazard posed to the workers and environment, all manipulations will be undertaken in the Micro-Containment Suite (MCS) C122 using Class II Microbial Safety Cabinet (MSC II) and cultures incubated in a cell incubator, also located in the MCS.

Access to the MCS is restricted via keycard entry to users who are carrying out the work described in the specific Risk Assessments and a training log is retained within C122 alongside the Risk Assessments.

Discard is undertaken according to GMM Risk Assessment and MCS guidelines. All discards will be labelled GMM for disposal purposes. Both solid and liquid waste will be fully decontaminated using 10% Anistel for 24hours then bagged and autoclaved by the individual user and removed from the MCS for autoclaving using a hoist system (autoclave located the floor above the Micro-Containment Suite), autoclaved and discarded following a strict and traceable protocol. Any solid human tissue will be disposed of in accordance with our in-house guidelines in adherence with the Human Tissue Act Scotland 2006. Only trained and registered personnel are permitted access to the MCS, domestic staff are not permitted access and are not allowed to dispose of any waste from this area.

Accidental spillages: Small spillages: contaminated surfaces will be treated with an appropriate disinfectant; eg 10% Anistel. Contaminated materials decontaminated by immersion in appropriate disinfectant, eg 10% Anistel for minimum 60 minutes or bagged and autoclaved.

Large spills: Anyone working in the MCS will be alerted to the spill. A Microbial Spill Kit (available in MCS) will be used to cover the area twice the size of the spill with disinfectant soaked tissue or surrounded with dry disinfectant. The contaminated tissue will be bagged for autoclave destruction and the area re-cleaned with disinfectant solution (2% Anistel or equivalent). If broken glass is involved, forceps or a brush will be used to transfer the glass to a sealable autoclavable discard pot. The pot will be labelled and discard technicians notified. Dr L (PI and Biological Safety Advisor) and Prof S (GMO officer) will be notified and the incident recorded through the accident recording system.
Reasons for recommendation of amendment: Two amendments were submitted for the original GMRA reference 24/15/AG/LS. These were circulated to the GMSC and the following feedback comments provided.

1. Location of work to change to Micro-containment suite (MCS) utilising viral disposal procedure. Training will be required for access.
2. Human tissue disposal procedures may require to be added for any tissue obtained, but cells may be decontaminated and disposed of via the local guidelines in MCS.
3. Disposal via original RA is not permitted and details provided for CU2 form should be used.
4. Plan is required for disposal, shipping and receipt of GMM cells from Biobank.

Risk assessment to human health: Cells may contain adventitious agents which under the COSHH may fall in to hazard group 3. No attempt will be made to seek and identify any pathogenic agents in the cells provided by the Biobank. Both primary and GM iPS cells of human origin will be utilised. This cell type is considered medium/high hazard level. Both cell types will be or have inserted vectors expressing biologically active molecules. As per original risk assessment, these molecules are growth factors or proteins that have been shown to increase proliferation and have demonstrated evidence of tumourigenesis. In addition, as the iPS cells are already modified we do not know the affect this has had on any adventitious agents present. For this purpose containment level 2 safety cabinets are required for manipulation to protect the user. Risk is further minimised by no use of sharps and the use of small volumes.

Risk assessment to the environment is deemed low/negligible. Escape and survival highly unlikely. Containment measures applied above sufficient.

Review of control measures: Shipment protocols for GMM iPS cells containing unknown biologic agents will be adhered to as per Biobank procedure and GMM legislation.

Final assignment of containment measures and risk class:
Containment levels required correspond to Level 2 with no additional measures. Risk posed to human health is considered low. This gives an overall risk classification of Class 2. Containment level 2 and Risk class level 2 therefore CU2 submission required. This was dated 24/10/16

Historical Significant Changes
**Project Additional Information**

**Purposes of the contained use**
To determine the tissue concentration of a gene therapy vector in the organs of mice treated with a modified human herpes simplex viral vector.

**Recipient or parental organism**
The recipients in the study are BALB-C mice.

**Host/vector system**
The vector is a replication competent herpes simplex type-1 virus. The strain is JS-1 ECACC Accession Number 01010209. It is deleted for the neurovirulence factor ICP34.5 and for the immune avoidance factor ICP47. The transgene codes for human GM-CSF the expression of which is under the control of the human cytomegalovirus immediate early promoter.

**Origin & function**
The human GM-CSF gene product will be delivered by intratumoural injection in human clinical trials not covered by this application. Covance are acting as subcontractors for the safety determination studies on this agent. The agent was produced by Biovex under a previous successful notification to HSE.

The function of the gene product is as an anti-tumour therapy.

**Evaluation of foreseeable effects**
HSV is not usually transmitted through the aerosol route. Infection is by contact. Humans are the only natural host for HSV.

All operations will be performed under class 2 containment levels. It is unlikely that the vector will reach the environment, if it did it could not cause harm to humans or animals which it came into contact with. Access to the facility will be restricted and appropriate disinfection and waste management procedures will be instituted. These measures will reduce the likelihood of hazards to negligible.

It is not thought that the modified virus would pose a serious risk to the environment. HSV is a human virus that can be propagated by lytic infection. No integration of the viral genome with the cellular genome occurs during replication.
The virus is fragile, and is rapidly inactivated by disiccation, lipid solvents and mild detergents. The fact that contact is required for transmission attests to the instability of the virus outside the host.

It is unlikely that the Oncovex HGMSCF vector will be harmful to humans, animals, or plants. The vector is modified so that replication only occurs in rapidly dividing cells and not in non-dividing cells. Considerable literature shows that HSV 1 deleted for ICP34.5 is non-pathogenic in animals and humans. Approximately 80% of the human population are seropositive for HSV-1. Infection is by contact, and transmission by the aerosol route is not thought to occur. The therapeutic gene delivered, human GM-CSF is present in normal, healthy humans.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

The study will involve the administration of the vector to 18 mice by I.V. injection and 18 mice by subcutaneous injection. Animals will be killed, organs removed and nucleic acid extracted. Nucleic acids will then be subjected to quantitative PCR analysis.

Doses will be prepared in a microbiological class II cabinet. Laboratory gowns, gloves, face masks will be worn, care will be taken not to generate aerosols.

In the animal room trained technicians will wear gowns latex/nitrile gloves and respirators. Care will be taken to prevent needlestick injuries and all waste will be transferred immediately to containers for autoclaving. Animals will be housed in an exclusive room with filtered air extract. After use cages will be disinfected and the room washed with hypochlorite solution.

Necropsy will be performed in ventilated workstations and staff will wear safety glasses, gowns and gloves and will be protected by glass screens. All workstations will be disinfected after use. Snapfrozen tissues will be received in the biotechnology department where small samples will undergo nucleic acid extraction in class II cabinets.

The vector will be inactivated by this step.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All animals cages will be disinfected using hypochlorite solution. All waste including food, bedding and carcasses will be double bagged and autoclaved within the facility prior to removal as clinical waste by White Rose Environmental. All surfaces will be disinfected with hypochlorite solution or "Virkon" used instruments will be autoclaved and disposed of in 'Sharps' boxes as clinical waste. Any re-usable equipment will be separately autoclaved. All laboratory coats will be autoclaved after use. This organism is an enveloped virus and hence is rapidly inactivated in air and highly susceptible to disinfectants and/or autoclaving. No viable organisms would survive de-contamination procedures.

Is an emergency plan required according to regulation 20?

Please enter comments on the GM safety committee on the risk assessment

02/03/2022
The Genetic Modification Safety Committee has been consulted throughout the development of the protocol and representatives of the various groups involved (animal technicians, necropsy, dispensary and biotechnology departments) attended the meeting at which the completed risk assessment was presented. All members were happy that the risk assessment was adequate and accurate and that the intended control procedures would result in a negligible risk to operatives. A study startup meeting will be arranged prior to commencement to reinforce control procedures and adherence to them. This meeting will involve all study operatives.

02/03/2022
The parent organism is Ovine Adenovirus

Host/vector system

OAdV 623 is a recombinant adenovirus which contains the full viral genome and a transgene containing a prostate specific promoter (derived from zgenes - the human prostate specific membrane antigen and the rat probasin gene) and the therapeutic gene, purine nucleoside phosphorylase (PNP).

Origin & function

The product of the therapeutic gene (PNP) will be expressed in human prostate cells and convert a non-toxic pro-drug fludarabine phosphate into the toxic agent 2-fluoradenine.

Evaluation of foreseeable effects

OAV has been shown to infect human cells, but is unable to complete its full replication cycle, therefore representing minimal risk to the worker. The therapeutic gene will be expressed at very low levels, if at all, in not target tissue. The gene product is non-pathogenic for humans. OAV 623 was derived from a virus that was recovered from a sheep in Western Australia. Due to lack of evidence OAV seroconversion in the UK, we have to assume that this virus is not endemic to the UK. Although the virus is not fatal in itself, secondary infections can be. Therefore, although the organism is considered Class 1, after reviewing potential environmental effects it is classified as Class 2.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All open manipulations will be performed in a Class II Safety Cabinet. All potentially contaminated material will be autoclaved before disposal. Any spillages will be disinfected with Virkon, and all materials to mop up spillages will be autoclaved. In vivo studies will be conducted in rodent animal houses. All bedding and carcasses will be autoclaved or collected in specifically identified bins for off-site incineration. Staff who have contact with sheep will be excluded from working with this organism.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All animal cages will be disinfected using hypochlorite solution. All waste, including bedding and carcasses, will be double bagged and either autoclaved or placed in identified bins which will be sealed and removed by White Rose Environmental for incineration. All surfaces will be disinfected with hypochlorite solution or Virkon. All other materials which come into contact with the organism will be autoclaved, including lab coats.

Project Ref 421/03.2

Date Ackn’d 18/07/2003

CU2 Project Title TESTING CELL BANKS OF MARINE VIBRIO SPP FOR IDENTITY, PURITY AND STABILITY.

Class Class 2

CultureVOL Class 2 < 1 litre

Consent Granted not applicable

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

Project Additional Information

Purposes of the contained use
To determinate freedom from adventitious agents and identity and stability testing of the host organism and transgene product.

Recipient or parental organism
The parental organism is a marine Vibrio, which has not been fully characterised but has been classified as most similar to Vibrio aguillarum.

Host/vector system
The parental organism, similar to Vibrio aguillarum, contains a plasmid which expresses the non-toxic B subunit of E. coli endotoxin. The plasmid is mobilisation defective preventing its transfer to other organisms.

Origin & function
The product of the transgene is the non-toxic B subunit of E. coli which is immunogenic and hence will be used as the basis for a vaccine against E. coli endotoxin.

Evaluation of foreseeable effects
Although not fully characterised, the host organism is very closely related to a marine Vibrio which is poorly tolerant of the saline conditions and is non-pathogenic to humans. There is a risk of marine fish infection though the laboratory is over 60 miles from the sea. The gene product is non-toxic to humans or animals.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All open manipulations will be performed in a class II safety cabinet. All potentially contaminated material will be autoclaved before disposal. Any spillages will be disinfected with Virkon. Any in vivo studies will be conducted in Rodent Animal Houses conforming to class II handling requirements. All bedding and carcasses will be autoclaved or collected in specifically identified bins for off-site incineration.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All open manipulations will be performed in a Class II Microbiological Safety Cabinet. All potentially contaminated material from this work will be autoclaved before disposal, reducing the likelihood of an escape of the GMO. The use of mobilisation-defective or non-mobilisable vectors would mean that the active transfer of 'foreign' DNA is not expected. Should in vivo studies be required then:

All animal cages will be disinfected using hypochlorite solution. All waste, including bedding and carcases, will be double bagged and either autoclaved or placed in identified bins which will be sealed and removed by White Rose Environmental for incineration. All surfaces will be disinfected with hypochlorite solution or Virkon. All other materials which come into contact with the organism will be autoclaved, including lab coats. No viable organism could survive the sterilisation and disinfection procedures employed.

### Project Additional Information

**Purposes of the contained use**

To demonstrate safety of the vaccines C2D 1 and C2D 2.

**Recipient or parental organism**

The parental organism is dengue (a flavivirus). Dengue is transmitted by Mosquito (ie requires injection) and not ingestion or inhalation.

**Host/vector system**

The candidate vaccines are live attenuated vaccines which retain antigenic activity but replicate poorly, are temperature sensitive and have reduced virulence in vitro and in vivo.

Dengue C2D 1 is a live attenuated GMO engineered using the backbone dengue 2 PDK53 (non structural protein and capsid) with structural proteins (premembrane and envelope) of dengue wild serotype 1 (live attenuated virus parental strain). This vaccine is developed on VERO cells.

Three mutations in nonstructural gene regions of the PDK-53 viral genome are responsible for the in vitro attenuated phenotypic markers and attenuated mouse neurovirulence phenotype of the DEN-2 PDK-53 virus.

The genetic loci encoding the attenuated phenotypic markers of the Mahidol candidate DEN-2 PDK-53 vaccine virus have been defined experimentally by the CDC. This strain showed good safety during clinical study with previous live attenuated vaccine studies.

