- Other (please specify below)

Use of a genetically-modified human cell line for protein expression

6. For class 1 contained use involving GMMs, describe the waste management measures (include the inactivation method(s), the degree(s) of kill and proposed process testing / monitoring measures), which you will apply to the contained use (note 6)

The GMSC found that the risk assessment adequately stated the risks of carrying out the activities as described (assessing the secretion of protein by ELISA using a GM cell line). The committee confirmed the activity class of the work to be 1. The control measures in place for this type of work were deemed suitable and were already in place in RxCelerate's cell laboratory as this is already categorised as Category 2 for carrying out work on human cell lines.
### GM Centre Number: 3308

Mycology  Transgenic Invertebrates  Transgenic Plants  Other (please specify below)

Other(s)

For activities involving GMMs, describe the waste management measures which will apply to the activity

Decontamination is achieved by treating with Virkon (effectively 100% kill) on site, followed by rotoclaving by the waste contractor of the building (i.e. Novus Environmental).

Tick to confirm that you are attaching a summary of the risk assessment  Y

Tick if you are claiming exemption from disclosure for sections of the risk assessment  

02/03/2022
Q1: Please give a fuller description of the CRISPR/Cas 9 system and explain why these bacterial systems would not result in a more harmful E. coli host when they are used.

A1: The CRISPR Cas9 system is a gene editing tool which makes use of the Streptococcus pyogenes adaptive immune system. In short, a guide RNA oligomer is designed complementary to a target DNA sequence. The guide RNA directs Cas9 nuclease to cut the DNA at the target site. The DNA break is repaired by recombination with a template containing the desired point mutation.

The CRISPR/Cas9 components are in two groups: (i) the Cas9 plasmids encode the Cas9 nuclease and a sequence targeting the nuclease to tau exon 10; (ii) the pcDNA3 plasmids encode a repair template, either normal or mutant tau exon 10.

As proteins, the Cas9 nucleases encoded have the potential to cut the human tau gene. However, only when the repair template and the Cas9 nuclease are mixed could mutant tau be inserted. To minimise the risks of this happening:

- Health and Safety Executive
- The two groups of plasmids were amplified separately using Stbl3 E. coli, and stored separately.
- Small volumes (always less than 300ul) of each plasmid were made to minimise the risk of spillage.
- Cas9 nuclease and repair template plasmids were only mixed in a volume of 100ul or less. in a Class II cell culture cabinet, 5 minutes prior to transfection into iPS cells.

Q2: No other questions brought up by the committee.
**Purposes of the contained use**

Our research focuses on understanding how diseases damage the nervous system, and developing methods to repairing this damage. Research spans basic biology through to clinical studies. Areas of research include the biology of neurons and glia, the process of myelination, the use of stem cells to repair the brain, axon regeneration, plasticity in the brain, mechanisms of neurodegeneration and inflammation. The techniques are multi-disciplinary, and include molecular and cell biology, electrophysiology, both tissue culture and in vivo work, behavioural studies, clinical studies. Specifically for this notification, human and rodent primary and cell line cultures will be transduced with different viral vectors (see below), in order to introduce coding genes or non-coding RNAs associated with pathogenicity and/or repair processes and to understand their role in the context of neurodegenerative diseases.

**Recipient or parental organism**

- Well characterised commercial bacteria (e.g. One Shot® TOP10 and Stbl3™ Chemically Competent E. coli) disabled, non colonising, non pathogenic.
- Commercial packaging cell lines, e.g. HEK-293T human cell line. This cells are highly transfecable derivative of human embryonic kidney 293 cells, containing the SV40 T-antigen. Thus this cell line is competent to replicate vectors carrying the SV40 origin of replication, giving high titers when used to produce viral particles. It has been widely used for lentiviral production, gene expression and protein production.
- Human and rodent primary neural cultures, somatic neural stem/precursor cells, embryonic stem cells, fibroblasts and induced pluripotent stem cells. Characteristic of cell cultures are never totally understood, so primary human cultures will be handled at containment level 2, considering the possibility of adventitious viruses. Rodent cultures will normally be handled at containment level 1, unless otherwise specified in the risk assessment.

**Host/vector system**

Only well characterised, replication deficient viral vector system with a history of safe use will be used:
- HIV-1 derived lentiviral 3rd and 4th generation, replication defective (e.g. eGFP pRRtsin.PPT-hCMV, pCDH-EF-1-
MCS-T2A-GFP).
- Adena virus vectors, replication defective (e.g. Adeasy and Adtrack, deleted E1 and E3 genes).
- Adena-associated virus vectors, replication defective (e.g. AAV6).

**Origin & function**

Inserts are arbitrarily grouped as follows:
Type 1. Human, murine eDNA (+/M TAG sequences) coding for proteins, for example:
Health and Safety
Executive
transcription factors (Wnt3a, Ngn2 etc.) are expected to influence cell fate decision and differentiation, but not expected to have an effect on cell proliferation. Other genes may code for disease associated proteins (alpha synuclein, tau etc).
Type 2. ncRNA sequences for example:
shRNAs and miRNAs (mmu-miR-1S5-5p, etc) will produce ncRNA sequences targeting cell endogenous mRNA (Wnt3a, p73). These sequences are not expected to affect cell proliferation. Notably, mmu-miR-1S5-5p is not implicated
in oncogenic processes,

Type 3. Reporter genes for example:
enhanced GFP (eGFP), mCherry, firefly luciferase etc will code for proteins with fluorescent properties allowing easy
identification of genetically modified (GM) cells. All of these labels are thought to have no deleterious biological effect
on expressing cells.

Type 4. Selection genes for example:
bacterial resistance (ampicillin) or mammalian resistance (puromycin) will express proteins with enzymatic activities to
allow selection of bacterial or GM cell cultures.

Type 5. Functional non-coding sequences for example:
promoter, enhancer, insulators, IRES, WPRE, of mammalian or viral orig in. Functional non-coding sequences will act
as promoters of transcription (promoters and enhancers), local chromatin structure modifiers (enhancers and
insulators), RNA transcript stabilizers (WPRE) or translation regulators (IRES). They will be used (independently or in
combination) into viral expression cassettes to achieve best control of transgene expression depending on targeted
cells.

Evaluation of foreseeable effects

- Human health considerations -
Only replication defective viral particles (non-infectious, i.e. unable to multiply and propagate after initial cell
transduction) will be used, and inserts will not produce compounds with acute toxicity (like bacterial toxins), no
additional risk will arise from the final genetically modified cells, compared to the initial cell source. A possible risk to
human health derives from the recombinant viral particles, via accidental infection of the researcher

The recombinant lentiviral particles (HIV-1 derived) will be packaged via the vesicular stomatitis virus (VSV-G). This
step will alter the tropism of the retroviral particles, as it only requires interaction with the plasma membrane of cells
rather than a specific receptor, thus allowing increased stability of the viral particles associated with the VSV-G
envelope. This may add the aerosol risk in addition to the percutaneous risk. Retroviruses stably integrate into the
host cell genome, and there may be a risk of insertional mutagenesis, with subsequent ectopic inhibition/activation of
host gene expression. Subsequent de-regulation of endogene expression could theoretically lead to transduction
associated detrimental effects such as initiation of oncogenic processes. Moreover the addition of the Woodchuck
hepatitis Post transcriptional Regulatory Element (WPRE) to the expression cassette in several retroviral backbones
could also enhance the oncogenic potential of such vectors (SACGM 2004). However, the use of a lentiviral
backbones is thought to be safer, as the genomic integration profile of lentiviral derived vectors do not show an
integration bias towards the transcriptional start site region of host cell genes.

Risk is also associated with inserted coding sequences. cDNA or shRNAmiRNA inserts carried by viral vectors will
direct ectopic expression or inhibition of transcription factors, and strong promoter/enhancer effects from non-coding
sequences could lead to ectopic activation of neighbour endogene expression. The risks described above will be
moderated by the fact that we will use the strictly replication defective viral vectors, 3rd or 4th generation system. The
third-generation HIV-1-derived lentiviral vector system consists of four plasmids. The transfer vector contains the
transgene or Silencing cassette to be delivered in a lentiviral backbone containing all the cis-acting sequences
required for genomic RNA production and packaging. Lentiviral transfer vectors can be designed to express
(constitutively or conditionally) both transgenes and shRNAs in single units or multiple combinations. Three additional
plasmids (pMDL, pRev and pVSVG) provide the trans-acting factors required for packaging. In addition, an important
safety feature is provided by a deletion of the promoter-enhancer region in the 3'L TR (SIN; self inactivating vectors).
During reverse transcription the proviral S'L TR is copied from the 3'L TR, thus transferring the deletion to the S'L TR;
the deleted S'L TR of the integrated provirus is therefore transcriptionally inactive, preventing subsequent viral
replication or mobilization in the transduced cell. In the 4th generation systems the gag is separated from the gag-propol
sequences normally found on 3rd generation vectors, making the production of recombinant lentivirus even more
unlikely, as extra recombination events would be needed. AAVs have no known link to human illness and are commonly used as vectors for the introduction of genes. In most cases Containment Level 1 will be sufficient, unless there are any additional risks due to the biological activity of the insert, identified by risk assessment.

For all viral vector types, in the event of an accidental contamination, (percutaneous or inhalation) the amount of viral vector able to effectively contaminate a workers cell will be minimal, the transduction for cells in vitro needing a specialized protocol for efficient uptake. The VSV-G pseudotyping results in complement sensitivity, increasing the likelihood of immunological neutralization in human hosts. Cells of the cornea, and lung, are terminally differentiated cells with a limited lifespan and high turnover, which greatly diminishes the chance of effective transformation.

- Environmental considerations-
VSV-G pseudotyping makes the recombinant viral particles amphotropic, able to infect a larger range of animal and cell types, however the viral particles are still sensitive to air, temperature and pH, and will have a short lifespan in the open environment. Importantly, they will be replication defective and so will not produce progeny able to spread from an infected host. Transgene mobilization is theoretically possible if infection occurs in a host cell, which is also infected by a wild-type retrovirus - if the wild-type virus is compatible with the recombinant lentivirus, it may provide encapsidation to allow production of a replication competent viral particle carrying the transgene. The likelihood of this mobilization is very low, and replacement of the VSV-G envelope would remove the amphotropism of the resulting viral particle. Viral particle production steps will be carried out under Containment level 2 conditions. This involves packaging of the separate constructs, concentration of the resultant viral supernatant, transduction of the target cells, and culture analysis of the resultant GM cell populations. All researchers will be trained in the use of hazards involved in working with recombinant viruses. To decrease the likelihood of infection, standard measures to decrease percutaneous as well as aerosolised transmission of viral particles will be adopted, such as no use of sharps and all work to be carried out within a Class II microbiological safety cabinet. All waste will be sterilised by validated means via immediate immersion disinfection and local autoclaving (see point 12 below).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Work involving GM animals will be carried out using facilities outside the Clifford Allbutt Building, namely centres GM 572, GM 793, GM 407, GM 486, GM 3021.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Decontamination for class 1 waste is achieved by treating with Virkon (effectively 100% kill) on site, followed by rotoclaving by the waste contralor of the building (i.e. Novus Environmental).

Decontamination for class 2 waste: all highly contaminated waste solid material, such as pipette tips, petri dishes. will be immersed in 2% Virkon solution for 24 hours, within the microbiological safety cabinet, effectively 100% kill.

All solid waste will be discarded to autoclave bags and autoclaved locally, at 121 degrees C for at least 45 minutes, before discard in clinical waste bag for incineration, 1 00% kill.

Small surface spills will be immediately soaked with Distel, followed by wiping with 70% Ethanol, effectively 100% kill.

Large spills will be sprinkled with Virkon powder before cleaning as above, effectively 100% kill.

Safety cabinet surfaces will be wiped down with Distel before and after working, effectively 100% kill.

All discarded GM modified cell cultures will be destroyed by soaking in 2% Virkon solution or 24 hours followed by autoclaving at 121 degrees C for at least 45 minutes and subsequent discard in clinical waste bag for incineration.
100% kill. Autoclave is temperature validated annually. All mammalian tissue which has been infected with virus will either be fixed with 4% paraformaldehyde or 2% glutaraldehyde, or if fresh will be subject to risk assessment of the possibility of infectious virus still being present and handled accordingly.

<th>Question</th>
<th>Answer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Q1: Reference is made to adena-associated virus vectors but the examples are actually adenovirus systems (E1 and E3 are adenovirus genes). Are both MV and adenovirus vector systems to be used or is this just a mix up?</td>
<td>A1: This was corrected now. More in detail, both systems will be used separately and independently. AAVs or AdVs are packaged using HEK 293 cells (whose DNA contains crucial elements required for virus propagation that are absent from the viral vectors, thus eliminating the possibility that the viruses produced will propagate outside these cells). To propagate AdVs, HEK 293 cells contain all the components required for viral propagation. The gene of interest is cloned into a replication-defective backbone under promoters such as PGK, CAMKII or synapsin, or tyrosine hydroxylase to target dopaminergic neurons (to target neurons). For AAV production HEK 293 cells are transfected with AAV vectors and with a helper vector that permits AAV packaging but does not produce virus independently.</td>

Project Ref 3308/19.1

Date Ackn'd 02/03/2022  CU2 Project Title

Class CultureVolClass2 CultureVolumeClass3-4
Transcriptional factor mediated reprogramming of somatic and human pluripotent stem cells

The generation of induced pluripotent stem cells (hiPSC, for induced pluripotent stem cells) from adult terminally differentiated somatic cells by ectopic expression of a small set of transcription factors represents a breakthrough in the field of hPSC research. This approach has eliminated the ethical issues associated with traditional ESCs and has the potential to revolutionise the manufacture of human cell types. The proposed use involves generation of new cellular identities and the development of novel reprogramming paradigms.

Recipient or parental organism

Recipient/Host(s):
- Escherichia coli, K12 derived strains – disabled
- Mammalian cells (primary cells and cell lines) – considered as especially disabled
  - Human embryonic stem cell lines (H9)
  - Human induced pluripotent stem cell lines (produced in situ)
  - Human somatic cell lines (HEK-293T)
  - Mammalian primary cells including human, rodent, bovine (embryonic and adult skin fibroblasts, keratinocytes, peripheral blood cells)

Host/vector system

Only well characterised, replication deficient viral vector system with a history of safe use will be used:
- Lentiviruses – HIV-1 derived, replication defective
- Adenoviruses – Ad5 derived, replication defective
- Sendai viruses (SeV) – Paramyxoviridae. Single chain RNA disabled virus, non-transmissible due to deletion of F protein (F), with temperature sensitive hemagglutinin-neuraminidase (HN) and M genes inhibiting the formation of non transmissible virus-like particles (NTVLP).
- Episomal vectors: vectors with an oriP/EBNA-1 (Epstein-Barr nuclear antigen-1) backbone for delivering the reprogramming genes. Episomal vectors are non-integrative. In addition, silencing of the viral promoter driving EBNA-1 expression and the loss of the episomes due to defects in vector synthesis and partitioning allows the removal of episomal vectors from the iPSCs without any additional manipulation.
Origin & function

Inserts
1. Human, murine, xenopus cDNA (+/- TAG sequences) coding for transcription factors, signal transducers, growth factors and surface receptors
2. shRNA and miRNA sequences against cell endogenous coding sequences
3. Reporter genes (GFP, LacZ, Luciferase, possibly fused to cDNA (type1 inserts))
4. Selection genes (NPT, PAC)
5. Functional non coding sequences (promoter, enhancer, insulators, IRES, WPRE, of mammalian or viral origin)
6. Neutral non coding sequences (introns, isolated exons)

Evaluation of foreseeable effects

• cDNA (Type1 inserts) will code for transcription factors, signal transducers, growth factors and receptors which are expected to play a role in pluripotency, cell fate decision and differentiation from pluripotent stem cells (PSCs).
• shRNA (Type2 inserts) will produce non-coding RNA sequences targeting cell endogenous mRNA from above mentioned families (Type1 list). Expression of both insert types may enhance/block commitment and differentiation of PSCs towards one of the three primitive germ layers and further differentiated progeny.
• Reporter genes (Type3 inserts) will code for proteins with fluorescent or enzymatic properties allowing easy identification of genetically modified (GM) cells. They are thought to have no deleterious biological effect on expressing cells.
• Selection genes (Type4 inserts) will produce enzymatic proteins able to inactivate specific antibiotic families allowing selection of GM cells. They are thought to have no deleterious biological effect on expressing cells.
• Functional non-coding sequences (Type5 inserts) will act as promoters of transcription (promoters and enhancers), local chromatin structure modifiers (enhancers and insulators), RNA transcript stabilizers (WPRE) or translation regulators (IRES). They will be used (independently or in combination) into viral expression cassettes to achieve best control of transgene expression depending on targeted cells.
• Neutral non-coding sequences (Type6 inserts) will be used in particular for gene targeting projects to promote homologous recombination at defined genomic loci (intrinsic/exonic genomic sequences). They should not have biological effect by themselves.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All highly contaminated waste solid material, such as pipette tips, petri dishes, will be immersed in 2% Virkon solution for 24 hours, within the microbiological safety cabinet. All solid waste will be discarded to autoclave bags and autoclaved locally, at 134 degrees C for at least 3 minutes, with printout verification of sterilisation cycle, before discard in clinical waste bag for incineration. Small surface spills will be immediately soaked with Chemgene or equivalent followed by wiping with 70% Ethanol. Large spills will be sprinkled with Virkon powder before cleaning as above. Safety cabinet surfaces will be wiped down with Chemgene or equivalent before and after working. All discarded GM modified cell cultures will be destroyed by soaking in 2% Virkon solution for 24 hours followed by autoclaving at 134 degrees C for at least 3 minutes with printout verification of sterilisation cycle, and subsequent discard in clinical waste bag for incineration.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N
1. Assume no needles are involved in the purification of the lentivirus vectors.

2. Under app D 1st para it is stated that transduced cells may be removed from CL2 – this may not be possible for all cells i.e. human primary derived cells. Addressed in revised risk assessment

3. Will the genomic loci targeting constructs present any more risk than others? The genomic loci will not present any more risk than other genomic targeting vectors. It is a PUC plasmid-based vector and the risk assessment is well characterised.

4. P9 app C bovine and mouse primary cells are given as hazard 1. How is this established? There are quite a few bovine zoonotic agents so the tissue type, source (veterinary?) and processing will determine whether these remain a risk. I think all these are bacterial so will be eliminated as part of the culturing process. For mice, this is less of an issue and one assumes these are SPF animals as source material. This is mainly a CoSHH consideration.

   The above risk has been addressed by a secondary biological risk assessment (for COSHH regs), where the hazard group has been identified. In brief, Rodent tissue is from a scientific animal facility where sentinel screening is carried out. With the bovine cell lines, the material will come from regulated farms and abattoirs, where health records are kept, and the source material has been checked by a meat inspector. Culturing process will eliminate most risk, and cells will move from CL2 to CL1 on sterility testing.

Recipient or parental organism

- Well characterised commercial bacteria (e.g. One Shot® TOP10 and Stbl3™ Chemically Competent E. coli) disabled, non colonising, non pathogenic.
- Commercial packaging cell lines, e.g. HEK-293T human cell line. This cell is highly transfectable derivative of human embryonic kidney 293 cells, containing the SV40 T-antigen. Thus this cell line is competent to replicate vectors carrying the SV40 origin of replication, giving high titers when used to produce viral particles. It has been widely used for lentiviral production, gene expression and protein production.
- Human and rodent primary neural cultures, somatic neural stem/precursor cells, embryonic stem cells, fibroblasts and induced pluripotent stem cells. Characteristic of cell cultures are never totally understood, so primary human cultures will be handled at containment level 2, considering the possibility of adventitious viruses. Rodent cultures will normally be handled at containment level 1, unless otherwise specified in the risk assessment.

Host/vector system

Only well characterised, replication deficient viral vector system with a history of safe use will be used:
- HIV-1 derived lentiviral 3rd and 4th generation, replication defective (e.g. eGFP pRRLSsin.PPT-hCMV, pCDH-EF-1-MCS-T2A-GFP).
- Adena virus vectors, replication defective (e.g. Adeasy and Adtrack, deleted E1 and E3 genes).
- Sendai virus vectors (hOct 3/4, hSox2, hKlf4, hc-Myc).
- Adeno-associated virus vectors, replication defective (e.g. AAV6).

Origin & function

Inserts are arbitrarily grouped as follows:
Type 1. Human, murine eDNA (+/- TAG sequences) coding for proteins, for example:
Hntth and Safety
Executive
transcription factors (Wnt3a, Ngn2 etc.) are expected to influence cell fate decision and differentiation, but not expected to have an effect on cell proliferation. Other genes may code for disease associated proteins (alpha synuclein, tau etc).

Type 2. ncRNA sequences for example:
shRNAs and miRNAs (mmu-miR-155-5p, etc) will produce ncRNA sequences targeting cell endogenous mRNA (Wnt3a, p73). This sequences are not expected to affect cell proliferation. Notably, mmu-miR-155-5p is not implicated in oncogenic processes.

Type 3. Reporter genes for example:
enhanced GFP (eGFP), mCherry, firefly luciferase etc will code for proteins with fluorescent properties allowing easy identification of genetically modified (GM) cells. All of these labels are thought to have no deleterious biological effect on expressing cells.

Type 4. Selection genes for example:
bacterial resistance (ampicillin) or mammalian resistance (puromycin) will express proteins with enzymatic activities to allow selection of bacterial or GM cell cultures.

Type 5. Functional non-coding sequences for example:
promoter, enhancer, insulators, IRES, WPRE, of mammalian or viral origin. Functional non-coding sequences will act as promoters of transcription (promoters and enhancers), local chromatin structure modifiers (enhancers and insulators), RNA transcript stabilizers (WPRE) or translation regulators (IRES). They will be used (independently or in combination) into viral expression cassettes to achieve best control of transgene expression depending on targeted cells.

Evaluation of foreseeable effects

Human health considerations -
H •• ~h and Safety
Executive
A possible risk to human health derives from the recombinant viral particles, via accidental infection of the researcher.
Because only replication defective viral particles (non-infectious, Le. unable to multiply and propagate after initial cell transduction) will be used, and inserts will not produce compounds with acute toxicity (like bacterial toxins), no additional risk will arise from the final genetically modified cells, compared to the initial cell source.
The recombinant lentiviral particles (H1V-1 derived) will be packaged via the vesicular stomatitis virus (VSV-G). This step will alter the tropism of the retroviral particles, as it only requires interaction with the plasma membrane of cells rather than a specific receptor, thus allowing increased stability of the viral particles associated with the VSV-G envelope. This may add the aerosol risk in addition to the percutaneous risk. Retroviruses stably integrate into the host cell genome, and there may be a risk of insertional mutagenesis, with subsequent ectopic inhibition/activation of host gene expression. Subsequent de-regulation of endogene expression could theoretically lead to transduction associated detrimental effects such as initiation of oncogenic processes. Moreover the addition of the Woodchuck hepatitis Post transcriptional Regulatory Element (WPRE) to the expression cassette in several retroviral backbones could also enhance the oncogenic potential of such vectors (SACGM 2004). However, the use of a lentiviral backbones is thought to be safer, as the genomic integration profile of lentiviral derived vectors do not show an integration bias towards the transcriptional start site region of host cell genes.
Risk is also associated with inserted coding sequences. cDNA or shRNA/miRNA inserts canied by viral vectors will direct ectopic expression or inhibition of transcription factors, and strong promoter/enhancer effects from noncoding
sequences could lead to ectopic activation of neighbour endogene expression.
The risks described above will be moderated by the fact that we will use the strictly replication defective viral vectors, 3rd or 4th generation system. The third-generation HIV-1-derived lentiviral vector system consists of four plasmids. The transfer vector contains the transgene or silencing cassette to be delivered in a lentiviral backbone containing all the cis-acting sequences required for genomic RNA production and packaging. Lentiviral transfer vectors can be designed to express (constitutively or conditionally) both transgenes and shRNAs in single units or multiple combinations. Three additional plasmids (pMDL, pRev and pVSVG) provide the trans-acting factors required for packaging. In addition, an important safety feature is provided by a deletion of the promoter-enhancer region in the 3’LTR (SIN; self inactivating vectors). During reverse transcription the proviral 5’LTR is copied from the 3’LTR, thus transferring the deletion to the 5’LTR; the deleted 5’LTR of the integrated provirus is therefore transcriptionally inactive, preventing subsequent viral replication or mobilization in the transduced cell. In the 4th generation systems the gag is separated from the gag-pro-pol sequences normally found on 3rd generation vectors, making the production of recombinant lentivirus even more unlikely, as extra recombination events would be needed.

AAVs have no known link to human illness and are commonly used as vectors for the introduction of genes. For all viral vector types, in the event of an accidental contamination, (percutaneous or inhalation) the amount of viral vector able to effectively contaminate a worker's cell will be minimal, the transduction for cells in vitro needing a specialized protocol for efficient uptake. The VSV-G pseudotyping results in complement sensitivity, increasing the likelihood of immunological neutralization in human hosts. Cells of the cornea, and lung, are terminally differentiated cells with a limited lifespan and high turnover, which greatly diminishes the chance of effective transformation. All manipulations using lentiviral vectors will be at containment level 2.

- Senda; Virus vectors consist of the viral proteins Nucleocapsid protein (NP), Phosphoprotein (P), Matrix protein (P), Fusion protein (F), Hemagglutinin-Neuraminidase (HN) and Large protein (L). Because Sendai virus infects cells by attaching itself to surface receptor sialic acid present on the surface of many different cells, it can infect a wide range of cell types. Activation of F protein by a protease is required for the virus-cell fusion process to take place. Following infection, the virus goes through genome replication, protein synthesis and then daughter virus particles are assembled and released. However, they are no longer capable of producing infectious particles from infected cells, because the viral genome lacks the F-gene. All activities involving senda; virus manipulations will be performed at containment level 2.

Expression of the vector genes leads to reprogramming of target cells and allows them to be come pluripotent. The Sendai virus replicates independently of the cell cycle in the cytoplasm and does not intergrate into the host cells genome. In addition the presence of functional mutations such as temperature sensitivity in the amino-acid sequence of several Sendai virus proteins (SeVITS.6.F and SeVITS15.6.F) allows for easy removal of the vectors from transduced cells.

- Adenovirus vectors are replication defective due to removal of E1 /3/4 regions. Because they can infect humans, containment Level 2 practices and facilities will be used for activities involving adenoviral vectoF5.

- Microbiological safety cabinets wi ll be used for all manipulations that can generate aerosols (e.g. pipetting, harvesting glinfected cells, opening sealed centrifuge containers). Aerosol containment devices will be used when centrifuging and V3ccum lines used for aspiration will be protected with liquid disinfectant traps and a micron filter.

Environmental considerations

VSV-G pseudotyping makes the recombinant viral particles amphotropic, able to infect a larger range of animal and cell types, however the viral particles are still sensitive to air, temperature and pH, and will have a short lifespan in the open environment. Importantly, they will be replication defective and so will not produce progeny able to spread from an infected host. Transgene mobilization is theoretically possible if infection occurs in a host cell, which is also
infected by a wild-type retrovirus - if the wild-type virus is compatible with the recombinant lentivirus, it may provide encapsidation to allow production of a replication competent viral particle carrying the transgene. The likelihood of this mobilization is very low, and replacement of the VSV-G envelope would remove the amphotropism of the resulting viral particle. Viral particle production steps will be carried out under Containment level 2 conditions. This involves packaging of the separate constructs, concentration of the resultant viral supernatant, transduction of the target cells, and culture/analysis of the resultant GM cell populations. All researchers will be trained in the use of hazards involved in working with recombinant viruses. To decrease the likelihood of infection, standard measures to decrease percutaneous as well as aerolised transmission of viral particles will be adopted, such as no use of sharps and all work to be carried out within a Class 11 microbiological safety cabinet. All waste will be sterilised by validated means via immediate immersion disinfection and local autoclaving (see point 12 below).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Work involving GM animals will be carried out using facilities outside the Clifford Allbutt Building, namely centres GM 572, GM 793, GM 407, GM 486, GM 3021.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

NJA

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Decontamination for class 1 waste is achieved by treating with Virkon (effectively 100% kill) on site, followed by rotoclaving by the waste contractor of the building (i.e. Novus Environmental). Decontamination for class 2 waste: all highly contaminated waste solid material, such as pipette tips, petri dishes, will be immersed in 2% Virkon solution for 24 hours, within the microbiological safety cabinet, effectively 100% kill. All solid waste will be discarded to autoclave bags and autoclaved locally, at 121 degrees C for at least 45 minutes, before discard in clinical waste bag for incineration, 100% kill. Small surface spills will be immediately soaked with Chemgene, followed by wiping with 70% Ethanol, effectively 100% kill. Large spills will be sprinkled with Virkon powder before cleaning as above, effectively 100% kill. Safety cabinet surfaces will be wiped down with Chemgene before and after working, effectively 100% kill. All discarded GM modified cell cultures will be destroyed by soaking in 2% Virkon solution or 24 hours followed by autoclaving at 121 degrees C for at least 45 minutes and subsequent discard in clinical waste bag for incineration 100% kill. Autoclave is temperature validated annually. All mammalian tissue which has been infected with virus will either be fixed with 4% paraformaldehyde or 2% glutaraldehyde, or if fresh will be subject to risk assessment of the possibility of infectious virus still being present, and handled accordingly.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
Please enter comments on the GM safety committee on the risk assessment

On the CU2:
Could there be some indication of the CLs used for the lentiviral vectors and the Sendai vectors?
Second to last paragraph, line 2 - Containment level instead of biQsafety level.
Nextflast para - Microbiological safety cabinets ...
On the risk assessment:
P6 - can the overall risk (of the recipient microorganisms) be low if one of the sub sections is medium?
Can there be some information of the potential modes of transmission of each of the viruses?
P9 - potential for transmission of naked NA is checked yes - is that correct?
P10 - will the host range be different to parental virus is checked no. It is in the case of lentiviral vectors bearing
VSV G. P12 ditto.
P10 - next question - above lentiviral VSVG are more susceptible to human complement, so yes.

Give brief details of the genetic modification safety committee

Operations and Site Director - 34 years laboratory experience and currently Operations and Site Director at TC BioPharm with responsibilities for Process Development, GMP Manufacture, Clinical operations, Engineering and Quality. Previous experience includes responsibility as GMO officer at contract manufacturing organisations; Excell Biotechnology and Angel Biotechnology. Conducted clinical trials to include ReNeurn - first in man treatment using genetically modified stem cells (primary human neuronal cells) with C-myc gene regulated by 4-OHT.

### Purposes of the contained use

The aim of this work will be the use of lentivirus particles to deliver transgenes to mammalian cells. Human cells (e.g. PBMCs, T cells, cell lines) will be co-cultured with the appropriate titre of lentiviral particles in a suitable cell culture medium to facilitate viral-mediated transfer of the genetic information transgene into the target cell line. The transduced cells will be cultured and used in immune or other assays - all assays will be performed as in vitro studies only. A genetically modified, replication defective lentivirus will be used to transduce the cells.

### Recipient or parental organism

Human cells; peripheral blood mononuclear cells (PBMCs), T cells and cell lines.

### Host/vector system

Recombinant, replication-defective lentivirus. The viruses are classified as Risk Group 2 by the World Health Organization (WHO).

### Origin & function

Please see section 17 for full details.

### Evaluation of foreseeable effects

The major risks associated with lentiviral vectors are 1) the potential generation of replication-competent lentivirus (RCL) and 2) the potential for oncogenesis via random chromosomal integration. These risks can be mitigated by the nature of the vector system and the nature of the transgene inserted. The potential generation of replication competent lentivirus is reduced due to the modification the recombinant virus has undergone to render it replication incompetent. This means that outside of a specific, complimentary packaging cell line, the viral DNA construct does not contain sufficient genetic material to produce infectious virions or the ability to self-replicate. Please see section 17 for a detailed description of the lentiviral vectors intended for use at TC BioPharm.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

None intended for use.

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste will be decontaminated by incubation with an appropriate volume and concentration of virkon solution for at least 16 hours. Virkon is a virucidal disinfectant known to be effective at killing at 47 strains from 35 different viruses. After this time, the decontaminated waste will be dipsoed of down the drain with copious amounts of running water.

All contaminated solid waste will be double bagged and uplifted by SRCL - a specialist clinical waste uplift service.

All contaminated sharps will be disposed into a sharps containers. The sharps container will be sealed and uplifted by SRCL - a specialist clinical waste uplift service.
SRCL's clinical waste disposal processes are fully compliant with all regulations, including those defined in the Controlled Waste Regulations act of 2012.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick if you are claiming exemption from disclosure for section of the risk assessment Y

Please enter comments on the GM safety committee on the risk assessment

The genetic modification safety committee was consulted regarding the proposed scheme of work detailed within this contained use notification. The committee was comprised of the Health & Safety Officer, the Biological Safety Officer, the CEO and three experienced laboratory scientists. The proposed scheme of work was considered and discussed in detail, as was the BioCOSHH assessment associated with this work. The committee were satisfied that the BioCOSHH assessment adequately identified and assessed the risks of this work and details the measures by which to minimise the risks to both the operators and the environment.

Following sterility analysis, the closed sterility unit (BioFlex® B90/S Flexible Film Sterility Test Isolator System or TPC Flexible Film Sterility Test Isolator System; each are equivalent) will be washed down with 70% IPA and sterilised with 35% Hydrogen Peroxide. It is intended that all waste product and non-reusable consumables used in the conduct of the sterility test will be de-contaminated with an appropriate agent (Hydrogen Peroxide 35%) and post analysis double bagged in sealed sterile plastic bags within the closed Isolator system, removed and placed in waste disposal bins prior to collection and incineration by a specialist contract waste management company licenced for clinical waste incineration. Reusable scissors and forceps are placed in sterile bags and autoclaved. Re-usable bottles following sterility analysis are placed in the autoclave using a 100% killing cycle. The facility has three Astell autoclaves available in the facility for this purpose.

For activities involving GMMs, describe the waste management measures which will apply to the activity:

Following sterility analysis, the closed sterility unit (BioFlex® B90/S Flexible Film Sterility Test Isolator System or TPC Flexible Film Sterility Test Isolator System; each are equivalent) will be washed down with 70% IPA and sterilised with 35% Hydrogen Peroxide. It is intended that all waste product and non-reusable consumables used in the conduct of the sterility test will be de-contaminated with an appropriate agent (Hydrogen Peroxide 35%) and post analysis double bagged in sealed sterile plastic bags within the closed Isolator system, removed and placed in waste disposal bins prior to collection and incineration by a specialist contract waste management company licenced for clinical waste incineration. Reusable scissors and forceps are placed in sterile bags and autoclaved. Re-usable bottles following sterility analysis are placed in the autoclave using a 100% killing cycle. The facility has three Astell autoclaves available in the facility for this purpose.

The Hologic GM and EH&S safety committee noted that the product has been previously assessed and approved by the manufacturer and by our client as requiring containment level 1. It was further noted that the purified viral vector is not considered ‘live’ at the formulation and filling stages to be completed at our clients facility nor at the sterility testing stage to be completed at Hologic Ltd. The project conducted at Hologic Ltd. involves the sterility testing of the finished product HIV-1 lentiviral vector.

Give brief details of the genetic modification safety committee

A Health and Safety Consultant has advised the school on setting up premises notification and risk assessment for proposed work with class 1 and 2 GMMS. They have also advised on the setting up of a GMSC to consist of the GMBSO, Faculty H&S Advisor, and appropriate expertise from the faculty. Additional advice will be sought for any proposed works outwith the experience or expertise of the committee members.

The consultant is a chartered Fellow of IOSH with a BSc (hons) Applied Biology and Masters degree in a Biological subject, and has worked in molecular biology laboratories. They have acted as a GMSO and chaired and administered GMSC's for over 10 years, dealing with assessments for work up to class 3 for a range of hosts (including plants, animals, insects) and a range of GMM's, inserts and vectors. They have organised BSO network meetings as well as teaching on a professional biosafety practitioner course.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Maximum culture volume (multiples of up to): 1 litre.
All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving by autoclaving at 15 lbs/sq inch pressure and 121 degrees C for at least 20 minutes (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. The autoclave is tested by the manufacturers (LTE Scientific Ltd) twice yearly.
Runs may also be monitored using TST (Time, Steam, and Temperature) test strips (Albert Browne Ltd., TST class 6 emulating indicator 121ºC for 20 min).

Consultant comments - The attached risk assessment is a broad assessment to cover class 1 work in undergraduate teaching laboratories using low risk, commercially available vectors and hosts. Research work at class 1 will also be undertaken (subject to review of the risk assessments already in place at the current host institutions) and if outside the scope of this assessment will be assessed separately. Class 2 work will be notified separately and appropriate acknowledgements and permissions received before the work is transferred to the facility.

Give brief details of the genetic modification safety committee:

Three members of the site Biological Safety Committee (Genetic Modification Safety Committee) who possessed appropriate knowledge, experience and training in the scientific area in question, reviewed the risk assessment and provided comments on aspects of the risk assessment that required additional supporting information. Following provision of this additional information the risk assessment was agreed to be appropriate and provided a sufficient assessment of the risks posed by the activities.

Material containing Class 1 GMMs will be disposed of by placing in a designated BLUE plastic box lined with a clear autoclavable bag. The petri dishes and bottles placed in these boxes will not be sealed.

Tips, Eppendorf tubes and sharps contaminated with the above materials will be placed in open plastic bottles to allow penetration of steam and then placed in a designated BLUE plastic box lined with a clear autoclavable bag.

The lid of the blue box must close properly, not rest on the contents and must not be sealed down with tape to allow penetration of steam.

All solid materials coming in contact with the GMM and all biological waste is inactivated by autoclaving at 121 C at 15psi for 15 minutes or by validated chemical means.

Small volumes of liquid GMM contaminated waste will be disinfected by validated means followed by sink disposal with copious amounts of water.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Reviewer 1: "If anyone is going to be involved in generating GM Agrobacterium tumefaciens strains, then they should also assess the risks of that activity in the same way they have for E.coli. It depends on where the service ends and the user requesting synthesis takes over."

[Note: this work will not involve generating GM Agrobacterium tumefaciens strains]

Reviewer 2: No comments

Reviewer 3: Provided minor edits to the draft risk assessment with particular emphasis on hazard identification with respect to environmental safety, assessment of class and containment level and double checking that all hazards are properly considered by the proposal.
The research projects in the Korcsmaros group aim at deciphering host-microbe interactions that take place particularly in the digestive tract. Evidences in the literature demonstrate that pathogens (in particular facultative intracellular pathogens like Salmonella enterica) highjack the host cell machinery for their benefit. Multiple microbial proteins have been shown to interfere with host cellular processes but the full regulatory mechanisms that modulate this effect remain unelucidated. We are interested in understanding how microbial proteins affect homeostatic host processes and functions (e.g. Autophagy, Antimicrobial protein production) during host-microbe interactions in health and disease. Investigating this crosstalk requires to modify the model system we use so that we can visualise and measure the specific impact microbial proteins have on specific signalling cascade of host cells.

Two approaches will be employed as alternative or complement of each other:
• either remove the gene from the bacteria and observe how it changes the phenotype in host cells; in some cases, this will also involve tagging the bacteria with a fluorescent report fusion (e.g. GFP, mCherry)
• or express only the bacterial protein inside mammalian cells from a genetic construct to exclude additional/synergistic effect of other bacterial factors and only assess the effect of the candidate bacterial protein on the mammalian cell function.
Salmonella enterica
Salmonella enterica serovar Typhimurium is a zoonotic food-borne pathogen affecting animals and humans, through consumption of contaminated food or water. In healthy individuals it causes a self-limiting gastroenteritis. Symptoms include headache and nausea, vomiting, diarrhoea, abdominal pain or cramps, fever.

Staphylococci spp.
S. aureus for example is a Gram-positive spherical bacteria, member of the Firmicutes of important clinical and biotechnological relevance. It is frequently found in the nose, respiratory tract and on the skin. It has been estimated that 20% to 30% of the human population are long-term carriers of S. aureus. Pathogenic S. aureus strains have been isolated from around the world. Symptoms of Staphylococcal infection caused by food intoxication are nausea, abdominal pain, vomiting, cramps, diarrhoea. Skin conditions caused by the bacterial exfoliative toxins include blisters, skin loss, pimples, furuncles, impetigo, folliculitis, abscesses, poor temperature control, fluid loss, and secondary infection. In immunocompromised individuals S. aureus can cause (very rarely) necrotizing fasciitis which is life-threatening and causes severe morbidity. Certain strains of S. aureus produce the superantigen TSST-1, which is responsible for 75% of toxic shock syndrome (TSS) cases.

Campylobacter spp.
Campylobacter jejuni and Campylobacter coli are the most common causes of campylobacteriosis. The typical symptoms are severe diarrhoea and abdominal pain.

Escherichia coli
Among the many strains of E. coli, only a few trigger diarrhoea. Other symptoms are severe stomach cramps and vomiting. The symptoms usually last up to seven days if there are no complications, but some infections can be severe and may be life threatening.

Listeria monocytogenes
Listeriosis affects primarily pregnant women, older adults and persons with weakened immune systems due to a disease (e.g., diabetes, organ transplant, cancer, age) or due to medications (e.g., steroids). Symptoms of listeriosis are fever, muscle aches, and sometimes gastrointestinal symptoms, such as nausea or diarrhoea. If infection spreads to the nervous system, symptoms can include headache, stiff neck, confusion, loss of balance, or convulsions.

Clostridium difficile
Clostridium difficile is commonly found in the gut without causing any symptoms. The symptoms associated with toxin-producing C. difficile infection (CDI) can include diarrhoea (mild to severe), fever, loss of appetite, nausea, abdominal pain or tenderness. In the most severe cases the pseudomembranous colitis may require emergency bowel surgery and can be fatal. C. difficile is able to form spores that are able to survive for long periods in the environment and contribute to its ability to spread between hosts.

While preparing the bacterial infectious inoculum staff will wear appropriate PPE and will be working in hazard group 2 containment laboratory and safety cabinet. New and expectant mothers are regarded as being at particular risk.

Additional COSHH risk assessments will be performed for new and expectant mothers as needed.

Adverse effects from establishment or dissemination of GMMs in the environment:
The generated mutants and plasmids used contain antibiotic resistance genes; selective antibiotic resistance markers will be chosen different from the drugs of choice for the treatment of infections by these infectious agents and thus would present no selective advantage in the event of an accidental release. For example, for culturing Salmonella antibiotics such as kanamycin, ampicillin, chloramphenicol will be used. Accidental release of the organisms should not occur as spillages are immediately disinfected and all contaminated liquid and solid waste is autoclaved to sterilise prior to discard.
Adverse effects from transfer of genetic material to or from other micro-organisms:
mCherry and GFP reporter/tag proteins are harmless proteins, and do not increase the risk associated with the strains or transfected cells.

Adverse effects from the interaction of GMMs with other organisms in the containment facility:
GMMs should not be able to accidentally interact directly with other GMMs within the facility. Nonetheless, coculturing of different bacterial strains with or without potentially GM mammalian cells is planned. This process will not raise the Hazard Group of either of the organisms to a higher Hazard Group, even in cases where genetic material might be transferred from one organism to another.

Host/vector system

We will use Hazard group 2 human and zoonotic foodborne pathogens (such as Salmonella enterica serovars, Staphylococci spp., Campylobacter spp., Escherichia coli, Listeria monocytogenes, Clostridium difficile) as well as commensal bacterial strains (such as Bifidobacteria spp., Lactobacillus spp., Bacteroides thetaiotaomicron, Ruminococcus spp.) usually not causing human disease. All strains that will be used are classified maximum as hazard group 2 organisms as per the HSE Approved List of biological agents (http://www.hse.gov.uk/pubns/misc208.pdf).

- We will construct transient or stable plasmid-borne expression systems in mammalian cells (e.g. intestinal epithelial cells like HT-29 colon cancer cell line, or organoid culture) enabling them to produce a bacterial protein of interest. For transient expression system, vectors such as CoIE1 replicon derivatives will be used. For stable expression system, integrated system such as the Flp-In Complete System (ThermoFisher Scientific, https://www.thermofisher.com/order/catalog/product/K601001). This will involve using weak to medium strength promoter such as that of the human Ubiquitin C gene, to reduce the toxicity risk associated with high level of expression of the microbial protein within the host cells. When strong expression of a protein is required, the expression systems will be based on commonly used viral promoters such as those from polyomavirus simian virus 40 (SV40) or Cytomegalovirus (CMV).

- The plasmids we use to replace a gene by a resistance cassette and remove that cassette post-gene deletion if necessary (such as pKD46 and pCP20 plasmids), express the RepA101ts thermosensitive DNA binding and polymerase activity. This is necessary for the plasmid replication (pSC101 ori), permissive at 30°C but no longer at 37°C to 42°C. Losing these plasmids will ensure no additional untraceable genome modification can occur in the recipient strains.

- The plasmids (such as pWKS.30 or pBR322) to be used for complementation do not harbour the genes necessary for self-mobilisation, however it may contain a bom site (such as pBR322) which can make the plasmid mobilisable and transferrable to other strains in the presence of a helper plasmid. Because of that, the risk is minimal for antibiotic resistances encoded by the plasmid to be transferred to other strains should infection with this modified organism happen in a context where gut microbiota strains harbour appropriate helper plasmids. The overall risk is therefore considered very low.

- Constructing GM bacterial strains will involve prokaryotic plasmid vectors (e.g. CoIE1 or pSC101 derivatives). These plasmids contain antibiotic resistance cassette(s) such as Chloramphenicol, Kanamycin, Ampicillin, etc used as selective markers. Some of these plasmids possess a thermosensitive replication system which allow the loss of the plasmid upon bacterial growth at increased non-permissive temperature for the plasmid replication (for gene replacement, fusion insertion or resistance cassette deletion).

- Reporter proteins such as GFP or mCherry will be used to monitor gene expression or to tag protein or bacterial cells and localise them within a biological sample.

During that process the organisms will be at their highest infectious state.
- The modified bacteria will be used in parallel to wildtype parental strains in in vitro (mammalian cell culture models) or in vivo (animal models) infection assays. At the end of the assays, the infected mammalian cells or the cells expressing candidate bacterial proteins will be analysed by techniques such as bioimaging, qPCR, RNAseq or Western blot analysis. Part of the sample collecting will involve physical separation of cells of interest from other cells. This will be performed using a flow cytometer.

### Origin & function

Strains we are going to use are a) commonly used in expert groups of the research field, and b) likely to be isolated from infection cases or human or animal gut.

For example S. enterica strain SL1344 is a hisG auxotroph derivative from the 4/74 strain, isolated from a calf with salmonellosis in the United Kingdom (Hoiseth and Stocker, 1981, Nature, 291: 238–239). S. aureus strains will derive from the parental strain NCTC8325-4 (RN450), a modified S. aureus NCTC8325 strain originally isolated in 1960 from a sepsis patient and primarily utilized in the laboratory for the study of S. aureus genetics.

All genes manipulated in these experiments will either be derived from the species under observation, or will be well-characterised genes that will not affect the pathogenicity or virulence of the species under investigation e.g. GFP, mCherry, antibiotic cassettes used in cloning.

Other related genes may be used, these would present no greater risk to the environment, humans or animals.

### Evaluation of foreseeable effects

All handling of the microorganisms will be performed in designated containment level 2 laboratories. The flow cytometer (such as a BD FACSMelody sorter instrument) is also in a containment level 2 laboratory and placed inside a containment level 2 safety cabinet to minimise the risk of exposure to generated aerosol.

Transmission and infection of laboratory personnel is most likely via the oral route for Salmonella, Campylobacter, Listeria, Staphylococci, Clostridium or by skin exposure (e.g. Staphylococci). Good laboratory practice and implementation of the recommendations outlined in Schedule 8 in The Genetically Modified Organisms (Contained Use) Regulations 2014 Guidance L29 will minimise risks. This includes personal protective equipment (PPE) appropriate for all pathogens used, and will include wearing lab coats, gloves, and safety glasses when necessary. All in vitro work will involve standard laboratory procedures where every procedural risk will be assessed. Given the level 2 containment and control measures, it is unlikely that the GMMs will reach the environment and cause harm to humans or animals outside the laboratory. Standard laboratory procedures will include restricting access to authorised workers, ensuring that all areas that have been in contact with potentially hazardous micro-organisms will be routinely swabbed with a recommended disinfectant, no laboratory clothing will be allowed outside the laboratory and all outdoor clothing will be stored in offices. All contaminated waste will be autoclaved and/or incinerated.

While transporting the GM Hazard Group 2 material to the Containment Level 2 lab across Containment Level 1 working area, samples will be fully contained. When transporting materials outside the containment laboratories they will be triple contained according to the SOP QA-SJB-009.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All GMM material will be handled using good microbiological practice (GMP). All GMM material will be inactivated by

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All GMM material will be handled using good microbiological practice (GMP). All GMM material will be inactivated by
autoclaving prior to disposal. All residual microbiological material will be stored in sealed containers and disposed of by autoclaving. Autoclave procedures are as follows: Microbiological solid waste is sterilised by autoclaving at 121 degrees C for a minimum of 30 minutes at 15p.s.i. Routine monitoring of autoclave efficiency is completed using Thermalog S strips. Annual 12 point validation of autoclaves is performed.

Date Ackn'd 28/02/2020

 CU2 Project Title Use of Lentiviral vectors for expression of cellular proteins and non-coding RNAs in eukaryotic cells

Class CultureVol

Class CultureVolume

Consent Granted

Project notified under transitional arrangements

Withdrawn

Tick if notifying a connected programme of work

02/03/2022
Research activities in Macaulay group focus on studying the effect of cellular proteins involved in signalling pathways and metabolic processes in eukaryotic cells of mesodermal and endodermal origin and in haematopoietic system. Furthermore, we want to utilize non-coding DNA and RNA for divisional history studies and lineage tracing purposes. We intend to modify eukaryotic cells using CRISPR-Cas9 system to evaluate in vitro effect of proteins and non-coding RNAs of interest.

Transduced cells will be used for in vitro experiments including imaging and biochemical analysis (e.g., qPCR, Western blotting, pull down or mass spectrometry).

Defective lentiviruses will be generated using a lentivirus vector plasmid which contains the LTR from HIV or MLV with SFFV, CMV, CAG, EF1alpha orland U6 promoters. This plasmid will be co-transfected with packaging plasmids: pVSV-G (encoding the envelope proteins under the control of the CMV promoter) and pCMVDR8.91 (encoding replication proteins). The resulting virus secreted from HEK293T/FT producer cells is defective in packaging signal and will be used for infection of recipient mammalian cells listed above. No productive virus that is infectious will be created.

Components of the TPO-cMpl, JAK-STAT signalling pathways, metabolic pathways including glycolysis, OXPHOS, Krebs cycle and gain/loss of function mutants, components of CRISPR-Cas9 system (Cas9 protein or/and its mutants). Short non-coding DNA sequence encoding the cellular barcode (semi-random sequence of 50-80 nucleotides long) or/and non-coding sequence consisting of un methylated DNA 200-500 bp. Specific shRNA and miRNA sequences for various proteins of metabolic pathways and key haematopoietic signalling pathways (e.g., TPO, JAK-STAT etc).

Fluorescent proteins GFP, eGFP, emGFP, DsRed, mCherry, tdTomato, BFP, Venus, luciferase
The mammalian cell hosts are non-pathogenic and unlikely to survive outside cell culture. It is recognised that lentivirus vectors can in principle cause insertional mutagenesis in the cells they enter, but the likelihood of a worker infecting themselves and causing a hazard in this manner is extremely low. Primary human lymphocytes, monocytes, stromal cells, adipocytes and leukaemia cells will be screened for HIV at the Norfolk and Norwich Hospital before being brought into the laboratory.

The replication incompetent lentivirus is not a risk as it will not infect further cells. That the lentivirus has a genome split into 3 plasmids means that recombination between packaging helper and vector is very low and the potential for generation of replication competent lentivirus is extremely reduced. The virus envelope protein is from VSV and there is no HIV envelope protein in the system and the minimal required HIV functions are from the helper plasmid that contains no packaging or L TR sequences. There is no chance that it will recombine with HIV from a HIV infected worker.

Fluorescent proteins are non-toxic and have been used in many laboratories over years with no adverse effects. Noncoding DNA fragments to be inserted are not oncogenes. Some of the proteins act as tumour suppressors and their knock-down could therefore pose a potential risk if a worker infected himself/herself. However, cancer formation is a multistep process in humans requiring at least six genetic changes, so it is highly unlikely that an infection would contribute to tumorigenesis. Also, as the lentiviral vectors are replication-defective they would not propagate in an infected worker.

EI tissue culture laboratory is CL2 lab and procedures in place will be followed to dispose of contaminated material. Plasticware will be autoclaved 1210C for 20 minutes, or 30 minutes for dense loads prior to disposal to landfill. Liquids will be autoclaved 1210C for 20 minutes and accidental spills disinfected using minimum 2% Chemgene.

All procedures will be performed in Class II Microbiological Safety Cabinets in a designated CL2 laboratory. Workers are required to wear lab coats and gloves at all times. Needles will not be used. Cultures will be grown in tissue culture flasks (T75 cm2) or dishes (P1 OOs) in DMEM or RPMI tissue culture media containing 10% FBS. The cultures will be grown in designated incubators.

Viral stocks will be routinely tested for the extremely rare event that the 'helper' virus (replication competent) has been generated. This is done by infecting 3T3 cells, collecting supernatants and testing if this supernatant can infect fresh 3T3 cultures.

All stocks will be destroyed by autoclaving should we find helper viruses.

Nitrile gloves will be worn during all experimental procedures.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

No genetically modified plants and animals will be created.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

No derogation is requested.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Solid biological waste will be sterilised by autoclaving at 121 °C for 20 minutes, or 30 minutes for dense loads. Liquid biological waste will be sterilised by autoclaving at 121 °C for 20 minutes. Any chemically contaminated biological waste will be sent for incineration by a licenced waste contractor.

### Project Additional Information

#### Purposes of the contained use

The purpose of these experiments is to study the role of plant genes in coordinating plant growth in response to changes in the environment e.g. changes in the availability of nutrients or water.

#### Recipient or parental organism

DNA sequences will be cloned into plasmid vectors in E. coli for experimental purposes. These will be introduced into non-disarmed Agrobacterium spp. and used for gene delivery to plant tissues. The GMO Agrobacteria are not expected to have any new characteristics except resistance to the selective agent encoded on the plasmid vector. The plant GMOs are expected to have resistance to the selective agent, to express a reporter gene such as green fluorescent protein and/or to have altered patterns of gene expression.

#### Host/vector system

Plasmid vectors: disarmed Ti plasmid derivative vectors used to modulate gene expression include pRK290 derivatives, Bin19 derivatives, Bin 400, pMSP1, PTA7002, PZP200, pCAMBIA, pICH, pAGM and pGreen/pSoup derivatives, pAgricola, pHellsgate, and pJawohl series.

E.coli: Strains include disabled strains of K-12 such as DH5a, HB101, JM109, XL-1Blue and commercial derivatives that are unable to reproduce in the natural environment and can only survive in laboratory conditions.

Agrobacterium: non-disarmed Agrobacterium spp. strains including A. rhizogenes LBA9402, 8196, ATCC15834, AR 1193, K599)

Plant species: Solanaceae; Solanum lycopersicon (tomato), S. tuberosum (potato) and Nicotiana spp., Gramineae; Hordeum vulgare (barley), Triticum aestivum (wheat); Brassicaceae; Arabidopsis thaliana (thale cress) and B. oleracea (cabbage); Asteraceae (Calendula spp., Inula Spp, Helianthus spp.).

#### Origin & function

Genes and/or other DNA sequences that express programmable nucleases. For example, constructs based on the CRISPR/Cas9 or Cas12a system will be used to generate mutations in plant genes.

Genes and/or other DNA sequences that express non-coding RNAs that are used to silence the expression of plant genes.

Genes and/or DNA sequences that express proteins involved in plant metabolic processes e.g. assimilation of nutrients, production of metabolites in response to stress.

Promoters: the expression of the transgene(s) can be driven either by its own promoter or by that from another plant species. Chemically inducible promoters (e.g. dexamethasone, glucocorticoid and estradiol) and/or viral promoters (e.g. CaMV, TMV and PVX) and/or bacterial promoters such as pNos and pOcs will also be used. Synthetic promoters comprised of motifs that bind eukaryotic transcriptional factors and/or transcriptional enhancers and repressors.

Reporter genes: fluorescent marker genes such as GFP or luciferase.

Marker genes: antibiotic or herbicide resistance genes such as those for resistance to kanamycin, hygromycin, streptomycin/streptovomycin and/or phosphinothricin.

#### Evaluation of foreseeable effects

GMO Agrobacteria are not expected to have any characteristics except resistance to the antibiotic conferred by the selectable marker gene in the plasmid backbone. All other foreign genetic material will have regulatory elements.
designed to confer expression in plant cells are therefore unlike to confer any new characteristics to the bacterial cells. GMO plants produced using A. rhizogenes are expected to be composite plants with wild-type shoots and transgenic roots. They must be cultured on solid media in the laboratory and clonally propagated. The root tissues are expected to have resistance to the antibiotic or herbicide conferred by the selectable marker gene. The root tissues is also expected to either express the reporter gene (e.g. GFP or luciferase) or to have an altered gene expression or metabolic profile depending on the plant gene that has been expressed or disrupted.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Composite plants with transgenic roots produced using Agrobacterium-mediated delivery will be maintained in the laboratory on solid selective media. They will be clonally propagated and will not be transferred to soil. All plant material and all laboratory consumables (petri dishes, tips), culture vessels and residual culture material will be sterilised and disposed of by autoclaving (blue kill boxes). All work will be performed following the Standard Operating Procedure (Laboratory work for work with Plant Health Licensed Pathogens) associated with the DEFRA licence held for the use non-disarmed Agrobacteria. Metal utensils such as forceps, scalpels and blades are sterilised using a dry bead sterilizer at 250°C or above. Any spills are treated using sodium hypochlorite with 2,500 ppm active chlorine before being cleaned up using paper towels which can then be discarded in biological waste (blue box) for autoclaving. The benches on which manipulations are carried out will be cleaned using Bioguard spray after each lab session. Laboratory coats and gloves are worn during the manipulation of the licensed material. Gloves are disposed of immediately after use or after any accidental contamination. These are autoclaved at 121°C, 15 psi for 20 minutes.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation is requested.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid biological waste will be sterilised by autoclaving at 121 °C for 20 minutes, or 30 minutes for dense loads. Liquid biological waste will be sterilised by autoclaving at 121 °C for 20 minutes. Any chemically contaminated biological waste will be sent for incineration by a licenced waste contractor.

Project Additional Information
Purposes of the contained use

Storage and Distribution Only.

Recipient or parental organism

The recipient organism is Adenovirus type 5; the taxonomy of which is detailed below:

- Scientific Name: Adenovirus Type 5 (Ad5)
- Group: Group III, Subgroup C
- Family: Adenoviridae
- Genus: Mastadenovirus
- Species: Human adenovirus
- Strain name: Serotype 5

Host/vector system

The gene transfer vector is a recombinant type 5 adenovirus vector containing the human interferon α2b (IFNα2b) gene.
The vector was generated by recombination between an IFN-α2b-containing plasmid and a derivative of adenovirus type 5.

Origin & function

- Replication deficiency: the final vector is replication deficient, as a consequence of removing the adenovirus E1a and E1b regions.
- Transfer of human IFN-α2b complementary DNA (cDNA): when administered locally to the pleural space, the vector transfects both normal mesothelial and malignant mesothelioma cells, resulting in the production of high and sustained local concentrations of IFN-α2b protein within the pleural space and tumor.

Evaluation of foreseeable effects

Expression is measured for each batch of rAd-IFN clinical material. Expression of IFNα2b is determined using a limit assay which is reported qualitatively (expresses/does not express IFN). The assay is complementary to the infectivity and potency assays.
rAd-IFN has been engineered to be replication-incompetent and is naturally integration deficient. Therefore infection leading to replication of the GMO (and therefore potential for dispersal) is not possible under normal circumstances.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A - Bolton facility is Storage and Distribution only.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A
If a spill occurs on site, the waste will be processed as follows:
Disposable items should be placed in biohazards bags (or appropriated designated containers) and
incinerated (rAd-IFN is sensitive to heat: 1 hours at 56 degrees is used to inactivate the virus, or
autoclaving at 121 degrees for A MINIMUM OF 15 MINUTES). Autoclaving will be carried out by an
approved contractor. Once the GMO has been autoclaved, it will be sent for incineration via an
approved contractor.

Y

Give brief details of the genetic modification safety committee

We have a Memorandum of Understanding that gives us access to advice from the Imperial College Biological Safety Officer who has 16 years relevant experience. We also have access to the ICL South Kensington GM committee (GMB) should we need to submit a proposal for Class 2 GMO's. This is a diverse committee with academic expertise from microbiologists, virologists and plant biologists as well as the ICL BSO.

Level 3 (GMMs)
Level 4 (GMMs)
Non-microbial
Other (please specify)
Tick if confidential

Bacteriology | Parasitology | Transgenic Birds | Microbiology Research
Yes
Liquid wastes will be inactivated using Distel at a minimum of 1% final concentration after dilution with the liquid waste, and will be incubated for at least 30 minutes, however will be left for 24 hours. Distel is known to inactivate mammalian cell lines under these conditions. Additionally the cell lines are unable to survive outside of the laboratory environment. Degree of kill is anticipated to be at least a Log 5 reduction in viable material.

Solid wastes are autoclaved. Solid wastes are then disposed of via Imperial Incubator hazardous waste dumpsters. The autoclave equipment is validated annually using certified, calibrated and traceable equipment to national standards through a UKAS accredited laboratory. The Degree of kill will be at least a log 5 reduction in viable material.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Please enter comments of the GM safety committee on the risk assessment

14th Jan 16 - Hi Sl- My comments for your consideration. Please send the completed and adjusted Bi01 back to Biosafety@imperial.ac.uk-thanks I
Title - The Title should be the title of the project in which the GMO's are being used. The Bi01 is a project registration and is specific to the PI and project.
1.1 A little more detail here. What are the aims and objectives of the project?
2.3 Just a little more information here. Explain why there are fragments of AD5 genome present.
2.13 to 2.18 I thought this was a GM project? Under the GM contained use regs cell lines form all eukaryotic species are considered as being microorganisms. Please complete the GM section. I assume you are transfecting or transducing the cell line with a vector, perhaps a viral vector containing a DNA insert? The recipient cell will be the HEK 293 cells (perhaps also the viral vector depending on how attenuated it is, a wild type viral vector would also be considered as a viable host organism), the vector (includes highly attenuated and replication deficient viral vectors)

Other (please specify)
Virkon is used in accordance with the manufacturer's instructions (i.e. 1% solution). It has been validated as being effective within 10 minutes at this concentration. See www.antechh.com/virkonapps.html.

We routinely decontaminate laboratory consumables by full immersion in 1% Virkon and then leaving to soak for at least 1 hour.

Virkon powder is added directly to liquid waste to a final concentration of 1%.

Decontaminated waste is double bagged into clinical waste bags, these are then transferred into large locked clinical wastebins which are collected from the site by a specialist commercial company (Grundon) for incineration.

Historical Significant Changes
### Purposes of the contained use

For drug development purposes.

### Recipient or parental organism

The cell lines to be used are commercially available genetically modified cell lines e.g. encoding SV40 temperature sensitive elements or those created in house by introduction of genes encoded by viral vectors or in plasmid based systems.

Viral vectors (lentiviral and retroviral vectors) encoding genes of interest will be propagated.

The viral vectors are all attenuated and replication deficient in the absence of accessory genes. The genes encoded in the viral vectors are likely to be reporter genes such as GFP. Other genes which may be encoded have known biological functions which are unlikely to present any human risk.

The inserted gene products are expressed at very low levels, however it is possible that they may cause an immune response in healthy subjects. Immunocompromised individuals may be less likely than normal healthy individuals to mount an immune response to incoming viruses, but as the modified viruses are replication defective, this should not lead to replicative spread of the virus. With respect to the environment, the viruses require a host to replicate; it is very unlikely that the GM strains will be able to form a successful infection.

### Host/vector system

Well characterised, commercially available cell lines and viral vectors e.g. lentiviral vectors such as PKO-1.

### Origin & function

Commercial sources, such as Sigma-aldrich, Thermoscientific.

### Evaluation of foreseeable effects

The risk of infection with plasmids is extremely low. The use of biological safety cabinets and appropriate PPE, negate the risk of this possibility.

In viral vectors packaged via the third generation (3 plasmid) system, the requirement for lentiviral Tat is removed via modification of the LTR, and Rev is supplied in trans in another plasmid. As a result, the third generation system
distributes the HIV genome elements over four rather than three plasmids, further improving safety profiles. Plasmids supplied by commercial companies (e.g. Thermo Scientific, Sigma-Aldrich, etc.) are of a similar format and have been already risk assessed and quality controlled by the companies, further reducing their risk. Cells, plasmids and material used are treated 2% virkon or disposed by incineration through approved disposal routes. The LV particles are self-inactivating (SIN) vectors since they have deletions in the parental U3 region of their long terminal repeat (L TR) which results in the deletion of the 5' and 3' L TR promoters on integration. As such, these vectors will only integrate once. The vector is pseudotyped with an alternative non-native HIV envelope, normally from Vesicular Stomatitis Virus G protein (VSV-G). This expands the host range of the vector but limits infection of CD4+ T cells which are the natural target of HIV-1.

All cells are screened by PCR for HIV and HSV, so the possibility of transfer of any of the sequences to a related virus through homologous recombination is very remote.

Replication competent lentivirus (RCL) is a very small but potential risk - this is tested for by serial infections of HeLa cells with viral stocks, and two rounds of removal of supernatant and transfer to uninfected stocks after 48 hours. The presence of RCL can easily be detected by transgene expression or Q-PCR.

The maximum volume of cultures or culture supernatants to be processed is up to 0.5 litre for medium scale vector production. In this dilute form, viral vector titres are relatively low and hence risk is mostly conferred by the volume of material to which there is a risk of exposure. Unconcentrated virus should be considered to carry mild risk in small quantities, as compared to the ultra-centrifuged high titre virus, which should be considered moderate risk. All work involving the use of viral vectors is only performed by trained personnel who use PPE which includes as a minimum of gloves, lab coat and eye protection and performed in biological safety cabinet in designated category 2 facilities. All staff are shown how to prevent and deal with spillages that may arise e.g. spill granules and virkon solutions and or powder.

Viral vectors are aliquoted and stored in minimal volumes in double sealed tubes to prevent inadvertent spillage. All centrifugation steps are performed in sealed rotors containing sealed tubes in order to prevent the risk of viral vector or transduced cell spillages. All directly-contaminated material is Virkon-treated prior to disposal, and transduced cellular material disposed of by normal GMO routes. The route of infection of HIV is via blood/mucosal exposure, which our SOPs are explicitly designed to prevent (e.g. no sharps during virus production and concentration).

Downstream assays using washed transduced cells should pose no extra risk beyond that inherent in the assays themselves, since the virus is internalised within 24 hours of transduction and no detectable residual virus remains. During virus collection risk is minimised by the availability of liquid Virkon for dousing spills of any size prior to their absorption and safe disposal. Smaller high titre viral spills, e.g. from dropped tips, are dealt with in the same manner, commensurate with risk being affected by both viral titre and volume.

The above measures ensure that the process and procedures are adequately controlled

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Virkon is used in accordance with the manufacturer's instructions (i.e. 1% solution). It has been validated as being effective within 10 minutes at this concentration. See www.antechh.com/virkonapps.html

We routinely decontaminate laboratory consumables by full immersion in 1% Virkon and then leaving to soak for at
least 1 hour. Virkon powder is added directly to liquid waste to a final concentration of 1%. Please enter comments of the GM safety committee on the risk assessment

As the adenoassociated viral vectors proposed to be used here do not carry trans gene sequences that are expected to aggravate the risk (oncogenes, toxins etc) these vectors can be handled at biosafety level 1 (BSL-1). Similar vectors have been used in animal studies at UCL (intraocularly and systemically) for a considerable time without raising safety concerns. Previous clinical trials of adenoviral mediated gene therapy in the eye have shown that shedding of vector through the tear fluid does occur rarely and in very small amounts. As most tear fluid is ingested, the likelihood of release of vector into the environment is minimal.

Waste disposal as 'contaminated clinical waste' will be sufficiently rigorous to guarantee inactivation of the GMM and integration of the waste disposal route with an existing system will minimise the chances of breaches occurring.

Give brief details of the genetic modification safety committee

The Genetic Modification Safety Committee is a subgroup of the Health and Safety Committee which is composed of the two founders (Managing Director (qualified to MSc) and Operations Director (qualified to PhD) of the company. These individuals have over 15 years prior experience working with genetically modified mammalian cell lines in the laboratory with GMP-compliant facilities and have been required to prepare and review a range of related COSHH assessments and GMO risk assessments.

The Genetic Modification Safety Committee is a subgroup of the Health and Safety Committee which is composed of the two founders (Managing Director (qualified to MSc) and Operations Director (qualified to PhD) of the company. These individuals have over 15 years prior experience working with genetically modified mammalian cell lines in the laboratory with GMP-compliant facilities and have been required to prepare and review a range of related COSHH assessments and GMO risk assessments.

The company’s procedures require the HSC to meet on a quarterly basis, along with the HSMC. I meetings can be arranged as and when required. The company has established Health and Safety procedures D... including HSOP004 (Use of Genetically Modified Organisms) which details the company’s approach to managing the risk associated with the contained use of GMOs.
Liquid waste will be inactivated by incubation overnight with 1% Virkon overnight; documented procedures are in place for preparation of the disinfectant with a defined expiry dates. Virkon has been demonstrated to be effective against a wide range of viruses and bacteria and will kill 100% of the agents. Solid waste, including sealed microtiter plates, will be collected by a third party and inactivated using a validated rotoclave/autoclave procedure that will result in 100% kill or inactivation of the agents.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

The risk assessment has been approved by the GMSC.

For activities involving GMMs, describe the waste management measures which will apply to the activity:

All materials will be routinely inactivated on site by autoclaving at 121 °C for fifteen minutes, which will be sufficient to obtain 100% kill of micro-organisms. The effectiveness of the procedure will be monitored at monthly intervals by inclusion of steriliser control tubes (Browne tubes; control indicator type 1: 121 °C 15 min) and the results recorded in a log book. The autoclave will be serviced and undergo validation testing by the service engineer on a yearly basis.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment:

'The procedures described are entirely appropriate for work at Biosafety Level 1 with disabled hosts E.coli K12 derivatives and the mammalian cell lines you mention which all have a history of safe use.'

Bacteriology | Parasitology | Transgenic Birds | Microbiology Research

Yes
Solids (e.g. plastic-ware such as pipettes, flasks, tubes, etc., and agar plates) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration or heat treatment or via the industrial (black bag) waste stream for landfill.

Liquids (e.g. samples, culture supernatants, tissue culture media) – autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge to drains.

Sharps (in sharps bin, e.g. needles, syringes, scalpels) - dispose via clinical waste stream for heat treatment.

Waste residues that cannot be autoclaved, or cell culture waste will be inactivated by treatment with disinfectant: 1% Virkon solution for plastic-ware (soak for 2 hours), for treatment of minor contamination (10 min contact time) and surface disinfection (benches and floors); 2% for disinfection of liquid cultures and supernatants that cannot be autoclaved. Equipment that cannot be autoclaved will be disinfected as above; physically clean surfaces may be disinfected with 70% ethanol. Presept may be used as an alternative to Virkon; 1,000 ppm for general wiping of equipment and benches, 2,500 ppm free chlorine for discard containers/liquid cultures.

Particular care will be taken to ensure that others in the laboratory do not help with the clear up of accidental spillage (especially where there has been an accident that involves broken glass) unless they are aware of the potential risks and trained in safe working practices.

If spillage occurs, allow aerosols to settle and then working from the outside of the spill, apply powdered Virkon disinfectant to absorb liquids before mopping up with paper towels and disposing of all waste via autoclave waste stream.

Give brief details of the genetic modification safety committee

The Stevenage Bioscience Catalyst (SBC) is an incubator hub for small and emerging biotechnology start-up and spin-out companies. It is a UK Government backed (Innovate UK) enterprise in collaboration with the Wellcome Trust and GSK. The SBC provides technical, business, organisational and commercial support to its tenant companies and also monitors Health and Safety compliance. It has set up a GMO committee to ensure that tenants are assessing the risks associated with their work appropriately and to disseminate best practice among researchers.

The SBC committee's chairman has reviewed and advised us on our GMO risk assessments.

Bacteriology | Parasitology | Transgenic Birds | Microbiology Research |
Waste Disposal

- Vikon is used as it is a validated disinfectant for transfected cells if used in the following way under manufacturers recommendations for 100% kill rate.
- Hard surfaces: A solution containing 1% Virkon for 1 hour contact time, 10mins for metal parts (longer can cause corrosion)
- Safety cabinets: 1% Virkon (10mins)
- Discard jars, plastic tissue culture flasks, glassware: A solution containing 1% Virkon.
- Ensure all surfaces are in contact with the disinfectant (10mins).
- Supernatants/liquid waste: 3% Virkon diluted 2:1 in culture medium
- All solid waste is going to be incinerated.
- Full bags (properly labelled and closed) are to be transported to the hazardous waste bins in the SBC storage area. Howie type Lab coats, safety glasses and nitrile gloves will be used during the waste handling.
- Bins are collected for off-site incineration by Grundon waste management

Accidental Release:
In our laboratories for class 1 contain use the floor is sealed and the labs are built to CL2 level, all the MSC are Class 2.
In an uncontained area, all persons should evacuate the area to avoid contact with any potential aerosols formed.
Only after 1 hour the room might be entered (to allow any aerosols to settle) and the procedures should be the same as in a contained area.
In a contained area Virkon powder should be applied all over the spill area. The spillage to be mopped up with damp cloths, it must not be brushed. This solid waste is then to be incinerated as described before.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Dr Mahendra Deonarain is the chairman of a 10-member SBC GM committee. Dr Deonarain has 25 years’ experience working with GMOs and has previously served as GM Officer in the Dept of Life Sciences at Imperial College. The GM committee has a wide range of experiences in GMO R&D.
Dr Deonarain and the committee have advised Tusk Therapeutics on evaluating GMO handling and waste disposal risks and are satisfied that they are acting appropriately, responsibly and with the best practice of the SBC. The R&D does not contain anything exceptional that requires special consideration. The SBC GM Committee have approved the associated risk assessment and support this notification.
Purposes of the contained use

Black Belt TX Limited (formerly known as Black Belt Therapeutics Ltd) is developing monoclonal antibody and small molecule inhibitor therapeutics aimed at stimulating the immune system for the treatment of various cancers. A key part of developing such therapeutics is to evaluate their biological activity in cell based bioassays. Non-GMO cell lines can often serve this purpose but sometimes because high levels of the target protein are required or because there is no suitable assay readout, cells must be transformed and genetically modified by means of viral infection or other methods, including CRISPR/Cas9 genome editing, as described below.

When non-viral transfection is suitable for bioassay development, the process will be preferred and carried out at Black Belt TX, utilising Karpas299, SUDHL-1, SR786, Jurkat, MDA-MB-231, SK-MEL, THP-1 and other cell lines, as well as pre-screened (for common blood borne pathogens) primary blood cells, including T cells and myeloid cells, such as monocytes or in vitro-differentiated macrophages and antigen presenting cells.

When viral transduction (infection of a cell with viral particles) is necessary, this can be either carried out at commercial providers, providing virally-infected cells to Black Belt TX (BBTX), or performed in house at BBTX utilising replication-incompetent and non-mobilizable lentiviral vectors, which are sourced from commercial providers as ready-to-transduce particles (e.g. from Horizon Discovery and Cellecta).

A series of different procedures involving GMOs will be carried out. Activities listed below under points 1) and 2) are BSL-1 level, while activities under 3) and 4) involve BSL-2 level.
1) The transfection reagent Lipofectamine 3000 (Life Technologies) is utilized to express the firefly luciferase enzyme under the control of Stat5 activation. This generates a Stat5 reporter assay. The DNA vector/plasmid utilized for that purpose is pGL4.52[luc2P/STAT5 RE/Hygro] from Promega. This vector does not contain oncogenes. After the transfection, a specific antibiotic (hygromycin) is utilized to ensure selection of cells that have been transfected and so express the Stat5 reporter gene (luciferase). The process might occasionally and eventually result in stable incorporation of the plasmid DNA, i.e. The cell line might become stably-transfected with the plasmid and kept in culture for indefinite time without losing the Stat5-reporter functionality. This stably incorporated Stat5-reporter plasmid DNA is non-mobilizable.

2) For some of the virally-transformed cells, the lentivirus vector construction and infection of HEK293 and CHO cells is performed at Vectalys (Toulouse, France). The cell-lines transferred to Black Belt TX will have the vector sequence verified, will not contain oncogenes in the vector and the cell-line multiplicity of infection will be reported. All vectors are non-mobilizable.

3) Lentiviral transduction at BBTX premises will be performed utilizing ready-to-transduce viral preparations sourced from commercial providers (e.g. Horizon Discovery, Cellecta and Flash Therapeutics). The lentiviral vectors are sequence verified by the providers, do not contain known oncogenes, are 2nd or 3rd generation, replication incompetent and non-mobilizable once integrated in the DNA of the infected cells. All work involving lentiviral particles/vectors is dealt with inside a BSL-2 laboratory following the appropriate risk assessments and SOPs, which are in place at BBTX.

4) CRISPR/Cas9-mediated genome editing will be carried out to knock-out specific genes of interest, including GCN2, PERK and other stress-related proteins, which can play some role in cellular energetics & metabolism. Knock-out of these proteins is not associated with cancer development: i.e. they are not known onco-suppressors. However, in some cases screening approaches with pooled gRNA, derived from lentiviral transduction will be carried out. For such screening, it is not possible to predict the biological effect of the knock down of each individual knock down or combination of them, where more than one gRNA can be expressed in a given cell. All screening work is performed in the BSL-2 laboratory. The Cas9 protein is transfected into the cells by either electroporation, liposome-mediated delivery (e.g. lipofectamine reagents from ThermoFisher), utilizing recombinant Cas9 protein or mRNA encoding the protein, or by employing genome non-incorporating LentiFlash Technology (from Flash Therapeutics). Moreover, the cell delivery of gRNA and Cas9 expression is temporally separated by at least 24h, with cell culture replacement in between of the two steps. Hence, there is no risk for recombination between different vectors and there is low and contained risk to human health and the environment.

Recipient or parental organism

- Chinese hamster ovary cells (CHO)
- Human embryonic kidney cells (HEK293)
- Human lymphoma cell lines (KARPAS 299, SU-DHL-1 and SR-786)
- Human breast cancer cell line (MDA-MB-231)
- Human melanoma cell line (SK-MEL)
- T-cell leukemia cell line (Jurkat)
- Acute monocytic leukemia cell line (THP-1)
- Primary immune cells derived from healthy donor blood (T cells, monocytes)
- In vitro differentiated macrophages and antigen presenting cells (derived from blood immune cells)

Host/vector system

1) Helper plasmid#1: pHIVgagpol: human Retrovirus derived from HIV.
   This plasmid carries the structure genes (gag) and functional genes (pol), but not the envelope gene.
   This plasmid carries the gag and pol genes under the control of CMV promoter/enhancer, allowing their constitutive expression in cells transfected by this plasmid. It is non-coding for the accessory proteins Vif, Vpr, Vpu and Nef.

2) Helper plasmid#2: pEnv:
   This plasmid carries the sequence allowing the expression of the VSV (Vesicular Stomatitis Virus) envelope G-glycoprotein, VSV-G. Only the sequence of the G protein of serotype Indiana (NCBI accession number: AM_690336.1) is manipulated in the laboratory.

02/03/2022
This plasmid carries the VSV-G gene under the control of CMV promoter/enhancer, allowing its constitutive and strong expression in cells transfected by this plasmid.

3) Expression plasmid pLV-EF1-hCD137
This plasmid is a Self Inactivating (SIN) HIV derived lentiviral vector, containing a Multi-Cloning Site to insert cDNA
Δ [U3]: SIN (self inactivating) vector: Self-inactivating (SIN) vectors lacks viral enhancers/promoters in their 3’ long terminal repeat (LTR). The deletion of the U3 region in the 3’ LTR allows:
- decrease the number of HIV-1 internal viral sequences
- LTR inactivation
- Prevent the CIS activation of genes closed to the integration site

4) PLASMID pGL4.52[luc2P/STAT5RE/Hygro] Vector
The pGL4.52[ luc2P /STAT5 RE/Hygro] Vector contains five copies of a STAT5 response element (STAT5 RE) that drives transcription of the luciferase reporter gene luc2P (Photinus pyralis). luc2P is a synthetically derived luciferase sequence with humanized codon optimization that is designed for high expression and reduced anomalous transcription. The luc2P gene contains hPEST, a protein destabilization sequence, which allows luc2P protein levels to respond more quickly than those of luc2 to induction of transcription. The vector backbone contains an ampicillin resistance gene to allow selection in E. coli and a gene for hygromycin resistance to allow selection of stably transfected mammalian cell lines.

5) Vector Edit-R lentiviral sgRNA from Horizon Discovery.
The vector backbone contains a gRNA sequence under the control of the U6 promoter and a Puromycin resistance gene under the control of the mCMV promoter to allow for selection of stably transduced mammalian cell lines.

6) Vector pRSGUP-U6-(sg)-UbiC-Puro from Cellecta
https://www.cellecta.com/resources/vector-information/#sgRNA2
The vector backbone contains gRNA sequence under the control of the U6 promoter and a Puromycin resistance gene under the control of the UbiC promoter to allow selection of stably transduced mammalian cell lines.

7) Vector pRSEGP-U6-(sg)-EF1-Puro from Cellecta
https://www.cellecta.com/resources/vector-information/#sgRNA2
The vector backbone contains a gRNA sequence under the control of the U6 promoter and a Puromycin resistance gene under the control of the EF1 promoter to allow selection of stably transduced mammalian cell lines. In other similar version of this vector, reporter genes such as GFP or mCherry are integrated and co-expressed with the antibiotic resistance gene.

8) pRSG21-U6-(sg)-CMV-TagGFP2-2A-Puro from Cellecta.
https://www.cellecta.com/resources/vector-information/#sgRNA2
The vector backbone contains a gRNA sequence under the control of the U6 promoter and a Puromycin resistance gene under the control of the CMV promoter jointly with the GFP2 reporter gene, allowing selection of stably transduced mammalian cell lines, while also monitoring efficiency of transduction. In other similar version of this vector, a different reporter gene is used, such as RFP.

9) The CRISPR/Cas9- dependent genome editing of cells in the absence of viral vectors
In some instances, genome editing is performed without contribution from DNA plasmids or viral vectors. Transfection can be carried out with the recombinant Cas9 protein and synthetic guide RNA directly incorporated into the Lipofectamine CRISPRMAX Cas9 reagent from ThermoFisher, which is subsequently fused with cell membranes, releasing protein and gRNA inside the cells. (https://www.thermofisher.com/order/catalog/product/CMAX00015). Alternatively, the NEON electroporation system is used.

02/03/2022
10) The CRISPR/Cas9-dependent genome editing of cells using genome non-incorporating lentiFlash particles from Flash Therapeutics (Vectalys)

In this case, genome editing is performed utilizing a transducing lentiviral particle, where all viral genes have been removed, rendering the vector incapable of genome integration. The particles are rather designed for direct delivery of mRNA into the target cell, allowing exogenous and transient over-expression of proteins, such as the Cas9 for the purpose of genome editing, when combined with appropriate gRNA.

https://www.vectalys.com/our-lentiviral-platform/for-research-project/premade-lentiflash-particles/

---

**GENE INSERTION:**

**CD38:** also known as cyclic ADP ribose hydrolase is a glycoprotein found on the surface of many immune cells (white blood cells), including CD4+, CD8+, B lymphocytes and natural killer cells.

**CD137:** is a member of the tumor necrosis factor (TNF) receptor family. Its alternative names are tumor necrosis factor receptor superfamily member 9 (TNFRSF9), 4-1BB and cell surface expression is induced by lymphocyte activation.

**CR-TAM:** CRTAM, (class-I MHC-restricted T-cell associated molecule), is homodimer protein belonging to Ig superfamily. It is expressed transiently on the surface of activated NK cells, NKT cells and a subset of CD8+ T cells. Nectin-like molecule-2 (Nect2, TSCL1) is the ligand of CRTAM. CRTAM plays an important role in cell adhesion and migration.

**Firefly Luciferase:** Firefly luciferase is a euglobulin protein that catalyses the oxygenation of luciferin using ATP and molecular oxygen to yield oxyluciferin, a highly unstable, singlet-excited compound that emits light upon relaxation to its ground state.

---

**GENE KNOCK-OUT:**

**GCN2:** Metabolic-stress sensing protein kinase that phosphorylates the alpha subunit of eukaryotic translation initiation factor 2 (eIF-2-alpha/EIF2S1) on 'Ser-52' in response to low amino acid availability (PubMed:25329545). Plays a role as an activator of the integrated stress response (ISR) required for adaptation to amino acid starvation. Converts phosphorylated eIF-2-alpha/EIF2S1 either to a competitive inhibitor of the translation initiation factor eIF-2B, leading to a global protein synthesis repression, and thus to a reduced overall utilization of amino acids, or to a translational initiation activation of specific mRNAs, such as the transcriptional activator ATF4, and hence allowing ATF4-mediated reprogramming of amino acid biosynthetic gene expression to alleviate nutrient depletion.

**PERK:** Metabolic-stress sensing protein kinase that phosphorylates the alpha subunit of eukaryotic translation initiation factor 2 (eIF-2-alpha/EIF2S1) on 'Ser-52' during the unfolded protein response (UPR) and in response to low amino acid availability. PERK converts phosphorylated eIF-2-alpha/EIF2S1 either in a global protein synthesis inhibitor, leading to a reduced overall utilization of amino acids, or to a translation initiation activator of specific mRNAs, such as the transcriptional activator ATF4, and hence allowing ATF4-mediated reprogramming of amino acid biosynthetic gene expression to alleviate nutrient depletion. Serves as a critical effector of unfolded protein response (UPR)-induced G1 growth arrest due to the loss of cyclin-D1 (CCND1). Involved in control of mitochondrial morphology and function.

---

**POOLED SCREENING and TARGET ID:** For the purpose of new target identification and validation, screening with pooled lentiviral vectors will be carried out in primary human cells, including T cells isolated from PBMCs or established cancer cells, such as Jurkat cells. Targets might be unknown in function and one given cell can be infected with one or more vectors, carrying different gRNAs. In such screening approach, it is not possible to predict the specific biological effect of the knock down for every single target or for a combination of them, when more than one infection per cell happens. All work involving lentiviral vectors is carried out in the BSL-2 laboratory. All vectors are 2nd or 3rd generation, sequence verified by the commercial provider (e.g. Horizon, Cellecta and Flash Therapeutics), engineered to be replication-incompetent and non-mobilizable once integrated in the DNA of the host cell, minimizing risk for human health and the environment.
The most hazardous procedure is the lentiviral transduction of human cells, utilising ready-to-transduce viral particles (from commercial providers). These engineered lentiviruses are classified as Risk Group 2 by the World Health Organization (WHO) and Biosafety Level 2 (BL2) or Enhanced BL2 (depending on the circumstances) by the U.S. Centers for Disease Control (CDC) Office of Health and Safety. Vector hazard includes tropism towards human cells, possibility of transducing his/her cells in the event of being in contact with wounds from the researcher. All vectors are 2nd or 3rd generation, sequence-verified, engineered as replication-incompetent and non-mobilizable once integrated in the DNA of the host cell. All work is performed in BSL-2 laboratory. Hence, the risk for human health and the environment is contained and low. Apart from the above, the rest of the work is Class 1 thus posing little or no risk.

BSL-1 GMO will comprise of:
A) Karpas299, SUDHL-1, SR786 and Jurkat cells transfected with pGL4.52[ luc2P /STAT5 RE/Hygro] Vector from Promega. The genes encoded in the plasmid are luciferase and hygromycin resistance gene, which are not oncogenes. The reporter gene is Luciferase. The plasmid is non-mobilizable.
B) CHO or HEK293 cells transfected with three plasmids: helper plasmid 1 comprising pHIV-gagpol, helper plasmid 2 comprising pVSVG and expression plasmid comprising pLV-EF1-Black Belt selected gene. The current list of selected genes is CD38, CD137 and CR-TAM. These are not oncogenes. All plasmids are non-mobilizable.
C) MDA-MB-231, SK-MEL, Jurkat, THP-1, Primary blood cells, including T cells, myeloid cells (monocytes, in-vitro differentiated macrophages and antigen presenting cells) transiently transfected with Cas9 recombinant protein and synthetic guide RNA (gRNA) to selectively knock-out genes of interests, which include PERK and GCN2. Knock-out of these genes is not known to cause cancer. Notably, no plasmid or viral vectors are utilised for this procedure. Either Lipofectamine CRISPRMAX Cas9 or NEON electroporation system from ThermoFisher is utilized to incorporate gRNA and Cas9 into the cells.

BSL-2 GMO will comprise of:
D) Primary cells, including Pan T cells isolated from blood PBMCs of healthy donors, which are pre-screened/ free of common blood borne pathogens (blood sourced via NHSBT or commercial providers), and established, commercially available cancer cells, such as Jurkat cells are transduced with vectors expressing gRNA. These viral preparations are sourced from commercial providers as ready-to-transduce particles. The work includes vector backbones such as the edit R Lentiviral sgRNA from Horizon Discovery (https://dharmacon.horizondiscovery.com/gene-editing/crispr-cas9/crispr-controls/edit-r-lentiviral-sgma-pooled-screening-library/) and vectors pRSGU6-6g-Ubic-Puro and Vector pRSGEP-U6-(sg)-EF1-Puro from Cellecta (https://www.cellecta.com/resources/vector-information/#sgRNA2). Alternative, similar vectors from these or other validated providers might be utilized. The vectors might further include reporter genes, such as GFP, mCherry or turboRFP, which are all established, non-oncogenic reporter genes utilized to monitor the efficiency of cell transduction. In all cases, the vectors are either 2nd or 3rd generation lentiviral, sequence-verified, replication-incompetent and non-mobilizable once integrated in the DNA. All work is carried out inside the BSL-2 laboratory at BBTX, following appropriate risk assessment and SOPs.

Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste Disposal:
- Presept tablets (from Johnson & Johnson) are used as it is a validated desinfectant for virally-transduced cells if used under manufacturers recommendations for 100% kill rate.
- Safety cabinets: cleaned with tissue soaked in Chemgene laboratory disinfectant, disposed of in bio-hazard waste bins.
- Plastic jars are used to disinfect both solid and liquid waste overnight.
The tissue culture plasticware are soaked in Presept solution overnight, ensuring that all surfaces are in contact with the disinfectant. Solid waste is then double bagged.
into bio-hazard yellow bins or lid-secured plastic yellow bins. All GMO LvL-2 solid waste is autoclaved before being transported to the hazardous waste bins of the SBC area. Autoclave cycle: minimum of 121°C, 1.15bar, 15 mins hold. 100% kill rate validation of BSL LvL2 waste in the autoclave is validated by Annual 12 point thermocouple testing of autoclave + routine/each run confirmation of 100% kill rate. Routine confirmation of kill rate either by built-in thermocouple recorder or by use of commercially available autoclave indicator (e.g., Browne TST) in each load, jointly with log book records. Full bags (properly labelled and closed) are transported to the hazardous waste bins in the SBC storage area. Howie type Lab coats, safety glasses and nitrile gloves will be used during all phases of the waste handling.

- Bins are collected for off-site incineration by Grundon waste management.

Accidental Release:
All our laboratories for contained use have sealed floor and working surfaces. The labs are built to CL2 level and all Biosafety cabinets are Class 2. In an uncontained area, all persons should evacuate the area to avoid contact with any potential aerosols formed. Only after 1 hour the room might be entered (after aerosols have settled) and the procedures should be the same as in a contained area.

In a contained area, Specific Biological spill kits are applied all over the spill area. The spillage is to be mopped up with damp cloths, it must not be brushed. This solid waste is then pre-soaked overnight in Presept solution and disposed as per above procedure (under waste Disposal measures).

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

D is the chairman of a 10-member SBC GMO committee. D has 25 years’ experience working with GMOs and has previously served as GM Officer in the Dept of Life Sciences at Imperial College. The GMO committee has a wide range of experiences in GMO R&D. D and the committee have advised Black Belt TX on evaluating GMO handling and waste disposal risks and are satisfied that they are acting appropriately, responsibly and with the best practice of the SBC. The R&D does not contain anything exceptional that requires special consideration. The SBC GMO Committee have approved the associated and updated risk assessment on 15th July, 2019 and support this notification.

Give brief details of the genetic modification safety committee

Biology SHE oversight committee
Role is to ensure Cambridge Consultants meets all necessary safety and legal requirements to commission and operate the microbiology lab, to provide expert advice to the commissioning team where necessary, to perform training for new staff where necessary; responsibilities include creating and supporting the commissioning and maintenance team, specifying tasks to be performed and documents to be created to commission and run the lab, review and sign-off of documents (particularly Risk assessments (PUWER, CoSHH, GMO), protocols and SOPs, equipment IQ/OQ/PQ), ensuring staff working in the lab are trained and competent to work there, and on-going oversight of lab use and safety

Members of the SHE oversight committee
1. CHAIR - Head of Quality Assurance (QA)
2. SHE Officer (20+ years experience in Health & Safety, including 8 years in biotechnology laboratory setting)
3. Analytical Lab Manager
4. Biological Safety Officer (PhD level and postdoctoral work, in total 9 years experience in microbiology / molecular biology laboratory); undertaking ISTR-accredited course (Biosafety Practitioner Level 1) starting 20 April, and
5. Technology Director

Yes

To minimise the risk of escape of GMMs to the environment, all contaminated waste streams generated through the course of this work will be disinfected within the laboratory premises covered by this notification.

All waste suitable for the local authority refuse collection, except recyclable paper and glass, will be placed in clearly marked waste bins ('Domestic-type waste') and these will be made available for collection by the cleaners. No cleaner staff will be given access to the laboratory. Recyclable (non-contaminated) paper and cardboard will be collected separately. Broken glass bins will be available in the laboratory (NB. distinct from ‘Sharps’ bins).

Items which are not allowed to be put in the domestic-type waste bins is regarded as ‘controlled waste’ and must be disposed of as follows:

- Glassware that has been in contact with cells must be subjected to disinfection by exposure to suitable disinfectant (e.g. Virkon® S or similar products) according to manufacturer’s instructions (e.g. 1% solution for at least 2 hours); glassware must be completely filled and swabbed on the outside, then thoroughly rinsed in water before washing in washing machine.
- Contaminated cultures and used media must be disinfected by exposure to suitable disinfectant (e.g. Virkon® or similar products) according to manufacturer’s instructions (e.g. 1% solution for at least 2 hours); once disinfected the liquid will be disposed of in accordance with Cambridge Consultants internal policies (either down the drain or via waste management providers); disposable solids must be disposed of in an appropriate manner (see below).
- Broken glassware and sharps must be disinfected before being discarded in the requisite Broken Glass or Sharps bins as appropriate.

The aim of the project is to design and construct new synthetic biology parts.

For activities involving GMMs, describe the waste management measures which will apply to the activity.
Plasticware that has been in contact with cells must be disinfected before placed in double autoclavable bags.

- Waste for autoclaving must be put in double autoclavable bags, sealed with autoclave tape, autoclaved as per manufacturer’s instructions and validated for full decontamination (autoclave tape turned black) before placing in black bag for disposal as domestic waste.
- Sharps (including all needles and glass Pasteur pipettes) must be placed in a regulation standard Sharps bin (orange-lidded yellow sharps box for incineration).
- All waste removal will be conducted by waste management providers as appointed by Cambridge Consultants Building Services.

- Any small or moderate (< 100 ml) spills on surfaces outside the safety cabinet must be dealt with immediately, and other workers in the laboratory must be made aware of the spill. Disinfectant must be kept at hand for these types of event. If contaminated, any PPE (Personal Protective Equipment) such as lab coats, gloves or safety spectacles must be removed, disinfected and autoclaved. The spill must be wiped with paper towels after disinfection for at least 30 minutes, paper towels are then disposed of in biohazard bin. After disinfection, sharps or broken glass must be picked up with forceps/tweezers and disposed of in sharps or broken glass bins.
- Any reusable item such as dustpan and brush that may be exposed to biological materials must be autoclaved after use; floor surfaces must be mopped after disinfection if exposed to a spill.
- Small spills (< 100 ml) inside the safety cabinet are dealt with by leaving the biosafety cabinet running and wiping equipment and the interior surfaces with an appropriate disinfectant. If the spill has gone into the interior of the cabinet (e.g. through grilles or similar), the cabinet must be disassembled as much as possible and decontaminated. The cabinet must be left running for at least 10 minutes after clean-up.
- Major spills (> 100 ml) inside or outside the safety cabinet must be dealt with by closing laboratory doors and evacuating the room, leaving the room empty for at least 30 minutes to let aerosols settle. The laboratory must then undergo clean-up procedure as for the small or moderate spills.
- All major spills must be recorded in the Laboratory Accident Log Book.

In the event of a spill leading to an employee being exposed to a hazard (e.g. face or eye splash, cut or puncture with sharps, exposure of non-intact skin), the following emergency protocol will be followed, depending on the nature of the accident:
- Remove gloves, encourage needle sticks and cuts to bleed, wash with soap and water for 15 minutes (no scrubbing)
- Flush eyes at eyewash station with clean water for 15 minutes; remove contact lenses if present
- Flush nose, mouth or skin with water for 15 minutes
- For all injuries and biological exposures, seek medical attention if employee has been exposed to synthetic nucleic acid molecules

Incident report forms must be completed following adverse events and kept with the Laboratory Accident Log Book. All biohazard exposures must be reported to the SHE Officer.

The aim of the project is to design and construct new synthetic biology parts and systems and to re-design existing genetic parts and systems for specific purposes. This will be done by assembling synthetic DNA for insertion into bacterial cells. The constructs will be grown at small scale (less than 10 litres). Taken together, the potential hazards of the GMM, the inserted genetic material and the vector will yield a system which is highly unlikely to cause harm to human health or the environment.

Give brief details of the genetic modification safety committee

The company internal safety committee encompasses the genetic modification safety committee and has reviewed the projects and risk assessments. The committee was set up and held its first meeting on 29th April 2016. The risk assessments were discussed and the planned genetic modification work was assessed to be class 1 by all members of the committee.

The members of the Safety committee includes the company chief scientific officer and 2 individuals who have over 10 years experience each in working with and reviewing genetic modification projects.

02/03/2022
For activities involving GMMs, describe the waste management measures which will apply to the activity

Liquid waste will be inactivated with Distel disinfectant for at least 8 hours prior to sink disposal. Solid waste (plasticware) will be rinsed with Distel prior to collection by a specified waste disposal contractor for incineration. The contractor is HSE licensed as a waste disposal contractor for GM waste.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

The safety committee requested further information on Distel disinfectant to be added to the risk assessments, as well as staff training logs. Both these items were added to the risk assessments and the safety committee approved the work as GM class 1.

Project Ref 3326/18.1

Date Ackn'd 01/08/2018

CU2 Project Title Generation of a subgenomic Respiratory Syncytial Virus (RSV) reporter system

Class 2

Culture Volume < 1 Litre

Consent Granted Not Applicable

Project notified under transitional arrangements N
**Project Additional Information**

**Purposes of the contained use**

To establish a subgenomic reporter system for RSV in which small molecule inhibitors of RSV can be tested and the effect of amino acids variations in the RSV genes in this system can be assessed.

**Recipient or parental organism**

Hep2 cells or BHK cells. Both are laboratory-adapted cell lines that have demonstrated safe use in GM projects.

**Host/vector system**

pcDNA3 or pBR322 based plasmid vectors which are considered nonmobilisable containing single RSV genes or a luciferase reporter gene flanked by RSV leader and trailer regulatory elements. Vaccinia virus modified to express bacteriophage T7 RNA polymerase, strain vTF-7 purchased from ATCC (VR-2153)

**Origin & function**

RSV genes P protein, L polymerase, N-protein, and M2-1 form the RSV ribonucleoprotein replication complex. Infectious RSV will not be produced. Firefly luciferase is a benign reporter gene that will be transcribed by the RSV replication complex. T7 RNA polymerase from bacteriophage provided by vaccina T7 drives the expression of the RSV genes to form the replication complex

**Evaluation of foreseeable effects**

The vectors used in this project individually express 4 proteins from RSV that form the RSV replication complex. No other RSV proteins, nor a replication competent RSV genome is expressed and therefore infectious RSV will not be produced. Mutations made in the individual RSV proteins are not expected to change the properties. The luciferase reporter will only be expressed if T7 RNA polymerase is present and the RSV replication complex is formed and therefore poses a minimal concern to the environment, this reporter construct contains RSV regulatory elements but is not replication competent and infectious RSV will
Vaccinia stably accepts large foreign sequences into its genome so it is a very popular tool in immunology and vaccine research and is a well-established and studied vector.

Vaccinia virus produced from a Vaccinia vector with the T7 polymerase gene insert is not likely to be any more or less infectious than a wild type Vaccinia virus.

Vaccinia virus is listed in the ACDP classification as a group 2 pathogen. Vaccinia virus was historically used as a live-virus vaccination strain against smallpox in humans and does not demonstrate any major health effects. Accidental inoculation with vaccinia can occur if the virus interacts with broken skin, or penetrates the dermis via a needlestick injury. Typical inoculation with vaccinia virus may result in skin lesions and scabbing, though serious complications such as ocular vaccinia, myopericarditis, and eczema vaccinatum have been reported in extremely rare cases.

Infectious Vaccina T7 will be handled at containment level 2 at all times. All manipulation of infectious material will be performed within a class II microbiological safety cabinet (MSC) to reduce the risk of exposure. Centrifuge bucket lids will be used, with lids only removed inside the MSC following centrifugation.

Volumes of vaccinia virus stock (titre not more than 10E7) will be kept under 30ml with dilute (titre <10E3) culture volumes kept below 200mL.

The Laboratory has controlled entry access to authorised individuals only. Any transport of virus stocks between laboratories will be in leak-proof locklid boxes. Anyone with known immunodeficiency or other predisposing medical conditions, including exfoliative skin conditions and pregnant staff will not be permitted to work with pathogenic viruses. The use of sharps is prohibited within the laboratory. Lab coats and disposable nitrile gloves will be worn at all times and hands will be washed after the work activity is completed and prior to leaving the lab. Safety spectacles will also be worn when handling vaccinia virus to reduce the risk of ocular exposure.

All work will be undertaken in a Class II MSC to minimise the risk of release to the environment. Some isolates of Vaccinia are stable on surfaces when dried, but are susceptible to disinfection by detergents and are heat-labile at 60°C. All surfaces will be cleaned with 1% Distel before and after use to minimise the risk of vaccinia survival on fomite surfaces, liquid waste will be disinfected with 1% Distel and solid waste will be disinfected with 1% Distel prior to autoclaving at 121°C, 1.15 bar with 15 mins hold time prior to disposal by incineration as described in waste management section below.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
1% Distel will be used for disinfection of liquid waste, following the manufacturer’s instructions and left to decontaminate overnight for a minimum period of 16 hours prior to laboratory sink disposal with large quantities of water. Distel (formerly TriGene) – is a high-level surface disinfectant that destroys RNA and DNA, and is tested and approved as bactericidal, fungicidal, virucidal and tuberculocidal. Hard surfaces such as the Microbiological Safety Cabinet will be disinfected with 1% Distel. Solid waste/plasticware including pipette tips will be submerged in 1% Distel and left to decontaminate overnight for a minimum period of 16 hours. Subsequently, solid waste will be autoclaved on a minimum of 121°C, 1.15 bar 15 minutes hold cycle which is expected to be sufficient for 100% kill. An indicator strip will be included in every autoclave run to ensure temperature and hold time is achieved. The autoclave is serviced annually and there is a back-up autoclave available if required. All autoclaved waste is transferred to hazardous waste bags and placed in hazardous waste bins in the SBC storage area. Bins are collected for off site incineration by an authorised waste management contractor (Grundons waste management).

Any spillages in MSC are decontaminated with 1% Distel, overnight if required. Trolleys and sealed packaging are used to minimise any spillage during any transportation e.g. of waste to the autoclave. Solid waste will be decontaminated by soaking in 1% Distel overnight prior to autoclaving and disposal by incineration, while liquid waste is decontaminated with Distel solution overnight, prior to disposal in the appropriate lab sink with large quantities of water. If a spillage occurs in a sealed centrifuge bucket, sealed buckets will be left to stand for 30 mins to allow aerosols to settle, and then opened in the MSC. All the contaminated components will be decontaminated with 1% Distel-soaked paper towel to remove worst of contamination, followed by a 30-minute soak in 70% ethanol. All solid waste, tissues, gloves etc., from the clean up will be autoclaved prior to waste disposal by incineration.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
The Stevenage Bioscience Catalyst (SBC) is an incubator hub for small and emerging biotechnology start-up and spin-out companies. SBC provides technical, business, organisational and commercial support to its tenant companies and also monitors Health and Safety compliance. It has set up a >10-member GMO committee from tenant companies to ensure that tenants are assessing the risks associated with their work appropriately and to disseminate best practice among researchers. The chairman of this committee and has 25 years experience working with GMO in academic and commercial settings and was Chairman of Imperial College Life Sciences GMO committee for 4 years. The SBC committee has reviewed and advised ReViral on its GMO risk assessment and are satisfied that they have considered the risks in terms of GM organisms and scale of work. They have appropriate control measures to contain the work and appropriate procedures for the class of GMO activity for waste disposal.

In addition, the ReViral internal safety committee encompasses the genetic modification safety committee and has reviewed this projects and risk assessment. The members of the Safety committee includes the company chief scientific officer and 2 individuals who each have over 10 years experience in working with and reviewing genetic modification projects. The ReViral safety committee agreed that the control measures and waste disposal are appropriate for the class and scale of the planned GMO activity.

Project notified under transitional arrangements N
### Project Additional Information

#### Purposes of the contained use

To establish a reverse system for RSV in which small molecule inhibitors of RSV can be tested and the effect of amino acids variations in the RSV genes in this system can be assessed.

#### Recipient or parental organism

| Lab adapted cell lines: Hep-2 and BSR-T7/5 cell line (BHK-21 cells that stably expressing phage T7 RNA polymerase under control of the cytomegalovirus promoter, pSC6-T7-NEO (Buchholz et al J Virol 1999. 73:251-259). | Differentiated airway epithelial cultures derived from healthy primary human cells. |

#### Host/vector system

| pcDNA3 based plasmid vectors which are considered non-mobilisable containing single RSV genes. | The RSV antigenome construct, pSynk-RSV119F is a BAC Vector which are F-factor-based plasmids which are conjugated-deficient. |

#### Origin & function

| RSV genome consisting of genes encoding the following RSV proteins: P protein, L polymerase, N-protein, M2, NS1, NS2, M, SH, G and F protein. mKate2 a benign reporter gene. T7 RNA polymerase from bacteriophage within BSR-T7 cells drives the expression of the RSV genes |  |

#### Evaluation of foreseeable effects

| When co-transfected into BSR-T7 cells along with the helper plasmids, the RSV antigenomic construct will produce infectious, replication competent RSV. |  |
RSV is listed in the ACDP classification as a group 2 pathogen. RSV is normally a mild and self-limiting infection without long term sequelae. Infectious RSV will be handled at containment level 2 at all times. All manipulation of infectious material will be performed within a class II microbiological safety cabinet (MSC) to reduce the risk of exposure. Centrifuge bucket lids will be used, with lids only removed inside the MSC following centrifugation. Volumes of RSV stock (titre not more than 10E7) will be kept under 60ml with dilute (titre <10E3) culture volumes kept below 200mL. The Laboratory has controlled entry access to authorised individuals only. Any transport of virus stocks between laboratories will be in leak-proof lock lid boxes. Anyone with known immunodeficiency or other possible predisposing medical conditions will not be permitted to work with RSV. The use of sharps is prohibited within the laboratory. Lab coats and disposable nitrile gloves will be worn at all times and hands will be washed after the work activity is completed and prior to leaving the lab. All work will be undertaken in a Class II MSC to minimise the risk of release to the environment. RSV is susceptible to disinfection by detergents and is heat-labile at 60°C. All surfaces will be cleaned with 1% Distel before and after use to minimise the risk of RSV survival on fomite surfaces, liquid waste will be disinfected with 1% Distel and solid waste will be disinfected with 1% Distel prior to autoclaving at 121°C, 1.15 bar with 15 mins hold time prior to disposal by incineration.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

1% Distel will be used for disinfection of liquid waste, following the manufacturer’s instructions and left to decontaminate overnight for a minimum period of 16 hours prior to laboratory sink disposal with large quantities of water. Distel (formerly TriGene) – is a high-level surface disinfectant that destroys RNA and DNA, and is tested and approved as bactericidal, fungicidal, virucidal and tuberculocidal. Hard surfaces such as the Microbiological Safety Cabinet will be disinfected with 1% Distel. Solid waste/plasticware including pipette tips will be submerged in 1% Distel and left to decontaminate overnight for a minimum period of 16 hours. Subsequently, solid waste will be autoclaved on a minimum of 121°C, 1.15 bar 15 minutes hold cycle which is expected to be sufficient for 100% kill. An indicator strip will be included in every autoclave run to ensure temperature and hold time is achieved. The autoclave is serviced annually and there is a back-up autoclave available if required. All autoclaved waste is transferred to hazardous waste bags and placed in hazardous waste bins in the SBC storage area. Bins are collected for off site incineration by an authorised waste management contractor (Grundons waste management). Any spillages in MSC are decontaminated with 1% Distel, overnight if required. Trolleys and sealed
packaging are used to minimise any spillage during any transportation e.g of waste to the autoclave. Solid waste will be decontaminated by soaking in 1% Distel overnight prior to autoclaving and disposal by incineration, while liquid waste is decontaminated with Distel solution overnight, prior to disposal in the appropriate lab sink with large quantities of water. If a spillage occurs in a sealed centrifuge bucket, sealed buckets will be left to stand for 30 mins to allow aerosols to settle, and then opened in the MSC. All the contaminated components will be decontaminated with 1% Distel-soaked paper towel to remove worst of contamination, followed by a 30-minute soak in 70% ethanol. All solid waste, tissues, gloves etc., from the clean up will be autoclaved prior to waste disposal by incineration.

---

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

### Please enter comments on the GM safety committee on the risk assessment

The Stevenage Bioscience Catalyst (SBC) is an incubator hub for small and emerging biotechnology start-up and spin-out companies. SBC provides technical, business, organisational and commercial support to its tenant companies and also monitors Health and Safety compliance. It has set up a >10-member GMO committee from tenant companies to ensure that tenants are assessing the risks associated with their work appropriately and to disseminate best practice among researchers. The chairman of this committee and has 25 years experience working with GMO in academic and commercial settings and was Chairman of Imperial College Life Sciences GMO committee for 4 years. The SBC committee has reviewed and advised ReViral on its GMO risk assessment and are satisfied that they have considered the risks in terms of GM organisms and scale of work. They have appropriate control measures to contain the work and appropriate procedures for the class of GMO activity for waste disposal.

In addition, the ReViral internal safety committee encompasses the genetic modification safety committee and has reviewed this projects and risk assessment. The members of the Safety committee includes the company chief scientific officer and 2 individuals who each have over 10 years experience in working with and reviewing genetic modification projects. The ReViral safety committee agreed that the control measures and waste disposal are appropriate for the class and scale of the planned GMO activity.

Both liquid and solid waste will be autoclaved with 100% expected degree of kill. Our autoclaves are examined and validated annually. Virkon disinfectant will be used to deal with any spills in the laboratory.

For activities involving GMMs, describe the waste management measures which will apply to the activity

The organisms employed are all ACDP Hazard Group 1 and not harmful to humans. The E coli strains for plasmid construction and maintenance are non-pathogenic laboratory strains. Synechocystis is not an infectious agent. The proposed genetic modifications will not change the infectivity of the microorganisms or allow them to persist in the environment. Although the plasmids used in the cloning procedures contain an antibiotic resistance marker that can be used for selection, the antibiotics used are not the same ones used in frontline patient treatment.

The proposed waste disposal by autoclaving should be sufficient to decontaminate the waste produced during the experiments.

Transient and stable expression of ion channel proteins in mammalian cell culture

---

**For activities involving GMMs, describe the waste management measures which will apply to the activity**

All cell cultures will be killed with Virkon and autoclaved prior to disposal.

---

**Tick to confirm that you are attaching a summary of the risk assessment**

Y

---

**Tick if you are claiming exemption from disclosure for sections of the risk assessment**

---

**Please enter comments of the GM safety committee on the risk assessment**

Growth constraints on mammalian cell cultures mean that the cell lines pose negligible risk to human health and the environment. The inserts being expressed are from non-viral vectors. Whilst the protein they encode is a functional ion channel expressed at the cell membrane, the protein is non-oncogenic, not cytotoxic, not immunomodulatory, non-pathogenic and non-allergenic.

Bacteriology        Parasitology   Transgenic Birds   Microbiology Research
All GMM waste is deactivated and disposed of via the James Cook University Hospital Pathology Decontamination Facilities (26.A.102a) Autoclaves. Deactivation is carried out using Getinge (The Sterilisation Company) GE6913-AR1 Lab autoclaves. This autoclave is a pre-vacuum sterilizer which operates with saturated steam as the sterilizing agent, and has a temperature range of up to 137°C (279ºF) and pressure up to 2.3 bar (34 psi). Deactivation is load dependant. Materials loaded will not exceed the “Validated Load” stated in the configuration manual.

Solid GMM waste is placed in a biohazard autoclave bag, filled to no more than 2/3 in the hinged lid autoclave tins provided (including plastic pipettes). All GMM waste will be transferred to the Pathology Decontamination Facility (26.A.102a) for deactivation. Solid waste is deactivated by autoclaving at 121ºC, 15 p.s.i. for 30 minutes. Deactivated material is then disposed of within the general waste stream.

Light clinical waste bags will be provided for non GMM waste.

Only clinical waste should be disposed of in these bags.

The bags are changed daily or as soon as they are full.

When 2/3 full the neck of the bag twisted and tied in a ‘swan neck’ using the green/white tape provided.

The bags should then be placed in the waste disposal hold in LRI centre for the Porters to collect.

Liquid GMM waste will be placed in 1L autoclavable containers no more than 2/3 full. Prior to use 2/3 sachets of safety gel will be placed in the container. When 2/3 full a further 2/3 sachets of safety gel will be added and the contents left overnight to solidify. These containers are then placed within the hinged lid autoclave tins and the hinges secured prior to transportation. The use safety gel minimizes the risk of spillage due to fluid leakage during transfer to Pathology decontamination facility. Liquid waste is deactivated by autoclaving at 121ºC, 15 p.s.i. for 30 minutes. Deactivated liquid waste is then disposed of down the drain.

6.4.1. Transfer of GMM Waste for Deactivation: GMM Waste for deactivation will be transferred from GlycoSeLect’s operation facility within the Second Floor, Learning and Resource Centre’s Research Laboratory (Room 12.C.008) to the Pathology Decontamination Area Room (26.A.102a) of the Trusts Pathology building. The transfer of the material (date, type, volume & deactivation cycle/run number) will be recorded by completion of a “GlycoSeLect: GMM Waste Transfer Log” form.

All GMM waste deactivation procedures executed by the Pathology Decontamination Facility (26.A.102a) are documented using established Pathology SOPs and logging systems. All deactivation runs are recorded by completion of an “Autoclave documentation monitoring system” form.

For activities involving GMMs, describe the waste management measures which will apply to the activity:

Other(s) - Molecular Biology: production of recombinant proteins using non-pathogenic E.coli cloning and expression.
Project Title:
To clone, mutagenize, express, purify and characterise carbohydrate-binding proteins (CBP’s –
including lectins & adhesins), carbohydrate-binding domains (CBD’s) and carbohydrate active enzymes
including lectins & adhesins), carbohydrate-binding domains (CBD’s) and carbohydrate active enzymes
(CAE’s) from a number of class 1 and class 2 microorganisms.
Decision
On behalf of the Biological Safety Committee, I hereby confirm approval for the project detailed above.
The committee have reviewed the application and associated risk assessment with no comment for
amendments.

Give brief details of the genetic modification safety committee

Risk assessments were written by the senior biologist in conjunction with the Head of Biology. Health and safety documentation including GMO risk assessment and Local Rules are reviewed and approved by independent health and safety advisors.

Experience:
- Head of Biology - PhD in Cellular Biology, 28 years experience in laboratory setting including hands on experience of mammalian cell culture of GMOs plus 20 years in Pharmaceutical Industry as line manager of scientific staff.
- Senior Biologist - PhD in Integrated Biology. 10 years practical experience with the contained use of GMO microbiological organisms (Mammalian and bacterial cells) under Class I and II biosafety classification.

Yes

All genetic modification work within Mironid biology will be conducted on microorganisms which are incapable of surviving in runoff water. However, all waste from bacterial (e.coli and K12 derivatives) cell and mammalian culture growth will be inactivated prior to disposal.

Liquid waste from Mammalian cell culture media and buffers will be chemically inactivated with a final concentration of 10% (v/v) Chloros bleach (minimum 2,500ppm chloros (hypochlorite)), and incubated for a minimum of 1 hour prior to sink disposal (100% kill).

Solid waste from mammalian cell culture (plastic flasks, plastic pipettes, gloves, plastic culture plates) will be autoclaved for 30 minutes at 126 C at -15 psi (100% kill) using an onsite autoclave which is annually validated using thermocoupled testing by independent inspectors.

Liquid waste from Bacterial (k12 derived e.coli) cells culture media will be inactivated using 2% (v/v) virkon disinfectant which has been validated for 100% kill by the manufacturer and in independent study.

Solid waste (pipettes, 15ml and 50 ml tubes) will be disinfected with 2% virkon prior to autoclaving for 30 mins at 1260C at - 15psi (100% kill) using an onsite autoclave which is annually validated using thermocoupled testing by independent inspectors.

LB agar plates used in the culture of debilitated e.coli strains will be autoclaved (as above, 100% kill) prior to disposal. Autoclave waste is disposed (incinerated) by outside contractor at a site distant to Mironid Biology Labs.

For activities involving GMMs, describe the waste management measures which will apply to the activity

All genetic modification work within Mironid biology will be conducted on microgramsims which are incapable of surviving in runoff water. However, all waste from bacterial (e.coli and K12 derivatives) cell and mammalian culture growth will be inactivated prior to disposal.

Liquid waste from Mammalian cell culture media and buffers will be chemically inactivated with a final concentration of 10% (v/v) Chloros bleach (minimum 2,500ppm chloros (hypochlorite)), and incubated for a minimum of 1 hour prior to sink disposal (100% kill).

Tick to confirm that you are attaching a summary of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The Genetic modification of established cell lines and debilitated e.coli bacteria proposed by Mironid Ltd poses no risk of adverse health effect to humans or the environment. All organisms are incapable of survival in runoff water, the delivery systems pose no additional risk and inserts pose low risk to human health and pose no threat to environmental safety. All GMMs created and grown as part of this work will be inactivated prior to disposal (100% kill).

Although all GM work proposed by mironid is considered Class 1, containment level 2 systems of work will be applied.

GMM contaminated waste (disposable plasticware and spent culture liquid) is treated by chemical disinfection overnight followed by autoclaving in a benchtop autoclave (121°C for 22 minutes) to inactivate the GM, with each run monitored using TST (time, steam and temperature) test strips. Autoclaved waste is disposed of in a clinical waste stream by incineration by a contractor to achieve 100% kill.

Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Give brief details of the genetic modification safety committee

QuantumDX’s Biological Safety Committee will also stand as the Genetic Modification Safety Committee and has been consulted throughout approval of risk assessments. The committee comprises a range of representatives from various safety and technical disciplines of the Company, representing both management and employees, health and safety advisors and, if necessary, input from clinicians. Between them they have extensive experience in biological safety and containment laboratory management and practice with specific experience handling elevated biological agent hazard groups and GMM. The committee meets frequently (minimum of 4 times a year) with additional meetings where required to discuss new procedures, use of new organisms, development of new assay targets or facilities requirements.

QuantumDX are also in the process of training two Biological Safety Officers (undertaking training APR-JUN 2018 with the Biosafety Training Institute at Edinburgh University).

The committee has reviewed and approved the risk assessment (QHS-342 appended) relating to the level 1 GMM work proposed to be undertaken.

An external Health and Safety consultant was also contacted for specific risk assessment review.

</tbody>
</table>
For activities involving GMMs, describe the waste management measures which will apply to the activity

GMMs will be handled under containment level (CL) 2 conditions due to additional work undertaken on the premises (HSE notified)

Waste Disposal
All waste (solid and liquid) is subject to autoclave (autoclave located in laboratory suite) before disposal as biological waste by an external contractor (Stericycle). Waste disposal procedures are fully detailed in internal procedure QLAB-65. Autoclaving: Autoclave housed within the laboratory suite serviced and calibrated twice a year, by a reputable service provider, to ensure the validation criteria are met. During normal, daily operation each run is recorded to ensure the required conditions are achieved (121C degrees for 47 minutes).

Disinfection
Virkon, as a 1% solution, or Acitchlor, as a 0.1% solution, is used to treat spills and wipe down surfaces and equipment after work. Both disinfectants are used in strict accordance with the manufacturer’s guidelines.

Monitoring
Safety Inspections are carried out annually to ensure internal policies and procedures are adhered to and that risk assessments and training records are in order. Inspection reports are kept by the Compliance Officer.

Please enter comments of the GM safety committee on the risk assessment

The committee has reviewed and approved the risk assessment (QHS-342 appended) relating to the level 1 GMM work proposed to be undertaken.
The H37Ra attenuated strain of M. tuberculosis is to be used as a model for the pathogenic strain of M. tuberculosis to allow development of a novel diagnostic system for pulmonary Tuberculosis infection. Bacteria expressing a coloured tag are required for visual analysis of bacterial extraction from a medium, concentration and lysis. M. tuberculosis is a Hazard Group 3 organism and as such a well-defined, attenuated substitute will be used to allow safer handling during early development.

Recipient or parental organism

Mycobacterium tuberculosis H37Ra is a fully sequenced (ATCC- 25177) attenuated laboratory strain of TB classified as a Hazard Group 2 pathogen.

Host/vector system

The plasmid the strains contain is based on pFPV2 first published/created in 1996 (Valdivia, Hromockyj, Monack, Ramakrishnan, & Falkow, 1996) and widely used in the mycobacterium community since. The plasmid encodes a fluorescent tag (mCherry) fused to a constitutive promoter in addition to a hygromycin resistance cassette to maintain selection. The plasmid does not integrate into the host genome and has no impact upon pathogenicity. The resistance cassette does not convey resistance to any front line TB treatment.

Origin & function
The mCherry protein, initially isolated from Discosoma sea anemones is widely used as a fluorescent reporter. When grown under selection (100ug/ml Hygromycin), the GMM H37Ra strain will express the mCherry protein and can be hence used for fluorescence imaging with 587/610 nm Excitation and Emission properties. No mutations or alterations will be made to the host genome.

**Evaluation of foreseeable effects**

No alterations or mutation to the host genome are made and no genetic material is inserted or excised from the genome.

The plasmid will only be maintained in the strain under selective pressures, namely the addition of hygromycin to the growth media at a concentration of 100ug/ml.

The addition of a fluorescent protein will not affect the viability or infectious capabilities of the host organism so poses no threat to humans.

The plasmid cannot propagate outside of the host cell and will not be maintained in the host without the addition of antibiotics to the growth media. As such, this modification poses no threat to the environment.

The antibiotics used to maintain selection are not frontline drugs used for the treatment of TB and the introduction of the hygromycin resistance cassette will not impact the efficacy of drugs used to treat active TB.

All GM material or potentially contaminated waste is subject to autoclave before waste disposal, further reducing the risk of environmental exposure.

The parental organism is an attenuated strain of TB classified as a HG2 pathogen

Plasmid is well characterised and has been previously used by QMDx in M. smegmatis stains (HSE notified in GM 3336 premises notification).

The GMM requires additional growth supplements to maintain GM status and as such pose no threat to the environment

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All culture and analysis of GMM is completed under CL2 conditions by fully trained staff.

**Waste Disposal**

All waste (solid and liquid) is subject to autoclave (autoclave located in laboratory suite) before disposal as biological waste by an external contractor (Stericycle). Waste disposal procedures are fully detailed in internal procedure QLAB-65.

Autoclaving: Autoclave housed within the laboratory suite serviced and calibrated twice a year, by a reputable service provider, to ensure the validation criteria are met. During normal, daily operation each run is recorded to ensure the required conditions are achieved (121C degrees for 47 minutes).

**Disinfection**

Disinfection of surfaces and equipment not compatible with autoclave is completed using Acichlor, as a 0.1% solution or Tristel as provided at working concentration. Tristel is used to treat spills. Both disinfectants are used in strict accordance with the manufacturer's guidelines and have been demonstrated to achieve a suitable degree of kill.
Monitoring
Safety Inspections are carried out annually to ensure internal policies and procedures are adhered to and that risk assessments and training records are in order. Inspection reports are kept by the Compliance Officer.

Spill response
Procedures are documented for dealing with accidental spillage of liquid culture.

Project Ref 3337/21.1

Designing gene regulatory logic for lentiviral-vector-based cell and gene therapy using a toolkit of regulatory elements

Class 2   < 1 L

Non-GMM

Consent Granted

Project notified under transitional arrangements

Historical Significant Changes

Historical Date of Additional Info
A system that enables a precise control over target gene expression with inducer-molecules is highly sought after. The design of such inducible systems that meets required performance metrics poses a great challenge in mammalian cell synthetic biology. The aim of our work will be to assemble a toolkit from well-characterised, highly tunable, synthetic genetic regulatory components that will enable precise control of gene expression for the production and targeting of lentiviral vectors used in cell and gene therapy applications.

Candidate gene regulatory elements will be assessed in the context of HEK293, Jurkat and primary T cells using transient transfection, CRISPR and 3rd generation lentiviral systems. The knowledge gained will also be used to address the problem of balancing viral yield optimisation with cellular metabolic burden in HEK293 cells.

Common, well-characterised fluorescent proteins will be used to assess the performance of chosen gene regulatory elements and as genetic payloads to assess lentiviral production and titres.

Cells: HEK293, Jurkat and primary T cells from commercial sources providing screened material.
Other than introducing metabolic burden associated with exogenous protein expression, genetic manipulation of these cells is not expected to alter their characteristics or safety profile.

Microorganisms: standard laboratory strains of non-pathogenic E. coli will be used for plasmid propagation and cloning.

Third generation lentiviral plasmids will be cloned and propagated in E. Coli and chemically transfected into HEK293 cells. Resulting lentiviral vectors will be used to transduce HEK293, Jurkat and primary T cells.

In order to optimise viral vector yields in HEK293 cells to a target level, we will fine-tune promoter strengths of the constituent viral plasmids using validated site-specific DNA modifications. Plasmids will be fully sequenced to ensure no off-site sequence alterations prior to their use for viral production. Promoter strength modification will not impact the safety profile of the lentiviral system.

Lentiviral vector will be used for delivery of inducible synthetic genetic circuits consisting of fluorescent proteins under the control of regulatory elements from well-characterised, published libraries of synthetic transcription factors, promoters and inhibitors developed for programmable control of gene expression in mammalian cells such as COSMOS (Donahue et. al. Nat Commun., 2020) and CRISPR-based toolbox for synthetic biology such as dCAS (Xu et. al. J of Mol Bio, 2019).

Gene regulatory elements are designed to target specific sequences located within the synthetic circuit and not to have interactions with the host cell's endogenous gene regulatory networks. The output of our synthetic circuits will be a precisely tunable intracellular expression of fluorescent reporter proteins controlled by exogenously added inducer-molecules.
Synthetic gene regulatory components we aim to utilise have been previously developed and tested in mammalian cell lines (HEK293 and Jurkat) and are designed to target specific DNA sequences not present in the host genome. Other than imposing additional metabolic burden onto the host cell, we don't expect further changes in cells' characteristics or safety profile following our genetic modifications.

In case of an accidental operator exposure to GM cells, we don't foresee additional hazards beyond ones posed by unmodified cells.

In case of an accidental operator exposure and infection with our lentiviral vector carrying synthetic circuits, we do not expect any active gene expression to occur from the circuit itself due to its dependency on the presence of inducer-molecules and its inability to interact with the host cell's endogenous gene regulatory networks.

However, there is a potential risk of insertional mutagenesis due to chromosomal integration of lentivirally delivered transgene that may disrupt a tumour-suppressor gene or activate an oncogene.

In addition, a very small risk is a self-reversion to replication competent lentivirus during viral vector production. This is highly unlikely with the 3rd generation of self-inactivating lentiviral system that will be used in our work. Moreover, to exclude the risk of vector recombination with a wild-type HIV-1 virus, we will be using fully screened primary T cells obtained from a commercial bloodbank.

**Evaluation of foreseeable effects**

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

n/a

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

n/a

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Small sharp plastic wear such as pipette tips will be collected into a hard-plastic, sealable container such as a sweetie jar or an empty 500 ml medium bottle. Plastic wear such as tissue culture plates and flasks will be sprayed with Virkon solution, placed inside a double ziploc bag. At the completion of work, tip-containing bottles and double Ziploc bags will be sealed, surface disinfected with Virkon spray or 70% ethanol and collected in a double autoclave bag in a dedicated waste bin. When the bag is full, it will be sealed with autoclave tape and decontaminated in our bench-top autoclave to achieve 100% kill of GM organisms. Virkon solution will be made according to manufacturer's instructions (10 g Virkon in 1L of water) and has been validated by the manufacturer to be highly effective against a broad spectrum of microorganisms.

Liquid waste will be decontaminated in the BSC using 500 ml plastic container such as a used medium bottle containing 1x5g Virkon tablet (which is enough to disinfect 500 ml liquid waste). Waste volume will not be allowed to exceed 500ml per bottle. The waste will be left to decontaminate for at least 20 min. After which, 2 sachets of VernaGel will be added to solidify the liquid. Once solid has formed (about 20 min), the lid will be closed, the bottle will be surface decontaminated and placed in a dedicated laboratory waste bin.

All autoclaved and chemically decontaminated waste will be stored in a dedicated laboratory waste bin for collection by a commercial disposal service.

Use of sharp materials such as glass pipettes, scalpels, needles, etc in conjunction with lentiviral work will not be permitted.

Small spillages will be immediately covered with a Virkon-soaked absorbent tissues, allowed to decontaminate for 20 min and wiped with additional tissues soaked in 70% ethanol. Absorbent tissues will be disposed of together with solid waste in a dedicated waste bin for subsequent autoclaving.
GM Safety Committee had the following comments:

- avoid use of sharps and large viral culture volumes or high viral titres (above 5x10e9 pfu/ml). In addition, aerosol generating procedures such as centrifugation or vortexing should be undertaken in sealed vessels. Flow cytometric analysis of virally transduced cells or other aerosol-generating analysis techniques should be performed on PFA-fixed, inactivated samples.

- restrict access to the class 2 activity area to authorised and trained personnel only

- keep written training records

- avoid the use of transgenes with known biological activity in host cells such as oncogenes, toxins, cytokines, growth factors and immunomodulatory proteins.

We have taken measures to address these points as outlined in the risk assessment and local rules for CL2 work. In particular, only 3rd generation lentiviral system will be used and the choice of transgenes for our work will include only common fluorescent proteins under the control of well-characterised inducible synthetic regulatory elements not expected to interact with host cells' endogenous gene regulatory pathways.

Work will be performed within the designated laboratory and all staff will be compliant with DNAwrite health and safety policy, which can be provide upon request. This requires risk assessment, the use of PPE (gloves, protective eyewear, laboratory coats) when in the designated area and also compliance with our waste disposable and management procedures.

Waste management:
Any contaminated solid waste (such as LB plates, pipette tips or gloves) will be inactivated by autoclaving and then disposed in Low-risk Hazardous Waste containers. These containers are collected and disposed of by Anglian Environmental Services Ltd and records of disposal will be kept.
Liquid waste will be decontaminated by exposure to 1% Virkon for >30mins. Liquid will then be disposed down the sink and rinsed with water. We anticipate no more than 500ml of liquid waste per month.
GMM work will be performed in a designated zone within the lab and the surfaces of the lab benches, will be de-contaminated by wiping with 1% Virkon and azowipes.

Monitoring:
The efficiency of our waste management will be routinely monitored using common microbiology techniques, such as dip slides, swabs and LB plates containing antibiotics.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Y

Give brief details of the genetic modification safety committee

Bactevo currently shares the same site as parent company Discuva. The GMO safety committee is made up of members from both companies including the Director of Biology, and Principal scientist and Senior research scientists. All have extensive experience working in research, biotech and drug discovery environments and previous involvement with health and safety, CoSHH assessments and/or GMO safety committees.

Any new planned GM work requires preparation of a GM Risk assessment, which is reviewed by the GMO safety committee prior to commencement of work.

The GMO Safety Committee will ensure procedures, safeguards and compliance to regulations are in place in advance of initiation of those projects. These meetings will be minuted and records of these meeting retained.

02/03/2022
Solid waste that is biologically contaminated (including the parent strain and the GMO) will be autoclaved (heating with steam under pressure at >121°C for >15 minutes) to achieve 100% kill before removal from the containment facility. This will be monitored by taking samples from the autoclaved waste (e.g., from small liquid cultures) onto solid growth medium with incubation to allow any viable bacteria to grow into visible colonies, and reviewed by the GM safety committee at quarterly intervals. The autoclave used for processing is validated annually. All processed solid waste will be transferred to an authorised Waste Management provider where waste will be processed via incineration.

Liquid waste that is contaminated will be treated with "Virkon" disinfectant according to the manufacturer’s instructions to achieve 100% kill. This will be monitored by taking samples from treated waste onto solid growth medium with incubation to allow any viable bacteria to grow into visible colonies, and reviewed by the GM safety committee at quarterly intervals.

For activities involving GMMs, describe the waste management measures which will apply to the activity:

The safety committee discussed the potential for modulation of pathogenicity by genetic manipulation procedures, but agreed that such modulation would most likely result in no change or reduced pathogenicity, although scientists will be vigilant for changes to pathogen characteristics. In addition, current working practices are sufficient to prevent exposure as all work is carried out within a class II microbiological safety cabinet.

Our screening platform allows the identification of individual 'producer clones' in very small volumes (<1nl) and are screened for desired phenotypes such as antimicrobial activity or specific killing of cancer cells. The small volume and nature of the phenotypic screen makes it extremely unlikely that we would isolate increased pathogenic strains or those producing toxins. Scale up only occurs once the clones have been genetically characterised and Mass-spec identification of the compounds produced by the clone has occurred making any risk to staffs minimal.
Manipulation of organisms isolated from various sources principally environmental such as soil but also other biomes so as to allow them to continuously produce the full chemical diversity they are naturally capable of making.

Purposes of the contained use

To allow easy identification, isolation and production of chemicals naturally made by organisms for use as pharmaceuticals such as anti-cancer and antibiotics avoiding chemical synthesis. This will allow the development of new drugs and chemicals to improve therapeutics across a broad range of diseases.

Recipient or parental organism

Bactevo are working with microorganisms from the natural environments and engineering them to constitutively produce compounds that are rarely or only made in specific conditions to allow identification of those that have value to society such as a therapeutic agent. All bacteria isolated are identified by sequencing the 16S rRNA prior to creation of transposon libraries. Libraries will only be made in bacteria that are not known to cause significant human or plant diseases. Initially we are targeting groups such as Pseudomonas and streptomycyes. None of the organisms will belong to ACDP hazard group 1 or 2 and will generally be opportunistic human pathogens at worst and unlikely to infect healthy individuals even with the modifications made.

Host/vector system

Well characterised laboratory strains of E. coli, Streptomycetes and Bacilli will be used as hosts for DNA vectors. It may be that we also utilise naturally occurring phage and plasmids from the species of interest such as Streptomycyes as vectors. These will already be present in the environment and so in the unlikely release from Class II laboratory are already prevalent in the natural populations including any resistance or other genes they carry so represent no additional hazard to the environment or people than that already present.
Bacterial plasmid DNA vectors will be used, and will include standard cloning vector plasmids, which are often commercially available. Suicide vectors will also be utilised which do not normally replicate in bacteria other than specific laboratory strains of E. coli, Bacillus or streptomycetes. Generally the plasmid vectors are not self-transmissible, significantly reducing the likelihood of their unwanted spread. In all cases and especially with ‘native’ vectors where there is a possibility of self-transmission. No resistance cassettes will be used that are not already found commonly in the environment and/or used to treat humans so as to further reduce the risk of spread or transmission of markers in the environment and prevent potential resistance to clinically relevant antibiotics. All assessment will have to specify cassettes to be used and no deviation from this is allowed without additional assessment by the GMM committee.

Origin & function

Plasmid vectors to be used will be constructed from components that occur naturally in the bacteria being used in the studies. These components include a replication origin to maintain the plasmid through replication cycles and an antibiotic resistance determinant to allow for selection of bacteria harbouring the plasmid vector. Some of the plasmid vectors may also include bacterial gene transcriptional promoters, such as the E. coli or Pseudomonas mB promoter, which function to promote expression of genes inserted into the plasmid, and genes such as sacB from Bacillus subtilis that codes for levansucrase and which allows counter-selection against the plasmid in the presence of sucrose.

The chromosomally-inserted DNA will normally code for a gene, or genes, of interest from the micro-organism, and may include the gene's native promoter, or potentially a heterologous inducible promoter (such as araBAD). The inserted DNA functions to complement existing gene function, or to mediate homologous recombination with the existing gene in the recipient in order to specifically replace, mutate, or knockout the gene or promoter of interest. Such mutations may serve to specifically inactivate the gene, or in some cases to specifically regulate expression of the gene.

Alternatively the chromosomal insertion may comprise an antibiotic resistance determinant (such as those found commonly in the environment, e.g. kanamycin resistance) and a functional promoter to increase expression of genes downstream of the insertion.

Evaluation of foreseeable effects

The DNA manipulation techniques to be employed allow the precise construction of DNA molecules, thus unforeseeable effects due to the presence of DNA not necessary for the experiment can be avoided. Some GMOs will become resistant to the specific antibiotics as a result of the resistance gene encoded by the plasmid vector or if inserted into the chromosome. However, only one or two antibiotic resistance determinants are used at a time, so the generation of multiple resistance GMOs will be avoided. Antibiotic resistance genes are chosen against antibiotics that would not normally be used in therapy, so they will possess no selective advantage over non-GM bacteria, would be expected to respond to treatment, and would be unlikely to spread outside the laboratory as no selective pressure. We also ensure that the cassettes used are already common in the environment and have in most cases been isolated from environmental strains meaning the spread and dissemination into the environment has already occurred and we are unlikely to enhance this propagation.

The inserted DNA does NOT possess any additional traits that would be expected to increase the GMO's ability to cause disease or survive in it's natural habitat, or any other environment. The inserted DNA would normally code for genes that have been identified to produce a defined product or enhance its production further. As such, some GMOs will possess increased production of a compound of interest, however this will be characterised by this stage including any toxicology and human health risk.

The work does not involve specifically the modulation or investigation of genes coding for pathogenicity determinants;
rather, it involves genes involved in producing valuable compounds such as human pharmacological compounds.
Scale up of production of the compound may be undertaken, but only once the compound has been identified and
evaluated for toxicity at a very small scale.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste that is contaminated with bacteria (including the parent strain and the GMO) will be autoclaved (heating with steam under pressure at >121°C for 15 minutes) to achieve 100% kill before removal from the containment facility. This will be monitored by taking samples from the autoclaved waste (e.g. from small liquid cultures) onto solid growth medium with incubation to allow any viable bacteria to grow into visible colonies, and reviewed by the GM safety committee at quarterly intervals. The autoclave used for processing is validated annually. All processed solid waste will be transferred to an authorised Waste Management provider where waste will be processed via incineration.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The safety committee discussed the potential for modulation of pathogenicity by genetic manipulation procedures, but agreed that such modulation would most likely result in no change or reduced pathogenicity, although scientists will be vigilant for changes to pathogen characteristics. In addition, current working practices are sufficient to prevent exposure.

Our screening platform allows the phenotypic identification of producer clones by co-culture with indicator or reporter cells in very small volumes (<1nl) and are screened for desired phenotypes such as antimicrobial activity or specific killing of a cancer cells. The small volume and nature of the phenotypic screen makes it extremely unlikely we would isolate increased pathogenic strains or those producing toxins. Scale up only occurs once the clones have been characterised genetically by sequencing and metabolically by Mass-spectrometry of the compounds produced. This massively reduces the risk of toxin production or strains that show enhanced pathogenic traits being isolated and cultured. Strains used are isolated from environments that individuals are commonly exposed to, such as soil or skin surface swab and are thus unlikely to infect healthy individuals.

Give brief details of the genetic modification safety committee

The Axol Bioscience Ltd genetic modification committee will consist of:
1. The Biosafety Officer who has extensive experience of genetic modification issues, being currently in charge of biosafety for a large research institute. The biosafety officer will chair all genetic modification committee meetings.
2. The Director of Operations has over 8 years experience of genetic modification in E.coli and mammalian cells, and previously ran research groups both in industry and academia. His function on the committee is to advise, provide the necessary resources for the actions of the committee and ensure that the actions are implemented.
3. Research & Scientist who is a specialist in mammalian cell culture has over 4 years experience. She will provide advice and write the minutes of the meetings.

The committee will meet every 6 months to review biosafety and whenever a new risk assessment is required. The first meeting will review the existing risk assessments.

**For activities involving GMMs, describe the waste management measures which will apply to the activity**

### GENERAL

All biological waste including reagents (cell culture media, washings, etc.) and materials (consumables such as pipettes, culture vessels, etc.) that have had contact with the organisms, GMM or otherwise, are contained within yellow sacks or in labelled yellow clinical bins and exit from the facility by 'controlled waste transfer' via a validated, contracted waste disposal party (Grundon Waste Management LTD). All contained organisms are rendered waste by HI041 pre-treatment and inactivation with a minimum of 24hrs to ensure 100% kill as per manufacturer's instructions and advice.

**SOLIDWASTE**

We intend to adopt similar waste disposal procedures used by the Babraham Institute (GM105) and other companies on the Babraham Research Campus (BRC) under derogation (GM105.1): Waste from laboratories carrying out GM work at Class1 will be placed into either yellow sacks (18kg, EWC Code 180103) or 60 litre yellow Clinical Poly Bin (EWC Code 020202) as appropriate. They will be sealed by the producer of the waste and removed to a central, lock secured collection point where they will be placed into 770 litre yellow bin (EWC Code 180103). Collections by the local registered clinical GM waste incinerator contractor (Grundon Waste Management LTD) will be made once a week to prevent a build-up. The Chesterford Research Park has 24/7 Security & Surveillance. The contractor uses solid bodied transport for waste transfer to the Colnbrook Clinical Incinerator (Berkshire SL3 0EG), and carries portable disinfection equipment in case of any spillage. Autoclave facilities will be maintained on site, as required by the Regulations, in case of IOSs of the contractor's facilities.

**LIQUIDWASTE**

Liquid waste is inactivated by the addition of HI041 (CHEMGENE, tested under EN protocols, biodegradable under OECD conditions) according to the manufacturer's instructions prior to disposal. Validation experiments will be carried out in-house using microbiological testing. Smaller volumes (i.e., <10ml) will then be disposed of in sealed tubes with the solid waste. Larger volumes will be disposed of via the common drainage system. This results in approximately 5 l of diluted, inactivated waste from each laboratory involved in GM activities. This treated liquid waste is then processed through our own sewage treatment plant which is closely monitored. The total eHluent volume from the Chesterford Research Park site is approximately 110,000 cubic metres per day.

**Project Additional Information**

**Purposes of the contained use**

Induced pluripotent stem cells (iPSCs) are genetically reprogrammed somatic cells which exhibit a pluripotent stem cell-like state similar to embryonic stem cells. iPSCs can be derived by inducing selected gene expression via various methods including retrovirus-mediated gene transduction and chemical induction.

**Recipient or parental organism**

Recipient experimental systems are human peripheral blood mononuclear cell (PBMNC), fibroblasts or other somatic cell types. SeV vectors used in this kit consist of viral proteins NP, P, M, F (activated), HN, and L, and the SeV genome RNA, from which the F gene is deleted. Because SeV infects cells by attaching itself to cell surface receptor sialic acid, present on the surface of many cell types of different species, the vectors are able to transduce a wide range of cell s. However, they are no longer capable of producing infectious particles from infected cells, because the
viral genome lacks the F-gene. In addition, the presence of functional mutations such as temperature sensitivity in the amino acid sequence of several SeV proteins (SeV(TS F, SeV(TS12 F, and SeV(TS15 F) renders the vectors easily removable from transduced cells.

SACGM containment classification: Level 2

Host/vector system

The CytoTune TM_iPS 2.0 Sendai Reprogramming Kit is a non-integrating system that uses Sendai virus (wild type ACDP 1) vectors to reprogram somatic cells into induced pluripotent stem cells (iPSCs). The CytoTune TM_iPS 2.0 Sendai Reprogramming Kit contains three CytoTune ™ 2.0 reprogramming vectors that are used for delivering and expressing key genetic factors necessary for reprogramming somatic cells into iPSCs (see below).

CytoTune® Sendai hOct3/4 (Human Oct3/4 ; NM_002701.4) Pluripotency
CytoTune® Sendai hSox2 (Human Sox2; NM_003106.2) Pluripotency
CytoTune® Sendai hKlf4 (Human Klf4; BC029923.1) Proliferation
CytoTune® Sendai hc-Myc (Human c-Myc; K02276.1) Proto-oncogene, Proliferation

Origin & function

Human transcription factor genes used to reprogram human fibroblasts and PBMCs to produce iPSCs including:
- Oct4
- Sox2
- Klf4
- c-Myc (a known oncogene linked with several forms of cancer)

Sendai virus vector is a Cytoplasmic RNA vector. Sendai virus vector replicates its RNA genome and produces proteins exclusively in the cytoplasm. It does not enter cell nucleus. In principle, the virus should not alter the chromosomes in the cell nucleus.

Evaluation of foreseeable effects

SeV vectors used in this kit consist of viral proteins NP, P, M, F (activated), HN, and L, and the SeV genome RNA, from which the F gene is deleted. Because SeV infects cells by attaching itself to cell surface receptor sialic acid, present on the surface of many cell types of different species, the vectors are able to transduce a wide range of cells. However, they are no longer capable of producing infectious particles from infected cells, because the viral genome lacks the F-gene. In addition, the presence of functional mutations such as temperature sensitivity in the amino acid sequence of several SeV proteins (SeV(TS F, SeV(TS12 F, and SeV(TS15 F) renders the vectors easily removable from transduced cells.

Regarding the sequences being carried by this vector, some transcription factors are oncogenic e.g. c-Myc is a known oncogene linked with several forms of cancer, therefore to minimise any potential risk of this oncogene getting into those working with this system use SACGM containment Level 2

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Instead of autoclaving waste in the building, we propose to follow the procedure used by the Babraham Institute described in their disposal notification GM1 05/4. 1 (see also above section 6 above for description). Reasons for

02/03/2022
adopting this method of waste disposal are:
1. We the company were prior tenants at the Babraham Institute & Research Campus and adherents to their waste management & disposal procedures and policies.
2. We do not have access to a waste autoclave within our facility or in the building area.
All liquid waste material will be inactivated by treatment with between 1-5% (w/v) "HL04L" solution prior to disposal.
Solid waste material will be placed in sealed plastic bags or bins and incinerated by an off-site incineration company (Grundon Waste Management LTD).
Waste from our GM work at Class1 will be placed into suitably labelled hermetically sealable 18kg yellow plastic bags or 60 litre bins. Sealed bags and bins are placed into a secondary 770 litre yellow bin in a secured and under surveillance enclosure. Contents and weight of the bin are recorded and collections by the local registered clinical/GM waste incinerator contractor will be made one times a week to prevent a buildup. The Chesterford site has 24/7 Security & Surveillance. The contractor uses solid bodied transport and carries portable disinfection equipment in case of any spillage. Autoclave facilities will be available in an adjacent building, as required by the Regulations, in case of loss of the contractor's facilities. The type of container and the secondary container means that the risk of any spillage of active GM waste on site is negligible. However, as active waste will leave the site, the risk to the environment and health is possibly marginally higher than autoclaving prior to incineration. The only real risk of release would be as a result of a major RTA, however, the containers are designed to withstand this. This disposal method is expected to achieve 100% inactivation of the GMM.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

See above 11.

Furthermore;
GENERAL
ALL biological waste including reagents (cell culture media, washings, etc.), materials (consumables such as pipettes, culture vessels, etc.) that have had contact with the organisms, GMM or otherwise, are contained within yellow sacks or in labelled yellow clinical bins and exit from the facility by 'controlled waste transfer' via a validated, contracted waste disposal party (Grundon Waste Management LTD). ALL contained organisms are rendered waste by HL04L pre-treatment and inactivation with for a minimum of 24hrs to ensure 100% kill as per manufacturer's instructions and advice.

SOLID WASTE
We intend to adopt similar waste disposal procedures used by the Babraham Institute (GM105) and other companies on the Babraham Research Campus (BRC) under derogation (GM105/04.1): Waste from laboratories carrying out GM work at Class1 and 2 will be placed into either yellow sacks (18kg, EWC Code 180103) or 60 litre yellow Clinical Poly Bin (EWC Code 020202) as appropriate. They will be sealed by the producer of the waste and removed to a central, lock secured collection point where they will be placed into 770 litre yellow bin (EWC Code 180103). Collections by the local registered clinical/GM waste incinerator contractor (Grundon Waste Management LTD) will be made once a week to prevent a build-up. The Chesterford Research Park has 24/7 Security & Surveillance. The contractor uses solid bodied transport for waste transfer to the Colnbrook Clinical Incinerator (Berkshire SL3 OEG), and carries portable disinfection equipment in case of any spillage. Autoclave facilities will be maintained on site, as required by the Regulations, in case of loss of the contractor's facilities.

LIQUID WASTE
Liquid waste is inactivated by the addition of "HL04L" (CHEMGENE, tested under EN protocols, biodegradable under OECD conditions) according to the manufacturer's instructions prior to disposal. Validation experiments will be carried out in-house using microbiological testing. Smaller volumes (i.e. <10ml) will then be disposed of in sealed tubes with the solid waste. Larger volumes will be disposed of via the common drainage system. This results in approximately 5
litres of diluted, inactivated waste from each laboratory involved in GM activities. This treated liquid waste is then processed through our own sewage treatment plant which is closely monitored. The total effluent volume from the Chesterford Research Park site is approximately 110,000 cubic metres per day.

The scope and particular aspects of safety risks described in the risk assessment were agreed upon, and satisfactory consensus was achieved regarding the adequacy of the SOPs, COPs and risk management planning protocols. Pending notification and acknowledgement by relevant authorities.

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Give brief details of the genetic modification safety committee:
The committee is a sub-committee of the Health & Safety Committee and consists of key representatives from sub-sections of the company involved in GM Organism work. The committee is chaired by a senior member of the scientific staff.
The committee will meet not less than four times per year to review the use of GMOs.

Other (please specify) Tick if confidential

Bacteriology Yes Parasitology Transgenic Birds Microbiology Research Yes
The class 1 GMMs that will be generated by Cerevance Ltd will be destroyed by the following regime. All laboratory waste (for example gloves, used plastic ware, pipettes, and anything other potentially contaminated material) will be subject to autoclaving before leaving the premises. Autoclaves are validated yearly by an independent contractor. Solid waste is then sent on site for incineration. In the case of liquid waste, a certified laboratory disinfectant (for example HDL4) will be used to inactivate material overnight before disposal via a designated sink. Bench tops are impervious to water and are resistant to moderate heat and the chemicals used to decontaminate work surfaces and equipment. For minor spillages it is anticipated that a solution of 70% industrial methylated spirit will be used to decontamination - any resultant solid waste will be autoclaved before leaving the building. The laboratory is designed so that it can be easily cleaned. Floors are sealed and impervious to liquids. Laboratory furniture is capable of supporting anticipated loading and uses. Spaces between benches, cabinets, and equipment are accessible for cleaning. Protective laboratory coats, designated for lab use are worn while in the laboratory. This protective clothing is removed and left in the laboratory before leaving for non-laboratory areas (e.g., cafeteria, administrative offices). All protective clothing is either disposed of in the laboratory or laundered by the company. Gloves are worn when working with any material or equipment. Gloves are changed frequently or when known to be contaminated and disposed of as solid waste. Gloves are not used for touching "clean" surfaces (keyboards, telephones, etc.), and they are not worn outside of the laboratory. Hands are washed following removal of gloves and before leaving the laboratory environment.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment
The proposed class 1 activities fall into two categories. The first is the use of attenuated commonly used fully verified commercial non-pathogenic laboratory strains of bacteria for generating plasmid DNA or the expression of non-toxic proteins. The bacteria represent a negligible risk to laboratory staff, the public and the environment. The second is the use of commonly used fully verified commercial laboratory level 1 mammalian cell lines that may be used to exogenously express proteins that are not known to be harmful to humans or the environment. These cell lines can not survive outside of the laboratory environment and represent a negligible risk to laboratory workers, the public and the environment. The methods for inactivating/killing the material will ensure no viable material leaves the laboratory.

**Purposes of the contained use**

The purpose of this project is to validate positive and negative modulators of cellular processes that might be useful drug targets that work to delay or halt Neuroregeneration, the process that underlines a number of diseases including dementia. These positive and negative modulators will be identified through a druggable RNAi high content screen in a human non-neuronal cell line that is currently being performed by an outside academic collaborator. Selected targets will be further assessed by looking at their effects in neuronal and non-neuronal cells. To ensure that the targets affect specific cellular processes each of the selected RNAi targets will also be coexpressed with a fluorescent protein (FP) reporter that is directed to a specific organelle. It is expected that depletion will not necessarily cause any major alterations in unstressed neurons. Target dependent depletion through RNAi will have to be performed in a disease relevant model. For this, a lentiviral construct containing a FP tagged or untagged human Neuro degeneration relevant disease mutation or Neurodegeneration disease relevant RNAi will be combined with the RNAi dependent
depletion of the relevant positive/negative regulator. Through this strategy, it is hoped that the identity and validity of one or more targets that may be useful targets for the treatment of Neurodegeneration can be determined. This work will involve the use of particles of lentiviral origin and so require containment to minimise the risk of exposure to both humans and the environment. It should be noted that we will be using third generation lentiviral self inactivating replication defective (SIN-RD) lentiviral particles. The fact that four different plasmids are required to generate these SIN-RD lentiviral particles reduces the risk even further. Nevertheless according to current statutes and as a precautionary measure, all generation and application of virus will be done under Level 2 containment.

Recipient or parental organism
Mammalian cells

Host/vector system

Lentivirus vectors: These are generated using a third generation production system. This uses four plasmids that will include modified versions of pRRL, pMDLgp-RRE, pRSV-REV and PMD2-VSVG. Env. The latter three are the minimum structural genes required for the production of the Self In-Activating (SIN) replication defective lentiviral particles in HEK293T cells that are commonly used for the packaging of lentiviral particles in laboratories. The target shRNA/miRNA or protein encoding gene will be inserted into the modified pRRL vector. This modified vector will have the following safety features: a deletion in the 3’ Long Terminal Repeat (LTR) making it SIN in the infected cells, the LTR containing plasmids Lentivirus vectors: pMDLgp-RRE, pRSV-REV and PMD2-VSVG. Env. The tat promoter has been replaced by a Polymerase Type 2 promoter, making them replication incompetent. The inclusion of these transfected HEK293T. Outside of this setting, viral replication cannot take place and so pose a minimal risk to both humans and the environment. Lentiviral particles are also unstable outside of cell environments or solutions with high protein content at room temperature. Particles are also sensitive to dessication reducing their ability to disseminate. The selected target mammalian cells do not express retroviral elements and due to the replication defective and SIN nature of the lentiviral vectors will not generate viral particles.

Origin & function

The SIN-RD lentiviral particles will contain the following sequences:
1. shRNA/miRNA directed towards the knock down of the expression of a particular endogenous mammalian target (Mouse, Rat, Human). These de novo derived sequences are not derived from an organism and will be designed to only target an individual species. In addition the sequences chosen will not target known oncogenes, tumour suppressors, cell cycle regulators, Immunomodulators and will not be of retroviral origin. Resources that will be used to assess these criteria will include the interrogation of genome wide RNA screens to assess Mitosis and cell death (www.mitocheck.org).

The particles will deliver shRNA/miRNA constructs that will either target one or two genes. For shRNA constructs transcription will be driven by a constitutively active Polymerase III U6 promoter. For some targets shRNA may not represent an effective methodology for knock-down of expression so miRNA constructs prove more effective. This methodology utilises an endogenous cellular mechanism for post-transcriptionlly regulation of target genes. Artificial miRNA sequences are generated using the human miR-30 microRNA cassette under the control of a polymerase II miRNA sequences or an additional protein. The miRNA sequences will be excised by the endogenous cellular machinery before expression of the protein.

2. Fluorescent protein (FP markers which have been identified from a range of different organism; are known to be benign in terms of their effects when expressed in mammalian cells but are essential for visualisation of these cells. When these in addition are fused to a subcellular marker gene, that is expressed only in a particular sub-cellular structure within a cell, will enable the visualisation of a particular process and any changes that occur in response to the knockdown of the expression of a particular gene. Expression of the FP will be either under the control of a CMV promoter which is constitutively active and commonly used in biological research or a promoter that only allows expression in neuronal cells.

3. Human disease relevant mutated gene expression which is intended to recreate a certain aspect of disease pathology. It is expected that its expression will be cytotoxic but will not be a growth factor (which does not include trophic factors), confirmed oncogene, tumour suppressor gene (TSG), cell cycle regulator or immunomodulator, and none of them will be of retrovirial orgin. Expression of these mutant proteins will be either under the control of a polymerase II promoter that is either constitutively active or only active in neuronal cells.

Lentiviral production - on site B60CRP or 430CSP
Where lentivirus is not available from the collaborator, lentiviral production will be carried out on-site. Lentiviral production will only be carried on HEK293T cells and will be carried out in a class 2 microbiological safety cabinet within a Biosafety level 2 laboratory. The HEK293T cells used for lentiviral production will be seeded in filter containing screw cap culture flasks in order to minimize the risk of spills and/or aerosol mediated viral spread. The modified pRL plasmid containing the necessary shRNA/miRNA & protein encoding sequences together with the chemical or lipid based transfection reagent (e.g. Polyethyleneimine (PEI), Lipofectamine) into the HEK293T packaging cell line. After 6-12 hours, the medium is replaced with fresh serum-free medium. (e.g. Neurobasal medium with 2% B-27 supplement and 1X Pen/Strep) and grown for an additional 72-96 hours. After 24-48 hours, sufficient to ensure the viability of the transfected HEK293T cells, medium from the cells is collected into screw cap tube and stored at 4°C and fresh serum-free medium is added to the cells. The cells are grown for an additional 24-48 hours before the second medium solution is added to the first harvest tube. All plastic ware and solutions will be treated as if contaminated.

Still within a Biosafety level 2 microbiological safety cabinet in a Biosafety level 2 laboratory, the harvested supernatants will be filtered using a 0.45 um filter before either being dispensed as aliquots or further purified by chromatography and/or concentrated by centrifugation. For certain application the lentiviral particles will need to be concentrated. The lentiviral particles may need to be purified be either chromatography (e.g. ViraBind™) and eluted in a high salt solution (50mM Tris, pH 7.5, 5 mM MgCl2, 2 M NaCl) and/or concentrated by ultrafiltration (e.g. LentiSelect™). For certain application where a highly concentrated, highly purified virus may be required, the traditional method of sucrose cushion based centrifugation may be necessary. To minimise the possible risk of accidental viral contamination and spread due to the need for an ultracentrifuge, all loading and unloading will be done in the Biosafety level 2 cabinet. Once the sucrose cushions have been added to the centrifuge tubes, they will be transferred into the Biosafety level 2 Safety Cabinet. The unpurified or chromatography purified lentiviral particles will then be added to the sucrose cushion. The tubes will then be transferred to their respective bucket holders and the bucket sealed using their respective screw caps and marked as containing virus. The bucket will then be transferred to a weighing scale and a counterpart bucket and centrifuge with water (and without lentivirus) will be prepared that is weight matched. The balanced buckets will be transferred to the rotor before being placed within the centrifuge chamber. The ultracentrifuge will be run at 70000g for 2 hours at 20°C. Upon return of the bucket to the Biosafety level 2 cabinet, the supernatant will be removed from the tubes before transfer of the resuspended virus pellet into individual screw cap cryovials. As the greatest risk for contamination occurs within the centrifugation bucket itselfs then during transport to and from the weigh scales and ultracentrifuge, not only will the centrifuge tubes but also the buckets decontaminated with DISTEL 10% and 70% isopropanol before removal from the Biosafety level 2. In any case, at no point will concentrated virus stock be exposed to outside of the Biosafety level 2 hood environment.

The lentiviral titre will be determined in terms of the number of viral particles (VP) or Transduction units (TU) per ml. Assessing the number of VP can be assessed relatively quickly and does not involve cell infection. In this case, a bead based enrichment assay (e.g. QuickTitre™ Quantification Kit) or a p24 ELISA assay (e.g.QuickTitre™ Lentivirus Titre Kit).will be chosen. The VP quantification methods tends to overestimate the TU by 10-100 fold. Thus, the TU/ml will in certain instances also be determined. For this, a titration range of lentiviruses expressing a fluorescent tag, serial dilution will be prepared and added to a 24 well cluster plate of T25 TC-flasks containing HEK293T for 48 hours. The percentage of fluorescent positive cells will be quantified manually under a fluorescent microscope or ideally using FACS analyser. The biological titre (TU/ml) according to the following formula: TU/ml = (P x N/100 x V) x 1/DF, where P=% GFP+ cells, N=number of cells at time of transduction =105, V=volume of dilution added to each well and DF=dilution factor.

Aliquots with not more than 1x108 viral per viral are subsequently stored at -80°C in individual screw capped cryotubes. The viral stock will consist of viral particles containing the vector genome (full capsids) and also of a variable number of empty viral capsids. Other trace components that might be present include, but are not limited to inorganic salts, vitamins, other nutrients, human cellular proteins, carbohydrates, amino acids, and fats.

Assessment of effects
Assessing whether the knock down has worked in neurons can be challenging. Consequently, initially the RNAi depletion of the target gene (using the FP tagged verison followed by the RNAi sequence) will be assessed in immortalised cell lines (mouse NIH/3T3 and human HEK293T and human HEK293T). This work will be done initially at Biosafety level 2. In order to determine whether the knock-down has worked; the levels of mRNA and protein will be assessed post-transduction, using suitable in vitro assays, including for example, RT-PCR, Western Blotting, and immunocytochemistry. These results will subsequently be confirmed on neurons such as those derived from human induced Pluripotent stem cells (iPCs) using immunocytochemistry.

The correct distribution and perturbed cellular functions of the relevant human Neurodegenerative disease mutations will also be assessed by subsequent
Immunocytochemistry and Bioenergetic analysis (using Seahorse™). Other physiological parameters, including, for example, the release of specific neurotransmitters from neurons or the expression of related proteins will be measured using suitable in vitro assays, including, for example, ELISA, PCR, neurite outgrowth, electrophysiology, and neuroprotection assays. In some instances, the vectors might need to be studied in rodent neuron-glial co-cultures in order to investigate the interaction between these two cell types.

Evaluation of foreseeable effects

Human health hazards

The method by which the lentivirus vector is produced means that it is highly unlikely that RCL can be generated even if an infection occurs in a person who is HIV-2 positive. Infection can lead to a permanent transduction of cells and the possibility of a harmful event either by transactivation or disruption of gene expression can not be ruled out. For this reason the work with stock viral aliquots will be conducted as a class II activity. Oral ingestion will be prevented by involving lentivirus particle-containing liquid may lead to transduction of a limited number of the laboratory worker's skin or mucosal cells with modified viruses. However, these modified virus particles carry an extremely low safety risk for human health, as they are replication-incompetent, and also because the particles carry an extremely low infection potential via the mucosal/skin routes, due to the inherent properties of the viral vectors. Moreover, the genes/proteins of interest that will be targeted by shRNAs do not include any growth factors, confirmed oncogenes, cytotoxins, or immunomodulators, and none of them are of retroviral origin. The mutant genes express proteins known to be cytotoxic to neurons but it is highly unlikely such cells would be transduced via the mucosal or skin routes. In the unlikely event of accidental transduction of a laboratory worker's skin or mucosa by lentivirus, this will be self-limited due to natural shedding of superficial epithelial skin and mucosal cell layers.

The most likely route of accidental infection with a lentivirus will be via inadvertent percutaneous inoculation. The likelihood of this occurring will, however, be minimised by adhering to appropriate risk management measures. Infection of the community at large with lentivirus particles is highly unlikely due to the viral vector particles being replication incompetent and being extremely sensitive to desiccation.

Hazard to the Environment

The chance that active viral particles will be accidentally released into the environment is considered to be highly unlikely, as effective containment procedures will be adhered to. However, in the unlikely event that active viral vector particles do accidentally get released into the environment, the safety risks posed by such an event is considered to be negligible, due to the vectors being self-inactivating and non-replicative. The main potential risk in such an event would be the subsequent contamination of a human population already infected with HIV, which would potentially allow for recombination events that could incorporate the inserted sequences into a viable RCL. This scenario is, however, extremely unlikely, and even if it was to occur, it is unlikely that the vectors could survive long enough in the environment to pose a risk if accidentally released.

Furthermore, lentiviral vectors have a short half-life at room temperature due to their structural characteristics making them highly susceptible to dehydration, and relatively unstable. For this reason, retroviruses become rapidly inactivated outside host systems, and this is illustrated by the fact that close contact is required for transmission. They can, however, survive for long periods in high protein media.

There are no conceivable hazards associated directly with the lentiviral vectors (containing the inserts) as they will not replicate/survive outside the laboratory and they have been designed to include many protective safety features. shRNA and miRNA sequences will also not survive as they are highly unstable, and they would, consequently, be rapidly inactivated/degraded if accidentally spilled into the environment. Moreover, as discussed above, there is a very low risk that the sequences contained within the viral vectors could be transferred to other organisms, as a rare recombination event would have to occur to allow this to happen.

Summary

The chance that active viral particles will be accidentally released into the environment is considered to be highly unlikely, as the viral vector studies that will be undertaken have been classified as Biosafety level 2, and effective containment procedures will be adhered to (see section C for details). However, in the unlikely event that active viral vector particles do accidentally get released into the environment, the safety risks posed by such an event is considered to be low due to the vectors being self-inactivating and non-replicative, and also due to the poor ability of the vectors to survive outside of their host systems (see above discussions).
### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Following transduction of cell lines that are designated as requiring Biosafety Containment Level 1 with lentivirus we wish to be able to use these cells at Biosafety Containment Level 1. This can be justified by the following procedure: under Biosafety Containment Level 2 media containing virus will be removed, the transduced cells will be extensively washed to remove any remaining virus. This liquid waste will be neutralised for at least 24 hours before disposal. The washed cells will then be cultured for a further 24 hours before being tested for the absence of infectious virus before being allowed to be treated as only requiring Biosafety Containment Level 1.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

- **General waste handling procedures:**
  - Solid waste will be neutralised by soaking it in a validated disinfectant solution (Virkon* or Distel) for at least 24 hours, after which the material will be 'double bagged', autoclaved and, ultimately, incinerated offsite.
  - At B60CRP, liquid waste will be disposed of into sealed biohazard containers filled with Virkon* for incineration. It will be routine practice that all liquid waste material be neutralised for at least 24 hours before disposal, and for the neutralised waste to be transported in leak-proof containers to prevent spillages. At 430CSP, liquid waste will be inactivated by Virkon* for 24 hours prior to drain disposal via a designated sink.

  *Virkon*
  - Rely+On™Virkon® is a multi-purpose disinfectant. It contains oxone (potassium peroxymonosulphate), sodium dodecylbenzenesulfonate, sulphamic acid; and inorganic buffers. Virkon oxidizes key structures and compounds such as proteins, leading to widespread, irreversible damage and subsequent deactivation/destruction of the microorganism. It is typically used for cleaning up hazardous spills, disinfecting surfaces and soaking equipment. With powerful, proven performance against over 500 strains of viruses, bacteria and fungi. Virkon offers a broad spectrum efficacious anti-microbial activity, and it is used by governments worldwide for Emergency Disease Control. Importantly, Virkon is sold as a powder which dissolves readily in water. It is intended to be mixed with water to form a 1% solution (i.e. 10g per litre) for hard surface and equipment disinfection. 1:100 is also the dilution rate advised for virucidal efficacy against HIV-1.
  - The product has a pink colour, which is useful in that it helps to guage the concentration of a prepared solution, and importantly, as Virkon ages, it discolours, making it obvious when it needs to be replaced. The solution is generally stable for five to seven days. Moreover, there is no evidence to suggest that bacterial disease-causing organisms develop resistance towards Virkon, as opposed to some other disinfectant products. Moreover, Virkon is not classified as R53, it is classified as readily biodegradable, and it does not persist in the environment.

  *Distel (formally Trigene advance)*
  - Distel is formulated as a nanoemulsion that enables the active molecules in the product to be carried rapidly through cell walls of micro-organisms, ensuring the rapid induction of cell death in treated micro-organisms. Distel works quicker than concentrated high level disinfectants and achieves apoptosis (cell death) rather than merely suspending activity as with conventional disinfectant products. Distel has been reported to be bactericidal, fungicidal as well as virucidal and sporicidal. It is recommended to be used at a 1:200 dilution for general purposes, 1:100d for high risk areas, and 1:50 for disinfection of blood and bio-hazard spillages.

**Summary**

As any active viral particles on surfaces or in waste material will be completely inactivated at the end of each experiment by the highly effective cleaning/disinfection protocols outlined above, it is considered highly unlikely that active virus particles would unintentionally become discharged into a sanitary sewage system. No forseeable adverse effects on human health and safety are expected.

---

**Is an emergency plan required according to regulation 20?**  N

**If yes, tick to confirm that it is attached to this form**  N
The GMSC has agreed that the production and handling of virus stocks is a Class 2 activity. This decision has been reached because although the lentivirus will be generated using a third generation, self-inactivating, 4 plasmid expression system, the possibility of a recombination event occurring that leads to replication competent virus can never be discounted with this type of virus. The potential oncogenic effects of the Woodchuck Post-transcriptional Regulatory Element have been negated by the use of the mutant form that prevents expression of the X protein. The production of large amounts of virus represents the most hazardous aspect of the proposal and the GMSC is satisfied that the necessary precautions have been put in place to ensure containment is maintained. Some of the proposed nervous system. The procedures put in place to ensure containment is maintained. Some of the proposed lentivirus will encode for proteins that are known to have neurotoxic effects and cause diseases of the human central nervous system. The procedures put in place will effectively prevent any chance of virus being delivered to the necessary tissues within a human in sufficient quantities to represent a hazard to human health. The FP and shRNA/miRNA encoded by the other lentivirus are not known to pose any inherent risk to human health or the environment. The proposed targets to be knocked down in this study also pose no known risk. The request to derogate the Biosafety Containment Level from 2 to 1 post transduction has been deemed acceptable given that the transduced cells will be washed extensively to remove any remaining viral particles and will be tested for the absence of transducing virus. It has been made clear that human iPSC cell lines that have been generated using lenti- or retrovirus methods tested negative for the absence of virus at least. These cells will always be tested for the absence of infectious particles before they can be used as if they only required Biosafety Containment Level 1.

Project Ref  3043/14.3

Lentiviral siRNA knockdown studies to identify and validate drug targets for psychiatric and neurodegenerative diseases

Date Ackn'd  02/12/2016
Date Project Ceased

Class 2
Consent Granted

Project notified under transitional arrangements  N
The lentiviral siRNA knockdown studies that will be carried out as part of this body of work will be focused on discovering the role of specific proteins in both physiological and pathological eNS processes, with the overarching aim of identifying and validating potential new drug targets for psychiatric and/or neurodegenerative diseases. The proteins that will be selectively knocked down by lentivirally expressed siRNA will include those that have been either directly or indirectly linked to relevant eNS disease states; and, in most cases, the targeted proteins will play a role in well characterised relevant disease-related biologicaVpathological processes. Relevant neurodegeneration related processes, for example, are likely 10 include, bioenergetics, oxidative stress, neure-inflammation, protein misfolding, excitotoxicity, and autophagy. Psychiatric disease related protein targets, on the other hand, are likely to play a role in neurogenesis, neural plasticity, or the functioning of one or more disease-linked neurotransmitter systems.

Importantly, the genes/proteins of interest that will be targeted by siRNAs do not include any growth factors, confirmed oncogenes, tumour suppressors, cell cycle regulators, cytotoxins, or immunomodulators, and none of them are of retroviral origin. All selected targets will be presented to the GMSC for approval.

Methods
The approach to be taken will be the application of lentiviral vectors to cell lines that are deemed biosafety level 2 or lower, including well characterised immortalised cell lines that are known not to contain lentiviral genetic material, and human induced Pluripotent stem cells (iPSCs). The lentiviral vectors will either express siRNA transcripts targeting specific mRNAs/proteins of interest, or with vectors expressing scrambled siRNAs, in the case of the negative control treatment groups. The extent of mRNA and protein knockdown that is achieved will then be assessed at different time points (e.g. 24h-48h-72h), post-transduction, using suitable in vitro assays, including for example, RT-PCR, Western Blotting, and immunocytochemistry. Once the conditions that lead to the optimal knockdown of the mRNAs/proteins have been determined, it will be evaluated what effects the knockdown of the proteins have on various physiological parameters, including, for example, the release of specific neurotransmitters from neurons or the expression of related proteins. These siRNA-induced alterations will be measured using suitable in vitro assays, including, for example, ELISA, PCR, neurite outgrowth, electrophysiology, and neuroprotection assays. In some instances, the vectors might need to be studied in neuron-glia co-cultures in order to investigate the interaction between these two cell types.

Description of the lentiviral vectors used for the experiment
Third generation HIV based shRNAmiRNA expressing lentiviral vectors will be produced either internally or sourced from external suppliers, which will include reputable commercial suppliers, and an academic group at the University of Bristol headed by Prof. James Uney. Each aliquot of lentiviral reagent will comprise of a small volume (5 to 301-Jl) that contains no more than 1x10e08 viral particles. Post-transduction of target cells, the vectors will
produce both a shRNmiRNA targeting the mRNAs of a protein of interest, and a reporter protein to facilitate the identification of transduced cells.

Recipient or parental organism
Mammalian Cells

Host/vector system

Vector system = self inactivating (SIN) non replication-competent HIV based lentiviral vectors

Health and Safety

Executive

The viral vectors that will be used in the proposed studies are third generation self-inactivating (SIN) non replication-competent HIV based lentiviral vector systems, which have been designed to produce stable gene expression in mammalian cells; and they are generated by co-transfecting a suitable immortalized packaging cell line (e.g. HEK 293T cells) with four separate plasmids. Each of the plasmids used (described below) expresses a different set of genes, and all of the genes from the different vectors, when combined (following co-transfection), provide the smallest possible set of essential viral genes that is SIN compatible with virus production. Moreover, the resultant vectors are all vesicular stomatitis virus (VSV-G) pseudotyped lentiviral vectors, which are self-inactivating and highly unlikely to undergo recombination. Importantly, the viral vector system is inherently incapable of replication in mammalian cells. Only in a patient with HIV could any form of recombination occur, i.e. the probability of the production of replication competent lentiviral vectors (RCL) is very small.

The plasmids

The sequences that are required to generate the viral vectors are sub-cloned into 4 standard bacterial plasmid vectors. The transgene expression plasmid will contain the transgene that codes for a relevant siRNA sequence and/or a transduction marker protein (e.g. GFP), while the other 3 packaging plasmids will contain 3 different sets of sequences that code for different viral packaging proteins. A brief overview of the 4 different plasmids is provided below:

Plasmids containing the transgene of interest

The transgene expression plasmid will contain the sequences that code for the siRNA transcript that will target a specific mRNA/protein of interest (or a scrambled siRNA in the case of the negative control), and also for a transduction marker protein. Control viral vectors that express only a marker protein and no siRNA will also be used in some experiments, and the corresponding plasmids for these vectors will only contain the sequence coding for the marker protein. Depending on the knockdown strategy taken, either shRNA or miRNA based constructs will be used to express the artificial siRNA sequences. In some of the constructs used, siRNA and marker protein sequences will be expressed as two separate transcripts under the control of Ivo separate promoter elements. In other instances, siRNA and marker protein expression will be under the control of a single promoter system. The promoter elements used to control transgene expression will vary depending on the specific plasmid that is employed. Only well characterized promoter systems will, however, be used to drive transgene expression. These will include the H1, U6 small nuclear, cytomegalovirus (CMV), elongation factor 1 alpha (EF10), phosphoglycerate kinase (PGK), ubiquitin C (UbC), and murine stem cell virus (MSCV) promoters; or in instances where siRNA expression in a specific cell subtype is desired, polymerase III promoters such as the synapsin I (SynI), neuron specific enolase (NSE), tyrosine hydroxylase (TH), calcium/calcmodulin-dependent protein kinase II (CamKII), or glial fibrillary acidic protein (GFAP) promoters.

Additionally, all of the transgene constructs will contain the WPRE, cPPT, RRE, and 41 sequences, as well as the modified LTR, and these sequences are the only other coding sequences (apart from the siRNA and transduction marker proteins) that will be present in the viral vectors. The latter elements are important for the expression of the
shRNA in targeted cells, and they will all be stably expressed in infected cells.

Plasmids containing the packaging related sequences
The three other plasmids that make up the 4 plasmid system will each contain a different set of sequences that code for proteins that are required for production and packaging of the viral vectors. Gag-pol will be expressed by one of the plasmids, rev by a second, and VSV-G by a third, and the latter proteins will only be provided in trans during the production phase. The specific packaging plasmids that will be used will vary depending on the packaging system that is employed. Only well characterized packaging plasmids will, however, be used in all cases. For example, in one system, gag-pol, rev and VSV-G will be expressed separately by pMDLgp-RRE, pRSVREV, and pMD2-VSVG.env packaging plasmids, respectively, whereas, in a second, they will be expressed by pPACKH1-GAG, pPACKH1-REV, and pVSV-G, respectively. Importantly, all of the above genes, that are essential for production of fulllength viral particles, have been removed from the expression plasmids containing the transgenes of interest. The 4 plasmids used in the system have also been engineered so as to have no common sequences, which greatly reduces the risk of a recombination event that would result in the insertion of production/packaging genes into the transgene expression plasmid.

The expression systems and the transgenes that comprise the lentiviral vectors that will be used have a very low risk for human health and safety, and the reasons for this are discussed below.

Lentiviral Vector Expression System
Lentiviruses belong to the Retroviridae virus family, a diverse and extensive family of viruses, which are capable of infecting both human and animal species. Retroviruses are characterised by a unique replication mechanism involving reverse transcription of the viral RNA genome, which gives rise to a DNA provirus that contains two positive sense copies of the viral RNA genome; and in a functional assembled virus, the viral genome is encased within a capsid that is surrounded by a host-cell derived envelope. Cellular entry of the virus involves interactions between glycoproteins contained in the virion's envelope and extracellular plasma membrane proteins on target cells. These interactions are generally specific and are believed to be the principal factor determining which species and type of cells a specific virus is capable of infecting. The binding of a virus's envelope glycoproteins to an appropriate receptor site on a target cell triggers the fusion of the virion's envelope membrane with the plasma membrane of the target cell, which results in the delivery of the virus capsid to the intracellular space of the target cell.

As the lentiviral vector system that will be used in these studies is based on HIV-1, a theoretical risk to human health exists. Retroviruses are, however, generally transmitted via exposure to contaminated body fluids or percutaneous inoculation and, they are, generally, not transmitted via the airborne route. Accidental piercing of the skin or other surface tissues with virus containing objects, therefore, represent the main potential route by which accidental infection could occur. Appropriate risk reduction measures will, however, be implemented to reduce the likelihood of this occurring.

In all of the transgene expression plasmids, the genes of interest are flanked by non-coding retroviral TRs, and no retroviral genes are encoded on the transgene plasmids. Therefore, no retroviral genes will be transferred into generated viral particles. The transgene construct is packaged into particles using an immortalised cell based packaging system, which requires the co-transfection of packaging cells (e.g. HEK293 cells) with three additional separate packaging plasmids (pMDLgp-RRE, pRSV-REV and pMD2-VSVG.env, for example). The latter 3 pJasmids express the envelope protein from VSVG and the non-structural proteins of the virion, and, importantly, none of these genes will be transferred into the assembled viral vectors, since they lack the packaging signal (+), which is only present on the transgene containing plasmids.

The lentiviral Expression System that will be used include the following key safety features:
All of the lentiviruses will be generated using a 4 plasmid/3 retroviral gene (gag, pol, rev) system, which yields replication-incompetent vectors that are devoid of all viral sequences, apart from essential cis-acting sequences, including the L TRs and the packaging signal '+', and only the transgene plasmids will contain l['1. This system allows for the expression in trans of proteins required to produce viral progeny (e.g. gal, pOl, rev, env) in producer cell lines, which do not contain L TRs or the '+' packaging sequence. None of the retrovirus structural genes will, therefore, actually be present in the packaged viral genome, which means that no new replication-competent lentivirus (RCL) can be produced.

Importantly, following infection of a target cell, lentiviral vectors are self-inactivating on integration into the host genome. This is achieved because the process of reverse transcription uses the 3' long terminal repeat (3' l TR) as a template to produce the S' l TR. In the transgene expression plasmids that will be used, the U3 region of the 3' l TR has been deleted, resulting in deletions in both 3' and S' L TRs on integration into the host genome. The deletion in the 3' l TR (aU3) does not affect generation of the viral genome in the producer cell line, but results in "self-inactivation" (SIN) of the vector after transduction of target cells, which ensures that the viral genome cannot be released from the host genome.

Moreover, deletion of enhancer and promoter elements from the 3' U3 region in the vector constructs will result in a provirus that is entirely devoid of the U3 enhancer sequences, which will result in a reduction in the potential for transactivation of cellular genes due to an insertion event. Self-inactivating vectors are also less likely to be mobilized following a superinfection with wild-type virus (HIV), and the VSV-G gene from Vesicular Stomatitis Virus is used in place of the HIV-1 or other retroviral envelope genes, obviating safety concerns associated with the use of HIV-1 gp120, which has known pathogenic consequences. Importantly, all of the 4 plasmids used in the system have been engineered not to contain any regions of homology with each other so as to prevent undesirable recombination events that could lead to the generation of a (RCI).

Lentiviral production - on site B60CRP or 430CSP

Lentiviral production will also be carried out on-site. Lentiviral production will only be carried on HEK293T cells and will be carried out in a class 2 microbiological safety cabinet (MSC) within a dedicated Level 2 laboratory. The HEK293T cells used for lentiviral production will be seeded in filter containing screw cap culture flasks in order to minimize the risk of spills and/or aerosol mediated viral spread. For this, a modified pRRL transgene expression plasmid together with three additional separate packaging plasmids (pMDLgp-RRE, pRSV-REV and PMD2-VSVG/env) will be transfected using a transfection reagent (e.g. Polyethylenimine (PEI), Lipofectamine) into HEK293T cells. After 6-12 hours, the medium is replaced with fresh serum-free medium (Neurobasal medium with 2% B-27 supplement and 1X Pen/Strep) and grown for an additional 72-96 hours. After 24-48 hours, so as to ensure the viability of the transfected HEK293T cells, medium from the cells is collected into screw cap tube and stored at 4°C and fresh serum-free medium is added to the cells. The cells are grown for an additional 24-48 hours before the second medium solution is added to the first harvest tube. After lentivirus collection has been completed, the cells in the flasks will be treated with a validated anti-microbial agent (e.g. DISTEL 10% or another equivalent product) for at least 24 hours prior to autoclaving on site. Autoclaved material will then subsequently be incinerated. Still within a Class 2 MSC in a Level 2 Biosafety laboratory, the harvested supernatants will be filtered using a 0.45 micron filter before either aliquotted or further purified by chromatography and/or concentrated by centrifugation. For certain applications, the lentiviral particles will need to be concentrated. The lentiviral particles may need to be purified by either chromatography (e.g. ViraBindTM) and eluted in a high salt solution (50mM Tris, pH 7.5, 5mM MgCl2, 2M NaCl) and/or concentrated by ultrafiltration (e.g. LentiSelectTM). For certain applications where highly concentrated, highly purified virus may be required, the traditional method of sucrose cushion based centrifugation may be necessary. To minimise the possible risk of accidental viral contamination and spread due to the need for
an ultracentrifuge, all loading and unloading will be done in a class 2 MSC. Once the sucrose cushions have been added to the centrifuge tubes, they will be transferred into a class 2 MSC. The unpurified or chromatography purified lentiviral particles will then be added to the sucrose cushion. The tubes will then be transferred to their respective bucket holders and the bucket sealed using their respective screw caps and marked as containing virus. The bucket will be transferred to a weighing scale and a counterpart bucket and centrifuge with water (and without lentivirus) will be prepared that is weight matched. The balanced buckets will then be transferred to the rotor before being placed within the centrifuge chamber. The ultracentrifuge will be run at 70000g for 2 hours at 20°C. Upon return of the buckets to the class 2 MSC, the supernatant will be removed from the tubes before transfer of the resuspended virus pellet into screw cap cryovials. As the greatest risk for contamination occurs within the centrifugation buckets themselves during transport to and from the weighing scales and ultracentrifuge, not only will the centrifuge tubes but also the buckets decontaminated with DISTEL 10% and 70% isopropanol before removal from the level 2 laboratory. In any case, at no point will concentrated virus stock be exposed to outside of the class 2 MSC environment.