Dengue C2D 4 is the same as above but has the structural proteins (premembrane and envelope) of dengue wild serotype 4 (live attenuated virus parental strain) in place of the same proteins serotype 1.

**Origin & function**

The intended function is to vaccinate against dengue fever.
Both vaccine GMO candidates are live-attenuated and some reactogenicity could be expected after a first injection related to viral replication. The parent DEN-2 PDK-53 vaccine virus replicates efficiently (MID50=5PFU) in humans and is safe and immunogenic in adult volunteers (Bharmarapravati et al., 1996). The chimeric GMO viruses CD2 1 and CD2 4 viruses which express the structural genes of heterologous flaviviruses (nonstructural replication machinery of the DEN-2 PDK-53 genotype) and premembrane and envelope of attenuated serotypes 1 or 4 should retain the attenuated phenotypic markers of DEN-2 PDK-53 virus (Huang et al 2000). These attenuated phenotypic markers of DEN-2 PDK-53 virus includes small plaque size and temperature sensitivity in LLC-MK2 calls and relative to the homologous wild-type DEN virus, poor replication efficiency in Aedes albopictus C6/36 cells, and avirulence for newborn mice following intracranial inoculation 104 PFU of virus (Huang et al., 2000).

It has been shown in previous clinical studies that Dengue attenuated virus vaccines (monovalent, bivalent, trivalent or tetravalent vaccine (Sabchereon et al., 2002) can induce within 2 weeks after vaccination dengue like symptoms with transient and mild fever, headache, myalgia, eye pain, rash associated with decrease of leukocytes and platelet counts and increase of transaminases levels.

If a harmful event were to occur, minor dengue-like symptoms are likely to be seen.

It is noted from the literature that exposure to one strain of Dengue virus and subsequent seroconversion can lead to the development of more serious (haemorrhagic) Dengue fever on subsequent exposure to a different serotype against which there would be no cross-protection. The major risk therefore is to laboratory personnel being injected accidentally and then being exposed to a mosquito bite infected with a different Dengue virus serotype. It is felt that this risk is remote and can be managed through proper handling procedures.

Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All open manipulations will be performed in a class II safety cabinet.
All potentially contaminated materials/clothing will autoclaved or soaked in hypochlorite/Virkon before disposal by incineration. Any spillages will be disinfected with Virkon and all materials used to mop up spillages will be autoclaved and incinerated. The study will be conducted in designated primate animal houses. All bedding and carcasses will be autoclaved or collected in specifically identified bins for off-site incineration.

Staff will wear protective clothing, including respirators, gloves, overalls, aprons, face shields which will be treated as above if contaminated and disposed of by incineration.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All animals cages will be disinfected using hypochlorite solution.
All waste, including bedding and carcasses will be double bagged and either autoclaved or placed in identified bins which will be sealed and removed by White Rose Environmental for incineration. ## Project Additional Information

### Purposes of the contained use

Repeat dose and local tolerance study in the rat to assess toxicity and immunogenicity of MVA-measles vaccine. Intended therapeutic use is the prevention of measles infection in man.

### Recipient or parental organism

MVA-measles is the test system and consists of MVA (Modified Vaccinia Ankara) as the vector. MVA is an attenuated vaccinia virus and is widely considered as the...
vaccinia of choice for clinical investigation because of its high safety profile.

### Host/vector system

**MVA (Modified Vaccinia Ankara)**

### Origin & function

The MVA-measles constructs contain the following measles antigens: F-antigen (responsible for fusion with the host cell), N-antigen (the nucleocapsid protein) and the H-antigen) hemagglutinin responsible for virus binding to suitable receptors on the host cell and essential cofactor for F-protein-mediated fusion.

For re-categorisation of the MVA-measles construct the client has performed "human cell growth" assays in which preliminary data suggests there are no growth anomalies.

### Evaluation of foreseeable effects

Accidental human exposure may lead to an inflammatory response or irritation to the eye. Potential for allergic reaction.

Affected eyes should be irrigated thoroughly, skin should be washed thoroughly with soap and water and rinsed with 80% ethanol. Medical attention should be sought.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

When handling test compound in bulk respiratory protection or working under a laminar air flow cabinet is required. The wearing of safety glasses is required as are disposable gloves when handling the test material. Environmental characteristics of the test material have not been fully evaluated. Release to the environment should be avoided. The test compound can be denatured or inactivated by a variety of organic solvents. None of the components of the test compound are listed as carcinogenic.

Release into the environment is unlikely and if so will be in small quantities. Spillages should be contained using absorbent material. Spill area should be cleaned thoroughly with water and afterwards 80% Ethanol.

The inability of MVA to replicate, as demonstrated in the in-vitro and in-vivo studies detailed above, indicates that the impact on the environment should there be an accidental release will be minimal, localised and of a minor nature. Existing control measures for the disposal of waste materials, carcasses and test compound should be adequate to ensure that there is minimal risk of exposure to the environment.

Test material should be stored in a refrigerated environment and should be maintained within sealed containers. These should be placed within and additional impervious containers. Such measures will prevent other test materials being cross-contaminated.

Test material will be supplied within sterile glass vials incorporating a rubber septum. There will not be any requirement to conduct any dilutions or formulations procedures. The test material will be supplied ready for use and will only be required to be withdrawn from the vial immediately prior to administration.

Storage measures should be appropriate to ensure the glass vials cannot be damaged. They should be placed within a second impervious, sealed container (polypropylene) to prevent and where necessary contain any accidental damage/spillage.

Administration of the test material will be conducted within a dedicated work area separate to other studies and test materials. Existing personal protection worn by operational staff within rodent rooms will be sufficient to provide adequate protection against accidental spillages.

Lab staff will wear appropriate safety equipment including, lab coats and gloves.
All potentially contaminated material will be inactivated by chemical disinfection or by autoclaving at 121 degrees C for a minimum of 15 minutes. The likelihood of release is therefore low.

In the event of spillage, the contaminated work area will be disinfected with a viracidal agent.

Where applicable, activities involving the virus and potentially infectious fluids will be performed using Biosafety Level 2 contamination facilities. Procedures where the risk of aerosolisation is high should be performed inside a class 2 biological safety cabinet.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The test compound can be denatured or inactivated by a variety of organic solvents. All materials exposed to the GMO will be autoclaved using validated means, leading to inactivation of the GMO and incineration. Animals treated with GMO will be disposed of by incineration, according to the conditions of the GMO agreement with the external contractor.

All stored GMO material will be held in waterproof secondary containers so that in the event of leakage of the primary storage vessels the GMO is contained and can be dealt with as described in Section 8.

Existing control measures for the disposal of waste materials, carcasses and test compound should be adequate to ensure that there is minimal risk of exposure to the environment.

Test material should be stored in a refrigerated environment and should be maintained within sealed containers. These should be placed within and additional impervious containers. Such measures will prevent other test materials being cross-contaminated.

Test material should be stored in a refrigerated environment and should be maintained within sealed containers. These should be placed within and additional impervious containers. Such measures will prevent other test materials being cross-contaminated.

**Project Additional Information**

**Purposes of the contained use**

The project is a GLP preclinical toxicity and repro-toxicity study of an HZV-2 vaccine candidate, Immuno VEXHSV-2, by subcutaneous administration to Crl:CD(SD) rats.
Intended therapeutic use is the prevention of herpes simplex viral infections in man.

Recipient or parental organism

Immuno VEXHSV-2 is a replication impaired vaccine based on HSV-2 strain HG52. It has deletions in the genes that encode vhs, ICP47, UL43 and ICP34.5. Deletion in these genes render the virus avirulent in mouse models as demonstrated by intracranial, intranasal and subcutaneous administration of doses up to 10 (6) pfu in mice and guinea pigs. It would therefore be anticipated that Immuno VEXHSV-2 would have greatly reduced pathogenicity in humans compared to wild type HSV-2.

Host/vector system

The strain of HSV-2 used to produce Immuno VEXHSV-2 is HG52.

Origin & function

Immuno VEX HSV-2 contains deletions with the vhs, ICP47, UL43 and ICP34.5 genes. Deletions in either of the ICP34.5 or vhs genes have been shown to render the virus avirulent and greatly reduce levels of reactivation in animal models compared to wild type virus (Perng et al, 1995; 1996; Strelow and Leib, 1995, Strelow et al. 1996). Deletion of ICP34.5 from HSV has been shown to provide the greatest level of attenuation of any single gene deletion that still allows the virus to replicate efficiently in culture. Deletions in the ICP47 gene have also been shown to greatly reduce the virulence of HSV (Goldsmith et al., 1998). Deletions in the ICP47 gene have also been shown to greatly reduce the virulence of HSV (Goldsmith et al., 1998). Deletions in the ICP47, UL43 and ICP34.5 genes will not alter the host range of Immuno VEX HSV-2 compared to the wild type, parental virus. Dose of Immuno VEX HSV-2 up to 1x10 (6) pfu have been shown to be non-toxic when administered via the intranasal, intracranial and subcutaneous routes in both mice and guinea pigs. This is in contrast to the wild type HSV-2 strain HG52 which has an LD50 of 1x10 (2) pfu when administered intracranially (MacLean et al., 1991).

There are no exogenous genes inserted into ImmunoVEX HSV-2.

Evaluation of foreseeable effects

Accidental infection in the laboratory is by splash to a mucosal surface, or the eye, or by entry through broken skin. HSV can infect various parts of the eye including the cornea and retina.

Except in neonates and the immuno-compromised, wild type HSV infection is not systemic but is limited to epithelial cells at the infection site and to the sensory ganglia that innervate that site. The standard treatment for HSV-2 infection are the anti-viral agents acyclovir and valacyclovir. The thymidine kinase (TK) gene required for the activity of these drugs is intact and expressed from ImmunoVEX HSV-2. Thus ImmunoVEX HSV-2 is sensitive to the standard drugs used to treat HSV-2 infections, so can be used in the unlikely event of an accidental infection.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

When handling test compound in bulk respiratory protection or working under a laminar air flow cabinet is required.

The wearing of safety glasses is required as are disposable gloves and masks when handling the test material.

Any cuts should be covered with a suitable dressing.

Persons handling the virus must wash their hands with a suitable anti-viral soap before touching their skin or eyes.

Any spills must be immediately treated with a suitable disinfectant (such as 1% Virkon solution).

Syringes should be placed in a sharps bin and destroyed by incineration.

The work area should be cleaned with a suitable disinfectant on completion of the work.
None of the components of the test compound are listed as carcinogenic.

The vector is fragile and cannot survive for long periods outside the host. Infectivity is eliminated by a temperature of greater than 56°C maintained for ~20 hours, or exposure to pH of less than 4. It is also rapidly inactivated by desiccation, lipid solvents, mild detergents and bleaches and common disinfectants. The fact that direct contact is required for transmission attests to the instability of the virus outside the host.

Existing control measures for the disposal of waste materials, carcasses and test compound should be adequate to ensure that there is minimal risk of exposure to the environment.

Test material should be stored in a frozen (-80°C) environment and should be maintained within sealed containers. These should be placed within and additional impervious containers. Such measures will prevent other test materials being cross-contaminated.

Administration of the test material will be conducted within a dedicated work area separate to other studies and test materials.

Existing personal protection worn by operational staff within rodent rooms will be sufficient to provide adequate protection against accidental spillages.

Lab staff will wear appropriate safety equipment including, lab coats and gloves.

All potentially contaminated material will be inactivated by chemical disinfection. The likelihood of release is therefore low.

In the event of spillage, the contaminated work area will be disinfected with a viricidal agent.

Where applicable, activities involving the virus and potentially infectious fluids will be performed using Biosafety Level 2 contamination facilities. Procedures where the risk of aerosolisation is high should be performed inside a class 2 biological safety cabinet.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The test compound can be denatured or inactivated by chemical disinfection.

All materials exposed to the GMO will be disinfected using a suitable chemical disinfectant, leading to inactivation of the GMO and incinerated.

Animals treated with GMO will be disposed of by incineration, according to the conditions of the GMO agreement with the external contractor.

All stored GMO material will be held in waterproof secondary containers so that in the event of leakage of the primary storage vessels the GMO is contained and can be dealt with as described in section 8.

Existing control measures for the disposal of waste materials, carcasses and test compound should be adequate to ensure that there is minimal risk of exposure to the environment.

Test material should be stored in a frozen environment and should be maintained within sealed containers. These should be placed within and additional impervious containers. Such measures will prevent other test materials being cross-contaminated.
Administration of the test material will be conducted within a dedicated work area separate to other studies and test materials.

Existing personal protection worn by operational staff within rodent rooms will be sufficient to provide adequate protection against accidental spillages.

Historical Significant Changes

02/03/2022 Page 7313 of 15326
The influenza vaccine strain NIBRG-14 is an attenuated strain of H5N1 avian pandemic flu. The attenuation results in part from modification of the haemagglutinin which eliminates the pathogenicity in avian species. The present work is to monitor batches of vaccine to ensure the genetic modification is intact.

NIBRG-14 pandemic vaccine reassortant has been produced using 6 reassortant RNAs (Excluding the haemagglutinin (HA) and neuraminidase (NA) from the human strain A/PR/8/34 (PR8). PR8 has had over 100 passages in each of the mice, ferrets and embryonated chicken eggs. The result of such a passage history is complete attenuation of the virus and its inability to replicate in man.

PR8 grows to high titre in embryonated chicken eggs and since the late 1960’s it has been used to produced ‘high growth reassortants’ in combination with the prevailing influenza A vaccine strain. Such parental strains possess phenotypic markers of vaccine safety, such as temperature sensitivity, cold-adaptation and attenuation in ferrets or rodents and moreover have a demonstrated attenuated phenotype in man.

Due to the nature of influenza viruses, vectors are made by introducing different combinations of the 8 RNAs making up the influenza genome (reassortants). In NIBRG-14, 6 reassortant RNAs derive from PR8 and 2 are derived from H5N1 though the haemagglutinin is modified to remove avian pathogenicity. The products of the inserted genes is, at minimum, the modified HA (H5) and NA (N1) of the pandemic strain virus. The H5 HA has been derived from a highly pathogenic H5 strain by reverse genetics, the HA has been modified so that the multiple basic amino acids at the HA cleavage site, which are associated with high pathogenicity, have been reduced to a single basic amino acid. Any protein derived from the wild type strain, on its own is rather inherently infectious nor harmful.

The origins of the genetic materials are as described above. The intended functions are that the HA and NA genes code for proteins which are immunogenic but are contained in a virus which is non-pathogenic and non-transmissible hence act as a vaccine strain.

Published information indicates that a reassortant between PR8 and a wild-type human influenza virus is likely to be avirulent in man. Although such information is difficult to interpret because the genetic composition of the reassortants was not clear, it is known that the degree of attenuation increases as reassortants include more PR8 genes. The NIBRG-14 reassortant, contains six out of eight viral genes from PR8 and the NA and modified HA genes of the H5N1 virus. Furthermore, the H5 HA retains a preference for α2,3 linked residues (see below), so the ability of the NIBRG-14 to bind to and replicate in human cells should be minimal. It is therefore envisaged that NIBRG-14 reassortant would be attenuated for humans compared to the H5 wild type. Furthermore, it is clear that such reassortants are expected to be of low chicken and animal pathogenicity compared to the highly pathogenic parental wild strains, and this has been borne out by experience to date. Nevertheless, as the factors affecting pathogenicity (see below) are not fully understood, genetic manipulation to remove the polybasic sites theoretically could have unpredicted effects on both transmissibility and pathogenicity.

Although it is considered that, an H5N1/PR8 reassortant such as NIBRG-14 will be either attenuated or possibly non-infectious for man, an indirect hazard may exist through secondary reassortment with a human or animal influenza virus as influenza viruses are known to exchange genes by the process of reassortment. In order for secondary reassortants to be generated several events need to occur; firstly infection of the laboratory staff with the reassortant strain; secondly, for an infected worker to
have a mixed infection with a wild type influenza virus, and thirdly for a reassortment event to take place. In practice, manufacturers, and associated laboratories, have 30 years of experience with large scale production of vaccines based on PR8 reassortants and no reported cases of human illness although it should be noted that data are not available on whether human infections may have occurred. Staff working with this strain will be vaccinated with current seasonal influenza vaccines to reduce the chances of infection with wild-type virus.

It should also be considered that poultry and pig farmers are continually exposed to animal influenza viruses and there have been few documented cases of human infection in this population with a reassortant between an avian or porcine and a human influenza virus (es) in human cells is considered to be minimal.

The influenza HA is responsible for attachment of virus to the target cell and has specificity for sialic acid receptors on cell surface molecules. The HA present on human influenza A viruses preferentially bind to receptors containing α2,6 linked sialic acid residues, whereas avian influenza viruses preferentially bind to α2,3 linked sialic acid (Rogers and D'Souza, 1989). Human tracheal cells have mainly α2,6 linked residues (Nelson et al, 1993), so the acquisition of an avian HA by PR8 virus is expected to minimise potential binding to human respiratory epithelial cells. Although the α2,3 receptor specifically of avian viruses will reduce the efficacy of such binding, it may not completely prevent infection in man. Moreover, the presence of avian-like receptors has been demonstrated in human respiratory tract epithelium (Matrosovich et al, 2004). Beare and Webster (1991) found that extremely large quantities of avian viruses (between 10^6.8 and 10^9.2 egg infectious doses) were needed for replication in man and, since replication was poor, that it was not possible to induce person-to-person transmission.

The HA of influenza virus must be cleaved into HA1 and HA2 by host cell proteases for a productive infection. Pathogenicity of H5 influenza A viruses for chickens is largely determined by the nature of the amino acids at the HA cleavage site. H5 viruses with multiple basic amino acid sequences are highly pathogenic and their HA can be effectively cleaved by ubiquitous furin-like proteases, which are expressed in most organs of birds and humans. In contrast, the HA of H5 viruses of low pathogenicity for birds and certain laboratory animals contain a single basic residue at the cleavage site, a feature common to all other subtypes of influenza HA, and which can only be cleaved by trypsin-like proteases, which are restricted to certain cell types, e.g. epithelial cells lining the respiratory tract of man and the gut of birds. Thus, HA cleavability influences tissue specifically and is a major determinant of pathogenicity for H5 viruses in chickens and certain laboratory animals. Multiple basic amino acids at the cleavage site have not been observed for any other HA subtype.

The available evidence suggests that virulence of the 1997 and later H5N1 viruses for man is related to the presence of the HA multiple basic amino acids. It is therefore considered imperative to remove them and has been done in the NIBRG-14 strain. This procedure will also increase the safety of the reassortants for avian species as cleavage site modifications have resulted in reduced killing of avian embryos.

The PR8/H5N1 6:2 reassortants created by reverse genetics for H5N1 vaccine production such as NIBRG-14 do not contain the gene constellation considered necessary for pathogenicity in chickens, mice and ferrets and in contrast have internal genes that confer sensitivity to the innate immune response.

By virtue of PR8 attenuation, avian receptor specificity, loss of multiple basic amino acids at the HA cleavage site and the absence of other H5N1 genes associated with pathogenicity in humans (ie NS1 or PB2 genes), it is envisaged that an H5N1xPR8 2:6 reassortant (NIBRG-14), while possibly infectious for man and ferrets, will have only a theoretical probability of causing harm to human health. On the basis of these arguments, reassortants derived from H5 strains in which the multiple basic amino acid HA cleavage site has been removed, using PR8 as the recipient virus, likely would be similarly attenuated.

If staff are exposed to aerosols containing high titre reassortant virus, there is a possibility that sub-clinical infections could result. If this happened, it is unlikely that a reassortant virus would transmit to human contacts as it is likely that replication will be attenuated and virus shedding, if it occurs, may be below the titres considered to be needed for human infection.

However, although there is no precedent, as described above there is a theoretical possibility of secondary reassortant with normal influenza human viruses and that such reassortant viruses may be replication-competent in humans, whilst having avian-like coat proteins. Although very unlikely, the secondary reassortant could become adapted to human infection and transmission in which case the public health consequences would be serious. All staff will be vaccinated against seasonal flu to reduce still further the likelihood of this occurring.
Environmental consideration

Influenza A viruses are endemic throughout the world in some agricultural animals (swine and horses) and some populations of wild birds. Of the influenza A viruses, a number can cause highly pathogenic disease in domestic poultry including H5 strains. Infections have occurred in the big cats following consumption of dead chickens infected with H5N1 viruses.

In the case of an H5N1 reassortant, the virus will have avian receptor specificity, and thus birds would be the species theoretically most susceptible. The contribution of the six PR8 internal genes to replication and virulence in birds is unknown.

However, it has been demonstrated by the use of reverse genetics that acquisition of only one PR8 gene by an avian influenza virus can abolish virus replication in ducks. Experimental evidence has demonstrated that PR8 virus is attenuated in not only humans (see above) but also chickens. Furthermore, a reassortant between PR8 (internal protein genes) and the 1997 Hong Kong H5N1 virus (NA and HA with a single basic aminio acid) was barely able to replicate in chickens ans was not lethal. Similar studies have been performed with the 2003 Hong Kong H5N1 virus at the WHO Collaborating Centre, Memphis, USA, where the 6:2 PR8 reassortant did not replicate or cause disease signs in chickens. The removal of the multiple basic amino acids from the H5xPR8 reassortant in both studies probably played a major role in reducing the risk for chickens.

Although replication occurs in chicken embryos, for reasons that are unknown, the risk of environmental transmission via such replication in nature is remote.

Pigs are uniquely susceptible to infection by all strains of influenza A virus because they have both alpha 2,3 and alpha 2,6 receptors in abundance. Although pigs are not susceptible to infection with PR8, it is conceivable that pigs are susceptible to infection by an H5N1 reassortant, as viruses with avian receptor specificity are known to replicate in this species. It is also possible that these species would be susceptible to secondary reassortments between the H5N1 reassortant and a pig virus. There is infact evidence that triple reassortants between avian, pig and human influenza viruses can circulate in pigs in the USA.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste must be considered infectious and must be decontaminated daily.

Liquids are inactivated by autoclaving within the facility. The liquid is then disposed of down the sink using large amounts of water followed by disinfectant.

Solid wastes are inactivated by autoclaving. The biohazard autoclave bags should not be taped closed prior to autoclaving. After autoclaving, all waste leaving the facility must be double bagged before placing in the designated bins.

Daily Waste
Prior to commencement of work within the class II safety cabinet (in the class III facility), a medium sized pipette tip waste box shall be filled with approximately 2L of an appropriate disinfectant and carefully placed, ensuring airflow is not restricted, within the class II safety cabinet. All consumables and reagents should be disposed of into this box after use. At the end of the work for that day, the pipette tip box should be sealed, cleaned with 70% ethanol, placed into an autoclave bag and autoclaved.

Decontamination Spills
Spills with in the class II safety cabinet

In the event of a spill, all surfaces and items shall be disinfected and cleaned before being removed from the class II safety cabinet.

If the spill results in puddles:

The area will be flooded with an appropriate disinfectant, and left for 30 minutes

The area is then wiped clean with water followed by 70% ethanol.
All items in contact with the spill are autoclaved.

After a spill is decontaminated, the area shall be thoroughly cleaned and dried. Residual materials can support the growth and multiplication of microorganisms, and can jeopardise the product protection normally provided by the class II safety cabinet.

Spills in Incubators

An appropriate disinfectant is added to the tray of water at the bottom of the incubator.
The materials in the incubator are removed and disinfected by wiping them with appropriate disinfectant and placed in another incubator.
Contaminated materials are placed in a biohazard waste bag prior to autoclaving.
Incubator internal surfaces are wiped with an appropriate disinfectant, followed by water and then surfaces wiped with 70% ethanol.

Spills in centrifuges or in the laboratory

Work is stopped immediately. All persons must evacuate the room immediately removing all laboratory clothing in the airlock prior to exit. No entry into the laboratory is permitted. The room would then be decontaminated using a validated procedure involving a portable hydrogen peroxide generator which can be operated from outside the laboratory via ports in the laboratory wall.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

Please enter comments on the GM safety committee on the risk assessment

First risk assessment for this study was thought by members of the GMO committee not to be good enough.
A re-assessment was carried out and the committee agreed this was an accurate assessment. It was agreed that facilities at the Harrogate site were suitable in respect of containment for this study to proceed after notification.

Project Additional Information

Purposes of the contained use

Immuno VEXHSV-2 is a replication competent herpes simplex virus type-2 (HSV-2) based vector, ImmunoVEXHSV-2 contains deletions with the vhs, ICP47, UL43, US5 and ICP34.5 genes. Deletions in either of the ICP34.5 or vhs genes have been shown to render the virus avirulent and greatly reduce levels of reactivation in animal models compared to wild type virus.

Recipient or parental organism

The GMO will be injected subcutaneously into laboratory mice in laboratory conditions.

Host/vector system

N/A

Origin & function

Approximately 15% of the human population are seropositive for HSV-2 infection is by direct contact, and transmission by aerosols is not thought to be a natural infection route. HSV-2 infection in the immune-competent host is restricted to the epithelium and sensory nerves. HSV-2 rarely causes severe problems unless the virus enters the brain or the eye which may lead to encephalitis or retinopathy respectively.

Primary infection occurs most commonly in genital mucosal tissue. The major characteristic of HSV is its ability to establish a latent infection in the dorsal root ganglia of the sensory neurones innervating the primary infection site, from where it can reactive and cause secondary disease symptoms. In these latently infected neurones the virus remains as an episome for the duration of the host's life—it does not integrate into the host's genome.

**Evaluation of foreseeable effects**

Accidental infection in the laboratory is by splash to mucosal surface, or the eye, or by entry through broken skin. HSV can infect various parts of the eye including the cornea and retina. Personal protective equipment will be in place to minimise the risk. Except in neonates and the immuno-compromised, wild type HSV infection is not systematic but is limited to epithelial cells at the infection site and to the sensory ganglia that innervate that site. Very rarely (< 1 in 106 people/year) the virus enters the CNS and causes meningoencephalitis; or may disseminate and cause multiorgan disease. This type of wide spread viremia is limited to immune-compromised patients. The standard treatment for HSV-2 infection is acyclovir, either administered topically or orally.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A - materials are micro-organisms.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Existing control measures for the disposal of waste materials, carcasses and test compound should be adequate to ensure that there is minimal risk of exposure to the environment.