The lentiviral titre will be determined in terms of the number of viral particles (VP) or Transduction units (TU) per ml. Assessing the number of VP can be assessed relatively quickly and does not involve cell infection. In this case, a bead based enrichment assay (e.g. QuickTitre™ Quantification Kit) or a p24 ELISA assay (e.g. QuickTitre™ Lentivirus Titre Kit) will be chosen. The VP quantification methods tend to overestimate the TU by 10-1000 fold. Thus, the TU/ml will in certain instances also be determined. For this, a titration range of lentiviruses expressing a fluorescent tag, serial dilution will be prepared and added to a 24 well cluster plate or T25 TC-flasks containing HEK293T for 48 hours. The percentage of fluorescent positive cells will be quantified manually under a fluorescent microscope or ideally using FACS analyser. Aliquots with not more than 1x10⁸ virus per vial are subsequently stored at -80°C in screw capped cryotubes. The viral stock will consist of viral particles containing the vector genome (full capsids) and also of a variable number of empty viral capsids. Other trace components that might be present include, but are not limited to, inorganic salts, vitamins, other nutrients, human cellular proteins, carbohydrates, amino acids, and fats.

Transgene: proteins to be expressed

Health and Safety

Executive

Additional hazards that arise from the properties of the genetic material that will be inserted into the viral vectors and expressed in transfected cells.

A. Transduction Marker Proteins

Only well characterised transduction marker proteins that are not associated with any cytotoxic, immunogenic or oncogenic responses will be employed, including, for example, fluorescent proteins such as GFP, GFPem, YFP, OsRed, mCherry, CFP.

B. shRNmiRNA: Endogenous proteins to be depleted

The proteins that will be selectively knocked down by lentivirally expressed siRNA will include proteins that have been either directly or indirectly linked to psychiatric and/or neurodegenerative disease states; and, in most cases, the targeted proteins will play a role in well-characterised relevant disease-related biological/pathological processes. Relevant neurodegeneration-related processes, for example, are likely to include, bioenergetics, oxidative stress, neuro-inflammation, protein misfolding, excitotoxicity, and autophagy. Psychiatric disease-related targets, on the other, are likely to play a role in neurogenesis, neural plasticity, or the functioning of one or more disease-linked neurotransmitter systems. Importantly, the genes/proteins of interest that will be targeted by siRNAs do not include any growth factors.
confirmed oncogenes, tumour suppressors, cell cycle regulators, cytotoxins, or immunomodulators, and none of them are of retroviral origin. Depending on project objectives and human vs. rodent mRNA sequence homology, siRNA sequences will be designed either to specifically target only the human or mouse/rat mRNA sequence of a target protein, or both the human and mouse/rat sequences.

RNA interference (RNAi)

RNA interference (RNAi) is an antisense technology that exploits a normal cellular antiviral response that acts to inhibit viral protein synthesis through the production of short hairpin RNAs (shRNAs) that bind and target viral double-stranded RNA (dsRNA) molecules for degradation. The shRNA molecules are processed by cellular enzymatic pathways to produce small inhibitory RNA (siRNA) species, and it is the latter RNA molecules that bind and target complementary RNA sequences for degradation by the RNA-induced silencing complex (RISC). With the use of shRNA-expressing viral vector systems, the expression of specific mammalian genes/proteins can be 'knocked-down', in order to study their functions. Potential deleterious effects such as off-target and immunomodulatory responses can be minimised through screening designed siRNA sequences against databases of known mammalian gene/mRNA sequences during the design stage.

MicroRNAs (miRNAs) are endogenously encoded 22-nl-long RNAs that are generally expressed in a highly tissue and/or developmental-stage specific fashion, and they function to post-transcriptionally regulate the expression of target genes. In certain experimental RNA interference approaches, this miRNA system can be harnessed/manipulated to study the functions of specific genes/proteins. The additional benefit is that one can place these miRNA sequences under the control of a Polymerase II promoter in which the miRNA or multiples thereof are co-transcribed with a coding sequence. For example, RNA polymerase II promoters can be experimentally activated so as to over-express endogenous microRNAs in cell culture systems. Alternatively, artificial microRNAs can also be engineered to match the features of existing microRNA genes, such as the gene encoding the human miR-30 microRNA. In an analogous method, the BLOCK-iTTM Pol II miR RNAi expression vectors from life Technologies allow for selected miRNA sequences that are flanked on both ends with flanking sequences that allows for their successful transcription under a Polymerase II promoter. Additional coding sequences containing a fluorescent protein tag are placed 5' to the miRNA. Some of the viral vectors that will be used contain a sequence of interest that has been scrambled (scrambled shRNA/miRNA), and which is not complementary to any known mammalian sequences. These vectors will be employed as negative controls to demonstrate that any observed effects are due to the knockdown of a specific mRNA/protein of interest, rather than being due to any non-specific effects that the delivery of the viral vectors might cause. This sequence will adopt a hairpin structure as with any shRNA/miRNA, but it should not target any mRNA of mouse, rat or human origin. It will only serve as the negative control for the vector producing shRNA/miRNA. Consequently, these sequences are unlikely to pose any safety risks for the environment or human health.

Summary

The transgenes that will be expressed by the viral vectors have a very low safety risk to human health. This is because accidental contamination with a vector would lead to only a small number of cells becoming infected, and it would be highly unlikely that expression in only a few cells would be sufficient to lead to a disease state. The inability of the lentiviral vectors to propagate in mammalian cells also reduces the risk. The transduction marker proteins that will be employed are not known to cause any relevant toxicities, and the genes/proteins of interest that will be targeted by siRNAs do not include any growth factors, confirmed oncogenes, cytotoxins, tumour suppressors or immunomodulators, and none of them are of retroviral origin.

Evaluation of foreseeable effects

Human health hazards
Although the lentiviral vectors that will be used are replication incompetent and contain only \(-20\%\) of the original HIV-1 genome, there is a small risk that subsequent infection of cells already infected with the lentiviral genome by HIV-, could lead to a rare recombination event in which the transgene is transferred to a replication-competent virus. Thus, the sequences in the vector that will be expressed could potentially be transferred to surrounding cells. This event is, however, extremely unlikely to occur, and it has been shown that, even under permissive in vitro conditions, wild-type HIV-1 cannot rescue a self-inactivating HIV-1 based lentivirus once integrated into the host genome (Bukovsky et al. 1999).

Additionally, there is a theoretical risk that an infection event with the vectors could lead to the infected cells becoming cancerous, as lentiviral integration into a host genome could potentially lead to the activation of an endogenous oncogene. All transcriptionally active long-terminal repeats (LTRs) have, however, been removed from the viruses as well as all promoter-like elements other than that required to drive expression of the transgene, which should prevent unforeseen activation of such genes. The deletion of the retroviral enhancer in self-inactivating systems reduces the risk of activation but not of disruption, and, therefore, retroviral infection might still have permanent effects upon a cell (including oncogenic effects).

Importantly, the likelihood of a worker becoming accidently infected is, however, considered to be low, as appropriate risk reduction measures will be implemented. Notably, micro-syringes will be filled with viral vectors only in a class 2 BSL to avoid the production of aerosols. The most likely route of accidental infection with a lentivirus will be via inadvertent percutaneous inoculation. The likelihood of this occurring will be minimised by following the correct procedures. Oral ingestion will be prevented by standard laboratory safety practices. Moreover, the genes/proteins of interest that will be targeted by shRNAs do not include any growth factors, confirmed oncogenes, tumour suppressors, cytotoxins, or immunomodulators, and none of them are of retroviral origin. In the unlikely event of accidental transduction of a laboratory worker's skin or mucosa by lentivirus particles, this will be self-limited, due to natural shedding of superficial epithelial skin and mucosal cell layers.

HAZARDS TO THE ENVIRONMENT

The chance that active viral particles will be accidentally released into the environment is considered to be highly unlikely, as effective containment procedures will be adhered to. However, in the unlikely event that active viral vector particles do accidently get released into the environment, the safety risks posed by such an event is considered to be negligible, due to the vectors being self-inactivating and non-replicative. The main potential risk in such an event would be the subsequent contamination of a human population already infected with HIV, which would potentially allow for recombination events that could incorporate the inserted sequences into a viable RCL. This scenario is, however, extremely unlikely, and even if it was to occur, it is unlikely that it would lead to any untoward effects.

The vectors have been pseudotyped with the VSV-G envelope in order to increase tropism, and they are, in theory, capable of transducing all dividing and non-dividing mammalian cell types. As emphasised before, the vectors, however, cannot self-propagate after infection, and successful transduction is also critically dependent on the presence of high enough concentrations of virus particles; and viral vector stock solutions will be managed in a way that will prevent contaminations with relatively high viral titres. After production, the vectors are aliquoted and stored in small volumes (each tube contains at maximum 30μl) at -SO·C, and when taking into account that the infectivity of the vectors rapidly decrease at room temperature, it is considered highly unlikely that the vectors could survive in the long term after being accidentally released into the environment.

There are no conceivable hazards associated directly with the lentiviral vectors (containing the inserts) as they will not replicate/survive outside the laboratory and they have been designed to include many protective safety features. shRNA and miRNA sequences will also not survive as they are highly unstable, and they would, consequently, be rapidly inactivated/degraded if accidentally spilled into the environment. Moreover, as discussed
above, there is a very low risk that the sequences contained within the viral vectors could be transferred to other organisms, as a rare recombination event would have to occur to allow this to happen.

Summary
The chance that active viral particles will be accidentally released into the environment is considered to be highly unlikely, as the viral vector studies that will undertaken have been classified as CL2, and effective containment procedures will be adhered to. However, in the unlikely event that active viral vector particles do accidently get released into the environment, the safety risks posed by such an event is considered to be low due to the vectors being self-inactivating and non-replicative, and also due to the poor ability of the vectors to survive outside of their host systems (see above discussions).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Following transduction of eel! lines that are designated as requiring Biosafety Containment level 1 with lentivirus, we wish to be able to subsequently use these cells at Biosafety Containment level 1. This can be justified by the following procedure: under Biosafety Containment Level 2 media containing virus will be removed, the transduced cells will be extensively washed to remove any remaining virus. This liquid waste will be neutralised for at least 24 hours before disposal. The washed cells will then be cultured for a further 24 hours before being tested for the absence of infectious virus before being allowed to be treated as only requiring Biosafety Containment Level 1. Sources of iPSC cells that have been shown to lack viral integration and test negative for infectious virus can be regarded as requiring biosafety level 1 containment. Such iPSC cells can also be derogated to biosafety level 1 containment once tested for the absence of infectious virus.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

General waste handling procedures:
Solid waste will be neutralised by soaking it in a validated disinfectant solution for 24 hours, after which the material will be 'double bagged', autoclaved and, ultimately, incinerated offsite. At B60CRP, liquid waste will be disposed of into sealed biohazard containers filled with Virkon* for incineration. It will be routine practice that all liquid waste material be neutralised before disposal, and for the neutralised waste to be transported in leak-proof containers to prevent spillages. At 430CSP, liquid waste will be inactivated by Vir<on* for 24 hours prior to drain disposal.

• Virkon
Rely+OnT~ Virkon® is a multi-purpose disinfectant. It contains oxone (potassium peroxymonosulphate), sodium dodecylbenzenesulfonate, sulphamic acid; and inorganic buffers. Virkon oxidizes key structures and compounds, such as proteins, leading to widespread, irreversible damage and subsequent deactivation/destruction of the microorganism. It is typically used for cleaning up hazardous spills, disinfecting surfaces and soaking equipment. With powerful, proven performance against over 500 strains of viruses, bacteria and fungi, Virkon offers a broad spectrum efficacious anti-microbial activity, and it is used by governments worldwide for Emergency Disease Control. Importantly, Virkon has specifically been validated for lentiviral inactivation (Antec-Biosentry).

Virkon is sold as a powder which dissolves readily in water. It is intended to be mixed with water to form a 1% solution (i.e. 10 g per litre) for hard surface and equipment disinfection. 1:100 is also the dilution rate advised for virucidal efficacy against HIV-1.

The product has a pink colour, which is useful in that it helps to gauge the concentration of a prepared solution, and importantly, as Virkon ages, it discolors, making it obvious when it needs to be replaced. The solution is generally
stable for five to seven days. Moreover, there is no evidence to suggest that bacterial disease-causing organisms develop resistance towards Virkon, as opposed to some other disinfectant products. Moreover, Virkon is not classified as R53, it is classified as readily biodegradable, and it does not persist in the environment.

• Distel
Distel is formulated as a nanoemulsion that enables the active molecules in the product to be carried rapidly through cell walls of micro-organisms, ensuring the rapid induction of cell death in treated micro-organisms. Distel works quicker than conventional high level disinfectants and achieves apoptosis (cell death) rather than merely suspending activity as with conventional disinfectant products. Distel has been reported to be bactericidal, fungicidal as well as virucidal and sporicidal. It is recommended to be used at a 1:200 dilution for general purposes, 1:100 for high risk areas, and 1:50 for disinfection of blood and bio-hazard spillages.

Summary
As any active viral particles on surfaces or in waste material will be completely inactivated at the end of each experiment by the highly effective cleaning/disinfection protocols outlined above, it is considered highly unlikely that active virus particles would unintentionally become discharged into a sanitary sewage system. No foreseeable adverse effects on human health and safety are expected.

Please enter comments on the GM safety committee on the risk assessment

The GMSC has agreed that the production, handling and use of lentivirat siRNA stocks is a Class 2 activity. This decision has been reached because although the lentivirus will be generated using a third generation. self-inactivating 4 plasmid expression system, the possibility of a recombination event occurring that leads to replication competent virus can never be discounted with this type of virus. The potential oncogenic effects of the Woodchuck Post-translational Regulatory Element have been negated by the use of the mutant form that prevents expression of the X protein. The proposal includes the potential to produce large amounts of virus. This represents the most hazardous aspect of the proposal and the GMSC is satisfied that the necessary precautions have been put in place to ensure containment is maintained. Some of the proposed lentivirus may encode for proteins that are known to have neurotoxic effects and are associated with diseases of the human central nervous system. The procedures put in place will effectively prevent any chance of virus being delivered to the necessary tissues within a human in sufficient quantities to represent a hazard to human health. The FP and shRNmiRNA encoded by the other lentivirus are not known to pose any inherent risk to human health or the environment. The proposed targets to be knocked down in this study also pose no known risk. The request to derogate the Biosafety Containment level from 2 to 1 post transduction has been deemed acceptable given that the transduced cells will be washed extensively to remove any remaining viral particles and will be tested for the absence of transducing virus. It has been made clear that human iPSC cell lines that have been generated using lenti- or retrovirus methods tested negative for the absence of virus at least. These cells will always be tested for the absence of infectious particles before being they can be used as if they only required Biosafety Containment level 1.

**Historical Significant Changes**

Transferred from GM3043 02/12/2016

**Project Additional Information**

**Purposes of the contained use**

**Aim**
The purpose of this project is to use lentivirus to deliver programmable nucleases, specifically zinc finger nucleases and Cas9/CRISPR, to disrupt gene function in mammalian cultured cells. The primary aim is to use gene targeting to validate novel targets for drug discovery and to set up disease relevant model systems in vitro.

**Recipient or parental organism**

Rodent Origin: Immortalised cell lines.
Human Origin: HEK293T, immortalised cell lines and induced pluripotent stem cells
Host/vector system

Lentivirus vectors: The four plasmids that will be used will be a modified version of pRRL, pMDLgp-RRE, pRSV-REV and PMD2-VSVG.env. The latter three are required for the production of the SIN replication defective lentiviral particles in HEK293T cells. The target shRNA/miRNA or gene will be inserted into the modified pRRL vector. This modified vector will have the following safety features: a deletion in the 3'LTR making it SIN in the infected cells, the packaging sequence is only found in the pRRL with the packaging constructs being provided by the remaining non-LTR containing plasmids Lentivirus vectors: pMDLgp-RRE, pRSV-REV and PMD2-VSVG.env. The Tat promoter has been replaced by Polymerase Type 2 promoter, making them replication incompetent. The inclusion of these features ensures that the production of these SIN replication defective lentiviral particles only occurs in the transfected HEK293T. Outside of this setting, viral replication cannot take place and so pose a minimal risk to both humans and the environment.

Origin & function

The proposal involves the use of existing lentiviral constructs purchased commercially and the generation of new constructs on site. These constructs will contain a combination of programmable nuclease plus accessory sequences and a fluorescent protein as lineage marker. In some cases constructs will contain a combination of programmable nuclease plus accessory sequences and a selectable marker giving rise to a selectable trait in transduced cell lines. Programmable nucleases function by binding to, and cleaving, user-defined target DNA sequences. This in turn instigates a robust DNA repair response which ultimately leads to disruption of the target sequence by deletion at the cleavage site or by recombination with user-supplied synthetic vector containing sequences complementary to the target gene. Insertion of the sequences into the third generation lentiviral vector on site will be achieved by either conventional cloning or Recombineering. Lentiviral particles will either be purchased ready for use or produced in-house using the third generation system described below. Nuclease encoding lentivirus may be used in isolation or co-transduced with lentivirus encoding a targeting construct designed to recombine and insert defined sequences into the target gene.

The SIN-RD (Self-Inactivating-Replication Deficient) lentiviral particles will contain a combination of the following sequences:
1. Programmable nucleases (Zinc fingers and Cas9/CRISPR) designed to cause double stranded breaks in particular endogenous mammalian targets (Mouse, Rat, Human).
2. Fluorescent protein markers that are known to be benign in terms of their effects when expressed in mammalian cells but are essential for visualisation of these cells. When these in addition are fused to a subcellular marker gene, subcellular visualisation of a particular process can be visualised.
3. Selectable marker for conferring a selectable trait to mammalian cells in vitro. Exposure to the relevant compound will result in survival of cells containing the viral vector (positive selection) or elimination of cells containing the viral vector (negative selection).

A. Programmable nucleases: zinc finger nucleases and Cas9/CRISPR
Zinc finger nucleases and Cas9/CRISPR are both programmable nucleases systems that are designed to cause cleavage of a pre-determined DNA sequence. Zinc fingers are proteins of mammalian origin comprising a DNA binding domain which confers sequence specificity and a nuclease domain which cleaves the target sequence subsequent to precise binding. Cas9/CRISPR is a bacterial protein/RNA complex that contains a nuclease domain and an RNA-binding domain; the sequence specificity of Cas9 is determined by the sequence of the RNA (referred to as the guide RNA) with which it is complexed. To effect cleavage the guide RNA has to be supplied by co-expression with Cas9.
Zinc fingers or Cas9 protein will be directed against genes of therapeutic interest identified by literature reports or by in-house screens. Since the purpose of programmable nucleases is to cause mutations in defined DNA sequences the primary hazard is that such a mutation would lead to deleterious cellular effects. The genes/proteins of interest that will be targeted do not and will not include any growth factors (which does not include trophic factors), confirmed oncogenes, tumour suppressors or immunomodulators. In isolation these sequences are unlikely to pose any safety risks for the environment or human health.

B. Fluorescent protein tag proteins:
Genetically encoded Fluorescent proteins, such as green fluorescent protein (GFP), have been widely used as a reporter for biological research over the past decades. Their exogenous expression is not associated with any cytotoxic, immunogenic or oncogenic response. A large selection of different FP constructs have been and continue to be generated, which differ in their optical and stability properties. A current non-exhaustive list of such FPs that will be used include, GFP, GFPem, YFP, DsRed, mCherry, CFP. Further variants that may be used can be found here (http://www.einstein.yu.edu/research/facilities/fluorescent/)
Genes that confer resistance or sensitivity to antibiotic compounds are routinely used in mammalian cell culture. Examples include Neo (G418 resistance), Puro (puromycin resistance), Bsd (blasticidin resistance), Hyg (hygromycin resistance), Zeo (zeocin resistance), and HSVTK (gancyclovir sensitivity). All of these genes have been used extensively in mammalian cell genetics with no reported adverse effects in humans or animals.

Evaluation of foreseeable effects

Procedures
During all procedures that involve the handling/use of the viral vectors, all workers (incl. those that are not working directly with the vectors) that are present within a lab where the work is undertaken are required to wear personal protective equipment (incl. both appropriate clothing and gloves) at all times. The use of two pairs of gloves is advised so the external pair can be disposed in an autoclave bag and replaced whenever necessary (e.g. in the case of contact with the viral reagent). Face masks are also available for use, where appropriate. In addition, all workers are made aware of the nature of the viral work that is going on within the laboratory, and they have to follow appropriate procedures to ensure that there is no cross-contamination into non-viral working areas. All the workers using the viral delivery systems are experienced research scientists, and junior scientists will be closely supervised until they are competent in the handling of the viruses.

In vitro assessment
Assessing whether the genome manipulation has worked will be carried out by a combination of PCR and sequencing, and will normally take place initially in biosafety level 1 immortalised cell lines that are known not to contain lentiviral genetic material. Application of lentiviral particles will be done at Biosafety level 2. After at least 24 hour incubation and extensive washing, the cells will be treated as Biosafety level 1 (see below the justification for derogation of cells post-infection to Biosafety level 1). Once validated the same procedure will be carried out in the target cell line which will be immortalised biosafety level 1 cell lines or human induced Pluripotent stem cells (iPSCs). In the latter case these will subsequently be differentiated into defined lineages for phenotypic analysis by manipulating the culture conditions. Where viral transduction is undertaken on a class 2 cell line the resultant material will remain under biosafety level 2 conditions. In all cases phenotypic analysis will be performed using suitable in vitro assays, including for example, RT-PCR, Western Blotting, immunocytochemistry and imaging.

Human health hazards
The methods by which the lentivirus vector is produced means that it is highly unlikely that replication competent lentivirus (RCL) can be generated even if an infection occurs in a person who is HIV-1 positive. Infection can lead to a permanent transduction of cells and the possibility of a harmful event either by transactivation or disruption of gene expression cannot be ruled out. For this reason the work with stock viral aliquots will be conducted as a class II activity. Oral ingestion will be prevented by standard laboratory safety practices. Aerosol formation resulting from an accident outside of the safety cabinet and involving lentivirus particle-containing liquid may lead to transduction of a limited number of the laboratory worker's skin or mucosal cells with modified viruses, due to the inherent properties of the viral vectors. Moreover, the genes/ proteins of interest that will be targeted by shRNAs do not include any growth factors, confirmed oncogenes, cytotoxins, or immunomodulators, and none of them are of retroviral origin. In the unlikely event of accidental transduction of a laboratory worker's skin or mucosa by lentivirus particles, this will be self-limited, due to natural shedding of superficial epithelial skin and mucosal cell layers.

The most likely route of accidental infection with a lentivirus will be via inadvertent percutaneous inoculation. The likelihood of this occurring will, however, be minimised by adhering to appropriate risk management measures. Infection of the community at large with lentivirus particles is highly unlikely due to the viral vector particles being replication incompetent and being extremely sensitive to dessication.

Hazard to the Environment
The probability that active viral particles will be accidentally released into the environment is considered to be extremely low, as effective containment procedures will be adhered to. However, in the unlikely event that active vector particles do accidentally get released into the environment, the safety risk posed by such an event is considered to be negligible, due to the vectors being self-inactivating and non-replicative. The main potential risk in such an event would be the subsequent contamination of a human population already infected with HIV, which would potentially allow for recombination events that could incorporate the inserted sequences into a viable RCL. This scenario is however, extremely unlikely, and even if it was to occur, it is unlikely that it would lead to any untoward effects.

The vectors have been pseudotyped with the VSV-G envelope in order to increase tropism, and they are, in theory, capable of transducing all dividing and non-dividing mammalian cell types. As emphasised before, the vectors cannot self-propagate after infection, and successful transduction is also critically dependent on the presence of
high enough concentrations of virus particles; also viral vector stock solutions are aliquoted and stored in small volume (each tube contains at maximum 10µ at 80\(^\circ\) so the potential for a high titre dose is reduced. The infectivity of the vectors rapidly decreases at room temperature so it is considered highly unlikely that the vectors could survive long enough in the environment to pose a risk if accidentally released.

Furthermore, lentiviral vectors have a short half-life at room temperature as their structural characteristics make them highly susceptible to dehydration, and relatively unstable. For this reason, retroviruses become rapidly inactivated outside host systems, and this is illustrated by the fact that close contact is required for transmission. They can, however, survive for long periods in high protein media.

There are no conceivable hazards associated directly with the lentiviral vectors (containing the inserts) as they will not replicate/survive outside the laboratory and they have been designed to include many protective safety features. shRNA and miRNA sequences will also not survive as they are highly unstable, and they would, consequently, be rapidly inactivated/degraded if accidentally spilled into the environment. Moreover, as discussed above, there is a very low risk that the sequences contained within the viral vectors could be transferred to other organisms, as a rare recombination event would have to occur to allow this to happen.

Summary
The chance that active viral particles will be accidentally released into the environment is considered to be highly unlikely, as the viral vector studies that will be undertaken have been classified as Biosafety level 2, and effective containment procedures will be adhered to (see section C for details). However, in the unlikely event that active viral vector particles do accidentally get released into the environment, the safety risks posed by such an event is considered to be low due to the vectors being self-inactivating and non-replicative, and also due to the poor ability of the vectors to survive outside of their host systems (see above discussions).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Following transduction of cell lines that are designated as requiring Biosafety Containment Level 1 with lentivirus, we wish to be able to subsequently use these cells at Biosafety Containment Level 1. This can be justified by the following procedure: under Biosafety Containment Level 2 media containing virus will be removed, the transduced cells will be extensively washed to remove any remaining virus. This liquid waste will be neutralised for at least 24 hours before disposal. The washed cells will then be cultured for a further 24 hours before being tested for the absence of infectious virus before being allowed to be treated as only requiring Biosafety Containment Level 1. Sources of IPSC cells that have been shown to lack viral integration and test negative for infectious virus can be regarded as requiring biosafety level 1 containment. Such IPSC cells can also be derogate to biosafety level 1 containment once tested for the absence of infectious virus.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

General cleaning procedures
Surfaces will be thoroughly cleaned with Virkon* Or Distel 10% (or an equivalent product) at the end of each experiment or after the occurrence of an accidental spillage of infectious material. Application of these anti-microbial agents will totally inactivate any viral vectors that might be present. According to the biosafety literature, all of the viruses to be used are susceptible to these disinfectants. Anything that might have potentially come into contact with the virus will be treated with Virkon* or Distel 10% before being autoclaved/incinerated.

Waste handling procedures
Solid waste will be inactivated by soaking it in a validated disinfectant solution for 24 hours, after which the material will be 'double bagged', autoclaved and, ultimately, incinerated offsite.

Liquid waste will be disposed of into sealed biohazard containers filled with Virkon* for incineration. It will be routine practice that all liquid waste material be neutralised before disposal, and for the neutralised waste to be transported in leak-proof containers to prevent spillages. Neutralised liquid waste will be securely sealed for collection and off-site disposal by an approved agent (B60CRP) or discarded down an approved sink (430CSP).
Summary

As any active viral particles on surfaces or in waste material will be completely inactivated at the end of each experiment by the highly effective cleaning/disinfection protocols outlined above, it is considered very unlikely that active virus particles would unintentionally become discharged into a sanitary sewage system. No foreseeable adverse effects on human health and safety are expected.

*Virkon

Rely+On™ ® is a multi-purpose disinfectant. It contains oxone (potassium peroxymonosulphate), sodium dodecylbenzenesulfonate, sulphamic acid; and inorganic buffers. Virkon oxidizes key structures and compounds, such as proteins, leading to widespread, irreversible damage and subsequent deactivation/destruction of the microorganism. It is typically used for cleaning up hazardous spills, disinfecting surfaces and soaking equipment. With powerful, proven performance against over 500 strains of viruses, bacteria and fungi. Virkon offers a broad spectrum efficacious anti-microbial activity, and it is used by governments worldwide for Emergency Disease Control. Importantly, Virkon has specifically been validated for lentiviral inactivation (Antec-Biosentry).

Virkon is sold as a powder which dissolves readily in water. It is intended to be mixed with water to form a 1% solution (i.e.10g per litre) for hard surface and equipment disinfection. 1:100 is also dilution rate advised for virucidal efficacy against HIV-1.

*DISTEL (formerly known as Trigene advance)

DISTEL is formulated as a nonmulsion that enables the active molecules in the product to be carried rapidly through cell walls of micro-organisms, ensuring the rapid induction of cell death in treated micro-organisms. DISTEL works quicker than conventional disinfectants and achieves apoptosis (cell death) rather than merely suspending activity as with conventional disinfectant products. DISTEL has been reported to be bactericidal, fungicidal as well as virucidal and sporicidal (http://tristel.com/products/healthcare/laboratories/distel-high-level-laboratory-disinfectant/). It is recommended to be used at a 1:100 dilution for general purposes, 1:10 dilution for high risk disinfection.

Please enter comments on the GM safety committee on the risk assessment

The GMSC has agreed that the production, handling and use of the lentiviral siRNA stocks is a Class 2 activity. This decision has been reached because although the lentivirus will be generated using a third generation, self-inactivating, 4 plasmid expression system, the possibility of a recombination event occurring that leads to replication competent virus can never be discounted with this type of virus. The potential oncogenic effects of the Woodchuck Post-translational Regulatory Element have been negated by the use of the mutant form that prevents expression of the X protein. The proposal includes the potential to produce large amounts of virus. This represents the most hazardous aspect of the proposal and the GMSC is satisfied that the necessary precautions have been put in place to ensure containment is maintained. The encoded Cas9 protein and guide RNA to be delivered by lentivirus in this proposal is now an established and widely used technique. Cas9 itself is not known to have any detrimental effects on human health or the wider environment. The proteins targeted by the guide RNAs will be assessed on a case by case basis to ensure their potential risk is minimal. The request to derogate the Biosafety Containment Level 2 from 2 to 1 post transduction has been deemed acceptable given that the transduced cells will be washed extensively to remove any remaining viral particles and will be tested for the absence of transducing virus. It has been made clear that human iPSC cell lines that have been generated using lentiviral or retroviral methods must be negative for the absence of virus at least. These cells will always be tested for the absence of infectious particles before they can be used as if they only require Biosafety Containment Level 1.
**Project Additional Information**

**Purposes of the contained use**

This work will involve the use of particles of lentiviral origin to deliver modifiers of gene expression to mammalian cells. The aim is to dysregulate key disease-related pathways and then assess the effect of such manipulations on gene expression with a view to identifying novel disease-modifying targets.

**Recipient or parental organism**

- **Rodent Origin:** Mouse cell lines
- **Human Origin:** Immortalised cell lines and induced pluripotent stem cells
lentivirus vectors: The four plasmids that will be used will be a modified versions of pRRI, pMDlgp-RRE, pRSV-REV and PMD2-VSVG.env. The latter three are required for the production of the SIN replication defective lentiviral particles in HEK293T cells. The target shRNmiRNA or gene will be inserted in to the modified pRRl vector. This modified vector will have the following safety features: a deletion in the 3'L TR making it SIN in the infected cells, the packaging sequence is only found in the pRRl with the packaging constructs being provided by the remaining non-L TR containing plasmids Lentivirus vectors: pMDLgp-RRE, pRSV-REV and PMD2NSVG.env. The Tat promoter has been replaced by Polymerase Type 2 promoter, making them replication incompetent. The inclusion of these features ensures that that the production of these SIN replication defective lentiviral particles only occurs in the transfected HEK293T. Outside of this setting, viral replication cannot take place and so pose a minimal risk to both humans and the environment.

### Host/vector system

The SIN-RD lentiviral particles will contain the following sequences:

#### Health and Safety

1. shRNmiRNA directed towards the knock down of the expression of a particular endogenous mammalian target (Mouse, Rat, Human). These de novo derived sequences are not derived from an organism.
2. Fluorescent protein marker which are known to be benign in terms of their effects when expressed in mammalian cells but are essential for visualisation of these cells. When these in addition are fused to a subcellular marker gene, subcellular visualisation of a particular process can be visualised.
3. Cre recombinase which catalyses excision of sequences flanked by its recognition site, loxP.
4. Fluorescent marker protein fused to a ribosomal subunit to enable visualisation of cells where vitally delivered gene expression is taking place and immunoprecipitation of ribosomes from such cells.

#### Methods

This proposal involves the use of existing lentiviral constructs purchased commercially and the generation of new constructs on site. These constructs will contain a combination of shRNmiRNA and a fluorescent protein as lineage marker. In some cases constructs will contain a combination of shRNmiRNA and Cre recombinase giving rise to a pre-determined deletion event in transduced cell lines. Insertion of the sequences into the third generation lentiviral vector on site will be achieved by either conventional cloning or Recombineering. Lentiviral particles will either be purchased ready for use or produced in-house using the third generation system described below.

#### Lentiviral production - Uney laboratory

Some of the lentiviral vectors will be produced on site whilst others will be obtained from the Uney laboratory, which is based at the University of Bristol. The lentiviral vectors provided by the Uney laboratory will be stock solution containing up to 1x10^10 transducing units (TU) l ml of vector in TSSM buffer (20 mM TRIS, 100 mM NaCl, 10 mg/mL sucrose, 10 mg/ml mannitol), and will be essentially free of the HEK293T helper cell line used to expand the viral titre. Each purified and concentrated aliquot of lentiviral vector solution will comprise of small volumes (up to 10 1-11) containing no more than 1x10^8 viral particles. The material is normally shipped frozen and stored within manufacturer designed racks in a _80°C freezer.

#### Lentiviral production - on site 860CRP or 430CSP

Lentiviral production will also be carried out on-site using HEK293T cells and will be carried out in a class 2 microbiology safety cabinet within a dedicated Biosafety level 2 laboratory. The HEK293T cells used for lentiviral production will be seeded in filter containing screw cap culture flasks in order to minimize the risk of spills and aerosol mediated viral spread. For this the modified pRRI plasmids together with three additional separate plasmids (pMDLgp-RRE, pRSV-REV and PMD2-VSVG.env) will be transfected using a transfection reagent (e.g.
Polyethylenimine (PEI), lipofectamine) into HEK293T packaging line. After 6-12 hours, the medium is replaced with fresh serum-free medium (e.g. Neurobasal medium with 2% B-27 supplement and 1X PeniStrep) and grown for an additional 72-96 hours. After 24-48 hours, so as to ensure the viability of the transfected HEK293T cells, medium from the cells is collected into screw cap tubes and stored at 40C and fresh serum-free medium is added to the cells. The cells are grown for an additional 24-48 hours before the second medium solution is added to the first harvest tube.

After lentivirus collection has been completed, the cells in the flasks will be treated with a validated anti-microbial agent (e.g. DISTEL 10% or another equivalent product) for at least 24 hours. Liquid waste will be disposed off-site via an approved waste disposal agent (B60CRP) or via a designated sink (430CSP) after at least 24 hours neutralisation with 10% DISTEL or equivalent. Solid material will be autoclaved on-site and then collected for incineration by an approved waste disposal agent.

Still within a Class 2 microbiology safety cabinet in a Biosafety level 2 laboratory, the harvested supernatants will be filtered using a 0.45um filter before being either aliquoted or further purified by chromatography and/or concentrated by centrifugation. The lentiviral particles may need to be purified by either chromatography (e.g. ViraBindTlo1) and eluted in a high salt solution (50 mM Tris, pH 7.5, 5 mM MgCl2, 2 M NaCl) and/or concentrated by ultrafiltration (e.g. lentiSelect™). For certain applications where highly concentrated, highly purified virus may be required, the traditional method of sucrose cushion based centrifugation may be necessary. To minimise the possible risk of accidental viral contamination and spread due to the need for an ultracentrifuge, all loading and unloading will be done in the Class 2 microbiology safety cabinet. Once the sucrose cushions have been added to the centrifuge tubes, they will be transferred into the Class 2 microbiology safety cabinet. The unpurified or chromatography purified lentiviral particles will then be added to the sucrose cushion. The individually capped tubes will then be transferred to their respective bucket holders and the bucket sealed using their respective screw caps and marked as containing virus. The bucket will be transferred to a weighing scale and a counterpart bucket and tubes with water (and without lentivirus) will be prepared that is weight matched. The balanced buckets will then be transferred to the rotor before being placed within the centrifuge chamber. The ultracentrifuge will be run at 70000g for 2 hours at 20oC. Upon return of the buckets to the Class 2 microbiology safety cabinet, the supernatant will be removed from the tubes before transfer of the resuspended virus pellet into individual screw cap cryovials. As the greatest risk for contamination occurs within the centrifugation buckets themselves during transport to and from the weigh scales and during ultracentrifugation, not only will the centrifuge tubes but also the rotor be decontaminated with DISTEL 10% before removal from the Level 2 laboratory. Optionally the centrifuge rotor can be autoclaved at 121oC. In any case, at no point will concentrated virus stock be exposed to outside of the Class 2 hood environment. All supernatants will be treated as above.

The lentiviral titre will be determined in terms of the number of viral particles (VP) or Transduction units (TU) per ml. The number of VP can be assessed relatively quickly and does not involve cell infection. In this case, a bead based enrichment assay (e.g. QuickTitre™ Quantification Kit) or a p24 ELISA assay (e.g. QuickTitre™ Lentivirus Titre kit) will be chosen. The VP quantification methods tend to overestimate the TU by 10-100 fold. Thus, the TU 1 ml will in certain instances also be determined. For this, a titration range of lentiviruses expressing a fluorescent tag, serial dilution will be prepared and added to a 24 well cluster plate or T25 Te-flasks containing HEK293T for 48 hours. The percentage of fluorescent positive cells will be quantified manually under a fluorescent microscope or ideally using FACS analyser. The biological titre (TU/ml) according to the following formula: 

\[
TU/ml = \left( \frac{P \times N \times 1000 \times V}{DF} \right),
\]

where? = % GFP+ cells, N = number of cells at time of transduction = 10^5, V = volume of dilution added to each well and DF = dilution factor = 1 (undiluted), 10-1 (diluted 1/10), 10-2 (diluted 1/100), and so on.

Aliquots with not more than 1x10^8 viral per vial are subsequently stored at -800C in individual screw capped cryotubes. The viral stock will consist of viral particles containing the vector genome (full capsids) and also of a variable number of empty viral capsids. Other trace components that might be present include, but are not limited to,
inorganic salts, vitamins, other nutrients, human cellular proteins, carbohydrates, amino acids, and fats.

Transgene: proteins to be overexpressed

Additional hazards could also arise from the properties of the genetic material that will be inserted into the viral vectors and expressed in transfected cells.

A. Fluorescent protein tag proteins:

The green fluorescent protein (GFP) is a protein composed of 238 amino acid residues (26.9 kDa) that exhibits bright green fluorescence when exposed to light in the blue to ultraviolet range. GFP traditionally refers to the protein first isolated from the jellyfish Aequorea victoria, which has a major excitation peak at a wavelength of 395 nm and a minor one at 480 nm. Its emission peak is at 509 nm, which is in the lower green portion of the visible spectrum.

EGFP is a variant of GFP containing two point mutations; S65T and F64L. These mutations dramatically improve the spectral characteristics of GFP, resulting in increased fluorescence, photostability, and a shift of the major excitation peak to 488 nm, with the peak emission kept at 509 nm. This matches the spectral characteristics of commonly available FITC filter sets and also improves folding efficiency at 37 °C thereby allowing practical use in mammalian cells. Genetically encoded Fluorescent proteins such as green fluorescent protein have been widely used as a reporter for biological research over the past decades. Their exogenous expression is not associated with any cytotoxic, immunogenic or oncogenic response.

B. ere recombinase

Gre Recombinase is a tyrosine recombinase enzyme derived from the P1 Bacteriophage. The enzyme uses a topoisomerase I like mechanism to carry out site specific recombination events. The enzyme (3SkOa) is a member of the Integrase family of site specific recombinase and it is known to catalyse the site specific recombination event between two DNA recognition sites (loxP sites). This 34 base pair (bp) loxP recognition site consists of two 13bp palindromic sequences which flank an 8bp spacer region. Two separate DNA species both containing loxP sites can undergo fusion as the result of Gfe mediated recombination. DNA sequences found between two loxP sites are said to be "flxed". The enzyme plays important roles in the life cycle of the P1 Bacteriophage such as cyclization of the linear genome and resolution of 1meric chromosomes that form after DNA replication.

ere recombinase is a widely used tool in the field of molecular biology. The enzyme's unique and specific recombination system is exploited to manipulate genes and chromosomes in a huge range of research, such as gene knock out or knock in studies. The enzyme's ability to operate efficiently in a wide range of cellular environments (including mammals, plants, bacteria, and yeast) enables the ere-Lox recombination system to be used in a vast number of organisms, making it a particularly useful tool in scientific research.

The simplicity and robustness of the Gre-loxP systems has enabled scientists to exploit the Gre enzyme in order to manipulate DNA both in vivo and ex vitro. As the enzyme has a specific 34bp DNA substrate the genome of the organism would have to be 1018bp in length for there to be a likely occurrence of a loxP site. As mammalian genomes are on average in the region of 3x10^9 bp there is a very low chance of finding an endogenous 10xP site. For ere to be functional in a foreign host, exogenous loxP sites must be engineered. This allows precise control over the activity of the ere enzyme in test organisms.

ere recombinase is not known to cause any diseases in humans or animals.

C. shRNA: endogenous proteins to be depleted

RNA interference (siRNA)

RNA interference (siRNA) is an antisense technology that exploits a normal cellular antiviral response that acts to inhibit viral protein synthesis through the production of short hairpin RNAs that bind and target viral double-stranded RNA (dsRNA) molecules for degradation. The shRNA molecules are processed by cellular enzymatic pathways to produce small inhibitory RNA (siRNA) species, and it is the latter RNA molecules that bind and target complementary
RNA sequences for degradation by the RNA-induced silencing complex (RISC). With the use of shRNA-expressing viral vector systems, the expression of specific mammalian genes/proteins can be 'knocked-down', in order to study their functions.

The effects of the siRNA species that are generated in these experimental systems may have broader effects on the cell than just modulating the expression of a particular gene/protein. There may be sequences within a specific siRNA molecule that are homologous to other coding sequences within the mammalian genome that are not necessarily linked or closely related to the intended target. It is, therefore, theoretically possible that a specific siRNA may knock down the expression of genes other than the intended target one, and for this reason, the siRNA systems have been designed carefully to minimise the likelihood that there will be unwanted or potentially adverse effects arising from a non-target gene being inadvertently targeted. This is done by screening designed siRNA sequences against databases of known mammalian gene/mRNA sequences.

RNA interference may also have deleterious effects upon cellular metabolism due to the triggering of antiviral responses. It has been shown that siRNA molecules (even if less than 30nt in length) can trigger dsRNA antiviral responses. Such responses not only lead to the degradation of dsRNA molecules, but also results in interferon production, which, in turn, leads to inflammation and the non-specific inhibition of protein synthesis.

In some of the lentiviral vectors that will be used in the proposed studies the eukaryotic U6 Polymerase III promoter will be used to drive the expression of specific shRNAs of interest. The U6 promoter is well suited to drive the expression of shRNAs as it possesses the following favourable characteristics: (i) it initiates from position +1 of the transcripts, and (ii) it yields transcripts that do not terminate with a poly-A tail but with a series of four to five thymidine residues, which results in a series of 3' U residues leading to a fully functional shRNA sequence. Indeed, the structure of the transcribed product closely resembles synthetic double-stranded siRNAs, except for the fact that the two strands are linked by a spacer sequence. This system has been used to successfully inhibit gene expression in mammalian cell lines, with efficiencies comparable with that of synthetic siRNA.

Some of the viral vectors that will be used contain a sequence of interest that has been scrambled (scrambled shRNA), and which is not complementary to any known mammalian sequences. These vectors will be employed as negative controls to demonstrate that any observed effects are due to the knockdown of a specific mRNA/protein of interest, rather than being due to any non-specific effects that the delivery of the viral vectors might cause. This sequence will adopt a hairpin structure as with any shRNA, but it should not target any mRNA of mouse, rat or human origin. It will only serve as the negative control for the vector producing shRNA. Consequently, these sequences are unlikely to pose any safety risks for the environment or human health.

### Evaluation of foreseeable effects

#### Procedures

During all procedures that involve the handling/use of the viral vectors, all workers (incl. those that are not working directly with the vectors) that are present within a lab where the work is undertaken are required to wear personal protective equipment (incl. both appropriate clothing and gloves) at all times. The use of two pairs of gloves is advised so the external pair may be disposed in an autoclave bag and replaced whenever necessary (e.g. in the case of contact with the viral reagent). Face masks are also available for use, where appropriate. In addition, all workers are made aware of the nature of the viral work that is going on within the laboratory, and they have to follow appropriate procedures to ensure that there is no cross-contamination into non-viral working areas. All the workers using the viral delivery systems are experienced research scientists, and junior scientists will be closely supervised until they are competent in the handling of the viruses.

#### In vitro assessment

Assessing whether the gene modulation has worked will be carried out by a combination of PCR and fluorescence microscopy, and will normally take place initially in biosafety level 1 immortalised cell lines that are known not to contain lentiviral genetic material. Application of lentiviral particles will be done at Biosafety level 2. After at least 24
hour incubation and extensive washing, the cells will be treated as Biosafety level 1 (see below the justification for removal of cells post-infection to Biosafety Level 1). Once validated the same procedure will be carried out in the target cells. Where viral transduction is undertaken on a class 2 cell line the resultant material will remain under biosafety level 2 conditions. In all cases phenotypic analysis will be performed using suitable in vitro assays, including for example, RT-PCR, Western Blotting, immunocytochemistry and imaging.

In vitro studies

Transduction of cells (e.g. human derived iPSC neurons, mouse and human immortalised cell lines) with the lentiviral vectors will be carried out in a Class 2 microbiology safety cabinet within a dedicated Biosafety level 2 laboratory. In the in vitro studies, the TUs, and consequently volumes added, will be dependent on the number of cells in the tissue culture dish/flask to be infected. However, as the maximum number of cells to be handled per experiment is around 1 x 10^8, not more than 1 x 10^8 viral particles per experiment will be used. None of these cells win be cultivated in the filter screw cap flasks used for HEK293T mediated lentiviral production. This is to ensure that, in particular, the HEK293T cells used for lentiviral production are not inadvertently used for lentiviral assessment! Any plastic ware or solutions that are used to handle the transduced cells will be chemically inactivated in the Biosafety level 2 laboratory with a validated anti-microbial agent (e.g. DISTEL 10% or another equivalent product) for at least 24 hours. Liquid waste will be disposed of on-site via an approved waste disposal agent (B60CRP) or via a designated sink (430eSP). Solid material will be autoclaved on-site and then collected for incineration by an approved waste disposal agent.

Once the medium containing the lentiviral particles has been removed and the cells (e.g. mouse NIH/3T3, human HEK293T) have been extensively washed, which all is done in a Class 2 microbiology safety cabinet, the cells can be used following Biosafety level 1 guidelines, as no virus will be present and the latent virus in the transduced cells is replication incompetent, unless the cell line was originally classified as biosafety level 2 in which case the material will continue to be treated as such. A viral titre determination assay may on occasion be used to verify the absence of virus in the medium from transduced cell lines. This will be performed by PCR using oligonucleotides specific to the conserved regions within the viral genome.

An additional level of safety and screening procedure for the handling human iPSC cells will be applied for the following reason. The procedure for the generation of iPSC neurons was originally developed in 2006 by Yamanaka, which allows for the reprogramming of adult differentiated cells into stem cells through the introduction of four transcription factors using replication incompetent retrovirus. Since then the biosafety level of the retroviral constructs has been improved, such that both retroviral and non-viral methods of reprogramming have been reported. Even assuming that the source of our human iPSC cells resulted from work using first or second generation replication incompetent lentiviral particles, the risk of producing active lentivirus from the additional exposure to a third generation replication incompetent virus is considered negligible. Nevertheless, a number of precautionary measures will be implemented for use of these cells. Any new human iPSC line that is brought onto our site and was generated using SIN-RD lentiviruses or retroviruses (preference will be given to those lines for which there is documentation from the provider that no viral particles are being made and released) will be initially cultured at Biosafety Level 2 and tested by titre assessment to confirm that no virus is being generated. Further, and after the removal of our SIN-RD lentivirus and extensive washing, the cells will be incubated in fresh medium and will be maintained at Biosafety Level 2 safety for at least 24 hours. These cells can then only be treated as Biosafety Level 1, once a virus titre assay has confirmed that no virus is being released into the medium.

Human health hazards

The method by which the lentivirus vector is produced means that it is highly unlikely that replication competent lentivirus (RCL) can be generated even if an infection occurs in a person who is HIV-1 positive. Infection can lead to a permanent transduction of cells and the possibility of a harmful event either by transactivation or disruption of gene expression cannot be ruled out. For this reason the work with stock viral aliquots will be conducted as a class II.
activity. Oral ingestion will be prevented by standard laboratory safety practices. Aerosol formation resulting from an accident outside of the safety cabinet and involving lentivirus particle-containing liquid may lead to transduction of a limited number of the laboratory worker's skin or mucosal cells with modified viruses. However, these modified virus particles carry an extremely low safety risk for human health, as they are replication-incompetent, and also because the particles carry an extremely low infection potential via the mucosal/skin routes, due to the inherent properties of the viral vectors. Moreover, the genes/proteins of interest that will be targeted by shRNAs do not include any growth factors, confirmed oncogenes, cytotoxins, or immunomodulators, and none of them are of retroviral origin. In the unlikely event of accidental transduction of a laboratory worker's skin or mucosa by lentivirus particles, this will be self-limited, due to natural shedding of superficial epithelial skin and mucosal cell layers.

The most likely route of accidental infection with a lentivirus will be via inadvertent percutaneous inoculation. The likelihood of this occurring will, however, be minimised by adhering to appropriate risk management measures. Infection of the community at large with lentivirus particles is highly unlikely due to the viral vector particles being replication incompetent and being extremely sensitive to desiccation.

Hazard to the Environment

The probability that active viral particles will be accidentally released into the environment is considered to be extremely low, as effective containment procedures will be adhered to. However, in the unlikely event that active viral vector particles do accidentally get released into the environment, the safety risk posed by such an event is considered to be negligible, due to the vectors being self-inactivating and non-replicative. The main potential risk in such an event would be the subsequent contamination of a human population already infected with HIV, which would potentially allow for recombination events that could incorporate the inserted sequences into a viable RCL. This scenario is, however, extremely unlikely, and even if it was to occur, it is unlikely that it would lead to any untoward effects.

The vectors have been pseudotyped with the VSV-G envelope in order to increase tropism, and they are, in theory, capable of transducing all dividing and non-dividing mammalian cell types. As emphasised before, the vectors cannot self-propagate after infection, and successful transduction is also critically dependent on the presence of high enough concentrations of virus particles; also viral vector stock solutions are aliquoted and stored in small volumes (each tube contains at maximum 101J1) at -80°C so the potential for a high titre dose is reduced. The infectivity of the vectors rapidly decreases at room temperature so it is considered highly unlikely that the vectors could survive long enough in the environment to pose a risk if accidentally released.

Furthermore, lentiviral vectors have a short half-life at room temperature as their structural characteristics make them highly susceptible to dehydration, and relatively unstable. For this reason, retroviruses become rapidly inactivated outside host systems, and this is illustrated by the fact that close contact is required for transmission. They can, however, survive for long periods in high protein media.

There are no conceivable hazards associated directly with the lentiviral vectors (containing the inserts) as they will not replicate/survive outside the laboratory and they have been designed to include many protective safety features. siRNA and miRNA sequences will also not survive as they are highly unstable, and they would, consequently, be rapidly inactivated/degraded if accidentally spilled into the environment. Moreover, as discussed above, there is a very low risk that the sequences contained within the viral vectors could be transferred to other organisms, as a rare recombination event would have to occur to allow this to happen.

Summary

The chance that active viral particles will be accidentally released into the environment is considered to be highly unlikely, as the viral vector studies that will be undertaken have been classified as biosafety level 2, and effective containment procedures will be adhered to (see section C for details). However, in the unlikely event that active viral vector particles do accidentally get released into the environment, the safety risks posed by such an event is considered to be low due to the vectors being self-inactivating and non-replicative, and also due to the poor ability of the vectors to survive outside of their host systems (see above discussions).
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Following transduction of cell lines that are designated as requiring Biosafety Containment level 1 with lentivirus, we wish to be able to subsequently use these cells at Biosafety Containment level 1. This can be justified by the following procedure: under Biosafety Containment Level 2 media containing virus will be removed, the transduced cells will be extensively washed to remove any remaining virus. This liquid waste will be neutralised for at least 24 hours before disposal. The washed cells will then be cultured for a further 24 hours before being tested for the absence of infectious virus before being allowed to be treated as only requiring Biosafety Containment Level 1.

Sources of iPSC cells that have been shown to lack viral integration and test negative for infectious virus can be regarded as requiring biosafety level 1 containment. Such iPSC cells can also be derogated to biosafety level 1 containment once tested for the absence of infectious virus.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

General cleaning procedures
Surfaces will be thoroughly cleaned with Virkon* or Distel 10%* (or an equivalent product) at the end of each experiment or after the occurrence of an accidental spillage of infectious material. Application of these anti-microbial agents will totally inactivate any viral vectors that might be present. According to the biosafety literature, all of the viruses to be used are susceptible to these disinfectants. Anything that might have potentially come into contact with the virus will be treated with Virkon- or Distel 10% before being autoclaved/incinerated.

Waste handling procedures
Solid waste will be neutralised by soaking it in a validated disinfectant solution, after which the material will be ‘double bagged’, autoclaved and, ultimately, incinerated offsite.
liquid waste will be disposed of into sealed biohazard containers filled with Virkon- for incineration. It will be routine practice that all liquid waste material be neutralised before disposal, and for the neutralised waste to be transported in leak-proof containers to prevent spillages. Neutralised liquid waste will be securely sealed for collection and off-site disposal by an approved agent (B60CRP) or discarded down an approved sink (430eSP).

Summary
As any active viral particles on surfaces or in waste material will be completely inactivated at the end of each experiment by the highly effective cleaning/disinfection protocols outlined above, it is considered very unlikely that active virus particles would unintentionally become discharged into a sanitary sewage system. No foreseeable adverse effects on human health and safety are expected.

*Virkon
Rely+OnTM Virkon® is a multi-purpose disinfectant. It contains oxone (potassium peroxymonosulphate), sodium dodecylbenzenesulfonate, suiphamic acid; and inorganic buffers. Virkon oxidizes key structures and compounds, such as proteins, leading to widespread, irreversible damage and subsequent deactivation/destruction of the microorganism. It is typically used for cleaning up hazardous spills, disinfecting surfaces and soaking equipment. With powerful, proven performance against over 500 strains of viruses, bacteria and fungi. Virkon offers a broad spectrum efficacious anti-microbial activity, and it is used by governments worldwide for Emergency Disease Control.

Importantly, Virkon has specifically been validated for lentiviral inactivation (Antec-Biosentry).
Virkon is sold as a powder which dissolves readily in water. It is intended to be mixed with water to form a 1% solution (i.e. 10 9 per litre) for hard surface and equipment disinfection. 1:100 is also the dilution rate advised for virucidal efficacy against HIV-1.
DISTEL (formerly known as Trigene advance)
DISTEL is formulated as a nanoemulsion that enables the active molecules in the product to be carried rapidly through cell walls of micro-organisms, ensuring the rapid induction of cell death in treated micro-organisms. DISTEL works quicker than conventional high level disinfectants and achieves apoptosis (cell death) rather than merely suspending activity as with conventional disinfectant products. DISTEL has been reported to be bactericidal, fungicidal as well as virucidal and sporidical (http://www.tristel.com/products/healthcarelaboratories/distel-high-levellaboratory-disinfectant). It is recommended to be used at a 1:100 dilution for general purposes, 1:10 dilution for high risk disinfection.

The GMSC has agreed that the production, handling and use of the lentiviral siRNA slacks is a Class 2 activity. This decision has been reached because although the lentivirus will be generated using a third generation, self-inactivating, 4 plasmid expression system, the possibility of a recombination event occurring that leads to replication competent virus can never be discounted with this type of virus. The potential oncogenic effects of the Woodchuck Post-translational Regulatory Element have been negated by the use of the mutant form that prevents expression of the X protein. The proposal includes the potential to produce large amounts of virus. This represents the most hazardous aspect of the proposal and the GMSC is satisfied that the necessary precautions have been put in place to ensure containment is maintained. The encoded fusion-protein to be delivered by lentivirus in this proposal has been used extensively in the literature and is not known to have any detrimental effects on human health or the wider environment. The request to derogate the Biosafety Containment Level from 2 to 1 post transduction has been deemed acceptable given that the transduced cells will be washed extensively to remove any remaining viral particles and will be tested for the absence of transducing virus. It has been made clear that human iPSe cell lines that have been generated using lentiv- or retrovirus methods must be negative for the absence of virus at least. These cells will always be tested for the absence of infectious particles before being they can be used as if they only required Biosafety Containment Level 1.

Please enter comments on the GM safety committee on the risk assessment

The GMSC has agreed that the production, handling and use of the lentiviral siRNA slacks is a Class 2 activity. Animal Units | Large Scale Activities | Human Clinical Applications
Use of the Expli293 MembranePro Expression technology system (Life Technologies) for the expression and display of mammalian cell surface membrane proteins including G-protein coupled receptors (GPCR), Ion channels transporter and other membrane bound molecules in an aqueous-compatible format.

Expi293F cells are based on the HEK293 (primary human embryonic kidney cells) immortalised cell line. The Expi293F will be used to generate the VLPs, these cells have been adapted from HEK293 cells to grow in high density suspension culture. The HEK293 cell line is a permanent line established from primary embryonic human kidney cells transformed with sheared human adenovirus type 5 DNA. The E1A adenovirus gene expressed in HEK293 cells participates in the transactivation of some viral promoters, allowing these cells to produce very high levels of protein. This enables the efficient generation of viral capsids when these genes are introduced transiently into the the cell. The adenovirus genetic sequence present in HEK293 cells has been found to be non mobilisable and as such is not packaged into viral particles. This means that the cells themselves are essentially non-hazardous. These properties have meant that many virus packaging cell lines have been derived from the HEK293 cell line.
Host/vector system

The system uses pEF-V5-His_ TOPO to express the gene of interest. This plasmid does not contain any lentiviral genes and therefore poses no risk. The lentiviral gag gene or protein (packaging mix) is provided in enhancer solutions provided with the Expi293 Membrane Pro Expression Technology system kit which will be used in the production of the VLPs. The exact nature of this enhancer material is proprietary to Life Technologies but as it contains the ability to supply the gag gene or protein it will be managed as needing to be treated as a class 2 material. This system lacks any other lentiviral genes and as such does not produce or encapsulate viral DNA. Once the VLPs have been generated and purified the enhancer solution will have been removed.

Origin & function

The system relies upon the presence of the lentiviral gag core structural protein to drive the self assembly of sub viral particles that should not encapsulate DNA. These VLPs bud off from the cell surface taking membrane proteins with them. As such they will contain the proteins of either GPCR, ion channel, enzymes, transporters or other cell surface membrane proteins that are expressed in the cell.

Targets of interest that will be over-expressed for incorporation into VLPs will not be known to have cytotoxic, oncogenic or immunomodulatory effects. The purified VLPs can then be used in a variety of vitro assays to assess small molecule, peptide and protein interactions with the protein of interest present in the VLP membrane.

Evaluation of foreseeable effects

Human Health Hazard

The production method for VLPs means that it is highly unlikely that infectious virus can ever be generated. The only lentiviral gene present in the production of the VLPs is the gag gene. As the system lacks the env and pol genes infectious virus particles can not be generated and there is no viral genome to be packaged. The vectors used to express the genes of interest do not contain packaging sequences and will not therefore be packaged into the VLPs. These vectors will essentially be absent once the VLPs have been purified. There is a small chance that the gag gene and/or the vector encoding the gene of interest introduced in trans may become trapped with a VLP as it forms. As such there is a theoretical risk that if fusogenic particles do come in to contact with cells it may introduce DNA and lead to a permanent genetic change in the cell. This risk is minimal because the number of VLPs containing any DNA will be minimal, they will be dilute and as they lack the env protein they are highly unlikely to be able to infect cells. To ensure that the other lentiviral genes are not introduced into the system VLPs will not be used with other cell cultures and production will be kept separate from cells being used for the production of lentiviral vectors. As the system does utilise a lentiviral gene during the generation of the VLPs this work will be carried out at biosafety level 2. The generation of VLPs will therefore be treated as a class II activity. Standard health and safety procedures of working will be followed throughout to eliminate any risk of infection.

Hazard to the environment

The chance that infectious lenti virus is released into the environment is considered to be negligible. The VLPs that are generated are designed to only contain the gag protein of the lentiv virus and not the gag gene. Infectious VLP generation would have to involve the gag gene encountering the remaining pol or env genes and infecting cells in the environment, the risk of this is negligible given that the VLPs lack the product of the env gene and are highly unlikely to be able to infect cells. In the event of release of the VLPs into the environment, they are labile outside of the laboratory environment being sensitive to temperature and will rapidly degrade at room temperature.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
The production of the VLPs is the point at which large volumes of concentrated material will be generated in a system that has had the gene encoding gag present. The purification process will essentially remove genetic material. Once aliquots of this final material has been dispensed there should be essentially no genetic material present. Subsequent experiments will not involve the use of cells and limited amounts of material will be diluted and it is thought appropriate to handle this material with good laboratory practice.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste, including pipette tips and tissue culture flasks will be neutralised by soaking in a validated disinfection solution (5% HLD4L solution, Chemgene) for 24 hours, after which the material will be double bagged, autoclaved and taken off site for incineration. Liquid waste will be chemically deactivated with 5% HLD4L solution, Chemgene for a minimum of 24 hours prior to drain disposal via a designated sink.

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The system described above for the production of VLP for the enrichment of membrane proteins for subsequent analysis of molecular interactions with other molecules poses a very low risk to human health and the environment. The system utilises genetic material from HIV, which is known to mutate rapidly, and there is the small possibility that genetic material may be enclosed in the VLP. With this in mind the Genetic Modification Safety Committee (GMSC) agrees that the production of VLPs should be carried out at biosafety level 2 when concentrated VLP suspensions will be generated. Once generated the resultant VLP material should contain no viral genetic material and will be diluted for use in further experiments. This reduces the risk and the GMSC views that it is appropriate that subsequent downstream work can be carried out using good laboratory practices.

Purposes of the contained use

The human immortalised neural progenitor cells will be used as a tool cell line in Neurodegeneration to investigate cellular pathways involved in the development of neurodegenerative disorders, in particular Huntingtons. To better understand these cellular pathways, the expression or the activity of the gene of interest will be modulated by several methods:

1- The utilisation of tool compounds
2- The knock-down of the gene of interest by shRNA
3- The generation of modified somatic cells using programmable nucleases (CRISPR or Zinc finger nucleases)
4- The generation of reporter gene cell line (Le. fluorescence protein or enzyme) under the promoter of the gene of interest.

The experiments involving the transfection of vectors such as shRNA or programmable nucleases may be performed by lentivirus. The effect of modulating the expression or the activity of the target of interest will be determined by the expression level of the proteins, mRNA or mediators involved in the target signalling pathway.

Recipient or parental organism

1- The human immortalised neural progenitor cells, ReNcell 197VM
• ReNcell VM is an immortalized human neural progenitor cell line with the ability to readily differentiate into neurons and glial cells.
• ReNcell 197VM was derived from the ventral mesencephalon region of a human fetal brain tissue. Immortalized by retroviral transduction, using replication incompetent retrovirus, with the avian v-myc myelocytomatosis viral oncogene.
These immortalised human neural progenitor cells, ReNcell197VM, will be purchased from Millipore. Millipore have tested the cell line and shown that it does not produce infectious virus particles.

2- Human immortalised neural progenitor cells, ReNcell mHTT Exon1 197VM

• ReNcell 197VM cells were transduced with lentiviral virus particles containing varying length HTT exon 1, eGFP, cPPT, WPRE, LTR U3 del (pHRsincpptUOCE+htt exon1 IRES eGFP 29CAG/71CAG/129 CAG WPRE).

These immortalised human neural progenitor cells, ReNcell mHTT Exon1 197VM, will be provided by UCL. This cell line contains the v-myc oncogene, a WPRE element that may contain the WHV-X oncogene ORF and therefore will be maintained in a biosafety level 2 confinement.

Host/vector system

Description of the lentivirus containing shRNA, programmable nucleases sequences or gene reporter vectors

To utilise the neural progenitor cells to study neurodegeneration, the expression of a target of interest may be decreased in the ReNcell line by the transduction of shRNA or programmable nuclease by lentivirus.

The modulation of a particular cellular pathway may be studied with the use of a reporter gene assay. In this case, the vector containing the reporter gene under the regulation of the promoter of the gene of interest may be introduced by lentivirus into the ReNcells. In addition other exogenous genes may also be introduced using lentiviral vectors.

This proposal may involve both the use of existing lentiviral constructs purchased commercially and the generation of new constructs on site using the third or fourth generation system. Both commercially acquired and in-house lentivirus will use the same transfer vector plasmid. Target genes will be selected based on the needs of drug discovery projects; programmable nucleases and shRNA will not be produced against any growth factors, tropic factors, quiescence factors, confirmed oncogenes, tumour suppressors or immunomodulators (these targets will be presented to the GMSC for approval prior to any work taking place).

The production of lentivirus containing the vectors of interest are described below:

1- Generation of lentivirus

Health and Safety

Executive

Lentiviral vectors will be purchased commercially or produced in-house using the third or fourth generation system described below. Each purified and concentrated aliquot of lentiviral reagent comprised of a small volume (5 to 10ul) that contains no more than 1 X 1 Oe8 viral particles.

Vector System = self-inactivating (SIN) non replication-competent HIV based lentiviral vectors

The viral vectors that will be used in the proposed studies are self-inactivating non replication-competent HIV based lentiviral vector systems, which have been designated to produce stable gene expression in mammalian cells; and they are generated by co-transfecting HEK 293T cells with four to six separate plasmids. Each of the plasmids used expresses a different set of genes which, when combined following co-transfection, provide the smallest possible set of essential viral genes that is still compatible with virus production. Moreover, the vectors are all vesicular stomatitis virus (VSV-G) pseudotyped lentiviral vectors, which are self-inactivating and highly unlikely to undergo recombination. Importantly, the viral vector is inherently incapable of replication in mammalian cells.

The plasmids

Third Generation

The sequences that will be included in the viral vectors are sub-cloned into 4 standard bacterial plasmid vectors.

• Plasmids containing the packaging related sequences

Each of the three other plasmids, pCgpV, pRSV-Rev and pCMV-VSVG contain a different set of sequences that code for proteins that are responsible for packaging the viral vectors. All the genes (gag-pol, rev and env) required for production and packaging of the full length viable viral RNA particles have been removed from the pSMPUW lentiplasmids containing the transgenes of interest.
Fourth Generation
The sequences that will be included in the viral vectors are sub-cloned into 6 standard bacterial plasmid vectors
• Plasmids containing the packaging related sequences
Each of the other plasmids, pTRE-gag-pro, LTRHIV2-vpr-pol, penv(VSV-G), pTet-Off and ptat-RES-rev contain a
different set of sequences that code for proteins that are responsible for packaging the viral vectors. All the genes
(gag-pol, rev and env) required for production and packaging of the full length viable viral RNA particles have been
removed from the pSMPUW lenti-plasmids containing the transgenes of interest. An integrase deficient version of the
fourth generation packaging mix is available which contains a mutation in the sequence encoding the viral integrase.
The resulting integrase-deficient lentivirus (IDLV) generates circular vector episomes in transduced target cells that
are gradually lost by dilution in dividing cells (transient expression), but are stable in quiescent cells.

Origin & function

Plasmids containing the transgene of interest
The fourth plasmid, pSMPUW, will contain the sequences that code for shRNA, or programmable nuclease sequence,
or reporter gene sequence under the promoter of the gene of interest.

a- Vector containing shRNA
As mentioned above, pSMPUW plasmid will contain the sequences that code for one shRNA transcript that will target
one mRNA/protein of interest (or a scrambled shRNA in the case of negative control). The shRNA or scrambled
shRNA sequences will be under the control of polymerase II or III promoter. The shRNA sequences will be chosen to
target a single gene. The shRNA will not be produced against any growth factors, tropic factors, quiescence factors,
confirmed oncogenes, tumor suppressors or immunomodulators.

b- Vector containing CRISPR or Zinc-finger nucleases
Programmable nucleases function by binding to, and cleaving, user-defined target DNA sequences. This in turn
instigates a robust DNA repair response which ultimately leads to disruption of the target sequence by deletion at the
cleavage site or by recombination with a user-supplied synthetic vector containing sequences complementary to the
target gene allowing insertion of exogenous genetic sequence.
For Cas9/CRISPR, nuclease target specificity is determined by an accessory sequence, the guide RNA, which
consists of a short (18-20 nucleotide) sequence homologous to the target gene and an additional short sequence that
forms a complex with the Cas9 enzyme. In this case, the plasmid pSMPUW, will contain the sequences that code for
a Cas9/CRISPR plus accessory sequences comprising a short guide RNA that determines target specificity. The
guide RNA sequences will be under the control of a Polymerase III promoter.

Health and Safety

Executive
In the case of Zinc finger nucleases target specificity is dependent upon the zinc finger protein sequence. The
pSMPUW will contain in that case the sequence of zinc finger nucleases under the control of either a polymerase II
promoter. In addition, a fluorescent protein or enzyme under the control of a polymerase II promoter or the promoter
of a gene of interest may be included. Control viral vectors that express only the fluorescent protein/enzyme and no
programmable nuclease will be used in some experiments.
The Cas9/CRISPR, if introduced into any cell line by lentivirus, will use the integrase deficient version of fourth
generation packaging mix.

Health and Safety

Executive
In the case of Zinc finger nucleases target specificity is dependent upon the zinc finger protein sequence. The
pSMPUW will contain in that case the sequence of zinc finger nucleases under the control of either a polymerase II
promoter. In addition, a fluorescent protein or enzyme under the control of a polymerase II promoter or the promoter
of a gene of interest may be included. Control viral vectors that express only the fluorescent protein/enzyme and no
programmable nuclease will be used in some experiments.
The Cas9/CRISPR, if introduced into any cell line by lentivirus, will use the integrase deficient version of fourth
generation packaging mix.

a- Reporter gene vector
The pSMPUW vector will contain the sequence coding for a reporter protein (enzyme or fluorescent protein) under the
control of the regulating elements of the promoter of the gene of interest or the a polymerase II promoter. An
appropriate selection marker i.e.; neomycin could also be included to allow the selection of stable human neural
progenitor cells containing the reporter gene sequence under the control of the promoter of the gene of interest.
Target genes will be selected based on the needs of drug discovery projects; programmable nucleases, shRNA or exogenous genetic material will not be produced against any growth factors, tropic factors, quiescence factors, confirmed oncogenes, tumour suppressors or immunomodulators (proposed targets will require approval internally by the company GMSC before work can start)

Procedures:
During all procedures that involve the handling/use of the viral vectors or cells, all workers (incl. those that are not working directly with the vectors) that are present within a lab where the work is undertaken are required to wear personal protective equipment at all times. The use of two pairs of gloves is advised so the external pair can be disposed in an autoclave bag and replaced whenever necessary (e.g. in the case of contact with the viral reagent). In addition, all workers are made aware of the nature of the viral work that is going on within the laboratory, and they have to follow appropriate procedures to ensure that there is no cross-contamination into non-viral working area. All the workers using the viral delivery systems are experienced research scientist, and junior scientists will be closely supervised until they are competent in the handling of the viruses.

Lentiviral production
Lentiviral production will also be carried out on-site using a modified procedure based on Bukovsky et al. (Bukovsky et al, 1999, J. of virology). Lentiviral production will only be carried out in HEK293T cells in a biosafety level 2 cabinet within a culture flask with screw cap filter in order to minimize the risk of spills and/or aerosol mediated viral spread. For this the modified pSMPUW plasmids together with three to five additional separate plasmids (pCgpV, pRSV-Rev and pCMV-VSVG or pTRE-gag-pro, L TRHIV2-vpr-pol, penV(VSV-G), pTet-Off and plat-IREs-rev) will be transfected, using a standard chemical transfection method, into HEK293T packaging line. After 6-12 hours, the medium is replaced with fresh serum-free medium and grown for an additional 72-96 hours. After 24-48 hours, so as to ensure the viability of the transfected HEK293T cells, medium from the cells is collected into screw cap tube and stored at 40°C and fresh serum-free medium is added to the cells. The cells are grown for an additional 24-48 hours before the second medium solution is added to the first harvest tube. After lentivirus collection has been completed, the cells and the flasks will be decontaminated and disposed of (detailed later). Still within a biosafety level 2 safety cabinet in a biosafety level 2 laboratory, the harvested supernatants will be filtered using a 0.45μm filter before either aliquoted or further purified by chromatography and/or concentrated by centrifugation. The lentiviral particles may need to be purified by either chromatography and eluted in a high salt solution and/or concentrated by ultrafiltration. For certain applications, where highly concentrated and purified virus may be required, the traditional method of sucrose cushion based centrifugation may be necessary. To minimize the possible risk of accidental viral contamination and spread due to the need for an ultracentrifuge, all loading and unloading will be done in the biosafety level 2 safety cabinet. Once the sucrose cushions have been added to the centrifuge tubes, the unpurified or chromatography purified lentiviral particles will be added to the sucrose cushion. The individually capped tubes will then be transferred to their respective bucket holders and the bucket sealed using their respective screw caps and marked as containing virus. The buckets containing viruses will be balanced with buckets containing a tube with water and without lentivirus. The balanced buckets will then be transferred to the rotor before being placed within the centrifuge chamber. The ultracentrifugation will be run at 70000g for 2 hours at 200°C. Upon return of the buckets to the biosafety level 2 cabinet, the supernatant will be removed from the tubes before transfer of the resuspended virus pellet into individual screw cap cryovials. As the greatest risk for contamination occurs within the centrifugation buckets themselves during transport to and from the weight scales and during ultracentrifugation, the centrifuge tubes, the buckets and the centrifuge rotor will be decontaminated by spraying Chemgene HLD4L 5%. Optionally, the centrifuge rotors could be autoclaved at 1210°C. In any case, concentrated virus stock will not be exposed to the environment outside of the biosafety level 2 cabinet. All supernatants will be treated as above.
The lentiviral titre will be determined in terms of number of viral particles (VP) or transduction units (TU) per mL. The number of VP can be assessed relatively quickly and does not involve cell infection. In this case, a bead based enrichment assay or a p24 ELISA assay will be chosen. The VP quantification methods tend to overestimate the TU by 10-1000 fold. Thus, the TU/mL will in certain instances also be determined. For this, a titration range of lentiviruses expressing a fluorescent tag will be prepared and added to a 24 well cluster plate or T25 TC-flasks containing HEK293T for 48 hours. The percentage of fluorescent positive cells will be quantified manually under a fluorescent microscope or ideally using FACS analyser/Bioanalyser. The biological titre (TU/mL) according to the following formula: TU/uL = (P x N 100 x V) x 1DF, where P = % GFP+ cells, N= number of cells at time of transduction = 105, V = volume of dilution added to each well and OF = dilution factor = 1 (undiluted), 10-1 (diluted 1/10), 10-2 (diluted 1/100), and so on.

Aliquots with not more than 1x10e8 viruses per vial are stored at -80°C in individual screw capped cryotubes. The viral stock will consist of viral particles containing the vector genome (full capsids) and also of a variable number of empty viral capsids. Other trace components that might be present include, but are not limited to, inorganic salts, vitamins, other nutrients, human cellular proteins, carbohydrates, amino acids, and fats.

a- Assessing efficacy of the lentivirus into a BSL 1 cell line
Assessing whether the genome manipulation or the knock-down has worked will normally take place initially in biosafety level 1 immortalised cell line that are known not to contain lentiviral genetic material. Application of lentiviral particles will be done at biosafety level 2 confinement. After at least 24 hour incubation and extensive washing, the cells will treated as biosafety level 1 (see below the justification for removal of cells post-infection to biosafety level 1). In order to determine whether the knock-down or the genome manipulation has worked, the levels of mRNA and protein of the gene of interest will be assessed post-transduction.

b- Transduction of the lentivirus and the generation of stable expression into ReNcell VM neural progenitor cells
Once validated the same procedure will be carried out in the ReNcell VM neural progenitor cells. As these cells are maintained in a biosafety level 2 confinement, the inoculation of lentiviral particles, the transformed cells and the phenotypic analysis will also be performed in a biosafety level 2 containment. When a lentivirus containing a programmable nuclease or the reporter gene will be used, a stable cell line could be established by selecting the cells in which the genome has been modified. In all cases phenotypic analysis will be performed using suitable in vitro assays, including for example, RT-PCR, Western Blotting, immunocytochemistry and imaging, or cellular bioenergy (Le.: mitochondria respiration function or glycolysis function).

Evaluation of foreseeable effects

* Human Health
The immortal human ReNcell VM neural progenitor cell that will be used has a low risk to human health. The expression systems and the transgenes that comprise the lentiviral vectors that will be used have also a very low risk for human health and safety, and the reasons for this are discussed below.

A- Lentivirus containing shRNA, or programmable nucleases sequence or reporter gene vectors
Lentiviral Vector Expression System
Lentiviruses belong to the Retroviridae virus family which are capable of infecting both human and animal species. As the lentiviral vector system that will be used in these studies is based on HIV-1, a theoretical risk to human health exists. However, retroviruses are generally transmitted via exposure to contaminated body fluids or percutaneous inoculation and generally not transmitted via the airbone route. Therefore, accidental piercing of the skin or other surface tissues with virus containing objects represents the main potential route by which accidental infection could occur. Appropriate risk reduction measures will be implemented to reduce the likelihood of this occurring.
In all of the modified pSMPUW plasmids (containing shRNA, or programmable nucleases or reporter gene sequences), the sequences inserted are flanked by non-coding retroviral L TRs, and no retroviral genes are encoded on the modified pSMPUW plasm ids. Therefore, no retroviral genes will be transferred into generated viral particles.
This construct is packaged into particles using a HEK293T cell based packaging system, which requires the cotransfection of these cells with three to five additional separate plasmids (as detailed above). The additional plasmids express the envelope protein from VSVg and the non-structural proteins of the virion, and, importantly, none of these genes will be transferred into the assembled viral vectors, since they lack the packaging signal (psi), which is only present on the modified pSMPUW plasmids.

The lentiviral Expression System what will be used include the following key safety features:

* All of the pSMPUW contain a hybrid 3'LTR that does not affect generation of the viral genome in the producer cell line, but results in "self-inactivation" (SIN) of the vector after transduction of target cells. Once integrated into a transfected target cell, the lentiviral genome is no longer capable of producing viral genomic material that can be packaged. Moreover, presence of an SV40 polyA after the hybrid 3'L TR in the vector construct will result in a provirus which should reduce the potential for transactivation of cellular genes due to an insertion event. Furthermore, the development of self-inactivating vectors improves the biosafety of vectors, as they are less likely to be mobilised following a superinfection with wild-type virus (HIV).

* The VSV-G gene from Vesicular Stomatitis Virus is used in place of the HIV-1 or other retroviral envelope genes. Heterologous envelopes, like VSV-G, typically broaden the tropism and allow gene transfer into a broad variety of cells. The risk will mitigated by the use of self-inactivating virus and limiting the number of viral particles that will be handled at anytime time.

* Sequences encoding the proteins required for packaging of the viral genome are separated onto three to five plasmids, and all of the 4-6 plasmids used in the system have been engineered not to contain any regions of homology with each other so as to prevent undesirable recombination events that could lead to the generation of a replication-competent lentivirus (RCL), which could potentially be harmful to humans. It is important to note that no such RCL has ever been observed despite large-scale production and testing of lentiviral vectors.

* All of the pSMPUW containing plasmids/vectors will be used are devoid of all viral sequences apart from essential cis-acting sequences, including the L TRs and the packaging signal psi. Although the packaging plasmids used in these systems allows for the expression in trans of protein required to produce viral progeny (e.g. gal, pol, rev, env) in the HEK293T producer cell lines, none of them contain L TRs or the psi packaging sequence. Several of the lentiviral accessory genes (vif, vpr, vpu and nef) that are dispensable for lentiviral vector production/transduction have been deleted from the packaged construct. Therefore, none of the retrovirus structural genes will actually be present in the packaged viral genome, and they will never be expressed in the transduced target cells, which means that no new RCL can be produced.

* The lentiviral particles produced in this system are replication-incompetent, only carry the sequences of interest, and no other viral species are produced.

* Expression of the gag and pol genes from pgag-pol-RRE has been rendered Rev-dependent by virtue of the HIV-1 RRE (Rev Responsive Element) in the gag/pol mRNA transcript. Addition of the RRE in these plasmids prevents gag and pol expression in the absence of rev, which is contained in the pRSV-REV plasmid only. The Rev/RRE system is highly conserved among lentiviruses, and removal of the RRE sequence and associated splice donor/acceptor sequences result in a loss of transduction efficiency.

* L TR has been modified so as to increase lentiviral vector production, and also to allow lentiviral vector production to be independent of tat expression. It is known that Tat-deleted mutants of wild-type HIV-1 are not replication competent. Therefore, the deletion of Tat should decrease the risk of generating a putative RCL.

* Lentiviral vectors have a very low potential to cause immunogenicity.

* The central poly purine tract (cPPT), from the pol ORF, is included in all of the viral vectors that will be used to improve the nuclear import of the proviral DNA and hence accelerate transduction.

Health and Safety
Executive

While the lentiviral vectors that are produced using this system contain only about 20% of the original genome of HIV-1, there is a very small risk that subsequent infection of cells already infected with the lentiviral genome of HIV-1 could lead to a rare recombination event in which the transgene is transferred to a replication-competent virus. Thus, the sequences in the vector that will be expressed could potentially be transferred to surrounding cells. This event is, however, extremely unlikely to occur for a number of reasons:

1- The lentiviral vector is replication-competent and self-inactivating. In the case of a subsequent HIV-contamination, wild-type HIV-1 cannot rescue a self-inactivating HIV-1 based lentivirus once integrated into the host genome, although non-self-inactivating vectors can be.

2- In order for the spread of the gene of interest to occur following accidental infection (assuming that this has lead to viral integration), a series of unlikely events have to occur:
   a- The worker would have to become infected with HIV-1 or to be already infected with the virus.
   b- The viral and lentiviral genomes would have to integrate into the host worker's genome in the same cells and in a position where they could interact to effect homologous recombination (point 1 above)
   c- Recombination would have to occur in just the right regions to allow for transfer of the gene of interest from the lentivirus to the HIV-1 genome, which could also involve the transfer of the HIV-1 genes to the lentiviral genome. In that case, it is conceivable that a non-self-inactivating HIV could be generated that contained the gene of interest but not the rest of the genome it requires. The other gene products could be provided in trans from the lentiviral genome that may now contain the HIV-1 genes or from other HIV-1 integrants.
   d- The situation in c could conceivably lead to the production of an infectious particle containing the gene of interest, but again no genes necessary for subsequent replication. In order for another round of infection to occur, the process would have to begin again.

In these circumstances, the effects of lentiviral infection are likely to be minor in comparison to the effects of the HIV-1 infection, which would be required to affect the spread of the gene of interest. In addition, the scenario described is essentially equivalent to the rescue of the lentiviral genome from the host, which has already been shown not to occur.

3- It is extremely unlikely that any worker would infect themselves with a significant dose of lentivirus as the volumes that are used in transfection experiments are small (aliquots contain a maximum of 10μl of vector solution).

4- Moreover, insertional mutagenesis into the host genome may be considered as an oncogenic risk. We cannot rule out the possibility that, when the lentiviral genome integrates into the host genome, it will not lead to the activation of an endogeneous oncogene. However, all transcriptionally active long-terminal repeats (LTRs) have been removed as well as all promoter-like elements that required to drive expression of the transgene. This should prevent unforeseen activation of such genes. It is noted that deletion of retroviral enhancer in self-inactivating systems reduces the risk of activation but not of disruption, therefore, retroviral infection might still have permanent effects upon a cell (including oncogenic effects).

Importantly, we do not consider that the use of these lentiviral vectors will result in a significant increased risk of oncogenic activation compared to the risk possessed by any other viral delivery system. Moreover, the risk of transduction leading to tumourigenesis or other untoward harm following exposure is related in part to the titre of the viral vectors; exposure of workers to quantities of virus high enough to cause such effects would be unlikely during standard laboratory-based manipulations of lentiviral vectors.

Transgenes:

Additional hazards could arise from the properties of the genetic material that will be inserted into the viral vectors and expressed in transfected cells.
With the use of shRNA-expressing viral vector systems, the expression of specific mammalian genes/proteins can be knocked-down, in order to study their functions. Potential deleterious effects such as off-target and immunomodulatory responses can be minimised through screening designed shRNA sequences against databases of known mammalian/mRNA sequences during the design stage. The genes/proteins of interest that will be targeted by shRNA do not and will not include any growth factors, tropic factors, quiescence factors, confirmed oncogenes, tumor suppressors and immunomodulators. Some of the viral vectors that will be used contain a sequence of interest that has been scrambled (scrambled shRNA), and which is not complementary to any known mammalian sequences. This sequence will adopt a hairpin structure as with any shRNA, but it should not target any mRNA of human, mouse or rat origin. Consequently, these sequences are unlikely to pose any safety risks for the environment or human health (this will be approved by the GMSC).

Programmable nucleases: zinc fingers or Cas9/CRISPR

Zinc fingers or Cas9 protein will be directed against genes of therapeutic interest. Since the purpose of programmable nucleases is to cause mutations in defined DNA sequences the primary hazard is that such a mutation would lead to deleterious cellular effects. The genes/proteins that will be targeted do not and will not include any growth, trophic factors, confirmed oncogenes, tumor suppressors or immunomodulators. In isolation, these sequences are unlikely to pose any safety risks for the environment or human health.

Reporter genes: Fluorescent protein or enzymes

The reporter gene could be a fluorescent protein or an enzyme. Fluorescent proteins, for example GFP or dsRed, are not known to cause any diseases in human or animals and have no direct effect on cellular processes. Enzymes used frequently in reporter gene assay ie luciferase or b-galactosidase are not known to cause any diseases in humans or animals and as no direct effect on cellular processes. The expression of fluorescent protein or enzymes under the control of a promoter of a gene of interest is unlikely to pose any safety risks for the environment or human health.

Summary on lentivirus

The transgenes have a low safety risk to human health because accidental contamination with a vector would lead to only a small number of cells becoming infected, and it would be highly unlikely that expression in only a few cells could be sufficient to lead to a disease state. The inability of the lentiviral vectors to propagate on mammalian cells also reduces the risk. The programmable nucleases (CRISPR or Zinc finger or Cre recombinase) that will be employed in this viral vector system are not known to cause any relevant toxicity that might represent a safety risk to human health. The fluorescent proteins or the enzymes are not known to cause any relevant toxicities that might represent a safety risk to human health. For both programmable nucleases and shRNA, the genes/proteins of interest that will be targeted will not include any growth factors, tropic factors, quiescence factors, confirmed oncogenes, tumor suppressors or immunomodulators, and none of them are or will be of retroviral origin. Therefore the risk of use will be low.

8- Immortalised human neural progenitor cells ReNcell 197VM & mHTT Exon1 197VM and transduced immortalised immortalised ReNcell197VM & mHTT Exon1 197VM cells

Immortalised ReNcell197VM & mHTT Exon1 197VM neural progenitor cells

The immortalised ReNcell 197VM cell line has been immortalized by retroviral transduction, using replication incompetent retrovirus, with the avian v-myc myelocytomatosis viral oncogene. One of the major risks would be if the sequences coding for the v-myc oncogene were mobilised. This could happen if the ReNcell 197VM or mHTT Exon1 197VM cells are accidentally inoculated to a worker already infected by a retroviral genome. Even in that case, a series of unlikely events would have to occur to:

a. The worker would have to be already infected with the HIV-1 virus

b. The retroviral genomes would have to integrate into the immortal human neural progenitor cells genome in a
position where they could interact to effect homologous recombination.
c. Recombination would have to occur in precise regions to allow for transfer of the v-myc oncogene sequences from
the ReNcell197VM or mHTT Exon1 197VM genome to the HIV-1 genome.
d. The situation in c could conceivably lead to the production of an infectious particle containing the gene of interest.
Although the risk for human health is low, all measures will be in place to minimize the risk of human health to avoid
any accidental inoculation of a worker (see measures below).
The ReNcell mHTT Exon1197VM cells also contain the sequences forWPRE, cPPT and deltaU3 of HIV-1 virus.
However these cells should not contain the viral genes gag-pol and env required for virus production and therefore
cannot produce viruses. It is not known if the WPRE sequence has been mutated to remove the oncogenic WHV-X
protein from an open reading frame found in WPRE sequence. One of the major risk factors associated with the
utilisation of this cell line would be in that case accidental percutaneous inoculation of a worker. This ReNcell mHTT
Exon1 197VM cell line could theoretically not survive in the inoculated worker but would be quickly cleared by
the human immune system. Further modification of the ReNcell197VM or mHTT Exon1197VM cell line may enhance the
risk of mobilisation of the sequence coding for v-myc oncogene, or WPRE and the sequence of OU3 in the case of
ReNcell mHTT Exon1 197VM. Application to these cells of additional lentivirus particles could result in the
mobilisation of these sequences but should not result in the liberation of replication-competent retroviruses as the viral
genes gag-pol and env should not be present in the genome of the immortalised ReNcell mHTT Exon1 197VM neural
progenitor cells. The deltaU3 region contained in the ReNcell197VM mHTT Exon1 cells contains a deletion within
the 3'L TR region rendering it self-inactivating and the 3'L TR contained in any virus generated in house, using
pSMPUW, contains a hybrid enhanced polyA in the U3 region. If further modification is performed using lentivirus in
the ReNcell 197VM mHTT Exon1 cells, the L TR regions will be sequenced to check for lack of homology.
The ReNcell 197VM cells are likely to contain retroviral L TR sequences, with the v-myc oncogene. These L TR
sequences would be derived from MMLV and L TRs present in any lentivirus generated in house using pSMPUW
lentivirus backbone would derive from HIV-1 . There should not be sequence homology between these regions. If
further modifications are performed using lentivirus, these regions will be sequenced to check.
Furthermore, the risk can be minimised by ensuring that any lentivirus used in experiments with the host cells does
not contain gag-pol, env or any other significant retroviral genes involved in packaging and replication.
The ReNcell mHTT Exon1 197VM cells contain a mutant form of Huntingtin Exon 1. Data indicate that exon 1 proteins
are highly neurotoxic (Landles et al., 2010; Barbaro et al., 2015), and models that express either mutant full length
HTT or mutant exon 1 of HTT can be used effectively to study HD. Exon-1 expressing models demonstrate disease
phenotypes such as aggregate formation (Landles et al., 2010). One of the major risks would be if the sequence
coding for the mHTT Exon1 were mobilised. This could happen if the mHTT Exon1 197VM cells are accidentally
inoculated to a worker already infected by a retroviral genome. Even in that case, a series of unlikely events would
have to occur to (as described above for v-myc mobilisation).
Even if the events are unlikely, the immortalised human neural progenitor cell line and the transduced ReNcell 197VM
& mHTT Exon1 197VM cells will be maintained at biosafety level 2 containment. Therefore all measures will be in
place to minimize the risk to human health.
Human health hazards
Oral ingestion will be prevented by standard laboratory safety practices. Aerosol formation resulting from an accident
outside of the safety cabinet and involving lentivirus particle-containing liquid may lead to transduction of a limited
number of the laboratory worker's skin or mucosal cells with modified viruses. However, these modified virus particles
carry an extremely low safety risk for human health, as they are replication-incompetent, and also because the
particles carry an extremely low infection potential via the mucosal/skin routes, due to the inherent properties of the
viral vectors. Moreover, the programmable nucleases and shRNA that will be expressed or targeted will not be
designed to disrupt any growth factors, trophic factors, quiescence factors, confirmed oncogenes, tumour suppressors or immunomodulators. In the unlikely event of accidental transduction of a laboratory worker's skin or mucosa by lentivirus particles, this will be self-limited, due to natural shedding of superficial epithelial skin and mucosal cell layers.