Waste that has been or is potentially contaminated with GMOs must be collected in appropriate containers (eg autoclave bags for autoclave waste, hermetically sealed units for GMO waste that can not be inactivated) separately from other waste. This applies to all forms of disposable waste eg personal protective equipment (PPE), laboratory equipment, animal cage tray liners, animal tissues/carcasses etc.

All materials exposed to GMO will be disposed of by incineration, according to the conditions of the GMO agreement with the external contractor.

Non-disposable items must be treated (by autoclave or effective disinfectants) in order to render any GMO contamination inactive.

Any spills must be immediately treated with a suitable disinfectant (such as 1% Virkon solution). Syringes should be placed in a sharps bin and destroyed by incineration. The work area should be cleaned with a suitable disinfectant on completion of work.

Project Additional Information

Purposes of the contained use

MVA is an attenuated Vaccinia virus and is widely considered as the Vaccinia virus strain of choice for clinical investigation because of its high safety profile. MVA-BN® is claimed not to replicate in humans due to its inability to fully replicate in a vaccinated individual. In addition, it neither does result in the reversion of the attenuated property of the backbone vector MVA-BN® nor does it result in a higher virulence of MVA-BN®. Recombination is reduced by decreased homology with the viral gene sequence homology.
**Recipient or parental organism**
The GMO will be injected subcutaneously into laboratory rats in laboratory conditions.

**Host/vector system**
N/A

**Origin & function**
The parental organism is MVA-BN which is highly attenuated Vaccinia virus. This provides the backbone vector and is not classified as a GMO.

The MVA virus backbone is generated by 516 serial passages on chicken embryo fibroblasts of the Ankara strain of vaccinia virus (CVA) which results in the deletion of 31 kilobases of genomic sequence.

The test article to be used in this study (MVA-mBN157B) is a recombinant MVA-BN product which contains genetic information which encodes the protective antigen (PA) of bacillus anthracis. This additional antigen does solely have anthrax-specific translocation properties (which are not biologically active since it is the only anthrax-specific antigen encoded in the GMO).

**Evaluation of foreseeable effects**
Accidental human exposure may lead to a mild inflammatory response or irritation to the eye. Potential for allergic reaction.

No occupational exposure limit or short term exposure limit has been evaluated.

The inability of MVA to replicate indicates that the impact on the environment, should there be an accidental release, will be minimal, localised and of a minor nature.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
N/A materials are micro-organisms.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**
N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**
Existing control measures for the disposal of waste materials, carcasses and test compound should be adequate to ensure that there is minimal risk of exposure to the environment.

Waste that has been or is potentially contaminated with GMOs must be collected in appropriate containers (eg autoclave bags for autoclave waste, hermetically sealed units for GMO waste that can not be inactivated) separately from other waste. This applies to all forms of disposable waste eg personal protective equipment (PPE), laboratory equipment, animal cage tray liners, animal tissues/carcasses etc.

All materials exposed to GMO will be autoclaved using validated means, leading to inactivation of the GMO and incinerated.

Animals treated with GMO will be disposed of by incineration, according to the conditions of the GMO agreement with the external contractor.

Non-disposable items must be treated (by autoclave or effective disinfectants) in order to render any GMO contamination inactive.
The test compound can be denatured or inactivated by a variety of organic solvents. Spillages should be contained using absorbent material. Spill area should be cleaned thoroughly with water and afterwards with 80% ethanol.

In the opinion of the committee final classification of the organism should be designated as Class 2 GMO. The reason is that, as stated, the environmental impact has not been fully investigated. Details of discussions were as follows:

Based on the fact that MVA-BN® is non-replicating, has been demonstrated not to replicate in primate, murine or human cell lines, and is so far found to be safe in humans. MVA-BN® can be classified as a Class 1 organism. MVA-mBN157B can also be considered as a Class 1 organism since the only additional antigen it is encoding for is the protective antigen (PA) of bacillus anthracis. This additional antigen does solely have anthrax-specific translocation properties (which are not biologically active since it is the only anthrax-specific antigen encoded in the GMO), does not result in the reversion of the attenuated property of the backbone vector MVA-BN® and does not result in a higher virulence of MVA-BN®. Thus, MVA-mBN157B can be classified as a Class 1 organism. However, as the environmental impact has not been fully investigated, the overall classification of the organism should be class 2.

Project Additional Information

Purposes of the contained use
The objective of the study is to determine the toxicity of the test article, OncoVEXGM-CSF, following 5 repeated subcutaneous administrations (on days 1, 4, 7, 10 and 13) to the mouse followed by a 24 hour, or 28 day observation period. Analysis of various tissues and bodily fluids will also be conducted.

Recipient or parental organism
CDI mouse for use in laboratory work to evaluate toxicity

Host/vector system
OncoVEXGM-CSF is replication competent herpes simplex type-I virus (HSV-1) used for treatment of solid tumours

Origin & function
OncoVEXGM-CSF was generated from the wild type is JS-1 strain of HSV-1 (ECACC Accession Number 01010209). Strain JS-1 is a recently prepared clinical isolate from a reactivating individual. The genes encoding 1CP34.5 and ICP47 have been deleted from Onc0VEXGM-CSF. 1CP34.5 is known as the neurovirulence factor. The deletion of ICP34.5 allows the vector to replicate in dividing cells but prevents replication in non-dividing cells. Deletions in the ICP34.5 gene have been shown to render the virus avirulent and greatly reduce levels of reactivation in animal models compared to wild type virus (Perng et al, 1995; 1996). In fact, deletion of 1CP34.5 from HSV has been shown to provide the greatest level of attenuation of any single gene deletion that still allows the virus to replicate efficiently in culture. The vector is also deleted for ICP47. The role of ICP47 is to block antigen presentation to MHC class I and II molecules by blocking transporter associated with antigen processing (TAP1 and TAP2). Deletions in the ICP47 gene have also been shown to greatly reduce the virulence of HSV (Goldsmith et al., 1998).

Onco0VEXGM.CSF contains the coding sequence for human GM-CSF (hGM-CSF), a cytokine involved in the stimulation of T-cells. hGM-CSF expression is under the control of the human cytomegalovirus immediately early promoter (HCMV IE) and this expression cassette has been inserted into the 1CP34.5 locus of the JS-1 genome. Both copies of the 1CP34.5 gene have been removed as the majority of the virus sequence has been confirmed by Southern blot analysis.

Evaluation of foreseeable effects
It is not thought that the modified virus would pose a serious risk to the environment. HSV is a human virus that can be propagated by lytic infection. No integration of the viral genome with cellular genome occurs during replication. The virus is fragile and is rapidly inactivated by desiccation, lipid solvents and mild detergents. The fact that contact is required for transmission attests to the instability of the virus outside the host.

It is unlikely that OncoVEXGM-CSF will be harmful to humans, animals or plants. The vector is modified so that replication only occurs in rapidly dividing cells and not in non-dividing cells. Approximately 80% of the population are
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Existing control measures for the disposal of waste materials, carcasses and test compound should be adequate to ensure that there is minimal risk of exposure to the environment. Animal carcasses, animal bedding, laboratory blood samples and laboratory urine samples are bagged and placed in hermetically sealed units which are then sprayed with virkon. The units are then placed in labelled 'Taylor Bins' and removed offsite for incineration. Collections are available 4 days per week with a fleet of approximately 60 appropriately labelled specific bins, each containing up to 75kg material. The contents of bins are tipped into the incinerator using an automatic lifting system with no manual handling involved. Incineration is undertaken by SRCL (formally White Rose Environmental), Knostrop Leeds, registered with the HSE as a premises handling GMM’s. GMO consignment notes are available for all GMO waste movements. An application for derogation from the use of an autoclave on site is hereby made.

### Project Additional Information

**Purposes of the contained use**
The aim of this project is to isolate viral DNA from a human adenovirus serotype 5 (Ad-5)-based conditionally replication competent adenovirus (CRAd) named As(1/PPT-E1A) and perform a PCR on the DNA to evaluate whether unwanted recombinants have occurred during the production steps.

**Recipient or parental organism**

N/A - test material will not be dosed to organisms/cell lines

**Host/vector system**

Modified adenovirus serotype 5 used for treatment of prostate cancer.

**Origin & function**
The prostate-specificity of I/PPT was first evaluated in an adenoviral vector with the luciferase reporter gene, Ad (I/PPT-Luc). An extensive screening of 17 cell lines was performed and the results showed that Ad (I/PPT - E1A) confers absolute prostate specificity (Cheng et al., 2004).

The I/PPT comprises the following:

1) an H19 insulator (I) shielding the PPT sequence from the LITR/E1A enhancer sequence, preventing the LITR/E1A enhancer sequence overlapping with the virus encapsidation sequence needed for virus assembly.

2) the PPT sequence, a chimeric sequence comprising the prostate specific antigen enhancer (PSAe) followed by the prostate-specific membrane antigen enhancer (PSMAe) and the T cell receptor y-chain alternate reading frame protein promoter (TARPp).

This yields gene expression which is restricted to cells of prostate origin and is highly active in prostate cancer cells both in the presence and absence of testosterone.
Evaluation of foreseeable effects
As the GMO is specific to replication in human prostate cells, including prostate cancer cells the risk to human health is considered low. Human adenoviruses do not replicate in animal cells and therefore, this also means that the risk to animal/plant health and environment should also be considered to be low. The precautions to be followed when manipulating this GMO, which are detailed in the selections below, should also minimise the risks to the environment and to human/animal health.

Ad5 infects the upper respiratory tract. Causing a mild non-chronic disease (common cold symptoms). Individuals with a functional immune system clear an adenovirus infection within a few days. Furthermore Ad5 is considered endemic in the Western World, and infection is usually acquired during childhood, which means that most individuals have neutralizing antibodies against the virus and may therefore not even notice if they get infected (the immune system very quickly clears the infection).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All potentially contaminated material will be inactivated by chemical disinfection, 1% Virkon for 15 minutes or autoclaving at 121°C for a minimum of 15 minutes. The likelihood of release is therefore low.
In the event of spillage the area will be covered by an impregnated chemical disinfectant (as above) cloth for at least 15 minutes, the cloth will then be autoclaved 121°C for a minimum of 15 minutes.
Where it is not possible to autoclave or chemically deactivate contaminated materials, they will be placed into hermetically sealed containers, marked with biohazard tape and disposed of by incineration through SRCL. All stored vessels the GMO is contained and can be dealt with as described above.
An application for derogation from the use of an autoclave on site is hereby made.

02/03/2022
The genetically modified virus will be the test material in biosafety studies. It will be in the form of supernatant containing infectious virus particles. These studies will look for the presence of contaminating viruses or reverse transcriptase activity indicative of retroviral contamination.

Recipient or parental organism

Influenza virus A/Puerto Rico/8/34 (Pr8) (recipient virus)

Wild type Influenza virus A/Indonesia/5/2005 have been inserted onto plasmids and mixed with the genes from PR8

Host/vector system

N/A

Origin & function

Influenza virus A/Purto Rico/8/34 (PR8) recipient virus is completely attenuated following hundreds of passages in eggs, mice and ferrets. It is therefore unable to replicate in man

Wild type Influenza virus A/Indonesia /5/2005 (an avian H5N1 influenza strain and the donor virus) is the virus of interest but is considered highly pathogenic in man.
Due to the nature of influenza and the fact that they have different genes on different segments of their genome, reassortants of the virus can occur naturally if two strains infect one host.

Using reverse genetics, the HA (H5 and NA (N1) genes from A/Indonesia/5/2005 have been inserted onto plasmids and mixed with the genes from PR8. It is the HA and NA proteins that are recognised by the immune system.

The H5 gene in the modified virus has a deletion and mutation in the multiple basic amino acids at the cleavage site, which results in a loss of pathogenicity associated with H5. The resulting virus reassortant should elicit an immune response that will protect against wild type A/Indonesia/5/2005 but will not be pathogenic in man.

Evaluation of foreseeable effects

There is considered to be a low probability that the reassortant virus will reassort again with a third influenza virus and produce a pathogenic strain that could replicate in man. There is considered to be a low chance of a worker becoming infected with the reassortant strain as the virus does not readily infect man and all staff working with this virus will be vaccinated with the seasonal influenza vaccine, reducing the chance of a co-infection further still.

This virus grows well in vitro and staff will be handling high titre virus. However, this virus does not readily infect man. There may be a possibility of a sub-clinical infection with low virus shedding but replication is attenuated in humans and it is not believed that the virus could replicate to high levels. The severity of the infection would be greatly reduced compared to the wild-type virus.

Influenza viruses can also infect birds and pigs. This reassortant virus has a high replication rate in chicken embryos but with minimal pathogenicity. However, data from other PR8 and H5N1 reassortants show that those viruses were barely able to replicate in chickens and were not lethal. The acquisition of one gene from PR8 was enough to abrogate virus replication in ducks.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

In the event of spillage the area will be covered by an impregnated chemical disinfectant (1% w/v Virkon) cloth for at least 20 minutes, the cloth will then be autoclaved 121º for a minimum of 15 minutes. If fumigation is required, the appropriate SOP will be followed.

All potentially contaminated material will be inactivated by chemical disinfection (1% w/v Virkon for 20 minutes) and/or autoclaving at 121º for a minimum of 15 minutes in the autoclave located in the BDL3 laboratory. The likelihood of release is therefore low. Disposal methods will follow documented laboratory procedures.

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
The original risk assessment assigned in the final Activity Class as 3. The committee recommended this was amended to a 2+. Following discussions with HSE Biological Agents Unit Covance was advised to submit as Activity Class 2. This was on the basis that the virus and system is well characterised, widely used and proven to be relatively safe.

The location of the unitacentrifuge was also discussed but after consultation with the HSE it was agreed the location was acceptable.

It was discussed if staff could be vaccinated against H1N1 but to date vaccinations are not available.

Non-GMM Consent Granted

Tick if notifying a connected programme of work N

**Project Additional Information**
### Purposes of the contained use

To determine the toxicity, biodistribution and shedding profile of the test RP1, following subcutaneous administrations in Crl:SD rats.

### Recipient or parental organism

Crl:SD rats

### Host/vector system

RP1

### Origin & function

RP1 is a disabled recombinant herpes simplex type virus (HSV-1) containing the therapeutic genes.

#### Evaluation of foreseeable effects

**Hazards associates with the host/recipient/vector:**

Humans are the only natural host for HSV-1. Other species can be infected experimentally, but these appear to be "dead end" hosts- there are no natural non-human reservoirs for the virus. The deletion of ICP34.5 and ICP47 will not alter the host range of RS1 compared to the wild type, parental virus.

RP1 is attenuated and has a limited if any replicative capacity in normal cells in vivo. The virus is enveloped and hence is fragile and readily inactivated outside the host. Infectivity is eliminated by a temperature of greater than 56°C maintained for ~20 hours, or exposure to pH of less than 4. It is also rapidly inactivated by desiccation, lipid solvents, mild detergents and bleaches and common disinfectants. The fact that direct contact is required for transmission attests to the instability of the virus outside the host.

The doses will be prepared in a class 2 microbiological safety Hazards arising directly from the inserted gene: There are no known hazards directly associated with these genes.

RP1 contains the coding sequence for encoding ***** (*****), a cytokine involved in the stimulation of T-cells. ***** expression is under the control of the human cytomegalovirus immediately early promoter (HCMV IE) and this expression cassette has been inserted into the ICP34.5

RP1 also expresses a truncated ***** (***** envelope glycoprotein, incorporated as a fusion protein.

Hazards arising from the alteration of existing pathogenic traits:

RP1 is a disabled, non-pathogenic version of HSV-1, modified so that replication occurs selectively in tumour cells. Considerable literature shows that HSV-1 deleted for the neurovirulence factor is non-pathogenic in...
humans and animals. Because the virus is attenuated in normal cell, no adverse effects would be expected with exposure to individuals who may come into contact with it. Additionally, wild type HSV-1 is a universally prevalent virus that rarely causes severe problems. The potential for recombination with wild type HSV-1 is low, as this could only occur if both strains were present and replicating in the same cell. If this were to happen, any resulting virus would itself be non-pathogenic due the deletion of the neurovirulence factor ICP34.5. Consideration relating to whether an inserted sequence, that does not give rise to a harmful phenotype in the recipient, could give rise to harm as a result of natural gene transfer to other, possibly related, organisms: RP1 is attenuated and has a limited if any replicative capacity in normal cells in vivo. The virus is enveloped and hence is fragile and readily inactivated by desiccation, lipid solvents and mid detergents. Direct contact is required for transmission. There is no indication that transfection between viruses could occur.

Estimation of the severity of the harmful event were it to occur: Accidental parenteral inoculation, droplet exposure of mucous membranes or contamination of broken skin.

Wild type HSV-1: 7-10 days.

RP1 is attenuated and has a limited if any replicative capacity in normal cells in vivo. The virus is enveloped and hence is fragile and readily inactivated. RP1 is expected to be sensitive to the anti-viral agents such as the tyrosine kinase inhibitors (TKI) Acyclovir, valacyclovir, famciclovir and cidofovir. RP1 is also known to be susceptible to common disinfectants – 1% sodium hypochlorite, iodine solutions containing ethanol, 70% ethanol, glutaraldehyde and formaldehyde. In the event of accidental exposure through a splash to the eyes or mucous membranes, flush with copious amounts of clean water for at least 15 minutes. In the event of exposure to broken skin or a needle stick, thoroughly clean the site with soap and water or use a skin disinfectant. See a physician for monitoring for signs of infection. Acyclovir or other TKI anti-viral drugs may be administered prophylactically.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

**Disposal of affected sharps:** Used needles and syringes should be disposed of in the yellow sharps bins and placed with other GMO waste in dedicated wheeled bins for incineration.
Inactivation of the GMO:
All potentially contaminated material will be inactivated by chemical disinfection (1% Virkon for 30 minutes) and/ or autoclaving at 121ºC for a minimum of 15 minutes. The likelihood of release is therefore low. Disposal of GMO waste in dedicated wheeled bins for incineration. Where it is not possible to autoclave or chemically deactivate contaminated materials, they will be placed into hermetically sealed containers, marked with biohazard tape and disposed of by incineration through a licensed contractor.

Please enter comments on the GM safety committee on the risk assessment

1. In section ‘Hazards arising directly from the inserted gene’ This paragraph states what the inserted Genes are, but does not detail what/if any hazards are known.
Amended
2. I've just added a couple of comments to the assessment: Named RPM1 in header and is it possible to get these contact times consistent for Virkon in the assessment; we typically use 20 minutes for viral inactivation in virology, I think it would save confusion.
Amended to 30 minutes

Project Ref 421/19.1

Date Ackn’d 17/07/2019
CU2 Project Title The test article is a modified Newcastle Disease virus, strain NDV 73T modified with

Class 2
CultureVolClass2 < 1 Litre
CultureVolumeClass3-4

02/03/2022 Page 7332 of 15326
human granulocyte-macrophage colony stimulating factor (GM-CSF). It is being used in clinical studies to infect tumour cells and subsequently cause reductions in the size of solid tumours.

**Project Additional Information**

**Purposes of the contained use**

A QPCR assay will be developed and validated using the recombinant NDV MEDI5395 as a positive control. Subsequently, human patient samples containing this GMO will be assessed for the quantity of the GMO using molecular biology techniques. No in-vivo activities to be undertaken.

**Recipient or parental organism**

Modified Newcastle Disease virus of strain NDV 73T.

**Host/vector system**

NDV 73T is derived from NDV MK-1 07, a commercial poultry vaccine that was first marketed in 1948. MK-1 07 virus was further studied by Cassel and Garrett in the 1960s as an oncolytic agent, and subsequently passaged 73 times in Ehrlich ascites tumour cells to generate an adapted oncolytic virus called NDV 73-T. NDV 73T was modified using reverse genetics to produce recombinant NDV 73T (r73T) virus and additional r73T derivatives were also generated that have sequence modifications that attenuate the virulence. Attenuation of virulence has been demonstrated by intra-cerebral pathogenicity index tests in chicken host. Only derivatives with an ICPI <0.4 were selected.

**Origin & function**

These rNDV viruses are produced by standard reverse genetics methodologies i.e. transfecting modified viral genomic cDNA into a tissue culture cell and resulting recombinant virus is then amplified in specific pathogen free embryonated chicken eggs or human cell lines. The major virulence factor is the F protein cleavage site which is modified by removing the native protein cleavage site. In addition, therapeutic transgene(s) have been inserted into the viral genome to further attenuate the virus whilst providing oncolytic activity. Recombinant NDV 73T viruses are recovered by reverse genetics with various modifications in:

1. F protein cleavage site, the native site has been modified to ensure the virus has ICPI < 0.4
2. Transgene(s) are inserted into the viral genome for enhancing immuno-modulation and virulence attenuation.
(3) F and HN chimera are constructed that contains the ectodomain, transmembrane domain of other viruses and cytoplasmic domain of 73T. The other viruses include PIV5 (dog is a natural host) and PPMV-1 (ICPI < 0.025, pigeon is a natural host).

(4) Other mutations may be introduced into F, HN and V genes to ensure genetic stability and virulence attenuation in chickens.

Evaluation of foreseeable effects

Hazard identification in respect of human health and environmental safety

Hazard associates with the host/recipient/vector:
Vaccine strains of NDV with pathogenicity index <0.4 are considered to be non-pathogenic to poultry and humans however are categorised as ACDP hazard group 2. The modifications made to this virus do not increase the likelihood of pathogenicity.

Hazard arising directly from the inserted gene:
None - the genetic changes to the viral RNA sequence or insertion of therapeutic transgenes is for the purpose of attenuating virulence levels. rNDV with demonstrated low virulence levels is less hazardous than wild type NDV. NDV that is characterised and has an ICPI value of less than 0.4 is categorised as ACDP hazard group 2.

Hazard arising from the alteration of existing pathogenic traits:
None - modifications make the virus less virulent however NDV that is characterised and has an ICPI value of less than 0.4 is categorised as ACDP hazard group 2.

Consideration relating to whether an inserted sequence, that does not give rise to a harmful phenotype in the recipient, could give rise to harm as a result of natural gene transfer to other, possibly related, organisms:
Genes would be unable to recombine with other hosts.

Estimation of the severity of the harmful event were it to occur:
Minimal. Newcastle disease virus (NDV) is a paramyxovirus that is pathogenic in birds but causes only mild symptoms in humans and is therefore considered to pose minimal risk to human health. Laboratory exposure to NDV purified virus or by extensive contact with infected birds (such as eviscerating infected poultry in processing plants) can cause mild transient conjunctivitis and influenza-like symptoms in humans, and outbreaks of this population have been limited primarily to laboratory workers and vaccination teams exposed to large quantities of virus. No human-to-human transmission has been observed. The disease has not been reported in people who rear poultry or consume poultry products.

Health and Safety Executive

Newcastle disease virus (NOV) otherwise poses no hazard to human health. Interest in the use of NOV as an anticancer agent has arisen from the ability of NOV to selectively kill human tumour cells with limited toxicity to normal cells. No treatment for NOV exists, but the use of prophylactic vaccines and sanitary measures reduces the likelihood of outbreaks.

NOV is only considered a select agent! specified animal pathogen, and is thought to pose an environmental risk, if it has a virulence level (ICPI- Intra-cerebral pathogenicity index) of >0.4. Below this level NOV is not considered a specified animal pathogen. The virus in this assessment is thought to have similar risks to the current vaccines used for NOV. NOV that is characterised and has an ICPI value of less than 0.4 is categorised as ACOP hazard group 2.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Inactivation of the GMO:

All potentially contaminated material will be inactivated by chemical disinfection (1% Virkon for 20 minutes) and/or validated autoclaving at 121°C for a minimum of 15 minutes. The likelihood of release is therefore low. Disposal methods will follow documented laboratory procedures.

Where it is not possible to autoclave or chemically deactivate contaminated materials, they will be placed into hermetically sealed containers, marked with biohazard tape and disposed of by incineration through licensed contractor, Stericycle (SRCL) Leeds.

Please enter comments on the GM safety committee on the risk assessment  

N/A
Committee Meeting 16 May 2019

If you think this GMO is associated to a risk, you need to update accordingly the section Hazard as the vector is non-pathogenic, and no hazard associated to the inserted gene or the modifications done therefore is this a class 2?

Add extraction to study procedure/aims to make it clear that only extracted DNNRNA will be used for QPCR, so the higher risk is before/during extraction

Confirmed that the material did not require a SAPO as it has an ICPI less than 0.4
(consultant)
Confirmed this as a Class 2
Confirmed that it did not require a SAPO license
Confirmed that that it was not subject to the requirements of the ATCSA; referance made to the foot note to schedule 5:
Excludes non-viable microorganisms - e.g., in fixed tissues
Excludes medicinal products - e.g., vaccines, immunotoxins, future gene therapy agents?
Excludes clinical specimen for diagnostic purposes
Must be disposed of as soon as reasonably practicable following diagnosis
Covers GM forms of listed micro-organisms if still capable of causing serious harm to humans or animals - require same or higher containment level
Covers micro-organisms that have been modified by any means - passage, mutagenesis, protoplast fusion
Excludes established vaccine strains even if not part of a medicinal product
Recommended additions: Validation of the Autoclave and that it should stat whether sharps are to be used or not in the activity
All containment arrangements discussed and agreed.

<td>The GMO is a live virus vaccine of Herpes Simplex Type 2 (HSV-2) virus that has</td>
<td>Class 2</td>
<td>Not Applicable</td>
<td></td>
</tr>
</tbody>
</table>
The parent virus is Herpes Simplex Type 2. It has been modified to remove the ICP0 gene, which encodes infected cell protein 0. This is a critical regulatory protein involved in controlling the switch between latency and replication. 205 amino acids have been deleted from the ICP0 gene, including the nuclear localisation signal (NLS) and the oligomerisation domain, which are essential for the ICP0 to serve as a potent co-activator of viral mRNA synthesis. The removal of the ICP0 gene makes the virus sensitive to interferon, which would be present in humans. In addition, this deleted region has been replaced with a Green Fluorescent Protein (GFP) gene to facilitate the visualisation and tracking of the virus.