The most likely route of accidental infection with a lentivirus or with the ReNcell 197VM & mHTT Exon1 197VM cell line will be via inadvertent percutaneous inoculation. The likelihood of this occurring will, however, be minimised by adhering to appropriate risk management measures. Infection of the community at large with lentivirus particles is highly unlikely due to the viral vector particles being replication incompetent. Infection of the community at large by ReNcell197VM or mHTT Exon1 197VM cells is highly unlikely due to the impossibility of the cells to survive outside of a laboratory environment.

* Environment Considerations

The chance that active viral particles will be accidentally released into the environment is considered to be highly unlikely, as effective containment procedures will be adhered to. However, in the unlikely event that active lentiviral vector particles do accidently get released into the environment, the safety risk posed in such an event is considered to be negligible, due to the vectors being self-inactivating and non-replicative. The main potential risk in such an event would be the subsequent contamination of a human population already infected with HIV, which would potentially allow for recombination events that could incorporate the inserted sequences into a viable replication-competent lentivirus. However, this scenario is extremely unlikely and even if it was to occur, it is unlikely that it would lead to any untoward effects. As the HIV virus is a human pathogen, infection of another species would not be expected to allow any form of recombination event leading to a viable transmissible entity and so the risk from this scenario is considered to be negligible. Rodents, such as wild-type mice and rats, cannot support replication of infectious HIV-1 (Goffinet et al, 2007 Retrovirology). As a result, the potential for shedding of replication-competent lentiviruses from such animals is very low (even if they were present in the original vector inoculum).

The vectors have been pseudotyped with the VSV-G envelope in order to increase tropism, and in theory they are capable of transducing all dividing and non-dividing mammalian cell types. As emphasized before, the vectors cannot self-propagate after infection, and successful transduction is critically dependent on the presence of high enough concentrations of virus particles. Viral vector stock solutions will be managed in a way that will prevent contaminations with relatively high viral titres. After production, the vectors are aliquoted and stored in screw capped cryovials at -80°C. Taking into account that the infectivity of the vectors rapidly decreases at room temperature, it is considered highly unlikely that the vectors could survive in the long term after being accidentally released into the environment. Lentiviral vectors have a short half-life, at room temperature due to their structural characteristics making them highly susceptible to dehydration, and relatively unstable. For this reason, retroviruses become rapidly inactivated outside host systems, as illustrated by the fact that close contact is required for transmission. They can, however, survive for long periods in high protein media.

There are no conceivable hazards associated directly with the lentiviral vectors (containing the inserts) as they will not replicate/survive outside the laboratory and they have been designed to include many protective safety features. shRNA sequences will also not survive as they are highly unstable, and they would, consequently, be rapidly inactivated/degraded if accidentally spilled into the environment. Moreover, as discussed above, there is a very low risk that the sequences contained within the viral vectors could be transferred to other organisms, as a rare recombination event would have to occur to allow this to happen.

The risk to the environment following accidental release of the immortalised human neural progenitor cells would be negligible since the cells are incapable of surviving outside of laboratory conditions. If ReNcell 197VM cells or mHTT Exon1 197VM cells were to directly inoculate animals, they would be quickly cleared by the immune system and would not produce active viruses. The likelihood of this occurring will, however, be minimised by adhering to
appropriate risk management measures and ensuring that all potentially contaminated material is totally inactivated before disposal.

Summary
The chance that active viral particles will be accidentally released into the environment is considered to be highly unlikely, as the viral vector studies that will be undertaken have been classified as biosafety level 2, and effective containment procedures will be adhered to. In the unlikely event that active viral vector particles do accidentally get released into the environment, the safety risks posed by such an event is considered to be low due to the vectors being self-inactivating and non-replicative, and also due to the poor ability of the vectors to survive outside of their host systems. It is also unlikely that the immortalised human neural progenitor cells, ReNcell 197VM/mHTT Exon 197VM cells, and the transduced ReNcell197VM/mHTT Exon1 197VM cells will be accidentally released into the environment, as the cell handling and studies that will be undertaken have been classified as biosafety level 2, and effective containment procedures will be adhered to.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Following transduction of cell lines that are designated as requiring Biosafety Containment Level 1 with lentivirus, we wish to be able to subsequently use these cells at Biosafety Containment Level 1. This can be justified by the following procedure: under Biosafety Containment Level 2 media containing virus will be removed, the transduced cells will be extensively washed to remove any remaining virus. This liquid waste will be neutralised for at least 24 hours before disposal. The washed cells will then be cultured for a further 24 hours before being tested for the absence of infectious virus before being allowed to be treated as only requiring Biosafety Containment Level 1.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

General cleaning procedures
Surfaces will be thoroughly cleaned with Chemgene HLD4L 5%* (or an equivalent product) at the end of each experiment or after the occurrence of an accidental spillage of infectious material. Application of these validated chemical inactivators will totally inactivate any viral vectors that might be present. According to the biosafety literature, all the viruses to be used are susceptible to these disinfectants. Anything that might have potentially come into contact with the virus will be treated with Chemgene HLD4L* before being autoclaved/incinerated.

Waste Handling
Following all work requiring biosafety level 2 containment including work with lentiviruses and ReNcell VM cells, solid waste will be neutralised by soaking in a validated disinfectant solution for 24 hours, after which the material will be "double bagged", autoclaved and, ultimately, incinerated offsite. It will be routine practise that all liquid waste material be neutralised before disposal, and for the neutralised waste to be transported in leak-proof containers to prevent spillages. Liquid waste will be inactivated by Chemgene HLD4L * for 24 hours prior to drain disposal.
As any active viral particles or ReNcell VM cells on surface or in waste material will be completely inactivated at the end of each experiment by the highly effective cleaning/disinfection protocols outlined above, it is considered highly unlikely that active virus particles or ReNcell VM cells would unintentionally become discharged into a sanitary sewage system. No foreseeable adverse effects on human health and safety are expected.

* Chemgene HLD4L
Chemgene HLD4L is formulated as a micelle cleaning technology that enables the active molecules in the product to be carried rapidly through the cell walls or micro-organisms. Swift penetration of the cell walls ensures cell death is
equally rapid. Chemgene HLD4L has been reported to be bactericidal, fungicidal as well as virucidal (HIV, hepatitis B, Herpes Simplex, Norovirus and Coronavirus) and sporicidal. It is recommended to be used at a 1:100 dilution (1%) for general purposes, 1:20 dilution (5%) for high risk areas, and for disinfection of blood and bio-hazard spillages.

Please enter comments on the GM safety committee on the risk assessment

The proposal outlined above uses ReNcelis that have been immortalised by self-inactivating retroviral integration of vMyc. A derivative of this cell line has been generated by the random integration of genetic sequence predominantly to express mHTT Exon 1 to generate a useful tool cell line for the study of Huntington's disease. It is not known if the WHV-X protein ORF has been deleted from the WPRE element in the lentivirus used for the expression of the mHTT Exon 1. The proposal then covers the knock down of gene targets via either shRNA, CRISPR/Cas9 or ZFN that could be delivered using lentivirus. In addition certain genes or variants of genes involved in disease may be integrated into the cell genome again by lentiviral vectors. Although it is noted that no viral particles are reported to be shed from the ReNcelis due to the presence of oncogenes delivered via retroviral & lentiviral integration into the host genome the GMSC confirms that the cell lines must be maintained under biosafety containment level 2. The GMSC is satisfied that because of the pre-cautions put in place around the lentiviral vectors to be used and genetic sequences to be delivered that this level of containment is suitable for the subsequent use of the cell lines.

Project Additional Information

**Purposes of the contained use**

To utilise human induced pluripotent stem cells (hiPSC) generated using retroviral reprogramming by third party organisations for target identification, target validation and compound/biologics testing to facilitate drug discovery. HiPSC generated from healthy control donors and patients with disease-relevant mutations, will be used to investigate genes and cellular mechanisms involved in the initiation and development of human disease, for example neurodegenerative disorders, such as Alzheimer's disease, Parkinson's disease, ALS, Huntington's disease. The hiPSC will be differentiated into a variety of both central nervous system (CNS) and non-CNS like mature cell types using non-genetic methodologies. These differentiated cells will be used in experiments including, but not limited to, cell-based assays, ELISA, western blotting, electrophysiology, immunocytochemistry/microscopy.

To expand understanding of the cellular mechanisms of a disease, or to use the cells for drug discovery-related work, the expression or the activity of genes of interest may be further modulated in the iPSC by several methods:

1. The utilisation of tool compounds
2. The over-expression of a protein of interest
3. The knock-down of the gene of interest by shRNA
4. The generation of modified somatic cells using programmable nucleases (CRISPR or Zinc finger nucleases)
5. The generation of reporter gene cell line (i.e. fluorescence protein or enzyme) under the promoter of the gene of interest.

**Recipient or parental organism**

HiPSC derived from primary human cells, most commonly fibroblasts.

The hiPSC that will be used will have been generated using 3rd and or 4th generation self-inactivating (SIN) nonmobilisable integrating retroviral systems based on, but not limited to, mouse Maloney murine leukaemia virus (MMLV), Maloney murine sarcoma virus (MMSV), myeloproliferative sarcoma virus (MPSV), or human HIV. Some of the original donor material will not have been screened for human pathogens but donors will have a known medical history and will be classified as being low risk for retroviral pathogens. As such the hiPSC are highly unlikely to be producing replication competent lentivirus particles (RCLs).

Reprogramming of the hiPSC is achieved using a variety of factors, that are integrated into the cell genome by the retroviral vectors, that induce pluripotency in the donor cells. The following factors may be present in the supplied
hiPSCs:
SOX2: is a transcription factor that is essential for maintaining the pluripotency of undifferentiated embryonic stem cells.
KLF4: is a transcription factor that regulates proliferation, differentiation, apoptosis and somatic cell reprogramming. KLF4 may also act as a tumour suppressor gene.
OCT4: is a homeodomain transcription factor of the POU family. This protein is critically involved in the self-renewal of undifferentiated embryonic stem cells and is used as a marker for undifferentiated stem cells. It is indispensable for generating iPSC.
CMYC: is a transcription factor that plays a role in cell cycle progression, apoptosis and cellular transformation. Mutated c-Myc is found in many cancers, where it is constitutively expressed, leading to the unregulated expression of many genes, some of which are involved in cell proliferation leading to oncogenesis. This factor poses a risk if mobilised into RCL.
NANOG: is a transcription factor critically involved with self-renewal of undifferentiated embryonic stem cells.
LIN28: encodes a microRNA-binding protein; overexpression of which in mice can cause gigantism and a delay in puberty onset. Human GWAS studies indicates the LIN28B gene to be associated with human height and puberty timing. The biosafety risk is low for adults.
GLIS1: is a highly promiscuous transcription factor, positively or negatively regulating the expression of a number of genes.

Host/vector system

The vectors and factors used to generate any hiPSC that is supplied will be fully described prior to receipt and be reviewed by the Genetic Modification Safety Committee (GMSC) at Takeda Cambridge Ltd (TCB). Secondary transduction of the hiPSC with lentiviral vectors is planned. The hiPSC already contain integrated lentiviral sequences so subsequent lentiviral vectors will be non-homologous to mitigate the small risk of a recombination event leading to mobilisation of genetic material, such as the myc oncogene or immunomodulatory genes, that might pose a risk to human health. The integrated murine based lentivirus pose no additional risk to the environment. Secondary transduction would modify the hiPSCs to explore the underlying disease process or to generate tools for drug discovery. To this end the following could be used based upon the needs of drug discovery programs:
• Integration of shRNA constructs to ‘knock down’ expression of a gene of interest
• The over-expression of particular genes
• Specific modification of the host genome to using programmable nucleases:
  • Cas9/CRISPR
  • Zinc finger
• Reporter genes under the control of selected transcriptional regulatory sequences to study effects on cellular pathways.

The lentivirus used will either be obtained commercially or generated de novo internally using third of fourth generation vector systems. The vector backbone and promoters used to drive vector generation in these systems will be consistent. Genes selected for study will not include growth factors, tropic factors, quiescence factors, confirmed oncogenes or tumour suppressors.

Vectors will be generated using a non replication-competent HIV based lentiviral system that upon integration into the host genome loses part of its long terminal repeat (LTR) preventing excision at a later time point. Such selfinactivating (SIN) vectors are designated to produce stable gene expression in target mammalian cells. The viral particles can only be generated upon co-transfecting a packaging cell line (HEK 293T) with at least four separate plasmids. Three of which provide the minimal set of genes required for viral production (gag-pol, rev and env). The env gene used expresses the vesicular stomatitis virus (VSV-G) to increase tropism. The final plasmid supplies the...
genetic material to be supplied to the target cell and as such contains packaging sequences directing it to be incorporated into nascent viral particles. Only the minimum amount of lentiviral genome is used in the system and all of the plasmids lack homologous sequences to minimise any chance of recombination. The resultant lentiviral particles are VSV-G pseudotyped, SIN and replication incompetent in mammalian cells. Small aliquots of no more than 1 x 10^8 viral particles in 5 to 10 microlitres will be used further reducing the risk.

Third Generation Systems use 4 standard bacterial plasmid vectors. Three plasmids encode for proteins required for production and packaging of full length viral RNA (pCagV, pRSV-Rev and pCMV-VSVG). The gene of interest is contained in the pSMPUW plasmid. This is the only plasmid that contains the packaging sequence for incorporation into the virus particle.

Fourth Generation Systems use 6 standard bacterial plasmid vectors. The system uses tetracycline to control when viral particles are produced adding yet another level of control to production. pTRE-gag-pro, LTR HIV2-vpr-pol, penv(VSV-G), pTet-Off and ptat-IRES-rev contain the sequences that code for proteins that are responsible for the tetracycline control and packaging the viral vectors. As above pSMPUW only contains the genetic material to be packaged into the vector and no other lentiviral gene sequence. An integrase deficient version of the fourth generation is available which contains a mutation in the sequence encoding the viral integrase.

The plasmid, pSMPUW, will contain the genetic sequence to be introduced. These will not include growth factors, tropic factors, quiescence factors, confirmed oncogenes or tumour suppressors. All proposed sequences to be used will require approval by the GMSC.

- Vector containing shRNA - each vector will code for one shRNA transcript that will be designed to target one mRNA/protein of interest (or a scrambled shRNA in the case of negative control). This will be under the control of a polymerase II or III promoter.
- Vector containing CRISPR or Zinc-finger nucleases - Programmable nucleases function by binding to, and cleaving, user-defined target DNA sequences. This instigates a robust DNA repair response which can either be used to disrupt the target sequence by deletion at the cleavage site or to introduce user-supplied genetic material via recombination with a vector containing complementary sequences to the target gene.
  - For Cas9/CRISPR, nuclease target specificity is determined by a guide RNA, which consists of a short (18-20 nucleotide) sequence homologous to the target gene and an additional short sequence that forms a complex with the Cas9 enzyme. Vector will encode Cas9/CRISPR plus a guide RNA under the control of a Polymerase III promoter.
  - Zinc finger nuclease target specificity is dependent upon the zinc finger protein sequence which will be under the control of a polymerase II promoter.

A fluorescent protein or enzyme under the control of a polymerase II promoter or the promoter of a gene of interest may be included. Control vectors only expressing fluorescent protein/enzyme will also be used.

- Reporter or overexpression gene vector - The vector will contain either sequence coding for a reporter protein, a protein to be overexpressed under the control of regulatory elements of a promoter of a gene of interest or a polymerase II promoter. An appropriate selection marker i.e.; neomycin could also be included to allow the selection of cells stably containing either the introduced genetic material.

The efficacy of lentiviral vectors will first be assessed using cell lines that routinely require biosafety level 1 containment (BSL 1). Application of lentiviral particles will be done at biosafety level 2 containment. At least 24 hours post transduction the cells will be washed to remove any residual viral particles and then treated as BSL 1 as the potential risk has been minimised. The efficacy of the genome manipulation will be assessed using in vitro assays. hiPSC will be transduced with validated lentivirus. All procedures will be conducted at BSL2. Stable cell lines will be documented. Resultant cells will be studied to further understand disease processes or used for drug discovery efforts. This will be done by phenotypic analysis using a range of common in vitro assays, including but not limited to
Evaluation of foreseeable effects

hiPSC are pluripotent and are capable of uncontrolled proliferation. Lentiviruses belong to the Retroviridae virus family which are capable of infecting both human and animal species. The lentiviral vector system that will be used is based on HIV-1. Retroviruses are generally transmitted via exposure to contaminated body fluids or percutaneous inoculation and generally not transmitted via the airborne route. Piercing of the skin represents the main potential route by which material could be accidentally introduced into an individual. Appropriate risk reduction measures will be implemented to reduce the likelihood of this occurring.

Accidental introduction of hiPSC into healthy individuals should not lead to the formation of teratomas because the immune system will rapidly destroy these cells. As mentioned above the pathogen status of some cells is not known. However the material is not derived from high-risk clinical patients and procedures are in place to deal with needle stick incidents. Individuals with compromised immune systems are not permitted to work with this material.

The genetic material to be incorporated into the viral particles is flanked by non-coding retroviral LTRs in the pSMPUW plasmid. No retroviral genes are encoded on this plasmid minimising the chance any will be packaged into viral particles. As the system requires the co-transfection of three to five additional separate plasmids into a permissive cell line the chance of recombination occurring that leads to the incorporation of any or all of the retroviral genes necessary for the production of a replication competent lentivirus (RCL) is very low and the risk is therefore low.

The lentiviral Expression System includes the following key safety features:

* Only pSMPUW includes LTR and packaging signal sequence required for incorporation into viral particles and integration into the genome of a transduced cell. A hybrid 3’LTR is used that does not affect generation of the viral genome in the producer cell line, but upon integration into the genome of a target cell, the 3’LTR SIN and prevents production of viral genomic material that can be packaged and reduces the chance of mobilisation due to secondary infection with lentivirus. No transcriptionally active LTRs are present in the system and an SV40 polyA is included after the hybrid 3’LTR to reduce the potential for transactivation of cellular genes due to an insertion event that might promote inappropriate gene expression leading to oncogenic effects.

* The LTR has been modified to enable lentiviral production independent of Tat expression. HIV-1 devoid of Tat is known to be replication incompetent. This decreases the risk of RCL occurring.

* The essential genes encoding the proteins required for packaging of the viral genome are separated onto three to five plasmids. These express the proteins (gag, pol, rev, env) required to generate viral particles transiently in the HEK-293T packaging cell line. Other retroviral structural genes are not present in the system. None of the plasmids have regions of homology which will prevent undesirable recombination. As multiple recombination events would be required to generate a RCL the risk of this happening is very low and has so far not been observed in large-scale production and testing of lentiviral vectors.

* Expression of the gag and pol genes has been rendered Rev-dependent by virtue of the HIV-1 RRE (Rev Responsive Element) in the gag/pol mRNA transcript. Expression requires the presence of rev, which is supplied by the pRSV-REV plasmid. The Rev/RRE system is highly conserved among lentiviruses and loss of the RRE sequence and associated splice donor/acceptor sequences results in a loss of transduction efficiency.

* Lentiviral vectors have a very low potential to cause immunogenicity.

* The central poly purine tract (cPPT), from the pol ORF, is included in all of the viral vectors that will be used to improve the nuclear import of the proviral DNA and hence accelerate transduction.

Whilst pseudotyped VSV-G is used as the envelop protein to increase the cell types that can be infected this increase in risk is mitigated by the SIN non-replication nature of the viral vectors generated. Insertional events that disrupt gene function can occur and in some instances might lead to undesirable effects and could be oncogenic. The resultant lentiviral vectors contain about 20% of the original HIV-1 genome. Recombination with wild-type HIV-1 is still potentially possible and would result in mobilisation of the transgene. This is highly unlikely because:
1. Wild-type HIV-1 is not used with in the laboratory environment.
2. hiPSC are not derived from donors either known to be HIV positive or from a high-risk population; so HIV contamination is highly unlikely.
3. Wild type HIV-1 cannot rescue a SIN HIV-1 based lentivirus once integrated into the host genome.
4. It is likely that any recombination would actually decrease the ability of HIV-1 to infect other cells or to replicate.
5. Even if a worker was already or became HIV-1 positive and was accidentally infected with lentiviral vector any recombination would require infection of the same cells. Generation of RCL would require homologous recombination to be in the right regions to enable mobilisation and incorporation to the HIV-1 genome without loss of replication ability. If such a rare event were to occur it is likely to be self limiting and the HIV-1 infection itself is of greater concern to the worker.

The use of lentiviral vectors is an efficient manner with which to deliver genetic material to numerous cell types. The design of the vectors minimises the chance for subsequent mobilisation of transgenes and inappropriate activation of endogenous oncogenes. Insertional events can lead to harmful side effects but are still very unlikely. As such the greatest risk from these vectors comes with their production where much larger volumes and numbers of vectors are being generated. The risk here is mitigated by the correct use of containment measures and the absence of sharps. Lentiviral vectors are susceptible to dehydration and loss of viability if they are not stored in high protein conditions which reduces the risk to workers and the wider environment.

Transgenes to be delivered to target cells:
Additional hazards could arise from the properties of the genetic material that will be inserted into the viral vectors and expressed in transfected hiPSC cells.
Gene products to be overexpressed will not include any growth factors, confirmed oncogenes, or tumor suppressors. The focus of the research is on neurodegenerative diseases so with justification to and with GMSC approval immunomodulators or proteins known to be involved in neurodegeneration may be delivered by lentivirus. The 'knock-down' of specific gene expression using shRNA can lead to off-target and immunomodulatory responses in vivo. shRNA sequences will be screened against databases of known mammalian/mRNA sequences during the design stage to avoid such complications. Genes encoding any growth factors, tropic factors, quiescence factors, confirmed oncogenes, or tumor suppressors will not be targeted. Control vectors containing a sequence of interest that has been scrambled (scrambled shRNA), and which is not complementary to and therefore do not target any known mammalian sequences. Such sequences are unlikely to pose any safety risks for the environment or human health.
Programmable nucleases: zinc fingers or Cas9/CRISPR will be directed against genes of therapeutic interest. Again genes that will be targeted will not include any growth, tropic factors, confirmed oncogenes, tumor suppressors or immunomodulators. In isolation, these sequences are unlikely to pose any safety risks for the environment or human health. Programmable nucleases may be used to generate isogenic controls lines by correcting disease causing mutations back to wild-type sequence. This is low risk because the sequence is aimed to revert back to non-disease forms of the gene.
Reporter genes: Commonly used fluorescent proteins or enzymes under the regulatory control of promoters of interest may be used to monitor effects on cellular pathways. Such proteins are not known to cause any human or animal disease and pose no-risk.
In all cases justification for any target must be submitted to the GMSC for approval prior to any work commencing.

Summary
hiPSC will be derived from low risk patient populations but may not be screened for human pathogens. The lentiviral systems are replication incompetent and SIN minimising the potential for transgene mobilisation and propagation. The transgenes that can be used will on their own have a low risk to human health. Infection of mucosal cells may occur...
via aerosols but is highly unlikely due to the use of microbiological safety cabinets and secondary containment. Such infection is self limiting due to the natural shedding of epithelial cells coupled with the replication incompetent nature of the vectors. The most likely route of accidental infection with a lentivirus or with the hiPSC line will be via inadvertent percutaneous inoculation via stick injury or open wound. The likelihood of this occurring will be minimised by following standard BSL2 containment practices. Infection of the community and environment with lentivirus particles is highly unlikely due to small quantities used, their intrinsic instability and rapid loss of viability with time. hiPSC can not survive outside of the laboratory environment so pose no wider risk. Therefore the risks towards workers, co-workers, the public and the environment associated with the use of these lentiviral vectors with hiPSC will be low and BSL2 containment is sufficient.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste Handling
Solid waste will be neutralised by soaking in a validated disinfectant solution (5% Chemgene HLD4L), after which the material will be autoclaved and then sent for incineration via a registered waste disposal company. All liquid waste will be inactivated for 24hrs prior to disposal to drains via a designated sink.
Chemgene HLD4L: is formulated as a micelle cleaning technology that enables the active molecules in the product to be carried rapidly through the cell walls or micro-organisms. Swift penetration of the cell walls ensures cell death is equally rapid. Chemgene HLD4L has been reported to be bactericidal, fungicidal as well as virucidal (HIV, hepatitis B, Herpes Simplex, Norovirus and Coronavirus) and sporicidal. It is recommended to be used at a 1: 1 00 dilution (1 %) for general purposes, 1 :20 dilution (5%) for high risk areas, and for disinfection of blood and bio-hazard spillages.
General cleaning procedures
Surfaces will be thoroughly cleaned with Chemgene HLD4L 5%* (or an equivalent product) at the end of each experiment or after the occurrence of an accidental spillage of infectious material. Application of these anti-microbial agents will totally inactivate any viral vectors that might be present. According to the biosafety literature, all the viruses to be used are susceptible to these disinfectants. Anything that might have potentially come into contact with the virus will be treated with Chemgene HLD4L* before being autoclaved/incinerated.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
It is noted that the primary human cell lines used for the generation of hiPSES will be taken from patient populations with a known medical history meaning that there is a low risk of material containing harmful human pathogens. This does not rule out the presence of latent viral infection but the use of third or fourth generation integrating lentiviral systems that are self-inactivating and essentially non-mobilisable makes it highly unlikely that infective replication competent virus will be generated. Important due to the presence of the potentially oncogenic Mye sequence. Additional rounds of lentiviral transduction should not be able to mobilise any genetic elements because self-inactivating systems will be used that lack the necessary genes for viral replication and packaging. As an additional measure the GMSe will have a clear understanding of how each cell line was generated and steps will be taken to ensure overlapping and therefore potential sites for recombination are not present in lentiviral vectors. These vectors are for the introduction of further modifications. Those aimed at correcting disease mutations do not pose a risk to health. The introduction of non-disease causing genetic material for exogenous expression is not seen as a risk either. In the instance where immune-modulators may be targeted the risk although increased is well contained by the avoidance of sharps during transduction procedures. Once cells are transduced and virus removed the risk posed here is very low. Due to the use of iPSe derived from primary human cells and integrating lentiviral vectors this dictates propagation, differentiation and further transduction of cell lines at BSL2. Subsequent testing of the cells will also continue at BSL2 although the genetic modification of the cells is of very low risk.

Purposes of the contained use

To utilise human induced pluripotent stem cells (hiPSC) generated using episomal reprogramming by third party organisations for target identification, target validation and compound/biologics testing to facilitate drug discovery. HiPSC generated from healthy control donors and patients with disease-relevant mutations, will be used to investigate genes and cellular mechanisms involved in the initiation and development of human disease, for example neurodegenerative disorders, such as Alzheimer's disease, Parkinson's disease, ALS, Huntington's disease. The hiPSC will be differentiated into a variety of both central nervous system (CNS) and non-CNS like mature cell types using non-genetic methodologies. These differentiated cells will be used in experiments including, but not limited to, cell-based assays, ELISA, western blotting, electrophysiology, immunocytochemistry/microscopy. To expand understanding of the cellular mechanisms of a disease, or to use the cells for drug discovery-related work, the expression or the activity of genes of interest may be further modulated in the iPSC by several methods:

1. The utilisation of tool compounds
2. The over-expression of a protein of interest
3. The knock-down of the gene of interest by shRNA
4. The generation of modified somatic cells using programmable nucleases (CRISPR or Zinc finger nucleases)
5. The generation of reporter gene cell line (i.e. fluorescence protein or enzyme) under the promoter of the gene of interest.

Recipient or parental organism

HiPSC derived from primary human cells, most commonly fibroblasts.

Host/vector system

The hiPSC will have been generated using an Epstein Barr Virus episomal system by a third party. By the time of transfer to Takeda Cambridge Ltd these vectors will have been lost and the cells deemed 'foot-print' free. The cells are also checked for absence of active expression of the genes present on the episomes. Although the gene expression profile has been altered they are essentially not genetically modified and the only risk is associated with any human pathogens present in culture. This risk is mitigated by donors having a known medical history and
Secondary transduction would modify the hiPSCs to explore the underlying disease process or to generate tools for drug discovery. To this end the following could be used based upon the needs of drug discovery programs:

- Integration of shRNA constructs to 'knock down' expression of a gene of interest
- The over-expression of particular genes
- Specific modification of the host genome to using programmable nucleases:
  - Cas9/CRISPR
  - Zinc finger
- Reporter genes under the control of selected transcriptional regulatory sequences to study effects on cellular pathways

The lentivirus used will either be obtained commercially or generated de novo internally using third of fourth generation vector systems. The vector backbone and promoters used to drive vector generation in these systems will be consistent. Genes selected for study will not include growth factors, tropic factors, quiescence factors, confirmed oncogenes or tumour suppressors.

Vectors will be generated using a non replication-competent HIV based lentiviral system that upon integration into the host genome loses part of its long terminal repeat (LTR) preventing excision at a later time point. Such self-inactivating (SIN) vectors are designated to produce stable gene expression in target mammalian cells. The viral particles can only be generated upon co-transfecting a packaging cell line (HEK 293T) with at least four separate plasmids. Three of which provide the minimal set of genes required for viral production (gag-pol, rev and env). The env gene used expresses the vesicular stamatis virus (VSV-G) to increase tropism. The final plasmid supplies the genetic material to be supplied to the target cell and as such contains packaging sequences directing it to be incorporated into nascent viral particles. Only the minimum amount of lentiviral genome is used in the system and all of the plasmids lack homologous sequences to minimise any chance of recombination. The resultant lentiviral particles are VSV-G pseudotyped, SIN and replication incompetent in mammalian cells. Small aliquots of no more than 1x10⁸ viral particles in 5 to 10 microlitres will be used further reducing the risk.

Third Generation Systems use 4 standard bacterial plasmid vectors. Three plasmids encode for proteins required for production and packaging of full length viral RNA (pCgpV, pRSV-Rev and pCMV-VSVG). The gene of interest is contained in the pSMPUW plasmid. This is the only plasmid that contains the packaging sequence for incorporation into the virus particle.

Fourth Generation Systems use 6 standard bacterial plasmid vectors. The system uses tetracycline to control when viral particles are produced adding yet another level of control to production. pTRE-gag-pro, LTRHIV2-vpr-pol, penv(VSV-G), pTet-Off and ptat-RES-rev contain the sequences that code for proteins that are responsible for the tetracycline control and packaging the viral vectors. As above pSMPUW only contains the genetic material to be packaged into the vector and no other lentiviral gene sequence. An integrase deficient version of the fourth generation is available which contains a mutation in the sequence encoding the integrase domain.

The hiPSC will have been generated using an Epstein Barr Virus episomal system by a third party. By the time of transfer to Takeda Cambridge Ltd these vectors will have been lost and the cells deemed ‘foot-print’ free. The cells are also checked for absence of active expression of the genes present on the episomes. Although the gene expression profile has been altered they are essentially not genetically modified and the only risk is associated with any human pathogens present in culture. This risk is mitigated by donors having a known medical history and belonging to low risk populations. Secondary transduction would modify the hiPSCs to explore the underlying disease process or to generate tools for drug discovery. To this end the following could be used based upon the needs of drug discovery programs:
Integration of shRNA constructs to 'knock down' expression of a gene of interest
• The over-expression of particular genes
• Specific modification of the host genome to using programmable nucleases:
  • Cas9/CRISPR
  • Zinc finger
• Reporter genes under the control of selected transcriptional regulatory sequences to study effects on cellular pathways

The lentivirus used will either be obtained commercially or generated de novo internally using third of fourth generation vector systems. The vector backbone and promoters used to drive vector generation in these systems will be consistent. Genes selected for study will not include growth factors, tropic factors, quiescence factors, confirmed oncogenes or tumour suppressors.

Vectors will be generated using a non replication-competent HIV based lentiviral system that upon integration into the host genome looses part of its long terminal repeat (LTR) preventing excision at a later time point. Such selfinactivating (SIN) vectors are designated to produce stable gene expression in target mammalian cells. The viral particles can only be generated upon co-transfecting a packaging cell line (HEK 293T) with at least four separate plasmids. Three of which provide the minimal set of genes required for viral production (gag-pol, rev and env). The env gene used expresses the vesicular stamatitis virus (VSV-G) to increase tropism. The final plasmid supplies the genetic material to be supplied to the target cell and as such contains packaging sequences directing it to be incorporated into nascent viral particles. Only the minimum amount of lentiviral genome is used in the system and all of the plasmids lack homologous sequences to minimise any chance of recombination. The resultant lentiviral particles are VSV-G pseudotyped, SIN and replication incompetent in mammalian cells. Small aliquots of no more than 1x10^8 viral particles in 5 to 10 microlitres will be used further reducing the risk.

Third Generation Systems use 4 standard bacterial plasmid vectors. Three plasmids encode for proteins required for production and packaging of full length viral RNA (pCgpV, pRSV-Rev and pCMV-VSVG). The gene of interest is contained in the pSMPUW plasmid. This is the only plasmid that contains the packaging sequence for incorporation into the virus particle.

Fourth Generation Systems use 6 standard bacterial plasmid vectors. The system uses tetracycline to control when viral particles are produced adding yet another level of control to production. pTRE-gag-pro, LTRHIV2-vpr-pol, penv(VSV-G), pTet-Off and plat-IRES-rev contain the sequences that code for proteins that are responsible for the tetracycline control and packaging the viral vectors. As above pSMPUW only contains the genetic material to be packaged into the vector and no other lentiviral gene sequence. An integrase deficient version of the fourth generation is available which contains a mutation in the sequence encoding the viral integrase.

Evaluation of foreseeable effects

hiPSC are pluripotent and are capable of uncontrolled proliferation. Lentiviruses belong to the Retroviridae virus family which are capable of infecting both human and animal species. The lentiviral vector system that will be used is based on HIV-1. Retroviruses are generally transmitted via exposure to contaminated body fluids or percutaneous inoculation and generally not transmitted via the airborne route. Piercing of the skin represents the main potential route by which material could be accidentally introduced into an individual. Appropriate risk reduction measures will be implemented to reduce the likelihood of this occurring.

Accidental introduction of hiPSC into healthy individuals should not lead to the formation of teratomas because the immune system will rapidly destroy these cells. As mentioned above the pathogen status of some cells is not known. However the material is not derived from high-risk clinical patients and procedures are in place to deal with needle stick incidents. Individuals with compromised immune systems are not permitted to work with this material.

The genetic material to be incorporate into the viral particles is flanked by non-coding retroviral LTRs in the pSMPUW plasmid. No retroviral genes are encoded on this plasmid minimising the chance any will be packaged into viral
particles. As the system requires the co-transfection of three to five additional separate plasmids into a permissive cell line the chance of recombination occurring that leads to the incorporation of any or all of the retroviral genes necessary for the production of a replication competent lentivirus (RCL) is very low and the risk is therefore is low. The lentiviral Expression System includes the following key safety features:

* Only pSMPUW includes LTR and packaging signal sequence required for incorporation into viral particles and integration into the genome of a transduced cell. A hybrid 3’LTR is used that does not affect generation of the viral genome in the producer cell line, but upon integration into the genome of a target cell, the 3’LTR SIN and prevents production of viral genomic material that can be packaged and reduces the chance of mobilisation due to secondary infection with lentivirus. No transcriptionally active LTRs are present in the system and an SV40 polyA is included after the hybrid 3’LTR to reduce the potential for transactivation of cellular genes due to an insertion event that might promote inappropriate gene expression leading to oncogenic effects.

* The LTR has been modified to enable lentiviral production independent of Tat expression. HIV-1 devoid of Tat is known to be replication incompetent. This decreases the risk of RCL occurring.

* The essential genes encoding the proteins required for packaging of the viral genome are separated onto three to five plasmids. These express the proteins (gag, pol, rev, env) required to generate viral particles transiently in the HEK-293T packaging cell line. Other retroviral structural genes are not present in the system. None of the plasmids have regions of homology which will prevent undesirable recombination. As multiple recombination events would be required to generate a RCL the risk of this happening is very low and has so far not been observed in large-scale production and testing of lentiviral vectors.

* Expression of the gag and pol genes has been rendered Rev-dependent by virtue of the HIV-1 RRE (Rev Responsive Element) in the gag/pol mRNA transcript. Expression requires the presence of rev, which is supplied by the pRSV-REV plasmid. The Rev/RRE system is highly conserved among lentiviruses and loss of the RRE sequence and associated splice donor/acceptor sequences results in a loss of transduction efficiency.

* Lentiviral vectors have a very low potential to cause immunogenicity.

* The central poly purine tract (cPPT), from the pol ORF, is included in all of the viral vectors that will be used to improve the nuclear import of the proviral DNA and hence accelerate transduction.

Whilst pseudotyped VSV-G is used as the envelop protein to increase the cell types that can be infected this increase in risk is mitigated by the SIN non-replication nature of the viral vectors generated. Insertional events that disrupt gene function can occur and in some instances might lead to undesirable effects and could be oncogenic. The resultant lentiviral vectors contain about 20% of the original HIV-1 genome. Recombination with wild-type HIV-1 is still potentially possible and would result in mobilisation of the transgene. This is highly unlikely because:

1. Wild-type HIV-1 is not used with in the laboratory environment.
2. hiPSC are not derived from donors either known to be HIV positive or from a high-risk population; so HIV contamination is highly unlikely.
3. Wild type HIV-1 cannot rescue a SIN HIV-1 based lentivirus once integrated into the host genome.
4. It is likely that any recombination would actually decrease the ability of HIV-1 to infect other cells or to replicate.
5. Even if a worker was already or became HIV-1 positive and was accidentally infected with lentiviral vector any recombination would require infection of the same cells. Generation of RCL would require homologous recombination to be in the right regions to enable mobilisation and incorporation to the HIV-1 genome without loss of replication ability. If such a rare event were to occur it is likely to be self limiting and the HIV-1 infection itself is of greater concern to the worker.

The use of lentiviral vectors is an efficient manner with which to deliver genetic material to numerous cell types. The design of the vectors minimises the chance for subsequent mobilisation of transgenes and inappropriate activation of endogenous oncogenes. Insertional events can lead to harmful side effects but are still very unlikely. As such the
greatest risk from these vectors comes with their production where much larger volumes and numbers of vectors are
being generated. The risk here is mitigated by the correct use of containment measures and the absence of sharps.
Lentiviral vectors themselves rapidly lose ability to transduce cells if not stored in high protein buffer and are
susceptible to dehydration. This reduces the risk of accidental exposure to workers and the environment.
Transgenes to be delivered to target cells:
Additional hazards could arise from the properties of the genetic material that will be inserted into the viral vectors and
expressed in transduced hiPSC cells.
Gene products to be overexpressed will not include any growth factors, confirmed oncogenes, or tumor
suppressors. The focus of the research is on neurodegenerative diseases so with justification to and with GMSC
approval immunomodulators or proteins known to be involved in neurodegeneration may be delivered by lentivirus.
The 'knock-down' of specific gene expression using shRNA can lead to off-target and immunomodulatory
responses in vivo. shRNA sequences will be screened against databases of known mammalian/mRNA sequences
during the design stage to avoid such complications. Genes encoding any growth factors, tropic factors, quiescence
factors, confirmed oncogenes, or tumor suppressors will not be targeted. Control vectors containing a sequence of
interest that has been scrambled (scrambled shRNA), and which is not complementary to and therefore do not target
any known mammalian sequences. Such sequences are unlikely to pose any safety risks for the environment or
human health.
Programmable nucleases: zinc fingers or Cas9/CRISPR will be directed against genes of therapeutic interest.
Again genes that will be targeted will not include any growth, trophic factors, confirmed oncogenes, tumor
suppressors or immunomodulators. In isolation, these sequences are unlikely to pose any safety risks for the
environment or human health. Programmable nucleases may be used to generate isogenic control lines by correcting
disease causing mutations back to wild-type sequence. This is low risk because the sequence is aimed to revert back
to non-disease forms of the gene.
 Reporter genes: Commonly used fluorescent proteins or enzymes under the regulatory control of promoters of
interest may be used to monitor effects on cellular pathways. Such proteins are not known to cause any human or
animal disease and pose no-risk.
In all cases justification for any target must be submitted to the GMSC for approval prior to any work commencing.
Summary
hiPSC will be derived from low risk patient populations but may not be screened for human pathogens. The cell
supplied to Takeda Cambridge Ltd will be 'foot-print' free and can be regarded as not being genetically modified.
Subsequent lentiviral vector systems are replication incompetent and SIN essentially preventing transgene mobilisation
and propagation. The transgenes that can be used will on their own have a low risk to human health. Infection of
mucosal cells may occur via aerosols but is highly unlikely due to the use of microbiological safety cabinets and
secondary containment. Such infection is self limiting due to the natural shedding of epithelial cells coupled with the
replication incompetent nature of the vectors. The most likely route of accidental infection with a lentivirus or with the
hiPSC line will be via inadvertent percutaneous inoculation via stick injury or open wound. The likelihood of this
occurring will be minimised by following standard BSL2 containment practices. Infection of the community and
environment with lentivirus particles is highly unlikely due to small quantities used, their intrinsic instability and rapid
loss of viability with time. hiPSC can not survive outside of the laboratory environment so pose no wider risk.
Therefore the risks towards workers, co-workers, the public and the environment associated with the use of these
lentiviral vectors with hiPSC will be low and BSL2 containment is sufficient.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste Handling

Solid waste will be neutralised by soaking in a validated disinfectant solution (5% Chemgene HLD4L), after which the material will be autoclaved and then sent for incineration via a registered waste disposal company. All liquid waste will be inactivated for 24hrs prior to disposal to drains via a designated sink.

Chemgene HLD4L is formulated as a micelle cleaning technology that enables the active molecules in the product to be carried rapidly through the cell walls or micro-organisms. Swift penetration of the cell walls ensures cell death is equally rapid. Chemgene HLD4L has been reported to be bactericidal, fungicidal as well as virucidal (HIV, hepatitis B, Herpex Simplex, Norovirus and Coronavirus) and sporicidal. It is recommended to be used at a 1:100 dilution (1 %) for general purposes, 1 :20 dilution (5%) for high risk areas, and for disinfection of blood and bio-hazard spillages.

General cleaning procedures
Surfaces will be thoroughly cleaned with Chemgene HLD4L 5%* (or an equivalent product) at the end of each experiment or after the occurrence of an accidental spillage of infectious material. Application of these anti-microbial agents will totally inactivate any viral vectors that might be present. According to the biosafety literature, all the viruses to be used are susceptible to these disinfectants. Anything that might have potentially come into contact with the virus will be treated with Chemgene HLD4L * before being autoclaved/incinerated.

Please enter comments on the GM safety committee on the risk assessment

It is noted that the primary human cell lines used for the generation of hiPSCs will be taken from patient populations with a known medical history meaning that there is a low risk of material containing harmful human pathogens. This does not rule out the presence of latent viral infection but the use of third or fourth generation integrating lentiviral systems that are self-inactivating and essentially non-mobilisable makes it highly unlikely that infective replication competent virus will be generated. None of the factors used to generate the hiPSC will still be present in the cells. The lentiviral vectors described here pose a low risk because they non-mobilisable, self-inactivating and replication incompetent. In addition they lack the genetic elements necessary for viral replication and packaging. As an additional measure the GMSC will have a clear understanding of the proposed modifications. Vectors aimed at correcting disease mutations do not pose an additional risk to health. The introduction of non-disease causing genetic material for exogenous expression is not seen as a risk either. In the instance where immune-modulators may be targeted the risk although increased is well contained by the avoidance of sharps during transduction procedures. Once cells are transduced and virus removed the risk posed by the lentivirus is essentially removed. The main continuing risk is from the hiPSC and the potential presence of human pathogens. For this reason any propagation, differentiation, transduction and testing of cell lines will be carried out at BSL2.

**Project Additional Information**

**Purposes of the contained use**

Human induced pluripotent stem cells (hiPSC), generated from healthy control and patients with disease-relevant mutations (specifically one healthy parental control & three offspring samples with varying CAG expansions within Huntingtin exon 1 coding sequence), will be used to investigate genes and cellular mechanisms involved in the initiation and development of neurodegenerative disorders, for example, Alzheimer's disease, Parkinson's disease, ALS, Huntington's disease etc.

To better understand these genes and cellular mechanisms, the expression or the activity of the gene of interest will be modulated by several methods:

1. The utilisation of tool compounds
2. The knock-down of the gene of interest by shRNA
3. The generation of modified somatic cells using programmable nucleases (CRISPR or Zinc finger nucleases)
4. The generation of reporter gene (e.g., fluorescence protein or enzyme) under the control of a promoter of the gene of interest or an overexpressing cell line under the control of a promoter of the gene of interest or a ubiquitously expressing promoter

The experiments involving the transfection of vectors such as shRNA or programmable nucleases may be performed by lentivirus. The effect of modulating the expression or the activity of the target of interest will be determined by the expression level of the proteins, mRNA or mediators involved in the target signalling pathway.

<tr>
<th>Description of the human induced pluripotent stem (iPS) cells</th>
</tr>
</thead>
</table>
| The iPS cells are established by reprogramming human fibroblasts. These fibroblast cells have been derived from healthy and patient skin biopsies following informed consent. Reprogramming of human fibroblast cells to iPS cells was performed at the Rockefeller University using a commercially available kit sold by Life Technologies, Cytotune - iPS 2.0 Sendai Reprogramming Kit. The reprogramming vectors include the four Yamanaka factors, Oct, Sox2, Klf4 & c-Myc, shown to be sufficient for efficient reprogramming (Takahashi et al, 2007). These are expressed from the following vectors, CytoTune 2.0 KOS, CytoTune 2.0 h-c-Myc & CytoTune 2.0 hKlf4. iPS cells have been tested with Applied Biosystems TaqMan iPSC Sendai Detection kit. This kit is used to detect the presence of and determine the levels of Sendai virus and exogenous transcription factors (cMyc, Oct3/4, Klf4, Sox2) delivered by the Sendai virus. No expression was detected in RNA from the reprogrammed iPS cells. This would indicate that there is no virus present in these iPS cells. Sendai virus is a negative sense single stranded RNA virus which must be converted to positive RNA (mRNA) before translation. The virus remains in the cytoplasm, does not enter the nucleus and does not go through a DNA intermediary, therefore the reprogramming should not result in a permanent genetic modification of these cells. Fibroblast lines from donors have been provided as a basic research tool to investigate human disease. Consent to screen for major human pathogens is not sought at the time of donation. The donors are not known to be positive for any human pathogens. However, screening the cells for major human pathogens would have potentially significant clinical health implications for patients (e.g., HIV), for which explicit consent has not been given at the time of donation. As such, the cells and subsequent iPSC lines generated, have not and cannot be screened for human pathogens and must therefore be handled at Biological Safety Level 2.

Host/vector system

B- Description of the lentivirus containing shRNA, programmable nucleases sequences or gene reporter vectors

To utilise the iPS cells to study neurodegeneration, the expression of a target of interest may be decreased in the iPSC line by the transduction of shRNA or programmable nuclease by lentivirus. The modulation of a particular cellular pathway may be studied with the use of a reporter gene assay. In this case, the vector containing the reporter gene under the regulation of the promoter of the gene of interest may be introduced by standard transfection methods or lentivirus into the iPS cells This proposal may involve both the use of existing lentiviral constructs purchased commercially and the generation of new constructs on site using either a third or fourth generation system. Both commercially acquired and in-house lentivirus will use the same transfer vector plasmid. Target genes will be selected based on the needs of drug discovery projects; programmable nucleases and shRNA will not be produced against any growth factors, tropic factors, quiescence factors, confirmed oncogenes, tumour suppressors or immunomodulators (these targets will be approved internally by the GMSC). The production of lentivirus containing the vectors of interest are described below:
1- Generation of lentivirus
Lentiviral vectors will be purchased commercially or produced in-house using either a third or fourth generation system described below. Each purified and concentrated aliquot of lentiviral reagent comprised of a small volume (5 to 100 μl) that contains no more than 1x10^8 viral particles.

Vector System = self-inactivating (SIN) non replication-competent HIV based lentiviral vectors

The viral vectors that will be used in the proposed studies are self-inactivating non replication-competent HIV based lentiviral vector systems, which have been desiganted to produce stable gene expression in mammalian cells. They are generated by co-transfecting HEK 293T cells with four to six separate plasmids. Each of the plasmids used expresses a different set of genes which, when combined following co-transfection, provide the smallest possible set of essential viral genes that is still compatible with virus production. Moreover, the vectors are all vesicular stomatitis virus (VSV-G) pseudotyped lentiviral vectors, which are self-inactivating and highly unlikely to undergo recombination. Importantly, the viral vector is inherently incapable of replication in mammalian cells.

The plasmids

Third Generation
The sequences that will be included in the viral vectors are sub-cloned into 4 standard bacterial plasmid vectors. Plasmids containing the packaging related sequences

Each of the three other plasmids, pCgpV, pRSV-Rev and pCMV-VSVG contain a different set of sequences that code for proteins that are responsible for packaging the viral vectors. All the genes (gag-pol, rev and env) required for production and packaging of the full length viable viral RNA particles have been removed from the pSMPUW lentiplasmids containing the transgenes of interest.

Fourth Generation
The sequences that will be included in the viral vectors are sub-cloned into 6 standard bacterial plasmid vectors
Plasmids containing the packaging related sequences

Each of the other plasmids, pTRE-gag-pro, L TRHIV2-vpr-pol, penv(VSV-G), pTet-Off and p tat-IRES-rev contain a different set of sequences that code for proteins that are responsible for packaging the viral vectors. All the genes (gag-pol, rev and env) required for production and packaging of the full length viable viral RNA particles have been removed from the pSMPUW lentiplasmids containing the transgenes of interest. An integrase deficient version of the fourth generation packaging mix is available which contains a mutation in the sequence encoding the viral integrase. The resulting integrase-deficient lentivirus (IDLV) generates circular vector episomes in transduced target cells that are gradually lost by dilution in dividing cells (transient expression), but are stable in quiescent cells.

Plasmids containing the transgene of interest

The plasmid, pSMPUW, will contain the genetic sequence that codes for either shRNA, programmable nuclease, a reporter gene under the promoter of the gene of interest or protein of interest under the control of the regulating elements of the promoter of the gene of interest or a ubiquitously expressing promoter.

a- Vector containing shRNA
As mentioned above, pSMPUW plasmid will contain the sequence that code for a selected shRNA transcript that will target one mRNAs/protein of interest (or a scrambled shRNA in the case of negative control). The shRNA or scrambled shRNA sequences will be under the control of polymerase II or III promoter. The shRNA sequences will be chosen to target a single gene. The shRNA will not be produced against any growth factors, tropic factors, quiescence factors, confirmed oncogenes, tumor suppressors or immunomodulators.

b- Vector containing CRISPR or Zinc-finger nucleases
Programmable nucleases function by binding to, and cleaving, user-defined target DNA sequences. This in turn instigates a robust DNA repair response which ultimately leads to disruption of the target sequence by deletion at the
Programmable nucleases function by binding to, and cleaving, user-defined target DNA sequences. This in turn instigates a robust DNA repair response which ultimately leads to disruption of the target sequence by deletion at the cleavage site or by recombination with a user-supplied synthetic vector containing sequences complementary to the target gene.

For Cas9/CRISPR, nuclease target specificity is determined by an accessory sequence, the guide RNA, which consists of a short (18-20 nucleotide) sequence homologous to the target gene and an additional short sequence that forms a complex with the Cas9 enzyme. In this case, the plasmid pSMPUW, will contain the sequences that code for a Cas9/CRISPR plus accessory sequences comprising a short guide RNA that determines target specificity. The guide RNA sequences will be under the control of a Polymerase III promoter.

In the case of Zinc finger nucleases target specificity is dependent upon the zinc finger protein sequence. The pSMPUW will contain in that case the sequence of zinc finger nucleases under the control of a polymerase II promoter. In addition, a fluorescent protein or enzyme under the control of the polymerase II promoter or the promoter of a gene of interest may be included. Control viral vectors that express only the fluorescent protein/enzyme and no programmable nuclease will be used in some experiments.

The Cas9/CRISPR, if introduced into any cell line by lentivirus, will use the integrase deficient version of fourth generation packaging mix.

c- Reporter gene/Overexpression vector

The pSMPUW vector will contain the sequence coding for a reporter protein (enzyme or fluorescent protein) or protein of interest under the control of the regulating elements of the promoter of the gene of interest or a ubiquitously expressing promoter. An appropriate selection marker i.e.; neomycin could also be included to allow the selection of stable human iPS cells containing the reporter gene sequence or gene of interest under the control of the promoter of the gene of interest or a polymerase II promoter. Any overexpression will not be of growth factors, tropic factors, quiescence factors, confirmed oncogenes, tumor suppressors or immunomodulators. Any protein to be overexpressed will be approved by GMSC beforehand.
the gene of interest or a polymerase II promoter. Any overexpression will not be of growth factors, tropic factors, quiescence factors, confirmed oncogenes, tumor suppressors or immunomodulators. Any protein to be overexpressed will be approved by GMSC beforehand.

**Evaluation of foreseeable effects**

* Human Health

The human iPS cells that will be used have a low risk to human health. Samples are derived from patients that are not known to be infected but the disease status cannot be confirmed. Hence treated with caution at BSL2. The expression systems and the transgenes that comprise the lentiviral vectors that will be used have also a very low risk for human health and safety, and the reasons for this are discussed below.

A- Reprogrammed human iPS cells

The reprogrammed human iPS cells have been generated by reprogramming human skin fibroblasts using Sendai virus expressing a number of reprogramming factors. This Sendai reprogramming kit includes a number of safety features, as described below:

- The host species for the Sendai virus (SeV) reported so far are mouse, rat, hamster and guinea pigs, all of which have been described to be serologically positive so should be non-pathogenic to humans.
- SeV is transmitted by aerosol and contact with respiratory secretions. The virus is highly contagious but the infection does not persist in immunocompetent animals.

Cytotune Sendai reprogramming vectors are based on a modified, non-transmissible form of SeV, which as a Fusion protein (F) deleted, rendering the virus incapable of producing infectious particles from infected cells. The presence of functional mutations such as temperature sensitivity in the amino acid sequence of several SeV proteins (SeVITS~F, SeVITS12~F, and SeVITS15~F) renders the vectors easily removable from transduced cells. As mentioned previously in the description of the human iPS cells, the RNA from one of the cell lines has been tested with Applied Biosystems TaqMan iPSC Sendai Detection kit. This kit is used to detect presence of and determine levels of Sendai virus and exogenous transcription factors (cMyc, Oct3/4, Klf4, Sox2) delivered by the Sendai virus. No expression was detected in RNA from the reprogrammed iPS cells. This would indicate that there is no virus present in these iPS cells.

The time needed to derive vector-free iPSCs may vary depending on culture and passage conditions. In the case of human neonatal foreskin fibroblast cells (strain BJ), it takes about 1-2 months after gene transduction to obtain vector free iPSCs. The iPS cells were cultured at the Rockefeller post transduction for at least 2 months prior to being received at UCL.

All cells have been treated in the same manner and cultured for the same length of time post transduction so should be free of virus but RNA from the other 3 cell lines will be tested.

The major risks of this line is the unknown human pathogen status. Fibroblast lines from donors have been provided as a basic research tool to investigate human disease. Consent to screen for major human pathogens is not sought at the time of donation. Screening the cells for major human pathogens would have potentially significant clinical health implications for patients (e.g. HIV), for which explicit consent has not been given at the time of donation. As such, the cells and subsequent iPSC lines generated, have not and cannot be screened for human pathogens and must therefore be handled at Biological Safety Level 2.

Due to the unknown pathogen status of the iPS cells, using lentivirus on these cells could pose a risk regarding potential recombination of lentivirus with retrovirus that could already be present within the cells. As consent has not been given to screen for human pathogens the supernatant from transduced cells cannot be tested for the presence of viral particles. Therefore iPS cells treated with lentivirus must be handled at Biological Safety Level 2.

Therefore all measures will be in place to minimize the risk to human health.

B- Lentivirus containing shRNA, or programmable nucleases sequence or reporter gene/overexpression vectors

**Lentiviral Vector Expression System**
Lentiviruses belong to the Retroviridae virus family which are capable of infecting both human and animal species. As the lentiviral vector system that will be used in these studies is based on HIV-1, a theoretical risk to human health exists. However, retroviruses are generally transmitted via exposure to contaminated body fluids or percutaneous inoculation and generally not transmitted via the airbone route. Therefore, accidental piercing of the skin or other surface tissues with virus containing objects represents the main potential route by which accidental infection could occur. Appropriate risk reduction measures will be implemented to reduce the likelihood of this occurring.

In all of the modified pSMPUW plasmids (containing shRNA, programmable nucleases or reporter gene sequences), the sequences inserted are flanked by non-coding retroviral LTRs, and no retroviral genes are encoded on the modified pSMPUW plasmids. Therefore, no retroviral genes will be transferred into generated viral particles. This construct is packaged into particles using a HEK293T cell based packaging system, which requires the cotransfection of these cells with three to five additional separate plasmids (as detailed above). The additional plasmids express the envelope protein from VSVg and the non-structural proteins of the virion, and, importantly, none of these genes will be transferred into the assembled viral vectors, since they lack the packaging signal (O), which is only present on the modified pSMPUW plasmids.

The lentiviral Expression System what will be used includes the following key safety features:
* All of the pSMPUW contain a hybrid 3'LTR that does not affect generation of the viral genome in the production cell line, but results in "self-inactivation" (SIN) of the vector after transduction of target cells. Once integrated into a transfected target cell, the lentiviral genome is no longer capable of producing viral genomic material that can be packaged. Moreover, presence of an SV40 polyA after the hybrid 3'LTR in the vector construct will result in a provirus which should reduce the potential for transactivation of cellular genes due to an insertion event. Furthermore, the development of self-inactivating vectors improves the biosafety of vectors, as they are less likely to be mobilised following a superinfection with wild-type virus (HIV).
* The VSV-G gene from Vesicular Stomatitis Virus is used in place of the HIV-1 or other retroviral envelope genes. Heterologous envelopes, like VSV-G, typically broaden the tropism and allow gene transfer into a broad variety of cells. The risk will mitigated by the use of self-inactivating virus and limiting the number of viral particles that will be handled at anyone time.
* Sequences encoding the proteins required for packaging of the viral genome are separated onto three to five plasmids, and all of the 4-6 plasmids used in the system have been engineered not to contain any regions of homology with each other so as to prevent undesirable recombination events that could lead to the generation of a replication-competent lentivirus (RCL), which could potentially be harmful to humans. It is important to note that no such RCL has ever been observed despite large-scale production and testing of lentiviral vectors.
* All of the pSMPUW containing plasmids/vectors will be used are devoid of all viral sequences apart from essential cis-acting sequences, including the LTRs and the packaging signal O. Although the packaging plasmids used in these systems allows for the expression in trans of protein required to produce viral progeny (e.g. gal, pol, rev, env) in the HEK293T producer cell lines, none of them contain LTRs or the 0 packaging sequence. Several of the lentiviral accessory genes (vif, vpr, vpu and nef) that are dispensable for lentiviral vector production/transduction have been deleted from the packaged construct. Therefore, none of the retrovirus structural genes will actually be present in the packaged viral genome, and they will never be expressed in the transduced target cells, which means that no new RCL can be produced.
* The lentiviral particles produced in this system are replication-incompetent, only carry the sequences of interest, and no other viral species are produced.
* Expression of the gag and pol genes from pCpgV has been rendered Rev-dependent by virtue of the HIV-1 RRE (Rev Responsive Element) in the gag/pol mRNA transcript. Addition of the RRE in these plasmids prevents gag and pol expression in the absence of rev, which is contained in the pRSV-REV plasmid only. The Rev/RRE system is
highly conserved among lentiviruses, and removal of the RRE sequence and associated splice donor/acceptor sequences result in a loss of transduction efficiency.

* LTR has been modified so as to increase lentiviral vector production, and also to allow lentiviral vector production to be independent of tat expression. It is known that Tat-deleted mutants of wild-type HIV-1 are not replication competent. Therefore, the deletion of Tat should decrease the risk of generating a putative RCL.
* Lentiviral vectors have a very low potential to cause immunogenicity.
* The central poly purine tract (cPPT), from the pol ORF, is included in all of the viral vectors that will be used to improve the nuclear import of the proviral DNA and hence accelerate transduction.

While the lentiviral vectors that are produced using this system contain only about 20% of the original genome of HIV-1, there is a very small risk that subsequent infection of cells already infected with the lentiviral genome of HIV-1 could lead to a rare recombination event in which the transgene is transferred to a replication-competent virus. Thus, the sequences in the vector that will be expressed could potentially be transferred to surrounding cells. This event is, however, extremely unlikely to occur for a number of reasons:

1- The lentiviral vector is replication-incompetent and self-inactivating. In the case of a subsequent HIV-contamination, wild-type HIV-1 cannot rescue a self-inactivating HIV-1 based lentivirus once integrated into the host genome, although non-self-inactivating vectors can be.

2- In order for the spread of the gene of interest to occur following accidental infection (assuming that this has lead to viral integration), a series of unlikely events have to occur:
   a- The worker would have to become infected with HIV-1 or to be already infected with the virus.
   b- The viral and lentiviral genomes would have to integrate into the host worker's genome in the same cells and in a position where they could interact to effect homologous recombination (point 1 above)
   c- Recombination would have to occur in just the right regions to allow for transfer of the gene of interest from the lentivirus to the HIV-1 genome, which could also involve the transfer of the HIV-1 genes to the lentiviral genome. In that case, it is conceivable that a non-self-inactivating HIV could be generated that contained the gene of interest but not the rest of the genome it requires. The other gene products could be provided in trans from the lentiviral genome that may now contain the HIV-1 genes or from other HIV-1 integrants.
   d- The situation in c could conceivably lead to the production of an infectious particle containing the gene of interest, but again no genes necessary for subsequent replication. In order for another round of infection to occur, the process would have to begin again.
   e- It is conceivable the above could also happen if the iPS cells are already retrovirus positive.

In these circumstances, the effects of lentiviral infection are likely to be minor in comparison to the effects of the HIV-1 infection, which would be required to affect the spread of the gene of interest. In addition, the scenario described is essentially equivalent to the rescue of the lentiviral genome from the host, which has already been shown not to occur.

3- It is extremely unlikely that any worker would infect themselves with a significant dose of lentivirus as the volumes that are used in transfection experiments are small (aliquots contain a maximum of 10J.l1 of vector solution).

4- Moreover, insertional mutagenesis into the host genome may be considered as an oncogenic risk. We cannot rule out the possibility that, when the lentiviral genome integrates into the host genome, it will not lead to the activation of an endogeneous oncogene. However, all transcriptionally active long-terminal repeats (LTRs) have been removed as well as all promoter-like elements that required to drive expression of the transgene. This should prevent unforeseen activation of such genes. It is noted that deletion of retroviral enhancer in self-inactivating systems reduces the risk of activation but not of disruption, therefore, retroviral infection might still have permanent effects upon a cell (including oncogenic effects).

Importantly, we do not consider that the use of these lentiviral vectors will result in a significant increased risk of
oncogenic activation compared to the risk possessed by any other viral delivery system. Moreover, the risk of transduction leading to tumourigenesis or other untoward harm following exposure is related in part to the titre of the viral vectors; exposure of workers to quantities of virus high enough to cause such effects would be unlikely during standard laboratory-based manipulations of lentiviral vectors.

Transgenes:
Additional hazards could arise from the properties of the genetic material that will be inserted into the viral vectors and expressed in transfected cells.

shRNA
With the use of shRNA-expressing viral vector systems, the expression of specific mammalian genes/proteins can be knocked-down, in order to study their functions. Potential deleterious effects such as off-target and immunomodulatory responses can be minimised through screening designed shRNA sequences against databases of known mammalian/mRNA sequences during the design stage. The genes/proteins of interest that will be targeted by shRNA do not and will not include any growth factors, tropic factors, quiescence factors, confirmed oncogenes, tumor suppressors and immunomodulators. Some of the viral vectors that will be used contain a sequence of interest that has been scrambled (scrambled shRNA), and which is not complementary to any known mammalian sequences. This sequence will adopt a hairpin structure as with any shRNA, but it should not target any mRNA of human, mouse or rat origin. Consequently, these sequences are unlikely to pose any safety risks for the environment or human health (this will be approved by the GMSC).

Programmable nucleases: zinc fingers or Cas9/CRISPR
Zinc fingers or Cas9 protein will be directed against genes of therapeutic interest. Since the purpose of programmable nucleases is to cause mutations in defined DNA sequences the primary hazard is that such a mutation would lead to deleterious cellular effects. The genes/proteins that will be targeted do not and will not include any growth, trophic factors, confirmed oncogenes, tumor suppressors or immunomodulators. In isolation, these sequences are unlikely to pose any safety risks for the environment or human health.

Reporter genes: Fluorescent protein or enzymes/ Overexpression of proteins
The reporter gene could be a fluorescent protein or an enzyme, this reporter gene may be fused to a ribosomal subunit (L 1 Oa). Fluorescent proteins, for example GFP or dsRed, are not known to cause any diseases in human or animals and have no direct effect on cellular processes. Enzymes used frequently in reporter gene assay ie luciferase or b-galactosidase are not known to cause any diseases in humans or animals and as no direct effect on cellular processes. The expression of fluorescent protein or enzymes under the control of a promoter of a gene of interest is unlikely to pose any safety risks for the environment or human health.

Proteins of therapeutic interest will be targeted for potential overexpression. Genes/proteins that will be overexpressed do not and will not include any growth factors, tropic factors, quiescence factors, confirmed oncogenes, tumor suppressors or immunomodulators. Any protein to be overexpressed will be approved by GMSC beforehand.

Summary on lentivirus
Health and Safety
Executive
The transgenes have a low safety risk to human health because accidental contamination with a vector would lead to only a small number of cells becoming infected, and it would be highly unlikely that expression in only a few cells could be sufficient to lead to a disease state. The inability of the lentiviral vectors to propagate on mammalian cells also reduces the risk. The programmable nucleases (CRISPR or Zinc finger or Cre recombinase) that will be employed in this viral vector system are not known to cause any relevant toxicity that might represent a safety risk to human health. The fluorescent proteins or the enzymes are not known to cause any relevant toxicities that might

02/03/2022 Page 14120 of 15326
represent a safety risk to human health. For both programmable nucleases and shRNA, the genes/proteins of interest that will be targeted will not include any growth factors, tropic factors, quiescence factors, confirmed oncogenes, tumor suppressors or immunomodulators, and none of them are or will be of retroviral origin. Therefore the risk of use will be low.

Human health hazards

Oral ingestion will be prevented by standard laboratory safety practices. Aerosol formation resulting from an accident outside of the safety cabinet and involving lentivirus particle-containing liquid may lead to transduction of a limited number of the laboratory worker's skin or mucosal cells with modified viruses. However, these modified virus particles carry an extremely low safety risk for human health, as they are replication-incompetent, and also because the particles carry an extremely low infection potential via the mucosal/skin routes, due to the inherent properties of the viral vectors. Moreover, the programmable nucleases and shRNA that will be expressed or targeted will not be designed to disrupt any growth factors, trophic factors, quiescence factors, confirmed oncogenes, tumour suppressors or immunomodulators. In the unlikely event of accidental transduction of a laboratory worker's skin or mucosa by lentivirus particles, this will be self-limited, due to natural shedding of superficial epithelial skin and mucosal cell layers.

The most likely route of accidental infection with a lentivirus or with the human iPS cell line will be via inadvertent percutaneous inoculation. The likelihood of this occurring will, however, be minimised by adhering to appropriate risk management measures. Infection of the community at large with lentivirus particles is highly unlikely due to the viral vector particles being replication incompetent. Infection of the community at large by human iPS cells is highly unlikely due to the impossibility of the cells to survive outside of a laboratory environment.

* Environmental Considerations

The chance that active viral particles will be accidentally released into the environment is considered to be highly unlikely, as effective containment procedures will be adhered to. However, in the unlikely event that active lentiviral vector particles do accidentally get released into the environment, the safety risk posed in such an event is considered to be negligible, due to the vectors being self-inactivating and non-replicative. The main potential risk in such an event would be the subsequent contamination of a human population already infected with HIV, which would potentially allow for recombination events that could incorporate the inserted sequences into a viable replication-competent lentivirus. However, this scenario is extremely unlikely and even if it was to occur, it is unlikely that it would lead to any untoward effects. As the HIV virus is a human pathogen, infection of another species would not be expected to allow any form of recombination event leading to a viable transmissible entity and so the risk from this scenario is considered to be negligible. Rodents, such as wild-type mice and rats, cannot support replication of infectious HIV-1 (Goffinet et al, 2007 Retrovirology). As a result, the potential for shedding of replication-competent lentiviruses from such animals is very low (even if they were present in the original vector inoculum).

The vectors have been pseudotyped with the VSV-G envelope in order to increase tropism, and in theory they are capable of transducing all dividing and non-dividing mammalian cell types. As emphasized before, the vectors cannot self-propagate after infection, and successful transduction is critically dependent on the presence of high enough concentrations of virus particles. Viral vector stock solutions will be managed in a way that will prevent contaminations with relatively high viral titres. After production, the vectors are aliquoted and stored in screw capped cryovials at -80°C. Taking into account that the infectivity of the vectors rapidly decreases at room temperature, it is considered highly unlikely that the vectors could survive in the long term after being accidentally released into the environment. Lentiviral vectors have a short half-life, at room temperature due to their structural characteristics making them highly susceptible to dehydration, and relatively unstable. For this reason, retroviruses become rapidly inactivated outside host systems, as illustrated by the fact that close contact is required for transmission. They can, however, survive for long periods in high protein media.
There are no conceivable hazards associated directly with the lentiviral vectors (containing the inserts) as they will not replicate/survive outside the laboratory and they have been designed to include many protective safety features. shRNA sequences will also not survive as they are highly unstable, and they WOUId, consequently, be rapidly inactivated/degraded if accidentally spilled into the environment. Moreover, as discussed above, there is a very low risk that the sequences contained within the viral vectors could be transferred to other organisms, as a rare recombination event would have to occur to allow this to happen.

The risk to the environment following accidental release of the human iPS cells would be negligible since the cells are incapable of surviving outside of laboratory conditions. Despite the cells being reprogrammed using Sendai virus they do not produce virus and therefore would not be able to infect any rodent population. If human iPS cells were to directly inoculate animals, they would be quickly cleared by the immune system and would not produce active viruses. The likelihood of this occurring will, however, be minimised by adhering to appropriate risk management measures and ensuring that all potentially contaminated material is totally inactivated before disposal.

Summary

The chance that active viral particles will be accidentally released into the environment is considered to be highly unlikely, as the viral vector studies that will be undertaken have been classified as biosafety level 2, and effective containment procedures will be adhered to. In the unlikely event that active viral vector particles do accidently get released into the environment, the safety risks posed by such an event is considered to be low due to the vectors being self-inactivating and non-replicative, and also due to the poor ability of the vectors to survive outside of their host systems. It is also unlikely that the human iPS cells will be accidentally released into the environment, as the cell handling and studies that will be undertaken have been classified as biosafety level 2, and effective containment procedures will be adhered to.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

General cleaning procedures

Surfaces will be thoroughly cleaned with Chemgene HLD4L 5%* (or an equivalent product) at the end of each experiment or after the occurrence of an accidental spillage of infectious material. Application of these validated chemical inactivators will totally inactivate any viral vectors that might be present. According to the biosafety literature, all the viruses to be used are susceptible to these disinfectants. Anything that might have potentially come into contact with the virus will be treated with Chemgene HLD4L * before being autoclaved/incinerated.

Waste Handling

Following all work requiring biosafety level 2 containment including work with lentiviruses and ReNcell VM cells, solid waste will be neutralised by soaking in a validated disinfectant solution for 24 hours, after which the material will be "double bagged", autoclaved and, ultimately, incinerated offsite. It will be routine practise that all liquid waste material be neutralised before disposal, and for the neutralised waste to be transported in leak-proof containers to prevent spillages. Liquid waste will be inactivated by Chemgene HLD4L * for 24 hours prior to drain disposal as per 430CSP and 418CSP permit requirements.

As any active viral particles or ReNcell VM cells on surface or in waste material will be completely inactivated at the end of each experiment by the highly effective cleaning/disinfection protocols outlined above, it is considered highly unlikely that active virus particles or ReNcell VM cells would unintentionally become discharged into a sanitary
sewage system. No foreseeable adverse effects on human health and safety are expected.

* Chemgene HLD4L
Chemgene HLD4L is formulated as a micelle cleaning technology that enables the active molecules in the product to be carried rapidly through the cell walls or micro-organisms. Swift penetration of the cell walls ensures cell death is equally rapid. Chemgene HLD4L has been reported to be bactericidal, fungicidal as well as virucidal (HIV, hepatitis B, Herpex Simplex, Norovirus and Coronavirus) and sporicidal. It is recommended to be used at a 1:100 dilution (1%) for general purposes, 1:20 dilution (5%) for high risk areas, and for disinfection of blood and bio-hazard spillages.

Is an emergency plan required according to regulation 20?

Please enter comments on the GM safety committee on the risk assessment

The GMSC has reviewed the current risk assessment and agrees with the class 2 categorisation for this work. It is noted that although the hiPSC were generated using Sendai virus that needs to be handles at BSL2 the actual cells that will be provided to TCB will be free of Sendai virus and will have lost all detectable levels of plasmid. The main risk from the hiPSCs is their unknown pathogen status but this is mitigated because all donors are of low risk clinical populations. The lentiviral systems that will be subsequently used are inherently designed to prevent inappropriate recombination and subsequent mobilisation of transgenes into replication competent viral particles. Third and fourth generation systems deliver replication incompetent, self-inactivating viral particles that lack even the minimum set of genes required for virus production. The cells themselves cannot survive outside of a lab environment and the lentiviral particles lose viability rapidly if not stored properly being susceptible to desiccation. Risk associated with these activities to humans and the environment is deemed low. The use of biosafety level 2 containment is appropriate and sufficient because of the use of lentiviral elements and the unknown pathogen status of the cells.

None of the measures in containment level 2 of Table 1 (of Schedule 8) are required for safety reasons, however some of these may be employed to prevent contamination of the GMM. The activity is therefore Class 1.

Give brief details of the genetic modification safety committee

- Counsel was sought within an extended network of academic and private researchers, whom have all worked with GMM in the past, and are acquainted with the implications of GMM class 1 contained use.
- Work will be limited to Class 1 GMM only, suggesting a single, qualified individual is sufficient to provide advice on the risks involved with GMM work. The skilled individual in question has held a post for over 8 years as Biological Safety Officer at a large, Cambridge-based research organisation dealing with GMM and GM plants on a regular basis.

For activities involving GMMs, describe the waste management measures which will apply to the activity

To prevent release of viable Class 1 GMMs, the following inactivation protocols are to be implemented:

- **Inactivation of liquid GM matter** - including liquid cultures, their derivatives, containers and accidental spills, is to be performed using a 1% solution of DuPont RelyOn Virkon and left for at least 10 minutes. After this, liquid waste can be safely washed down the drain with generous amounts of water, or absorbed with lab tissues and disposed of in the correct bin.

- **Inactivation of solid GM matter** - including GM biomass, tools and agar plates, is to be performed via autoclaving. GM waste should be placed in an autoclavable bag, and put through a 121 degrees Celsius 115 min inactivation programme. Following inactivation, the waste should be disposed of in the correct bin.

- **Microbiological Safety Cabinet (MSC) Inactivation** - Following GMM work in the Level 2 MSe, a germicidal UV light (UVe, 254-280 nm) will be turned on and left for a minimum of 2 hours. This will ensure any viable leftover GMM are destroyed. The risks of such GMM remaining in the MSe in the first place will be mitigated by disinfection of the MSC with 70% isopropanol solution before and after each session.

- **Inactivated waste disposal** will be performed by a licenced subcontractor. If inactivation is not possible, disposal will be performed by inceneration (subcontractor).

- **Inactivation quality controls** will be performed when commencing work with new GMM organisms, and routinely every 6 months to ensure inactivation protocols work appropriately.

All genetically-modified human cells will be fully inactivated by cell fixation (using formalin). Glass flasks containing residual transformed bacterial cells (in LB broth) will be inactivated by treatment with the bacterial agent Virkon (freshly made) at the manufacturers' specified concentration of 10g per litre for at least 2 hours. All solid waste, including LB/agar plates covered with bacterial colonies, pipettes/stripettes and plastic centrifuge tubes, will also be inactivated by submerging in Virkon (as above) for at least 2 hours. All inactivated solid waste will be discarded using strong, leakproof yellow biological waste bags (or plastic incineration bins), which will be sealed and finally incinerated off-site by a reputable commercial biological waste service provider. All liquid waste will be inactivated by chemical treatment with Virkon (as above) for 2 hours before discarding down the sink. As a matter of course, a fresh solution of formalin cell fixative will be prepared for every experiment. A strict procedure has been developed to ensure fresh Virkon solutions are made on a routine basis. Both methods are well-established to fully inactivate the GMOs (i.e. the transfected human cells and the transformed bacteria).

For activities involving GMMs, describe the waste management measures which will apply to the activity

The host organisms meet the criteria for work to be safely carried out under CL 1 containment and the genetic modifications involved are not foreseen to alter this. The work is therefore appropriate for categorisation as a risk class 1 activity.
**Project Additional Information**

**Purposes of the contained use**

To determine if x2 BSL-2 viruses interact with selected protein targets included in CR protein library with interactions being detected using cell microarray technology (on fixed slides only).

**Recipient or parental organism**

The study will use human HEK293 cells which are especially disabled recipients of the virus, and not expected to survive in the environment, nor able to colonise the operator (non-self). HEK293 is a human embryonic epithelial cell line stably expressing the transforming gene of the human Type 5 adenovirus. However, HEK293 cells fall into the category of Low Hazard under the SACGM guidance for determining containment level for cell cultures.

**Host/vector system**

The viruses supplied by the client are a Adenovirus type 5- based virus. These are non-enveloped double-stranded DNA virus with a linear DNA genome.

The Adenovirus provided by the client is based on human adenoviral type 5 backbone and is replication-competent, permissive in cell lines such as HEK293 cells and A549 cells. However, it is important to note that viral particles will only be added to fixed HEK293 cells in this study.

**Origin & function**

The targets being screened against in this study are part of the CR extensive library of plasma membrane and secreted proteins. The CR DNA library is expressed in a custom vector which is based upon Clontech's non-mobilisable pIRES2-ZsGreen vector, which has been adapted to receive human ORF cDNAs using Invitrogen's Gateway™-mediated recombination technology. In this vector, expression of the human cDNA insert is driven by the powerful and constitutive CMV IE promoter. This is followed by an IRES-ZsGreen element, such that the fluorescent protein ZsGreen will be co-expressed in transfected HEK293 cells.

The client will provide CR with 3 x 10^11 particles for each test Adenovirus type virus. CR will screen each test virus at 0, 5,000 and 10,000 virus particles.

**Evaluation of foreseeable effects**

RC Ads are being studied intensely for cancer therapeutics. Their mechanism of action is to induce the lysis of cancer cells with the released viral particles then targeting neighboring tumor cells. In cancer cells, the pattern of gene expression makes the cells more permissive for Ad replication whereas in non-cancerous (healthy) cells multiple Ad proteins must be expressed to force cells into a permissive state. The Ad virus supplied by the client have been further engineered to permit replication only in cancer cells and that limit replication in non-cancerous cells [1].
HEK293 cells transiently transfected with CRL High Peak custom vectors+ gene inserts where any risk to human health has previously been assessed to be very low. Under routine cell microarray tests these transfected cells are handled under Containment level 1. The recombinant test Ad particles will be only added to fixed cells and so the likelihood of generating replicative competent Adenovirus (Ad) is effectively zero.

References

All work will be carried out in a single designated Class II Safety cabinet and the particles will be added to cell microarray slides (after cell fixation). The cells will then be washed to remove excess viral particles, and the bound particles will be further fixed in place at this point. Excess viral particles removed in the wash step will be Disinfectant treated and disposed of in hazardous waste. Any viral stocks will be autoclaved prior to disposal (see below for details) In the unlikely scenario that the operator was exposed to the adenoviral particles it is unlikely further adenoviral particles would be created since the virus is engineered to not replicate in healthy cells. However, the existing particles could trigger a strong immune response in the operator. To mitigate the risk of exposure by aerosols all work will be done within a Class II Safety cabinet

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All genetically-modified HEK293 cells will be fully destroyed by cell fixation (using formalin).

Any viral stock will be disposed of by autoclaving at 121°C for 15 minutes.

All inactivated solid waste will be discarded using yellow biological waste bags (or plastic incineration bins), which will be sealed and finally incinerated off-site by a reputable commercial biological waste service provider.

All liquid waste will be inactivated by chemical treatment with the bactericidal agent Virkon (freshly-made) at the manufacturer’s specified concentration of 10 g per litre for at least 2 hours before discarding down the sink.

As a matter of course, a fresh solution of formalin cell fixative will be prepared for every experiment. A strict procedure has been developed to ensure fresh disinfectant solutions are made on a routine basis. Both methods are well-established to inactivate the GMOs (i.e. the transfected human cells).

Please enter comments of the GM safety committee on the risk assessment

The genetic modification safety committee has reviewed related risk assessments and confirms that the recombinant organisms are not expected to be more hazardous than the parent strain (both considered to be BSL category 2). The inserted vector provides no advantage to the host bacterium in terms of virulence, a very modest increase in resistance to antimicrobial agents (as selectable markers), and low risk of escape into the environment.
Project Additional Information

Purposes of the contained use
To visualise microorganism during growth phases

Recipient or parental organism
Staphylococcus aureus NR-46158

Host/vector system
Escherichia coli - staphylococcal shuttle vector pCN5? Vector pCN5? contains the E. coli ColE1 replication origin, the S. ·aureus pT181 cop-wt-repC replicon, the Pbla promoter and a promoterless B-lactamase reporter gene, gfpmut2 .

Origin & function
Vector pCNS? is a member of a series of novel shuttle vectors that were developed using PCRdesigned cassettes to allow for easy exchange of vector components. The function of the vector is to insert a DNA sequence that will allow the production of green fluorescent protein (GFP) such that the bacterium will generate GFP.

Evaluation of foreseeable effects
Vector pCNS? is a member of a series of novel shuttle vectors that were developed using PCRdesigned cassettes to allow for easy exchange of vector components. The function of the vector is to insert a DNA sequence that will allow the production of green fluorescent protein (GFP) such that the bacterium will generate GFP.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
The recombinant organisms are not expected to be more hazardous than the parent strain.
Risk 1) Infection of staff by pathogenic organisms.
Risks are low as Personal Protective Equipment, including laboratory coat, disposable gloves and safety goggles will be used to avoid direct contact with these samples. Organism is not spread by the aerosol route and is of low pathogenicity with an infectious challenge of >10119 cfu required to establish an infection.
Risk 2) Release into the environment.
The risk is low as all procedures will be performed in a BSL Containment level 2 laboratory. The laboratory benefits from...
from design and equipment suitable for working with BSL 2 organisms. All contaminated waste is autoclaved within
the facility. Autoclaved waste is transported in sealed bins for final disposal by incineration by a registered company.
Risk 3) Accidental transfer of plasmid into an unrelated microbe ..
The risk is low as isolates will be handled as BSL 2 pathogens and will not be knowingly mixed with other cultures.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Is an emergency plan required according to regulation 20? N

GM cultures (cell culture media, agar or broth) will be handled according to standard practice (BSL class 2 microbes)
for the prevention of contamination. All spent organism / waste media will be decontaminated by autoclaving at 134C
for 20 minutes followed by incineration; spillages will be treated with 1 % Virkon left in place for 15 minutes with wipe
up materials disposed in a sealed bin for incineration. No additional precautions are required compared to the wild
type isolates.

Y

Give brief details of the genetic modification safety committee

Discussions have taken place with a Biological Safety Officer (Level 1 Biosafety Practitioner and M-ISTR) from the Norwich Research Park. Discussions included classification of GM work and appropriate containment measures that should be employed and risk assessment of work activities.

Two members of the Biological Safety Committee (Genetic Modification Safety Committee) from the JI Site, who possessed appropriate knowledge, experience and training in the scientific area in question, reviewed the risk assessment for the proposed work and provided comments on aspects of the risk assessment that required additional supporting information. Following provision of this additional information the risk assessment was agreed to be appropriate and provided a sufficient assessment of the risks posed by the activities.

**Waste liquid treatment** - All process solutions and laboratory sink waste feed into a waste liquid effluent treatment facility located outside the facility. The treatment facility inactivates any residual microbiological material that is contained in the solutions by heat treatment at a minimum of 121 degrees C at 15psi for 20 minutes. This will be validated upon commissioning of the system. Controls (procedural and system) exist on the effluent treatment plant so that loads of waste effluent cannot be discharged to the foul sewer without the required parameters (temperature and time) being achieved. The system works in a batch mode by filling a tank and processing accordingly. If the required parameters are not met an alarm is activated and the system will stop with no risk of discharge before appropriate rework or assessment is made.

**Autoclave** - Any solid waste (plant debris, soil, pots etc.) will be autoclaved on a validated cycle to ensure complete inactivation of any microbiological material. Media containing bacterial cultures will be inactivated using the same equipment. All autoclave loads will be treated at 1210C for a minimum of 20 minutes, but the length of the cycle will be dependent on the validation that is performed. For denser loads the length of time is likely to be increased to 30 minutes. The cycle will be validated to ensure that the kill requirements have been achieved before operation. Controls (procedural and system) exist to ensure loads are processed to the required settings (time, temperature and pressure). Disinfection of accidental spillages will be performed using validated processes followed by sink disposal with copious amounts of water.

**For activities involving GMMs, describe the waste management measures which will apply to the activity**

Validation tests of autoclave will be documented and performed placing a biohazard bag into a secondary autoclavable container with an autoclave indicator tape strip inside the bag. The program will run for 20 min at 125°C and 1 Ba. After completing the cycle the state of the chemical integrator strip will be checked. If the validation is not successful, the autoclaving cycle will be run again extending 10 min the program. For bench-top collection of contaminated goods small plastic containers will be used. This will be transferred to a larger leak-proof container with the biohazard symbol and an autoclave bag until is autoclaved. The bags containing the waste must be clearly identified as biohazardous at any point of the treatment. GMM inactivation and removal of biological components in dry contaminated solid (plastic disposables, tissue paper, gloves, culture plates…) material will be performed through sterilisation via autoclaving at 125°C this will be achieved by maintaining 1 bar pressure for 20 minutes prior to disposal. The autoclave is located in the laboratory and is composed of a pressure cooker and an electrical induction hob. The autoclaved waste will be placed in a non-see-through bag or container and finally disposed as regular trash. Additional chemical inactivation methods are also available to dispose liquids or disinfect glass containing genetically modified organisms. A 10% concentration of Virkon or bleach can be used to decontaminate liquids when allowing to sit overnight. Volumes larger than 1 litre of waste will be autoclaved. After sterilisation the liquids can be discarded on the sink with a copious amount of water. Glass will be immersed in the disinfectant solution. Surface and equipment disinfection will be performed with 70% denatured alcohol. If sharps contaminated with GMM are generated they should be disposed of in a designated sharps collection bin marked with the biohazard symbol. Sharps container must be permanently closed, puncture-resistant and leak-proof container. Sharps disposal should be via the organisation's authorised waste contractor only. ASCUS Lab has contacted two waste disposal agencies that have agreed to one-off uplifts from Summerhall.

For activities involving GMMs, describe the waste management measures which will apply to the activity
The ASCUS Lab premises are equipped and prepared to work with class 1 GMM. The projects taking place in the ASCUS Lab will be focused on the genetic modification of model or well-characterised microorganisms. These modifications will mostly involve performing routine transformations in disabled E. coli strains therefore containment level 1 is adequate for the nature of the premises and the projects undertaken. Please find the risk assessment summary attached to this form.

The ASCUS lab premises are also capacitated to work with larger non-notifiable GMO’s, which do not pose a greater risk to humans than its unmodified organism as described in Part 2 Schedule 12 paragraph 5, The Genetically Modified Organisms (Contained Use) Regulations 2014. This will include active ties involving C. elegans for which risk assessment for human health and safety is attached. Although this form indicates that work that involves plants can be undertaken within these premises, work is not expected to start and there are no currently projects planned to be started in the near future and for this reason risk assessment is not included. The ASCUS Lab will perform a risk assessment for these potential projects and determine whether they can be undertaken in the premises and comply with the regulations and containment measures of a BSL class 1 laboratory. Activities with plants would potentially involve modifications of Rhizobium or Agrobacterium after additional risk assessments have been undertaken. These projects would include non-toxic plants for human or animal health that cannot disseminate in the environment. The modifications would not be heritable and the plants will be grown in small numbers. There should not be evidence that the resulting plants could survive and spread if accidentally released into the environment and therefore would not represent an environmental risk. Risk assessments for plant use will be undertaken with the advice of GM plant experts.

* All GMO work is conducted inside a Class II Biosafety cabinet that is thrice sterilised with Virkon or Distel before and after use.  
* Solid waste and materials are collected into Biohazard bags and autoclaved at 121 degrees Celsius for 80 minutes.  
* Liquid waste is mixed with an equal volume of double-concentrated sterilising agent such as Virkon or Distel for 1 hour before being poured down the sink.

Give brief details of the genetic modification safety committee

The Storm Therapeutics genetic modification safety committee consists of VP R&D, Head of Biology and a health and safety laboratory manager.

The health and safety committee meets monthly to address all aspects of health and safety including all matter relating to genetic modifications.

All risk assessments of experiments involving genetic modifications and genetically modified organisms are reviewed by the biological safety officer and the head of health and safety.

In accordance with the Babraham Research Campus Biosafety policy for containment level 1, all solid waste including agar plates and contaminated consumables will be disposed in sealable yellow clinical waste Eurobins that will be incinerated. All liquid cultures contaminated with GMMs and genetically modified cells will be inactivated by adding 1% Virkon and being left to stand for at least 1 hour before diluting and disposing via the sink flushing with plenty of water.

For activities involving GMMs, describe the waste management measures which will apply to the activity

The Storm Therapeutics safety committee contains VP R&D and Head of Biology who are competent in risk assessment. The Head of Biology is the company Biological Safety Officer and has recently updated his training.

Please enter comments of the GM safety committee on the risk assessment

The generation and use of Adeno Associated Virus (AAV), Y-retrovirus and lentivirus vectors for investigating the biological function of RNA modifying enzymes in disease

**Project Additional Information**

**Purposes of the contained use**

The aim of this project is to use AAV, \(\gamma\)-retroviral and lentiviral delivery systems to introduce various mammalian DNA sequences into mammalian cells in culture. These sequences direct expression of either (i) RNA species (aptamers, siRNAs, gRNAs, miRNAs or shRNAs) that modulate the expression of various mammalian genes or (ii) the corresponding mammalian mRNAs/proteins themselves. The generation of AAV, \(\gamma\)-retroviral and lentiviral vectors is intended as in vitro tool for the generation of transient and stable mammalian cell lines and the subsequent use of such modified cell lines in vitro for the validation of novel oncogenes and putative drug targets.

**Recipient or parental organism**

Cloning, propagation and amplification of component plasmids for AAV, \(\gamma\)-retroviral and lentiviral vector systems will take place in K12 strains of E. coli (with a history of safe use).