### Purposes of the contained use

The following methods will be used for batch release and stability testing:

- Plaque Assay (Class 2 Activity)
- Interferon (IFN) sensitivity assay (Class 2 Activity)

### Class 1 Activities:

- Host cell protein ELISA
- Host cell DNA QPCR
- DNA Size distribution
- Picogreen assay
- DNA extraction
- ICP0 deletion assay
- GFP insertion assay
- BCA total Protein assay
- Residual BSA ELISA
- Residual Benzonase ELISA
- Residual Doxycycline ELISA

# Project Additional Information

## Recipient or parental organism

The parent virus is Herpes Simplex Type 2. It has been modified to remove the ICP0 gene and add a GFP gene. Pre-formulated vector supplied by the client. The methods will then be used for batch release and stability testing of the HSV-2 vaccine (RVx201).
### Host/vector system

N/A

### Origin & function

The GMO is a live virus vaccine of Herpes Simplex Type 2 (HSV-2). The parent virus is Herpes Simplex Type 2. It has been modified to remove the ICP0 gene, which encodes infected cell protein 0. This is a critical regulatory protein involved in controlling the switch between latency and replication. 205 amino acids have been deleted from the ICP0 gene, including the nuclear localisation signal (NLS) and the oligomerisation domain, which are essential for the ICP0 to serve as a potent co-activator of viral mRNA synthesis. The removal of the ICP0 gene makes the virus sensitive to interferon, which would be present in humans. In addition, this deleted region has been replaced with a Green Fluorescent Protein (GFP) gene to facilitate the visualisation and tracking of the virus.

### Evaluation of foreseeable effects

#### Hazards associates with the host/recipient/vector:

Wild type HSV-2 causes genital herpes. The deletion of the ICP0 gene in this GMO severely affects its ability to replicate. It is still capable of replication, but in order to achieve full replication competency it requires propagation in a complementary cell line that contains ICP0.

#### Hazards arising directly from the inserted gene:

The inserted gene encodes for Green Fluorescent Protein. This is a well characterised gene, which allows the virus to fluoresce, and is not considered to be hazardous.

#### Hazards arising from the alteration of existing pathogenic traits:

The deletion of the ICP0 gene reduces the virus’s ability to replicate and therefore reduces its pathogenicity. The addition of the GFP gene has no impact on pathogenicity.

#### Consideration relating to whether an inserted sequence, that does not give rise to a harmful phenotype in the recipient, could give rise to harm as a result of natural gene transfer to other, possibly related, organisms:

It is highly unlikely that this GMO will come into contact with wild type HSV-2 during the course of this work. The presence of wild type HSV-2 is required for gene transfer as the GMO contains a deletion and reinstatement of the gene is only possible with wild type virus. Recombination with the cell culture that grows the virus is unlikely to occur due to the absence of overlapping sequences. Transfer of the GFP gene is not considered likely due to the lack of overlapping sequences, and GFP is not considered to be a hazardous gene.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Wild type HSV-2 is classified as Hazard Group 2, requiring Containment Level 2 in the UK. The modifications to this virus, described here, reduce its ability to replicate and therefore its pathogenicity. This assessment covers different activities that require different levels of containment. Where the GMO is grown in the presence of the complimentary cell line, Containment level 2 is required (Plaque assay and IFN-sensitivity assay). Where no cells are present (and hence no ICP0 gene) Containment level 1 is sufficient with the disinfection procedures detailed below.

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The GMO will be inactivated by soaking in 1% (w/v) of Virkon for 20 minutes. All waste materials that have come in contact with the GMO will be autoclaved at 121°C for 15 minutes.

Project Ref 421/21.2

The replication attenuated TheraT vector is based on Pichinde virus strain passage 18 (PICV p18; GenBank Access)

Class CultureVolClass2 CultureVolumeClass3-4

- Class 2
- Not Applicable

Non-GMM Consent Granted

Project notified under transitional arrangements

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

02/03/2022
**Project Additional Information**

**Purposes of the contained use**

RNA from the TheraT (PIC) E6E7 will be extracted and used as a positive control in the development and validation of an RT-qPCR assay.

**Recipient or parental organism**

The recipient Pichinde virus (PICV) virus belongs to the family of Arenaviridae which are enveloped ambisense RNA viruses containing two RNA genome segments ("bi-segmented"): segment L, which encodes an RNA dependent RNA polymerase and a zinc finger binding "Z" protein (GenBank EF529747.1) and segment S, which encodes a nucleoprotein (NP; GenBank EF529746.1) and a glycoprotein (GP).

**Host/vector system**

Hazards associated with the host/recipient/vector:

The natural host of parental virus PICV are rice rats (Oryzomys albicularis) from which PICV was isolated in Colombia. Since PICV is geographically restricted by its natural host, there is little to no preexisting immunity against PICV in the general human population. In general, PICV is not known to cause diseases in humans (Arenaviruses: Biology and Immunology; MBA Oldstone 2013 Springer Publishing; Center of Disease Control and Prevention publication New World Arenaviruses).

TheraT vectors developed by HOOKIPA Biotech GmbH are based on PICV passage 18 (PICV p18; GenBank Access. Nr. EF529747.1 and EF529746.1). PICV p18 was established by passaging PICV 18 times in spleen of inbred guinea pigs. Infection of inbred guinea pigs with PICV p18 is an established model which allows to recapitulate clinical and pathological features of infection with another arenavirus. Animals infected with the guinea pig-adapted PICV strain p18 develop a severe disease that mimics Lassa fever. In contrast to strain p18 of PICV, the low spleen passage strain p2 causes only limited febrile illness in infected animals.

Arenaviruses generally have rodent reservoirs and are not adapted to human hosts. Accordingly, human clinical isolates of arenaviruses bear the hypothetical risk of adaptation with a consequent increase in pathogenicity for humans (Center of Disease Control and Prevention publication "Biosafety in Microbiological and Biomedical Laboratories 5th edition" Section VIII-E: Viral Agents). In contrast, the genetic traits of the p18 variant of Pichinde virus, which differentiate it from p2, reflect the adaptation of the parental p2 variant to guinea pigs and not to humans or primates. As expected, adaptation of Pichinde virus to guinea pigs was reported not to augment its pathogenicity of non-human primates (Jahrling PB et al. Infect Immun. 1981 May;32(2):872-80).

Accordingly, the adaptation of the ancestral Pichinde virus p2 to p18, which was used for TheraT vector generation, does not interfere with attenuation which is based on inefficient packaging of all three TheraT genomic segments. Therefore TheraT vectors based on Pichinde Virus exhibit impaired replication kinetics when compared to parental PICV (PICV wt) in cultured human cells, in immunodeficient mice and in guinea pigs which are highly susceptible to infection with PICV strain p18.

**Origin & function**

For TheraT, a proprietary vaccine vector platform of Hookipa Biotech GmbH, the originally bi-segmented arenavirus genome was modified by segregating the essential viral nucleoprotein (NP) and viral glycoprotein (GP) from one genomic segment onto artificially duplicated segments. Each TheraT vector thus contains three genome segments, including one large (L) genomic segment and two S segments in which the S segments encode either PICV GP or NP but not both. The genetic design of these S segments prevents intersegmental recombination and reversion to a functional wild type-like single S segment encoding both PICV GP and NP. As all four original PICV
genes encoded on L and S-segments are required for virus replication, all three genetic segments are required for generation of replication-competent progeny TheraT vectors. Attenuation is based on inefficient packaging of the three genetic segments.

The encoded antigens are based on HPV strain 16 proteins E7 and E6. The proteins are artificially expressed as a fusion protein that is rendered non-functional due to several mutations as described in Cassetti M et al, 2004. Therefore, the original activity of the individual proteins is abrogated and the expressed fusion protein E7E6 non-oncogenic.

### Evaluation of foreseeable effects

Hazards arising directly from the inserted gene:

- The HPV antigens encoded by the vector were modified by various mutations to disable the wild-type function. There are no anticipated adverse effects from the inserted genes.

Hazards arising from the alteration of existing pathogenic traits:

- Insertion of the antigen sequence is not expected to alter pathogenicity of TheraT vector. Attenuation is based on inefficient packaging of all three genomic segments and is independent of the transgene.

Consideration relating to whether an inserted sequence, that does not give rise to a harmful phenotype in the recipient, could give rise to harm because of natural gene transfer to other, possibly related, organisms:

- During the replication cycle, arenaviruses exists exclusively in the form of RNA and do not normally integrate into the host genome. Likewise, any other form of gene transfer is not expected to happen.

Estimation of the severity of the harmful event were it to occur:

- TheraT vectors are attenuated, replication competent viral vectors based on PICV. These vaccine vectors were genetically engineered to allow for expression of genes of interest against which a cytotoxic T-cell response is induced and confer an attenuated replication competent phenotype. Any unintentional infection of humans would be expected to lead to a transient infection associated with activation of the immune system.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**N/A**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

- Disposable items will be placed in autoclave bags, or sharps bins held within the laboratory where the work is being performed. Sharps bins will be sealed prior to removal from the laboratory. Containers and bags will be identified as containing biohazard waste.

**Project Additional Information**

### Purposes of the contained use
The lentivirus will be used to infect cells that express the ACE-2 receptor. The assay will be used to identify and quantify antibodies that neutralise via the S-protein of SARS-CoV-2 by preventing infection of the lentivirus and expression of the luciferase gene.

### Recipient or parental organism
The GMO is a lentivirus virus that has been modified to remove the Envelope gene. A gene encoding luciferase has been inserted in its place. In addition, the virus was produced in the presence of the plasmid encoding the S-Protein from SARS-CoV-2. This protein is therefore expressed on the surface of the lentivirus and allows the lentivirus to bind to and infect cells expressing the ACE-2 receptor. The gene for the SARS-CoV-2 Spike protein however is not incorporated into the pseudovirus.

### Host/vector system
The lentivirus is well characterised. It is developed from Human Immunodeficiency virus type 1 (HIV-1) but has been genetically modified to remove the envelope gene. It is therefore unable to target its usual receptor CD4. Progeny virions are therefore non-infectious. Lentiviral vectors as categorised as Hazard Group 2 requiring Containment Level 2. In addition, it has a self-inactivating deletion in the U3 region of the 3' LTR which minimises the chance of production of replication-competent particles via a recombination event. Due the retroviral replication process, the 3'LTR serves as the template for the generation of the 5'LTR in the viral progeny. Thus the proviruses (integrated copies of the viral genome) that are established in infected target cells lack functional 5'LTR sequences, including the viral transcriptional promoter and enhancer. Therefore, further replication of the virus cannot occur even if the HIV envelope gene was present.

### Origin & function
The inserted gene encodes the luciferase protein. There are no hazards associated with this gene/protein and it is well characterised.

### Evaluation of foreseeable effects
The inserted gene encodes the luciferase protein. There are no hazards associated with this gene/protein and it is well characterised.

The gene for the SARS-CoV-2 Spike Protein was present during production of the pseudovirus and therefore the pseudovirus expresses the Spike Protein. However, this gene is not present in the pseudovirus. There are no hazards associated with the Spike Protein as the rest of the SARS-CoV-2 virus is not present.

Hazards arising from the alteration of existing pathogenic traits:

The lentiviral particles have been modified in order to remove genes required for any infection into its target cell. This significantly reduces any risk associated with the parent virus. The addition of the S-protein from SARS-CoV-2 changes the tropism of the Lentivirus from CD4+ T-cells to cells expressing ACE2, but the gene for the S-protein is only expressed transiently during the original pseudovirus production and is not contained within this lentivirus pseudovirus therefore does not allow it to replicate or increase its pathogenicity.

Consideration relating to whether an inserted sequence, that does not give rise to a harmful phenotype in the recipient, could give rise to harm as a result of natural gene transfer to other, possibly related, organisms:

The genes are unlikely to transfer and require specific culture conditions and the other plasmids to be present in order to produce complete virus particles.
Due to the deletion of replication and pathogenic genes there is little risk of the GMO establishing more harmful forms of the vector. There is a self-inactivating deletion in the U3 region of the 3’ LTR which minimises the chance of production of replication-competent particles via a recombination event. Estimation of the severity of the harmful event were it to occur: The GMO is considered infectious however it is non-pathogenic and replication deficient so will not likely cause a hazardous event.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All potentially contaminated material will be inactivated by chemical disinfection (minimum 1% w/v Virkon for 20 mins) and/or autoclaving at 121°C for a minimum of 15 minutes. The likelihood of release is therefore low. Disposal methods will follow documented laboratory procedures. Where it is not possible to autoclave or chemically deactivate contaminated materials, they will be placed into hermetically sealed containers, marked with biohazard tape and disposed of by incineration through a licensed contractor.

02/03/2022
The maximum culture volume that could be released at any one time is 50 litres resulting from a fermentor failure. The waste is deactivated by autoclaving in situ and the process is physically monitored by measuring temperature, pressure and time. Validation of our autoclaves is obtained using TST control integrators. Cells of Escherichia coli are destroyed at 120 degrees C.

Non-GMM

Consent Granted

Tick if notifying a connected programme of work: N

Historical Significant Changes: transferred to centre 774 on 12/7/06.
**Project Additional Information**

**Purposes of the contained use**

We aim to investigate the effects of expressing HPV genes in human epidermal keratindyes. We will investigate cellular responses to viral gene expression in the context of ultraviolet radiation. The main purpose of these experiments is to determine whether the viral encoded activities could account for effects in skin cancer.

**Recipient or parental organism**

HPV genes will be propagated in bacteria (E. coli K12 strains HB101 and sure). DNA will then be introduced into suitable mammalian retroviral packaging cell lines (murine) for virus production. Recombinant viruses will then be used to transduce human cells.

**Host/vector system**

- pBabe Puro/pBabe-bsd retroviral vectors, propagated in recombination deficient bacteria (E. coli HB101/Sure).
- Phoenix cells: murine retro viral packaging cell line.

**Origin & function**

All HPV DNA sequences used are previously cloned in plasmid vectors and freely available.

Likely that the HPV encoded sequences will modify the cell cycle, differentiation status and apoptotic responses of the infected human cell.

**Evaluation of foreseeable effects**

Recombinant virus is potentially hazardous. Contact will therefore be minimised. Work will be carried out in a safety cabinet thereby reducing the risk of aerosol. Sharps will be avoided. If contact does occur; recombinant virus is replication defective, effect thereby localised; immune rejection of virally infected cells of human/murine origin; handling only one virus at a time will minimise changes of recombination.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

All work will be carried out in purpose built and equipped laboratory space designated and reserved for such experiments.

All liquid waste will be decontaminated with 1% Virkon or 5% sodium hypochlorite. Solid waste will be autoclaved. A 100% kill will result.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

- Liquid waste - decontaminated with 1% Virkon or 5% Sodium Hypochlorite. Then to drains.
- Solid waste - autoclaved followed by incineration. 100% kill is expected in both cases.
The committee considers this work to be class II and therefore all retroviral work will be carried out in our Cat II suite, Room 1.18.

TRANSFERRED TO GM CENTRE 774 - 12/7/06.

Tick if you are claiming exemption from disclosure for section of the risk assessment N
**Project Additional Information**

**Purposes of the contained use**

The purpose of the contained use is to generate immortalised human cell lines derived from the skin that can be used for research and drug screening.

**Recipient or parental organism**

Recipient cells will include human oral, anogenital and cutaneous keratinocytes. Hair follicle, germinative epithelium, matrix, outer root sheath keratinocytes, dermal papilla and connective tissue sheath fibroblasts as well as sebocytes from sebaceous glands.

**Host/vector system**

The pBABE retroviral vector consists of the long terminal repeat (LTR) packaging sequence from the Moloney murine leukemia virus (MoMuLV). Because the env and reverse transcriptase genes have been deleted and as there is no origin of replication this vector is considered by the ACGM to be non-mobilisable and incapable of further replication in the target cell.

**Origin & function**

It is intended that infecting cultured human cells with hTERT and SV40LT inserts will result in the production of immortalised cell lines. Therefore, the foreseeable effects of this activity are the generation of immortalised human cell lines.

**Evaluation of foreseeable effects**

Foreseeable effects will be the immortalisation of skin derived cell lines.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

PT67 packaging cells are considered to be disabled hosts and are not considered to be pathogenic to humans or animals and would have a very limited ability to survive in the environment.

pBabe will be used to express hTERT and SV40LT in human primary cell lines. The human cell lines in both their primary and transformed state are unable to survive outside of the tissue culture flask and are therefore, unlikely to spread or cause damage to the environment. If a human or animal were to be infected by one of these transformed human cell lines, these cells would be rejected by the normal immune system.

All work will be carried out in purpose built and equipped laboratory space designated and reserved for such experiments.

All liquid waste will be decontaminated with 1% Virkon or 5% Sodium Hypochlorite. Solid waste will be autoclaved. A 100% kill will result.

Retroviral supernatants for infection of cell cultures will be produced in volumes of <(less than) 100 ml.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Retroviral vectors to be used in this study are considered by the ACGM to be non-mobilisable and incapable of further replication in the target cell.

Human cell lines in both their primary and transformed state are unable to survive outside of the tissue culture flask and are therefore, unlikely to spread or cause damage to the environment. If a human or animal were to be infected by one of these transformed human cell lines, these cells would be rejected by the normal immune system.
As sharps will not be used in these studies the risk of inoculation into humans is negligible. All work with retroviral supernatants will be carried out by the worker wearing laboratory coat, facemask and double gloves. The risk of human infection is considered negligible.

All liquid waste will be decontaminated with either 1% Virkon or 5% Sodium Hypochlorite. Solid waste will be autoclaved followed by incineration. Members of the MuLV group of viruses require high titre to establish infection in immunologically competent animals and so the risk of harm to either the environment associated with accidental release of the vector is low.

The committee considers this work to be class II and therefore all retroviral work will be carried out in our Cat II suite, Rm 1.18.

### Project Additional Information

#### Purposes of the contained use

To identify and study the behaviour of mammalian epithelial stem cells. After the basic epithelial stem cell patterns have been established, work will examine how intrinsic stem cell patterns are altered by the forced expression of certain genes that are putatively associated with control of stem cell growth and differentiation. This project will use combined techniques of stem culture, retroviral transduction, tissue reassembly to determine: a) the size and distribution of stem cell territories in a range of human and murine epithelia of differing complexities, b) the influence of stromal/epithelial interactions in determining stem cell patterns, c) how stem cells are altered in malignancy, and d) how stem cell behaviour is influenced by the expression of genes associated with cell differentiation and cell death.

#### Recipient or parental organism

The recipient or parental organism for the standard cloning are disabled non-pathogenic E coli strains. The recipient cell lines for expression of the proteins are standard cell culture lines which cannot survive out of culture and which are kept free from any adventitious agents as far as can be determined by our routine assays for contaminating agents which are problematic in tissue culture, e.g. mycoplasma.

#### Host/vector system

<table>
<thead>
<tr>
<th>Host</th>
<th>Vector</th>
</tr>
</thead>
<tbody>
<tr>
<td>DH5a (bacterial cloning)</td>
<td>pPinco</td>
</tr>
</tbody>
</table>

#### Source of Nucleic Acid:

- GFP cDNA
- Alkaline phosphatase cDNA
- Galactosidase cDNA
- RAS human cDNA
- Bcl-2 related human cDNAs

#### Description of DNA to be manipulated:

- Modified jellyfish gene, Mammalian placenta & E.Coli - Lineage markers
- Mammalian GTPase & Mammalian homologs of C.Elegans ced genes - Potential modifiers of Stem cell behaviour

#### Evaluation of foreseeable effects

To introduce modified oncogenes and anti-oncogenes into mammalian cells in culture, the cDNA of the gene in question is sub-cloned into a replication defective retroviral vector plasmid. This is transfected into a "packaging" cell line which therefore secretes retroviral virions capable of coding for the inserted sequence. These are able to infect human cells but are not capable of further cycles of replication. There is therefore no risk of subsequent spread of infection. The viruses are extremely fragile and are extremely sensitive to desiccation, the recipient cell lines are unable to survive outside culture conditions.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All cells and media which may contain infectious virus are handled by designated specially trained workers in a class II biological safety cabinet equipped with external ducting. All liquid waste will be sterilised at point of use by sodium hypochlorite, as per College and Trust sterilisation and disinfection policy. All solid waste will be sterilised in an adjacent autoclaving facility which is regularly tested by Cardiff and Vale Trust engineers.

Is an emergency plan required according to regulation 20?  
If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

Risk assessment suitable and sufficient, agree with assigned containment level and classification.

<td>Modulation of the interplay between extracellular matrix and cells by adenoviral gene transfer</td>
<td>Class 2</td>
<td>1-50 Litres</td>
<td></td>
<td>Not Applicable</td>
<td></td>
</tr>
</tbody>
</table>
The function and the structure of the extracellular matrix (ECM) is controlled by regulatory molecules as well as by modifying enzymes which can crosslink or cleave matrix constituents. Some of these molecules have functions in the ECM and also control cells residing in the matrix by regulating the availability of cytokines or by direct effects on cells: (1) decorin (see below) can regulate collagen fibril formation as well as TGF-B availability and has direct effects on cell differentiation and survival (Kresse & Schonherr, 2000, J. Cell Physiol. 189:266). (2) Tissue transglutaminase does not only influence cell-matrix interactions but also has GRPase activity and via this activity can contribute to the regulation of intracellular signalling cascades that control cell spreading and motility (Stevens et al., 2004, J. Cell Sci. 117:3389). To investigate the contribution of these distinct functions to biological effects, we plan to use adenoviruses for the expression of wild type or mutant components in different types of cells. Adenoviral gene transfer is necessary (a) to mimic the situation in vivo (because naturally these molecules are induced and not constitutively expressed), (b) the cells used in the investigation (e.g., endothelial cells, primary fibroblasts, macrophages) are difficult to transfect and easily damaged, and (c) adenoviral infection allows a reproducible induction of a specific molecule.

Small leucine-rich proteoglycans (SLRPs) are multifunctional regulatory molecules of the extracellular matrix. Members of this family are decorin, biglycan, fibromodulin, and lumican. In the past, SLRPs were primarily considered as organizers of collagenous networks. More recently their interactions with TGF-B and their direct effects on cells have come into focus. We showed with the help of adenoviral vectors that decorin induces capillary formation and survival of endothelial cells, but it induced programmed cell death in tumour cells (Schonherr et al. 1999, Eur. J. Cell Biol. 78:44; Tralhao et al. 2003 FASEB J., 17:464). Our studies on endothelial cells further indicated that protein kinase B (Akt) is involved in decorin-mediated signalling leading to cell differentiation and survival (Schonherr et al., 2001, J. Biol. Chem 276, 40687). In collaboration with Dr. P. at this institution we plan to use adenoviruses that have already been prepared to investigate signalling cascades in other cell systems. These adenoviruses have already been generated under approval of the Genetic Modification Sub-Committee (GM 312/DWT.pB/3) of the Institution of HSE notification. These adenoviruses will allow us to carry out in-depth analysis of decorin-induced intracellular signalling pathways(s). We will use these viral vectors to transfect endothelial cells and fibroblasts in culture. The already existing adenoviral vectors will allow us to carry out in-depth analysis of decorin-induced intracellular signalling pathways(s). We plan to use adenoviral vectors containing different mutated forms of SLRPs to analyse which parts of these molecules have specific functions. Therefore, we will use the cDNAs of the SLRPs which are available in our laboratory to construct new adenoviral vectors. The resulting replication deficient viruses will subsequently be used in different cell culture models to analyse the function of SLRP mutants.

Transglutaminases are enzymes that have extracellular as well as intracellular functions. One of the best characterised members of this family of multifunctional enzymes is tissue transglutaminase (TGase2). In the extracellular matrix, this enzyme can catalyse the formation of isopeptide bonds leading to protease resistant high molecular weight complexes, while intracellularly, the enzyme acts as a G-protein in signal transduction and mediates PKCa activation via regulation of PLC81. Recent evidence demonstrates that TGase2 controls cell morphology, differentiation and survival by modulating cell-matrix interactions. We have shown that fibroblasts deficient in TGase1 are defective in cell spreading, migration and matrix assembly (Stevens et al., 2004 J.Cell Sci. 117:3389). Recent work by us and others also showed that lack TGases2 have delayed healing of skin wounds and have a deficiency in TGF-B1 production (Szondy et al., 2003. Proc. Natl. Acad. Sci. USA 100:7812). While previous cell culture data also implicated the enzyme in the activation of latent TGF-B the mechanism has not been elucidated. At present it is unclear whether the effects in the wound healing...
relate to defects in fibroblasts or in cytokine release by macrophages and also which of the activities of the enzyme is are essential for normal wound healing. We plan therefore to generate different adenoviruses which contain transglutaminase and different transglutaminase to determine whether we can rescue the phenotype of cells isolated from mice lacking transglutaminase and to analyse which activity of the enzyme is relevant for which biological function.

Recipient or parental organism

Adenovirus is an ACDP category 2 pathogene. Ad5 is primarily associated with mild upper respiratory tract infections of childhood. Deletion of the E1 gene region renders the adenovirus replication deficient. Replication deficient adenoviral vectors by their nature have a limited potential for lateral spread, although this could be facilitated by co-infection with wild-type adenovirus or gene rescue from helper cells.

To generate new replication deficient adenoviruses containing transgenes preliminary prokaryotic cloning steps are necessary. Genetically disabled E. coli K12 strains specifically developed for the applications in recombinant DNA cloning experiments will be used. These strains have limited potential to colonise the gut or survive in the environment.