Mammalian cell lines (e.g. immortalized lines derived from human cancer tissues) fall into two types:

a) Packaging/helper cell lines into which plasmids containing lentiviral or retroviral DNA will be introduced, and from which infectious virus will be secreted into the medium to high titre. The media from these cell lines poses a risk because of the high viral titre. As such this could provide a risk of infection to personnel working with the media.

b) Recipient mammalian cell lines in culture. These cells will initially be exposed to a high titre of virus to permit infection. Viral particles will either be derived from packaging cell cultures (as above in a) or will be purchased commercially from approved suppliers. However, the infected cell lines will be incapable of themselves producing active virus and as such are no more dangerous than the parental cell lines, i.e. once infected they pose a negligible risk to staff.

**Host/vector system**

The AAV vector technology that we will use is based on a non-enveloped single-stranded DNA virus (Adeno Associated Virus - which are ACDP Hazard Group 1 biological agents) as vehicles to efficiently deliver and express genes in mammalian cells. AAV viruses are taken up by endocytosis, released for transcription and expression following migration to the nucleus. Given the low pathogenicity of the recipient virus, the major hazards that will be posed by recombinant AAV vectors will depend upon the properties of the inserted genetic material and any products that it may encode.

The \(\gamma\)-RETOVIRAL vectors which will be used are derived from either Moloney Murine sarcoma Virus (MoMLV), Mouse Mammary Tumour Virus (MMTV) or Feline Leukaemia Virus (FeLV), all of which are ACDP Hazard Group 1 biological agents. On the other hand, the virus will be packaged by transfecting transfer vector into specific amphoteric 'helper' cell line (gag, pol and env stably incorporated into host chromosome cells). NOTE: amphotropic packaging will widen the host range of the virus and allow it to infect a wide range if mammalian species (including humans) and cell types. This means that the viruses produced for this experiment could potentially infect a number of species, including man.
However, bearing this in mind we should consider that the viruses that will be used have been modified in a number of ways which will make them safer to handle:

- The genes encoding structural and other components of the viral genome have been separated. These genes have been engineered to minimise the risk of recombination that could lead to production of a replication-competent virus.

- The packaging cell lines allow expression of proteins, required to produce progeny virus: But the transfer vector is the only genetic material transferred to the target cells, consequently these cells cannot produce the proteins which are essential for viral assembly and infectivity.

- Second, third generation or Self inactivating vectors retrovirus vectors will be used in all experiments (see SACGM compendium of guidance part 2, section 2.11 (Retroviruses) pp117)

The LENTIVIRAL vectors that will be used are derived from HIV-1, which is an ACDP Hazard Group 3 biological agent. However, second and third generation lentiviral vectors have several of the lentiviral accessory genes (required for pathogenesis only) deleted to increase biosafety and viral packaging is achieved by providing three helper constructs in trans containing gag, pol and rev sequences.

For example, second and third generation Lentiviral Expression Systems include the following key safety features:

In the second and successive generation lentiviral vectors several lentiviral accessory genes (vif, vpr, vpu and nef) are deleted from the transfer plasmid since they are not required for in vitro replication and the products they encode have cytotoxic activities.

In addition to this in the third generation lentiviral vectors:

- The Lenti expression vectors contain a deletion in the 3’ LTR (ΔU3) that does not affect generation of the viral genome in the producer cell line but instead results in “self-inactivation” of the lentivirus after transduction of the target cell (Yee et al., 1987; Yu et al., 1986; Zufferey et al., 1998). Once integrated into the transduced target cell, the lentiviral genome is no longer capable of producing a packageable viral genome.

- The number of genes from HIV-1 that are used in the system has been reduced to three (i.e. gag, pol, and rev).

- Genes encoding the structural and other components required for packaging the viral genome are separated onto four plasmids. All four plasmids have been engineered not to contain any regions of homology with each other to prevent undesirable recombination events that could lead to the generation of a replication-competent virus (Dull et al., 1998).

- Although the three packaging plasmids allow expression in trans of proteins required to produce viral progeny (e.g. gal, pol, rev, env) in the 293FT producer cell line, none of them contain LTRs or the Ψ packaging sequence. This means that none of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. No new replication competent virus can be produced.

Despite the above safety features, use of these lentiviral vectors (which include WPRE) falls within SACGM 2 criteria due to the potential biohazard risk of possible recombination with endogenous viral sequences to form self-replicating virus, or the possibility of insertional mutagenesis. In addition, the virus will be packaged by transfecting transfer vector into specific amphoteric ‘helper’ cell line (gag, pol and env stably incorporated into host chromosome cells). NOTE: amphotropic packaging will widen the host range of the virus and allow it to infect a wide range if mammalian species (including humans) and cell types.

This means that the viruses produced for this experiment could potentially infect a number of species, including man.

### Origin & function

1) **Selection markers** – examples such as (but not restricted to):
   - Ampicillin resistance gene Beta lactamase derived from E. coli.
   - Neomycin resistance gene Aminoglycoside phosphotransferase derived from Streptomyces.
   - Puromycin resistance gene Puromycin acetyl transferase derived from Streptomyces alboniger.

2) **Reporter proteins** such as (but not restricted to):
   - Fluorescent proteins as reporters - e.g. GFP derived from the jellyfish Aequorea victoria and its derivatives.
   - Luciferase – class of oxidative enzymes used in bioluminescence such as Renilla luciferase derived from the Sea pansy (Renilla reniformris) or Firefly luciferase derived from the firefly Photinus pyralis and its derivatives.

3) **Open reading frames (ORFs), cDNAs and gene sequences encoding potential drug targets or therapeutic proteins** derived from human or other mammalian genomes.
This could include the expression of potentially harmful genes, for example encoding known proto-oncogenes, or genes with known oncogenic mutations that can contribute to cellular transformation.

4) shRNAs, siRNAs, miRNAs and gRNAs derived from human or other mammals designed to modulate the expression of gene sequences, open reading frames and mRNAs encoding potential drug targets or therapeutic proteins. Modulating the expression of either oncogenes (e.g. upregulation) or tumour suppressor genes (e.g. downregulation) could lead to cellular transformation.

**Evaluation of foreseeable effects**

All viral vectors employed in this protocol exhibit broad tropism and potential to infect human. Risks conferred following infection are identified as:

1) Genetic insertion of viral sequences with potentially deleterious effects on endogenous genes: we will employ transgene promoters and other viral sequences that may affect host gene function in a wide range of cell types (e.g. CMV promoter). We assess retro-, lenti- or adenovirus infection might induce permanent changes in infected cells including a risk for tumorigenesis. Risks conferred are previously described and categorised under Class 2 risks [SACGM compendium of guidance part 2, page 121]: “…The effects of integration upon the infected cell should be considered. For instance, promoter sequences present in the provirus might activate genes adjacent to the integration site or, alternatively, insertion may disrupt genes and prevent their expression.”

2) Expression of human-derived or homologous transgenes with potentially deleterious effects: various transgenes may be employed, wherein intrinsic function of the transgene confers potentially harmful effects. For example, expression of human oncoproteins could induce transformation of infected cells. Beyond endogenous homeostatic mechanisms that may lessen this risk (e.g. apoptosis and other host tumour suppression responses), we assess that standard precautions under Class 2 risk mitigation procedures are adequate to address such risks.

3) Expression of exogenous transgenes directed to modulate host genes with potentially deleterious effects: multiple transgene technologies (antisense, RNAi, CRISPR or related gene conversion) may be employed to modify the function of endogenous genes with potentially deleterious effects. For example, RNAi or gene editing by CRISPR could reduce the function of genes necessary to control cell apoptosis, potentially resulting in tumorigenesis. As above, we assess that Class 2 risk management procedures adequately address these risks.

4) Expression of heterologous genetic sequences with potentially deleterious effects: we will employ diverse collections of non-human derived, exogenous transgene sequences that carry potential risks following infection. Risks from expression of these collected transgene sequences are mitigated and attenuated through several means. First, known pathogenic transgenes were systemically removed and other exogenous gene products are fragmented or rearranged, such that potentially pathogenic or other biologically deleterious genetic functions are not recapitulated in their complete endogenous configuration. Second, potentially deleterious transgenes in any infectious viral preparation are highly titrated, such that any single deleterious sequence comprises less than 1 part in 100,000 parts of an inoculum with infectious potential. In total, we assess these risks are adequately managed via the same Class 2 risk precautions employed above.

We assess environmental hazards are adequately addressed through the proposed personnel risk management measures. We employ multiple attenuation strategies and protocols to severely limit independent virus propagation beyond the intended use, and therefore anticipate minimal risks of GMM release.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Instead of autoclaving waste in the building we propose to follow the procedure used by the Babraham Institute described in their disposal notification GM105/4.1 (see also section 6 above for description). Reasons for adopting this method of waste disposal are:

1. We do not have access to an autoclave within our area of the building;
2. The waste disposal system used by the Babraham Research Campus is safe and has been running since October 2004.

All liquid waste material will be inactivated by treatment with 1% (w/v) Virkon solution prior to disposal. Solid waste material will be placed in sealed bins and incinerated by
Waste from our GM work at Class 2 will be placed into suitably labelled hermetically sealable (red lid to distinguish them from Class 1 waste) 60 litre UN approved (to Class 3) Type 3H21Y30/S/2003 bins. Sealed bins are placed into secondary 210 litre yellow labelled "Eurobins". Contents of the bin are recorded and collections by the local registered clinical/GM waste incinerator contractor will be made three times a week to prevent a build-up. The site has 24/7 Security. The contractor uses solid bodied transport and carries portable disinfection equipment in case of any spillage. Autoclave facilities will be available in an adjacent building, as required by the Regulations, in case of loss of the contractor's facilities. The type of container and the secondary Euro container means that the risk of any spillage of active GM waste on site is negligible. However, as active waste will leave the site, the risk to the environment and health is possibly marginally higher than autoclaving prior to incineration. The only real risk of release would be as a result of a major RTA, however, the containers are designed to withstand this.

This disposal method is expected to achieve 100% inactivation of the GMM.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste material will be inactivated by treatment with 1% (w/v) Virkon solution prior to disposal. Solid waste material will be placed in sealed bins and incinerated by an off-site incineration company (see derogation application above). Waste from our GM work at Class 2 will be placed into suitably labelled hermetically sealable bins. They will be sealed by our staff and removed to a central collection point where they will be placed into 210 litre yellow labelled "Eurobins". Collections for incineration will be made by the local registered clinical/GM waste incinerator contractor.

This disposal method is expected to achieve 100% inactivation of the GMM.

Is an emergency plan required according to regulation 20? N

Tick to confirm that it is attached to this form N

Tick if you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

The scope of work and the particular aspects of safety risks described in the risk assessment were discussed and satisfactory consensus was achieved regarding the adequacy of Safe Operating Procedures (SOPs) and Code of Practice (COP) as well as risk management measures and protocols.

Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Give brief details of the genetic modification safety committee

TTP encourages a healthy and safe working environment, and believes this will be achieved through cooperation at all levels within the organisation. This includes the development of its staff, monitoring and improvement to working practices and facilities, and implementing procedures and practices to ensure that any hazards or risks involving GM research are assessed and controlled.

A biological safety advisor with significant experience will review all research projects involving genetically modified organisms. This biological safety advisor will provide advice where required on GM biological safety issues, as well as maintain a record of all GM projects, competent persons performing this work, and relevant project risk assessments (completed by the project leader of each GM project). This person will ensure that all GM work at TTP complies with the Genetically Modified Organisms (Contained Use) Regulations (2014), at a level appropriate for the type of research undertaken. This person will additionally periodically inspect laboratory and workshop areas to ensure safety precautions are adequate. Any deficiencies will be reported to the appropriate Division Manager, Safety Officer, and Project leader. Where necessary the biological safety adviser will report concerns and other information to the TTP Health and Safety committee, who are responsible for overall monitoring and review of TTP Health and Safety.

The biological safety advisor is a senior cell biologist with a PhD in Cell biology and Molecular Physiology. This person has eighteen years research experience in academia including 7 years leading a research group, as well as extensive experience in the safe handling, storage, and transportation of GMOs. Experience includes cloning, RNA and DNA handling, stable and transient transfections, lentivirus and retrovirus preparation and transduction, and genetic modification of bacterial and mammalian cells (including established and primary human cell lines, organoid cultures, tissue slice cultures, and human primary stem cells). From 2011-2016 this person acted as a University Genetic Modification Safety Officer, responsible for risk assessment and review of numerous GMO applications. They also held a GMO license for lentiviral transduction and modification of mammalian cells during this time.
Mammalian cell culture

Liquid waste from GMM use is to be aspirated into a DuPont Rely+On-containing bottle and left for at least 2 hours before disposal with waste water (as per manufacturer's instructions, attached). Monitoring of decontamination and disinfectant replenishing schemes will be according to the manufacturer's instructions (DuPont, optically). Solid waste, including wipes, gloves, test tubes and culture vessels, are to be disposed in biohazard waste containers [e.g., DisposaFlatPak 50], collected by Biffa [carrier licence, insurance permit and PPC permit in appendix] and destroyed by incineration [Veolia Tyseley - site permit in appendix]. Mammalian cells will be cultivated in a CO2 incubator which has a dry heat cycle to disinfect the interior. At the end of each experiment, the incubator disinfection cycle will be executed to disinfect all interior surfaces. GMO laboratory bench surfaces and biological safety cabinets (including laminar flow hoods) will be cleaned after every use with 70% ethanol which will be sprayed and allowed to remain for at least 1 minute. This ethanol concentration and contact time kills most bacteria, e.g. Pseudomonas aeruginosa, Serratia marcescens, E. coli and Salmonella typosa in 10 seconds. It also deactivates lipophilic viruses like Herpes, Influenza or Vaccinia and many hydrophilic viruses (eg Adenovirus, Enterovirus, Rhinovirus and Rotavirus. While
effective against most bacteria and viruses, some organisms can survive this disinfection process. Therefore, once every three months, all surfaces will be treated with 10% sodium hypochlorite. Sodium hypochlorite treatment for >5min will decontaminate any residual bacteria or other organisms.

Bacterial cell culture
Liquid waste from non-pathogenic bacterial cultures (e.g., laboratory strain E. coli such as TOP10, DH5alpha) will be treated with Rely+On Virkon for >2h and then disposed of with waste water (as per the manufacturer's instructions). Monitoring will be achieved optically as outlined above. Solid waste, including bacterial plates, tips, tubes and wipes will be disposed of in biohazard waste containers as detailed above (disposed in biohazard waste containers [e.g. DisposaFlatPak 50], collected by e.g. Biffa [carrier licence, insurance permit and PPC permit in appendix] and destroyed by incineration [e.g. Veolia Tyseley - site permit in appendix]).

All solid waste material from mammalian and bacterial cultures will be stored in a room with electronic (key fob) access control. GMO facilities will be regularly inspected (at least 2x/month) to ensure appropriate cleaning procedures are followed, and all laminar and microbiological safety cabinet surfaces cleaned at least every 3 months using appropriate agents (e.g., 10% sodium hypochlorite). Biohazard containers once full will be sealed, labelled with a unique project identifier and date of storage, and held until collection (collection schedule every 2 weeks). The number, content and origin of biohazard waste bins will be recorded.

Please enter comments of the GM safety committee on the risk assessment
GMO work at TTP will be at Level 1 and risk assessment procedures and documentation have been put in place to cover all work. The requirements for Level 1 GMO handling, storage and waste management have been analysed and provisions put in place to meet these requirements. Additional provisions for record keeping, staff training and GMO material tracking, including procedures of waste storage and incineration, have been put in place. A quarterly, and on demand, review schedule of provisions and processes is in place and is designed to ensure provisions match current requirements and to keep recording processes up to date.

### Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities: [Y]

Give brief details of the genetic modification safety committee:

The GM safety committee person at the Babraham research campus where Stemnovate's laboratory work will be conducted is MSc, PhD, Tech IOSH, MISTR, and works as Health, Safety and Quality Assurance of Research Manager & Biosafety Officer, Babraham Institute, Babraham Research Campus, Cambridge CB22 3AT. The risk assessment documentation for the Babraham research campus have been duly submitted by the company following a meet up and discussion with facilities management.

At company, CEO is B.V.Sc, M.V.Sc, M.Res (Stem Cell Research) and PhD. She has over 10 years experience in induced pluripotent stem cell (iPSC) research including reprogramming with several vector systems including retroviruses, lentiviruses, sendai viral systems. She did postdoc at University of Cambridge in a MRC (UK-RMP) project for generation of iPSCs for cellular therapies followed by working as operation manager in a company dealing in cellular products for in vitro R&D and was responsible for all risk assessments and implementation of biosafety.

There is dedicated waste management system at Babraham Research Campus. The work is conducted in Cat-2 Lab with lock and batch identification system where trained personnel are only allowed to conduct work who are also trained on proper waste disposal. Work is conducted in a safety hood, all tissue culture plastic is treated in Virkon as disinfectant solution before disposal in yellow bin with lid for Cat-2 waste properly lined with autoclave bags for Cat-2 waste. All microtips, pipettes are disposed off in disinfectant solution and disposed after 24 hrs in Cat-2 waste bags. The safety hoods are wiped with 70% ethanol and disinfectant wipes and UV irradiated before and after use. All cryovials and microcentrifuge tubes are properly sealed. The spillage is treated with disinfectant and proper cleaning and reporting is mandatory. All liquid culture waste is directly disposed off in a container with virkon solution through proper aspirator tubing and a vacuum pump. Disinfectants: Virkon as virucidal disinfectant; HAZ tabs and 70% ethanol. All cat-2 waste bins are disposed off at designated location on campus and thereafter are managed by on campus facilities management team and waste disposal service.
The comments from GM safety committee personnel for the human iPS project using Sendai vector system: the ACDP do not classify the Sendai virus as a class 2 (containment 2), but using it as a vector of a proto-oncogene (e.g. c-myc) would require containment 2.

The comments from GM safety committee personnel for the animal iPS project using retroviral vector system: Though MMLV retroviral system is considered Cat1 work but as the pCl-10A1 is used for packaging, the envelope protein confers a wide host range (including humans) and, together with the use of proto-oncogenes e.g. c-myc, would move it into ACGM2 = containment 2 (see SACGM compendium of guidance part 2 (attached), section 2.11 (Retroviruses) pp 121).

---

**Project Ref**  3361/17.1

**Date Ackn'd**  04/05/2017
**Project Title**
The use of retroviral vector systems and Sendai viral vector system for generation of induced pluripotent stem cells from human and animal primary cells.

**Class**  Class 2  **Culture Vol**  < 1 Litre

**Date Project Ceased**

**Consent Granted**

**Non-GMM**

**Project notified under transitional arrangements**  N

**Historical Significant Changes**

**Historical Date of Additional Info**

**Significant Change ID**

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**
Generation of induced pluripotent stem cells (human and animal) for cellular differentiation and develop organ on chip technology for in vitro toxicology studies

**Recipient or parental organism**
Human primary cells and animal (canine, bovine, porcine, equine, mouse) primary cells

**Host/vector system**
The retrovirus vector systems have been based on the oncoviruses of the murine (MuLV) groups of retroviruses. These can be assigned to ACGM containment level 1 on the basis of their inherent properties. These are disabled vectors.

CytoTuneTM 2.0 Sendai reprogramming vectors in this kit are based on a modified, non-transmissible form of SeV, which has the Fusion protein (F) deleted, rendering the virus incapable of producing infectious particles from infected cells. (see attached risk assessment for details)

Origin & function

Human OCT4, SOX2, MYC, KLF4, Pluripotency genes and cell proliferation
Mouse OCT4, SOX2, MYC, KLF4

Evaluation of foreseeable effects

SeV vectors used in this kit consist of viral proteins NP, P, M, F (activated), HN, and L, and the SeV genome RNA, from which the F gene is deleted. Because SeV infects cells by attaching itself to cell surface receptor sialic acid, present on the surface of many cell types of different species, the vectors are able to transduce a wide range of cells. However, they are no longer capable of producing infectious particles from infected cells, because the viral genome lacks the F-gene. In addition, the presence of functional mutations such as temperature sensitivity in the amino acid sequence of several SeV proteins (SeV/TSΔF, SeV/TS12ΔF, and SeV/TS15ΔF) renders the vectors easily removable from transduced cells.

For Retroviral based vectors The packaging cell line is HEK, The inserted genes (OCT4, SOX2, KLF4 and C-MYC).

The final virus is replication defective. Retroviruses require close contact for their transmission and their survival in the general environment is poor. Members of the MuLV oncovirus group frequently require high titres of virus to establish persistent infections in immunologically competent animals so that the risk of harm to the environment associated with accidental release of vectors is generally low.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

There is dedicated waste management system at Babraham Research Campus. The work is conducted in Cat-2 Lab with lock and batch identification system where trained personnel are only allowed to conduct work who are also trained on proper waste disposal. Work is conducted in a safety hood, all tissue culture plastic in treated in Virkon as disinfectant solution before disposal in yellow bin with lid for Cat-2 waste properly lined with autoclave bags for Cat-2 waste. All microtops, pipettes are disposed off in disinfectant solution and disposed after 24 hrs in Cat-2 waste bags. The safety hoods are wiped with 70% ethanol and disinfectant wipes and UV irradiated before and after use. All cryovials and microcentrifuge tubes are properly sealed. The spillage is treated with disinfectant and proper cleaning and reporting is mandatory. All liquid culture waste is directly disposed off in a container with virkon solution through proper aspirator tubing and a vaccum pump. Disinfectants: Virkon as virucidal disinfectant; HAZ tabs and 70% ethanol. All cat-2 waste bins are disposed off at designated location on campus and thereafter are managed by on campus facilities management team and waste disposal service.
The comments from GM safety committee for human iPS project using Sendai vector system: the ACDP do not classify the sendai virus as a class 2 (containment 2), but using it as a vector of a proto-oncogenes (e.g. c-myc) would require containment 2. The comments from GM safety committee for animal iPS project using retroviral vector system: Though MMLV retroviral system is considered Cat1 work but as the pCl-10A1 is used for packaging, the envelope protein confers a wide host range (including humans) and, together with the use of proto-oncogenes e.g c-myc, would move it into ACGM2 = containment 2 (see SACGM compendium of guidance part 2 (attached), section 2.11 (Retroviruses).

## Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Give brief details of the genetic modification safety committee

- Company Chief Operating Officer responsible for Business Operations at GammaDelta Therapeutics who has a degree and DPhil in Pharmacology followed by over 15 years of experience working in operational roles supporting R&D activities within biotechnology companies. The Company Chief Operating Officer is the Company nominated Safety Champion.
- Company Vice President of Research is leading Research and Gene Engineering activities at GammaDelta Therapeutics since January 2019. She holds a PhD in Biochemistry and has 14 years’ experience working with genetically modified cells and viral vectors. 9 years experience were gained in an industry setting, where she has also held positions as chair of a GMSC and been a member of H&S committees.
- Company Gene Engineering Team Lead is leading the gene engineering activities at GammaDelta Therapeutics since 2017 October. He holds a medical (MD, University of Debrecen, Hungary) and Phd degree (UCL, London) and has over 10 years of experience working with gene modified cells, lentiviral vector production gained both in academic and biotechnology environment.
- Company Laboratory Manager & Safety Officer who manages the facilities at GammaDelta Therapeutics and who has received considerable formal Health & Safety training. She holds an Honours Bachelor of Science in Biology and has over 15 years’ experience working in the research field in both academic and biotechnology environments.
- An external Safety Advisor who is laboratory based and a chartered member of the Institution of Occupational Safety and Health (12 years). They are a member of a University GMSC.

<table>

</tbody>
</table>
- Any surface/equipment which is known or thought to be contaminated with GMOs will be disinfected using 1:10 Distel or 1:10 Chemgene solution. A contact time of at least 5 minutes is required. After contact time, any residue is wiped away using absorbent tissue, which is then disposed of via autoclave bags.
- Liquid wastes are to be inactivated by adding Virkon solution to a concentration of 2% (contact time in solution of 24 hours). After contact time, liquid wastes are disposed of via a designated laboratory sink, flushing with plenty of water.
- At a concentration of 1:10 Distel or 1:10 Chemgene solution there is a greater than 5 log degree of kill on a range of bacterial, fungal and viral strains. Please see link for Distel [https://www.starlabgroup.com/Documents/eng/186645.pdf](https://www.starlabgroup.com/Documents/eng/186645.pdf) and link for Chemgene [https://www.starlabgroup.com/Documents/eng/339784.pdf](https://www.starlabgroup.com/Documents/eng/339784.pdf).
- At 1% Virkon solution with contact time of 10 minutes kills a wider range of bacterial, fungal, yeast and viruses. Please see link for Virkon [https://relyondisinfection.com/fileadmin/user_upload/RelyOn_Virkon_UK.pdf](https://relyondisinfection.com/fileadmin/user_upload/RelyOn_Virkon_UK.pdf).
- Consumables or re-usable equipment contaminated with GMO waste will be autoclaved with a holding time of 15 minutes at 121 degree C. GammaDelta Therapeutics Limited (GDT) facilities will be used to autoclave waste. Designated staff at GDT are fully trained to treat and handle waste effectively and safely. Autoclaves are 12-point thermocouple and load tested annually. Bagged waste for autoclaving will be transported from GDT laboratories inside sealed containers, containers will remain closed when being transported from laboratories to Lab 4.01 where autoclaves are located. There is more than one autoclave present in GDT facilities, meaning that there is a back-up autoclave if required.
- Untreated waste is stored securely inside GDT laboratories.
- After waste is autoclaved by GDT staff it is sent for incineration at a site certified to deal with clinical waste, contracted by GDT. The company handling the waste is Stericycle.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Tick to confirm that you are attaching a summary of the risk assessment □
The Company's GMSC reviewed the draft risk assessment on 30 March 2017 and the external Safety Advisor additionally reviewed the updated risk assessment on 13 April 2017.

Comments from the Company's GMSC (30 March 2017):
- The draft GMO risk assessment (annotated by the external Safety Advisor) for proposed lentiviral work at GammaDelta Therapeutics Limited ("GDT") was reviewed and discussed by the GMSC.
- It was agreed that the risk assessment provided a good overview of the proposed activity and described the risks, hazards and control measures. Minor suggestions were made concerning the wording and presentation of information. It was noted that the viral titre should be added and agreed that, subject to confirmation of viral titre, the described work would likely be classified as a GM class 1 activity.
- The Safety Officer was actioned to update the assessment for final review by the external Safety Advisor.

Comments from the final review by external Safety Advisor (13 April 2017):
- Following confirmation of the viral titre (less than 6e6 transducing units per ml) using a third generation lentiviral vector and bearing in mind that the project does not use sharps or glass and that staff are protected by a number of control measures such as MSC2 cabinets and PPE with negligible dissemination of GMO products into the environment, the project was assigned to GM class 1 activity.
- Final minor changes were made to the risk assessment, including adding that GDT labs have been designed to CL2 standard and that the holding time for autoclave is 15 mins.

The final risk assessment was circulated again to the GMSC on 20th April 2017 and there were no further comments.

Other(s)

- Fermentation experiments as per RA.

- All cultures to be clearly labelled “YKO”.
- Maximum volume of concentrated cultures will be 5 ml, 10A8 cfu/ml yeast strain) in screw-top tubes.
- Maximum volume of fermentation will be 300 ml with 10A7 cfu/ml yeast strain using airlocks.
- Storage of YKO strain cultures will be at -80°C in 96-well plates (2001-li/well) or in screw top-vials (1.5 ml).
- Cultures on solid agar plates may be temporarily stored in the fridge sealed with parafilm.
- Material containing Class-1 GMO YKO Saccharomyces cerevisiae strains will be discarded through the landfill waste route.

No

Give brief details of the genetic modification safety committee

The GOI and vector derivative material are already in use by our contract process development client. As such a competent member of the client team (the Process & Technology Transfer Lead) has provided relevant safety information for use in our own risk assessment, has reviewed the completed risk assessment and visited the lab itself.

Bacteriology | Parasitology | Transgenic Birds | Microbiology Research
Two autoclaves are available for relevant waste. Solid/contaminated waste will be disposed into biohazard bins/boxes, sealed and placed into lockable clinical waste containers and disposed of by GMO registered waste management company (http://www.labwaste.co.uk). Decontamination of surfaces will be conducted using elevated levels of the disinfectant ChemGene HLD4L and 70%(v/v) Kleercide spray. Inactivation of liquids will be performed using Virkon tablets as per manufacturer instructions.

For activities involving GMMs, describe the waste management measures which will apply to the activity

The GOI and vectors have been evaluated and are deemed safe for use in the CL 1 lab at Exmoor Pharma. Concepts based on a thorough risk assessment exercise conducted both on the use of this GOI and vector/host cell type at an academic centre operating a cell and gene therapy MHRA approved GMP facility which was witnessed and conducted by their GM safety committee and a repeat risk assessment based on the prior but localised for eXmoor Pharma's lab, which is attached in this premises 1° use of a CL 1 GMO. Alan is content that all minimum requirements are met according to best practice. Furthermore, the natural invaribility of the material in question along with defunct replication competent ability and the inability of rAAV to integrate into its preferred site of genomic integration on human chromosome 19 as seen in wt AAV, also adds a layer of risk mitigation when using this GOI and GMO in a controlled environment. Due diligence has been followed against the most contentious questions for handling of this material and there is no substantial proof that any mishandling of this GMO and derivatives will impact the safety of personnel or the environment it is contained within.

Project Ref 3365/19.1

Date Ackn'd 02/03/2022
### Purposes of the contained use

This work is a part of a process development program to help a client develop and optimise an efficient lentiviral vector manufacturing process at a smaller laboratory scale, which will enable them to take products through the clinic to commercial manufacture. The work in the lab involves cell culture in shake flasks and bioreactors (both in a closed system) between 1L and 40L working volume, using a common bioreactor operating and control platform. Cell culture is followed by induction of the cells to produce viral vector particles, and various steps of downstream purification and analysis of the material. Closed processing is maximised with all open processing operations conducted within a Class II Biological Safety Cabinet.

### Recipient or parental organism

Human embryonic kidney cells (HEK293T).

### Host/vector system

Lentiviral beta-globin (GLOBE) vector system induced from stable HEK293T cell line using doxycycline, that is replication-defective and intended for ex vivo use for modification of autologous CD34+ stem cells.

### Origin & function

Replication-defective lentivirus encoding beta-globin (GLOBE) transgene. Genetic sequence of interest: transgene genetic material is of human origin and intended for ex vivo use for therapeutic modification of autologous CD34+ stem cells. Lentiviral genes: genes for packaging and encapsulation. Sequences are available from client 87363.

### Evaluation of foreseeable effects

HEK293T cells containing genetic sequences of stable lentivirus engineered to be replication-defective. The host HEK293T cell line is a stable lentiviral vector (LVV) producer where LVV production is induced thus transfection is not required. Genetic sequences with stable lentivirus are intended in therapeutic use to increase the expression of beta-globin, which in itself would not have a detrimental effect on human host cells.
Replication-defective lentiviral vectors are non-infectious according to the client's Material Safety Data Sheet. Stable suspension HEK293T cells pose no significant hazard for members of the laboratory or environment.

Closed processing and single use disposable equipment and components are used wherever possible to minimise personnel exposure in the lab and to contain process materials. A biological safety cabinet class II is used for all open processing steps.

The work will use standard laboratory and bioreactor methods and will not involve any processes that generate significant quantities of aerosols.

Post cell growth in the bioreactor, cells are immediately induced to release the viral vector of interest which is subsequently clarified free of cells and cellular debris for further purification. Spent cell culture media and process fluids generated during downstream purification will be inactivated, along with single use materials, as previously described.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

A derogation request is sought for the secure storage, transport and incineration off-site of Class 2 solid waste. It is proposed that a licensed contractor will remove disinfected solid waste from the laboratory location where it is generated for off-site inactivation and disposal (also see section 12. below).

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

There is no autoclave of sufficient size in the building, so inactivation in the laboratory is by initial treatment with a disinfectant. Class 2 liquid waste will be chemically inactivated by the addition of Virkon (1% final working concentration) and overnight treatment at room temperature prior to being disposed of down the laboratory drain with copious amounts of water. As per manufacturer's data these conditions result in complete inactivation of GMOs. Class 2 solid waste including plastic ware will be inactivated within a sealed container by immersion in Virkon (1% final working concentration) overnight at room temperature, prior to collection for off-site incineration by a licensed 3rd party waste management contractor (www.srl.com). Inactivated solid waste will be placed in double yellow clinical waste bags within contractor-supplied bins fitted with a sealed lid, located in each laboratory room. When filled, waste bags are securely closed and taken to a larger contractor-supplied 770 litre lockable wheeled bin which will be tagged with a unique barcode. The waste management contractor will remove the filled bin and replace with an empty bin on a weekly collection schedule. A consignment note is generated for each bin of waste material removed by the waste contractor. Waste is transported in the sealed bin and disposed of at an off-site incineration (100% kill). The Avonmouth incinerator where the waste material is handled is licensed to process class 2 GMO waste and is registered under GMO reference centre number GM 779.

Decontamination of surfaces will be conducted using elevated levels of the disinfectant Distel spray.

Spill procedures are available for spills; in this event spill kits and PPE are used to treat all materials and surfaces with 1% Virkon for one hour. All contaminated materials would be collected securely and sent for off-site incineration as described above.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Project Additional Information

Purposes of the contained use
This work is a part of a process development program to help eXmoor's client to manufacture CD20 expressing γδ T-cell product for the treatment of haematological and solid tumours. The work in the lab involves cell culture using closed small scale multilayer cell stack system between 250ml and 10L working volume. The work will involve transient transfection of HEK293T cells using a three-plasmid transfection system (detailed below) in closed process conditions to generate the virus of interest which is subsequently clarified free of cells and cellular debris for further downstream purification and analysis of the material.

Recipient or parental organism

HEK293T, sourced from ATCC (CRL-3216) by eXmoor's client.

Host/vector system

Replication-incompetent and self-inactivating γ-RV encoding the CD20 CAR construct.

Origin & function

Replication-incompetent and self-inactivating γ-RV encoding CD20 CAR construct.
Genetic sequence of interest: of human origin and intended for autologous modification of γδ T cells.
γ-RV genes: gag-pol and env genes for packaging and encapsulation provided on separate plasmids to improve biosafety.
Sequences are available from eXmoor's client 100365.

Evaluation of foreseeable effects

γ-RV based on Moloney murine leukemia virus (MoMLV), pseudotyped with RD114 envelope (feline RD114 endogenous retrovirus envelope) will be packaged using transient transfection with the three-plasmid system (the transfer plasmid, a packaging plasmid and an envelope plasmid) into HEK293T cells to prevent recombination. The transfer vector contains modified long-terminal repeats (LTRs), the transgene and Ψ packaging signal. The other plasmids are a gag-pol packaging plasmid and a RD114 envelope plasmid. This multi-plasmid approach results in no single plasmid containing all the accessory genes necessary for viral replication. In addition, most of U3 is deleted from 3'LTR, making the viral promoter non-functional and self-inactivating after integration into the host genome which further negates the possibility of viral replication and improves biosafety.
Replication-incompetent and self-inactivating γ-RVs are non-infectious according to client 100365 information. Transiently transfected HEK293T cells pose no significant hazard for members of the laboratory or environment.
Closed processing and single use disposable equipment and components are used wherever possible to minimise personnel exposure in the lab and to contain process materials. A biological safety cabinet class II is used for all open processing steps.
The work will use standard laboratory methods and will not involve any processes that generate significant quantities of aerosols.
Post cell growth in small scale multilayer cell stack system, cells are transiently transfected in closed process conditions to generate the virus of interest which is subsequently clarified free of cells and cellular debris for further purification. Spent cell culture media and process fluids generated during downstream purification will be inactivated, along with single use materials (see section 12. below).

Give brief details of the genetic modification safety committee

The AMRC Safety Committee includes individuals with many years experience working in drug development including three medicinal chemists and two experienced microbiologists with expertise in molecular microbiology including, but not limited to recombinant DNA techniques and mutagenesis. These individuals have the necessary know-how to risk assess the use of GMOs at AMRC and find alternative approaches to negate the use of GMOs where possible.

All agents will be handled in a cat 2 microbiology laboratory and handled in a Class 2 biological safety cabinet. All users are appropriately trained to handle these organisms, and utilise personal protective equipment including a howie lab coat, nitrile gloves and safety glasses at all times in the laboratory. The facility is equipped with appropriate waste streams for disposal of infectious materials and GMMs.

- Sharps - contaminated sharps are disposed of via sharps bins which are autoclaved using the Alderley park site facility (validated via annual thermocouple testing) and then disposed of as clinical waste and incinerated (via Veolia waste collection)
- Small plasticware - contaminated plastics such as pipette tips are inactivated using 1% ChemGene (http://medimark.co.uk/images/uploads/CHEMGENE_HLD4L_EN_TEST_SUMMARY.pdf)
- For recyclable glassware - a laboratory bench autoclave is used for inactivation of waste (validated via annual thermocouple testing). Inactivated material is then discarded as non-infectious ie. washed away and glassware washed and re-used.
- For all other solid waste - Solid waste is collected in autoclave bags and then inactivated using the Alderley Park site autoclave and then disposed of as clinical waste and incinerated (via Veolia waste collection).

AMRC Safety Committee includes V S, D L, I C, N O, J K and S L. V S and N O have a collective experience of around 30 years in microbiology and molecular biology. Having worked in both academia and industry they have the necessary experience to assess the risk of utilising GMMs in the AMRC laboratory and minimise this risk. The committee meets every 3 months to discuss and review new biological agents for acquisition, GMMs if applicable, accidents/incidents/near misses where they have occurred, and observations from lab and office inspections.

Give brief details of the genetic modification safety committee

The Spybiotech GMO Biological Safety Committee has been established to review risk assessments and give guidance on all safety aspects of projects proposed within the company. It does so by identifying possible hazards associated with the proposed work that could compromise the safety to the general public, the risk of cross contamination or recombination, the risk of release into the community of GMOs and any ethical considerations that may be relevant. Its members are drawn from a variety of backgrounds and bring a diverse range of expertise both within and outside of the company itself. The Committee meets on an ad hoc basis whenever new GMO projects are proposed.

### For activities involving GMMs, describe the waste management measures which will apply to the activity

Liquid waste is disinfected with Distel at 1:10 dilution or Chemgene at 1:20 for a minimum of 12 hours before sink disposal.

Solid waste (including plasticwares) is double-bagged in yellow clinical waste bags, placed in a 1100L yellow eurobin with lock and removed weekly by waste management contractor for off-site treatment (autoclaving) and incineration.

Spillages of GMMs will be disinfected with Distel at 1:10 dilution or Chemgene at 1:20 for a minimum 10 minutes.

All disinfectant are used in strict accordance with the manufacturer's guidelines and efficacy data.

**Tick to confirm that you are attaching a summary of the risk assessment** Y

**Tick if you are claiming exemption from disclosure for sections of the risk assessment**

---

**Please enter comments of the GM safety committee on the risk assessment**

The GMO Biological Safety Committee reported that the proposed projects to be conducted at Spybiotech poses little to no risk to any of the company staff, the environment, or the general public. It is of a non-infectious, non-hazardous nature and the genes product have no inherent biological toxicity. The committee wanted to remind the company to keep all manufacturer's literature and product information for any vectors, organisms or cells that are being purchased, to add to the background safety information. The committee also noted that every risk assessment should be reviewed on a regular basis to ensure they are still accurate and applicable.

For activities involving GMMs, describe the waste management measures which will apply to the activity

All contaminated solid waste will be inactivated by autoclaving (100% kill) prior to disposal by incineration, the autoclave will be validated by annual thermocouple mapping and each run will be monitored by continuous chart (or digital) recording of the temperature/time profile.

All contaminated liquids will be placed into a suitable waste container and disinfected by adding Virkon disinfectant to a final concentration of 1% Virkon. Leave for at least 12 hours before disposing down the sink with plenty of water.

### Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Yes

Give brief details of the genetic modification safety committee

The applicant has previously written risk assessments that were approved by the MRC's LMB GMAG Committee and by the Biological Safety Committee in the Faculty of Medicine and Health at the University of Leeds. He has also previously sought and obtained permission for contained use for his previous organisation, Aptuscan/Avacta Life Sciences Ltd. Additionally, advice has been sought from the Head of Health and Safety in the Department of Biological Sciences at the University of Leeds.

As the company grows, a GM Safety Committee will be established as a sub-committee of the Lab Safety Committee. The applicant is expected to Chair both Committees until sufficient experience has accumulated as the Company grows.

02/03/2022
Liquid waste that has been in contact with antibiotic-resistant micro-organisms must be decontaminated by autoclaving for at least 15 minutes at 121°C. Other biologically-contaminated liquid waste must be inactivated using an appropriate disinfectant (e.g. Virkon, Presept, Tegodyne) at a concentration and contact time appropriate to the level of contamination prior to disposal to the drains. Whilst chemical disinfection is not 100% effective, its use should result in at least a 4 to 5 log reduction in viable organisms, which will be monitored by plating on nutrient-rich agar. Where chemical disinfection is not possible (e.g. chemical incompatibility) then the liquids may be autoclaved. If neither of these methods is appropriate, consideration will be given to the use of a gelling agent to generate solidified waste that can be sent for incineration via our approved route for the disposal of clinical waste. Solid biological waste for disposal is double-bagged in biohazard autoclave bags (transparent). After autoclaving for at least 15 minutes at 121°C, the bags are closed and placed into heavy duty, opaque yellow bags for disposal and incineration via the clinical waste route using the BioCentre's approved contractor. Blades, needles, and glassware will not be used for biological work. Any contaminated pipettes (e.g. Stripettes) must be soaked in an appropriate disinfectant and then discarded into a UN approved Sharps-bin. Sharps bins must only be filled to the approved level (usually the three-quarters line). The lid must then be fastened and the bin securely stored to await collection and incineration via the clinical waste route. Incineration is well documented as killing 100% of viable organisms. Providing chemical disinfection is carried out in accordance with Appendix 1 then monitoring is not required.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Tick to confirm that you are attaching a summary of the risk assessment  Y

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

As the author of the risk assessment, I have taken every care to ensure that this meets both the needs of the legislation. Just as importantly, I am satisfied that the assessment correctly and conscientiously assigns risk, and clearly outlines measures that will minimise any hazard to MetaLinear's staff or visitors, and to the environment.
Antibiotic resistance of pathogenic micro-organisms is a major and growing problem in modern healthcare worldwide. metaLinear will be using genetic transformation of libraries of engineered proteins into pathogenic micro-organisms to screen for novel targets for antibiotics and for targets that break antibiotic resistance.

We are therefore seeking authorisation for the contained use of transiently transformed pathogenic micro-organisms, including Klebsiella pneumoniae, Acinetobacter baumannii, Pseudomonas aeroginosa, and Enterobacter spp (the so-called KAPE organisms). We will also need to transform lab-disabled strains of E. coli, of Saccharomyces cerevisiae, and of Pichia pastoris with genes isolated from the pathogenic organisms that encode the candidate targets. These comprise Class 1 GMOs.

Class 2: Clinical strains of gram negative microbes, including E. coli, Klebsiella pneumoniae, Acinetobacter baumannii, Pseudomonas aeroginosa, Enterobacter spp. These strains are, by their very nature, able to infect and colonise human beings and animals. After their transformation with the engineered protein libraries, 3 classes of foreseeable effects must be considered: those resulting in loss of viability or pathogenicity (which are the effects we are seeking) and which will reduce the harmfulness of these micro-organisms; those that are without measurable effect, where the organisms remain Class II; and those that alter the expression of bacterial proteins to increase pathogenicity; as these genes pre-existed in the micro-organisms, there is no increased risk in working with the GMO compared to the parental organism. It is extremely unlikely that one of the engineered proteins, once expressed in the micro-organisms, would alter its biology in such a way as to make the organisms more pathogenic than they already are.

Class 1: Laboratory strains of Escherichia coli K12 and derivatives, and laboratory strains of Saccharomyces cerevisiae or Pichia pastoris. These will be used for the development and storage of the libraries of engineered proteins, and for the subsequent expression of bacterial proteins. The same three classes of foreseeable effects need to be considered, none of which will increase the risk of working with the micro-organisms following transformation. As with mutagenesis, the expression of random proteins in any organism is far more likely to be deleterious than advantageous to the organism. In addition, the library proteins will be controlled by an inducible or repressible transcription system, meaning that the engineered proteins are unlikely to be able to affect the GMO.

Bacteriophage are not properly a biological organism as they are incapable of independent replication. Nonetheless, they are included here as they will be recipients of engineered gene products and there is a risk of cross-contamination by mobilization.
The host strains for screens will be clinical strains of gram negative microbes, including E. coli, Klebsiella pneumoniae, Acinetobacter baumannii, Pseudomonas aeruginosa, Enterobacter spp, each of which carries its own plasmids. The vector system will therefore need to be tailored for each screen, in each organism. The vector systems will need to be chosen so to minimise the likelihood of plasmid excision in each target strain, but will also be chosen so as to be non-mobiliseable, as far as predictable. All of these strains are Gram-negative bacteria, and will share mechanisms for the maintenance of plasmids, and for gene expression, which we anticipate to mean that we will be able to use common lab-safe vectors of the pBR and pET series (which are mobilisation defective) and pUC series, which are non-mobilisable. The hosts for protein expression will be common E coli K12-derived strains and yeast strains such as Pichia pastoris, together with their associated vector systems of the pBR322, pUC and pET series. These vectors are intrinsically non-mobilisable, although there is a minor risk of mobilisation should these vectors be transformed into the wild-type pathogenic KAPE strains. However, even if this happened, the vectors would only be carrying genes expressing proteins that are naturally present in these organisms (the protein targets for our therapeutic screens) or engineered proteins that were isolated by their ability to decrease the viability of the clinical strains. The risk of these escaping into the environment or infecting a human are therefore negligible.

Origin & function

Peptides constrained in three dimensions within the context of a constant, stable, folded scaffold protein interact with target molecules (usually but not exclusively proteins) with high affinity and specificity. Proteins comprising a scaffold and one or more constrained peptides are generically called peptide aptamers, and when engineered variants of the Stefin A scaffold is used the peptide aptamers are called Affimers. The genetic material to be used will be DNA encoding Affimers and Affimer libraries. To create collections of Affimers, oligonucleotides encoding a random collection of peptide sequences are inserted at defined positions within variants of the Stefin A open reading frame (ORF). Expression of the resulting collection of ORFs generates a library of proteins, the Affimers, randomized at specific regions on their surface. Libraries may be for work using phage display, yeast two hybrid screens, or manipulation of proteins within pathogenic micro-organisms. Following screening of any of these three libraries, larger amounts (µg - g) of individual Affimers may be produced, usually in E. coli or in Pichia pastoris or similar. The project will also include occasional cloning of open reading frames encoding target proteins for expression in E. coli or in S. cerevisiae or P. pastoris.

Evaluation of foreseeable effects

The foreseeable effects are that individual Affimer proteins expressed in a host cell will affect the biology of that cell. We are seeking Affimers that decrease the viability of the host cell (thereby identifying candidate antibiotic drug targets) or that break antibiotic resistance. By definition, these Affimers will not increase the risk of working with the transformed micro-organisms. Our experience is that the overwhelming majority of Affimers are without a positive effect of the growth of the host cell- out of 100s of millions of transformants we have worked with to date, we have never observed colonies with altered morphology, for example. Although it is conceivable that some Affimers may potentially lead to the expression of host genes that increase the viability and/or pathogenicity of the host cell, these genes are already present in the bacteria, and thus will not increase the hazard of working with them. Nonetheless, our risk assessment requires that all Petri dishes on which transformed E coli are grown be sealed with Parafilm, and never opened. Transformed bacteria will be inactivated by autoclaving within 3-5 days of transformation, and disposal will be by incineration by an approved contractor.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMOs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

We are not requesting derogation.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving (100% kill) prior to disposal of waste. Cleaning and recycling of reusable laboratory equipment, such as glassware, will require a minimal 15 minute incubation with 2% Virkon prior to dishwashing (wash at 80 C, drying 65 C) and autoclaving. Glassware that has been contacted with bacteriophage will be treated with 2% Virkon. Note that glassware not be used when working with the pathogenic strains, to minimize risk of contamination by inoculation.

Liquid growth media contaminated with pathogenic strains will be inactivated by autoclaving. Other liquid waste will be inactivated overnight with 2% Virkon prior to disposal.
via the sink.

All bench surfaces, including the insides of the microbiological cabinets, will be cleaned with 1% Virkon or 70% ethanol (if no open flame is present). The resulting paper waste will be inactivated by autoclaving prior to disposal by incineration.

Incineration of inactivated waste will be performed off-site by the York Science Park’s approved Clinical Waste contractor.

Autoclaves will be validated by annual thermocouple mapping and each run will be monitored using TST (Time, Steam, and Temperature) test strips (Albert Browne Ltd., TST class 6 emulating indicator 121°C for 20 min).

Antibiotic resistance of pathogenic micro-organisms is a major and growing problem in modern healthcare worldwide. metaLinear will be using genetic transformation of libraries of engineered proteins called RTeins into pathogenic micro-organisms to screen for novel targets for antibiotics and for targets that break antibiotic resistance.

We are therefore seeking authorisation for the contained use of transiently transformed pathogenic micro-organisms, including Klebsiella pneumoniae, Acinetobacter baumannii, Pseudomonas aeruginosa, and Enterobacter spp (the so-called KAPE organisms).

We will also need to transform lab-disabled strains of E coli, of Saccharomyces cerevisiae, and of Pichia pastoris with genes isolated from the pathogenic organisms that encode the candidate targets. These comprise Class 1 GMOs.

Recipient or parental organism

Class 2: Clinical strains of gram negative microbes, including E. coli, Klebsiella pneumoniae, Acinetobacter baumannii, Pseudomonas aeruginosa, Enterobacter spp. These strains are, by their very nature, able to infect and colonise human beings and animals. After their transformation with the engineered protein libraries, 3 classes of foreseeable effects must be considered: those resulting in loss of viability or pathogenicity (which are the effects we are seeking) and which will reduce the harmfulness of these micro-organisms; those that are without measurable effect, where the organisms remain Class II; and those that alter the expression of bacterial proteins to increase pathogenicity; as these genes pre-existed in the microorganisms, there is no increased risk in working with the GMO compared to the parental organism. It is extremely unlikely that one of the engineered proteins, once expressed in the micro-organisms, would alter its biology in such a way as to make the organisms more pathogenic than they already are.

Class 1: Laboratory strains of Escherichia coli K12 and derivatives, and
laboratory strains of *Saccharomyces cerevisiae* or *Pichia pastoris*. These will be used for the development and storage of the libraries of engineered proteins, and for the subsequent expression of bacterial proteins. The same three classes of foreseeable effects need to be considered, none of which will increase the risk of working with the micro-organisms following transformation. As with mutagenesis, the expression of random proteins in any organism is far more likely to be deleterious than advantageous to the organism. In addition, the library proteins will be controlled by an inducible or repressible transcription system, meaning that the engineered proteins are unlikely to be able to affect the GMO.

Bacteriophages are not properly a biological organism as they are incapable of independent replication. Nonetheless, they are included here as they will be recipients of engineered gene products and there is a risk of cross-contamination by mobilization.

**Host/vector system**

The host strains for screens will be clinical strains of gram negative microbes, including *E. coli*, *Klebsiella pneumoniae*, *Acinetobacter baumannii*, *Pseudomonas aeruginosa*, *Enterobacter spp*, each of which carries its own plasmids. The vector system will therefore need to be tailored for each screen, in each organism. The vector systems will need to be chosen so as to minimize the likelihood of plasmid excision in each target strain, but will also be chosen so as to be non-mobilizable, as far as predictable. All of these strains are Gram-negative bacteria, and will share mechanisms for the maintenance of plasmids, and for gene expression, which we anticipate to mean that we will be able to use common lab-safe vectors of the pBR and pET series (which are mobilization defective) and pUC series, which are non-mobilizable.

The hosts for protein expression will be common *E. coli* K12-derived strains and yeast strains such as *Pichia pastoris*, together with their associated vector systems of the pBR322, pUC and pET series. These vectors are intrinsically non-mobilizable, although there is a minor risk of mobilization should these vectors be transformed into the wild-type pathogenic KAPE strains. However, even if this happened, the vectors would only be carrying genes expressing proteins that are naturally present in these organisms (the protein targets for our therapeutic screens) or engineered proteins that were isolated by their ability to decrease the viability of the clinical strains. The risk of these escaping into the environment or infecting a human are therefore negligible.

**Origin & function**

Peptides constrained in three dimensions within the context of a constant, stable, folded scaffold protein interact with target molecules (usually but not exclusively proteins) with high affinity and specificity. Proteins comprising a scaffold and one or more constrained peptides are generically called peptide...
aptamers, and when engineered variants of the Stefin A scaffold is used the peptide aptamers are called RTeins. The genetic material to be used will be DNA encoding RTeins and RTein libraries.

To create collections of Affimers, oligonucleotides encoding a random collection of peptide sequences are inserted at defined positions within variants of the Stefin A open reading frame (ORF). Expression of the resulting collection of ORFs generates a library of proteins, the RTeins, randomized at specific regions on their surface. Libraries may be for work using phage display, yeast two hybrid screens, or manipulation of proteins within pathogenic micro-organisms.

Following screening of any of these three libraries, larger amounts ($\mu$g - g) of individual RTeins may be produced, usually in E. coli or in Pichia pastoris or individual RTeins may be produced, usually in E. coli or in Pichia pastoris or similar.

The project will also include occasional cloning of open reading frames encoding target proteins for expression in E. coli or in S. cerevisiae or P. pastoris.

**Evaluation of foreseeable effects**

The foreseeable effects are that individual RTein proteins expressed in a host cell will affect the biology of that cell. We are seeking RTein proteins that decrease the viability of the host cell (thereby identifying candidate antibiotic drug targets) or that break antibiotic resistance. By definition, these RTeins will not increase the risk of working with the transformed microorganisms.

Our experience is that the overwhelming majority of RTeins are without a positive effect of the growth of the host cell: out of 100s of millions of transformants we have worked with to date, we have never observed colonies with altered morphology, for example. Although it is conceivable that some RTeins may potentially lead to the expression of host genes that increase the viability and/or pathogenicity of the host cell, these genes are already present in the bacteria, and thus will not increase the hazard of working with them. Nonetheless, our risk assessment requires that all Petri dishes on which transformed E coli are grown be sealed with Parafilm, and never opened. Transformed bacteria will be inactivated by autoclaving within 3-5 days of transformation, and disposal will be by incineration by an approved contractor.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Alderley Park operates a full decontamination, sterilisation and incineration service that we propose to use for solid waste only. Double-bagged solid waste will be placed in sturdy yellow sterilisation bags within the lab, and then placed in yellow wheeble bins stored in locked cupboards immediately
outside the lab entrance. Trained Alderley Park personnel collect these bins and take them via a specified and approved route to the facility for sterilisation and incineration.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving (100% kill) prior to disposal of waste. Cleaning and recycling of reusable laboratory equipment, such as glassware, will require a minimal 15 minute incubation with 2% Virkon prior to dishwashing (wash at 80 C, drying 65 C) and autoclaving. Glassware that has been contacted with bacteriophage will be treated with 2% Virkon. Note that glassware not be used when working with the pathogenic strains, to minimize risk of contamination by inoculation.

Liquid growth media contaminated with pathogenic strains will be inactivated by autoclaving. Other liquid growth media contaminated with pathogenic strains will be inactivated by autoclaving. Other liquid waste will be inactivated overnight with 2% Virkon prior to disposal via the sink.

All bench surfaces, including the insides of the microbiological cabinets, will be cleaned with 1% Virkon or 70% ethanol (if no open flame is present). The resulting paper waste will be inactivated by autoclaving prior to disposal by incineration.

Incineration of waste will be performed o-site by Alderley Park's approved Clinical Waste contractor, Veolia Ltd.

Autoclaves will be validated by annual thermocouple mapping and each run will be monitored using TST (Time, Steam, and Temperature) test strips (Albert Browne Ltd., TST class 6 emulating indicator 121ºC for 20 min).

---

**Please enter comments on the GM safety committee on the risk assessment**

metroLinear Ltd is currently too small to form a committee. Every employee is working in the lab on these projects, and is required to read and sign off on the Risk Assessment attached. This risk assessment is based on that used by Avacta Life Sciences, from whom the RTein technology has been licensed, and that was written by Paul Ko Ferrigno and approved by Avacta's GM Safety Committee and Lab Safety Committee.

### Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Y

Give brief details of the genetic modification safety committee

- Composition of Biological/GM safety Committee
  - Person responsible for overall OHS (NNRCCO Head of Institute)
  - Biological Safety Officer
  - Management representatives (Department Managers for all teams using GMOs)
  - Representative from Operations
  - General staff representative(s) chosen by and from all members of the department who have access to genetic modification

The committee meets regularly (quarterly), and also as required, to review and make recommendations on proposed work to be carried out at the company's premises.

The GMSC will meet once yearly to review existing GM risk assessments.

The work will be carried out in compliance with good laboratory practice and local safety rules for GM work in a containment level 2 facility.

Bacterial cultures:
All solutions and consumables are subjected to overnight Virkon treatment. Liquid waste will be discharged to drain waste stream, according to established practises in Centre.

Cell cultures:
All solutions and consumables are treated by Virkon only, before entering the drain waste stream, according to established practises in Centre.

Autoclave-specific instructions:
Consumables (mainly plastic ware e.g. pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via black bag waste stream.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via black bag waste stream.

Degree of kill
Autoclaving, effectively 100% kill (annual validation)
Incineration, effectively 100% kill (licensed incinerator)
Chemical, effectively 100% kill (following manufacturer’s guidelines)

Work conducted at the NNRCO will aim to identify novel type 2 diabetes drug targets.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Please enter comments of the GM safety committee on the risk assessment
Work conducted at the NNRCO will aim to identify novel diabetes and metabolic disease drug targets via medium throughput cellular screens and smaller gene-specific studies. The genome of mammalian cells will be targeted by 'gene editing' tools such CRISPR, which cleave double-stranded DNA, and stimulate genomic repair via nonhomologous end joining (introducing indels), or homologous recombination (upon provision of an appropriate oligo template). This approach will allow study of endogenous gene knockout, as well as the effect of introduced/corrected mutations. Complimentary gene-targeting approaches using modified ('dead') Cas9 tethered to transcriptional regulators will also be used to enhance or repress gene expression. Similar approaches will also be used to generate reporter lines and genetically-encoded cell-signalling sensors. Functional characterisation of the resulting cells will involve standard laboratory techniques including (but not restricted to): secretion assays, reporter assays, kinetic assays, fluorescent microscopy, mass spec analysis, DNA sequencing, and gene expression studies.

Recipient or parental organism
Mammalian cell lines have been sourced from-, and well characterised by, commercial vendors. They are free of mycoplasma, bacteria and fungi, and human viruses (CMV, EBV, HBV, HCV, HIV1, HIV2, HPV, HSV1, and HSV2).
Risk = low. See list of example cell lines in Appendix 1.
Human embryonic stem cell (ESC) and induced pluripotent stem cell (iPSC) lines have been characterised extensively within Novo Nordisk, and are free of mycoplasma, bacteria and fungi, and human viruses (CMV, EBV, HBV, HCV, HIV1, HIV2, HPV, HSV1, and HSV2). Risk = low.
Human primary cells are considered especially disabled hosts under the Genetic Modification Regulations and are therefore minimal risk (considered to be ADCP hazard group 1). However, there is the potential for blood borne pathogens and as such samples will be handled at containment level 2 under CoSHH regulations. Where commercially-sourced, primary cells will also be tested by serology for the major human pathogens RPR (syphilis), Hepatitis B, Hepatitis C and HIV. All primary cell handlers will be vaccinated against hepatitis B purely for precautionary reasons (and in line with University of Oxford safety policy). All samples will be stored, used, and disposed of in line with the Human Tissue Act. Risk = low.
E.coli to be used in plasmid replication are ADCP category 1, as well as being inactivated and incapable of colonising the gut. Risk = low. See list of example bacteria in Appendix 2.
Virus or viral vectors have been well characterized. Third generation lentiviral vectors are safer as they are replication incompetent and are always SIN (self-inactivating). Adenovirus doesn't integrate into the genome and is not replicated during the cell cycle. Adenovirus spread from cells to cells. Risk = low.
Manipulation of endogenous genomic sequence will be achieved by the action of the site-specific nuclease delivered to the cell as a complex of nuclease protein and its cofactor nucleic acid, frequently an RNA molecule (RNP [ribonucleoprotein]).

CRISPR via viral transduction:
Manipulation of endogenous genomic sequence will be achieved by the action of the site-specific nuclease delivered to the cell via viral expression vector. This same vector will also express guide-RNA molecules which will be sequence-specific and target the nuclease to the desired genomic coordinates.

Additional exogenous DNA for insertion into the genome:
Examples include but are not limited to:
1) Linear single stranded oligonucleotides which are homologous to the region of interest and include the required sequence changes, e.g. point mutation changes or small sequence alterations.
2) Double stranded DNA as standard plasmids and BAC backbones harbouring:
   a) mammalian (e.g. human or mouse) genomic sequence
   b) mammalian (e.g. human or mouse) cDNA mini genes driven by tissue-specific promoters (e.g. human or mouse genomic promoter sequence), from inducible operons (e.g. the Lac or Tet bacterial operons), from ubiquitous promoters (e.g. viral CMV immediate early promoters) or a combination of promoter, exon, intron, splice acceptor elements (CAAGS promoter sequences)
   c) synthetic shRNAs and microRNAs driven by tissue specific or human ubiquitous Poilil promoter.

CONTAINMENT AND CONTROL MEASURES - OVERALL CONTAINMENT LEVEL 2
Under Genetic Modification regulations, cell lines are considered to be especially disabled hosts. However, as a precaution, all cell lines used will be handled at Containment Level 2 under COSHH Regulations. For aseptic purposes all cell lines will be cultured in a Class II microbiological safety cabinet located in a tissue culture laboratory (containment level 2). Risk=low
Primary cells are considered especially disabled hosts under the Genetic Modification Regulations and are therefore minimal risk (considered to be ADCP hazard group 1). However, there is the potential for blood borne pathogens and as such sample will be handled at Containment Level 2 under CoSHH Regulations. For aseptic purposes all cell lines will be cultured in a Class II microbiological safety cabinet located in a tissue culture laboratory (containment level 2). Risk=low

All work will take place in CL2 laboratories (leased from University of Oxford), and all local rules and University Biosafety policies will be followed whilst working with GMOs. Use of sharps will be avoided if possible and the generation of aerosols kept to a minimum.
Viral vectors/particles will only be used by trained individuals and contained within designated areas of the laboratory. Any procedure that can generate aerosols or splashes will be conducted inside a biological safety cabinet. All viral waste will be inactivated and disposed of in alignment with local (University of Oxford) safety rule (see below).

Expected biological action of inserted DNA/RNA or transcribed/translated gene product:
Normal mammalian cellular functions (as well as non-functional gene fragments and selective alterations of said gene/protein). Transgenes also include but are not limited to fluorescent, luminescent, or histochemical reporter genes, and previously-characterised recombinase and integrase enzymes. Inserts are not expected to affect pathogenicity of cloning.
CRISPR-Cas9:
The Streptococcus pyogenes Type II CRISPR-Cas system consists of the nuclease Cas9, and a guide (g)RNA. This gRNA determines DNA binding/cleavage specificity. Target DNA must immediately precede a 5'-NGG (PAM) sequence, with specificity directed by altering the 20-nt guide sequence within the sgRNA. The D10A Streptococcus pyogenes Cas9 nuclease mutant introduces single strand nicks at differing sites on the sense and antisense DNA strands. Other mutant 'dead' Cas9 proteins (with no nuclease activity) can be tethered to transcriptional regulators to modify gene expression levels at targeted/gRNA-specific loci. This nuclease, when directed against human genomic sequences, has the potential to be mutagenic, although the preparation would have to cross the cell membrane. Electroporation acts as an engineering control for this potential risk, as this makes it virtually impossible for the researcher to inoculate themselves by accident. When this nuclease is to be introduced into cells via an active transfection reagent (e.g. lipofection or viral infection), the risk is increased to containment level 2, and the appropriate handling and disposal rules will apply (see below).

As well as the intended, predictable on-target mutagenesis, the tolerance for some limited mismatches have been reported for site-specific nucleases, which suggests an additional risk of off-target mutagenesis. To minimize these unpredictable effects, all commercially-supplied gRNAs have been designed using proprietary algorithms that minimise predicted off-target events. As an additional safety measure, a list of all gRNAs and predicted off-targets will be kept, assessed, and reviewed on a regular basis.

Of note, there is hugely conflicting evidence in the field as to whether there is any, and if so what level risk there is, of off-target mutagenesis. Whilst studies involving many millions of cells report this phenomenon (doi:10.1038/nbt.2623, doi:10.1038/nmeth.4293), there are also many in which off-target mutagenesis is refuted (doi:10.1016/j.stem.2014.06.011, doi:10.1016/j.stem.2014.04.020). This refutation is was recently supported by opinion-leaders in the field (doi: https://doi.org/10.1101/153338).

Evaluation of foreseeable effects
All genetically modified E. coli, viruses, and some transfected lines will be antibiotic resistant for clonal selection; however this will not increase the risk from these GMOs, as such antibiotics would not be used in clinical treatment. All viruses and RNP-complexes (when transfected only) will be handled at containment level 2 to minimise risk of accidental inoculation. Generation of aerosols will be kept to an absolute minimum. Use of sharps will be avoided when using virus or RNP-complexes.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

A disinfection policy is in place within all NNRCO laboratory space (Appendix 5).

WASTE MANAGEMENT MEASURES
Liquids (eg samples, culture supernatants, tissue culture media)
  Disinfect with 1 % Virkon for 1 hour, discharge any excess liquid to drains.
Consumables (mainly plasticware eg pipettes, flasks, tubes)
Health and Safety
Executive
  Autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (the building discard autoclave sterilisation
cycle is 134nC for 5 minutes), discharge excess liquid to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Agar plates

Autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (see above), discharge excess liquid to drains, dispose of solids via the black bag waste stream for landfill.

Routine disinfection

Wash down benches and Class 2 Biosafety cabinets before and after each use and wipe clean equipment using 5% CHEMGENE and 70% EtOH. Deep clean Class II Biosafety cabinets with 5% CHEMGENE, followed by 70% EtOH, once Imonth.

Degree of Kill

Autoclaving I effectively 100% kill (annual validation)

Incineration I effectively 100% kill (licensed incinerator)

Chemical disinfection I effectively 100% kill (Rely+On Virkon)

Sharps (eg needles, syringes, scalpels) - NOTE: SHARPS WILL NOT BE USED WITH VIRUS/RNP COMPLEXES

Collect in suitable Sharps Bins for disposal via the usual building sharps waste stream; autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (see above) then dispose via clinical waste stream for incineration. Sharps must not be used for viral work.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

This notification and the information included within has been written and reviewed by NB, QW, SE, JJ, and AK. It aligns with safety policy already in place at the University of Oxford.

Retroviral vectors/AKD10 and 1624-5 cells
pET21/Various E.coli cells
pET-DUET vectors/ Various E.coli cells
Lentiviral vector - pLS018/primary cells, K562, Jurkat cells
Lentiviral vector - pCDH/primary cells, K562, Jurkat cells
Lentiviral vectors - LENTIGUIDE puro and pLENTICRISPRv2/primary cells, K562, Jurkat cells

Human scFv
Human Antibodies and fragments
Soluble antigens from different species (human, mouse, non human primate)
EBV viral genome
Human, mouse and chimeric TCRs
Luciferase
eGFP and GFP
TCRs/CARTs (human)
MHC-peptide complex (human)

Evaluation of foreseeable effects
HEK293 cells
Human adenovirus is a common virus for humans, that can cause illness. The virus is transmitted into the tissue via soft mucous membranes. It causes respiratory disease, the symptoms of which are a sore throat, runny nose and eyes, sneezing, headaches, cough and fever. In some persons infection with adenovirus may also cause croup or bronchitis. Some infections may also lead to conjunctivitis (pink-eye), skin rash, diarrhoea and bladder infections. Laboratory scientists who are displaying signs of adenoviral infections regularly when working with HEK cells need to notify the GMO safety committee and be referred to occupational health.
In HEK cells, the adenovirus is incomplete, and it would be able to replicate if other genes from the adenovirus were present. So, if a laboratory worker was already harbouring the adenovirus, this could combine with E1A and result in further active viral particles. This has the potential to infect other health humans if the virus was not contained and will harm the environment. All HEK cell work must take place in a class 2 microbiological safety cabinet. This would mean any possible aerosols created from HEK cultures would be HEPA filtered before leaving the laboratory. A class 2 MSC hood would protect the user from possible exposure to any harmful effects of the cell line. All members of staff will be trained on how to use a class 2 MSC effectively to minimise exposure to themselves and the environment. Along with our biological safety procedures.
EBV
The use of primary human tissue/cells along with EBV is the most hazardous GMO. EBV is the causative agent for infectious mononucleosis and is
associated with several malignancies in man, such as African endemic Burkitt's lymphoma, nasopharynx carcinoma of the undifferentiated form, B cell lymphomas in immunosuppressed individuals, and Hodgkin's disease. Infection with EBV commonly occurs during childhood in an asymptomatic form, leading to a rapid increase in EBV antibodies. Seroepidemiological data from various regions of the world demonstrate a prevalence of anti-EBV antibodies of 85–95% at the age of 20 years. Thereafter, primary EBV infections are a rare event, but are still observed. This suggests that some individuals remain EBV− due to natural resistance. It is unclear what would happen if the immortalized B cell was accidentally injected or was able to enter the systemic circulation via the mucous membranes. It could potentially cause malignancies, but the number of cells that need to systemically administered to observe that is unclear. Use of sharps is prohibited with this cell line. All work must also take place in a class 2 MSC. The immortalized cell line can also synthesise new virus, so levels of exposure to the virus could be high. So volumes of cells and virus must be kept low to less than 1L.

AKD10 cells
The AKD10R3 cell lines with TCRs transduced into them. This cell has the intracellular signalling of a mouse T-cell, but the extracellular receptors for human. So human antigens could trigger a signalling response. The human triggers for such a signalling response can only be cells expressing MHC-peptide with beta-macroglobulin molecules. These are found at such low concentrations, that the signalling response will be weak. In addition, the TCR can only signal when there is a specific MHC-peptide complex, so the likelihood that there is a clear match is very low. This is not a dangerous cell line, to the environment or human health, Our good laboratory practise is to wear appropriate PPE when handling this cell line and to work within a Class 2 biological safety cabinet to reduce any possible exposure risks.

Lentiviruses
The biosafety of lentiviruses has been looked at in great detail and is well documented (Debyser, 2003. Curr. Gen. Ther). The highest risk of infection of lentivirus is through sharps and scratches. Mucous membrane exposure is also very high, and can be a source of infection for laboratory scientists. The use of adequate use of biosafety cabinets and PPE can prevent this risk. Use of sharps in class 2 laboratories is prohibited. When lentivirus is made, it is centrifuged and filtered before infecting cells. The virus particles will be spun in a high speed centrifuge in the laboratory and all buckets must be taken into the MSC and bucket seals opened in the MSC to minimise aerosol formation. All tubes must also be opened in the MSC. Filtration via a 0.4 uM syringe filter also has the potential to spray aerosols. All this must be done in an MSC. PPE must be adhered to at all times.
General
All staff must be made aware of the class 2 GMOs generated in this RA. Immunocompromised individuals must be made aware of the HEK risk to themselves, and be monitored for any adverse effects by our occupational health consultants. When used in a Class 2 MSC, the likelihood of exposure of the GMO’s in this Risk assessment will be low.
PPE will be adhered to. Spot safety checks (monthly) and continual laboratory surveillance will be carried out to ensure that staff are adhering to Agenus’ PPE laboratory requirements, and disposal of class 2 GMOs will be monitored by the inspections also. All appropriate PPE will meet current the current ISO/BS/EN standard.
Hepatitis B vaccination is only required for laboratory scientists working on primary human cells and human tissue. Cells bought from ATCC are not screened for Hepatitis B. It is recommended that all scientists working with any human cells should be vaccinated for Hepatitis B. This will be a requirement for Agenus-UK, and immunisation surveillance will be enforced.

EBV Specific
Laboratory scientists working on this project must be made aware of the health risks to human health when working with EBV. There are no vaccinations available to EBV. There are strictly no sharps allowed in the class 2 laboratories. Laboratory scientists working with EBV should report any symptoms of mononucleosis (fever, sore throat, body aches) to the BSO or health and safety committee, at which the scientist may be referred to the GP or hospital for a blood cell count. EBV antibody tests can also be performed in hospitals to monitor scientists who are immune compromised or at high risk of catching EBV. EBV can only be transmitted by saliva. Immune compromised scientists should wear protective facial masks that are HEPA filtered to prevent exposure.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste coming out of the CL2 laboratories will be inactivated before removal (GMO level 1 and 2). All liquid waste and pipette tips will be submerged in 1% Virkon solution for a minimum of 1 hour before strained and disposed of in double sealed autoclave bags. The 1% Virkon solutions will be kept in the Class 2 MSC to prevent removing any liquid waste from the MSCs. (Virkon has been validated to show it will inactivate any human cells and viruses). All waste will be decontaminated further by autoclaving, before taken offsite by a specialist biohazard waste company for incineration and final disposal. The disposal of plasticware that is not routinely subject to Virkon or autoclaving must will be double sealed in biohazard bags collected and stored in plastic biohazard waste bins before transfer to a specialist biohazard waste company.

Is an emergency plan required according to regulation 20?  
N

If yes, tick to confirm that it is attached to this form
N

Tick to confirm that you have attached a risk assessment to this form  
Y
The only class 2 GMO many RAs is the use of HEK cells. The GMOSC highlighted the importance of face to face training on the use of HEK cells, particularly the waste streams and handling of the cell line. All liquid waste is disposed of with virkon and all solid waste autoclaved onsite before removal. This may change if we find a supplier to decontaminate our class 2 material. There will be an additional web based training for all new hires, and all scientific staff will be responsible for adhering to Agenus biological safety procedures.

EBV Specific

GMOSC agreed that this GMO is the most hazardous. Any intent to work on EBV must be provided in writing to the GMOSC prior to any work started, stating when the work will start, how long EBV will be in culture and when the work is to finish. Progress on the timelines should be given regularly to the GMOSC. The GMOSC is responsible for notifying all staff via email that EBV is being cultured, and in which laboratories. The GMOSC will also be responsible for sticking up notifications on the doors of these laboratories, to minimise scientist exposure. Sharps is strictly prohibited. Scientists working with EBV will also be required to wear double gloves, where outer pairs will be removed when moving from centrifuges to the class 2 MSC. Centrifuge bucket seals will be purchased for these laboratories, and any breakage of tubes would require scientists to keep the centrifuges closed for at least 2 hours to allow aerosols to settle before opening. All tubes and bucket seals must be open in the class 2 MSC. Weekly cleaning procedures must be adhered to, as specified in the Agenus biologicals procedures documents, and this will be monitored by laboratory champions. All scientific staff will be required to adhere to Agenus biological procedures.

Lentivirus Specific

The GMOSC agreed that although viruses are used in this RA, they are well understood and deactivated and are safer to use. There are risks, particularly with incubating the virus in the cold room, ultra-centrifugation of the virus, incubation in shaking incubators and syringe filtering. These are hazards that can produce scientist exposure and aerosol formation. All filtering must occur under a class 2 MSC. Lentivirus that is live and CL2 in the incubators require a poster fitted to the front of the incubator to make other scientists aware of the hazards. The same with the centrifuges and cold room. Double gloves are also required to reduce the spread of contamination. Centrifuge bucket seals will be purchased for these laboratories, and any breakage of tubes would require scientists to keep the centrifuges closed for at least 2 hours to allow aerosols to settle before opening. All tubes and bucket seals must be open in the class 2 MSC. Weekly cleaning procedures must be adhered to, as specified in the Agenus biologicals procedures documents, and this will be monitored by laboratory champions. All scientific staff will be required to adhere to Agenus biological procedures.

Both liquid and solid waste will be autoclaved with 100% expected degree of kill. Our autoclaves are examined and validated every three years. Virkon disinfectant will be used to deal with any spills in the laboratory.

For activities involving GMMs, describe the waste management measures which will apply to the activity

The E coli strains for plasmid construction and maintenance are non-pathogenic laboratory strains (E.coli DH5alpha). The proposed genetic modifications will not change the infectivity of the microorganisms or allow them to persist in the environment. Although the plasmids used in the cloning procedures contain an antibiotic resistance marker that can be used for selection, the antibiotics used are not the same ones used in frontline patient treatment.

The proposed waste disposal by autoclaving should be sufficient to decontaminate the waste produced during the experiments.

Give brief details of the genetic modification safety committee:

Axitan is a tenant company of the Imperial College Translation and Innovation Hub. The Axitan representative is the company director who is an experienced researcher holding both masters and doctoral qualifications. Axitan has sought advice from both the biological safety officer of the Department of Biochemical engineering at University College London and the Safety and Biorisk manager of Imperial College. Both individuals provided advice with respect to the risk assessment and HSE notification. In addition various literature sources and 3rd parties using the same materials were also consulted.

Waste Disposal
- Virkon is used as it is a validated cleaning method for material and transfected cells if used in the following way under manufacturers recommendations
- Hard surfaces: A solution containing 1% Virkon for 1 hour contact time, 10mins for metal parts (longer can cause corrosion)
- Safety cabinets: 1% Virkon (10mins)
- Discard jars, plastic flasks, glassware: A solution containing 1% Virkon.
- Ensure all surfaces are in contact with the disinfectant (10mins). Added to sealed bags for autoclaving at a minimum of 121 degrees C, 1.15bar, 20 mins hold.
- Supernatants/liquid waste: 3% Virkon diluted 2:1 in culture medium
- All autoclaved solid waste is to be placed into hazardous waste bags. There is one autoclave available and the equipment is regularly serviced, and an annual multi point thermo-couple test carried out with a suitable representative load, to ensure that it maintains its ability to provide a validated method of waste inactivation.
- Full bags are to be transported to designated hazardous waste bins in the storage area
- Bins are collected for off site incineration by waste management company

For activities involving GMMs, describe the waste management measures which will apply to the activity

Please enter comments of the GM safety committee on the risk assessment
The Translation and Innovation Hub (I-HUB) provides space for companies to work alongside Imperial researchers. It's facilities support businesses large and small and, include start-up and fast-growth companies as well as established biotech and scientific research organisations. Through the Imperial College safety department, I-HUB provides health and safety assistance to ensure that tenants are assessing the risks associated with the work appropriately and to disseminate best practice among researchers. Imperial College Biological Safety Officer Ian Hackford has reviewed and advised Axitan on its GMO risk assessment and are satisfied they have considered the risks in terms of GM organisms and scale of work. They have appropriate control measures to contain the work and appropriate procedures for the class of GMO activity for waste disposal.

Below are specific comments from the Imperial Biosafety officer that have since been addressed:

1. Section 6 of the CU1. I would recommend changing the following sentence in section 6 of the CU1 referring to the autoclave from "There is 1 autoclave available and the equipment is regularly serviced to ensure it maintains its ability to be a validated cleaning method" to "There is one autoclave available and the equipment is regularly serviced, and an annual multi point thermo-couple test carried out with a suitable representative load, to ensure that it maintains its ability to provide a validated method of waste inactivation”

2. Section 6 of the CU1. In the first sentence Virkon is missing the “r”

3. Section 1.2 of the risk assessment. You state that "none of the genes would be expected to make C. reinhardtii pathogenic or increase persistence in the environment relative to parent strain". I notice that you are introducing endolysin and antimicrobial genes into the Algae. I appreciate that the host organism is not capable of establishing an infection in a human host but could you please provide a brief explanation as to why these modifications would not provide the GM algae with a selective advantage in the environment if it were to be accidentally released?

4. Section 1.1 of the risk assessment. I appreciate that you may be inserting multiple variations of Bacteriophage endolysin genes, antimicrobial peptide genes, and pathogen antigen protein genes and you do not wish to make this assessment to narrow. However in order to help set the limits on the scope of this work could you please give a few examples of each gene. I appreciate that the risk of harm is low but are there any genes in these groups that you would not introduce?

### Waste Management Measures

Any solid microbiological and cell biological laboratory waste (e.g. bacterial agar plates, plastics, gloves) from our class 1 GM work is collected in laboratory waste bins (Eurobins) which are sealed and labelled by our staff. The sealed bins are then removed by the Babraham campus waste team to a central collection point where they will be placed into labelled 210 litre yellow Eurobins. The 210 litre bins are then collected by a nearby (off site) registered clinical/GM waste company and incinerated (see derogation application below).

Liquid class 1 GM culture waste (e.g. cultures and spent media after isolation of cells) is inactivated by treatment with Virkon. After full inactivation (1% Virkon treatment overnight), liquid waste is disposed of into the waste water supply. Associated plastics will then be disposed of as the solid waste.

Surfaces will be routinely cleaned and decontaminated with 2% Chemgene.

### Risk Assessment

**For activities involving GMMs, describe the waste management measures which will apply to the activity**

Any solid microbiological and cell biological laboratory waste (e.g. bacterial agar plates, plastics, gloves) from our class 1 GM work is collected in laboratory waste bins (Eurobins) which are sealed and labelled by our staff. The sealed bins are then removed by the Babraham campus waste team to a central collection point where they will be placed into labelled 210 litre yellow Eurobins. <th>CultureVolumeClass3-4</th>
</tr>
</thead>
<tbody>
<tr>
<td>Class 2</td>
<td>&lt; 1 Litre</td>
<td></td>
</tr>
</tbody>
</table>
Project Additional Information

Purposes of the contained use

To enable the generation of lentiviral and retroviral vectors and use them in cell lines for the expression of:

1) Open reading frame (ORFs) (including but not limited to oncogenes, tumor suppressor genes, Cas9 proteins), cDNA, peptides and other gene sequences
2) synthetic RNA sequences for gene expression regulation (including but limited to microRNA, short hairpin RNA, and short interfering RNA)
3) synthetic RNA for gene editing (including but not limited to synthetic guide RNAs for CRISPR/Cas9 technologies, template for gene editing)

Recipient or parental organism

The recipient organism will be of 2 types:
1) cell line used for virus production, either as a) helper cell lines (including but not limited to HEK293T and HEK293FT) into which the different plasm ids for virus production (encoding viral vector proteins and genome) will be transiently co-transfected, or b) packaging cell line stably expressing the proteins required to assemble virus particles that will be transiently transfected with plasm ids encoding the viral vector genome (including but not limited to GP2-293, Platinum, 293RTV, Phoenix cell lines). These cell lines will be used for the transient production of viral particles that will be released into the cell growth media. These viral particle suspensions could provide a risk for infection for the personnel handling them.
2) recipient cell line in culture that will be infected with the viral particles produced as described above. This includes (but are not limited to): immortalised cell lines, cancer cell lines, and other previously established cell lines and long term culture of human and animal origin. For the first few days after contact with virus, the infected cultures could provide a potential risk for infections for the personnel handling them.

Host/vector system

The retroviral vectors are derived from Xenotropic murine leukaemia virus-related virus, while the lentiviral vectors are derived from HIV-1 virus (Naldini et al., 1998). All the viral vectors that we will generate and use are devoid of the proteins required for virus replication and pathogenicity, and as so, they are replication-incompetent vectors that after
integration into the host cell genome cannot propagate nor replicate. Additional safety features of the retroviral and lentiviral vectors that we will use are:
- viral vectors are devoid of pathogenic accessory genes (vif, vpr, vpu and nef) required for viral replication and the genes from the parental virus strain contained in the viral vector is reduced to just the structural proteins: gag, pol, env (Naldini et al., 1998).
- genes encoding the structural and other components required for packaging the viral genome are separated onto 2 or more plasmids. All plasmids have been engineered to limit the regions of homology with each other so that undesirable recombination events that could lead to the generation of a replication-competent virus are minimised (Dull et al., 1998; Naldini et al., 1998).
- none of the packaging plasmids that allow expression in trans of proteins required to produce viral progeny, nor the constructs stably expressing the viral proteins in packaging cell lines, contain LTRs or the 4' packaging sequence. This means that none of the virus structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. No new replication-competent virus can be produced.
- whenever possible, we will use viral vector constructs that are "self-inactivating": those vectors contain a deletion in the 3' LTR (I'U3) that does not affect generation of the viral genome in the producer cell line, but results in "selfinactivation" of the viral vector after transduction of the target cell (Yee et al., 1987; Yu et al., 1986; Zufferey et al., 1998; Naldini et al., 1998). Once integrated into the transduced target cell, the viral genome is unable to transcribe a packageable viral genome, further reducing the possibility of production of any infectious viral progeny.
Despite the above safety features, use of these viral vectors (which include WPRE sequence) falls within SACGM 2 criteria due to the potential biohazard risk of possible recombination with endogenous viral sequences to form selfreplicating virus, the possibility of insertional mutagenesis, and the expression of potentially oncogenic genes. Also, the virus will be packaged with envelope proteins (including but not limited to VSV-G) that allow the transduction of a wide variety of animal species and cell types. This means that these viruses could potentially infect a number of species, including human beings. Despite this, the viral vectors will not be able to propagate nor produce in any way an infective progeny, due to the safety measures applied as described above.

Origin & function

Selectable markers - examples (but not restricted to):
- Ampicillin resistance: E.coli derived
- Neomycin resistance: bacteria derived aminoglycoside phosphotransferase gene
- Puromycin resistance (PAC): Puromycin acetyl transferase is derived from Streptomyces alboniger
- Blasticidin resistance: Streptomyces griseochromogenes-derived
- Hygromycin resistance: Streptomyces hygroscopicus-derived
- Zeocin resistance: Streptomyces verticillus derived

Reporter proteins such as (but not restricted to):
- Fluorescent proteins as reporters: GFP derived from the jellyfish Aequorea victoria and variants of this (BFP, YFP, CherryFP, CFP ...)
- Luciferase - class of oxidative enzymes used in bioluminescence; renilla luciferase derived from the Sea pansy (Renilla renifomris); firefly lu ciferase derived from the firefly Photinus pyralis.

Open reading frames, peptides, cDNAs and gene sequences from different species such as (but not restricted to):
- oncogene, tumor suppressor genes, CRISPR/Cas9 proteins for knockout, gene inactivation (CRISPRi), gene overexpression (CR ISPRa), TALEN proteins, endonuclease proteins, gene involved in DNA damage response, DNA repair, cell cycle, cell proliferation; and templates for gene editing.
- RNA sequences such as (but not restricted to): microRNA, short hairpin RNA, and short interfering RNA; synthetic guide RNAs for CRISPR/Cas9 techologies and templates for gene editing.
The viral vector that we will produce are, at worst, amphotropic or pseudo typed with VSV-G protein, either of which confers a broad host tropism including human cells. However, all the viral particles will be replication-incompetent and, when possible, self-inactivating, therefore there is no possibility of viral replication nor propagation further. Since some of the inserted DNA could code for potentially hazardous RNA or protein, the work is assessed as Class 2. This accords with HSE SACGM Compendium of Guidance for retroviruses (Part 2, para.18-20). Even for the non oncogenic inserted DNA, there is a slight but non negligible risk due to the presence in some of the viral vectors of the Woodchuck Post-transcriptional Regulatory Element. The WPRE containing vector DNA will be treated as potentially oncogenic and is assigned to class 2 (see HSE SACGM Compendium of Guidance for retroviruses (Part 2, para.13».

However, bearing this in mind we should consider that the viruses that will be used have been modified in a number of ways which will make them safer to handle:
- The genes encoding structural and other components of the viral genome have been separated. These genes and the plasmids encoding them have been engineered to minimise the risk of recombination that could lead to production of a replication-competent virus.
- The packaging cell lines allow expression of proteins, required to produce progeny virus, but the transfer vector (not encoding the structural viral proteins) is the only genetic material transferred to the target cells, consequently these recipient cells cannot produce the proteins which are essential for viral assembly and infectivity.
- The viral vector production in helper/packaging cell line will be transient, i.e. the component for the assembly of infective viral particles will be co-expressed exclusively for the few days of persistence of the transiently transfected plasmid encoding the viral genome.

Procedures and controls measures will therefore follow HSE SACGM Compendium of Guidance for retroviruses (Part 2, para.30-36) i.e. using multiple plasmids with minimum sequence homology (e.g. our 2nd or 3rd generation lentiviral or retroviral vector systems), gloves will be worn, use of class II safety cabinets, sharps avoided and all wastes be rendered harmless before disposal etc.

It is not thought that the modified virus would pose a serious risk to animals or plants in the environment. Although the VSV coat protein permits transduction of other mammalian cells, as in the case of humans, infection would be restricted to primary cells and productive virus would not be produced. In addition the control measures to protect human health will minimise release of virus to the environment. Therefore the environmental risk is low.

The viral vectors will be used to generate a cell population stably expressing the gene or RNA sequence(s) of interest. For the first week after infection, or until at least both 3 replications and 3 media changes have occurred, the cell population infected with the viral particle will be treated as potentially infective. After this period, these cell cultures and the derivative products will be considered as Class I since the viral particles will be cleared from the culture.

Evaluation of foreseeable effects

N/A

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Instead of autoclaving waste in the building we propose to follow the procedure used by the Babraham Institute described in their disposal notification GM1 05/4.1 (see also section 12 below). Reasons for adopting this method of waste disposal are:
1. We do not have access to an autoclave within our area of the building
2. The waste disposal system used by the Babraham Research Campus is safe and has been running since October 2004.
All waste material will be inactivated by treatment with 5% (w/v) Chemgene solution prior to disposal. Waste material will then be placed in sealed bins and incinerated by an off-site incineration company (Vetspeed - Their GM authorization is GM898) according to disposal notification GM1 05/4.1. Waste from our GM work at Class2 will be placed into suitably labelled hermetically sealable (red lid to distinguish them from class 1 waste) 60 litre UN approved (to Class 3) Type 3H21Y30/S/2003 bins. Sealed bins are placed into secondary 210 litre yellow labelled "Eurobins". Contents of the bin are recorded and collections by the local registered clinical/GM waste incinerator contractor will be made three times a week to prevent a buildup. The site has 24/7 Security. The contractor uses solid bodied transport and carries portable disinfection equipment in case of any spillage. Autoclave facilities will be available in an adjacent building, as required by the Regulations, in case of loss of the contractor's facilities. The type of container and the secondary Euro container means that the risk of any spillage of active GM waste on site is negligible. However, as active waste will leave the site, the risk to the environment and health is possibly marginally higher than autoclaving prior to incineration. The only real risk of release would be as a result of a major RTA, however, the containers are designed to withstand this. This disposal method is expected to achieve 100% inactivation of the GMM.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Instead of autoclaving waste in the building we propose to follow the procedure used by the Babraham Institute described in their disposal notification GM1 05/4.1. Reasons for adopting this method of waste disposal are:

1. We do not have access to an autoclave within our area of the building
2. The waste disposal system used by the Babraham Research Campus is safe and has been running since October 2004.

All waste material will be inactivated by treatment with 5% (w/v) Chemgene solution prior to disposal. Waste material will then be placed in sealed bins and incinerated by an off-site incineration company (Vetspeed - Their GM authorization is GM898) according to disposal notification GM1 05/4.1. Waste from our GM work at Class2 will be placed into suitably labelled hermetically sealable (red lid to distinguish them from class 1 waste) 60 litre UN approved (to Class 3) Type 3H21Y30/S/2003 bins. Sealed bins are placed into secondary 210 litre yellow labelled "Eurobins". Contents of the bin are recorded and collections by the local registered clinical/GM waste incinerator contractor will be made three times a week to prevent a buildup. The site has 24/7 Security. The contractor uses solid bodied transport and carries portable disinfection equipment in case of any spillage. Autoclave facilities will be available in an adjacent building, as required by the Regulations, in case of loss of the contractor's facilities. The type of container and the secondary Euro container means that the risk of any spillage of active GM waste on site is negligible. However, as active waste will leave the site, the risk to the environment and health is possibly marginally higher than autoclaving prior to incineration. The only real risk of release would be as a result of a major RTA, however, the containers are designed to withstand this. This disposal method is expected to achieve 100% inactivation of the GMM.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
The scope and particular aspects of safety risks described in the risk assessment were agreed upon, and satisfactory consensus was achieved regarding the adequacy of the SOPs, COPs and risk management planning protocols. Pending notification and acknowledgement by relevant authorities.

Give brief details of the genetic modification safety committee:

Stevenage Bioscience Catalyst (SBC) has a 10-member GM committee which includes representative tenants from each company working in the SBC. The chair of the committee has 25 years’ experience working with GMOs and has previously served as GM Officer in the Dept of Life Sciences at Imperial College. The GM committee has a wide range of experiences in GMO R&D.

**For activities involving GMMs, describe the waste management measures which will apply to the activity**

- Virkon is used as it is a validated cleaning method for viral vector material, transfected or transduced cells if used in the following way under manufacturers recommendations
  - Hard surfaces: A solution containing 1 % Virkon or Distel spray for 1 hour contact time, 10mins for metal parts (longer can cause corrosion)
  - Safety cabinets: 1 % Virkon (10mins) or Distel spray
  - Discard jars, plastic tissue culture flasks, glassware: A solution containing 1 % Virkon.
  - Ensure all surfaces are in contact with the disinfectant (1 Omins). Added to sealed bags for autoclaving at a minimum of 1210C, 1.15bar, 15 mins hold.
  - Supernatants/liquid waste: 3% Virkon diluted 2: 1 in culture medium
  - All autoclaved solid waste is to be placed into hazardous waste bags. There are 2x autoclaves available and the equipment is regularly serviced to ensure it maintains its ability to be a validated cleaning method. Chart recorder or display screen is attached to autoclave to monitor treatment.
  - Full bags are to be transported to Gyroscope's hazardous waste bins in the SBC storage area
  - Bins are collected for offsite incineration by Grundons waste management

---

**Please enter comments of the GM safety committee on the risk assessment**

The chair and the SBC GMO committee have advise Gyroscope Therapeutics limited on evaluating GMO handling and waste disposal risks and are satisfied that they are acting appropriately, responsibly and with the best practice of the SBC. The R&D does not contain anything exceptional that requires special consideration. The SBC GM Committee have approved the associated risk assessment and support this notification.

**Project Additional Information**

**Purposes of the contained use**

Research and Development of viral vectors as a cellular therapy relies on animal and in vitro cellular work to inform on the distribution and characterisation of viral vectors containing proprietary transgenes. The specialist nature of this administration means that Gyroscope utilises CROs and academics external to our premises at Stevenage, UK to generate AAV transduced cells or tissues from animals or primary human cells. To enable importation of tissues and biological fluids across International Borders our premises requires a CU2 designation to receive these tissues to enable research into the distribution and characterisation of the viral vectors containing our proprietary transgenes.

**Recipient or parental organism**

Humans and animals (rodent, dog, porcine, non human primate and lagomorpha). All animals used for Research Purposes at CRO's and academics will be obtained from reputable sources and designated as specific pathogen free.

HEK293, HEK293T and ARPE19 cells.

Human tissue samples will be generated as part of the human safety and efficacy studies conducted to support the development of this gene therapy.

**Host/vector system**

We utilise a proprietary replication incompetent virus: Adeno Associated Virus (AAV) serotype 2 for expression of proprietary transgenes to restore functionality of proteins deficient in ocular diseases.

**Origin & function**
All of the vectors used in this project are being developed for human therapies and thus have been significantly engineered to alter parts of the genetic code to create proprietary vectors that have a better safety profile than their wild type counterparts.

The key alteration is that all vectors have been altered to be replication incompetent. This means that they pose a minimal concern to the environment should they be released as they cannot replicate in any cell or organisms they are able to infect. The vectors used also pose minimal to no chance to infecting plant or livestock as they are developed/chosen to transfect human cells.

**Evaluation of foreseeable effects**

**AAV** is not currently known to cause disease. These vectors have the ability to infect humans via a number of methods e.g. direct contact with skin, mucous membrane of the eye, nose and mouth, ingestion, or injection. Infection could lead to the expression of the transgene and cause a very mild immune response.

Gene therapy vectors using AAV can infect both dividing and quiescent cells and persist in an extrachromosomal state without integrating into the genome of the host cell, although in the native virus some integration of virally carried genes into the host genome (albeit at a specific chromosomal locus) does occur in wtAAV2. The proprietary version used in this project has been altered to be replication incompetent and contain a benign reporter transgene or native human genes. In the SACGM Compendium of guidance Part 2: Risk assessment of genetically modified microorganisms (other than those associated with plants) wild-type (replication competent) AAVs are not categorised by ACDP and therefore, Containment Level 1 will be sufficient and should be adopted as a minimum requirement when handling wild-type virus.

If infection were to occur, by their nature and design the vectors are replication incompetent and so will be unable to propagate throughout an individual. There is the possibility that if an organism is also infected with a replication competent wild type vector that the transgene vector will also gain this ability. However control measures implemented as outlined below make this a highly unlikely event.

**HEK293 and HEK293T** were generated in 1973 by transformation of cultures of normal embryonic kidney cells with sheared adenovirus 5 DNA. This cell line is used to propagate the viral vectors which have been engineered to be replication incompetent. HEK cell lines pose minimal potential damage to the environment as they have been adapted to survive in an artificial cell culture environment under laboratory conditions. They are unlikely to thrive in the external environment if released.

**Control measures to be adopted:**

- Records and tracking of materials used are kept as part of Gyroscope’s good lab practice which involves both hard copy and electronic copies of lab books. All materials are clearly labelled and stored in specific safe storage areas within the facilities.
- PPE: lab coats, gloves and goggles to be worn at all times. This is to reduce the possibility of any physical contact with the vector.
- To avoid exposure to aerosol/droplets where feasible viral manipulations should be conducted in biosafety Level 2 (BSL2) cabinets with HEPA filters, conforming to a Containment Level 2 (CL2) to prevent release and possible inhalation.
- No sharps will be used – removes the possibility of introduction into the blood stream
- Centrifugation must be conducted in closed containers and using sealed rotors. Rotors must be opened in a Biosafety cabinet.
- Once the vector has been disrupted during preparation for nucleic acid or protein analysis it is safe to be used outside of the cabinet (PPE as outlined above should still be used).
- All wastes treated to destroy GMO material (see disposal section below)
- Volumes of dilute virus material to be kept under <20L of 1E13 virus particles to make waste handling and disposal easier and to reduce the severity of any adverse events
- Volumes of concentrated virus material to be kept under 20mL of 1E15 virus particles. This allows easy handling in the biosafety hood.
- HEK 293, HEK 293T, ARPE19 cell lines (volumes less than 20L). Once cells have been transduced or transfected they should only be handled in closed containers or in the CL2 cabinet
- All vector material when stored in fridge/freezer will be clearly labelled as to its contents.
- All experiments take place in the Stevenage Bioscience Catalyst which is on a secure site as part of the Glaxo SmithKline Campus. All areas where the virus is stored are only accessible by Gyroscope employees (via keycard or lock and key). Visitors are supervised at all times in the facility.
- Training for use of the vector material will be conducted by users who have prior experience of handling the vector material. The completion of training will involve the adding of the individuals name to the appropriate risk assessment. The signature will serve as a record of the training and be kept on file as part of the Gyroscope training
Where vector material is transported this will only be done in sealed containers which are labelled and placed inside sealed plastic packaging. These in turn will be put into larger boxes, sealed and the box labelled with Gyroscope name, sender’s name, address and contact details with the instruction not to open unless authorised.

The Gyroscope Health and Safety Policy covering lab practice and use of COSHH is to be followed at all times.

First Aid:
EYE EXPOSURE FROM SPLASH OR AEROSOLS: Rinse a minimum of 15 minutes in eye wash available at all sink hand wash areas or flush area with water. Seek medical attention.

CONTACT WITH SKIN: wash thoroughly with disinfectant. Hand sinks available in all labs for washing.

INHALATION EXPOSURE FROM AEROSOLS: Seek medical attention.

NEEDLESTICK AND/OR SHARPS EXPOSURE: No sharps are to be used

For personnel working with human Biological samples full health screening with Immunisation against Hepatitis B is made available by Gyroscope.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Rationale of Classification: After a review of the information sources and discussions with internal experts and SBC GMO committee.

CLASS 1
Vector: the rationale that vectors are replication incompetent and express what were considered to be biologically inert transgenes suggest a low risk for this biological material. Cell Lines: HEK293, HEK293T and ARPE cells are engineered to be suited to laboratory based cell culture conditions and are highly unlikely to survive in the external environment. E.Coli strain Stabl3 (Thermofisher) is a K-12 derivative used to propagate the plasmid and are non-pathogenic.

CLASS 2
The import and utilisation of animal tissues transduced with or without AAV vector determines that the laboratories where the characterisation of viral vectors and the analysis of transgene identity and activity/potency within animal and cellular tissues should be designated as Class 2 containment level.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Chemgene is used as it is a validated cleaning method for viral vector material and transfected cells if used in the following way under manufacturers recommendations

- Hard surfaces: A solution containing 1:20 and 1:40 Chemgene for 2 minutes contact time will precipitate the nucleic acids immediately.
- Safety cabinets: Wiping down of the safety cabinet with a solution containing 1:20 and 1:40 Chemgene for 2 minutes contact time will be used as this is known to precipitate nucleic acids immediately.
- Discard jars, plastic tissue culture flasks, glassware: A solution containing 1:20 and 1:40 Chemgene to a final concentration of 1:20 will be added to the glassware for 5 minutes
- Supernatants/liquid waste: Chemgene in culture medium to a final solution of 1:20.

All autoclavable solid waste is to be placed into hazardous waste bags. Sealed bags for autoclaving will be autoclaved at a minimum of 1210C, 1.15bar, 15 mins hold. A Chart recorder or display screen is attached to autoclave to monitor treatment. To verify the autoclave hold time/temp/pressure is achieved on every run an indicator will be used on each run.

There are 2x autoclaves available and the equipment is regularly serviced to ensure it maintains its ability to be a validated cleaning method.
Full bags are to be transported to Gyroscope's hazardous waste bins designated for CL2 waste in the SBC storage area. Bins are collected for off site incineration by Grundons waste management.

Accidental Release:
In a contained area allow aerosols to settle; wearing protective clothing, gently cover spill with paper towel and apply 10,000 ppm sodium hypochlorite or Chemgene solution, starting at perimeter and working towards the centre; allow sufficient contact time before clean-up (30 min). Alternatively, Chemgene can be applied all over the spill area and mopped up with absorbent non-hazardous material. This solid waste is then to be autoclaved as above.
In an uncontained area, all persons should evacuate the area to avoid contact with any potential aerosols formed. Only after 1 hour the room might be entered (to allow any aerosols to settle) and the procedures should be the same as in a contained area.
The floor is sealed and the lab is built to CL2 level.

Is an emergency plan required according to regulation 20? [N]
If yes, tick to confirm that it is attached to this form [N]
Tick to confirm that you have attached a risk assessment to this form [Y]
Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

Please enter comments on the GM safety committee on the risk assessment
The Stevenage Bioscience Catalyst (SBC) is an enterprise hub for small and emerging Biotechnology start-up and spin-out companies. It is a UK Government backed (Innovate UK) in collaboration with the Wellcome Trust and GSK. The SBC provides technical, business, organisational and commercial support to its tenant companies and also monitors Health and Safety Compliance. It has set up a GMO committee to ensure that tenants are assessing the risks associated with their work appropriately and to disseminate best practice amongst the researcher tenants. Dr Deonarain is the chairman of this committee and has 25 years experience working with GMO's in both academic and commercial settings and was chairman of Imperial College Life Sciences GMO committ for 4 years.
The SBC committee has reviewed and advised Gyroscope Therapeutics Limited on their GMO risk Assessment associated with Class 2 contained use activities involving animal tissues and are satisfied that we have in place appropriate control measures to contain the work and the appropriate procedures for GMO waste disposal and are acting appropriately, responsibly and with the best practice of the SBC.

Cell therapy using genetically modified Mesenchymal stem cells.

For activities involving GMMs, describe the waste management measures which will apply to the activity

N/A

Dr M D is the chairman of a 10-member SBC GM committee. Dr D has 25 years' experience working with GMOs and has previously served as GM Officer in the Dept of Life Sciences at Imperial College. The GM committee has a wide range of experiences in GMO R&D.

Dr D and the committee have advised Algaris Ltd on evaluating GMO handling and waste disposal risks and are satisfied that they are acting appropriately, responsibly and with the best practice of the SBC. The R&D does not contain anything non-standard or exceptional that requires special consideration. The SBC GM Committee have approved the associated risk assessment and support this notification.

Use of genetically modified Mesenchymal stem cells: hTMSC19 cells

Consent Granted

Project notified under transitional arrangements
The immortalized mesenchymal stem cells (hTMSC19 cells) which have been genetically modified are being used in the development of a bioreactor for adherent cell culture activities. Please note that these cells are only being used for cell culture purposes no further genetic modification or testing in humans or animals will be conducted.

Parental organism: Human
Cell type: Mesenchymal stem cells from a 18 year old male donor.

Host/vector system
Non-replicative, self-inactivating (third-generation) lentiviral vector.

Origin & function
Origins of cells: The donor cells were purchased from a stem cell bank in Spain and the genetic modification was conducted in a Spanish research institute.
Functions of the genetic material: The lentiviral vector contains HIV-1 non-coding cis-acting sequences which are non-functional outside of the vector producer cells. The integration of the vector in the genome results in the transcriptional inactivation of both LTRs (lentiviral promoters). It also contains an expression cassette under the control of the human cytomegalovirus (CMV) immediate-early enhancer/promoter region, a viral sequence commonly used to promote expression of cloned inserts. The codifying region is human telomerase reverse transcriptase (hTERT). This protein is responsible for catalyzing the addition of nucleotides in a TTAGGG sequence to the ends of a chromosome’s telomeres. The addition of these repetitive DNA sequences prevents degradation of the chromosomal ends following multiple rounds of replication. The constitutive expression of hTERT allows human cells, that would otherwise become postmitotic and undergo apoptosis over several passages in culture, to exceed the Hayflick limit and become potentially immortal without altering their phenotype or becoming tumorigenic in animal experimental models.

Evaluation of foreseeable effects
The GMO is immortal therefore allowing the cells to proliferate limetelessly. Although originating from class 2 pathogens, these viral sequences do not burden host cells with a phenotype that could cause illness to humans or could infier damage to the environment. The donor was tested negative for blood-borne human viruses including HIV-1, HIV-2, HBV and HCV and the cells have been tested and confirmed to be free from mycoplasma.
The cells will be primarily used to test different in vitro culture conditions, and will not be used in any in vivo studies, either in humans or animal models. No further genetic modification of the cells will be performed. Cell cultures will be handled inside a biosafety class II cabinet. Additionally, cells (in multi-well plates or tubes at volumes of ≤ 100mL) could be used to perform characterization studies, such as staining, cytometry (phenotyping) or PCR analysis. In these cases, cells (transported in double-contained containers) will be worked with inside a fume cabinet and immediately fixed with 4% formaldehyde or with protein-denaturizing agents which inactivate the relevant and known adventitious contaminating pathogens. These cells have been tested for the most common viruses thus the risk of viral contamination to the operator is very low. Any work to be done on the bench using open live cultures should be kept to the absolute minimum (≤ 50mL). Operators must wear all appropriate PPE (laboratory coat, lab gloves and eye protection), receive appropriate training, no work should be done using sharps or needles, any cuts or grazes must be covered with appropriate protection prior to work, cultures should be transported in sealed containers and cell suspensions should never be poured (aspirators should be used).
should be conducted in a manner which prevents the formation of aerosols, any spillages should be decontaminated immediately using virkon, and hands should be washed after any laboratory work is conducted.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

As stated in the risk assessment for the use of hTMSC19 the majority of work will be carried out in class II biosafety cabinets. However, it is requested that some work is conducted under biosafety containment level I. The work to be conducted at biosafety containment level I will be kept to the minimum and would include tasks such as live cell counting and staining for flow cytometry which require cells to be live so they cannot be deactivated prior to analysis. The cells have been tested negative for HIV-1, HIV-2, HBV, HCV and were modified using a non-replicative lentiviral vector which will not cause any harm to humans or the environment for this reason the risk of viral contamination of the operator is deemed to be low. However, measures will still be put in place to protect the operator when work is conducted outside of biosafety containment level II. These measures are detailed in full in the risk assessment under section 3E.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

- **Liquid waste:** All biological liquid waste will be treated with a tablet of virkon for every 500mL (1% virkon solution) of liquid waste for a minimum of 10 minutes this has been confirmed by the manufacture of virkon to kill by oxidizing key structures and compounds, such as proteins in bacteria cell walls and viral structures leading to widespread irreversible damage and subsequent deactivation/destruction of the microorganism. Once liquid waste has been killed it will be discarded with an excess of water into the drain.
- **Solid dry waste (including contaminated cultureware):** All contaminated dry waste will be disposed in double bagged sealed biohazard bags and autoclaved (at 121°C, 1.15 bar with a 15 minute hold) and then disposed of in solid bins provided by the Stevenage Bioscience Catalyst and collected by Grundon management for off site incineration. Pipette tips and stripettes are disposed in biobins and when full sealed and placed in the same biohazard bags for autoclaving. The autoclave is regularly serviced which ensures that it consistently performs validated cleaning and there is a display screen confirming if a autoclave run has been successful with the additional use of autoclave tape which changes colour to confirm the correct temperature was reached during an autoclave cycle. Contaminated sharps/glassware: No work with needles will be done with these cells however all broken contaminated laboratory glassware is disposed of in 5L sharp containers. Once full the sharps bins are closed permanently and labelled and then placed in large yellow bins which are collected by Grundon waste management for incineration.
- **Contaminated surfaces and safety cabinets:** Surfaces are cleaned with a 1% virkon solution for a minimum of 10 minutes (no longer if cleaning metal sufraces as virkon is corrosive) and any materials (tissues/wipes) used to clean the area are autoclaved as described above.
- **Spillages:** In the event of a spillage a 1% solution of virkon is prepared and sprayed on the spillage to ensure full coverage and left for a contact time of 10 minutes. The material along with any materials used to clean the area are then disposed in biohazard bags and autoclaved as described above.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

Give brief details of the genetic modification safety committee

The main project holder (Principal Scientist) has 20 years experience of working with GMMs and has previously successfully applied to perform Cat 1 and Cat 2 GMO work, HSE has completed detailed risk assessment for project included GMOs for many years. A new risk assessment will be performed whenever a new project is started and current risk assessments will be reviewed at least once a year.

All waste material containing GMMs or exposed to GMMs will be treated according to standard operating procedure for biohazardous waste. It will be decontaminated by treatment with a suitable disinfectant prior to disposal by a suitable route depending on the nature of the liquid. If these methods are deemed not to be suitable for particular items, they will be made safe by autoclaving in the on site autoclave prior to disposal by incineration. The estimated degree of kill by these combined methods is extremely close to 100%.

**Containment measures, addressing the relevant areas for Class 1 activity, in Schedule 8 Table 2 are as follows**;

Serial 1 - The GM waste will be held in containers. These containers will be sealed and security tagged, no work processes will take place involving this waste, it will remain sealed in the containers up to, and including, incineration.
Serial 4 - No sample collection will take place.
Serial 5 - No bulk culture fluids will be worked with; all other waste will be contained in sealed containers prior to collection from the waste producer, during transportation and during the incineration process.
Serial 7 - The controlled area has been designed to contain spillage of the entire contents through the use of sealed containers and absorption material.
Serial 11 - All waste will be contained in sealed containers prior to collection from the waste producer. No benches or surfaces will be exposed to the waste during transportation or storage.
Serial 12 - All waste will be contained in sealed containers prior to collection and will not be removed from these containers throughout these Contained Use processes.
Serial 17 - Work clothing will be worn at all times; this will include gloves when manual handling of the sealed containers takes place.
Serial 20 - The waste will be collected and transported direct to the incineration. A validation certificate for destruction will be signed by the disposal plant and copies provided to the waste producer and the transport company.

The Class 1 activity waste will be destroyed by High Temperature Incineration of +1000°C; 100% Kill.

CU 2 2015 (rev 11/15) Page 3 of 9

For GMMs only - application for any derogation from full containment (Schedule 8) (Measures and justification) (note 7)

We request a derogation from Schedule 8 for the following:
1. We will not carry out Class 1 activity GM work in Laboratories; Schedule 8, Part 2, page 68, Table 1 a.
2. Containment measures will not involve micro-organisms in plant growth facilities; Schedule 8, Part 2, page 71, Table 1b.
3. Containment measures will not involve micro-organisms in animal units; Schedule 8, Part 2, Page 72, Table 1 c.
Schedule 8, Part 2, Table 2 will be addressed above

**Tick to confirm that you are attaching a summary of the risk assessment**

**Tick if you are claiming exemption from disclosure for sections of the risk assessment**

Please enter comments of the GM safety committee on the risk assessment
The safety committee have concluded that the risk assessments attached were deemed sufficient for collecting Class 1 activity waste, from a GM registered waste producer, transporting and, if necessary, storing Class 1 activity waste, prior to incineration at the GM registered waste disposal site. At all times the Class 1 activity waste will be contained in the requisite UN Approved packaging for UN3291, following Packaging Regulations P621, strictly following the regulations for the Carriage of Dangerous Goods by Road. Class 1 activity waste will be held in sealed containers from collection, throughout transportation (and if necessary, storage), up to and including incineration. As stated on the attached risk assessment, in the event of an emergency, all surfaces exposed, or potentially exposed, to the Class 1 activity will be disinfected using a broad spectrum clinical disinfectant (e.g. Virkon 2%), using absorbent material. This will then be disposed of in a clinical bin and sealed.

Solid contaminated GMM waste of tissue culture plastics, tips and pipettes are placed in yellow clinical waste bags and placed in yellow bins provided by UCL estates. The bags are then taken off site and disposed of by an approved GM waste management company. Liquid waste is disinfected using 2% Virkon and treated overnight before disposed of down the designated laboratory sink. Virkon is a multi-component peroxyge-based oxidising agent. It is effective against bacteria, fungi, and viruses. Virkon is widely used for sterilization in laboratory or hospital settings. The UCL medical school laboratory disinfection code of practice suggests Virkon (1%) as suitable for use in laboratories performing low risk microbiological or Class 1 genetic modification work.

Give brief details of the genetic modification safety committee

We have been in correspondence with a GMO Notification Officer from the Microbiology & Biotechnology Unit of the HSE.

The University of Suffolk GMM Safety Committee will meet as a sub-committee of the thrice yearly Health and Safety Committee. The UoS HSC consists of one member of each department at UoS and GMM sub-committee will include N B (Trained Biological Safety Supervisor) and C M Laboratory Health and Safety Officer as well as T S and K W the head of H&S Department

Dr B has been a Biological Safety Supervisor for the Franklin Wilkins Building and Nutritional Sciences Department from 2005 - 2017 and sat on both the Biomedical and Medicine Biological Safety committee at King's College London ~ prior to his move to University of Suffolk in January 2017. C M. 10 years of experience in biological laboratory work and risk assessments writing, as well laboratory management and H&S advisor.
Tick if notifying a connected programme of work  N

**Project Additional Information**

**Purposes of the contained use**
In relation to the project areas mentioned in section 5
To protect the operator from transfer of genetic material from the cells/tissues utilised and to prevent the transfer of such material to other organisms.

**Recipient or parental organism**
In relation to the project areas mentioned in section 5
1-The iPSCs are derived from the UK Stem cell bank and ECACC that hold all due licences for dealing with GMOs. The cells were obtained via reprogramming with episomal vectors and/or Sendai virus which are deemed as 'non integrative'. The cells are distributed as free from any residual reprogramming system, as part of the quality control operated by the distributors. As a further precaution, all liquid waste contacting these cell cultures is treated with 1% Virkon for 12 h prior to discarding. All solid waste is treated with 1% virkon for 12 h and then autoclaved (121°C for 30 minutes) within the department before incineration off campus. The ESCs are not classified as GMOs.
2-The c20A4/Tc82 cells are derived from ECACC that holds all due licences for dealing with GMOs. Such cells are produced at the origin by transfecting primary cultures of rib chondrocytes from a 5-year-old male with vectors.

**Host/vector system**
In relation to the project areas mentioned in section 5:
1-nothing to declare
2-noting to declare
3-nothing to declare
4- Sendai virus-based reprogramming kits commercially available will be used and other viral-based vectors. Individual risk assessments are attached detailing the particulars of each vector system. Foreseeable effect are discussed in the next sections.

**Origin & function**
Sendai infects cells by attaching itself to cell surface receptor sialic acid, present on the surface of many cell types of different species, the vectors are able to transduce a wide range of cells. However, they are no longer capable of producing infectious particles from infected cells, because the viral genome lacks the F-gene. In addition, the presence of functional mutations such as temperature sensitivity in the amino acid sequence of several SeV proteins (SeV/TSΔF, SeV/TS12ΔF, and SeV/TS15ΔF) renders the vectors easily removable from transduced cells. To minimise any risk, manipulation of Sendai and any material coming in touch with Sendai will be treated under category 2 conditions. The sterile nature of the category 2 laboratory areas, together with the use of dedicated abcoats, hirnets, clogs and srupulous routines of disinfection and cleansing protocols will ensure that any risk of
Transfer to the environment or personnel is absolutely minimised. The same applies to other viral vectors that may be used as reporter systems in the generated iPSCs, to include pBABEneo, pPUROneo or pCIGNAL Lenti-TRE reporters that will be used under a biosafety hood, with operator protected by labcoat, gloves and relevant PPE, together with the use of filtered tips and filtered serological pipettes. Materials and cell waste coming in contact with such vectors will be neutralised as discussed above.

Evaluation of foreseeable effects

Cells derived from human tissues may contain blood borne pathogens such as Hepatitis B & C, HIV, HTLV and Cytomegalovirus. Primary human cells have the greatest risk of contamination, compared to the established MG-63, SW-882, C20A4/TC82 human cell lines. hESCs and iPSCs are grown in media antibiotic-free, and have an even greater chance of getting contaminated with bacteria and fungi.

Primary bovine cells may contain pathogens (Prions) but pose a low risk.

Retroviral expression of pBABE-neo containing the SV40 Large T Antigen has the potential to be oncogenic.

SeV is transmitted by aerosol and contact with respiratory secretions. The virus is highly contagious, but the infection does not persist in immunocompetent animals, moreover this virus is not pathogenic for humans. So far known hosts are rats, mouse, guinea pigs, and hamsters.

Given the condition of work, the level of operator protection and training, and the precautions associated with category 2 work procedures, including rigorous disinfection and cleaning and GLP adherence we foresee a minimum risk for operators, animals and environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste and cell waste (from both eukaryotic and prokaryotic cell models discussed above) is treated in a 10% solution of Vikron. This is followed by autoclaving at 121 Degrees Celsius for 20 minutes. Finally, the waste is placed in biohazard bags and collected by an external company for incineration off-campus. According to the procedure explained, all GMOs will be destroyed safely on site.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The University GMM safety committee has revised the risk assessment and no comments were added.

Give brief details of the genetic modification safety committee

GMOs which may harbour various genes of interest and molecular cloning derivities used as transport vectors are already in use by our contract process development and manufacturing client. As such, a competent member of the client team (Senior Development Lead) has provided relevant safety information for use in our own risk assessment, and has reviewed the completed risk assessment and visited the lab itself. Oftentimes these transport vectors are used as raw materials in larger scale manufacture of recombinant viral vectors.

For activities involving GMMs, describe the waste management measures which will apply to the activity

One autoclaves are available for relevant waste. Solid/contaminated waste will be disposed into biohazard bins/boxes, sealed and placed into lockable clinical waste containers and disposed of by GMO registered waste management company (Example: Labwaste).

Decontamination of surfaces will be conducted using elevated levels of the disinfectant ChemGene HLD4L and 70%(v/v) Klercide spray. Inactivation of liquids will be performed using Virkon tablets as per manufacturer instructions.

All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving, H2O2 gas (VHP) or chemical treatment using an anti-viral agent (Virkon) or Presept chlorine tablets to achieve a 100% kill, prior to disposal of waste or cleaning and recycling of reusable laboratory/manufacturing equipment, such as glassware. Inactivated liquid waste is disposed of down the sink with multiple volumes of water and pumped to waste handling room. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored by continuous chart (or digital) recording of the temperature/time profile.

Please enter comments of the GM safety committee on the risk assessment

MeiraGTx - the company are actively working in the gene therapy field, with the Assessment of AAV viral production isolated and harvested from transfected HEK293 cells with viral vector carrying gene replacement therapy related genes. This work is a part of a process development roadmap of work helping us to take AAV products through the clinic to commercial manufacture. It builds upon existing work contracted out by our CDMO partner at UCLB to a UK academic centre with a Cell and Gene Therapy GMP production capacity, within which Risk Assessments for the plasmid and host cell have already been completed and which are routinely upgraded.

Nativly AAV are a low risk organism, no reported pathologies have ever risen from AAV infection or mode of action. By performing an RA for AAV and HEK293 cells (the 2 biologicals at site), we postulate that we will be compliant within HSE expectations and guidelines.

**Project Additional Information**

**Purposes of the contained use**

The purpose of the controlled use is to reduce risk of GMM/GMO misuse and allows Biotech companies comply with their legal duties in relation to working with GMOs in contained facilities. This application and risk assessment register shall serve to describe and set out the containment measures and other controls that need to be considered and explains the role of the competent authority.

All identified risk class 2 category organisms are;

- Host cell of choice (HEK293),
- BioBall™ from Biomerieux
- rAAV 2/5/8 Reference standard material (RSM)
- Adenovirus 5 (Ad5) material
- HeLa[RC32] cells (for infectious assay)

MeiraGTx may use reference material from previously made recombinant Adeno-Associated Virus (rAAV) serotype 2/5/8 batches in order to quantify and validate upcoming in-house batches. MeiraGTx also plan to utilise BioBall™ for on-going environmental monitoring purposes, the BioBall contains a predetermined number of microorganisms in a water-soluble ball delivering unprecedented accuracy for Quantitative Microbiological Quality Control in 4 usable format ranges. [20 cfu -10e8 cfu].

Adenovirus 5 standard material (consists of purified Adenovirus, Type 5 (wild type adenovirus, see ATCC VR-5) formulated as a sterile liquid in 20 mM TRIS, 25 mM NaCl, 2.5% glycerol, pH 8.0) which will/may be utilised in order to correctly titre viral vector batches and used as a positive control infectious spike during our infectious titre QC assays. The volume and concentration is relatively low at low working volumes [100-1000ul] – and is contained within a Laminar flow cabinet and segregated.
from the manufacturing core.

MeiraGTx will recombinant Adeno-Associated Virus (rAAV) at present using the host cell type Human Embryonic Kidney (HEK293) cells to propagate the rAAV, these hosts do not enter the Downstream processing (DSP) unit operations. These cells have been widely used without any reported safety or health issues globally for years.

MeiraGTx may intend to one day manufacture Retro/Lentivirus as our GMM viral vector of choice, due to its higher packaging capacity for larger genetic fragments (i.e: Genes that are too large to package into AAV – 4.7kb), this allows us to cater for more patients whom have genetic defects resultant from larger wild type genes.

Furthermore, MeiraGTx aim to utilise a secondary cell line HeLa[RC32] cells. These cells contain human papilloma virus 18 (HPV-18) and are a derivative of HeLa parental cells. These cells generate rAAV preparations with high titres of infectious particles which are essentially free of adenoviruses for biological, preclinical, clinical or pharmaceutical applications. Being devoid of adenovirus, they are susceptible to infection by MeiraGTx Ad5 material and serve as a suitable control cell line for the infectious QC assay.

These biological materials can be classified as risk group 2 or BSL2 (low risk), and they can be safely contained within the MeiraGTx facility in London and the supporting laboratories based on the Risk assessment and cross referencing the control measures stipulated by the GMO Regulations and SACGM guidance appendices.

Recipient or parental organism

There exists a clear demarcation of wild type AAV (wtAAV) and recombinant (rAAV). By utilising rAAV we immediately reduce/attenuate the native virus by transitioning its genome (essentially 2 genes REP and CAP) to a separate plasmid which can be delivered in trans and replacing this genome with a transgenic gene of interest (GOI). This greatly reduces the risk of selfreplication (REP) of the transgene plasmid.

rAAV has long been established as a non-pathogenic cat 1 organism which has no know reports of disease causing effects. It is used as a docile vehicle for administering a therapeutic construct to a target tissue (natural ability of AAV to target certain tissue types).

The resulting rAAV approach does further require the presence of ‘helper’ genes provided from an adenovirus. These genes are well characterised and established regions which confer full packaging and permit rAAV assembly/maturity in the host cells.

Furthermore, as we also use native Adenovirus (Ad5) – it was highlighted by the MeiraGTx Biological safety committee (BSC) as the most hazardous organism. It is ubiquitous, causes only a mild respiratory disease in humans when exposure is very high which is self-limiting and does not require any specific treatment. This is minimised due to having very small volumes (1mL at any given time within a LAF cabinet) for use in a QC assay as a surrogate infectious virus to measure infectious particles of AAV.

Host/vector system

MeiraGTx utilise HEK293 host cells in order to propagate viral vectors. They
are derived from Human embryonic Kidney cells and are a well characterised and defined manufacturing cell line. They have also been stably generated with key Ad5 genes in order to recapitulate rAAV and other viral vectors. This was historically done to reduce the genetic burden on mammalian host cells via transfection as the genes can be quite large in base pair size. We may also use a variant HEK293T cell line or CHO cells in future process which will also be governed by GMP, GMO, and controlled use 2 (cu2) use handling and rigor. All these cell lines cells typically die/degrade rapidly outside the artificial environment created within the laboratory and culture vessels.

Furthermore, MeiraGTx have currently created a master cell bank (MCB) of these HEK293 cells from an approved and reputable source. From this MeiraGTx are generating a working cell bank (WCB) which provides a consistent seeding platform and removes variability from clonality. These cell banks will undergo GMP QC scrutiny before being released for use in the beginning of each campaign (which begins with a single WCB vial thaw). This initial culture is then grown up to increase biomass for propagating the virus to a predetermined expectant yield.

The genetic inserts that MeiraGTx have in their pipeline are human in origin and poses no risk to animal health or the environment if accidentally released. This genetic material is designed to replace faulty genes in the recipient after the vector has been propagated to sufficient quantities in the host cell (HEK293). As a worst case, Viruses could, depending on your gene insert, be potentially hazardous. Similar vectors have been approved for human gene therapy trials, attesting to their potential ability to express genes in vivo. For these reasons, due caution must be exercised in the production and handling of any recombinant viruses. Follow all applicable guidelines for research involving recombinant DNA. Take appropriate safety measures when producing or handling recombinant AAV, including working in a biological safety cabinet and wearing protective laboratory coats, face protection, and gloves.

Justifiably MeiraGTx inserted (GOI) genes have been carefully selected from preliminary experiments and have shown to biologically active in vitro but in very specific tissues. In principal this means that for example an ocular gene insert is used as the GOI then exposure of this gene into say the liver, will in theory have no harmful effect due to tissue specific nature of not only the virus but the gene itself. Additionally, the viral backbone never changes apart from the capsid protein (which gives it its tropism specificity), so the viral vector is simply a vehicle for the chosen gene insert (active component) to displace the faulty gene. Their properties as far as MeiraGTx are concerned thus far, relate to ocular
and neurological phenotypes only and have been extracted using best practice from cultured human cells. At administration level, Due to all our viral gene inserts being specific to the eye or CNS. Neither of these organs can be accessed (or accidentally exposed to rAAV) without specialised administration (Sub-retinal injection or Lumbar puncture) which shall be performed by a clinician in an operating theatre.

Evaluation of foreseeable effects

There is minimal risk for environmental and personnel effects due to handling and use of Cat 2 organisms. We have a dedicated H+S officer along with a dedicated GMO officer for which to continually assess and monitor GMO activities.

Level 2 containment measures will be in operation and the principles of Good Microbiological Practice will be applied. In conjunction with this access to the laboratory will be restricted when work with infectious agents is in progress. Persons at increased risk of acquiring infection or for whom infection may have serious consequences will not be allowed to enter the laboratory. A biohazard sign will be posted at the laboratory entrance bearing appropriate information including the agent(s) in use, containment level, the investigator’s name and telephone number, personal protective equipment requirements and exiting procedures if any. Biosafety procedures will be incorporated into Standard Operating Procedures (SOPs) or the biosafety manual and personnel will be advised of special hazards. All work will be done with the approval of the safety sub-committee.

Biological spills and GMO accidental release may happen from time to time even though measures exist to reduce this. If this happens, the Biological Safety Committee (BSC) will raise an incident and the remedial steps such as clean up, and reporting will be done in accordance with guidance set forth by the BSC.

We do not envisage any long-lasting effects detrimental to staff or technicians in our facility.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

We have safeguarded the facility with SOPs, spill kits, dedicated AHUs, personnel flows, transfer hatches which all maintain controlled use of GMMs to minimise risk and avoid cross contamination. In addition to having our viral manufacturing suites being segregated and having dedicated AHUs, while soliciting during every changeover, a bio-decontamination cycle of VHP to inactivate any residual virus that may arise from the manufacturing batch. As such, no transmittal of virus should occur from one suite or campaign to another.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving, Vapour Hydrogen Peroxide gas (VHP) or chemical treatment using an anti-viral agent (Virkon) or Presept chlorine tablets to achieve a 100% kill, prior to disposal of waste or cleaning and recycling of reusable laboratory/manufacturing equipment, such as glassware. Inactivated liquid waste is disposed of down the sink with multiple volumes of water and pumped to waste handling room. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored by continuous chart (or digital) recording of the temperature/time profile.

OR

All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory/manufacturing equipment, such as glassware. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored using TST (Time, Steam, and Temperature) test strips (Albert Browne Ltd., TST class 6 emulating indicator 121°C for 20 min). All waste will be carefully monitored and volumes accounted for.

Give brief details of the genetic modification safety committee

We have received advice from Webster's Biosafety, who specialize in High Biological Containment and have also established a genetic modification safety committee which meets every 2 months. This is comprised of:

- **Senior Manager-** Accountable to Board of Directors; experienced life sciences executive with over 15 years' working across the regenerative medicine, drug delivery and medical device sectors. Industrially trained pharmacist, with an Executive MBA and a PhD in tissue engineering.
- **Biological Safety Officer-** Previously managed pharmacology facilities with responsibility for health and safety/GMO policy implementation and staff training as well as sitting on many safety committees throughout their career.
- **Principal Investigator-** PhD educated, interdisciplinary scientist with over 10 years of research experience and 2 years of experience in managing a clean room environment. Has a sound understanding of complex research actions such as: stem cell isolation and culture; cell imaging and characterisation techniques; scaffold design and fabrication for tissue engineering; cell and tissue cryopreservation methods; the application of quality-by-design to cell product development and manufacture. Appreciates the significance of adhering to legislative demands and health & safety requirements; understands the detrimental impact non-compliance can have in relation to tasks and projects.
- **Company Safety Officer and Quality Systems Manager-** Has over 35 years of experience working in research and development in both academia and industry. Holds a PhD in the field of regenerative medicine and has held the role of Company Safety Officer for 3 years. Oversees the Company training programmes and has implemented a quality management system certified to ISO-13485:2016.
- **Administrator-** Office manager; minute taker.

Class 2

CultureVol

Class 2 1-50 Litres

ClassVolumeClass3-4
Project Additional Information

Purposes of the contained use

Our company is interested in a number of areas:
Using mammalian (including human) pluripotent stem cells, adult stem cells and differentiated cells to help understand tissue formation.
Improving differentiation of stem cells.
Developing future therapies using the above cell classes.

Recipient or parental organism

Non-mobilisable plasmid vectors will be constructed and amplified in E.coli for one of following purposes:
1. To constitutively express reporter genes to trace transfected mammalian cells.
2. To tissue-specifically express reporter genes from promoters or endogenous loci to trace mammalian cell behaviour.
3. To express modulators of gene expression and behaviour in cultured mammalian cells.
E.coli (lentiviral)
• Non-mobilisable plasmid vectors based on the pUC family of cloning vectors will be constructed and amplified in disabled E.coli.
• The three separate plasmids, previously approved (under assessment C07.01, Project Ref. 470/07.1) will be used to transfect Human Embryonic Kidney 293T cells to produce lentivirus. The lentivirus will then introduce the genes of interest into mammalian cells. For newly constructed systems 3rd and 4th generation lentivirus will be used.
• The genes will be reporters such as coloured fluorescent proteins, luciferases, differentiation markers or signal transduction markers, which will report on our cells in our tissue engineered constructs.
• Some primary cells will be immortalised.
Mammalian (lentiviral)
The host cells for lentiviral infection have no dormant viral auxiliary genes such as vpr, vif, vpu and nef which could reactivate lentiviral infectivity. The cell lines include human adult stem cells i.e. mesenchymal stem cells bought from a reputable supplier.
Cell selection will be via co-introduction of selectable markers neomycin, puromycin or thymidine kinase, or by FACS selection.
### Host/vector system

pUC based cloning vectors (eg pBluescript, pGEM and pCR-TOPO vector families) will be used to generate constructs in disabled E. coli strains. For introduction of genes into mammalian cells, a second generation, inducible lentiviral expression system may be used, which requires three separate plasmids. Newly generated constructs will use 3rd or 4th generation systems.

HOSTS to produce lentivirus
- Human Embryonic Kidney 293T cells

HOSTS to be genetically modified E.coli, and cultured human mesenchymal stem cells.

Source: Generated in-house at University of Nottingham from hMSCs from Lonza PT-2501
Human osteosarcoma cells MG-63
Genetic modification: None- NON-GMO.
Source ATCC CRL-1427

1) Constitutive or Tissue-specific Reporters:
GFP, mRFP and other colour/stability/localisation variants, luciferase, Iron binding reporters expressed from
constitutive (e.g. PGK, EF1a etc) and tissue-specific (e.g. Bry/T, Oct4, Nestin, Osteocalcin etc) promoters, or to insert
these reporters site specifically to control expression from endogenous loci (e.g. Bry/T, etc).
2) Selection markers:
Positive (e.g. neomycin or puromycin resistance genes etc) or negative (e.g. thymidine kinase [HSV-TK] gene etc)
selectable marker genes driven by the sequences described in point 1.
3) Gene Modulators and Modifiers (listed in Table 1):
Mammalian promoter driven vectors (e.g. PGK, EF1a etc) delivered by transfection with lipids, peptides or via
lentiviruses (described in 4.2 ‘Details of vectors’ section). These will express:
1. Transcription factors (e.g. RUNX2, GATA-4, NKX2.5, MEF-2C, TBX-5 etc).
The will program cells to change fate and identity, for example, RUNX2 will program cells to become
bone/osteoblasts.
2. Growth factors (e.g. BMP2, VEGF and PDGF). These will be used in cell culture models of angiogenesis and bone
formation in which growth factors are secreted locally by the cells and will act on recipient cells within the culture.
3. Reprogramming factors (e.g. NANOG, OCT4, SOX2 etc).
The will program cells to revert to earlier developmental stages and will allow them to be programmed to other fates
(i.e. skin cell to an iPSC which are similar to hESCs). These genes confer genome-wide epigenetic and gene
expression changes. These will also promote survival and increase cell proliferation.
4. Immortalisation/cell survival factors (e.g. TERT, CDK4, E6/E7, SV40T, KLF4 etc).
The will promote changes to cell growth or survival. These genes confer genome-wide epigenetic and gene
expression changes.
N.B. This will include the use of oncogene overexpression and knockdown of tumor suppressor genes.
Proteins produced are covered in COSHH assessment; they do not increase risk, hazard or consequence in class II
facilities.

Evaluation of foreseeable effects

The most dangerous combination of inserted material would be expression of a transcription factor or immortalisation
factor (such as TBX5 or TERT respectively) that promotes growth or cell survival. However, the episomal vectors we
will use are non-mobilisable and should not provide any fitness advantage to the bacterium and no increase in
pathogenicity is likely. Similarly, the viral system we will employ is second generation and replication defective.
Moreover, we will employ 3rd or 4th generation systems within new vectors to further minimise risk.
Consequently, it is unlikely that these modifications will materially alter the pathogenicity and virulence of the GMM
than prior to transfection. The use of non-mobilisable vectors and E. coli strains unable to survive out of the laboratory
mitigates the risk of these traits transferring to pathogenic strains.
The most hazardous cell types to be used are human cells with a theoretical, but not specific, risk of human
pathogens (e.g. primary fibroblasts, embryonic stem cells).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Any biological waste generated will be either autoclaved at 125°C for 20mins (cell culture flasks and plates, centrifuge tubes, tissue paper used for cleaning up any spills inside the biological safety cabinet, gloves, sleeve covers and shoe covers), cycle validated using 12 point thermocouple test; or treated with Distel validated disinfectant, used at 1:50 (pipette tips, stripettes and general cleaning of safety cabinet, cell culture lab and equipment); 1:20 for rapid disinfection of high risk areas and high risk equipment.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form N

Tick if you are claiming exemption from disclosure for section of the risk assessment Y

Please enter comments on the GM safety committee on the risk assessment

All of the GM safety committee members have all reviewed and discussed the Class 2 assessment and agree with the controls and classification of the activity.

CU2 Project Title Modulation of gene expression in mammalian (including human) cells and stem cells

Class Class 2

CultureVolClass2 < 1 Litre

CultureVolumeClass3-4

Non-GMM Consent Granted

Date Project 02/03/2022
**Purposes of the contained use**

Our company is interested in a number of areas:
- Using mammalian (including human) pluripotent stem cells, adult stem cells and differentiated cells to help understand tissue formation.
- Improving differentiation of stem cells.
- Developing future therapies using the above cell classes.

**Recipient or parental organism**

A) Non-mobilisable plasmid vectors will be constructed and amplified in disabled E.coli for one of the following purposes:
1. To constitutively express reporter genes to trace transfected mammalian cells.
2. To tissue-specifically express reporter genes from promoters or endogenous loci to trace mammalian cell behaviour.
3. To express modulators of gene expression and behaviour in cultured mammalian cells.
B) Propogation of disabled adenoviral and adeno-associated virus will be performed using HEK293 cells. These are well characterised and authenticated tissue culture lines used for this purpose.
C) We will use a variety of mammalian (including human) cell lines and primary cultures for transduction:
Mammalian cells (assigned to ACDP HG1):
Mouse embryonic fibroblasts (NIH3T3), mouse myoblast (C2C12), Mouse pre-osteoblast (MC3T3- E1 sub-clone 4),
Mouse areolar and adipose fibroblasts L929 (NCTC), rat mesenchymal stem cells.
Mammalian cells (assigned to ACDP HG2):
Human bone marrow mesenchymal stem cells (from healthy and diseased patients), human immortalised mesenchymal stem cells, human osteosarcoma cells (MG-63) and human tissue, not limited to but including, T cells, liver, lung and neural cells and haematopoetic stem cells. Cell lines are well characterised with a history of safe use and are purchased from a reputable supplier. Human cells/tissues are supplied from a reputable, HTAlicenced biobank or source.

**Host/vector system**

Adeno-associated virus (AAV) vector system:
AAV is member of the Paroviridae family that has no know link to any human disease. AAV is inherently
replication defective, requiring co-infection of a transduced cell with a helper virus (typically Adenovirus or Herpes simplex virus) in order to replicate. Wild-type AAVs are not categorised by ACDP and thus may be handled at Containment Level 1 (SACGM Compendium Of Guidance, 2007 Part 2:72; www.hse.gov.uk/ukbiosafety/gmo/acgm/acgmcomp/).

AAV based gene transfer vectors are generated by utilising the capsid protein shell of the wild-type virus, but replacing the genome of the natural virus with a recombinant DNA insert (typically a transgene expression cassette consisting of heterologous promoter, gene or cDNA of interest and a polyadenylation signal), retaining only the viral inverted terminal repeats (ITRs). Transduction with AAV vectors does not result in integration of the virus. Consequently, the main hazards associated with the use of AAV vectors relate to the properties of any inserted genetic material. AAV vectors are widely used to transduce mammalian cell culture systems, animal models and (in the context of clinical trials) humans; their use is associated with an excellent safety and efficacy profile (Wright, J.F. 2009 Human Gene Therapy 20:698).

The majority of genetic modification work involving AAVs has involved the use of the ITRs and capsid from AAV serotype 2. However, other serotypes are also available and the use of hybrid viral particles harbouring the ITRs of one serotype and the capsid of another are commonly used (Vandenberghe et al., 2009 Gene Therapy 16:311). AAV vectors to be used will typically utilise the capsid of AAV1-9.

AAV vector production will typically be performed by multiple plasmid transient transfection, where the helper viral functions required for packaging are provided by one or more plasmids. Alternatively stable producer cell lines harbouring the necessary AAV and helper-virus factors may also be developed. If only some of the required elements are included within a particular cell line, viral production may require transient transfection with the missing components. AAV vector production methods that rely on infecting producer cells with helper virus will not be utilised.

The main hazards associated with the use of AAV vectors relate to the properties of any inserted genetic material. Where non-harmful inserts are used, AAV vectors are considered a low-risk GM activity and can be handled at Containment level 1 (SACGM Compendium Of Guidance, 2007 Part 2:76;). However, as standard, viral work will be performed at Containment Level 2.

Adenoviral vector system:

The adenoviral vectors to be used are attenuated through deletion of the E1 region of the genome (containing E1A and E1B) and through deletions within the E3 gene that inactive it. This has several affects on the virus. Firstly deletion of the E1A gene eliminates the potential for viral transformation of cells, since the E1A gene product is absolutely required for this process. It is also required for activation of all other early genes (E1B, E2, E3 and E4). The E1B gene product (also deleted) co-operates with E1A in transformation. The E2 region (E2A and E2B) contains DNA binding (E2A) and DNA polymerase (E2B) activities that are absolutely essential for viral replication. The E3 gene product helps in viral avoidance of the immune system by binding to the major histocompatibility complex MHC polypeptides in the endoplasmic reticulum. However, this gene is also inactivated in this strain of adenovirus, resulting in the virus being highly susceptible to immune surveillance. The E4 gene product is required for formation of an active complex between the E1B gene product and the E4 gene product which can prevent apoptosis in the host cell.

The above characteristics means that the recombinant virus is unable to replicate in E1A-deficient cells of any organism. Under normal circumstances no human or animal cells contain the E1A gene product, resulting in the inability of this virus to replicate in any naturally occurring organism (human or non-human mammalian). Under conditions where an organism (human or non-human mammalian) was already suffering from an adenoviral infection, it is possible that the recombinant virus could be replicated and packaged. Since this is likely to be a
relatively rare event, and not one that could sustain a population of recombinant virus, the risks are extremely low. Additionally, any wild-type virus would be at a significant growth advantage with respect to the recombinant virus (for the reasons mentioned above concerning attenuation of the virus), meaning that the wild-type virus would outgrow the recombinant one very quickly.

The attenuated virus cannot recombine with wild-type virus in any way that produces viable virus (Becker T.C., et al Methods Cell. Biol. (1994) 43,161-89). Recombination with a wild-type virus would, by the nature of the recombination event, remove the E1 region from the wild-type virus thereby inactivating its ability to replicate. Taken together, the above means that the recombinant virus is essentially unable to propagate in the external environment. The wildtype adenovirus serotype 5 causes sub-clinical infections and is categorised by the ACDP as Hazard Group 2. Based on the information given above, the attenuated adenoviral vector can be classified as ACDP Hazard Group 1.

The vectors to be used will contain one of the following inserts:

1) Constitutive or Tissue-specific Reporters:
GFP, mRFP and other colour/stability/localisation variants, luciferase, Iron binding reporters expressed from constitutive (e.g. PGK, EF1a etc) and tissue-specific (e.g. Bry/T, Oct4, Nestin, Osteocalcin etc) promoters, or to insert these reporters site specifically to control expression from endogenous loci (e.g. Bry/T, etc).

2) Selection markers:
Positive (e.g. neomycin or puromycin resistance genes etc) or negative (e.g. thymidine kinase [HSV-TK] gene etc) selectable marker genes driven by the sequences described in point 1.

3) Gene Modulators and Modifiers (listed below):
Mammalian promoter driven vectors (e.g. PGK, EF1a etc) delivered by transfection with lipids, peptides or via lentiviruses (described in 4.2 'Details of vectors' section). These will express:
A. Transcription factors (e.g. RUNX2, GATA-4, NKX2.5, MEF-2C, TBX-5 etc).
These will program cells to change fate and identity, for example, RUNX2 will program cells to become bone/osteoblasts.

B. Growth factors (e.g. BMP2, VEGF and PDGF). These will be used in cell culture models of angiogenesis and bone formation in which growth factors are secreted locally by the cells and will act on recipient cells within the

C. Reprogramming factors (e.g. NANOG, OCT4, SOX2 etc).
These will program cells to revert to earlier developmental stages and will allow them to be programmed to other fates (i.e. skin cell to an iPSC which are similar to hESCs). These genes confer genome-wide epigenetic and gene expression changes. These will also promote survival and increase cell proliferation.

D. Immortalisation/cell survival factors (e.g. TERT, CDK4, E6/E7, SV40T, KLF4 etc).
These will promote changes to cell growth or survival. These genes confer genome-wide epigenetic and gene expression changes.

E. Gene editing: not limited to but including CRISPR/Cas9 and transposon systems such as Sleeping Beauty.
N.B. This will include the use of oncogene overexpression and knockdown of tumor suppressor genes. Proteins produced are covered in risk assessment; they do not increase risk, hazard or consequence when handled in class II facilities.

In some instances, the insert may be divided across two or more MV vectors. This approach relies on the natural propensity for MV genomes to concatamerise, which with appropriate placing of intronic sequences allows reconstitution of an expression cassette by cis- or trans-splicing (Hirsch et al., 2010 Molecular Therapy 18:6).
Evaluation of foreseeable effects

Insertion of the constructs will not alter the tissue tropism, or increase the infectivity or pathogenicity of the recipient vector. Scope for recombination with wild type virus is limited and, due to the packaging limits of adenovirus and AAV, if any such recombinants did arise they would be non-viable. Based upon there being no likelihood of any effect on the phenotypic characteristics of the recipient and the non-harmful nature of the inserts, the resulting replication defective viral/gene vector can be considered equivalent to the recipient vector in terms of hazard status, i.e., hazard group 1. Exception to this is perhaps GM viruses expressing a transcription factor or immortalisation factor (such as TBX5 or TERT respectively) that promotes growth or cell survival. However, the viral systems we will employ are replication defective and the Class II containment we will use as standard guarantees the minimised risk associated with the use of these vectors.

In the unlikely event of a release from the Class II Containment facility, adenovirus could remain viable in the environment for a similar period of time to the wild-type virus but AAV cannot survive if accidentally released. If the virus were to infect a susceptible host, then expression of the recombinant genes would occur in the infected cells. Since the virus cannot propagate (except in exceptional circumstances as detailed above), expression would be limited to the cells initially infected (i.e., once the cell divides, only ONE daughter cell will contain the adenovirus DNA. Eventually, this would result in loss of the DNA due to natural degradation of the episomal DNA. Additionally, the attenuated virus cannot recombine with wild-type virus in any way that produces viable virus (Becker T.C., et al Methods Cell. Biol. (1994) 43, 161-89). Recombination with a wild-type virus would, by the nature of the recombination event, remove the E1 region from the wild-type virus thereby inactivating its ability to replicate. Taken together, the above means that the recombinant virus is essentially unable to propagate in the external environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Any biological waste generated will be either autoclaved at 125°C for 20m ins (e.g. cell culture flasks and plates, centrifuge tubes, tissue paper used for cleaning up any spills inside the biological safety cabinet, gloves, sleeve covers and shoe covers), cycle validated using 12 point thermocouple test; or treated with Distel validated disinfectant, used at 1 :50 (e.g. pipette tips, stripettes and general cleaning of safety cabinet, cell culture lab and equipment); 1 :20 for rapid disinfection of high risk areas and high risk equipment.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form  

Tick to confirm that you have attached a risk assessment to this form  

Tick if you are claiming exemption from disclosure for section of the risk assessment
All of the GM safety committee members have reviewed and discussed the Class 2 assessment and agree with the controls and classification of the activity.

Give brief details of the genetic modification safety committee

This committee was put together as part of the project scope as GMM are not currently used at the site. The committee is made up of five team members, the site biological safety leader (qualified internally as the European Biosafety leader, and externally via the Biosafety Practitioner level 1 (foundation) SCQF level 11 BTI - ISTR registered), the site HS&E manager (NeBosh General Cert, NVQ level5 Occupation Health and Safety, P&G HSE Programme leader), microbiology management representative (PhD in Biotechnology, MSc in Microbial Genetics, Qualified Corporate QA Assessor), microbiology project leader (PhD in Biochemistry, MSc in Life Science, University of Edinburgh) and project technical leader (BSc Biological Sciences (Hons- Microbiology), PhD Chemical Engineering (Mammalian cell culture), Industrial co-supervisor (EPSRC, BBSRC, Marie Curie PhD's and Post docs) on biofilms related research. Panel D member BBSRC responsive mode.

It should be noted that the inserted material does not pose any additional hazard from the parent non-GMO strain. This results in no increased risk to the stability or survivability of the organisms and therefore the consequences of environmental release are negligible given the existing systems present in the lab for the disposal of BSL 2 organisms. Following the GMO Contained Use regulations, any GMO waste shall be inactivated prior to disposal. In this case, all GMO waste shall be autoclaved at 126°C for 30 minutes (validated cycle) prior to disposal in the biohazardous waste stream. Subsequent waste management is managed by contractors approved for the handling of "BSL 2 biohazard waste". Degree of kill = 100%.

For activities involving GMMs, describe the waste management measures which will apply to the activity.
Visualisation of hygiene benefits for R&D purposes and the use of generated images as potential commercial/publication material to develop and support superior products for consumers.

GMO GFP proteins will be used under standard EN European Antibacterial (AB) disinfection claims (e.g. BS EN 1276, BS EN 13697, BS EN 16615) methods and CDC reactor methods (e.g. ASTM E2562-17). GFP bacteria will be imaged using standard lab techniques such as microscopy and confocal imaging.

GMMs will be inactivated by autoclaving, using a cycle of 121 °C, 15 psi for 60 min. Autoclave is a routinely used and validated method for inactivation bacterial waste. We expect a 100% degree of kill, it was previously shown that autoclaving for 15 min or more at 121 °C kills 100% bacteria. Moreover, we have demonstrated that a heat treatment at 80°C for 30 min was sufficient to yield no viable cells for our recipient strains. Additionally, we will confirm inactivation by confirming the absence of viable cells after inactivation (swabs of from plates and liquid media will be plated on nutrient agar).

There is an autoclave dedicated to biological waste inactivation in the building. Pressure and temperature inside the autoclave are closely monitored during each cycle to ensure that the content reaches the appropriate temperature. The autoclave used for waste inactivation is tested and serviced yearly.

Inactivated liquid waste will be disposed down the drain. Inactivated solid waste will be placed in orange bags and collected regularly by NHS Grampian.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

We have submitted an application to the University of Aberdeen Foresterhill Genetic Modification Safety Committee for approval to carry out work with genetically modified micro-organisms. The Foresterhill Genetic Modification Safety Committee has reviewed our application and officially approved it on 13/10/2017.

Comments from the committee: "To be acceptable by the committee after minor modifications. It is a Commercial and requires a CU2 form."

The requested amendments were made and final approval was received on 13/10/2017.
The aim of this project is to inactivate bacterial genes involved in host interaction, adhesion and immunomodulation in anaerobic bacteria in order to gain an understanding of their biological function. The work will involve generating a number of targeted single gene knock-out mutants in a strain isolated from the gut microbiota of a healthy human. Gene inactivation will be performed using targeted gene disruption by plasmid insertion (through site-specific homologous recombination).

The recipient organism is a Gram-positive bacterial strain isolated from a healthy human. E. coli strains will be used as cloning hosts. A non-replicating vector will be used for gene disruption and generation of insertion mutants.

The genetic material will be extracted from the recipient organism. This project will focus on the genetic manipulation of genes involved in host interaction, adhesion and immunomodulation in order to gain an understanding of their biological function.

The genetically-modified strains to be generated are predicted to have reduced ability to colonise and interact with the host in comparison to the wild-type strain. We do not foresee any additional hazardous effects arising from the generation of those strains. Risks associated with the genetic manipulation of the wild-type strain and the resulting GMMs have been assessed and are predicted to be low.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

GMMs will be inactivated by autoclaving, using a cycle of 121 °C, 15 psi for 60 min. Autoclave is a routinely used and validated method for inactivation bacterial waste. We expect a 100% degree of kill, it was previously shown that autoclaving for 15 min or more at 121 °C kills 100% bacteria. Moreover, we have demonstrated that a heat treatment at 80°C for 30 min was sufficient to yield no viable cells of the recipient strain. We do not expect the proposed mutations to enhance the recipient strain's ability to survive exposure to the above conditions. Additionally, we will confirm inactivation by confirming the absence of viable cells after inactivation (swabs of from plates and liquid media will be plated on nutrient agar).

There is an autoclave dedicated to biological waste inactivation in the building. Pressure and temperature inside the autoclave are closely monitored during each cycle to ensure that the content reaches the appropriate temperature. The autoclave used for waste inactivation is tested and serviced yearly. Inactivated liquid waste will be disposed down the drain. Inactivated solid waste will be placed in orange bags and collected regularly by NHS Grampian.

Y

Give brief details of the genetic modification safety committee

Safety committee consists of a group of ex-industry leaders (from Novartis), University Professor (Nottingham University) and external University Associate Professor (Nottingham University) who have worked in the relevant field for many years and have previous sat on such committees in the past. The committee will meet bi yearly, and additionally as necessary, to ensure that current measures and risk assessments are up to date and that new regulations are implemented.

Terms of reference:
1. Review all risk assessments for work involving genetic modification
2. Advise on laboratory GMM procedures, based on current legislation
3. Review laboratory inspection outcomes and monitoring arrangements, to ensure implementation of safe working practice related to GMM

Level 1 (GMMs)
Yes

Level 2 (GMMs)

Level 3 (GMMs)
Established chemical (disinfectant) or physical (autoclaving) inactivation methods will be used for all GMM associated materials prior to disposal via off-site incineration. Chemical inactivation routes will use Chemgene I Distel, with each batch checked against manufacturer’s test data to validate expected kill rates and recommended conditions. For example, Chemgene HLD4L at 1:100 dilution provides >510 gl 10 bacteriocidal activity for E Coli on surfaces or in suspension, under dirty (high BSA) conditions, following room temperature incubation for 5 min. Manufacturer data demonstrates chemical inactivation is suitable for all GMOs involved in this work. Our chemical disinfection procedures also exceed manufacturer standards significantly by routinely using more concentrated solutions (1:50, 2%) for an extended period of time (typically overnight). Physical inactivation by autoclaving will use validated cycle (121 - 126°C for 15 min) and an autoclave sited within our laboratory space. Agar plates I solid waste in contact with GM bacteria will also be spayed with 70% IMS prior to autoclaving.

Summary of inactivation methods for GM modified mammalian eukaryotic cells. Waste tissue culture media will be incubated with 2% Chemgene overnight, prior to drain disposal. Spent tissue culture flasks will be incubated with 2% Chemgene for >30 min, the disinfectant discarded to the drain, and flasks to bagged waste for incineration.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Established chemical (disinfectant) or physical (autoclaving) inactivation methods will be used for all GMM associated materials prior to disposal via off-site incineration. Chemical inactivation routes will use Chemgene I Distel, with each batch checked against manufacturer’s test data to validate expected kill rates and recommended conditions. For example, Chemgene HLD4L at 1:100 dilution provides >510 gl 10 bacteriocidal activity for E Coli on surfaces or in suspension, under dirty (high BSA) conditions, following room temperature incubation for 5 min. Manufacturer data demonstrates chemical inactivation is suitable for all GMOs involved in this work. Our chemical disinfection procedures also exceed manufacturer standards significantly by routinely using more concentrated solutions (1:50, 2%) for an extended period of time (typically overnight). Physical inactivation by autoclaving will use validated cycle (121 - 126°C for 15 min) and an autoclave sited within our laboratory space. Agar plates I solid waste in contact with GM bacteria will also be spayed with 70% IMS prior to autoclaving.

Summary of inactivation methods for GM modified mammalian eukaryotic cells. Waste tissue culture media will be incubated with 2% Chemgene overnight, prior to drain disposal. Spent tissue culture flasks will be incubated with 2% Chemgene for >30 min, the disinfectant discarded to the drain, and flasks to bagged waste for incineration.
Glass and plastic pipettes, pipette tips, pots and cryovials in contact with GM cells will be soaked in 2% Chemgene overnight (with disinfectant drawn into pipette barrels), then to incineration bag or sharps bin waste. Equally experimental microtitre plates containing GM whole cells will be soaked in 2% Chemgene overnight, then to transferred to incineration waste disposal.

Summary of inactivation methods for GM modified E Coli. Agar plates, and other solid waste in contact with GM E Coli (e.g. DNA preparation columns) will be surface sprayed with 70% IMS, then autoclaved prior to bag disposal for incineration. Liquid bacterial cultures, and waste media will be incubated with 2% Chemgene overnight, followed by drain disposal. Eppendorf tubes, pipettes and pipette tips will be soaked in 2% chemgene overnight, followed by incineration (sharps).

Any spill procedures will use more concentrated disinfectant (10% Chemgene, in contact with associated surfaces for >15 min), with associated towel and solid waste being autoclaved.

Waste disposal procedures and monitoring will form an essential element of staff training in handling GMOs, with the appropriate routes for different types of waste clearly displayed in all relevant laboratory areas. For chemical disinfection procedures, manufacturer testing records will be checked for each batch of disinfectant used, together with product expiry and weekly monitoring of replacement of the appropriate stock dilutions. There will be daily replacement of 2% soaking solutions for plasticware and microtitre plate decontamination. Staff will be trained in the use of the autoclave, verification of the thermocycle and the need to repeat the autoclave cycle if uncertain. Annual servicing of the autoclave will validate sterilisation cycle parameters. On site testing of a small sample of treated media (by autoclave or chemical disinfection) will occur biannually, inoculating on solid agar or cell culture liquid media and assessing for overnight growth - with results reported to safety committee.

For activities involving GMMs, describe the waste management measures which will apply to the activity

| Disinfectant used is Biocleanse (Teknon) - Passes BS EN 1726 at 1%. Biohazard solid waste is stored in lined biohazard bins until removal by waste management staff, then transported by vehicle to the onsite permitted waste transfer station where it is autoclaved at 121°C; the process takes up to 2 hours to complete. Liquid waste: add equal volume of 10% biocleanse solution (Teknon) for minimum 30 minutes (final concentration =5%) - Wash down sink with at least 5x volume of water. Disposable plastics: disinfect with 1% biocleanse solution (30 mins) prior to incineration. Glass/plastic: disinfect with 1% biocleanse solution (30 mins), wash with plenty of water. Solid biohazard waste (e.g. gloves): send for autoclave disposal (100% kill) Surfaces: Spray with 1% biocleanse, wipe away with tissue, discard into autoclave waste. Spillage: Absorb onto paper towels, send for autoclave disposal. Swab area with 1% biocleanse, discard paper towels into autoclave waste. Spill in centrifuge: If breakage occurs during run, do not open lid. Leave for 30 mins to allow aerosol to disperse. Label centrifuge as to hazard. On opening, soak liquid onto paper towel and place in autoclave bag. Immense plastic parts in 1% biocleanse (30 mins). Swab bowl, rotor and buckets with 1% biocleanse. Remove rotor and/or bucket and rinse with water. Rinse bowl with water. Discard all towels into autoclave waste. |

All contaminated liquid waste (e.g. contaminated media, buffers), will be disinfected using Rely+On Virkon disinfectant according to the manufacturers instructions. This involves dissolving Rely+On Virkon into the liquid waste, such that the final solution of Rely+On Virkon is 1% (i.e. 10 grams per litre). Once fully dissolved, the waste is left at room temperature for 10 minutes before being sewer. Virkon reportedly kills 99.999% of microorganisms in less than 10 minutes. To monitor this efficacy, a sample will be taken from one in every 30 liquid waste loads. Before disinfection, the concentration of microbes will be measured via a OD600 reading. Following disinfection, the sample will be plated on nutrient agar and incubated at 37°C for 2 days. Any colonies that have grown on the plate will be counted. Comparing the concentration of cells pre-disinfection to the number of colonies on the agar plate will allow us to calculate a kill percentage.

All contaminated solid waste (e.g. pipette tips, plastic tubes, agar plates) will be sterilised in bags using an autoclave. The content of the autoclave will reach 121°C for 20 minutes in saturated steam. To ensure that the centre of the load reaches this temperature for the requisite time, the sterilisation cycle will run for 60 minutes. Using this method, 100% of microorganisms are killed. To monitor this, once a month, a Thermalog Steam Chemical Integrator will be placed in the centre of the waste load. Once the autoclave cycle is complete, the indicator will reveal whether the centre of the load has reached the requisite temperature to entirely sterilise it.

Project Additional Information

Purposes of the contained use

To transiently express genetically modified proteins, nanobodies and interleukins, from Homo sapiens, Mus musculus and Macaca fasciculari in characterised mammalian cell lines.

Recipient or parental organism

Recipient cells will be characterised mammalian cell lines - FreeStyle™ 293-F Cells (HEK293) and/or Expi293F™ Cells (HEK293) and/or FreeStyle™ CHO-S Cells and/or ExpiCHO-S™ Cells. The work involves generation of biomolecules selected for their therapeutic potential – inflammatory cytokines, their receptors and modified nanobodies designed to bind these proteins.

HEK293 cells were created using Adenovirus 5 DNA. Adenovirus type 5 is one of the most common viruses associated with lower respiratory tract infections. It is likely that lab personnel have already been exposed previously to a similar strain in childhood, so the likelihood of severe illness is very low. In the case of immuno-compromised individuals there is a risk of development of pneumonia. However, as this virus is attenuated is it highly unlikely to cause any infection.

HEK293 cells have been found to be tumorigenic in nude-mice, however there are no documented cases in humans. These cells are classified as non-hazardous under regulation (EC) No 1272/2008.

FreeStyle™ CHO-S Cells are not considered to be hazardous to human health (classified as non-hazardous under regulation (EC) No 1272/2008)

Host/vector system

List of vectors:
1. PSF-CMV-PURO-NH2-BM40-6HIS-EKT
2. PSF-CMV-PURO-NH2-6HIS-MBP-EKT
3. PSF-CMV-NH2-HIS-EKT-NCOI

Whilst the vectors used will have mammalian promoters, the GMM risk is considered to be low, working with nonhazardous
targets selected for their therapeutic potential. The expression vectors themselves are commercial DNA plasmids and are considered non-pathogenic. The cloned DNA products are unlikely to alter the pathogenicity of the host.

### Origin & function

The work involves generation of biomolecules selected for their therapeutic potential, as enzyme or binder to human proteins.

The genetic material involved are inflammatory cytokines, their receptors and modified nanobodies designed to bind these proteins. Proteins modified from Homo sapiens, Mus musculus and Macaca fasciculari.

### Evaluation of foreseeable effects

Interleukins and antibodies have been used in the clinic for a long time for immunotherapy with evidence of safety. Nanobodies clinical trials to assess safety have also been conducted with success. Gene transfer is a remote possibility. As inflammatory cytokines and their receptors are already present in the host, it is unlikely they would create an immune response, however they are linked in an increase in inflammation so could increase risk of inflammatory conditions. It is unknown the effect of nanobodies tailored against inflammatory cytokines and their receptors, however they are unlikely to pose much risk when compared to prior clinical trials on safety effects of nanobodies. Overall the risk of gene transfer and their effects are considered to be VERY LOW.

The recipient strains will not survive, and the vector used only contains mammalian promoters. It is highly unlikely this vector would survive and enter a viable host. Gene transfer into environmental bacteria is a remote possibility, however would be unlikely to provide a survival advantage to the host. The inserted sequences are not expected to represent a hazard to other organisms. None of the considered modifications are expected to alter the host range or infectivity of the vector.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste - Plasticware (i.e. tips, flasks, pipettes) - All potentially infected solid waste will be discarded in an approved autoclave bag. When the bag is ¾ full it will be closed with autoclave tape and placed within a second autoclave bag. Care will be taken to ensure that bags are not sealed, to ensure that steam will penetrate the waste inside the bag. Waste will be autoclaved at 121°C for 20 minutes. Autoclaved material will be put in the appropriate bins and disposed of with an authorized removal company.

Liquid waste - Mammalian cell cultures - Cell cultures will be treated with freshly prepared 1% Virkon disinfectant for at least 1h as per manufacturer’s recommendations.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

For activities involving GMMs, describe the waste management measures which will apply to the activity

All potentially contaminated GMM waste material (needles, syringes, wipes/swabs, PPE) and waste vaccine product will be placed into containers provided by GMO accredited/licenced clinical waste contractor, safely stored and then removed from our premises by said companies for destruction in the required manner, as described in the information from our waste contractor below.

Waste handling for GM Class 1 products

Under Schedule 8 of the Genetically Modified Organisms (Contained Use) Regulations 2014 Table 2 details the containment measures to be applied for non laboratory type facilities. Line 20 requires that inactivation of GMMs in contaminated material and waste is required by validated means where and to the extent the risk assessment shows it to be required. The waste is such that it cannot be disinfected and there is no available autoclave. The information detailed below indicates how the waste will be packaged to send directly to incineration.

Contaminated materials such as gauzes, bandages, gloves used during administration of product

All waste will be placed inside a yellow hazardous waste bag. This bag will be sealed with a plain cable tie. The bag is then placed inside a second yellow hazardous waste bag and sealed with another cable tie. The double-bagged
waste is then placed inside a 30L yellow hazardous waste burn bin containing at least 2 inches of vermiculite to act as spillage absorbent material. Clicking the lid closed seals this burn bin. The yellow burn bin is a UN approved biohazard waste bin used for transport of waste on public highways. The maximum weight of each burn bin must not exceed 20Kg.

Operationally, a yellow burn bin containing 2 inches of vermiculite in its base and 2 yellow bags (one inside each other) will be placed out at the start of each day. At the end of each day or when the container is three quarters full, the first bag will be sealed, the second bag sealed and then the lid of the burn bin closed. This will be performed in the room where the waste has been generated. Each burn bin is tagged with a uniquely numbered locking plastic tag. The tag reference is recorded.

The burn bin is labelled with a UN3373 label. Regular collections are arranged with the waste management contractor, Hazport. During collection the unique tag reference numbers on the will be noted onto the consignment note and confirmed to the hazardous waste safety advisor in order for a certificate of destruction to be requested. This waste must remain segregated from other burn bin waste generated from the building.

Sharps Bins

All sharps are placed inside a sharps bin. Needles are not resheathed.

A small sized sharps bin such as 1 L should be used. Once three quarters full or after 1 week, the sharps bin is locked closed and placed inside a second larger sharps bin eg 22L.

Multiple small sized sharps bins can be placed inside the larger sharps bin. This should be removed from the area at least monthly.

Each large sharps bin is tagged with a uniquely numbered locking plastic tag. The tag reference is recorded. A UN3373 label is applied to each large sharps bin.

Regular collections are arranged with the waste management contractor, Hazport. During collection the unique tag reference numbers on the will be noted onto the consignment note and confirmed to the hazardous waste safety advisor in order for a certificate of destruction to be requested. This waste must remain segregated from other sharps bin waste generated from the building.

Hazport Ltd

The waste is removed from the collection point and handed to Hazport waste management company as per the agreed schedule. The waste is transported by Hazport to Tradebe Ltd, Marlborough Road, Wrexham Industrial Estate, facility where it is processed direct through their High Temperature Clinical Waste Incinerator (CWI).

Hazport will leave the UN containers at Tradebe where they are placed into 770 L bins and wheeled onto the bin line where a mechanical handling device feeds them into the incinerator.

Waste in the primary combustion chamber burns for a minimum of six hours and then passes into the secondary combustion chamber which reaches temperatures of 1,100°C to burn off pharmaceutical and chemical agents. Off gases are cleaned through a gas scrubbing system to ensure that emissions meet European standards.

The Wrexham facility is licenced to process class 1 GMO, however Class 2 waste must be notified to the Home Office and prior agreement must be obtained.
The last sentence of Section 1.2 of the risk assessment states "Safety data (e.g. reactogenicity, AEs) of the HAV vaccine and TDV will be assessed by collecting data from all subjects during the course of the study". While there is strong data supporting the safety of either vaccine when administered on its own, this statement indicates that there is less certainty about this where there is co-exposure to both.

If the likelihood of co-exposure to both vaccines of persons administering the vaccines is negligible then this potential concern does not arise. I note that any such risk to workers can be completely eliminated by ensuring that if anyone administering either of the vaccines is accidentally exposed (e.g. needlestick) they will not be involved in administering the other and I recommend this is incorporated into relevant procedures.

Subject to the additional implementation of the foregoing requirement, the designation as a risk class 1 activity is appropriate. Implementation of that requirement together with the control measures specified in the risk assessment document should ensure that exposure of persons and the environment is minimized so far as is reasonably practicable consistent with the Principles of Good Microbiological Practice and Good Occupational Safety and Health.

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities [Y]

Give brief details of the genetic modification safety committee

Genetic modification safety committee, following the ethics committee guidelines. Committee gathers once per year and is led by the deputy CEO, representative director, a communications representative and other senior scientists. Further to this, any future meetings will include the biological safety advisor (BSA). All risk assessments and forms prepared for this license have been produced by the current and future biological safety advisor.

Bacteriology Parasitology Transgenic Birds Microbiology Research

02/03/2022
Consumables (mainly plasticware i.e.: pipettes, flasks, tubes) - disinfect with 2% Virkon for at least 30 minutes, autoclave using a make safe cycle (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration/dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (i.e.: samples, culture supernatants, tissue culture media) – disinfect with 2% Virkon for at least 30 minutes, autoclave using a make safe cycle (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge to drains.

Agar plates - autoclave using a make safe cycle (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration/dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (i.e.: needles, syringes, scalpels) - dispose via clinical waste stream for incineration.

Degree of kill
Autoclaving, effectively 100% kill (annual validation)
Incineration, effectively 100% kill (licensed incinerator)
Chemical disinfection with Virkon, used according to manufacturer’s instructions under standard conditions, manufacturers validation log reduction ([99.998]% kill).

For activities involving GMMs, describe the waste management measures which will apply to the activity

Production of recombinant protein/peptides in bacteria, yeast, insect, HEK cells and cell free sys

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

All forms and risk assessments have been prepared by the future biological safety advisor and discussed with the current biological safety advisor, genetic modification safety committee and health & safety department. The current team carrying this work and future biological safety advisor (who prepared the documents) are academically educated in molecular biology and hold expertise in the subject.
**Project Additional Information**

**Purposes of the contained use**
Small aliquots of wild type Salmonella and mutants will be received and grown so that their outer membrane lipids can be extracted for mass spectrometry identification.

**Recipient or parental organism**
Salmonella typhimurium LT2

**Host/vector system**
N/A

**Origin & function**
We would receive the Salmonella mutants - we won't be modifying the bacteria here. These have been reported to be resistant to antimicrobial peptides (Lofton et al 2013).

**Evaluation of foreseeable effects**
Mutants were reported to be more resistant than wild type, yet these advantage was also reported to come along with sacrifices to the fitness of the bacteria. Therefore, it is possible these mutants would not survive or replicate in the wild.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

For activities involving GMMs, describe the waste management measures which will apply to the activity

Non-radioactive (Very Low Level radioactive Waste VLLW) disposed of in BioHub clinical waste stream.
Radioactive (>VLLW) transferred to our radioactive waste management company (SRCL). Both for incineration.
Liquid waste from tissue culture, mixed with household bleach, disposed of to sewer.
Inactivation not required per Schedule 8 of the Constrained Use Regulations; Part 2; Table 1a; row 18 (inactivation at CL-1 "required by validated means where and to extent the risk assessment shows it is required."). The cell lines cannot survive outside the specialist cell culture environment and pose minimal risk to both human health and the environment.

Give brief details of the genetic modification safety committee

Dr M D is the chairman of a 10-member SBC GM committee. Dr D has 25 years' experience working with GMOs and has previously served as GM Officer in the Dept of Life Sciences at Imperial College. The GM committee has a wide range of experiences in GMO R&D.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Waste Disposal
- Glassware- decontaminated with 5% Distel for 1 hour contact time
- TC plasticware and agar plates- places in yellow clinical waste bags and transported via high sided trolley to Freeline's waste collection bins in the SBC storage area. Bins are collected by Grundons waste management and taken off site for incineration as offensive waste for final treatment.
- Liquid waste- treated with 5% distel for 1 hour contact, then disposed of down the sink.
- Hard surfaces: Distel spray for 1 hour contact time, 10mins for metal parts (longer can cause corrosion)
- Safety cabinets: Distel spray for 10 minute contact time

Distel is a laboratory disinfectant: Broad spectrum efficacy within short contact times-30 seconds to 5 minutes; Sporicidal, mycobactericidal, virucidal, fungicidal, and bactericidal efficacy; Performance validated with a wide range of peer-reviewed scientific publications; acknowledged and recommended by professional societies, public and private healthcare instruction.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

Dr D and the committee have advised Freeline Ltd on evaluating GMO handling and waste disposal risks and are satisfied that they are acting appropriately, responsibly and with the best practice of the SBC. The R&D does not contain anything non-standard or exceptional that requires special consideration. The SBC GM Committee have approved the associated risk assessments and support this notification.
Adeno-Associated Viral vectors will be used to deliver therapeutic genes

Recipient or parental organism
HEK-293 cells and HEK-293T cells

Host/vector system
Adeno Associated Virus: The proprietary versions of these vectors have been modified from the wild type to make them safe for use in human therapeutics. They have been altered to be replication incompetent and contain a benign reporter transgene (green florescent protein) GFP - minimising concerns for both operator and environment.

Origin & function
The transgene will be either a reporter gene for example GFP or a gene for a protein which will restore functional levels in human disease.

Evaluation of foreseeable effects
The vectors used in this project are being developed for human therapies and thus have been significantly engineered to alter parts of the genetic code to create proprietary vectors that have a better safety profile than wild type.

The key alteration is that all vectors have been altered to be replication incompetent. This means that they pose a minimal concern to the environment should they be released as they cannot replicate in any cell or organisms they are able to infect. The vectors used also pose minimal to no chance to infecting plant or livestock as they are...
developed/chosen to transfect human cells. These vectors have the ability to infect humans via a number of methods e.g. direct contact with skin, mucous membrane of the eye, nose and mouth, ingestion, or injection. Infection could lead to the expression of the transgene; insertional mutagenesis or an immune response.

However the transgenes of the vectors used do not encode for oncogenes, growth factor receptors or toxin molecules. The reporter transgenes used in this work will be green fluorescent protein and beta gal to minimise the chance of harm to either the environment or personnel. If an individual is infected the vectors are replication incompetent and so will be unable to propagate throughout an individual.

There is the possibility that if an organism is also infected with a replication competent wild type vector that that transgene vector will also gain this ability. However control measures implemented as outlined below make this a highly unlikely event.

HEK-293 cells and HEK-293T cells
HEK 293 cells were generated in 1973 by transformation of cultures of normal human embryonic kidney cells with sheared adenovirus 5 DNA. As this cell line includes adenovirus genes it allow the propagation of the viral vectors used which have been engineered to become replication incompetent.

The HEK cell lines pose minimal potential damage to the environment as they have been adapted to an artificial cell culture environment under laboratory conditions and so are unlikely to thrive in the external environment if released.

It is not the aim of this project to propagate virus for experimentation but rather use these cell lines to test the infectivity of the purified vectors via quantification of successfully transfected reporter transgene. Therefore the adherent cultures will be grown in multiwall plate formats of well columns less than 5mL (<500,000 cells per well). And not more than 1L of cell culture volume total. These wells will be infected with low viral concentrations (anticipated to be less than 10E6 per well). This makes handling and destruction of the viral infected cells easier to control, therefore minimising risk to operator or environment.

Rational of classification:
After a review of the information sources and discussions with our GMO committee:

Class 1
Vector: the rationale that vectors are replication incompetent and express what were considered to be biologically benign transgenes suggest a low risk for this biological material.
Cell lines: HEK 293 and HEK 293T cells are engineered to ideal lab based cell culture conditions and are highly unlikely to survive in the external enviroment. E.Coli strains DH5 alpha (New England Biolabs) and Stabl3 (Thermofisher), are both K-12 derivatives used to propagate the plasmid and are non-pathogenic.

Class 2
The import and investigational use of animal tissues with or without AAV vector use determines that the laboratory should maintain a Class 2 containment level.

Based on one essential category requiring Class 2, our laboratory will apply Class 2 containment.

Control measures adopted:
Records and tracking of materials used are kept as part of Freeline good lab practice which involves hard copy lab books. All materials are clearly labelled and stored in specific safe storage areas within the facilities.
- PPE: lab coats, gloves and goggles to be worn at all times. This is to reduce the possibility of any physical contact with the vector.
- To avoid exposure to aerosol/droplets viral manipulations should be conducted in biological safety cabinets with HEPA filters, conforming to a containment Level 2
(CL2) to prevent release and possible inhalation.
- Sharps used in the laboratory are restricted to 1; Dialysis bag filling 2; Electrophoresis Gel Cutting.
- Centrifugation must be conducted in closed containers and using sealed rotors. Rotors must be opened in a Biosafety cabinet.
- Once the vector has been disrupted during preparation for nucleic acid or protein analysis it is safe to be used outside of the cabinet (PPE as outlined above should still be used).
- All wastes treated to destroy GMO material (see disposal section below)
- Volumes of dilute virus material to be kept under <1L of 1E13 virus particles to make waste handling and disposal easier and to reduce the severity of any adverse events
- Volumes of concentrated virus material to be kept under 20mL of 1E15 virus particles. This allows easy handling in the biosafety hood.
- HEK 293, HEK 293T cell lines (volumes less than 1L). Once cells have been transfected they should only be handled in closed containers or in the CL2 cabinet
- All vector material when stored in fridge/freezer will be clearly labelled as to its contents.
- All experiments take place in the Stevenage Bioscience Catalyst which is on a secure site as part of the Glaxo Smith Kline Campus. All areas where the virus is stored are only accessible by employees (via keycard or lock and key). Visitors are supervised and wear badges to identify them.
- Training for the use of vector material will be conducted by users who have prior experience of handling the vector material. The completion of training will involve the adding of the individuals name to this risk assessment. The signature will serve as a record of the training and be kept on file as part of the Freeline training records.
- Where vector material is transported this will only be done in sealed containers which are labelled and placed inside sealed plastic packaging. These in turn will be put into larger boxes, sealed and the box labelled with Freeline’s name, address and contact details with the instruction not to open unless authorised.
- There will be no lone, of out of hours, work for this project.
- The Freeline Health and Safety Policy covering lab practice and use of COSHH is to be followed at all times.

Protein Purification in the AKTA Pure system
- The AKTA pure system does not have an enclosed fraction collector therefore the system is housed inside a CL2 cabinet, where the work is conducted.
- Viral material loaded to the loop inside the CL2 cabinet;
- Parafilm should be wrapped around the connections;
- Delta pressure alarm should be less than 2 MPa;
- To avoid the formation of aerosols, 10 minutes should be the minimum of time between the last fraction collected and before opening the drawer.

Together the implementation of these control measures make this project a “LOW” risk.

First Aid:
EYE EXPOSURE FROM SPLASH OR AEROSOLS: Rinse a minimum of 15 minutes in eye wash available at all sink hand wash areas or flush area with water. Seek medical attention.
CONTACT WITH SKIN: wash thoroughly with disinfectant. Hand sinks available in all labs for washing.
INHALATION EXPOSURE FROM AEROSOLS: Seek medical attention.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste Disposal
- Vikon is used as it is a validated cleaning method for viral vector material and transfected cells if used in the following way under manufacturers recommendations.
- Distel is used as it is a validated cleaning method for viral vector material and transfected cells if used in the following way under manufacturers recommendations.
• Hard surfaces: A solution containing 5% Distel for 1 hour contact time, 10mins for metal parts (longer can cause corrosion)
• Safety cabinets: 5% Distel (10mins) followed by 70% IMS.
• Discard jars, plastic tissue culture flasks, glassware: A solution containing 1% Virkon.
• Ensure all surfaces are in contact with the disinfectant (10mins). Added to sealed bags for autoclaving at a minimum of 1210°C, 1.15bar, 15 mins hold.
• Supernatants/liquid waste: 1% Virkon with minimum of 1 hour contact time.
• All autoclaved solid waste is to be placed into hazardous waste bags. There are 2x autoclaves available and the equipment is regularly serviced to ensure it maintains its ability to be a validated cleaning method. Chart recorder or display screen is attached to autoclave to monitor treatment.
• Full bags are to be transported to Freeline’s hazardous waste bins in the SBC storage area
• Bins are collected for off site incineration by Grundons waste management.

Accidental Release:
In a contained area Distel should be applied all over the split area. The solid waste is then to be autoclaved as above.
In an uncontained area, all persons should evacuate the area to avoid contact with any potential aerosols formed. Only after 1 hour the room might be entered (to allow any aerosols to settle) and the procedures should be the same as in a contained area.
The floor is sealed and the lab is built to CL2 level.

### Project Additional Information

#### Purposes of the contained use

Our project aims to use recombinant AAV to treat rare disorders such as Haemophilia and Lysosomal storage disorders. rAAV constructs will be evaluated to create the vector with the best performance to take forward to clinical trial.

- **Containment level 2 for working with a Group 2 biological agent and class 2 activities.**
- **Development of novel AAV capsid variants by a directed evolution approach.**
  - This system requires the use of human adenovirus type 5 to facilitate virus library replication.
  - Basic procedure requires cells in culture to be infected with a shuffled AAV vector library that is capable of replicating. Co-infection with a helper virus (Adenovirus 5) facilitates library replication. After successive rounds of infection, AAV capsid DNA is isolated and sequenced to identify novel capsid variants. These capsid variants will then be vectorised into the recombinant AAV (rAAV) system for evaluation.
- **Target validation / In vitro disease models**
  - This requires modulation of protein expression in vitro cell culture systems. Work involve using self-inactivating replication incompetent lentivirus/retrovirus, either overexpress or knockdown genes encoding for lysosomal hydrolases (e.g. GLA, GBA) in order to modulate protein expression in various primary cells or cell lines.
  - Lenti (2nd and 3rd generation) will be used to maximize laboratory biosafety procedures.
**Recipient or parental organism**

- HEK-293 and HEK-293T cells
- Hepatic cell line Huh-7
- other mammalian primary cells or cell lines

**Host/vector system**

- **E.Coli**
  - Strains DH5 alpha (New England Biolabs) and Stabl3 (Thermofisher), are both K-12 derivatives. These strains are non-colonising, disabled, and are non-pathogenic to humans and animals. These E.Coli strains will be used to propagate plasmids.

- **Wild type AAV**
  - Adeno-associated virus is a small (approximately 25 nm in diameter), nonenveloped, icosahedral, non-pathogenic parvovirus. AAV infects cells through a receptor-mediated binding and uptake, endosomal release, trafficking of viral particles to the nucleus and unloading of the viral DNA in the nucleus.

- **Recombinant AAV**
  - Recombinant AAVs (rAAV) are generated by gutting the AAV viral genome of the rep and cap genes and replacing with a proprietary cassette which includes a promoter, transgene and poly adenylation signal. The transgene cassette is flanked by the inverted terminal repeats, which are the only remaining viral DNA sequences. In order to produce rAAV HEK 293 or 293T cells are transiently transfected with a double or triple plasmid combination to provide the transgene cassette, the rep, Cap and adenoviral helper functions. In Freeline’s proprietary vectors the transgene will be either a reporter gene for example GFP or luciferase; or a gene for a protein which will restore functional levels in human disease, for example Factor IX for hemophilia. All the transgenes used will encode modified versions of nononcogenic, non-toxic proteins. Promoters used will either drive constitutive expression, or a tissue specific expression. Freeline Therapeutics is currently using a novel capsid S3 which is derived from two naturally occurring AAVs and developing novel capsids which are better suited to transducing human tissues.

- **Wild type Adenovirus Ad5** will be purchased from ATCC.
  - Strain: Adenoid 75 Classification: Adenoviridae, Mastadenovirus.
  - Adenoviruses are nonenveloped viruses with a double stranded DNA virus. They have a broad range of hosts.