Host/vector system

E. coli strains JM109, TOP 10, INV a F’ and DH5a will be used.

A commercial Ad5 vector system will be used for the construction of the replication deficient adenovirus (rendered replication deficient through deletion of the complete E1a and E1b gene function and further disabled by partial deletion of E3 gene). The Ad5 based AdEasy vector system from Stratagene. This system comprises pAdEasy-1, pShuttle, pShuttle-CMV, pShuttle-CMV-LacZ (control).

Replication deficient adenoviruses will be propagated in HEK-293 cells (a helper cell line expressing the E1 helper function). The resulting adenoviral vectors will be used to infect target cells in vitro.

Origin & function

All DNA are human and mouse cDNA clones previously generated by us or gifts from collaborators. DNA sequences are known and will be confirmed prior to generation of recombinant virus.

Replication deficient adenoviruses containing wild type human decorin and variant forms of decorin and variant forms of decorin have been previously generated with the AdEasy System in Germany or the USA (Schonherr et al. 1999, Eur. J. Cell Biol. 78:44; Tralhao et al. 2003FASEB J. 17:464). New adenoviral vectors containing additional mutations in the transgene will be prepared using the same technology. In addition, adenoviral vectors for other members of this protein family, ie human biglycan, fibromodulin, and lumican will be generated. The effect of transgenes cloned into these vectors on endothelial cells and fibroblast will be investigated using a number of established biological assays to study extracellular matrix assembly and angiogenesis. New adenoviral vectors containing mutants of human decorin using the same technology will be prepared.

Replication deficient adenoviruses containing mouse dominant negative and positive Akt were gifts from Boston USA (Fujiiy W & Walsh K, 1999, J Biol. Chem. 274:16349). These adenoviruses will be used to investigate the decorin signalling in target cells in culture. In addition, replication deficient adenoviruses approved by Genetic Modification Sub-Committee (GM 312/DWT./PB/3) will be used in collaboration to investigate pathways in these cells in culture.

Replication deficient adenoviruses containing human and mouse transglutaminase or mutants thereof will be generated to determine whether we can rescue in vitro in cell culture assays the phenotype of cells isolated from mice lacking transglutaminase and to analyse which activity of the enzyme is relevant for which biological function.

Evaluation of foreseeable effects

From experiments using adenoviral gene transfer of decorin we already know that the expression of decorin leads to differentiation and survival of normal cells (endothelial cells, primary fibroblasts). In addition, we and others have shown that decorin expression in tumour cells leads to a more differentiated phenotype or programmed cell death. Therefore, the transient expression of decorin in cells in culture does not present a foreseeable hazard. Furthermore, as these experiments should mimic the
situation in vivo, no large scale over-expression of the transgene is planned and thus fairly low concentrations of the adenoviruses will be used.

The generation of other adenoviral vectors containing the cDNA of molecules related to decorin is of low risk, because none of the SLRPs has been shown to have a transforming capacity. In contrast eg the lack of lumican or decorin expression in mammary tumours has been shown to be associated with a bad prognosis. In addition, over expression of biglycan in the pancreas carcinoma cells cause G1-arrest.

Potentially the largest risk is the use of the existing adenovirus containing active Akt which can enhance cell survival and proliferation. However, Akt alone is not sufficient to cause a malignant transformation of human primary cells. In addition, active Akt will only be used infrequently and only at a dose that results in activity mimicking the normal levels of activation in response to decorin. The adenovirus transducing the dominant negative form of Akt (which prevents Akt signalling) will be used to much greater extent. The potential hazard presented by these experiments is perceived to be low.

The generation of other adenoviral vectors containing the cDNA of transglutaminase which is a protein cross linking enzyme is also perceived to be very low. Transglutaminases have no transforming effect on cells. These enzymes strongly promote cell adhesion and several studies have shown that the malignant potential of cancer cell lines is reduced upon transfection with vectors directing constitutive expression of transglutaminase.

The host vector systems which will be used in the experiments are commercially available and well characterised. As the used adenoviruses are replication deficient they can only replicate in host cells which contain E1 sequences that have been deleted from the viral vector (these sequences are present eg in HEK-293, which are used for virus propagation). It is highly unlikely that the replication deficient viruses would regain spontaneously the ability for replication. In addition, large numbers of virus particles would be necessary for a sustained infection. Expression using the adenoviral vectors is only transient and is lost in rapidly replicating cells. Therefore, adenoviral vectors are unlikely to cause any permanent change in infected cells.

A potential hazard is the exposure of humans to recombinant virus. All manipulations of the virus will be done in a class 2 biological safety cabinet in the designated laboratory facility. The access will be limited to staff trained ACGM level 2 procedures. Any disposable materials that had contact with the virus will be disinfected chemically as well as by autoclaving prior to disposal. The use of sharps will be avoided to prevent accidental injury related risk. Therefore, any risk of the exposure of humans or the environment is very low.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Virus in solution (tissue culture media, buffers etc.) will be inactivated by adding no less than equal volume sodium dichloroisocyanurate (Actichlor) at a concentration of 2500 ppm. After 4 h, solutions can be discarded. Nevertheless, the solutions will be autoclaved ed prior to being discarded through the main drain. Pipettes immersed in 2500 ppm sodium dichloroisocyanurate for 4h will be transferred to plastic bags for autoclaving. All plastic ware is autoclaved after virus exposure. Actichlor is effective against all viruses and the high concentration overcomes the high organic contents of media.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

All disposable items are bagged and then autoclaved in an Astell Scientific Sterimate autoclave located within the laboratory suite. The effectiveness of the heat treatment is tested regularly using control indicator strips (Prestige Medical). The autoclave unit is also tested annually. The autoclaved bags are disposed of through a central college facility. Cell cultures, 1 litre or less, are deactivated using a standard sodium hypochlorite procedure.

In routine laboratory experiments, at most 2 litres of liquid culture medium is disposed of at any one time. Cultures are autoclaved for 20 minutes at 121 degrees C to inactivate them. A 100 ul sample from inactive culture which contained genetically modified E.coli is transferred to an LB plate containing the relevant genetic selection, spread out and then left at 37 degrees C overnight to verify efficiency of inactivation. Inactive cultures are disposed of in the laboratory sink.

All solid waste resulting from GM work is sealed in bags and autoclaved prior to incineration. Autoclaving is carried out in a regularly serviced and tested machine. Liquid culture waste, up to a maximal volume of 4 litres at a time is inactivated by autoclaving or by treatment with bleach prior to disposal. Inactivating efficiency is tested by re-plating of inactivated waste and examination of bacterial growth by colony counting. These are well established and standard procedures.

For activities involving GMMs, describe the waste management measures which will apply to the activity

All waste is disposed of by verified methods.
E.g. small quantities of GM waste (laboratory and growth rooms) are autoclaved, to sterilize all GM material, before disposal to landfill.

Larger quantities of GM waste (glasshouse) are disposed of by an approved external incineration contractor for certified disposal.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

Principal Investigators for all NIAB GM projects must complete a risk assessment and submit it to the Genetic Manipulation Safety Committee (GMSC) for approval. Only once the GMSC are satisfied that a risk assessment has been conducted in accordance with the genetic manipulations regulations will work on a project proceed.
Study of the infection process of Fusarium spp. (culmorum/graminearum) in Maize (Zea mays) using reporter genes

Maize varieties will be infected with Fusarium spp. harbouring the reporter genes uid A (GUS), GFP and DsRed. Maize tissues will be examined/ assayed for the presence of the reporter genes/reporter gene products in order to determine the extent of systemic infection and whether sytemic infection significantly contributes to Fusarium contamination of grain.

Recipient or parental organism

GMO1: Parental organism is Fusarium graminearum.
GMO2: Parental organism is Fusarium culmorum.

Both GMOs are natural pathogens of cereals such as maize, wheat, barley and oat and are endemic within Europe.

Origin & function

For GMO1 and GMO2 the inserted DNA will be a selectable gene conferring resistance to hygromycin (hph) and uidA (GUS) and Green Fluorescent Protein (GFP) and DsRed reporter genes (includes promoters etc.) Both reporter constructs were created in at Rothamsted Research (GFP, and JIC (DsRed), and have been routinely used to investigate the interaction between Fusarium spp. and small grain cereals. Hygromycin resistance will be used to select transformed Fusarium colonies, the reporter genes will be used to determine sytemic spread of the Fusarium species in Maize tissues.

Evaluation of foreseeable effects

The organisms studied are endogenous plant-pathogens on cereals across Europe and as such would be expected to survive and spread if accidentally released. The expression of the selection and marker genes will not alter the pathogenicity or fitness of the fungus, and will not confer any selective advantage in nature if accidentally
released. We are not aware of any reports where expression of these genes has been found harmful to human health or to the environment. Furthermore F. graminearum and F. culmorum are not considered pathogenic to humans (Hazard Group 1 organisms) or animals, however the toxins produced by the fungi are toxic if ingested. The modifications to the Fusarium strains should not alter their pathogenicity to humans or their ability to disseminate. It is expected that the GMMs will be able to produce toxins; however, infected plants will not be consumed. Health hazards from inhalation of Fusarium spores have not been reported and the toxins are not known to be carcinogenic. Fusarium spores may be irritant to skin and eyes and appropriate operating procedures are in place to prevent this with any Fusarium spp handled.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

GM Fusarium species will be used to inoculate maize seed/seedlings and as such they are plant-associated GM micro-organisms.

All manipulations of fungal cultures will be performed in a Class II Microbiological Cabinet.

Inoculated plants will be contained in dedicated spore proof growth facilities.

All operations will adhere to NIABs level 2 containment guide lines (attached SOP_GMM_001 – 009)

Both facilities are already approved for work with licensed (non indigenous) plant pathogens. (PHL 200/6871 (08/2012)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

All work will be conducted in Level 2 Containment Facilities (MSC Class 2, and sporeproof growth room) no derogation requested. Material for microscopic examination will be transported in triple wrapped containers (see SOP)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All work will follow NIAB standard operating procedures for working in level 2 containment facilities SOPs SOP_GMM_01 – 009 attached.

Waste will be in the form of fungal spores and mycelia on agar plates and associated contaminated waste such as tubes, filters, pipette tips, microscope slides, plant material, plant growth medium and containers.

Fungal growth medium and associated waste will be put in autoclaveable biohazard bags and sterilized by passage through a waste autoclave cycle (121 C for 30 minutes - degree of kill 100%).

All surfaces will be wiped with either a fresh 70% EtOH solution or a 10% Trigene solution dependent on surface type and detailed in attached SOPs (degree of kill greater than 99.999%).

All other consumables and plant material will be placed in autoclaveable biohazard bags and sterilized by passage through a waste autoclave cycle (132 C for 90 minutes) before disposal with general waste (landfill) (degree of kill 100%). Waste is autoclaved in a certified autoclave, load temperatures are recorded throughout the autoclave cycle and checked before waste disposal.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
Please enter comments on the GM safety committee on the risk assessment

Comments were received on the need to specify the exact facilities being used for level 2 operation, this has been done.

### Project Additional Information

#### Purposes of the contained use

To use potato virus X (PVX) modified with GFP (and truncated versions of this gene) to investigate the stability of genetic inserts in the PVX expression vector.

#### Recipient or parental organism

The plant virus PVX will be used. This virus is indigenous to the UK and is mechanically transmissible, infecting solanaceous plants. Vioral vectors based on PVX are available from the Sainsbury Laboratory, John Innes Centre, Norwhich. The constructs contain PVX under the CaMV 35S promoter and are cloned into a binary vector for the purposes of agroinoculation.

#### Host/vector system

The host plant will be Nicotiana benthamiana. Infection will be via agroinoculation, either from liquid cultures or via colonies from plates. PVX can only be spread by mechanical means.

#### Origin & function

A PVX virus vector will be used, containing the gene (and truncated versions of the gene) encoding green fluorescent protein (GFP) from the jellyfish Aquoria victoria. GFP will be used as a reporter gene to assess the stability of the construct during passaging experiments.

#### Evaluation of foreseeable effects

It is anticipated that expression of the inserted gene will not exceed 2% of total cell protein. None of the components of the vector system (Agrobacteria, PVX, GFP) pose a risk to human health. It is highly unlikely that either the PVX or GFP sequence will help either laboratory strains of E. coli or disarmed Agrobacteria strains overcome any disabling mutations. There is potential for PVX to survive outside containment and interact with wild type virus. It is generally believed that virus carrying extra genetic elements will be less fit than their wild type equivalents and that the gene will be lost. The aim of this work is to provide proof that this happens.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A (the PVX system serves as a transient expression system, the plant will not be transformed)

#### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Waste material will be in the form of liquid cultures and agar plates (and the associated lab ware that will have come into contact with the modified organisms), and, in addition, there will be infected plant material, soil and pots. Prior to autoclaving, all plastic ware and glassware for reuse will be soaked for 24h in 3% Virkon. All contaminated material will be autoclaved at 121 degrees C for 20 min using a regularly serviced and validated machine situated within the facility. Work surfaces will be wiped down with 3% Virkon after a procedure has been completed and any spills will also be treated with 3% Virkon. The treatment described have been shown to achieve 100% kill (see attached documents). The material used to wipe down surfaces and clear up spills will then be autoclaved, as above, before disposal. Treated waste will then be disposed of by incineration.