- **Lentivirus**
  - Self-inactivating replication incompetent lentivirus (viral particles or plasmids) based on viral vector such pLKO-1 backbone will be purchased from established vendors like Sigma-Aldrich, Applied Biological Materials, or Origene. The shRNA expression is controlled by the U6 promoter in the case of the shRNAs or the human cytomegalovirus (CMV) immediate-early enhancer and promoter or liver specific promoters (LSP) to knockdown or...
overexpress the genes of interest, respectively.
pCMV-dR8.2 dvpr (e.g. Addgene plasmid #8455) and pCMV-VSVG (e.g. Addgene plasmid #8454). HEK 293T cells are used to produce lentivirus.

Origin & function

The transgene will be either a reporter gene for example GFP or a gene for a protein which will restore functional levels in human disease

AAV
1. The plasmid for the transgene cassette will contain either a tissue specific promoter, typically a liver specific promoter or a constitutively active promoter. The transgene will encode a protein variant of a human factor IX protein, or an antibody fragment. Reporter genes used will typically be commercially available GFP or luciferase which are categorised as nononcogenic. Sequences will be validated by the vector development team.
2. Plasmids will contain the antibiotic resistance genes ampicillin or kanamycin for selection. These resistance genes will not be incorporated into the rAAV.

There are no inserted transgenes within the AAV replication competent library. The only gene products are Rep and Cap proteins associated with normal virus life cycle.

Adenovirus
3. There are no inserted transgenes within the Adenovirus. The only gene products will be proteins associated with normal virus function.

Lentiviral vectors (LV)
4. The viral vector carries a promoter such as U6 or a Liver specific promoter or strong/medium promoters such as CAG, PGK, CMV for stably expression cell line creation.
5. Vectors carrying an shRNA or a cDNA sequence to modulate the expression of a particular gene e.g. lysosomal enzyme genes such as GLA and GBA.

DNA sequence to be included in rAAV will be obtained by gene synthesis synthetic promoters may be used to drive expression of gene of interest. DNA sequence to be included in the AAV library will be derived by a combination of gene synthesis (ITRs and Rep) and PCR (shuffled capsid genes).

DNA sequence is to be included in lenti- or retrovirus will be obtained by gene synthesis. Synthetic promoters will be used to drive expression of genes of interest. Genes will be obtained by gene synthesis and will correspond to genes present in the human genome.

Evaluation of foreseeable effects

AAV
The final GMO (transduced cells) pose very low or no hazard. The elimination of 94% of the viral DNA reduces the probability of homologous recombination with related viruses that could lead to variants of the GMO.
Like the parent organism, AAV, the vector is non-pathogenic. As the Freeline vectors have had all viral genes removed it is assumed they are also nonpathogenic. The vector currently has fully wild-type capsid proteins and the immune response is not expected to be different from that of the parental virus.

Ad5/rAAV infected cells: Risk Ad5/AAV infected cells pose minimal risk. There will not be any genetic inserts (such as oncogenes etc) present that pose any risk to human health. The majority of people in Europe are seropositive for AAV and Adenovirus neutralising antibodies. If infections were to occur, it is likely an acute and self limiting immune response will take place to clear the virus. A risk of a more serious infection from Adenovirus can occur in immunocompromised individuals therefore an individual showing a compromised immune system will not work with this system. LV transduced cells should not acquire any pathogenicity or potential harm. The vectors used in this project are being developed for human therapies and thus have been significantly engineered to alter parts of the genetic code to create proprietary vectors that have a better safety profile than wild type. HEK-293 cells and HEK-293T cells
HEK 293 cells were generated in 1973 by transformation of cultures of normal human embryonic kidney cells with sheared adenovirus 5 DNA. The HEK cell lines pose minimal potential damage to the environment as they have been adapted to an artificial cell culture environment under laboratory conditions and so are unlikely to thrive in the external environment if released.

Rational of classification:
After a review of the information sources and discussions with our local GMO committee:
Class 1
rAAV Vector: the rationale that vectors are replication incompetent and express what were considered to be biologically benign transgenes suggest a low risk for this biological material.
Cell lines: HEK 293 and HEK 293T cells are engineered to ideal lab based cell culture conditions and are highly unlikely to survive in the external environment.
E.Coli strains DH5 alpha (New England Biolabs) and Stabl3 (Thermofisher), are both K-12 derivatives used to propagate the plasmid and are nonpathogenic.
Class 2
The import and investigational use of animal tissues with or without AAV vector
The use of Lentiviral vectors for target validation: this requires modulation of protein expression in vitro cell culture systems. Lenti (2nd and 3rd generation) will be used to maximize laboratory biosafety procedures.
Ad5/AAV co-infection for capsid development: basic procedure requires cells in culture to be infected with a shuffled AAV vector library that is capable of
replicating. Co-infection with a helper virus (Adenovirus 5) facilitates library replication. After successive rounds of infection, AAV capsid DNA is isolated and sequenced to identify novel capsid variants. These capsid variants will then be vectorised into the recombinant AAV (rAAV) system for evaluation.

Control measures adopted:
All materials are clearly labelled and stored in specific safe storage areas within the facilities.
• PPE: lab coats, gloves and goggles to be worn at all times. This is to reduce the possibility of any physical contact with the vector.
• To avoid exposure to aerosol/droplets viral manipulations should be conducted in biological safety cabinets with HEPA filters, conforming to a containment Level 2 (CL2) to prevent release and possible inhalation.
• All wastes treated to destroy GMO material (see disposal section below)
• HEK 293, HEK 293T cell lines (volumes less than 1L). Once cells have been transfected they should only be handled in closed containers or in the CL2 cabinet
• All vector material when stored in fridge/freezer will be clearly labelled as to its contents.
• Training for use of the vector material will be conducted by users who have prior experience of handling the vector material. The completion of training will involve the adding of the individuals name to this risk assessment. The signature will serve as a record of the training and be kept on file as part of the Freeline training records.
• The Freeline Health and Safety Policy covering lab practice and use of COSHH is to be followed at all times.
Together the implementation of these control measures make this project a "LOW" risk.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste Disposal
• Vikon is used as it is a validated cleaning method for viral vector material and transfected cells if used in the following way under manufacturers recommendations.
• Distel is used as it is a validated cleaning method for viral vector material and transfected cells if used in the following way under manufacturers recommendations.
• Hard surfaces: A solution containing 5% Distel for 1 hour contact time, 10mins for metal parts (longer can cause corrosion)
• Safety cabinets: 5% Distel (10mins) followed by 70% IMS.
• Discard jars, plastic tissue culture flasks, glassware: A solution containing 1% Virkon.
• Ensure all surfaces are in contact with the disinfectant (10mins). Added to sealed bags for
autoclaving at a minimum of 1210°C, 1.15 bar, 15 mins hold.
• Supernatants/liquid waste: 1% Virkon with minimum of 1 hour contact time.
• All autoclaved solid waste is to be placed into hazardous waste bags. There are 2x autoclaves available and the equipment is regularly serviced to ensure it maintains its ability to be a validated cleaning method. Chart recorder or display screen is attached to autoclave to monitor treatment.
• Full bags are to be transported to Freeline’s hazardous waste bins in the SBC storage area
• Bins are collected for off site incineration by Grundons waste management.

Accidental Release:
In a contained area Distel should be applied all over the split area. The solid waste is then to be autoclaved as above.
In an uncontained area, all persons should evacuate the area to avoid contact with any potential aerosols formed. Only after 1 hour the room might be entered (to allow any aerosols to settle) and the procedures should be the same as in a contained area.
The floor is sealed and the lab is built to CL2 level.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

Please enter comments on the GM safety committee on the risk assessment

The Stevenage Bioscience Catalyst (SBC) is an incubator hub for small and emerging biotechnology start-up and spin-out companies. It is a UK Government backed (Innovate UK) enterprise in collaboration with the Wellcome Trust and GSK. The SBC provides technical, business, organisational and commercial support to its tenant companies and also monitors Health and Safety compliance. It has set up a GMO committee to ensure that tenants are assessing the risks associated with their work appropriately and to disseminate best practice among researchers. Dr Deonarain is the chairman of this committee and has 25 years experience working with GMO in academic and commercial settings and was Chairman of Imperial College Life Sciences GMO committee for 4 years.
The SBC committee has reviewed and advised Freeline on its GMO risk assessment and are satisfied that they have considered the risks in terms of GM organisms and scale of work. They have appropriate control measures to contain the work and appropriate procedures for the class of GMO activity for waste disposal.

Give brief details of the genetic modification safety committee

Several meetings held and advice received for genetic modification work from a contracted Safety Consultant with many years experience of microbiology, genetic modification work and biosafety management.

A company Genetic Modification Safety Committee has been formed. This comprises of the Biological Safety Officer, Health and safety officer, Head of research at Evox Therapeutics, and a contracted Safety consultant and staff representatives. All members have at least 10 years of biological laboratory experience, and some of whom have over 10 years industrial level BSL2 experience.

The committee will meet at least quarterly.

All liquid waste generated during bacterial culture or will be autoclaved at 121°C and 100kPa, for 15 minutes. The sterile liquid will be disposed to drain. All liquid waste generated during mammalian cell culture will be treated with 1% Virkon (or equivalent disinfectant used at the manufacturer's recommended concentration) for a minimum of 4 hours, then disposed to drain. No more than 10L of either culture will be generated per week.

All solid wastes generated will be disposed of via a special waste contractor (Grundon) and sent for incineration or alternative treatment. All sharps will be placed into sharps containers and removed via the special waste contractor for incineration.

Members present:
Justin Hean (Biosafety Officer) Over a decade of experience in academic and industrial and academic BSL1 and BSL2 labs.
David Virley (Head of Research) 15+ years experience in BSL2 research within an industrial setting.
Mark Thornton (H&S Officer) 15+ years experience in BSL2 research within an industrial setting.
Sharon Wood (H&S experienced consultant)

Members of the committee were satisfied with the BSL1 risk assessment. Sharon Wood noted to define the parameters of liquid waste treatment – Virkon 1% final concentration for 4 hours.
The use of retroviral and lentiviral vectors to facilitate transgene expression in mammalian cell and tissue culture systems.

Purposes of the contained use

Here, we aim to generate stably expressing cell lines using 3rd or higher generation lentiviral or retroviral transduction systems. The cell lines may be of common commercial, academic or primary origins. The stable cell lines will express fusion proteins which generate exosomes and extracellular vesicles enriched with therapeutics proteins of interest.

Recipient or parental organism

Both parental (viral progenitor cell line) and recipient (transduced cell line) are auxotrophic cell lines and is deemed extremely unlikely for the cells to survive within the environment. Cell lines are sourced from commercial or academic sources, and where possible, are deemed fit for use under containment level 1. Where appropriate, cell lines requiring containment level 2 will be cultured and treated according to the associated CBAl notification.

Host/vector system

Plasmid DNAs will be transfected into mammalian cells to facilitate the production of retroviral and lentiviral particles. The packaging cell lines are of murine or human origin and are well characterised and obtained from academic or commercial sources. The inserted viral sequences permit the production of retroviral and lentiviral particles. The viral sequences are not expected to have harmful physiological or pharmacological properties or to affect pathogenicity of the packaging cell
The viral sequences are from either HIV, SIV, FIV, EIAV or other commonly used retro- or lentiviruses. Wild type EIAV is a specified animal pathogen however in this system deletion of a number of genes (52, tat, and rev) renders the particles replication defective and recombination events could not replace the deleted genes. This makes the virus unable to cause a productive infection and therefore not pathogenic.

Third or later generation lentiviral systems will be used, incorporating a self-inactivating 3' L TR (SIN) U3 deletion. These systems typically utilise 4 or 5 separate plasmids; one encoding viral gag and pol, another (where necessary) encoding viral rev and one or two plasmids encoding the envelope protein(s). These together with the recombinant viral 6 genome, containing the insert of interest (for over expression or silencing) are transfected into the packaging cell line, typically 293T or similar cells, enabling the production of replication defective, infective particles. The recombinant viral genome may be constructed with or without the Polypurine Tract (cPPT) and/or the Woodchuck Posttranscriptional Regulatory Element (WPRE) or similar sequences to enhance expression levels of the insert and/or viral titre. Envelopes that facilitate transduction of a wide range of cell types will be used including the commonly used ecotropic and amphotropic envelopes (Morgan et al., 1993, Journal of Virology 67:4712), VSV-G envelope (Emi et al., 1991, Journal of Virology 65:1202), the SeV/HN/SeV-F envelope system that has similar tropism to V5V-G (Kobayashi et al., 2003, Journal of Virology 77:2607) and baculovirus GP64 envelope that has similar tropism to V5V-G (Kumar et al., 2003 Human Gene Therapy 14:67).

Origin & function

Genetic material is derived from commercial sources or is synthesised through appropriate vendors, (such as IOT). Where deemed necessary, genes, expression cassettes or open reading frames are subjected to codon optimisation technology through appropriate online vendors.

Genetic material encoding exosome enrichment factors - sequences are derived from either mammalian or viral sources. Expression products are demonstrated to enrich within the endosomal/exosomal pathway, thus associate with exosomes and extracellular vesicles. As part of the fusion technology, these components are responsible for driving the enrichment of therapeutic products into exosomes and extracellular vesicles. Sequences, their derivatives and products are deemed non-harmful to humans and the environment.

Genetic material encoding investigative tools - These sequences may originate from a variety of sources, e.g. eGFP from Aequorea victoria and Luciferase from Phytinus pyralis. These tools are frequently used in molecular biology assays to determine exosome loading efficiency, cellular uptake efficiency and biodistribution studies. Sequences, their derivatives and products are deemed non-harmful to humans and the environment.

Genetic material encoding therapeutic products - In most instances, therapeutic product sequences will originate from Homo sapiens, however in some instances other mammalian sequences may be used (where sequence homology appropriate). Furthermore, therapeutics sequences may be derived from viruses (albeit unlikely). Following the exosomal enrichment of the therapeutic product via its fusion with the endosomal enrichment factor, application of the purified, loaded exosomes induces a cargo dependent response in recipient cells. Again, as the loaded proteins would be deemed of therapeutic in nature, their sequences and/or derivatives are considered non-harmful to humans and the environment.

Evaluation of foreseeable effects

The retroviral and lentiviral particles produced will have a broad tropism and be capable of infecting and transducing human and other mammalian cells, inserting viral and mammalian and/or reporter gene sequences (see below) into the host genome. This is an anticipated risk associated with the use of retroviral and lentiviral gene transfer vectors. The viral particles have however been rendered non-replicative by a number of safety features:

1) The viral genomes are self-inactivating, carrying a deletion in the U3 region of 3’ L TR. During integration into the host cell genome, the viral 3’ L TR is copied to the 5’ of viral genome rendering it transcriptionally inactive and unable...
1) To function as a replicative retroviral genome.
2) The viral genome does not contain any of the viral packaging or structural genes necessary for viral replication.
3) The viral packaging and structural genes factors necessary for viral particle production are supplied in the producer cell line in trans, either by the producer cell line itself or by co-transfection with packaging plasmids. Regions of homology (e.g. LTRs or packaging sequences) in the viral particle genome have been minimised to eliminate undesirable recombination events that could lead to the generation of replication competent virus (RCV).
4) In the case of lentiviral vectors, the viral particle genomes contain exogenous promoter sequences to permit transgene/RNAi factor expression. This allows viral tat gene, essential to wildtype lentiviral replication, to be completely eliminated from the packaging system. Thus no RCV can be produced.

Consequently, only retroviral and lentiviral particles which are unable to replicate, but which can deliver the transgene/RNAi insert of choice will be produced. These viral particles cannot contain additional viral genes as their sequences lack the LTR or packaging sequences necessary for their sequences to be incorporated into the viral particles.

Accidental human exposure to viral packaging cells carries minimal risk as the inserted sequences are not expected to affect the pathogenicity of the cells. It is anticipated that any cells would be rapidly cleared by the complement/immune system of any exposed individual.

Accidental human exposure to viral particles could lead to viral infection and the insertion of viral and mammalian and/or reporter gene sequences into the host genome. Importantly, in the context of human gene therapy clinical studies, high doses of retroviral and lentiviral vector particles have been administered in vivo with no observed complications. However, in the worst case scenario, integration within a tumour suppressor gene or the biological activity of the integrated sequences could lead to the generation of a tumour. Indeed, leukaemia-like tumours have been observed in a small number (~10%) of individuals infused with bone marrow stem cells that had previously been treated ex vivo with retroviral vectors. Despite these observations it is considered highly unlikely that accidental human exposure to the viral particles described in this risk assessment would lead to the generation of a tumour. Major differences between the described worse case scenario and any accidental exposure exist including large differences in transgene/host interactions, likely exposed viral particle numbers, in vivo rather than ex vivo delivery route, consequent exposure of viral particles to complement/immune system, likely access to relevant precursor stem cells and immune status of individuals involved.

Consequently, it is not anticipated that accidental human exposure to viral particles is associated with significant risk. However, given the nature of some of the mammalian gene sequences (discussed above), gene transfer could be hazardous.

The viral particles are infectious but cannot replicate. There is no evidence for vector transmission. The consequence of the hazards being manifest is considered to be low and the likelihood of manifestation is low when containment assigned above is taken into account. In all cases, taking into account the control measures assigned, the overall risks to the environment from the genetically modified micro-organisms produced in this work is effectively zero. Therefore no additional containment or control measures are considered necessary to protect the environment other than those described to protect human health and safety.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-1300°C for at least 10 minutes or 134-1380°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration or alternative treatment.

Liquids (e.g., bacterial and mammalian culture media, culture supernatants, viral samples) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-1300°C for at least 10 minutes or 134-1380°C for at least 3 minutes), or disinfect with 2% Virkon for at least 30 minutes, discharge to drains.

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-1300°C for at least 10 minutes or 134-1380°C for at least 3 minutes), or disinfect with 2% Virkon for at least 30 minutes, discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration or alternative treatment.

Degree of kill
- Autoclaving, effectively 100% kill (annual validation)
- Incineration, effectively 100% kill (licensed incinerator)
- Chemical disinfection with Virkon, used according to manufacturers instructions under standard conditions, manufacturers validation [e94.79] 109 reduction (log 99.998)% kill.

Members present: Justin Hean (Biosafety officer), Mark Thornton (H&S officer), Sharon Wood (H&S consultant).

Members of the meeting were satisfied with the risk assessment and CU2 notification.

Sharon Wood further noted to confine agar plate waste disposal to autoclaving, incineration and alternative treatment.

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities: Y

Give brief details of the genetic modification safety committee:

The Directors of Biomakespace Ltd have appointed a Safety Committee (SC) which is responsible for reviewing and providing advice on contained use risk assessments to the management. The SC consists of the Biological Safety Officer (BSO), two Directors of Biomakespace Ltd, and any additionally appointed Deputy Biological Safety Officers with relevant expertise as necessary. Principal investigators are required to submit risk assessments to the SC, who will review and provide advice on adequacy of the risk assessment. The BSO will integrate this advice into the risk assessment, approve or not and give final advice to the person responsible. The members of the SC represent a balance of experienced scientists, management, and lab users. The committee members include individuals with extensive postgraduate biological research experience. The BSO, particularly, has an extensive background working in class 1 and 2 contained use settings.

Through partnerships with local universities and other scientific institutions, the SC has access to a wide range of experts from who are willing to provide advice on risk assessments for contained use. In particular, we have sought specific advice from the Biological Safety Officers of the School of Clinical Medicine and the Department of Pathology at the University of Cambridge.

All wet lab users with GM projects receive an induction detailing the procedures for the handling and containment of GMOs, and this includes a section on waste management and monitoring measures. These procedures are regularly reviewed and updated by our internal safety committee, and also by external review by competent assessors and are detailed in our Biological Safety Policy. Compliance is enforced by the BSO with the full support of the management.

According to established practice all waste (solid and liquid) that have come into contact with GMOs are decontaminated by one of two means, dependent on the risk assessment:

1) Disinfected by Virkon according to manufacturer’s instructions. According to manufacturer’s testing this provides 99.999% kill efficacy using a wide variety of contact times, temperatures and organic challenge levels that are consistent with the organisms and conditions proposed.

2) Autoclaved at 121 C at 15 psi for at least 15 minutes with effectively 100% kill. Autoclaving is performed within the laboratory suite and the autoclave is tested annually to ensure that it is functioning to the manufacturer’s specification, and this is done in two ways, firstly using a programmed pressure/vacuum test is run and secondly autoclave test strips are used to ensure that the necessary temperature has been obtained. The results of these tests are recorded in a log book. A back-up autoclave is also available on-site.

These requirements are codified in our policies and SOPs and all lab users are required to follow them strictly.

Surfaces, worktops and equipment that may have come into contact with GMOs are cleaned with 1% Virkon solution before and after a protocol is performed, as per manufacturer’s instructions.

In the case of unanticipated spillages and similar accidents in the lab, the spillage will be covered with Virkon powder, left for three minutes, scraped into a safe receptacle and the area washed with 1% Virkon as per manufacturers instructions and as detailed in the Biological Safety Policy.
The Safety Committee reviewed the risk assessment and asked for further detail in terms of the project proposed. Following submission of these details they approved the risk assessment and approved the level of contained use and procedures described.

Waste disposal will be carried out according to an SOP. All solid waste is to be autoclaved before disposal carried out via Imperial College Innovation & Translation Hub central facility by incineration using a licenced outside contractor. All liquid waste is disinfected using a commercially available proprietary disinfectant solution and following the manufacturers instructions for maximum kill. Non-disposable labware is disinfected and washed prior to re-use. All spills to be cleaned using proprietary reagents e.g. spill kits. No further monitoring is deemed necessary due to the low/zero hazard presented by the GMM involved.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

For activities involving GMMs, describe the waste management measures which will apply to the activity

The disposal of waste was discussed, and the committee made aware of the use of Virkon as the disinfectant of choice. No other comments.

Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities  

Give brief details of the genetic modification safety committee

Advice on the contained use has been provided by the Biological Safety Officer of Talisman Therapeutics. The BSO has experience in assessing the risk of GMOs and carrying out GMO work. The BSO has a track record as postdoc of planning, supervising, managing and assessing the risk of GMO work. Additional advice has been provided by the Chief Scientific Officer who is also a research group leader at the Gurdon Institute of the University of Cambridge and has a long-standing track record in planning, supervising and assessing the risk of GMO work. Additionally, a GMO committee has been formed at Talisman Therapeutics consisting of the BSO, Talisman's Head of Research and the Health and Safety Officer. The GMO committee convenes quarterly or more frequently if required. It provides advise on risk assessment, organises training, reviews and updates local rules and ensures compliance with regulations.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Liquid waste is inactivated by autoclaving using an autoclave in the same building. Liquid waste is transported to the autoclave using secondary containment. For GMM inactivation a 'liquid cycle' at 121 degree Celsius for 15 minutes is used. Waste treatment by autoclaving ensures practically 100% inactivation. Inactivated liquid waste is then disposed of via the lab sink. The autoclave is serviced and maintained annually to ensure it is in proper working order. We propose to inactivate solid plastic waste by incineration (details are provided below).

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The GMO committee has reviewed the company's GM procedures and the risk assessments performed. The GMO committee confirmed the work to be carried out is Class 1 and were satisfied with the assessment of risks to both human health and the environment. The control and containment measures in place are appropriate for class 1 activities.

Y

Give brief details of the genetic modification safety committee

Discussions have taken place with a Biological Safety Officer (Level 1 Biosafety Practitioner and M-ISTR) from the Norwich Research Park. Discussions included classification of GM work and appropriate containment measures that should be employed and risk assessment of work activities.

Further advice has been taken from other members of the Biological Safety Committee from the Norwich Research Park, all possess the appropriate knowledge, experience and training in the scientific area in question.

The risk assessment has been reviewed and it has been agreed to be appropriate and provides sufficient assessment of the risks relevant to the activities being undertaken.

Containment Measures and disinfection routes. M15 Specified disinfection procedures in place. REQUIRED where and to the extent the risk assessment shows it is required. For small volume spills, 70% ethanol will be used to disinfect. Larger volume spills 50 ml-2 L, paper towels for absorbing the liquid and then wipe down with 70% ethanol. Paper towels can be autoclaved. Containing larger volume spills will depend on the surface type and surface area of the spill. 2-10 L, a specified sponge and mop & bucket will be in place to absorb liquid. The liquid will be treated with a Virkon (to 1-2% w/v; NB any liquid with Virkon will not be autoclaved as it can produce sulphur dioxide gas upon heating) or a hypochlorite compound to manufacturer's validated specifications (this varies depending upon the product; such as Virkon, hypochlorite solutions will not be autoclaved). The mop, sponge and bucket once rinsed can be autoclaved and re-used. The large spills from fermenter leakage, 10-50 L, will be treated similarly, but the potential spill area will be limited by rubber strips surrounding the fermenter. All treated liquid will be stored for 24 hours before disposal.

Fermenters and dyeing machinery will have disinfection routines as per manufacturer's specifications. Normally this is equivalent to internal autoclaving.

NB: Disinfection is defined as 10^5 reduction in live organisms (i.e. 99.999% kill).

Result: CL 1

Waste handling
M16 inactivation for handwashing effluent NOT REQUIRED
M17 inactivation of microorganisms in contaminated material (see above)

As the recombinant microbes will be Hazard Group I organisms, after inactivation via validated means (e.g. 1-2% Virkon, 70% ethanol or autoclaving at the previously validated regime(s); see above) the disinfected material can be disposed of as non-hazardous waste

Autoclave - Any solid waste (paper towels, mop, bucket, etc) will be autoclaved on a validated cycle to ensure complete inactivation of any microbiological material. Media containing bacterial cultures will be inactivated using the same equipment. All autoclave loads will be treated at 121 C for a minimum of 20 minutes, but the length of the cycle will be dependent on the validation that is performed. For denser loads the length of time is likely to be increased to 30 minutes. The cycle will be validated to ensure that the kill requirements have been achieved before operation.

Controls (procedural and system) exist to ensure loads are processed to the required settings (time, temperature and pressure).
Please enter comments of the GM safety committee on the risk assessment

Give brief details of the genetic modification safety committee

Nuclera's genetic modification safety committee comprises the company's CTO and CCO. The CTO has 6 years of experience working with level 1 GMMs and the CCO has 10 years of experience working with level 1 GMMs. The CTO and CCO have performed risk assessments of level 1 GMM work primarily in academic environments.

Project Additional Information

Purposes of the contained use

To produce viral vectored vaccines against infectious diseases and cancer by insertion of transgenes into vector backbones and testing immunogenicity of these vectors.

Recipient or parental organism

1) MVA (modified vaccinia virus Ankara). This highly attenuated orthopox virus is not capable of replication in mammalian cells, except for baby hamster kidney (BHK) cells. MVA will only replicate in chicken embryo fibroblasts (primary CEF, or DF1 cell line) or BHK cells. MVA is not capable of causing an infection in humans or animals, although it will transduce human and animal cells (i.e. the virus will enter the cytoplasm of a cell and express the recombinant protein, but no infectious viral particles can be produced).

2) replication-deficient adenoviruses of human or simian origin. These viruses have been made replication-deficient by removal of the E1 gene and can only replicate in cell lines that express E1. The E3 gene has also been deleted. The vector is therefore not capable of causing an infection in humans or animals, although it will transduce human and animal cells (i.e. the virus will enter a cell and express the recombinant protein, but no infectious viral particles can be produced).

Host/vector system

see above. MVA or adenovirus, produced in MVA-producer cells (CEF or DF1) or adenoviral producer cells (HEK293 derivatives)

Origin & function
commercially synthesised DNA encoding human cancer antigens, specifically, cancer-testis antigens (CTA), for example of the MAGE family. The Melanoma Antigen Gene (MAGE) protein family is a large, highly conserved group of proteins that share a common MAGE homology domain. A subset of these >40 human proteins are classified as cancer-testis antigens (CTA), and are aberrantly expressed in cancer where they can be immunogenic. MAGE-A3 expression may promote tumorigenesis and can cause transformation of fibroblasts ex-vivo. However, oncogenesis is a multistep process requiring mutations in more than one gene; the cell becoming more tumorigenic as the changes accumulate. A single event, such as the overexpression of one gene, is unlikely to result in oncogenic transformation.

Evaluation of foreseeable effects

All our viral vectors are classified as group 1 agents, so it is only the insertion of certain antigens that will elevate them to group 2 agents. We believe that the above-named cancer-testis antigens (CTA) qualify as group 2 agents. It is conceivable that they might contribute to a cancer phenotype (i.e. oncogenesis) when expressed in normal tissue.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid and liquid waste to be decontaminated by soaking for 2+ hours in a 1% Virkon solution, which has been shown to kill poxviruses and adenoviruses. Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration. Liquids (eg samples, culture supernatants, tissue culture media) – autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge to drains. Degree of kill: 100%

**Project Additional Information**

**Purposes of the contained use**

To generate candidate viral vector vaccines.

**Recipient or parental organism**
To produce plasmids, the recipient micro-organisms will be derivatives of the K-12 strain of E.coli e.g. DH 1 DB and DH5alpha. To produce viral vectors, the recipient cell lines will be those suitable for the production of Adenoviral and Modified Vaccinia virus Ankara (MVA) viral vectors: For adenoviral production, these include HEK293 cells and TR293 cell lines and for the production of MVA, these include DF1 and CEF cells.

**Host/vector system**

Adenoviral Vectors e.g. ChAdOX1

Vaccinia viral vectors e.g. MVA

**Origin & function**

The DNA constructs are either a pUC-based shuttle plasmids (encoding a mammalian antigen expression cassette and/or reporter gene), or a (bacterial artificial chromosome) which encodes all or part of elements of the viral genome including a mammalian antigen expression cassette. The producer cell lines express genes that can facilitate the packaging of the viral vectors after transfection/infection with the necessary components. The wildtype MVA viral genome and the MVA shuttle vector containing the recombinant antigen plus a reporter gene, recombines with the viral genome inside the cytoplasm of the cell, by means of a single cross-over event between the plasmid and virus genome. Recombinant viruses can be identified by the expression of the marker gene, which is a fluorescent protein. Further passaging of the virus allows a second recombination event to occur, which deletes the marker gene from the recombinant virus genome and permits the isolation of recombinant viral vectors encoding the antigen cassette.

Antigens encoded in the EVA fusion protein constructs, are previously undiscovered polypeptides that are encoded by previously uncharacterized RNA molecules. These proteins are elements of proteins that are specifically upregulated in human cancer tissues and designed to illicitate an immune response towards tumour cells when delivered as a viral vector.

**Evaluation of foreseeable effects**

MVA (modified vaccinia virus Ankara) is a highly attenuated orthopox virus, and is not capable of replication in mammalian cells, except for permissive cell lines. MVA will only replicate in restricted cell types e.g. chicken embryo fibroblasts. MVA is not capable of causing a symptomatic infection in humans or animals, although it will transduce human and animal cells (i.e. the virus will enter the cytoplasm of a cell and express the recombinant protein (antigen), but no infectious viral particles can be produced). Importantly, MVA cannot replicate in humans. There is a long history of the safe use of MVA and vectors produced on this platform e.g. Unmodified MVA is currently licenced as a third generation smallpox vaccine (Imvanex). Replication-deficient adenoviruses e.g. ChAdOx1 are viral vectors engineered to be replication-deficient by removal of the E1 gene and can only replicate in cell lines that express E1 in trans. The E3 viral gene has also been deleted. These regions of the adenovirus are essential for viral transmission and the vector is therefore not capable of causing any clinical symptoms in humans or animals, although it will transduce human and animal cells (i.e. the virus will enter a cell and express the recombinant protein, but no infectious viral particles can be produced).

There is an unknown hazard from expression of the EVA antigen encoded in these vectors. It is therefore conceivable that toxicity or oncogenicity from either the RNA transcript or the translated polypeptide could result from the antigen expression, although the likelihood is very low. While there is no evidence that the EVAs have any intrinsic biological activity, and thus no evidence that the resulting fusion protein would be oncogenic, the lack of information regarding the function or effect of the antigens on cell growth indicates that a cautious approach should be taken and the
vectors encoding these antigens, should be considered to be potentially harmful until evidence proves otherwise.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Agents will be decontaminated on site using validated methods e.g. Autoclaving or suitable disinfectants (Virkon) prior to disposal through the usual clinical waste routes. Clinical waste is collected by an approved and recognised waste disposal provider e.g. Grundon.

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 deg.C for at least 15 minutes or 126-130 deg.C for at least 10 minutes or 134-138 deg.C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration/dispose of solids.

Liquids (e.g. samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125 deg. C for at least 15 minutes or 126-130 deg. C for at least 10 minutes or 134-138 deg.C for at least 3 minutes) or treatment with a suitable validated disinfectant e.g. Virkon, according to manufacturers specifications. Discharge to drains post inactivation.

Solids - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250C for at least 15 minutes or 126-1300C for at least 10 minutes or 134-1380C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration/disposal.

Degree of kill: >99%

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

There is a theoretical risk of toxicity or oncogenicity arising from the expression of the transgenes, although the likelihood of this is low. While there is no evidence that the EVAs have any intrinsic biological activity, and thus no evidence that the resulting fusion protein would be oncogenic/toxic, the lack of information regarding the function or effect of the transgene on cell growth indicates that a cautious approach should be taken and that the transgene should be considered to be potentially harmful. Based on this, despite the vectors themselves being designated as Hazard Group 1 agents, we recommend that the Vectors encoding the EVA antigens should be designated as Hazard Group 2 agents and therefore handled under CU2 until potential hazards are proven otherwise.

We consider this to be a new program of work separate from the usual Vaccitech programmes. As such, we consider therefore consider this a significant change to current CU2 notification and a new notification is required.

All solid waste is autoclaved in the in-house sterilisation facility and record of sterilisation temperatures are kept. All liquid waste is treated with at least 1% Virkon solution for a minimum of 20 minutes. This has been shown to be effective for E.coli in several tests as evident from the manufacturers data. Autoclaving: Effectively 100% kill at this programme as shown by microbiological testing. Certificated testing of all autoclaves is carried out annually and records are held by the host Cambridge University Department. Printed readouts from each run are retained to ensure temperatures within the autoclave were maintained during the cycle. Liquid waste: Virkon is a total spectrum disinfectant prepared and used as per the manufacturer's instructions. Effectively 100% kill. Routine Disinfection: working surfaces are washed with 1% Virkon solution. Spillage: 1% Virkon solution, or Virkon powder directly. 1% Virkon solution has been shown to effective against the recipient organisms by the manufacturer. All spillages are recorded in a log book.

For activities involving GMMs, describe the waste management measures which will apply to the activity:

Disinfection of liquid waste is carried out using 1-2% Virkon for 10-15 min. In case of spillage, absorb liquid using paper towels or other absorbent material (collect solid waste in biohazard bag). Treat the area for 10-15 min with 1-2% Virkon prior to cleaning and disposal. Alternatively use 70% ethanol when the spill is on a metal surface as Virkon degrades metal. Containment level 2 (CL-2) biological safety cabinets (BSC) are disinfected with 70% ethanol followed by UV treatment for 30 minutes (if UV lamp is installed). Solid waste is collected in biohazard bags and autoclaved. Virkon-treated liquid waste is disposed into sink. Where possible, oil waste will be collected for incineration. Small volumes of oil (<10 mL) containing artificial tissues are collected in a tube. This oil is mixed with Virkon at 1:3 ratio and treated with ultrasonic noise (40 kHz, 15 min) to create a fine emulsion, with biological material exposed to Virkon within the emulsion. The emulsion will be left to stand until phase separated and the aqueous solution is disposed of the down the sink and the oil is collected with standard oil waste which is incinerated.

1) This seems reasonable to me, I am happy with the form.
2) This work appears to have been considered carefully. As long as the previous comments were addressed I am happy with the assessment.
3) No additional comments from me, I’m happy with the assessment and its classification.
4) The only thing I have spotted here is the mention of adding oil samples to Virkon to disinfect the cells. If the cells are surrounded by oil how will the Virkon be able to act on the cells? Is it not better to dispose of these samples via autoclaving/ burn bins? Otherwise I think that this is OK.

(updated to include new oil disposal method- JG, 27-4-18)

### Give brief details of the genetic modification safety committee

The committee consists of two PhD level scientists, employees of Phytoform Labs, with a combined experience of more than 10 years working with cloning and GM organisms. The committee will regularly inspect work areas and advise on improved safety procedures. All new employees will receive inductions and follow on safety information during their employment period. There will be an accident report procedure in place for employees. The committee will meet every quarter to discuss best safety practices and any reported accidents that have occurred.

Both solid and liquid waste will be treated with a confirmed kill procedure. Autoclaving of the liquid and solid material containing GMMs will be performed by a trained person in a serviced, validated autoclave. The autoclave is regularly inspected by third party engineers to ensure serviced functional autoclave that meets necessary conditions for confirmed kill.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Give brief details of the genetic modification safety committee:

The genetic modification safety committee comprises of the VP of Product Development, who also is responsible for ensuring the biosafety of the employees, alongside the Health & Safety Lead for the Laboratories and the Health & Safety representative of the employees. The team has extensive experience in a wide variety of pharmaceutical and biological safety within non-GMP laboratories for over a decade. As per the H&S Standard Operating Procedure (SOP) in-house the genetic modification safety committee meet at least bi-yearly to assess the general H&S implications of handling biological agents within the laboratories. The team assess the COSHH pertinent to the biological agent envisaged to be handled within the Containment Level 2 laboratory prior to commenting on the suitability of the designed procedure outlined in the COSHH as per the in-house H&S SOP document.

Project notified under transitional arrangements

Withdrawn

Historical Significant Changes
**Project Additional Information**

**Purposes of the contained use**

Enesi is performing this work in order to demonstrate that existing vaccines can be formulated into solid doses for use with Enesi's proprietary solid dose injection system. These solid doses are predicted to have improved stability and efficacy over the current product(s).

**Recipient or parental organism**

Examples include Replication-defective vaccinia virus (Copenhagen strain) and Modified Vaccinia Ankara (MVA) propagated in chicken cells, so chicken ("parental organism") - but they're going into mice ("recipient").

**Host/vector system**

Examples include Mammalian cells and specific pathogen-free chicken embryo fibroblasts. Vector is MVA.

**Origin & function**

Examples to such include genes from peanut (Arachis hypogea) associated with peanut allergy, chikungunya and zika virus structural proteins, Discosma sp. fluorescent reporter genes, mouse cytokine and human ubiquitin C as well as the following:

**Origins of MVA:**

MVA is a highly attenuated vaccinia virus developed specifically for use as a "safer" smallpox vaccine. MVA originated from the Dermovaccinia strain CVA, which was used in Germany in the 1950s as a smallpox vaccine. Dr. Mayr and colleagues passaged CVA more than 570 times to attenuate it further. In the process of serial passages in CEF, 9% of the DNA molecular weight of the viral DNA was lost from the original CVA strain and the virulence for mammalian cells was greatly reduced.

**Origins of inserts:**

The vaccine inserts constitute the genetic material that is added to MVA to create the recombinant MVA vaccines. The vaccine inserts encode antigens from the target pathogens. Each of the vaccine inserts was created in vitro using gene synthesis techniques and was then inserted into a plasmid and amplified in E. coli. The purified plasmid DNA from the E. coli cultures was used as the source material for the recombination processes that created the...
recombinant MVAs. The vaccine inserts were designed based on published sequences of the viral pathogens. For Lassa fever, we used the sequence of a well-characterized strain of Lassa virus. For Ebola, we used the sequence of the Makona strain of Ebola virus. For Zika, we used the sequence of a 2015 Suriname isolate.

**Intended functions of MVA:**
The MVA sequences serve to allow replication of the genetic material in cell culture, to allow an abortive infection of the cells of the recipient, to allow expression of the antigen sequences, and to elicit innate immune responses.

**Intended functions of inserts:**
The inserts encode the vaccine antigens, which elicit adaptive immune responses against the target pathogens.

### Evaluation of foreseeable effects

Some typical characteristics include:
Vaccinia virus is considered stable within the environment and has a broad host range. Vaccinia viruses have the potential to infect human cells, however, in the unlikely event of the GMO being unintentionally released into the environment, the likelihood of infection remains low since the virus would require direct contact with a mucosal membrane or an open wound to produce an infection. If this were to happen, infection of healthy individuals with vaccinia virus is generally mild and may include a rash or fever. In most cases, it would be expected that the person's immune response would rapidly clear infected cells and the virus. This work proposes use of a modified Vaccinia virus that is replication-incompetent and unable to produce progeny viruses. Therefore, consequences of infection with this modified Vaccinia are therefore likely to be less severe than with the parental virus and there is little risk of the virus spreading in the environment. Expression of foreign genes inserted into the replication-incompetent vaccinia virus are not foreseen to cause harm but intended to elicit protective immune responses. However, the effects are as yet untested, and persons with peanut allergy are potentially at risk of exposure to allergens.

Additionally, evaluation of foreseeable effects also include:
The foreseeable effects of the proposed research are: (1) the intended effect of generating data on the immunogenicity and efficacy of these vaccines in mice and (2) the unintended effect of generating small quantities of biohazardous waste, which will be disposed of properly.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All operations will be performed by suitably trained personnel within the containment level II laboratory. Appropriate signage warning of the biohazard risk will be placed on all doors to the laboratory. All formulation, manufacturing and analytical activities involving the vaccine will take place in a Cytotoxic Level 2 hood (unless the COSHH assessment indicates more stringent protection is required). All waste material potentially contaminated with vaccine (powder, wipes, gloves etc.) will be double-bagged in clinical waste bags, closed, and sealed in a clinical waste bin for disposal by an approved waste-handling agent. All potentially contaminated surfaces will be cleaned with Klercide Biocide B and either 70% denatured ethyl alcohol (ethanol) (DE) or 70% isopropyl alcohol (IPA) and left to dry. All equipment and parts potentially contaminated will be washed down with Klercide Biocide B and either 70% DE or IPA, or autoclaved at suitable conditions (typically 121°C for 30 minutes at 15 PSI but this will be adjusted for the weight and size of the item) to ensure sterility. All lab users will wash and dry their hands thoroughly before leaving the laboratory. All other lab procedures will be followed as per the Enesi’s Standard Operating Procedure for General Laboratory.
Control.

The risk assessment completed on the GMMs was approved

Give brief details of the genetic modification safety committee

The GM safety committee at the Medicines Discovery Catapult consists of 2 Lead Scientists (PhD, BSc) one of whom is the Biological Safety Officer (BSO) and a Head of Department (PhD). Together, they have >45 years of combined experience in the Academic, Biotech and Pharmaceutical sectors. All 3 have created GM risk assessments in their previous roles at AstraZeneca (AZ). Two of the 3 were Departmental representatives at AZ's internal GM Safety Committee charged with reviewing and aproving GM risk assessments. In addition to this internal expertise, MDC has retained the services of an exetrnal Safety Consultant Specialist who has lead the development of risk assessment process for GMO organisms and who has lead AZ's GM risk assessment committee.

Upon creation of a GM risk assessment by an MDC scientist, the GM committee will review then challenge or approve (as required) the proposed risk classification. Upon subsequent formal approval, the MDC scientist may commence the associated activities. GM RAs will then be indexed, stored and periodically reviewed. At each quarterly MDC H&S committee meeting, GM risk assessments are a standing agenda item. The BSO is a permanent member of the MDC H&S group and acts as the link to the GM risk assessment committee.

All liquid cell culture waste will be disposed of by mixing with Virkon to maintain an active concentration of >1%. This has become an accepted standard disposal measure. Liquids are left at room temperature for at least 6 hrs prior to discard. The manufacturer's website gives details of the application range of Virkon.

For activities involving GMMs, describe the waste management measures which will apply to the activity

- Consequences of exposure are low given the confined replication status of the vector and the low cytotoxicity nature of the expressed RFP protein.
- The likelihood of exposure in the laboratory setting is low given the procedures used, PPE for the operator, low volumes used and the complete absence of sharps.
- Viral titres of less than or equal to 5 x 10^6 per ml will be used
- As the consequences of RFP expression in humans have not been specifically addressed, the effect of transgene expression is uncertain.
- While it is possible that unwanted integration event could change the oncogenic potential of the affected cell, the control[s] in place make this event a low probability occurrence.
The aim of this project is to produce lentiviral particles in order to genetically modify mammalian cell types including but not exclusive to induced pluripotent stem cells (iPSC), iPSC-derived microglia, astrocytes and neurons, primary cells including but not exclusive to neurons, astrocytes, microglia and endothelial cells and cells lines including but not exclusive to SH-SY-5Y, A549, U87, PANC1, U2OS and BT474. The lentiviral particles encode reporter proteins either in response to activation of a signalling pathway or constitutive expression for whole cell labelling. A selectable marker gene, puromycin N acetyltransferase (PAC), will be co-expressed. These reporter cells will allow the operator to monitor and analyse morphological/signalling changes in response to injury or compound treatment via microscopy/quantitative plate based assay (luciferase). The inclusion of the puromycin resistance gene allows for selection and expansion of cells that have been transduced and are stably expressing the transgene cassette. Lentivirus technology is the most appropriate method for generating stable cell cultures in difficult to transfect cells. Lentivirus offers long term expression, which is required to monitor cells over a period of weeks or months. Moreover, lentivirus often infects with high efficiency which is also important as it can be difficult to generate large numbers of primary/iPSC derived cell types.

Recipient or parental organism

Recipient- Mammalian cells: HEK293T ATCC ® CRL-3216 iPSC-derived microglia, neurons and astrocytes as well as primary neurons, astrocytes, microglial Mammalian cell lines (e.g. BT474, U2OS, PANC1, A549, SH-SY-5Y, U87) The commercially available 293T cell line is a highly transfectable derivative of human embryonic kidney 293 cells, containing the SV40 T-antigen and is recommended for use when generating lentivirus particles. The main function of the SV40 T antigen is to facilitate increased expression of transgene of viral plasmids with an SV40 origin of replication by retaining/replicating plasmids in the cell after a transfection (although this is transient). This will in
Plasmids (obtained from Aldevron): pALD-GagPol (cat 5043), pALD Rev (cat 5033), pALD VSV-g (cat 5037). Derivative of pALD-LentiEGFP (cat 5031) (modified to encode reporter cDNA/PAC) The vector system is lentivirus production via plasmid transfection and the particles will be produced in HEK293T cells, only cells that receive all four plasmid will produce viable infectious particles. We intend to use the third generation lentiviral vector as this is considered the most safe available system although lower viral titers are expected than second generation. To increase the safety of the lentivirus, the components for viral packaging and production are split across separate plasmids; VSVg, Gag-Pol, Rev and the transfer plasmid containing the transgene of interest (reporter and puromycin resistance gene (PAC)). The VSV-g plasmid encodes the envelope of the virus and is broad spectrum so can infect many cell types. Gag antigens form the viral core structure, Pol encodes reverse transcriptase and pol and Rev facilitates the export of transcripts to the cytoplasm. The transfer plasmid contains reporter cDNA and PAC, under the control of a constitutive native mammalian promoter, EF1α or a minimal promoter to monitor signalling pathway cascades. The transgenes are flanked by long terminal repeats (LTRs), which are identical sequences of DNA that repeat and are necessary for viral integration into the genome. The transfer plasmid also contains the packaging signal for packaging into the viral genome. Plasmid DNA encoding the essential genes to produce functional virus will be transfected into 293T using standard lipid-based method (Lipofectamine 3000). The packaging and envelope plasmids are purchased commercially (Aldevron - pALD GagPol, pALD VSV-G, pALD Rev). Successful transfection of all 4 plasmids into a cell will result in the transient production of lentiviral particles that are isolated from the spent tissue culture media.

Origin & function
Lentiviral packaging plasmids are derived from the HIV-1 lentiviral genome and are required for the production of replication deficient viral particles with a broad tropism. The transgenes contained within the infectious lentiviral particles produced are luminescent and fluorescent proteins including but not exclusive to green fluorescent protein (GFP) and mCherry, a red fluorescent protein isolated from Discosoma sp.(derived from 'DsRed') and luciferase. GFP, isolated from Aequorea victoria, is a widely used reporter protein, exciting at 395nm and emitting at 509nm. mCherry is a widely used reporter protein that is highly stable and rapid to mature and is not known to cause toxicity (Shaner et al, 2004, Shemiakina et al, 2012). mCherry absorbs light between 540-590nm and emits light in the range of 550-650nm. Luciferase, a widely used quantitative enzyme that is responsible for the bioluminescence of fireflies and click beetles, will be expressed downstream of a relevant minimal promoter.
promoter to track cell signalling changes. The enzyme catalyses the oxidation of luciferin in the presence of ATP and oxygen. The inserted enzyme is not known to cause photodynamic toxicity in cancer cells (Schipper, Patel and Gambhir, 2006).

The above reporters will be used to either track whole cells in co-cultures by fluorescence microscopy or quantify intracellular signalling events in response to a compound or other stimuli (luciferase).

The other transgene encoded within the reporter cassettes, PAC, confers resistance to puromycin, an antibiotic toxic to eukaryotic cells. PAC is a bacterial enzyme produced by Streptomyces A and has been purified and characterised (Vara J. et al, 1985). PAC inactivates puromycin by acetylating the amino position of its tyrosinyl moiety. Having this gene co-expressed with mCherry, allows rapid selection of microglia harbouring the transgene cassette as all microglia that have not been transduced will die off upon exposure to puromycin.

Evaluation of foreseeable effects

The recombinant viral vectors do not have any regulatory or accessory genes ensuring that the particles produced cannot replicate. Although the VSV-G confers a wide tropism meaning a wide range of cell types can be infected, Evaluation of foreseeable effects confers a wide tropism meaning a wide range of cell types can be infected, the replication deficient properties of the lentivirus renders the risk minimal to human health. Control measures in place (containment within class II biological safety cabinet, secure access laboratories, absence of any sharps in the procedures and disinfectant processes) are appropriate to mitigate any risk associated with generating lentivirus. The transgenes encoded within the virus do not interfere with the properties of the virus.

Genetic modification of mammalian cells with reporter lentivirus produced is not expected to alter the properties or characteristics of the cells. The reporter proteins or PAC should not interfere with any of the cells endogenous pathways or induce toxicity (Sheminkina et al, 2012, Schipper, Patel and Gambhir, 2006).

Effects to human health - It is unlikely that the inserted genetic material will
have any direct consequences on human health as transduction and
eexpression of the transgene is restricted to microglia. A drawback to the
lentiviral system is that it is not possible to control the site of integration of
the vectors as lentivirus does not integrate into a safe harbour site. There is a
small chance that the integrations may cause insertional mutagenesis, a
process by which genes close to the integration site are deregulated. It is
possible that an oncogene may be switched on the proliferation or function of
the cells may be altered. However, this poses little to no risk to human
health, only to the recipient cell line which will be decontaminated and
discarded if an obvious change in cell cycling occurs. GM cells will be
monitored for their proliferation rate and that they maintain their regular
phenotype and function.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All lentivirus production and transduction will be performed in a class II ducted biological safety cabinet
within access controlled laboratories. Liquid waste (cell media) be produced during the lentivirus production process, maximum of 100ml.
Contaminated liquid waste will be decontaminated with Virkon™ S tablets to maintain an active concentration of 2% (supplemented with water). Virkon™ S tablets are
known to be effective against HIV-1 and it is non-corrosive and non-bleaching (if used correctly). Liquid waste will be left at room temperpature for 2 hours before disposal
down the sink. HEK293T cells that are used to produce the virus
temperature for 2 hours before disposal down the sink. HEK293T cells that are used to produce the virus
will also be incubated with Virkon™ S tablets in the flask prior to discarding down the sink also
Solid waste (from flasks, tubes etc) will be produced during the procedures. Contaminated solid waste
will be decontaminated with Virkon™ S tablets to maintain an active concentration of 2%
(supplemented with water) and will be left at room temperature for 2 hours before final disposal in a
clinical waste bin destined for autoclave followed by incineration.
All cells transduced with virus will be tested one week post transduction to ensure they are not
producing any viral particles (p24 viral capsid ELISA assay) (in media).

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

Please enter comments on the GM safety committee on the risk assessment
This risk assessment is sufficient to address the risks associated with retroviral vector production for the assessment of mammalian cells. The classification as a CLASS 2 activity is appropriate given the scale of vector production and use proposed (upto 100ml) and therefore the corresponding requirement to minimise aerosol formation in order to fully protect human health.

**Project Additional Information**

---
Purposes of the contained use

1) As primary cells reach senescence after a limited number of population doublings, cell immortalization is presented as a promising option to solve this problem. In this way, our purpose is to immortalise primary human NK cells by human Telomerase Reverse Transcriptase (hTERT) expression in order to establish a new NK cell line.

2) The second part of the project consists on the generation of a more efficient NK cell line. It is known that NK cells activation is determined by the balance of inhibitory and activating receptor stimulation. In this study, our purpose is to knock down two inhibitory NK receptors by CRISPR/Cas9.

Thereby, the final objective of this project is to generate a more active immortal NK cells, which would be tested as a powerful treatment against cancer.

Recipient or parental organism

Host/vector system

1) NK immortalization:
Vector: human Immunodeficiency Virus (HIV) - Lentivirus Expression System (Lenti-CMV-hTERT-GFP-2A-Puro Virus from abm (Cat# LV623)
Host: Peripherial blood CD56+ NK cells from Allcells (Cat# PB012F)

2) NK cells knock down:
Vector: Third generation lentiviral transfer vector from Oxford Genetics. CRISPR/Cas9 system. Single guide RNA (sgRNA) targeting the killer cell lectin like receptor (KLRC1) and LeukocyteImmonogobulin like receptor B1 (LILRB1) genes.
Host: NK cells

Origin & function

1) The most recently discovered approach to cell immortalization is through the expression of Telomerase Reverse Transcriptase protein (TERT), particularly for cells that are most affected by telomere length, such as human cells. This protein is inactive in most somatic cells, but when hTERT is exogenously expressed, the cells are able to maintain sufficient telomere lengths to avoid replicative senescence. Analysis of several telomerase immortalized cell lines has verified that the cells immortalized by hTERT over expression maintain a stable genotype and retain critical phenotypic markers. In this way, in this project human TERT protein will be overexpressed in primary peripheral blood NK cells using a lentiviral system, so NK cell senescence is expected to be blocked and its replicative capacity increased.

2) The modification of NK cells by knocking down two of its inhibitory receptors is planned to be developed by the CRISPR/Cas9 method using a third generation lentiviral transfer vector. This system is intended for the expression of a specific single guide RNA (sgRNA) along with the Cas9 protein in a target human cell. In our case, the sgRNAs will be targeted to the Killer cell lectin like receptor (KLRC1) and Leukocyte Immunogobulin like receptor B1 (LILRB1), which will allow the Cas9 protein to cut the DNA at the KLRC1 and LILRB1 locations. On the one hand, KLRC1 gene encodes the Natural killer cell receptor NKG2A protein, which pairs with CD94 to form a heterodimer that recognizes the nonclassical MHC class I molecule, HLA-E, in humans. On the other hand, LILRB1 encodes LIR-1 protein that normally binds to a wide range of MHC-I alleles, being the strongest MHC-I ligand, HLA-G. In this sense, the natural function of both is to induce tolerance against self blocking the killing activity of NK cells when they bind to their target antigens.

In brief, the intended functions of the genetic material involved are to increase the proliferative capacity and to reduce the stimulation of the inhibitory signals of the NK cells, thus generating an infinite source of active NK cells.

Evaluation of foreseeable effects

A) Lentiviral Expression Systems include the following safety features to ensure lack of Replication-Competent Lentivirus (RCL):
• An enhancer deletion in the U3 region of 3′LTR ensures self-inactivation of the lentiviral vector following transduction and integration into the target cell's genomic DNA
• The number of lentiviral genes necessary for packaging, replication and transduction is limited
to three (Gag/Pol/Rev), and their expression is derived from different plasmids, all lacking packaging signals. These plasmids share no significant homology to the expression vector, thus preventing the generation of replication-competent virus by recombination events.

- None of the Gag, Pol, or Rev genes will be incorporated into the packaged viral genome, thus making the mature virus replication-incompetent.

In this sense, the risks during lentivirus transduction of target cells are minimized, because a virus can then efficiently transduce target cells but, once the transduction has taken place, the virus cannot produce new virions.

B) In the theoretical case that the immortal and modified NK cell would reach the worker’s bloodstream the cells would be recognised as “non-self” by the immune system and eliminated. However, there is a low risk of these cells escaping the immune system and becoming a threat to the individual. The principal route of transmission of GM NK cells to laboratory workers bloodstream is by inoculation. Therefore, use of sharps will be prohibited. Other possible routes of transmission, including inhalation, ingestion and eye splashes, are less likely to happen because of the use of good laboratory practices and personal protection equipment.

Consequently, we would evaluate the risks of working with the GMO as medium/low.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Celixir has planned a waste disposal program which consists on:

1) The solid waste will be placed in a double-bagged bin with a lid and once full, it will be sealed and placed in a sure locking system with a permanent hermetic seal bin.
2) The liquid waste, such as culture media or supernatants, will be aspirated by the vacuum system to the Vacsax (3L) until it is ¾ full. Then, Vacsax is closed, shaken, to achieve it becomes jellified, and placed in a sure locking system with a permanent hermetic seal bin.
3) Properly closed sure locking systems with permanent hermetic seal bins will be autoclaved by a safe-cycle of 126°C for 20 minutes.
4) The external waste management contractor, Initial, will finally collect the waste for their incineration.

Autoclaves will be validated by annual thermocouple mapping and each run will be monitored by recording of the temperature/time profile.

Degree of kill
- Autoclaving, effectively 100% kill
- Incineration, effectively 100% kill

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
A Genetic Modification Safety Committee was created and the first meeting was focused on discussing the Use of Lentiviral system for human cell transduction Risk assessment. The main comments were:
1) To emphasize what people are at risk - Staff, cleaners, engineers.
2) To specify the use of personal protective equipment - To use lab coat and gloves that comply with regulatory rules to work with virus, and it was recommended to use different colour lab coat and gloves from the rest of activities.
3) Waste management - The external contractor to be validated
4) To create and Standard Operating Procedure (SOP).

Then, an SOP explaining the use of the Containment Level 2 room in Celixir Laboratories has been created and it is also attached to this notification.

Give brief details of the genetic modification safety committee

The Evonetix genetic modification safety committee (GMSC) consists of a first person with over 15 years of experience working in academic laboratories conducting genetic modification of microorganisms. This person was responsible for the preparation of biological risk assessments at a Cambridge University lab. The second member of the committee has extensive experience in a UK industrial lab setting with regular GMM work. This member will not be directly involved in GMM work at Evonetix, giving the member independence and professional distance. A third member has 10 years of experience with GMM work (in academic labs) and will be directly involved with GMM work in the lab. A fourth member, who is also the chairperson of the Evonetix Chemistry Safety Committee, will ensure full integration of the GMSC within the Health and Safety Committees of Evonetix. A fifth member will represent higher management.

To inactivate liquid waste, Virkon powder is to be added to a final 1% concentration. Virkon is a total spectrum disinfectant prepared and used as a 1% virkon solution as standard procedure. It has an effective 100% kill rate. Solid waste is to be disposed of in yellow clinical waste burn bins provided by contractor Grundon. The contractor will treat the waste by incineration, resulting in an effective 100% killing-off of micro-organisms.

For activities involving GMMs, describe the waste management measures which will apply to the activity

## Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Give brief details of the genetic modification safety committee:

- **Genetic modification safety committee:**
  - CEO (chair) - PhD, Frederick James Quick Professor of Biology, FRS
  - Laboratory manager (biological safety officer) - MSc Molecular Biotechnology
  - Scientific Adviser (member) - PhD in human genetics
  - Research Scientist (member) - PhD in Cell and Molecular Biology

Any work involving GMO must first be approved by the genetic modification safety committee. In order to do so, all the necessary risk assessments must be completed or read and sign. Furthermore, all personal carrying on such work must have received all the necessary training to ensure safe work by the biological safety officer. The genetic modification safety committee meets as necessary on a regular basis with a frequency no less than 3 times a year.

| Level 1 (GMMs) | Yes |
| Level 2 (GMMs) | Yes |
| Level 3 (GMMs) |     |
| Level 4 (GMMs) |     |
Solid waste will be inactivated by autoclave (degree of kill effectively 100%) and liquid waste treated with Distel, or other approved desinfectant according to manufactures’s instructions. Autoclave is tested and certified annually, and during each run is shown to hold temperature correctly. Sharps will be collected in a sharps disposal bin and disposed of by University-approved contractors.

For activities involving GMMs, describe the waste management measures which will apply to the activity

# Project Additional Information

## Purposes of the contained use

CRISPR-Cas9 mediated knock-outs generation for genetic screens.

## Recipient or parental organism

Standart laboratory used mammalian cell lines, such as, but not limited to: U20S and RPE-1.

## Host/vector system

Second or third generation lentiviral vector system.

## Origin & function

AAV1-EF1ahCas9 (Cas9 expressing plasmid) and pCLlP-dual-SFFV-ZsGreen screening sgRNA library from Transomic Technologies (guide RNAs expressing library for CRISPRiCas9 mediated generation of knock-outs) were provided by Prof. Steve Jackson's laboratory at Gurdon Institute, Cambridge, UK. Both plasmidic vectors will be packaged into lentiviral vectors in HEK293T cells and delivered to host cells (U20S and RPE-1) by transduction aiming to generate Cas9-stably expressing RPE-1 cells and CRISPR/Cas9-mediated U20S and RPE-1 knock-out cells to be screened for sensitivity to DNA damaging agents.

## Evaluation of foreseeable effects

Lentiviruses are retroviral vectors derived from Human immunodeficiency virus type 1 and 2 (HIV-1/-2), classified as HG3. However, replication incompetent lentiviral vectors bear little resemblance to wild-type HIV. The infected cell lines cannot survive outside of sterile tissue culture environment. The lentiviral vectors do not encode for any oncogene or transgene.

## Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Solid waste will be inactivated by incubation in distel or bleach solution followed by autoclave treatment in autoclavable bags and then disposed according to the university of Cambridge procedure (degree of kill effectively 100%).

Liquid waste will be treated with Distellbleach, or other approved disinfectant according to manufacturer's instructions and disposed in the sink.

Autoclave is tested and certified annually, and during each run is shown to hold temperature correctly.

**Project Additional Information**

**Purposes of the contained use**

To enable the generation and use of recombinant self-inactivating second and third generation lentiviral particles (by commercial research organisations or in house using commercially available 2nd and 3rd generation lentivirus systems) encoding:

1. Open Reading Frames (ORFs), cDNAs,
2. Specific gene sequences
3. Short hairpin RNAs (shRNAs) for the knockdown of Open Reading Frames (ORFs), cDNAs or specific gene sequences by RNA Interference (RNAi)
4. guide RNAs sequences for CRISPR/Cas9-based gene editing for knockout cell lines generation.

To enable the use of such cell lines for genetic high-throughput screens; specifically: a) production of lentiviral particles carrying DNA sequence coding for Cas9 for the generation of Cas9 expressing human cell lines.

**Recipient or parental organism**

To enable the generation and use of recombinant self-inactivating second and third generation lentiviral particles (by commercial research organisations or in house using commercially available 2nd and 3rd generation lentivirus systems) encoding:

1. Open Reading Frames (ORFs), cDNAs,
2. Specific gene sequences
3. Short hairpin RNAs (shRNAs) for the knockdown of Open Reading Frames (ORFs), cDNAs or specific gene sequences by RNA Interference (RNAi)
4. guide RNAs sequences for CRISPR/Cas9-based gene editing for knockout cell lines generation.

To enable the use of such cell lines for genetic high-throughput screens; specifically: a) production of lentiviral particles carrying DNA sequence coding for Cas9 for the generation of Cas9 expressing human cell lines.

**Host/vector system**

The lentiviral vectors which will be used are derived from HIV-1, which is an ACDP Hazard Group 3 biological agent.

However, second and third Generation lentiviral vectors have several of the lentiviral accessory genes (required for pathogenesis only) deleted to increase biosafety. These include the vit, vpr, vpu and nef accessory genes which are not required for in vitro replication. The tat gene is also deleted and the Tat-responsive promoter present in the S’L TR is replaced with heterologous promoters, for example with the Rous sarcoma virus U3 region. An additional biosafety feature is achieved by deletion of the rev gene from the viral transfer vector. Viral packaging is achieved by providing three helper constructs in trans containing gag, pol and rev sequences (figure 1).
An additional biosafety feature is that these vectors are self-inactivating (SIN), whereby the U3 region of the 3' L TR (which contains the major viral promoters and enhancers) is copied to the S' end of the provirus during reverse transcription. Deletion of enhancer and promoter elements from the 3' U3 region in the vector construct will result in a provirus that is entirely devoid of U3 enhancer sequences, therefore reducing the potential for transactivation of cellular genes as a result of insertion. Furthermore, such vectors are not easily mobilisable as a result of a superinfection with wild-type virus.

For example, third generation Lentiviral Expression Systems include the following key safety features:
- The Lenti expression vectors contain a deletion in the 3' L TR (.6.U3) that does not affect generation of the viral genome in the producer cell line, but results in "self-inactivation" of the lentivirus after transduction of the target cell (Yee et al., 1987; Yu et al., 1986; Zufferey et al., 1998). Once integrated into the transduced target cell, the lentiviral genome is no longer capable of producing packageable viral genome.
- The number of genes from HIV-1 that are used in the system has been reduced to three (i.e. gag, pol, and rev).
- Genes encoding the structural and other components required for packaging the viral genome are separated onto four plasmids. All four plasmids have been engineered not to contain any regions of homology with each other to prevent undesirable recombination events that could lead to the generation of a replication-competent virus (Dull et al., (998).
- Although the three packaging plasmids allow expression in trans of proteins required to produce viral progeny (e.g. gal, pol, rev, env) in the HEK-293FT or HEK-293-LentiX producer cell line, none of them contain LTRs or the '+' packaging sequence. This means that none of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. No new replication competent virus can be produced.

Despite the above safety features, use of these lentiviral vectors (which include WPRE) falls within SACGM 2 criteria due to the potential biohazard risk of possible recombination with endogenous viral sequences to form self-replicating virus, or the possibility of insertional mutagenesis. Also, the virus will be packaged by transfecting transfer vector into specific amphoteric ‘helper’ cell line (gag, pol and env stably incorporated into host chromosome cells). NOTE: amphotropic packaging will widen the host range of the virus and allow it to infect a wide range if mammalian species (including humans) and cell types.

This means that the viruses produced for this experiment could potentially infect a number of species, including human.

Origin & function

- **Selectable markers - examples (but not restricted to):**
  - Ampicillin resistance: E.coli derived
  - Neomycin resistance: bacteria derived aminoglycoside phosphotransferase gene
  - Puromycin resistance (PAC): Puromycin acetyl transferase is derived from Streptomyces alboniger
- **Reporter proteins such as (but not restricted to):**
  - GFP derived from the jellyfish Aequorea victoria and variants of this
  - LuCiferase - class of oxidative enzymes used in bioluminescence
- **Open reading frames, cDNAs and gene sequences and I or shRNAs, gRNAs and cyclic peptides - all human derived.**

Evaluation of foreseeable effects

The lentiviruses are, at worst, amphotropic or pseudo-typed with VSV-G protein, either of which confers a broad host tropism including human cells. However, infectivity is unstable and infection is only obtained by co-cultivation of the packaged viruses with the recipient cells. The retrovirus is self-inactivating and there if thus no possibility of
further transfer.
Since some of the inserted DNA codes for potentially hazardous RNA or protein, the work is assessed as Class 2. This accords with HSE SACGM Compendium of Guidance for retroviruses (Part 2, para 18-20).
Even for the non-oncogenic inserted DNA, there is a slight but non-negligible risk due to the presence in the lentiviral vector of the Woodchuck Post-transcriptional Regulatory Element. The WPRE-containing vector DNA will be treated as potentially oncogenic and is assigned to class 2 (see HSE SACGM Compendium of Guidance for retroviruses (Part 2, para 13)).
However, bearing this in mind we should consider that the viruses that will be used have been modified in a number of ways which will make them safer to handle:

- The genes encoding structural and other components of the viral genome have been separated. These genes have been engineered to minimise the risk of recombination that could lead to production of a replication-competent virus.
- The packaging cell lines allow expression of proteins, required to produce progeny virus: But the transfer vector a.

Third generation or Self INactivating vectors retrovirus vectors will be used in all experiments.
Procedures and controls measures will therefore follow HSE SACGM Compendium of Guidance for retroviruses (Part 2, para 30-36) i.e. using multiple plasmids with minimum sequence homology (e.g. our 3rd generation SIN lentivirus vector system), gloves should be worn, use of class II safety cabinets, sharps avoided and all wastes be rendered harmless before disposal etc.

It is not thought that the modified virus would pose a serious risk to animals or plants in the environment. Although the VSV coat protein permits invasion of other mammalian cells, as in the case of humans, infection would be restricted to primary cells and productive virus would not be produced. In addition the control measures to protect human health will minimise release of virus to the environment. Therefore the environmental risk is low.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All waste material will be inactivated by treatment with 1 % (w/v) Virkon solution prior to disposal. Waste material will then be placed in sealed bins and incinerated by an off-site incineration company. Collections for incineration will be made by the local registered clinical/GM waste incinerator contractor Vetspeed (GM authorisation number GM898).
This disposal method is expected to achieve 100% inactivation of the GMM.
The data sheets describing inactivation by Virkon are attached. No Sharps or glass will be used and plastics are collected in disposal bin and disposed of by approved contractors.

Give brief details of the genetic modification safety committee

The Genetic modification safety committee (GMSC) comprises of three individuals. The Biological safety officer (BSO) who holds the lab manager position for the BioEscalator and two Divisional safety officer from the University of Oxford expertise in biological safety. The specific role of the BSO will be the management and implementation of health and safety legislation (Management of Health & Safety at Work Regulations) by inspecting the laboratory, ensuring sufficient stocks of disinfectants etc and observing workers and will write regular reports to ensure a safe working environment. The BSO will implement genetic modification (GM) safety induction and compliance with GM safety procedures. The BSO will be immediately informed if there are GM incidences and containment measures will be taken and a report written and filed for HSE inspection. In the context of the GM safety and Contained Use Regulations, meetings between the BSO and Divisional safety officers will be held six monthly to review safety measures, disposal issues and implementation of further safety measures will be implemented and a written report will be filed.

</table>

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

GM safety committee seeks to maintain good microbiological practice for handling of E. coli, i.e. containment measures for level 1 organisms. K12 commercial E. coli used are not considered pathogenic to humans or animals. The E. coli strains used are very unlikely to survive or thrive in the environment as they have auxotrophic requirements or other debilitating mutations. The E. coli strains used would not be hazardous to the environment even if they did survive. The GMOs are unlikely to be any more harmful or better able to survive than the original host. There are no special measures necessary to protect the environment & details of waste disposal and emergency clean-up procedures have been described in section 6. Agar plates, batch cultures and all other contaminated materials will be autoclaved before disposal. E. coli K12 strains are recognised as non-colonising to humans and are unlikely to persist in the gut, lung, or survive outside of the special culture medium which provides their auxotrophic requirements.

HEK 293 cell, the Human Embryonic Kidney 293 cells are class 1 GMO organisms. This line was originally derived from human embryonic kidney cells grown in tissue culture. HEK293 cells are available from Sigma Aldrich and are easy to grow and transfect cells and have been widely used for cell biology research and also used by the biotechnology industry. This line has been extensively used for several years and is also thought to be safe.

Give brief details of the genetic modification safety committee

Prokarium is relocating to new premises in London following spinning out from Cobra Biologics (Keele, Staffordshire) and a former Biological Safety Officer of Cobra Biologics (Prokarium's Chief Scientific Officer) will be the Biological Safety Officer of Prokarium, with over 15 years’ experience serving in a Genetic Modification safety committee. As a newly separate entity, Prokarium will set up a GM safety committee that will meet periodically when there are new GM risk assessments to be discussed, with a committee secretary to be appointed and minutes taken.

Please enter comments of the GM safety committee on the risk assessment:

Genetic modification in relation to an organism is defined as "the altering of the genetic material in that organism by a way that does not occur naturally by mating or a natural recombination or both". Techniques involving direct introduction of heritable genetic material, including methods such as particle bombardment, direct injection of naked DNA into an animal and the use of other gene delivery system e.g. liposomes are considered to be genetiC modification where the introduced material is intended to be incorporated into the organisms genetic material in a reasonably stable way. All work that is covered by this definition must have a risk assessment carried out and approved by the genetic modification safety committee prior to the work beginning.

Y

Give brief details of the genetic modification safety committee

Advice was sought from the REPROCELL Clinical Alliance Manager (PhD).

- Over 20 years of experience within academic research institutions working mainly within the field of pathogen research, laterally as a Research Fellow and Project Investigator.
- Extensive experience of preparing and assessing risk assessments associated with contained use and pathogen research.
- Prepared or contributed to past applications for consideration by University GM committees and the HSE.

Other (please specify) Tick if confidential
All liquid cell culture waste is inactivated with 1% Virkon for at least 30 minutes prior to disposal (greater than 99.999% kill, manufacturer validated). Liquid waste is stored in a sealed vessel during inactivation, prior to disposal via liquid drain waste with copious volumes of running water. Any spillages are covered with Virkon powder for at least 3 minutes before being scraped into a safe receptacle and the area is washed with 1% Virkon (greater than 99.999% kill, manufacturer validated). Single use/disposable labware e.g. cell culture vessels, serological pipettes, pipette tips etc. are used where possible and reusable labware is decontaminated with 1% Virkon (greater than 99.999% kill, manufacturer validated) after each use.

Incineration

All solid laboratory waste is destined for incineration (100% kill).

Waste Disposal

All solid laboratory waste is treated as clinical waste and is uplifted by an approved waste disposal contractor (registered under the GMO contained use regulations 2001 to 2010) for disposal by incineration (100% kill).

For activities involving GMMs, describe the waste management measures which will apply to the activity

A copy of the risk assessment was provided for review. Based on the information provided I would concur that risks associated with this body of work are low and that all work should be performed under containment level 2 conditions. I agree with notification of this work to HSE as Class I.

Yes

Give brief details of the genetic modification safety committee

University of Southampton Genetic Modification and Biological Safety Committee have agreed to review and provide advice for risk assessments from University Hospital Southampton.

The University of Southampton GMBSC sits three times a year. The Committee is Chaired by a senior Professor and Committee members are from academic research departments within the Faculty of Medicine, Faculty of Environmental and Life Sciences and the Faculty of Engineering and Physical Sciences. The University Biological Safety Adviser is also a Committee member and can pre-approve any activity class 1 risk assessments prior to formal approval at a GMBSC meeting.

GMBSC-0221 A Phase 3 Open-Label, Single-Arm Study To Evaluate The Efficacy and Safety of BMN 270, an AdenoAssociated Virus Vector-Mediated Gene Transfer of Human Factor VIII

It was noted that this project had been submitted by the trust under the agreement that the University of Southampton Genetic Modification & Bio-Safety Committee review their projects.

It was highlighted that a specific sentence in the risk assessment stating that the virus did ‘too little to do any harm’ made no sense.

<td>Gene therapy product RP1 (Common name rHSV-hGM-CSF/GALV-GP) is an oncolytic immunotherapy product that is developed for the treatment of solid tumours</td>
<td>Class 2</td>
<td>&lt; 1 Litre</td>
<td></td>
</tr>
</tbody>
</table>

Date Project 02/03/2022
The purpose of the release is to perform an Open-Label, Multicenter, Phase 1/2 Study of RP1 as a Single Agent and in Combination with PD1 Blockade in Patients with Solid Tumors (IGNYTE). The Phase 1 portion of the study has completed enrollment and includes patients with advanced solid tumours. The Phase 2 portion of the study assesses the safety and efficacy of RP1 using the recommended Phase 2 dosing (RP2D) from Phase 1 in combination with nivolumab.

RP1 (rHSV-hGM-CSF/GALV-GP) is a selectively replication competent Herpes Simplex Virus-1 (HSV-1). The virus contains a codon-optimised sequence for human granulocyte macrophage colony stimulating factor (hGM-CSF) and a codon optimised sequence for the gibbon ape leukemia virus surface glycoprotein (GALV-GP) with the R- sequence deleted (R-) [GALV-GP-R-]. GALV-GP-R- expression leads to cell to cell fusion (syncytial) formation in infected tumour cells through binding to the constitutively expressed PiT-1 receptor for GALV. This results in the death of the cells by membrane fusion and is also intended to enhance the spread of the virus through the tumour. Since the RP1 selectively replicates in tumour cells, the expression of the GALV-GP-R- is minimised in normal tissues. The oncolytic destruction of tumour cells leads to the release of tumour associated antigens that are intended to engender an antitumour immune response, enhanced by the local expression of GM-CSF. This is intended to be further enhanced through GALV-GP-R- mediated killing, fusion associated cell death which also results in the production of the highly immunogenic exosomes, which is expected to contribute to this immune effect. The immune response generated may then lead to immune destruction of distant, uninjected tumours, and/or delay the progression of distant disease, and/or vaccinate against relapse. RP1 is intended for direct injection into solid tumours.

RP1 (rHSV-hGM-CSF/GALV-GP) is derived from the RH018 strain of Herpes Simplex Virus-1. RP1 is produced in Vero cells and virus is released into the culture media by budding from the cells and during cell lysis, prior to purification.
RP1 expresses the immune stimulatory protein GM-CSF, which augments therapeutic activity. GALV-GP-R- binds to the PIT1 receptor, which is widely expressed on mammalian cells including human tumour cells. PIT1 is also critical for cell proliferation, and its expression is therefore unlikely to be lost or down-regulated in response to cancer treatment. The truncated R- version of the protein provides constitutive fusion activity without GALV (i.e. the virus) itself. Expressing GALV-GP-R- together with GM-CSF is expected to increase clinical activity as compared to only expressing GM-CSF. As well as causing direct tumour cell death by cell to cell fusion, cell to cell fusion followed by death is highly immunogenic and includes the release of Immunogenic tumour antigen-containing exosomes. Expression of GALV-GP-R- from an oncolytic virus is therefore expected to improve systemic, immune mediated, effects, as well as effects in the directly treated tumour thereby increasing synergy with other immune-mediated approaches to cancer therapy such as immune co-inhibitory pathway blockade.

Evaluation of foreseeable effects

As described above (under Recipient or Parental Organism), the oncolytic destruction of tumour cells (upon transduction with RP1) leads to the release of tumour associated antigens that are intended to engender an antitumour immune response, enhanced by the local expression of GM-CSF. This is intended to be further amplified through GALV-GP-R- mediated killing, fusion associated cell death which results in the production of the highly immunogenic exosomes and is expected to contribute to this immune effect. The immune response generated may then lead to immune destruction of distant, un.injected tumours, and/or delay the progression of distant disease, and/or vaccinate against relapse. RP1 is intended for direct injection into solid tumours.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation is requested

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Ill used and unused vials of RP1 will be disposed of per institutional policies and procedures and in line with the RP1 IS.

As per the wild-type HSV-1 virus, the recombinant HSV-1 vector particles that represent RP1 are highly susceptible to dehydration, rapidly inactivated outside the host and easily inactivated (for example with 1% Virkon solution). All materials contaminated with RP1 will be disposed of in compliance with local institutional policies and SOPs. Incineration is appropriate.

How must infected waste be treated before disposal and how has this been validated as being effective?

Liquid waste - All potentially contaminated material will be inactivated by chemical disinfection (1% Virkon for 30 minutes) and/or autoclaving at 121°C for a minimum of 15 minutes.

Solid waste - All potentially contaminated material will be inactivated by chemical disinfection (1% Virkon for 30 minutes) and/or autoclaving at 121°C for a minimum of 15 minutes.

How is waste to be disposed of after it has been made safe by validated means?

Treated Liquid waste - Liquid waste would have been placed in a bucket containing freshly made 2% Virkon solution for a minimum of 30 Min. At the end of this time the liquid contents will be carefully Upped through a fine sieve into the lab sink; the contents of the sieve will be placed into a blue waste box for disposal via incineration.

Treated Solid waste - Disposal of GMO waste in dedicated wheeled bins for Incineration.

All staff identified as at risk of exposure will be trained appropriately during the trial setup process during trial
Uncontrolled if printed 29 April 2020 Page 9 of 18

setup either at the site initiation visit or at separate dedicated meetings; records of this training will be kept as per local SOPs and GCP guidance in the training log kept in the site file.

In the event of exposure to broken skin or needle stick, the site will be cleaned thoroughly with soap and water or a skin disinfectant. A physician for monitoring signs of infection and occupational health will be contact for support.

Acyclovir or other anti-herpes drugs may be administered prophylactically.

Patients will be provided full instruction sand support from the Principal and co-investigators which will include care of the lesions and advice on shedding. Patients will be provided with spare dressings, instructions for use and safe disposal equipment which will be returned to the clinical site. In addition, the patients are given out of hours contact numbers and advice will be available from the clinical site team, if needed. All advice given will be in line with the sponsor's instructions and the study protocol.

The GM herpes virus is replication deficient in normal healthy individuals.
Risks considered and appropriate measures taken to prevent accidental transmission of virus.

Looks like all sensible precautions are in place for AC2 contained use.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [Y]

Please enter comments on the GM safety committee on the risk assessment

The GM herpes virus is replication deficient in normal healthy individuals.

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

This work is considered to be low hazard (class 1) to the environment and human health due to the following
1. No virus is constructed on site (obtained through a commercial supplier)
2. The virus is replication incompetent so the infection cannot spread beyond the cells initially exposed
3. The genes involved are non hazardous to human health (eg reporter genes such as GFP)
4. The infected human cells are not able to survive outside of the specific incubator environment (5% CO2, 37°C)
5. The risk to human health is minimised as no sharps are used, in addition all samples will be handled in a class 2 tissue culture hood to maintain experiment purity, thus further minimising risk to human health via aerosols.
6. All waste will be handled correctly minimising risk to the environment.

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment:

All work currently carried out by Orbit Discovery Ltd and any future work planned falls into biosafety level 1. This work includes the use of well characterised mammalian (human and non human eg CHO, HEK293) continuous cell lines that may have been genetically modified to express proteins of human origin (eg G protein coupled receptors - GPCRs), such cell lines are purchased from commercial sources (ECACC, ATCC).
None of the cell lines used will be modified by or exposed to pathogenic agents. Wont integrating lentivirus into the genome count as modification? We also use chemicals that are pathogenic?
Orbit Discovery currently have and will have at the new site (The Schrodinger Building, Heatley Road, Oxford, OX4 4GE) laboratory facilities suitable for biosafety level 2 and the appropriate processes and systems in place to handle biosafety level 1, and level 2 in the future if required. All cell cultures will be routinely monitored for the presence of bacterial or mycoplasma contamination.
Lentiviral transduction of mammalian cell lines, recombinant protein expression and generation of stable cell lines

The overall aim is the generation of mammalian cell lines for use as tools to screen for active peptides. Cell lines will be generated that overexpress a cell membrane receptor [predominantly G-protein coupled receptors (GPCR)] along with a reporter system to allow for detection of receptor activation. More specifically, mammalian cell lines (such as CHO-K1, HEK293T, HEK293, A549, TO2J) will be transduced with lentivirus carrying sequences encoding for a cell membrane receptor (e.g. GPCR) and/or an inducible reporter construct (e.g. cAMP response element linked GFP). Different combinations of receptor and reporter constructs will be used and most of the sequences will include an antibiotic resistance cassette (such as Puromycin or Hygromycin) in order to select for cells that were successfully transduced. The lentiviral particles (3rd or 4th generation) will be sourced from commercial suppliers and will arrive pre-packaged with the RNA cargo. Commercially available, well characterized mammalian cell lines such as (but not limited to) CHO-K1 and HEK293 will be used. Mammalian cells have very stringent requirements for growth and are very susceptible to dehydration and to exposure to ultraviolet radiation. Outside of the animals from which they are derived, growth and survival requirements can only be met by using specialised media, the correct temperature range, optimum pH and an adequate oxygen concentration. These constraints mean that cell lines will pose minimal risk to both human health and the environment. In addition, due to immune rejection of non-self-tissue, it is highly improbable that accidental exposure would result in survival and replication in normal healthy individuals. However, there is some possibility that any cell culture could contain yet unidentified adventitious agents, thus cells will be handled in a class II biological safety cabinet meaning that the risk to human health is low.
Lentiviral constructs are well characterised vectors that enable insertion of genetic material into host cell genomes. A 3rd or 4th generation lentiviral vector will be used for transduction of mammalian cells, this generation of vectors are not considered harmful due to being replication incompetent (self-inactivating). Lentiviral particles will be sourced from commercial suppliers pre-packaged with the RNA cargo and pseudotyped with VSV-G (or similar). The VSV-G pseudotyped lentivirus has a broad tropism and thus could infect a variety of cell types (most mammalian cells). A high concentration of virus is present in culture for a short time and will be washed away over progressive media changes and passages. Once the insert has been incorporated into the cell, the virus is no longer infectious. The main risk to laboratory staff comes from accidental inoculation or entry through broken skin while handling the virus. No sharps will be used in this procedure, gloves and a class II cabinet will be used to prevent exposure. If exposure did occur the lack of ability for the virus to replicate would result in Infection of cells at the site of injection only (in vivo experiments have shown diffusion of infectious particles no more than millimetres from the injection site), the nature of the insert is such that it will pose minor risk. Overall, the risk of an infection with a lentivirus particle is very low as:
• the virus and the transduced cells will be handled in a class II biological safety cabinet,
• small quantities of virus are used (< 1 ml of stock virus in used in smaller aliquots, ~3-4*10^8/ml TU, diluted/remaining virus in up to 30 ml medium).
• the packaged viral vector will be sourced commercially,
• the virus is replication defective and present in the cultures for a limited time
• Sharps are not used when virus particles are present and are otherwise avoided.

Origin & function

The proteins expressed in the transduced mammalian cells will pose no risk, as these will be mostly Human GPCRs, GPCR signal pathway molecules or reporter proteins. These proteins do not possess oncogenic properties and do not classify as toxins.

Evaluation of foreseeable effects

The resulting GMO will be a cell line that over-expresses a cell surface receptor and reporter construct, no virus particles will remain, so the risk from the GMO will be equivalent to that for mammalian cell lines. Mammalian cells have very stringent requirements for growth and are very susceptible to dehydration and to exposure to ultraviolet radiation. Outside of the animals from which they are derived, growth and survival requirements can only be met by using specialised media, the correct temperature range, optimum pH and an adequate oxygen concentration. These constraints mean that cell lines will pose minimal risk to both human health and the environment. PPE must be worn, and personnel must be trained in handling mammalian cells and virus.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

For waste where virus particles are present in culture:
The presence or absence of virus particles in culture waste will be calculated using using the Viral particle reduction rate calculation (Dautzenberg et al. 2020):
Reduction ratio = (Wash^W x (Wash x Tryp)^I x 2^(HL x T)) / (10 x Ci)
where “Wash” represents the reduction factor upon a wash step of the transduced cells (50 for 1x6w, 20 for 10 cm dish) and “W” signifies the number of times the cell culture was washed. The parameter “Tryp” indicates the vector-dependent reduction factor for treatment of the cells with trypsin (for VSV-G: 1), where “I” is the amount of trypsin treatments after a wash step. “HL” is the reduction factor based on the half-life of the envelope-pseudotyped vector particles at 37 °C in culture medium (for VSV-G: 0.7) and “T” the total culture time in days since the transduction of the cells. The parameter “Ci” represents the measured amount of infectious vector particles in the inoculum. The formula includes a safety margin of 10-fold to correct for the underestimation of infectious titre of the inoculum by multiplying the amount of initial vector particles in the culture medium (Ci) by 10. All waste generated where Viral particles could be present will be treated as follows.

Solid waste and liquid waste will be disinfected inside a biological safety cabinet using a final concentration of at least 1 % Virkon, with a contact time of 1h. All disinfected solid waste material will be double bagged in autoclavable bags or put in Bio-bins and then autoclaved. This includes any materials used for handling leakages, spillages or breakages. This waste will be later incinerated by a GMO licenced waste company. Disinfected liquid waste will be drained down an approved sink with excess of water. The autoclave will be validated by yearly service and the success of each run will be monitored by recording run temperature and time.

For waste where virus particles are no present:
All solid material or waste that comes into contact with cells will be soaked in a final concentration of at least 1 % Virkon for at least 15 min before draining off the Virkon and disposing of in the lab waste that is later incinerated by an external laboratory waste management specialist.
All liquid waste/media in contact with cells is inactivated in a final concentration of 1 % Virkon for at least 15 min before draining down an approved sink with excess of water.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

Please enter comments on the GM safety committee on the risk assessment

The risk assessment has been read and discussed at a meeting held by the GMO biological safety committee, they are satisfied that the proposed measures will provide adequate containment.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Sterilisation of small amounts of solid contaminated waste (eg tips, gloves), and small cultures (<10L) will be performed by on site autoclaving (Prestige Medical Classic, 12L capacity electrical autoclave, steam disinfection type). Waste is then disposed of through domestic routes.

Large volume liquid culture will be pumped into external waste containers (large IBC drum) and treated with virkon (1% for a minimum of 1 hour) prior to being removed by specialist chemical disposal company. Equipment that has been in contact with GMMs will be sanitised by treatment with sodium hypochlorite (0.5% for minimum 30 minutes to 1 hour). For the fermenter vessel 0.5% sodium hypochlorite (~50L) will be recirculated throughout the entire vessel for one hour. Vessel with then be extensively flushed with water to remove bleach. Liquid waste from this procedure will be pumped in to external waste containers (large IBC drum) for removal by specialist chemical disposal company. Site is not connected to domestic drains so any liquid waste will go into IBC waste drums. Confirmation of effective sterilisation/sanitisation will be performed by periodic test swabbing the laboratory equipment and culturing on GMM-specific agar plates, which will be performed in the MIB.

The fermenter will have 100% liquid external containment capability (bunding) in the case of a spillage or leak. For small spills, these will cleaned up with absorbant paper or mats, from spills kits, which are then autoclaved. The area is then sanitized with 1% virkon. Gaseous emissions will be filtered (0.2 um) to eliminate the risk of accidental GMM aerosol exposure to the air.

Please enter comments of the GM safety committee on the risk assessment

All genetic manipulations will be performed at the Manchester Institute of Biotechnology. A similar small-scale project (University of Manchester GM Project no. NSC1803) has already been approved by the faculty of science and engineering GM and biological safety committee, and the work undertaken at the MIB. Small starter cultures will be produced in the MIB, then transported by courier from the MIB with the correct packing and labelling.

No genetic manipulations will be performed on site, only small and large-scale fermentations of the recombinant microorganisms (20-300 L).

This project will be assessed by the University of Manchester faculty of science and engineering GM and biological safety committee, in order to ensure a level of oversight on the biological safety aspects of the project, although none of the large-scale fermentation work will be completed on university premises.

All biological laboratory waste will be autoclaved prior to disposal (with the exception of discared gels which will be sealed ahead of specialist disposal by Labwaste). The autoclave is located within the suite of laboratories where the work is being conducted. The waste cycle will be run at 121°C for 45 minutes which will achieve a kill of at least 10^5 or higher. After autoclaving, the waste will be stored in a locked Eurobin before collection by a specialist waste removal firm (we will be using Labwaste part of TradeBe). The autoclave will be under a service contract to ensure it is functioning as required. The autoclave run will be monitored by the use of the onboard software. Preuse and every three months after, the kill level will be verified by the use of Geobacillus stearothermophilus biological indicator spore strips containing a known number of spores. Each run will be verified by the use of autoclave indicators such as autoclave tape and Browne tubes or similar.

For activities involving GMMs, describe the waste management measures which will apply to the activity

GMSC comprises of two indivduals. Project Manager/Health and Safety Officer holds a PhD in Microbiology, is an expert on gut pathogens and has extensive industrial experience in Human Medical Diagnostics. Lab/Quality Manager has 18 years experience in GMP/Pharmaceutical Microbiology and CL 1/2 microorganisms.
## Project Additional Information

### Purposes of the contained use

Development of live biotherapeutic products and analysis of in vitro and in vivo experimental samples.

### Recipient or parental organism

C. butyricum, C. sporogenes, C. novyi. All non-toxigenic variants

### Host/vector system

N/A

### Origin & function

Genetic material is derived from genom sequences of other bacteria or humans. All material is synthesised and introduced into bacterial strains to confer a metabolic, anti-inflammatory, anti-microbial function.

### Evaluation of foreseeable effects

Expression of therapeutic metabolites and peptides from recipient organisms. Does not confer any growth or niche benefit to strains.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Directly contaminated waste (petri dishes, liquid media) will be autoclaved where possible to achieve a kill of 10^5. After autoclaving, the waste is stored in either a drum or locked clinical waste bin until full. Once full, it is taken off site by a specialist waste carrier. Where it is not possible to autoclave the waste e.g. where the vessel size exceeds the capacity of the autoclave, the waste is chemically neutralised using a validated procedure, the waste is then taken off site by specialist waste carrier.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form N

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The risk assessment and relevant information is freely available to all members of CHAIN staff. CHAIN have seven members of active laboratory staff who are all satisfied that the control measures in place are sufficient to ensure their safety and the safety of others.

The cell lines that we are using require specific conditions in order to survive (e.g. specific media, temperature and CO2 concentration). They should not survive after disposal outside those conditions, but to ensure cell killing we will use a biocide such as Virkon (1%) to decontaminate tissue culture fluid in a vacuum reservoir prior to disposal. This will ensure 100% of cells are killed.

## Project Additional Information

### Purposes of the contained use

The purpose of the notified activity relates to the usage of lentiviral vectors for stably transfecting mammalian cells for performing preclinical studies.

### Recipient or parental organism

Mammalian cells derived from homo sapiens, mus musculus or other rodent species.

### Host/vector system

Second or third generation lentiviral plasmids (such as psPAX2 (Addgene plasmid #12260) and pMD2.G (Addgene plasmid #12259)) will be used to transflect HEK293T cells and generate viral particles.

### Origin & function

Multiple methods will be used to modify the cellular expression of certain proteins by incorporating DNA sequences onto the genome. The vectors used may contain an shRNA sequence, a guide RNA, Cas9 protein or a sequence coding for full or part of proteins present in homo sapiens, mus musculus or other rodent and non-human primate species. The function of the genetic material will be to modify (up and downregulate) the expression of certain proteins involved in the development of a variety of diseases, with an initial focus on oncology indications.

### Evaluation of foreseeable effects

2. Healthy volunteers screened blood purchased from a commercial source: it may be wrongly screened or contain diseases it has not been screened for.
3. Growth media and supplements: Cells are cultured in growth media supplemented with Penicillin, streptomycin, fetal calf serum and L-glutamine. Additional biological agent supplements such as insulin, hydrocortisone and recombinant cholera toxin may be used as required.
4. Biocides such as Virkon (1%) that is used to decontaminate tissue culture fluid in a vacuum reservoir prior to disposal can cause irritation to skin and respiratory tract.
5. Puncture injuries from disposal of tips that may be contaminated with cells or cell culture fluids.
6. Use of vacuum reservoir for aspiration of biological fluids
7. Chemical agents in use. DMSO, used for freezing down cells lines in classed as non toxic.
8. 2-propanol. Mr. Frosty freezing container are filled with 2-Propanol which is highly flammable, can cause serious eye irritation and may cause dizziness or drowsiness. Appropriate PPE required and use in Fume hood.

10. Cells may be plated on glass coverslips in tissue culture dishes for use in immunofluorescence. The coverslips are delicate and break easily which can result in sharp debris left in the hood.

11. Scissors used to open buffy coat packs.

12. Reagents IL-2, IL-4, GM-CSF and M-CSF, are biological agents and potential irritants to the skin and eyes, however, they are not hazardous in the concentrations used.

All the work will be performed under a strict CL2 risk assessment that will aim to mitigate the aforementioned effects on the people and the environment (attached).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

No larger GMOs will be used in these premises.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste:
Pipette tips and stripettes will be disposed in a plastic waste bin within the BSL-2 cabinet and sealed prior to removal from the biosafety cabinet. Waste will be transported in sealed containers prior to autoclaving. All contaminated materials will be decontaminated by autoclaving (100% kill) prior to disposal of waste. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored by continuous chart or digital recording of the temperature/time profile. Following autoclaving the non-hazardous waste will be sent for incineration following local regulations. Glass coverslips will be handled on tissue. In case of breakage, all the pieces can be gathered up in the tissue and disposed of in a sharps bin.

Liquid waste:
Liquid waste with low contamination risk (e.g. routine cell culture media) will be aspirated into a bottle containing Virkon, a peroxygen based disinfectant, which will be used according to the manufacturer’s instructions. Following a 24-hour chemical inactivation, the resulting non-hazardous waste will be disposed of in an excess of water. Liquid waste with higher contamination risk (e.g. human blood products and excess viral supernatants) will be incubated with Presept disinfection according to the manufacturer’s instructions for at least 24 hours. The resultant non-hazardous waste (100% kill) will then be disposed of with an excess of water.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]
The risks associated with the use of CL2 GMMS have been appropriately identified and mitigated on the risk assessment attached. Sixfold Bioscience Ltd. has systems in place to review and update those on a yearly basis or before if there are any improvements suggested or significant changes on the R&D processes.

Please enter comments on the GM safety committee on the risk assessment

For activities involving GMMs, describe the waste management measures which will apply to the activity

Disinfection measures: A 2% Virkon solution will be prepared prior to working with viruses and will be available should a spillage occur. After use the consumable and liquids containing virus will be exposed to 2% Virkon for a minimum of 30 minutes, as will all materials (e.g. tips, tubes) used during the experiment to ensure complete decontamination. Excess liquid is disposed of down the drain. Plasticware and consumables will then be entered into tissue culture waste and autoclaved (see below).

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250C for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration/dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration.

Degree of kill
Autoclaving, effectively 100% kill (annual validation)
Incineration, effectively 100% kill (licensed incinerator)
Chemical disinfection, used according to manufacturers instructions under standard conditions, manufacturers validation (99.998% kill)

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The safety committee agreed with the assessment of risk, containment facilities and disposal routes.

Project Ref 3441/18.1

Date Ackn’d 14/11/2018

Date Project 02/03/2022

CU2 Project Title Expression of reporter genes in adenovirus for laboratory research

Class Class 2

CultureVol Class 2 < 1 Litre

Class Volume Class 3-4

Non-GMM

Consent Granted
Adenoviruses have been studied in laboratories for many decades in order to gain insights into the biology of both viruses and cells. To help understand how they infect or replicate in cells under different conditions, it is common practice to add in reporter genes. These genes are non-hazardous and facilitate observation by techniques such as fluorescent microscopy.

In this project, we intend to modify adenoviruses to express fluorescent proteins, enzymes such as luciferase and control proteins to help with understanding adenovirus infection and replication in cancer cells.

Recipient or parental organism

Adenoviruses modified with reporter genes will be evaluated in laboratory tissue culture experiments. The recipient cells will be standard laboratory cancer cell lines and immortalised cells available from national biobanks. The reporter gene will be used to monitor the progress of adenovirus in short-term replication experiments. For comparison, some studies will be conducted in culture normal cells.

Host/vector system

Adenoviruses from group 8-G, for example adenovirus type 5, group C will be modified to express innocuous reporter genes, such as beta-galactosidase, tags (such as His tags or HA) green fluorescent protein (GFP; or similar fluorescent protein) or luciferase. Reporter genes will be driven by conventional promoters (e.g. CMV immediate early gene promoter) or by inserting IRES or P2A sites to link expression of the transgene to that of specific virus proteins. Alternatively, the transgene is under control of the virus endogenous promoters or splice acceptor sites.

Origin & function

1. Beta-galactosidase is a bacterial exoglycosidase that hydrolysos end terminal beta-galactopyranosyl residues. Natural substrates include lactose; the enzyme is also active e.g. ONPG, or X-gal which is used to produce an intense blue colour which can be used to visualise the distribution of the enzyme e.g. in different cells on a tissue culture plate or in tissue sections; it is widely used as a reporter gene and is considered innocuous.
2. Green fluorescent protein is a naturally fluorescent protein from the jellyfish, several variants of the natural gene have been produced which encode a protein with modified adsorption/emission characteristics and which have been optimised for higher level expression, e.g. the "EGFP". GFP's or similar fluorescent proteins are widely used...
and no hazardous properties have been reported.

3. Luciferase from firefly and sea pansy are widely used as reporter genes and are not considered to have harmful properties.

**Evaluation of foreseeable effects**

The addition of reporter genes will not have any incremental safety risk to the virus already in routine use in research laboratories and handled under category 2 containment conditions. When used in appropriately equipped laboratories by trained staff adenovirus (wild type or expressing reporter genes) do not pose a significant health risk to workers or the environment.

The virus does not integrate its DNA into the host genome as part of its life cycle.

Adenovirus are species specific and are not fully permissive in animals and the reporter genes are non-hazardous.

There should be no risk to the environment.

All work will be carried out by trained staff in category 2 conditions.

A full risk assessment has been written and has been signed off by the institutional health and safety committee.

**Purposes of the contained use**

Adenoviruses have been studied in laboratories for many decades to gain insight into the biology of both viruses and
cells.
The purpose of this project is to identify adenovirus genome sequences that facilitate selective lysis of cancer cells and attenuated activity in normal cells.

Recipient or parental organism

Parental: Human adenoviruses
Recipient: Standard laboratory cancer cell lines or immortalised cell lines available from national biobanks.

Host/vector system

Human adenovirus group 8-G (e.g. group C Ad5)

Origin & function

In this project we will use established genetic engineering techniques (restriction enzyme cloning, Gibson assembly, CRISPR/Cas9) to develop cancer specific adenovirus variants by identifying genome segments across adenovirus serotypes with utility against cancer. Adenovirus chimeras in specific gene regions important for oncolytic potential, notably E1-4 and L 1-5 will be created. Oncolytic candidates with modified genomes that show the highest therapeutic index (activity in cancer cells vs normal cells) will be taken forward for future studies.

For clarity, this project does not include the insertion of transgenes into adenovirus that may have additional associated risks. The use of transgene to individual oncolytic viruses identified in this project will be the subject to specific risk assessment in the future.

Evaluation of foreseeable effects

Viruses will be handled under category 2 containment conditions. When used in appropriately equipped laboratories by trained staff adenoviruses do not pose a significant health risk to workers or the environment. The virus does not integrate its DNA into the host genome as part of its life cycle. Adenoviruses are species specific and are not fully permissive in animal models. There should be no risk to the environment.

All work will be carried out by trained staff in category 2 conditions. A full risk assessment has been written and has been signed off by the institutional health and safety committee.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogations applied for

Project Ref  3441/21.1

Date Ackn’d  22/04/2021

Date Project  02/03/2022

CU2 Project Title  Use of replication-defective retroviral and lentiviral vectors expressing reporter genes
Project Additional Information

Purposes of the contained use

We plan to generate and use recombinant replication-defective retroviral and lentiviral particles expressing genes of interest (e.g. reporter genes) using a 3rd generation lentivirus plasmid vector system. This work will be performed in a research laboratory, to assist the development of new safe and effective cancer therapies. This work will use a 3rd generation lentivirus plasmid vector system which further improves on the safety of the 1st and 2nd generations. The vectors produced will not be used in any human or animal experiments, and will not be transferred outside the laboratory area or into the wider environment.

Recipient or parental organism

Recipient cells will be standard laboratory cancer cell lines and immortalised cells available from national biobanks.

Host/vector system

Lenti-SFFV is a typical lentivirus plasmid, which may be engineered to introduce reporter transgenes and promoters and then co-transfected into packaging cells with other plasmids providing the proteins. Providing the packaging genes on three separate plasmids minimises the opportunity for recombination leading to replication competent virus (RCV). Only one plasmid contains packaging signals and hence only this plasmid, including any transgene, is packaged into the vectors produced.

Origin & function

Transgenes will include only reporter genes and/or selectable markers. No other proteins will be encoded (for example there will be no toxins, super-antigens or oncogenes). Transgenes may include:

- Reporter genes: Photinus (firefly) and renilla luciferase, Beta-galactosidase, Secreted Alkaline Phosphatase, Chloramphenicol acetyltransferase, fluorescent proteins from marine organisms (CFP, EGFP and YFP). These naturally fluorescent proteins emit light when excited by high-intensity light of specific wavelengths. Several variants of natural genes have been produced that encode a protein with modified adsorption/emission characteristics and which have been optimised for higher level expression, e.g. the “EGFP”. GFPs are widely used and no hazardous properties have been reported. Other proteins have been isolated from other organisms, however, each of these proteins has no cellular toxicity in normal cells, otherwise, they would not function as a successful reporter gene. Luciferase from
Firefly and Sea Pansy are widely used as reporter genes and not considered to have harmful properties. No hazardous effects are anticipated because all the parent proteins are without harmful properties.

- CRISPR genes targeted to virus genes for knockdown of virus function: The gene for the Cas9 endonuclease from the Streptococcus pyogenes Type II CRISPR/Cas system along with a guide RNA specific to Viral genomes and guide RNA scaffold for the Cas9 system.
- Mammalian selectable markers: Hygromycin resistance, Puromycin resistance, Zeomycin resistance, Neomycin resistance, Blasticidin resistance, and Geneticin resistance. Never shall any vector contain more than one of these markers. They do not function in bacteria. The promoter of the mammalian antibiotic resistance or selectable marker is recognised by the mammalian RNA polymerase and allows transcription of the gene of the mammalian antibiotic resistance or selectable marker in mammalian cells.
- Promoters: Different promoters will be used to regulate reporter gene expression in order to achieve different levels of expression. Typically these will include CMV, SFFV, SV40, U6 and EF1α promoters. There are no risks associated with the promoters, as they do not themselves encode any proteins, they merely influence the level of transgene expression achieved.

Evaluation of foreseeable effects

Only replication incompetent lentiviruses will be used under this contained use application. This reduces the potential for generation of replication-competent viral particles (RCPs). Extensive safety profiling has been carried out on lentiviral vector systems and they are commonly used worldwide for stable expression of transgenes.

With non-replicating vector systems the potential remains for possible insertional mutagenesis resulting from integration of the virus into the cell genome. This risk is mitigated to some extent when using self-inactivating vectors, handled at containment level 2 and with adequate waste disposal measures.

Risks to humans will be further mitigated through appropriate safety measures such as PPE to protect from splashes and, most notably, the strict prohibition of working with sharps at any stage of the process.

The addition of reporter genes will not have any incremental safety risk. All work will be carried out by trained staff in category 2 conditions. A full risk assessment has been written and has been signed off by the local genetic modification safety committee.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogations applied for.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) – treat overnight with Virkon following manufacturer’s guidelines, discharge any excess liquids to drains, dispose of solids into a solid sided yellow bin for licensed incineration.

Liquids (eg samples, culture supernatants, tissue culture media) – treat overnight with Virkon following manufacturer’s guidelines, discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (134C for 15 mins), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for incineration.

Degree of kill

Autoclaving, effectively 100% kill (annual validation)

Incineration, effectively 100% kill (licensed incinerator)
Chemical disinfection with Virkon, used according to manufacturer’s instructions under standard conditions, manufacturers validation [e.g. 4.79] log reduction ([e.g. 99.998]% kill).

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Comment from the GMSC:
"Under waste management can you be specific to what decontamination method you will be using for solids, liquids and agar plates waste?"
This change has been made (the updated risk assessment is attached with this notification form) and the final version accepted.

Please enter comments on the GM safety committee on the risk assessment

- Cultures, glassware, disposable plasticware and consumables exposed to non-transformed/phagemid carrying micro-organisms in the absence of helper phages will be autoclaved at 134°C for 30 min within 24 hours of the work being completed.
- Cultures and glassware that have been in contact with high titre cultures of phagemid/helper phage will be treated with solutions of Virkon S and allowed to stand overnight prior to autoclaving as above.
- Autoclaved solid waste will be disposed of properly in waste containers, while liquid waste (deactivated cultures) collected in sealed vessels will be disposed of via the main drainage system.
- Large volume spills of liquids containing high titre cultures of phagemid/helper phage will be contained using absorbent materials (e.g. paper towels), treated with undiluted Virkon S powder and left for 5 min. The waste will be disposed of by autoclaving and the area cleaned with Virkon S solution immediately following the spill.

These measures are based upon validated, well-established regimes for handling E. coli based GMMs and bacteriophage based work. Their implementation should result in complete elimination of GMMs and helper phage particles.

For activities involving GMMs, describe the waste management measures which will apply to the activity

The proposed work will employ disabled, non-pathogenic E. coli host strains for cloning, sequencing, and protein expression of recombinant DNA sequences. They are generally recognised to be noncolonising and are unlikely to survive outside of a laboratory environment. The strains are not considered to pose any hazard to humans, animals or plants. The stated host will be used in conjunction with non-mobilisable vector systems (plasmids and phagemids) that have been widely used over many years and have a long history of safe application. Furthermore, the insert gene sequences are safe and non-pathogenic. Therefore, the overall materials used in this work could be classified as GM1.

Any potential risk of gene transfer arising from the combination of phagemid and helper phage has been addressed adequately in the risk assessment (section 3.5) and appropriate measures will be taken to avoid these.

Give brief details of the genetic modification safety committee

The BioEscalator GM safety committee is composed of a number of Life Science professionals, many of whom hold PhDs and NEBOSH General Certificates in Occupational Health and Safety. Members include a BioEscalator Biological Safety Officer (PhD qualified laboratory manager), senior Oxford University Safety Officers, and senior representatives from the companies within the Bioescalator unit. The committee meets in its official capacity on an annual basis. Agenda items for the GMSC include committee member updates, and risk assessment reviews and updates. Meetings are minuted with actions and emailed to the committee for comments and final approval. GM risk assessments are sent (via email) to the BioEscalator BSO for circulation to the GMSC members for comment. Once the forms have been approved by the GMSC, risk assessments are signed off by the BioEscalator BSO as record of final approval.

</tr>
</tbody>
</table>
**Project Additional Information**

**Purposes of the contained use**

The aim of this project is to produce transgenic plant propagules of an endogenous British plant species. The transgenic propagules are to be used for:

1. Characterising the localization of the transgene's product, and/or
2. Characterising the function of the genomic locus where the transgene is located

Both wild type and transgenic T-DNA mutant lines (already available) will be transformed, using a disabled Agrobacterium tumefaciens strain GV3101. Plasmids used for transformation of plants with marker transgenes contain the coding sequences for the genes conferring resistance to kanamycin or spectinomycin in Agrobacterium and chlorsulfuron or hygromycin or geneticin in plants.

**Recipient or parental organism**

Endogenous British plant species and T-DNA mutant lines derivatives of the same.

**Host/vector system**

Agrobacterium tumefaciens and Gateway vector plasmids.

**Origin & function**

The intended function of the transgenes is to produce proteins that localize to cellular areas of interest or to perturb the function of neighbouring DNA sequence.

**Evaluation of foreseeable effects**

Characteristics of the GMOs and evaluation of the foreseeable effects are detailed in the attached risk assessment. Overall environmental effects are estimated to be low:

The unmodified plant species is native to Britain, and the inserted genetic material does not offer a selective advantage outside the laboratory unless antibiotics are in use. In addition, the fluorescent proteins used have no toxic effects. The vector (Agrobacterium tumefaciens) can infect plants, however, only disabled strains are to be used which are at a competitive disadvantage to wild type strains. The strain used here have not been associated with harm to the environment and will be handled in the laboratory under controlled conditions. Material is Virkon treated or autoclaved prior to disposal.

The genetically modified plant is not expected to be toxic to other plants nor to display increased invasiveness of natural habitats. The resulting plants are not expected to be pathogenic and are not expected to alter host plants.
resistance to other pathogens. It is unlikely that these genes could enhance weediness.
In the event that sensitivity to chemical compounds proves to be true, then the transgenic plants may have a selective
advantage over natural accessions in the context of agricultural environments where the relevant compound is used
for crop protection. The targeted editing is not expected to lead to plant changes outside the assessment of
associated risks.
Hazards to human health are estimated to be effectively zero:
The unmodified plant is non hazardous, the inserted genetic material is not hazardous, and the marker genes are not
hazardous. Antibiotic resistance genes do not offer a selective advantage outside the laboratory unless antibiotics are
in use. Fluorescent proteins have no toxic properties. The vectors are not hazardous to humans and none of the
transgenic plants are expected to be hazardous to humans.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
All plants are grown in environmentally controlled cabinets and contained in sealed pots after fertilization to stop any
unlikely escape of plant material. Details of which are in the attached risk assessment.
These will be in laboratories with restricted access. All contents treated as GM.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Solid GM waste materials (agar, culture dishes and pots, plant material and soil etc) will to be collected and
autoclaved in a validated autoclave prior to disposal. Any non GM plant material grown in the same growth cabinets
as GM material will also be treated as GM waste and autoclaved prior to disposal. Solid waste will be disposed of via
the clinical waste stream for incineration. Pots or other containers in which GM plants have grown will be
decontaminated (soaking overnight in 2% Virkon solution) before being re-used.
Disinfection measures for Agrobacterium: A 2% Virkon solution will be prepared prior to working with Agrobacterium
and will be available should a spillage occur. After use the consumable and liquids containing vector will be exposed
to 2% Virkon for a minimum of 30 minutes, as will all materials (e.g. tips, tubes) used during the experiment to ensure
complete decontamination. Excess liquid is disposed of down the drain. Plasticware and consumables will then be
autoclaved (see below) and then disposed of via clinical waste stream for incineration.
Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS
2646, Part 3, 1993 (134°C for 15 minutes) and then dispose of solids via clinical waste stream for incineration.
Sharps (eg syringes, slides, razor blades scalpels) will be autoclaved and then disposed of via clinical waste stream
for incineration
Degree of kill
Autoclaving, effectively 100% kill (annual validation)
Incineration, effectively 100% kill (licensed incinerator)
Chemical disinfection, used according to manufacturers instructions under standard conditions, manufacturers
validation [eg4.79] log reduction ([eg99.998]% kill).
Approved by Bioescalator GM safety committee 26th October 2018.

Y

Give brief details of the genetic modification safety committee

The premises has multiple companies as tenants. A genetic modification safety committee has been constituted from a representative from each company carrying out GMO work (all are or were until recently tenured academic staff at HE institutions and have experience in preparing risk assessments for GMO use) plus one staff representative elected by staff members, and the health and safety lead of Unit OX. The committee is chaired by an external HE academic who is a member of another genetic modification safety committee and has experience in reviewing and approving contained use activities. Two committee members have experience as HE biological safety officers and have had responsibility for reviewing contained use risk assessments.

</tbody>
</table>

Highly contaminated material - tips and loops, and similar plasticware will be collected in the laboratory within small benchtop containers (waxed card waste bins, not biohazard marked). This waste will be combined with agar plates and larger volume plasticware and sterilised by autoclaving. Transport to autoclave will be in a leakproof container on a trolley. Following confirmation of autoclave cycle using TST strips waste will be disposed of to landfill by a licenced contractor. Failure of cycle as indicated by either autoclave or TST strips will mean waste is autoclaved again. Autoclaves are inspected and tested for temperature and time conformance annually. TST indicators are used as a failsafe.

Sharps will be contained within an autoclavable sharps bin, autoclaved as above, then collected by a licenced contractor for incineration.

Liquid waste will be sterilised by the addition of Virkon from stocks made up weekly. This will be added to a concentration of 2%, the mixture left to stand for 60 minutes before discharge to drain. Glassware will be autoclaved as above.

Low risk material - hand towels and gloves will be collected in yellow bags disposed of by incineration off site after collection by a licenced contractor.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

Lab users should use PPE - lab coat with elasticated cuffs and high neck, and gloves at all times. Coats must not be worn outside of the laboratory. When transporting waste to autoclave this must be on a trolley.

TST indicators should be used in autoclave loads and these ensured to be specific to 121 C for 15 min at 15 PSI.

These have been incorporated into the risk assessment.
The overall aim of this project is to inform the development of gene-targeted therapeutic agents for the control of bacterial diseases. In the initial stages of this work, this will entail identification of gene targets by knockout and complementation within an individual bacterium and also expression of the target genes in a second bacterial species, usually the common expression vector E. coli. In order to develop diagnostic tests for the particular target bacteria and genes expression of partial and full length proteins is also necessary. This will enable the calibration of protein sequencing tests and ELISAs for the target pathogens, and identify cross-reactivity, sensitivity and specificity of such tests.

The significance of this work is that it is developing agents which can replace antibiotics in food animal production, as a response to the antibiotic resistance now commonly found in these bacteria. It is necessary to use GMMs as targets for the various therapeutics under test target individual genes, and without producing GMMs the target cannot be verified.

Specifically for this individual project, the aim is to establish the validity of such an approach across multiple bacterial species which are known to be animal and zoonotic pathogens. This is a key enabling step in informing the future design of gene-targeted agents.

### Recipient or parental organism
- Salmonella (non-typhoidal serotypes)
- E. coli serotypes
- Streptococcus spp.
- Staphylococcus spp.
- Campylobacter spp.

### Host/vector system
Standard antibiotic resistance cassettes will be used for gene disruption: ApR (ampicillin), KnR (kanamycin), Sm/SpcR (spectinomycin), TcR (tetracycline), CmR (chloramphenicol). Also, a range of standard plasmids (all nonconjugative) conferring antibiotic-resistance will be employed for cloning purposes. All routine cloning will be in E. coli K-12 using standard plasmids (pUC series and derivatives) and will include strains such as E. coli K-12 (BW25113, TOP10, DH5a, MC4100, W3110, MG1655, S17::pRP4), E. coli B (BL21/DE3). Gene expression will use standard commercially available backbones such as pOPIN-E/F, pBAD, pCDF-duet and may be under the control of inducible promoters such as arabinose and tetracycline. Green fluorescent and other FPs will be cloned in to assess expression in model systems. The commercial source is Clontech pGFPuv Vector.

### Origin & function

Partial or whole gene sequences from Salmonella (non-typhoidal serotypes), E. coli serotypes, Streptococcus spp., Staphylococcus spp. Campylobacter spp. Genes encoding toxins, or that enhance virulence, will be specifically excluded from the work. For expression outside E. coli, vectors may be altered by modifying the promoter and ribosome binding site and/or origin of replication by inserting artificially synthesised gene fragments.

### Evaluation of foreseeable effects

Expression of target genes in bacteria would not increase the virulence of any organisms containing them. Created strains would be either as virulent or less virulent as the parent organism, and would likely be less fit in terms of survival and competition in the environment. Forseeable effects would be as for the parental organisms. Plasmid carriage or knockout will render them less fit than the wild type, limiting their ability to compete and survive.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**NA**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Yes

Give brief details of the genetic modification safety committee

- Genetic modification safety committee members are drawn from a cross-section of the business in both senior and junior roles. Members are:
  - Scientist 2 - Virologist
  - Senior Scientist - Molecular Biologist
  - Technical Lead - Molecular Biology
  - H&S Manager
  - H&S Advisor
  - QA Engineer
  - Facilities Manager

1.1. General

1.1.1 All material generated in working practices must be inactivated or autoclaved prior to removal from the CL3 laboratory. Procedures for inactivation and disposal of waste are detailed in this SOP.

1.1.2. The only exceptions being waste that cannot physically fit into the autoclave, and waste that would damage the autoclave (e.g. batteries, lightbulbs). For these exceptions, individual risk assessments should be made, before disinfection and disposal for incineration.

1.1.3. Liquid waste must be chemically inactivated overnight with Virkon (final concentration of no less than 1% w/v) prior to being discharged to drains and flushed with water. Discharge of inactivated liquid waste to drains must be logged on Liquid waste form, S_QMS-SOP-30143.F1.

1.1.4. Solid waste that has been in contact with infectious material (e.g. cell culture plastics) must be inactivated with Virkon (no less than 1% w/v) prior to being autoclaved. Gloves that have been used within MSCs must be sprayed with 70% IPA prior to being discarded and autoclaved. Other solid waste (e.g. paper, packaging, dirty disposable lab coats) can be autoclaved without prior chemical inactivation.
1.1.5. All solid waste must be autoclaved at 121°C for 15 minutes at the earliest opportunity. After autoclaving, solid waste will be bagged before being removed from the laboratory and sent for incineration. It is the responsibility of all personnel to ensure their waste is autoclaved at the earliest opportunity.

1.1.6. For trained personnel, it is their responsibility to ensure that their waste is decontaminated and disposed of appropriately, as per the guidelines laid out in this SOP, risk assessments and Code of Practice: Containment Level 3 (CL3) laboratory (S-OHS-SOP-30016).

1.1.7. If this policy is breached, the Lab manager must be notified immediately and a non-conformance must be raised in accordance with S-QMS-SOP-30005, Reporting of Quality Events.

2. Waste from within MSC
2.1. Liquid waste
2.1.1. Small volumes (<25ml) of liquid can be disposed of by pipetting or submerging their container directly into 2% w/v Virkon. Ensure the final concentration is no less than 1% w/v. Leave overnight prior to discharge to drains. Log decontaminated waste discharged to drain on Liquid waste disposal form, S-QMS-SOP-30143.F1.
2.1.2. Larger volumes (such as T75 and T150 flasks) can be poured gently directly into a suitable container containing 2% w/v Virkon. Ensure the final concentration is no less than 1% w/v. Leave overnight prior to discharge to drains. Log decontaminated waste discharged to drain on Liquid waste disposal form, S-QMS-SOP-30143.F1.

2.2. Solid waste

2.2.1. All solid waste from within a MSC has to be treated as potentially infectious.

2.2.2. Spray gloves used within MSCs with 70% IPA. Discard into an autoclavable waste box outside of the MSC for autoclaving.

2.2.3. Discard tissue and papers (e.g. wrapping) into an autoclavable waste box outside of the MSC for autoclaving.

2.2.4. Discard cell culture plastics which have been in contact with potentially infectious material into a tub/jar containing 2% w/v Virkon.

2.2.5. For larger items (such as flasks), add sufficient amount of 2% w/v Virkon to cover the surface area that has been in contact with biological material. Alternatively, add Virkon powder/tablets to reach final concentration of no less than 1% w/v. Rotate the item to ensure all surfaces have come in contact with disinfectant.
2.2.6. Discharge disinfectant to suitable vessel within the MSC. Disinfect exterior surface with 70% IPA and discard into an autoclavable waste box for autoclaving.

2.2.7. For Gilson style pipette tips, aspirate 2% w/v Virkon solution from the tub/jar into pipette tips. Ensure tips are full (to the level used in the experimental action) prior to expelling into a tub/jar containing 2% w/v Virkon.

2.2.8. For serological pipettes, discharge contents into 2% w/v Virkon solution and aspirate with 2% w/v Virkon using a volume greater than that used in the experiment prior to submerging in a jar inside the MSC containing 2% w/v Virkon.

2.2.9. Spray or wipe down racks, tip boxes, etc. used in the working procedure with 70% IPA prior to removal from MSC. Re-use or discard into an autoclavable waste box for autoclaving.

2.2.10. Loosely seal tubs/troughs. Label with date waste has been generated, user's initials and pathogen used. Store in the designated area until relevant disinfection time has passed, prior to discharging to drain as below.

2.3. Discharge of disinfected waste

2.3.1. Waste from MSCs (Gilson-style pipette tips, serological pipettes submerged in Virkon 2% w/v). Check date to ensure overnight disinfection (or longer) prior to discharging to drains through a colander/suitable sieve.

2.3.2. Log decontaminated waste discharged to drain on liquid waste form, S-QMS-SOP-30143.F1. After draining, place plasticware in autoclavable box for autoclaving.

2.4. Disposal of MSC HEPA filter

2.4.1. Contaminated HEPA filters are sterilised in situ during MSC fumigation.

2.4.2. When required, and after purging of fumigant, the filters are replaced by the external contractor.

2.4.3. Double wrap the contaminated filter in specifically designed large plastic bags and label as containing a biological hazard. Filters are not autoclaved but disposed of directly into autoclavable waste box.

3. Waste from Outwith MSC

3.1. Procedure

3.1.1. Dispose of solid waste, including dirty disposable laboratory coats and gowns, in an autoclavable waste box for autoclaving.

3.1.2. Discard liquid waste (from incubators, defrosting of fridge/freezer, etc.) in a container. Add Virkon powder/tablets to reach a final minimum concentration of 1% w/v. Leave overnight prior to discharging to drains.

4. Autoclaving

4.1. General

4.1.1. All solid waste is to be autoclaved at 121°C for 15 minutes prior to disposal, see S-QMS-WI-30232 for Operation of the Autoclave.

5. Waste Disposal

5.1. General

5.1.1. Post autoclaving, solid waste is incinerated.

5.1.3. Solid material is incinerated post autoclaving. This requires disposal via a Registered Waste Contractor.

5.1.4. Collect all autoclave waste in clinical waste bags and put into clinical waste bins at the rear of the facility.

5.1.5. Place all sterilised solid waste in plastic clinical waste bags and close with tie wraps. Put into clinical waste bins.

5.2. Clinical Waste

5.2.1. All clinical waste from a CL3 laboratory prior to leaving the site must be in clinical waste bags/containers as described above labelled with UN3291 and marked “for incineration”.

6. DOCUMENT

6.1. General

6.1.1. All Autoclave records and records of Decontaminated waste discharged to drain will be maintained in the laboratory for 6 months prior to being archived by the Lab manager according to S-QMS-SOP-30003, Submission and Archiving of Quality System Records.
The internal LumiraDx GMM safety committee is composed of a cross-functional group with expertise in Virology, Quality Assurance, Health and Safety, Environment, and Biological Sciences. Several members have experience in working in CL3 laboratories, and one member has 10 years particular experience working with GMMs. The risk assessment has been presented and agreed by the committee, and will be revised on an ongoing basis at least annually.

Y

Give brief details of the genetic modification safety committee

Menarini Biotech UK Branch is part of Menarini Biotech S.r.l, Pomezia (Rome), Italy which has an established Biological Safety Committee and reviews all GMOs in use at the Facility in line with regional legislation.

The UK branch of Menarini Biotech will only use GMOs that have been created for MBH Pomezia and are accompanied by an approved Biological Risk Assessment.

3 Document are attached to this Contained Use license application.

This is the Risk Assessment on cell line OBT_357NF_19C4, translated from Italian into English, approved for use on 25Sep2013. This document originally risk assessed OBT_357 as Cat 2.

Doc2. "report valutazione rCHO 8.5.2018_signed.pdf"

This native Italian language Risk Assessment updated the Risk Classification of all GMOs in use at MBH's Pomezia (Italy) facility as Cat 1.

The Menarini Biotech UK Branch facility will only work on GMO's that originate through the parent Italian organisation and have therefore been risk assessed by the parent organisation's Biological Safety Committee and by the responsible Biological Safety Officer.

02/03/2022
An Astell autoclave (63L model AMA240) has been purchased/installed within the Menarini Biotech UK branch labs for the inactivation of relevant waste. Solid/contaminated waste will be disposed into biohazard bins/boxes, sealed and placed into a lockable clinical waste container and disposed of by a registered waste management company (Select Environmental Services).

Decontamination of surfaces will be conducted using elevated levels of the disinfectant ChemGene HLD4L, Distel and 70%(v/v) Kleercide spray. Inactivation of liquids will be performed using Virkon tablets as per manufacturer instructions.

For activities involving GMMs, describe the waste management measures which will apply to the activity

02/03/2022
GM bacteria and mammalian cells will be deactivated in virkon, such that all GMOs will be destroyed, before disposal in wastewater. It is expected that this will kill 99.98% (as per the manufacturer's validation) of bacteria and/or mammalian cells. Testing will consist of spread plate bacteria after virkon deactivation, and measuring remaining viable cells by trypan blue exclusion assay for virkon treated mammalian cells.

All plastic ware will be autoclaved in a BS 2646, Part 3, 1993 (either 121-125°C for a minimum of 15 minutes, or 126-130°C for a minimum of 10 minutes, or 130-136°C for a minimum of 3 minutes). Excess liquids will be discharged to the drains, solid wastes will be disposed of via the clinical waste stream for incineration/disposal. Any sharps used will be disposed of via clinical waste stream for incineration. Autoclave and incineration will deliver a degree of killing of 100%.

For activities involving GMMs, describe the waste management measures which will apply to the activity

The University of Oxford, Innovation Buildings Biological safety committee was pleased to approve our risk assessments with no modifications.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The University of Oxford, Innovation Buildings Biological safety committee was pleased to approve our risk assessments with no modifications.

Project Ref 3449/19.1

Date Ackn'd 14/03/2019

CU2 Project Title Use of replication-defective retroviral and lentiviral vectors expressing reporter genes

Class CultureVolClass2 CultureVolumeClass3-4

Class 2 < 1 Litre
**Project Additional Information**

**Purposes of the contained use**

The purpose of our work is to develop improved cellular therapeutics for treatment of disseminated cancer. The risk assessments to human health and the environment show that the genetic material to be generated during this project has a relatively low risk, warranting using containment level 2. The final GM activity class is containment level 2.

**Recipient or parental organism**

**Working in vitro**

1. Typically cells will include human and murine cancer cell lines (e.g., human breast cancer cell lines such as MB-MDA-268 or human colorectal cancer cell lines such as HT29, HCT116 or murine colorectal CT26 and MC38 cell lines), primary human and murine blood cells and other cell lines such as 293 and THP cells.
2. All cells will be incubated in vitro with retro/lentiviral vectors at a multiplicity of infection (MOI) between 1 and 100, with virus left in place for at least 24h.
3. Cells are then washed three times to remove free virus and either evaluated for reporter gene expression (using flow cytometry or luminometry) or expanded to allow for selection of transduced cells to create enriched preparations of transduced cells.
4. Sometimes cells may be grown as single cell clones to allow for characterisation of expression and/or copy number and integration site analysis.

**Working in vivo**

Typically cells (including THP cells, monocytes, other leukocytes) will be incubated with virus in vitro using the procedures and PPE (see attached risk assessment for details). The transduced cells will be selected by treatment with puromycin, sorted by flow cytometry or subject to at least three media changes and used as a mixed preparation of transduced and untransduced cells. See below, or the attached risk assessment, for details of the protocol.

**Host/vector system**

Replication defective retro/lentiviruses are generated by transfection of producer cells (commonly HEK293 cells or derivatives of) with multiple plasmids which together provide the required genes for packaging the gene of interest into infectious replication defective viral particles.

The viral vectors are derived from numerous wild type viruses, such as MoMLV, HIV, SIV and EIAV. However non-essential genes have been removed from the vectors and the remaining genes split onto separate plasmids with minimal homology to reduce the risk of homologous recombination. For example lentiviral vectors derived from HIV are devoid of tat, vif, vpu, vpr nef and the envelope gene has been replaced by VSV-G envelope. Gag, pol and rev are generally on one plasmid, env on a second and the gene of interest is on a third plasmid along with cis-acting signals required for reverse transcription and integration. As the gag, pol, rev and env plasmids do not contain
the packaging sequence none of the genes are present in the package viral genome. The likelihood of these viral particles obtaining the missing genes is very low and therefore the risk of replication competent viruses being created is minimal.

In addition, some of the later generation viral vectors also include a self inactivating feature, a deletion within the 3’ LTR, which is transferred to the 5’ LTR after reverse transcription and integration in infected cells. This results in the transcriptional inactivation of the LTR in the provirus and reduces the risk of transactivating genes around the site of insertion.

Some concern has been raised with regards to the potential oncogenic activity of the post-transcriptional regulatory element from the woodchuck hepatitis virus (WPRE) which is frequently included in lentiviral systems. Following the guidance from the Health and Safety Executive these systems must be handled at Containment Level 2

Retro/lentiviral particles will be pseudotyped with common glycoproteins such as RD114 or Vesicular Stomatitis Virus glycoprotein G (VSV-G), which allow efficient gene transfer to a broad array of cell types and species.

Producer cells are especially disabled hosts having strict nutritional and environmental requirements for survival. The modifications are not expected to increase their survival in the environment, nor increase their ability to evade the immune system. Therefore the only risk is from the viral particles themselves.

The inserts are all thought to not increase the risk of the virus. Known oncogenes, proto-oncogenes or immunomodulatory genes are not covered by this risk assessment. No genetic alterations will be made to the retroviral/lentiviral packaging plasmids or retro/lentiviral backbone transfer vector plasmid

Assignment of provisional containment level: Containment level 2 with Good Microbiological Practice and Good occupational Hygiene.

Origin & function

Transgenes to be expressed include:

• Reporter genes: Photinus (firefly) and renilla luciferase, Beta-galactosidase, Secreted Alkaline Phosphatase, Chloramphenicol acetyltransferase, fluorescent proteins from marine organisms (CFP, EGFP and YFP). These naturally fluorescent proteins emit light when excited by high-intensity light of specific wavelengths. Several variants of natural genes have been produced that encode a protein with modified adsorption/emission characteristics and which have been optimised for higher level expression, e.g. the “EGFP”. GFPs are widely used and no hazardous properties have been reported. Other proteins have been isolated from other organisms, however, each of these proteins has no cellular toxicity in normal cells, otherwise, they would not function as a successful reporter gene. Luciferase from Firefly and Sea Pansy are widely used as reporter genes and not considered to have harmful properties. No hazardous effects are anticipated because all the parent proteins are without harmful properties.

• Mammalian selectable markers: Hygromycin resistance, Puromycin resistance, Zeomycin resistance, Neomycin resistance, Blasticidin resistance, and Geneticin resistance. Never shall any vector contain more than one of these markers. They do not function in bacteria. The promoter of the mammalian antibiotic resistance or selectable marker is recognised by the mammalian RNA polymerase and allows transcription of the gene of the mammalian antibiotic resistance or selectable marker in mammalian cells.

• Promoters: Different promoters will be used to regulate reporter gene expression in order to achieve different levels of expression. Typically these will include CMV, SFFV, SV40 and EF1α promoters. We will also include mammalian promoters associated with differentiated macrophages, such as the promoters for CD80 and CD86, CD206 and others. We may also include synthetic promoters. There are no risks associated with the promoters, as they do not themselves encode any proteins, they merely influence the level of transgene expression achieved.

Evaluation of foreseeable effects

Working in vivo

As above, typically cells (including THP cells, monocytes, other leukocytes) will be incubated with virus in vitro using the procedures and (see attached risk assessment).
The transduced cells will be selected by treatment with puromycin, sorted by flow cytometry or subject to at least three media changes and used as a mixed preparation of transduced and untransduced cells.

All animal work will be performed under the Project licence led by Prof L Seymour, currently PPL: 30/3391

Procedure: [19(b)]:2 Studies in tumour-bearing animals

METHODS:
1. Immune-compromised mice such as NSG will be used, suitable for engrafting human tumour xenografts and also administration of human immune cells.
2. Administration of tumour cells or mixtures of tumour and normal cells with/without matrigel (on one or two occasions; as suspension) by inoculation subcutaneously. Animals may receive two subcutaneous injections of tumour cells in different sites.
3. Following tumour growth, administration of retrovirus/lentivirus-treated therapeutic cells (+/- loaded with a fluorescent dye for in vivo tracking) by intravenous injection (i.v.) or inter-tumoral (i.t.)
4. Irradiation of tumour either given in a single fraction (maximum 30 Gy) or utilising a fractionated regime, up to a maximum of 50 Gy total (maximum five times per week, maximum 5 Gy per fraction). Mice will be anaesthetised throughout. Lead-lining or SAARP may be utilised to minimise dose to normal tissue.
5. Light imaging up to 12 times, 24hrs minimum interval between imaging sessions. Animals will be placed in an imaging camera for 5-30 minutes.
6. At the end of the experiment animals will be killed by Schedule 1 method or exsanguination under terminal anaesthesia with or without perfusion
7. Animals will be checked and scored daily for signs of discomfort, and weighed at least 3 times a week. If general condition becomes poor and recovery is deemed unlikely, animals will be killed by a schedule 1 procedure.

Transgenes and their potential risks
Transgenes will include only reporter genes and/or selectable markers. No other proteins will be encoded (for example there will be no toxins, super-antigens or oncogenes).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
n/a - We will not be generating GM animals or plants

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

We will use full containment class 2, with no derogation.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Please see specific control measures in Table 1 of the attached risk assessment
i) For E.coli work
The containment and control measure that will be applied for work with these genetically modified micro-organisms are shown on Table 1. Containment level 1 will be applied with Good Microbiological Practice and Good Occupational Hygiene. Class 1.

ii) For viral production work
The containment and control measure that will be applied for work with the genetically modified cell lines are shown on Tables 1. Containment level 2 will be applied with Good Microbiological Practice and Good Occupational Hygiene. A microbiological safety cabinet, eye protection and gloves will be used for protection and to maintain sterility. Class 2.

iii) For in vitro and in vivo work
The containment and control measure that will be applied for work with the genetically modified cell lines and the infectious vector preparations are shown on Tables 1.
Containment level 2 will be applied with Good Microbiological Practice and Good Occupational Hygiene. A microbiological safety cabinet, safety glasses and gloves will be used for protection and to maintain sterility. Class 2.

WASTE MANAGEMENT MEASURES

Consumables (mainly plasticware eg pipettes, flasks, tubes) – treat overnight with Virkon following manufacturer’s guidelines or autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for incineration.

Liquids (eg samples, culture supernatants, tissue culture media) – treat overnight with Virkon following manufacturer’s guidelines or autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for incineration.

Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration

Animal bedding – depending on the location. Will be autoclaved using make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes) and disposed as industrial (black bag) waste, or sent directly for incineration.

Animal carcases – Sent directly for incineration

Degree of kill

Autoclaving, effectively 100% kill (annual validation)

Incineration, effectively 100% kill (licensed incinerator)

Chemical disinfection with Virkon, used according to manufacturer’s instructions under standard conditions, manufacturers validation [eg 4.79] log reduction [eg 99.998]% kill.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
The safety committee had no collective comments on our risk assessment, given the limited nature of our work, they were happy to approve the work without modifications.

Individual comments included:
"I agree with the classification and the assessment is comprehensive and well written." Dr Julie Hamilton, Divisional Safety Officer (Clinical) Medical Sciences Division, University of Oxford
"No comment from me. The RA looks really comprehensive."
"I have no comments as all have been answered now."
"No comment"
"This looks reasonable to me"

Give brief details of the genetic modification safety committee

The genetic modification committee consists of three members. The first member has a BSc and PhD in microbiology, and has 14 years’ post-qualification experience working with genetically modified micro-organisms. The second member also holds a PhD and has over four years’ experience working with genetically modified organisms. The third member Julian is the Environmental and Health Safety (EHS) representative for Building 760. The committee will meet every four months, or on an ad hoc basis where the need arises. The role of the committee is to confirm that the work being undertaken falls within Class 1 in that none of the host organisms or transgenes are likely to pose a risk to human health, and the correct procedures are followed for the handling and disposal of waste.

Laboratory | Animal Unit | Growth Room | Glass House | Large Scale
---|---|---|---|---
Level 1 (GMMs) | Yes | | | |
Level 2 (GMMs) | | | | |
Level 3 (GMMs) | | | | |
Level 4 (GMMs) | | | | |
Non-microbial | | | | |
Other (please specify) | Tick if confidential | | | |
Liquid waste will be sterilized by either autoclaving or chemical disinfection. Where practically possible, autoclaving is the preferred method for the inactivation of liquid waste. For autoclaving, the liquid waste will be held at temperature equal to or greater than 121°C for at least one hour per gallon. For chemical disinfection, Presept tablets will be added to a final concentration of at least one 2.5 gram tablet per litre of liquid waste.

Solid waste will be disposed of by autoclaving for at least one hour at 121°C. Once sterilized, the autoclaved waste will be enclosed within clinical waste bins (which are incinerated).

To prevent risk of incomplete inactivation, colour-change indicators will be used for each autoclave run. The autoclave will also be validated annually during its service.

The work that will be undertaken will include the transfer of enzyme-encoding plant genes into micro...

Give brief details of the genetic modification safety committee

Initial guidance on risk assessments was provided by an external biosafety consultant. Ongoing advice is provided by the Genetic Modification Safety Committee (GMSC).

The GMSC is composed of:

Committee Chair - Environmental, Health and Safety Team Leader
Committee secretary - Biological Safety Officer - Consultant Scientist Technical Services/Manufacturing Science (TSMS). PhD qualified scientist with accredited Biological Safety Officer Training (Biosafety Practitioner Level 1 validated by the University of Edinburgh)
Core Team Member - Environmental Advisor
Core Team Member - Development Team Leader, TSMS. PhD qualified scientist with management responsibility for process development

Attendance at the GMSC by other management and technical personnel is on an ad hoc basis according to the needs of the areas represented by those personnel at the time of the committee meeting.

The GMSC meet at least 6 times per annum on a scheduled basis. Additional ad hoc meetings are held if matters requiring GMSC advice and/or review arise outside of the planned meeting schedule.

A self inspection programme, led by the Biosafety Officer, is in place and a minimum of 6 inspections are carried out per annum.

All wastes are inactivated before leaving the premises. Where at least a 5 log reduction in viable cells can be assured inactivated wastes are disposed of via normal drain or laboratory waste routes. Where at least a 5 log reduction in viable cells cannot be assured wastes are incinerated via an approved waste contractor.

At laboratory and pilot plant scale: Liquids and liquid contacting consumables are primarily chemically inactivated. Heat inactivation is used in some laboratories.

At plant scale bulk liquids are heat inactivated. Residues on plant processing equipment may be chemically and/or heat inactivated. Small liquid volumes, such as samples, and consumables which come in to contact with samples are chemically inactivated.

Spills are chemically inactivated. Where chemical inactivation is employed proprietary disinfectants are used which conform to standard CEN1276 and therefore assure at least a 5 log reduction in viable cells. As such no additional monitoring is proposed.

Where heat inactivation is used initial data are generated to demonstrate the level of inactivation achieved. Heat inactivation generally results in full inactivation. Ongoing monitoring is achieved through normal process and equipment monitoring and maintenance programmes.
All risk assessments are reviewed by appropriate technical and management personnel including the Biological Safety Officer and the GMSC Chair. Please refer to section 10 for the qualifications of the Biological safety Officer.

Non-GMM Consent Granted

Project notified under transitional arrangements

Tick if notifying a connected programme of work: N

**Project Additional Information**

**Purposes of the contained use**
To produce a protein for development purposes

**Recipient or parental organism**
Aspergillus niger randomly mutated from ATCC 13496

**Host/vector system**
Several copies of the target gene have been integrated into the genome of the parent A. niger strain. No other foreign DNA or vectors are present in the final GMM.

**Origin & function**
The target gene has been inserted to allow the GMM to produce the protein of interest and secrete it extracellularly.
### Evaluation of foreseeable effects

The A. niger parent strain presents a low hazard to humans and to the environment. The changes made to the parent strain, to create the GMM, do not present any additional hazards to humans or the environment.

The product of the GMM is extracellularly expressed. It is generally recognised as safe for use in human food. It is not a skin allergen or sensitiser but may cause sensitisation and allergic response, by inhalation, in hypersensitive individuals. Given that the material is to be produced in liquid culture there is a low risk of inhalation.

The product of the GMM is not ecotoxic. It is water miscible and biodegradable and is unlikely to bioaccumulate or persist in the environment. It is produced by environmental microbes, consequently an inadvertent release from a laboratory is unlikely to increase the already low potential for impact to the environment.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

| N/A |

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation is requested.

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

| Flask seed cultures which are not transferred to the seed fermenter will be chemically inactivated with a proprietary disinfectant, to guarantee at least a 5 log reduction in viable cells, with 100 % inactivation being expected. The actual level of inactivation will be experimentally determined. The waste will not be disposed of until this determination has been made. Routinely, this chemically inactivated liquid waste will be sent to drain. Completed seed fermenter cultures, which will not be transferred to main fermenters, and completed main fermenter cultures, which will not be transferred to the downstream development laboratory, will be heat inactivated to guarantee 100 % inactivation. The heat inactivation temperature/time conditions will be experimentally determined. Until the heat inactivation conditions have been proven all fermenter cultures will be additionally sterilised at 121°C, or greater, for at least 15 minutes, to guarantee 100 % inactivation, before being cooled and sent to drain. Routinely, heat inactivated fermenter cultures will be sent to drain. The first step in the downstream process will be to remove biomass from the culture sample. This biomass will be autoclaved at 121°C for 15 minutes, on a small fluids load, to guarantee 100 % inactivation. This autoclave cycle has already been validated for 100 % inactivation of a worst case test organism, Bacillus stearothermophilus. Routinely, autoclave inactivated biomass waste will be sent to drain. Once the biomass has been removed, the downstream process stream will be considered non-GMM. Laboratory consumables, such as sample bottles, pipettes, cuvettes, nitrile gloves, which have been in contact with live cultures will be placed in an autoclavable waste bag and autoclaved on a 134 °C porous load cycle to guarantee 100 % inactivation. This autoclave cycle has already been validated for 100 % inactivation of a worst case test organism, Bacillus stearothermophilus. |

Give brief details of the genetic modification safety committee
Risk assessments have been conducted by an experienced research scientist, with over 12 years experience of working in bioscience pharmaceutical industry, with extensive experience generating, expressing, analysing and disposal of genetically modified organisms, up to and including GMO level 2 organisms. Scientist has spent the past 2 years working as a member of a biosafety committee for a large pharmaceutical company.

Risk assessments and HSE applications have been reviewed by a biosafety committee comprising of:
- The author of the risk assessment - as outlined above
- a highly experienced molecular biologist and mammalian cell culture specialist with >25 years experience in the drug discovery of generating large scale mammalian and insect cell genetically modified organisms.
- a highly experienced protein expression scientist with >25 years experience in the pharmaceutical industry of generating and expressing genetically modified organisms in a range of host organisms, including bacteria, mammalian cell lines, yeast etc.
- A consult Biosafety Officer, with a background of >20 years working in oncology drug discovery in the pharmaceutical industry, supporting researchers to provide biosafety awareness training, legislative awareness, supporting bioscientists to risk assess both biohazards and genetically modified organisms for their respective experiments prior to initiating work.
- A Senior Lab Technician, currently supporting scientists in a large pharmaceutical company, but with no formal scientific qualifications past GCSE.

02/03/2022
For activities involving GMMs, describe the waste management measures which will apply to the activity

access. The solid waste will be comprised mainly of plasticware and contaminated tissues used in the decontamination process. To deactivate, 2% virkon strength for a minimum contact time of 2 hours will be implemented. As a result, there will be no viable genetically modified microorganisms (GMM) remaining in solid waste.

All samples within Cryosphere Services are treated as GMM level 2 waste, due to the samples we store being generated by third parties, and therefore we cannot guarantee their validity, for example the risk of mis-labelled tubes. As such, all solid GMM contaminated waste post deactivation is double bagged into biohazard autoclave waste bags and secured with autoclave tape. Should there be any chance of liquid drip escape, absorbent pads are used within the bag. The bags are labelled and a trained waste technician will transfer the bags using medibins and specifically designed wheeled clinical waste carrier, to an on-site and enclosed waste facility, where the waste is transferred into a nearby building, via an internal corridor, and into the autoclave for 100% sterilisation. The waste does not go outside until it has undergone complete deactivation.

All liquid waste will be disinfected with 2% virkon solution. Solutions will be left soaking for a minimum of 2 hours before disposal via the drain with copious amounts of water.

Procedures, relevant training, supervision and safety inspections are in place to ensure that all staff comply with waste protocols correctly as specified above.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment
1. Given the remit of this risk assessment solely covering storage of genetically modified microorganisms, in well established facilities, with an existing support infrastructure in place, this is very low risk to both staff, downstream operatives and the environment.

2. Although the GMO level risk is captured upon receipt of each sample from a third party, and tracking on an inventory management system, is it possible to highlight the locations of these samples in the laboratory, or segregate them?

   Whilst the majority of our samples will not be genetically modified, or GMO risk class 1, our day-to-day storage processes are not impacted by their containment level, as we are only storing samples, not using them. However, should a container break and sample contents be released in the laboratory, our standard procedure is to treat all material at containment level 2, and disinfect and dispose of the sample and associated cleaning materials, to ensure 100% sample is killed. This is for two reasons;
   - We cannot wholly guarantee that our customer hasn't accidentally mis-labelled a vial, or contaminated a sample with a class 2 microorganism, and
   - The safety of our employees, downstream contractors and the environment is paramount, and due to the inability to guarantee the first point, we do not wish our staff to be complacent around samples, and not react with due diligence and haste should a sample be broken.

3. Is it possible to put GMO 2 level samples in an additional layer of storage?

   Samples are currently secured in bespoke made sample containers specific for the sample type and conditions under which they are being stored. Samples are visually inspected prior to placing in secure storage boxes, with sample container level tracking in place. Storage boxes are placed in purpose built storage boxes, with sample container level tracking in place. Storage boxes are placed in purpose built locked storage units, e.g. ultra-low temperature freezers, in a locked premises accessible only accessible to Cryosphere Services trained staff and contractors. Additional level of storage has been considered, however due to the purpose built, tight fit, nature of the storage containers and racking, it was deemed that additional containment, would make it cumbersome to handle and increase the risk of dropping samples.

4. How are you able to guarantee that no customer deposits class 3 or 4 material with you?

   Whilst we are not able to validate the authenticity of every sample we receive, we do have robust contracts in place, coupled with deposition forms, which we expect customers to declare the containment level associated for the samples. We reserve the right at any time to decline receipt of samples, return samples to the customers or ask for a copy of their detailed risk assessment, should we have any doubts about the information they have provided. We have worked in the industry for 13 years, and as such have a wealth of knowledge to understand the types, and risks, of a variety of samples. The industry we work in, equally is well connected and as such customers credibility is frequently known.

**Project Additional Information**

**Purposes of the contained use**

This proposal covers 'storage only' activities for all microorganisms, which would be assigned to risk classes 1 or 2 for normal laboratory operations. It covers only storage of microorganisms where no other activity is being conducted. Any work using relevant organisms, other than for storage will need to be the subject of a separate risk assessment conducted by the responsible scientist, for example in the third party company.

Customers may require Cryosphere Services to either:
- arrange transport of genetically engineered biological materials from Cryosphere premises to other sites or,
- arrange disposal of genetically engineered biological samples,

In both of these instances, Cryosphere Services employees will coordinate the transport, and/or disposal of samples via third-party contracting parties, specialising in handling and disposal of genetically modified organisms.

Cryosphere Services have investigated a number of contracting companies and have identified preferred suppliers, whom are experts in their fields and can guarantee the containment of the samples, ensuring safety of people and the environment.

**Recipient or parental organism**

Cryosphere Services will be providing storage service for third-parties and as such there will be multiple parental and recipient organisms.

**Host/vector system**

The cloning will be carried out by third parties, and not Cryosphere Services, and therefore various hosts and vector systems may be used.

Customers will likely have used cloning systems such as the following outlined below:

Non mobilisable and mobilisation-defective plasmids containing established mammalian expression and maintenance features. Some may also contain viral sequences for plasmid maintenance. Lentiviral and retroviral particles (or vectors) based on a range of human virus (HIV) or animal virus (eg. MMLV, MMTV and MSCV). Adenoviral and adeno associated viral vectors containing minimal adenoviral sequences. Also includes Bacmam vectors which are a modified form of the Baculovirus vectors containing mammalian promoters and other viral sequences. Viral vector
systems, such as second generation retroviruses contain minimal viral sequences and the transgene plasmid is separated from the packaging signal to minimise possibility of replication. Second generation lentiviruses are further de-risked by the transgene and packaging signals being split across three vectors. These modifications mean that the viral elements are covered under class 2 containment. Baculovirus vectors for insect cell expression - although replication competent are incapable of transducing human cells. Other vectors may be derived from viruses, e.g. Semiliki Forest virus and Alpha virus. Viral packaging where appropriate is achieved using plasmids containing minimal viral sequences. All viral vectors are extremely unlikely to be able to mobilise or replicate in human cells and are unable to survive in the wider environment. As such they are unable to present the pathogenesis associated with the originating pathogen.

Vectors may include some which are potentially mobilisable in an appropriate host background (i.e. mobilisationdefective) and which include antibiotic resistance genes for use as selection markers. Some vectors include transposons or encode transposase functions. They include non-expression and expression vectors. Expression vectors include those designed for expression in mammalian, insect, bacteria and yeast systems and include vectors used in the generation of recombinant viral particles. The resulting viral particles are all designed to be attenuated as described in the original proposals for their use. Where cells are capable of producing recombinant viral particles, these may be able to deliver to human cells, sequences able to express biologically active molecules. There may be harmful effects associated with these when expressed in an unregulated manner in cells in which expression is normally subject to tight control, or where they are expressed in cells in which they do not normally occur at significant concentrations. There is also a risk of activation and recombination events with native retroviruses, e.g. ecotropic, xenotropic, amphotropic and polytropic viruses. Considering the storage-only scope of this risk assessment, as long as material is treated under containment level 2 material and material handled accordingly, this is low risk. Where cells are designed to produce recombinant viral particles these are all designed to be attenuated and with the exception of recombinant baculoviruses, the viral particles are designed to minimise production of replication competent viruses.

Historically, replication competent viruses may have been employed to engineer certain cell lines and some laboratories may still use this system. As standard, all material stored within Cryosphere Services is treated as risk class 2 material.

Origin & function

Inserts are from a wide variety of sources including rodent and human tissues, and include both genomic and cDNA sequences. Both hazardous and non-hazardous modifications may be introduced either via insertion, deletion of sequences or the presence of mutations generated by genetic modification techniques, including but not exclusively CRISPR (Clustered Regularly Interspaced Short Palindromic Repeats). The properties of the proteins covered by this proposal as they exist in the native microorganisms cover a wide range of known protein functions including enzymes, receptors, and other proteins involved in regulation of normal cellular activities including cell growth and division. Details are set out in separate risk assessments, which are generated by the third-party depositing these micro-organisms for storage at Cryosphere Services. These task specific risk assessments are completed by the third-party scientist intending to use the cell lines.

There will be occasions where genes would be expressed in an active form, however this risk is not covered under this assessment, as only storage, of samples is considered under this proposal.

Some recombinant microorganisms are able to express products which may be oncogenic, toxic or allergenic, and human primary material, in particular, can also present adventitious agents which may affect a normal immune status. It is for this reason that all material is treated as risk class 2 and all Cryosphere Services employees are given the opportunity to be immunised for Hepatitis B. This is considered a low risk for this particular risk assessment given samples are to only be stored.
It is possible that under culture conditions, recombination events between viral vectors and host viruses may lead to resistant strains, however this is not in scope for this risk assessment, and therefore this is considered a low risk for this particular risk assessment given samples are only being stored.

**Evaluation of foreseeable effects**

None of the microorganisms would be classified as greater than risk class 2 in normal operations and most are risk class 1. Having regard to the restriction of the activities covered by this proposal to storage only, and the conditions under which they are stored as described elsewhere in this proposal, the risk of exposure of persons or the environment is negligible to low. Due to the high number of vials handled by employees on a daily basis, all material is treated at containment level 2, and personal protective equipment used, which include lab coats, safety glasses and gloves. Hand wash facilities are available in all laboratories. Cryosphere Services staff are also provided the opportunity to be immunised for Hepatitis B.

Employees undergo a rigorous training programme prior to working independently with samples. This includes reading and understanding of standard operating procedures, 1:1 hands-on training, including assessments and a Biosafety Awareness course. Upon completion of the training procedure, the employee signs off the training task to accept they have undergone the complete training programme and deem themselves competent to undertake the task on their own. The trainer then countersigns to confirm the employee has shown clear understanding, skill and competence to undertake the task independently, at which point they are able to work with the samples. All procedures and training are reviewed annually, and day-to-day working practices are reviewed and standards maintained.

The potential for dissemination of genetically modified microorganisms to the environment is negligible for storage only activities. Disposal of risk class 2 GMO is a consideration, upon unintentional breakage of vials, however samples are stored in purpose built storage containers, further secured in plastic boxes and secure metal racking, within the storage unit. Any disposal of samples is carried out using validated methods in deSignated laboratories or by specialist on-site waste management contractors, with whom Cryosphere Services have audited. Please refer to section 12 for details.

Breakage of vials in liquid nitrogen Dewars. This risk has been mitigated by the optimisation of the tower and box materials used. In the event of vials dropping to the bottom of the tank and being crushed by the weight of the existing towers, sample retrieval and decontamination procedure must be carried out by the Facility Manager. In this situation, all existing well-stored stock is transferred to a spare back-up freezer, samples from the bottom of the tank are retrieved using a long-handled scoop. All retrieved samples are immediately transferred to a double contained bag, kept at -1960C prior to transfer to the quarantine facility for decontamination with 2% virkon for a minimum of 2hrs, ensuring 100% kill.

Any moisture/spillage-is mopped up with 2% virkon infused blue towel, area wiped with water prior to a final wipe with 70% ethanol infused blue towel.

All inactivated liquid waste after virkon decontamination is washed down the sink with copious quantities of water.

Class 2 solid waste is chemically deactivated before leaving the laboratory. The solid waste will be comprised mainly of plasticware and contaminated tissues used in the decontamination process. To deactivate, 2% virkon strength for a minimum contact time of 2 hours will be implemented. As a result, there will be no viable genetically modified microorganisms remaining in the solid waste.

All solid genetically modified microorganism contaminated waste will then be double bagged into biohazard autoclave waste bags, and secured with autoclave tape. Should there be any chance of liquid drip escape, absorbent pads are used within the bag. The bags are labelled and a trained waste contractor will transfer the bags using medibins and a specifically designed wheeled clinical waste carrier, to the on-site, enclosed waste facility into the autoclave for 100% sterilisation. The waste will not leave the building until post autoclaving.

Procedures, relevant training, supervision and safety inspections are in place to ensure that all staff comply with
waste protocols correctly as specified above.
In the event of a sample breakage, Cryosphere Services are able to request a copy of the company's risk assessment for the sample to understand and investigate the biosafety impact of the incident.
All genetically modified organisms will be 100% killed prior to leaving the building.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not applicable.
Cryosphere Services will only be offering storage services for genetically modified microorganisms.
Contained

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Class 2 solid waste will be chemically deactivated before leaving the laboratory. Access to the laboratory is restricted.
The solid waste will be comprised mainly of plasticware and contaminated tissues used in the decontamination process. To deactivate, 2% virkon strength for a minimum contact time of 2 hours minimum will be implemented. As a result, there will be no viable genetically modified microorganisms (GMM) remaining in the solid waste. All solid GMM contaminated waste will then be double bagged into biohazard autoclave waste bags, and secured with autoclave tape. Should there be any chance of liquid drip escape, absorbent pads are used within the bag. The bags are labelled and a trained waste technician will transfer the bags using medibins and a specifically designed wheeled clinical waste carrier, to an on-site and enclosed waste facility where the waste is transferred into a nearby building, via an internal corridor, and into the autoclave for 100% sterilisation. The waste does go outside until it has undergone complete deactivation.
All liquid waste will be disinfected with 2% virkon. Solutions will be left soaking for a minimum of 2 hours before disposal via the drain with copious amounts of water.
Procedures, relevant training, supervision and safety inspections are in place to ensure that all staff comply with waste protocols correctly as specified above.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N
1. Given the remit of this risk assessment solely covers the storage of genetically modified microorganisms in well established facilities, with an existing support infrastructure, this is low risk.

2. Although the GMO level risk assessment for each sample is captured on the deposition form and tracking system, is it worth noting down in the laboratory clearly where the GMO samples are, or segregating their storage?

   - 1=

   Whilst the majority of our samples will not be genetically modified, or GMO risk class 1, our day-to-day storage processes are not impacted by their containment level. However, should a container break and sample contents be released in the laboratory, our standard procedure is to treat all material at containment level 2 and disinfect and dispose of the sample and associated cleaning materials accordingly, to ensure 100% sample is killed. This is for two reasons;

   1. We cannot wholly guarantee that our customer hasn’t accidentally mislabelled a vial, or contaminated a sample with a class 2 microorganism, and

   2. The safety of our employees and downstream contractors and the environment is paramount, and due to the inability to guarantee point 1, we do not wish our staff to be complacent around samples, and not react with due diligence and haste should a ‘non-GMO class 2’ sample be broken.

3. Is it possible to put GMO 2 level samples in an additional layer of storage?

   Samples are currently secured in bespoke made sample containers specific for the sample type and conditions under which they are being stored. Samples are visually inspected prior to placing in a secure storage box, with sample container level tracking in place. Storage boxes are placed in purpose built locked storage units, e.g. ultra-low temperature freezers, in a locked premises accessible only to Cryosphere Services trained staff and contractors. Additional level of storage has been considered, however due to the purpose built, tight fit, nature of the storage containers and racking, it was deemed that additional containment, would make it cumbersome and increase the risk of dropping of samples, due to the lack of dexterity when using thermal protective gloves.

4. How are you able to guarantee that no customer deposits class 3 or 4 material with you?

   Whilst we are not able to validate the authenticity of every sample we receive, we do have robust contracts in place, coupled with deposition forms, which we expect customers to declare the containment level associated for the samples. We reserve the right at any time to decline receipt of samples, return samples to the customer or ask for a copy of their detailed risk assessment, should we have any doubts about the information they have provided. We have worked in the industry for 13 years, and as such have a wealth of knowledge to understand the types, and risks associated with a variety of samples. The industry we work in, equally is well connected and as such customers credibility is frequently known.

Y

Give brief details of the genetic modification safety committee

This form, together with the CU2 form has been assembled under the guidance of:
- two experimental scientists with a combined experience handling prokaryote and eukaryote micro-organism GMOs of over 30 years, and;
- HSE consulting company with highly successful track record in HSE procedures in work-places, including laboratories and in HSE teaching in HE.

The GMSC comprises the Head of Protein Sciences and the Collaborations Pharmacology Director, both Exscientia employees.

02/03/2022
Deactivation of biological waste for level 1 activity is not necessary but is carried out in line with good practice procedures to deactivate all biological waste before disposal, except for waste securely stored for collection and incineration by the approved Exscientia clinical waste contractor.

Disinfection measures: A 2% Virkon solution will be prepared prior to working with viruses and will be available should a spillage occur. After use the consumable and liquids containing virus and GMOs will be exposed to 2% Virkon for a minimum of 60 minutes. Liquid waste will then be disposed of via an approved laboratory sink (thoroughly flushed with water).

Biologically contaminated glassware will decontaminated with a 2% Virkon solution for 20 minutes prior to disposal via an approved laboratory sink.

Biologically contaminated plasticware and consumables will be autoclaved (121°C for at least 15 minutes) and disposed of in the waste collection by the local authority.

Sharps (eg needles, syringes, scalpels) will be disposed via incineration (carried out by external laboratory waste management specialist).

Degree of kill
- Autoclaving, effectively 100% kill
- Incineration, effectively 100% kill
- Chemical disinfection, used according to manufacturer’s instructions under standard conditions, manufacturers validation (99.998% kill).

**Project Additional Information**

**Purposes of the contained use**

To support drug discovery programs.

1. Expression of recombinant proteins, including potential therapeutic targets and anti-targets, in bacterial, insect and mammalian cells for purification and use in structural, biophysical and biochemical activity studies for drug discovery projects.

2. Expression and genetic knock-down of potential drug targets and anti-targets in mammalian cell lines for target characterisation and the development of screening assays. Functional characterisation of the resulting cells will involve standard laboratory techniques including (but not restricted to): secretion assays, reporter assays, kinetic assays, fluorescent microscopy, DNA sequencing, and gene expression studies.

**Recipient or parental organism**

Mammalian cells:

Standard laboratory mammalian cell-lines used are class 1 GMOs. These cell-lines have been widely used for
molecular and cell biology research and are also used by the biotechnology industry. The cell lines are sourced from and characterised by commercial vendors, e.g. ATCC or ECACC, and are provided pre-screened for the presence of blood-borne mycoplasma, bacterial, fungal and viral contaminants.

Insect cells:
The commonly used Hi5 and SF9 insect cell lines used are class 1 GMOs. These strains are harmless to humans and will not survive in the human body or the environment. Baculoviruses have only been isolated from invertebrates, primarily insect species. Although baculoviruses can be taken up by certain mammalian cells (notably hepatocytes cells, Boyce FM & Bucher NL, 1996, Proc.Natl. Acad. Sci USA 93, 2348- 2352; Hofmann et al. 1995, Proc.Natl. Acad.Sci.USA 92, 10099-10103) it is recognised they do not productively infect mammalian cells. Therefore, these viruses do not pose an inherent risk to humans and may be assigned ACDP hazard group 1.

Bacterial cells:
K12 commercial E. coli strains used are not considered pathogenic to humans or animals are recognised as noncolonising to humans and are disabled and thus unlikely to persist in the gut, lung, or survive outside of the special culture medium which provides their auxotrophic requirements. Thus the E. coli strains used would not be hazardous to the environment even if they did survive. Thus, they may be assigned to ACDP hazard group 1. E.coli BL21 is unlikely to be pathogenic and can be considered as broadly equivalent to K12 strains (Chart et al. J.Appl.Microbiol. 2000, 89 1048-1058). Therefore, for the benefit of this assessment it can be categorised as ACDP group 1.

Commercially sourced and a proprietary series of vectors (pEXS) using standard vector backbones will be employed, e.g., those containing and not limited to CoIE1/pMB1/pBR322/pUC, R6K, pACYC, p15A, pSC101 and pRSF1030 replicons. The backbones will include a range of fusion partners eg polyhistidine tags and selection (resistance) markers including but not limited to ampicillin, Zeocin, chloramphenicol and G418 as well as additional sequences such as promoters necessary for expression in specific host cells. The vector sequences are stored on a central drive. All plasmids are non-mobilizable.

Host cells including but not limited to:
Mammalian host cells: HEK293T, Expi293F, CHO, ExpiCHO, Jurkat, A549, MCF-7
Bacterial host cells: DE3 E. coli cells such as BL21, Lemo21, Rosetta 2 and additionally cloning strains such as DH5alpha.
Insect host cells: Sf9, SF21, ExpiSf, Hi5 and drosophila S2.
Transfer of DNA to heterologous hosts will be via transformation of E. coli, transfection and baculovirus mediated infection of insect cells, and transfection or baculovirus mediated infection (BAC-MAM) of mammalian cells. Under Genetic Modification regulations, the bacterial strains and cell lines to be used are considered to be especially disabled hosts. For aseptic purposes, all eukaryotic cell lines will be cultured in a Class II microbiological safety cabinet located in a tissue culture laboratory (containment level 2). The bacterial cells will be cultured in a safety cabinet in a preparative laboratory (containment level 2).

Origin & function
The genetic material will be derived from a range of species and have a variety of functions. This will include cytokines and growth factors, putative and known oncogenes and tumour-suppressor genes, cell signalling and cell cycle pathway genes and short hairpin RNA (siRNA) molecules intended to inhibit the expression of a range of genes including those known or suspected to be involved in pathways of oncogenesis. Genetic material is derived from mammalian or bacterial genomic DNA or cDNA, supplied from commercial sources.
or synthesised through appropriate vendors, (such as IDT). Where deemed necessary, genes, expression cassettes
or open reading frames are subjected to codon optimisation technology through appropriate online vendors.
Gene sequences will require approval internally by the company GMSC before work can start.
Gene functions will include but are not limited to:
1. cDNAs encoding wild-type or mutant known and candidate oncogenes, tumour suppressor genes, cytokines,
growth factors and genes involved in cell signalling.
2. Expression cassettes encoding siRNA molecules under the control of human or viral promoter. siRNAs will be
targeted primarily but not exclusively to genes that may be, or are known to be, involved in cancer development and
progression.

Evaluation of foreseeable effects

Specific hazards associated with inserted genes include:-
Expression/over-expression of known or potential oncogenes: while oncogenesis is known to be a multi-factorial
process, the risk of insertional activation of other oncogenes by the vector, or of insertional inactivation of tumour
suppressor genes is unpredictable, and, could act in concert to contribute to oncogenic pathways.
Expression of cell signalling and cell-cycle genes: constitutive expression of these genes at high levels could be
regarded as oncogenic: similar risk to oncogene expression, above.
Expression of siRNAs designed to knock down known or potential tumour suppressor genes: similar risk to oncogene
expression, above.
Expression of cytokines and growth factors: these proteins have the potential to cause inappropriate growth,
differentiation or apoptosis of cells, which are associated with oncogenesis. Growth factors and cytokines may also
be teratogenic, and have other effects on the immune response, so consideration will have to be given during the
individual risk assessment as to whether expectant mothers and workers with other health issues should be excluded
from such work.
Oncogenic, cytokine and growth factor sequences are capable of encoding biologically active proteins which are
potentially pathogenic to humans. Some of the prokaryotic and eukaryotic vector systems are optimised for high level
expression of protein. The sequences are highly unlikely to alter the pathogenicity or properties of bacterial host
cells. Enforced expression of such sequences in mammalian cells will, in some instances, affect the malignant
properties of the cells. Sequences encoding biologically active oncogenic proteins are classified as carcinogens for
which containment level 2 is appropriate.
Neither the DNA, encoded protein, bacterial or mammalian transfectants are likely to have any deleterious effect on
the environment and the work is at a small-scale (< 15 L). The GM microorganisms are incapable of surviving
outside of the laboratory environment. All laboratory procedures will follow good microbiological practice. GM
microorganisms will be manipulated in a Microbiological safety cabinet. Written records of staff training will be
obtained and checked before commencement of work by individuals. Handling and manipulation of naked DNA will
require the wearing of disposable gloves. Mammalian cell cultures for DNA transfection procedures will be handled in
a Class 2 cabinet. Where possible, sharps will be avoided in all operations; in the cases where it is necessary, sharp
handling training will be provided and all sharps will be disposed in yellow shar disposable bins that will be sealed
and collected for incineration by a trusted contractor. Disposable plasticware (pipettes especially) will be used for cell
culture.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Disinfection measures: A 2% Virkon solution will be prepared prior to working with viruses and will be available should a spillage occur. After use, consumables and liquids containing virus or GMOs will be exposed to 2% Virkon for a minimum of 60 minutes. Liquid waste will then be disposed of via an approved laboratory sink (thoroughly flushed with water).

Biologically contaminated glassware will be decontaminated with a 2% Virkon solution for 20 minutes prior to disposal via an approved laboratory sink.

Biologically contaminated plasticware and consumables will be autoclaved (121°C for at least 15 minutes) and disposed of in the waste collection by the local authority.

Sharps (e.g., needles, syringes, scalpels) will be disposed via incineration (carried out by external laboratory waste management specialist).

Degree of kill
- Autoclaving, effectively 100% kill
- Incineration, effectively 100% kill
- Chemical disinfection, used according to manufacturer’s instructions under standard conditions, manufacturers validation (99.998% kill).

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form  

Tick to confirm that you have attached a risk assessment to this form  

Tick if you are claiming exemption from disclosure for section of the risk assessment

Yes

Give brief details of the genetic modification safety committee

The GMO safety committee consists of four members: The laboratory Head, a Senior Scientist and 2 Directors of Safety and Environment, one with responsibility for EMEA with specialist Sio-safety expertise. The team combines experience in biological safety and molecular biology/cell biology. This team will meet quarterly once the laboratory is operational.

Project Ref 3456/19.1

Date Ackn'd 31/07/2019

CU2 Project Title Transduction of a variety of cell types with replication incompetent and self-inactivating lentiviral vectors to generate reporter cells expressing GFP and luciferase

Class 2

CultureVolClass2 < 1 Litre

CultureVolumeClass3-4 Non-GMM Consent Granted
### Project Additional Information

**Purposes of the contained use**

The purpose of this project is to generate reporter cell lines that will fluoresce and express a secreted form of luciferase upon activation of a particular signalling pathway. 2nd generation replication incompetent, self-inactivating, VSV-G pseudotyped lentiviral vectors will be produced using HEK293T cells and then will be used to transduce different type of cell lines to generate reporter cells expressing GFP and luciferase.

**Recipient or parental organism**

The lentivirus will be used to transduce various different host cell lines.

**Host/vector system**

2nd generation replication incompetent, self-inactivating, VSV-G pseudotyped lentiviral vectors purchased from a commercial supplier.

**Origin & function**

Marker genes (e.g. GFP, Cypridina luciferase and Nanoluc luciferase).

**Evaluation of foreseeable effects**

Evaluation of foreseeable effects: Resulting GM reporter cell lines are not expected to possess harmful properties for humans, animals and the environment as the inserts do not encode any products with potentially harmful biological activity, for example toxins, cytokines, growth factors, allergens, hormones or oncogenes. Additionally the inserts do not encode viral specific proteins, nor do they interfere with known activities of the virus and so are unlikely to have any effect upon the basic nature of the virus as a vector.

In the event of an environmental release, neither the lentiviral particles nor transduced cultured cells are expected to survive outside culture medium. This rules out any possibility of survival, establishment or dissemination in the external environment. In the event of accidental release, viral particles are not capable of causing any infection in the host cells due to absence of viral genes and their replication incompetent nature. Transduction can only happen one round before virus inactivates itself and even if they manage to transduce cells, the resulting gene expression of GFP and luciferase is not expected to cause any harm.

CL2 control measures will be applied throughout the project in addition to local hygiene rules, good microbiology practices, and waste management. The control measures overall are accepted to be suitable and sufficient to reduce any residual risk to negligible/acceptable levels.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A.
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Plasticware vessels, tips, and stripettes will be immersed into 2% Virkon solution for at least 1 h and then they will be placed inside Bio-bins which later will be autoclaved and incinerated.

Manufacturer's validation states 100% kill when left in contact with 1% Virkon for a minimum of 10 minutes.

https://www.fishersci.co.uk/webfiles/uk/web-docs/SLSDG05.PDF

Contaminated PPE such as gloves and flasks will all be disposed of in Bio-bins and autoclaved and later incinerated. Waste is autoclave sterilised using Boxer 400/300V at 121°C for a minimum of 20 minutes. The sterilisation process is logged and checked for successful completion using a Thermo-log. The contents of the bin are then treated as clinical waste, re-bagged, sealed and labelled before disposal into the outdoor Silo bin.

Liquid cell media waste will be aspirated into sealed containers and then autoclaved as above.

Autoclaves undergo annual service, calibration and statutory inspections arranged by London Bioscience and Innovation Centre (LBIC).

No sharp waste will be generated in this project.

Solid laboratory waste that doesn't come into contact with any viable cells and lentivirus will be treated as clinical waste and incinerated via licenced waste contractors.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

Please enter comments on the GM safety committee on the risk assessment

The project bioburden assessment was appraised by the Environment, Health and Safety (EHS) committee and minor revision was recommended. All recommended points were implemented and the Committee has concluded the existing control measures are suitable and sufficient to reduce remaining risk to negligible levels. Committee consent form is issued on 21 June 2019.

For activities involving GMMs, describe the waste management measures which will apply to the activity

All waste will be streamed according to Alderley Park Site Waste guidelines
Contaminated solid waste will be denatured and deactivated in a centralised autoclave that operates under an environmental permit and is remote from these activities. All waste transported to the autoclave facility by trained waste operators in drop-sided wheelie bins. The autoclave sterilising cycle is 125°C for 30 minutes. Autoclave waste will be sent for incineration
Cell culture liquid waste will be inactivated in 2% Virkon for at least 1 hour as solution before disposal down drains and flushing with copious amounts of water
All activities are covered by appropriate COSHH Risk Assessments

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The proposal has been reviewed as a team of scientists including advice from the Site Safety Manager.
All are satisfied that the risk class identified is appropriate for the work to be carried out and the facilities meet the required standard

Yes

For activities involving GMMs, describe the waste management measures which will apply to the activity

All biological waste must be inactivated by treatment with a 1% Virkon solution prior to disposal and yellow bins will be processed by incineration off-site by Vetspeed- GM authorisation number GM898. Incineration eliminates 100% infectious material. Treatment of culture fluids with 2% Virkon and soaking of recyclable lab ware in 1% Virkon for 16h eliminates 100% infectious material. Bench/cabinet surfaces will be wiped down with Chemgene or similar detergent. Small spills will be covered with paper towels, sprayed with 2% Virkon or Chemgene solution, left for 10min before transferring the paper towels to the designated containment level 2 bins. Excess liquid will be dried with additional paper towels using the same disposal method. Large spills will be contained by paper towels at the perimeter and Virkon powder will be spread over the spill. After 10 minutes the liquid waste will be absorbed by paper towels disposed as described previously.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

As tenants of Babraham Bioscience Technologies all laboratory work, including genetic modifications can only take place once it is approved by the Babraham Biological and Chemical Safety Committee which meets weekly.

CU2 Project Title Investigating transcriptional regulatory networks by modulating non-coding DNA and RNA

Class 2

Class Culture Volume

Volume Class 3-4

Consent Granted

Project notified under transitional arrangements

Tick if notifying a connected programme of work

Withdrawn
Our aim is to gain an understanding of transcriptional regulatory networks that determine cell fate choice based on a network model that we are developing from deep machine learning. This is a broadly applicable approach across multiple cellular systems. Our prototype experiments involve using mouse organoids to study the mechanisms of T-cell specification, which is also relevant to the development of leukaemia. We are initially targeting the non-coding region encoding ThymoD RNA, which is required for T-cell specification and causes leukaemia in mice when knocked down. We plan to use CRISPR to knock this down in our organoid system and investigate the phenotype in the broader context of our network model.

Our other prototype experiments involve using a human lung cancer cell line to dissect inducible epithelial to mesenchyme transitions in which several non-coding RNA have been implicated. The rationale behind targeting non-coding RNAs is their prevalence, high cell-type specificity and wide associations with disease phenotypes. In understanding their behaviour within a network we are working towards comprehensive therapeutics. After establishing our prototypes, we plan to move on to a variety of other cellular systems, developing 3D organoid cultures. This will involve using patient derived cells such as matched samples available from EBISC.

Established commercially available mouse (e.g. EML) and human (e.g. A-549 VIM RFP) cell lines. Primary human stem cells e.g. CD34+ blood stem cells from Stem Cell Technologies. Patient derived iPSC lines from resources such as the Cambridge Blood and Stem Cell Biobank, EBISC and HipSci. The likelihood of transfer to humans is minimal given the level of containment and aim to use transient, specific targeting.

Our current approach is to avoid vector based systems and deliver CRISPR reagents as a ribonuclease protein (RNP) complex by electroporation or (preferably) lipofection/vesicle transfer. However, we have consider other delivery systems for more challenging cells types which may require viral
delivery. In this case we will select harmless viral delivery systems such as recombinant Adeno-Associated Virus (rAAV) and second or (preferably) third generation lentivirus systems.

**Origin & function**

The non-coding RNAs that will be modified, either at the DNA or RNA level will be part of a suite of nucleic acids that will have been predicted to be critical for determining cell fate. For example, in our mouse prototype project to study T-cell specification, the non-coding RNA ThymoD is required for T-cell specification and knockdown in mouse results in leukaemia. Our other prototype project, studying the epithelial to mesenchyme transition of a human lung cancer cell line, is likely to predict oncogenic and tumour suppressor type properties of non-coding RNA which we will experimentally validate. Furthermore, future projects aim to functionally test novel noncoding transcripts that may prove to be oncogenic, tumour suppressors and/or convey alterations in growth kinetics. Therefore, until fully characterised, the genetic modifications that we are generating should be handled as possessing these potential properties. All modified cells will be contained at containment level 2 by trained personnel.

Beyond genomic insertions/deletions of targeted non-coding RNA sequences, there may be incorporation of the Cas9 protein sequence which has no known harmful effect. It may also be desirable to insert fluorescent reporter genes, which are biologically inert.

**Evaluation of foreseeable effects**

Our first choice CRISPR delivery system is a vector free RNP complex. This is highly specific, carries a nuclear localisation signal and designed with a single strand oligo donor DNA (ssODN) along with reagents to facilitate homology directed repair rather than inaccurate non-homologous end joining. This reduces off target effects in recipient cells, not least due to the transient presence of exogenous proteins and nucleic acids. Editing potential is therefore limited to a narrow time frame.

If this approach does not work for some difficult to transfect cells, safe harbour viral systems will be used. The non-pathogenic recombinant adeno-associated virus (rAAV) will be the first choice, but if larger constructs are necessary, second or third generation lentiviral systems will be used. The second generation viruses lack all accessory protein associated with virulence and cytotoxicity, while retaining Rev, Tat, Gag and Gag-pol in the packaging vector. A second (transfer) vector contains the viral LTRs (including a Tat-transactivated promoter), the targeted insert and a psi packaging signal, while a third (envelop) vector contains the envelop protein. The third generation lentivirus advances the safety features of the second generation packaging vector by splitting it into two. One vector contains Rev, and the other contains Gag and Gag-pol. Tat is eliminated and an alternative chimeric promoter is present in the transfer vector, independent of Tat
Transactivation. While safer, the third generation system can be cumbersome and so the second generation may have to be considered in difficult to transfect cells. In both systems, the multi-vector approach considerably reduces the probability of recombinant events producing a replication competent virus.

While this is highly unlikely, the potential hazard of a recombinant virus as well as a packaged virus prior to transfection of cells, or residual virus in media should be considered. A virus has the potential to infect multiple cell types via entry routes such as abraded skin and mucous membranes. These entry routes can be protected by standard PPE, gloves, lab coat, safety glasses. Infection is only likely at high titre and high titre viruses are only likely to be achieved by ultracentrifuge concentration, not a remit of our project plans.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All biological waste must be inactivated by treatment with a 1% Virkon solution prior to disposal and yellow bins will be processed by incineration off-site by Vetspeed - GM authorisation number GM898. Incineration eliminates 100% infectious material. Treatment of culture fluids with 2% Virkon and soaking of recyclable lab ware in 1% Virkon for 16h eliminates 100% infectious material. Bench/cabinet surfaces will be wiped down with Chemgene or similar detergent. Small spills will be covered with paper towels, sprayed with 2% Virkon or Chemgene solution, left for 10min before transferring the paper towels to the designated containment level 2 bins. Excess liquid will be dried with additional paper towels using the same disposal method. Large spills will be contained by paper towels at the perimeter and Virkon powder will be spread over the spill. After 10 minutes the liquid waste will be absorbed by paper towels disposed as described previously.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
The Babraham Genetic Safety Committee have reviewed the risk assessment, and once the means of delivering genetic editing agents to the cells was established, approved the document. There is currently only one person in place to perform GM work and future personnel will be made fully aware of this risk assessment.

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Yes

Give brief details of the genetic modification safety committee

The Agentus Bioscience Ltd genetic modification committee will consist of:
1. The head of the Cambridge site who will serve as the chair of the committee and has over 30 years of relevant research experience.
2. Five Agentus staff who have PhDs in various relevant fields of research and more than 10 years research experience including genetic modification and GMOs.
3. The external biosafety consultant (see section 8).
4. The Agentus USA EH&S manager.

The Agentus GM committee agreed that the risk assessment included with this notification was suitable and sufficient. The committee will meet at least every 6 months to review risk assessments and GM procedures.

All waste material will be inactivated by treatment with 1% (w/v) Virkon solution prior to disposal. Waste material will then be placed in sealed bins and incinerated by an off-site incineration company (see derogation application below). Waste from our GM work at Class1 will be placed into suitably labelled hermetically sealable bins. They will be sealed by our staff and removed to a central collection point where they will be placed into 210 litre yellow labelled "Eurobins". Collections for incineration will be made by the local registered clinical/GM waste incinerator contractor. This disposal method is expected to achieve 100% inactivation of the GMM. The data sheets describing inactivation by Virkon are attached.

Tick to confirm that you are attaching a summary of the risk assessment  

Tick if you are claiming exemption from disclosure for sections of the risk assessment  

Please enter comments of the GM safety committee on the risk assessment
The Agentus GMO committee reviewed the GMO risk assessment (see attached). The Agentus GMO committee consists of 6 people who have PhDs in different fields with at least 10 years research experience including genetic modification and GMOs. The GMO committee have previously written GMO risk assessments for similar work prior to joining Agentus and they understand the science around the work carried out.

The Health and safety consultant reviewed the GMOs. The consultant has a B.Sc in Animal Sciences - Wye College (part of Imperial), London University, M.Sc. Animal Parasitology, Ph.D. The immunology and pathology of Sarcocystis ovicanis infections in sheep (both at U.C.N.W., University of Wales). Technical member of the Institution of occupational safety and health (Tech IOSH), NEBOSH National Diploma in Occupational Health and Safety (in progress), NEBOSH National General Certificate in Occupational Health and Safety, Member of the Institute of Safety in Technology and Research, MRC Biological Safety Officer Training Certificate. 1986 to 2010 at the Babraham Institute (Cambridge) where experience of handling pathogens and GMO obtained during research. 2006 made Babraham Research Campus Biological Safety Officer (part time plus research). 2009 onwards teach the genetic modification safety section of the One Nucleus 'Biological Safety: Management and Practice' course (IOSH approved). 2010 onwards Babraham Institute Health, Safety and Quality Assurance Manager and Babraham Bioscience Technologies (BBT) Biosafety Officer (Full time). 8 years experience in risk assessments and has health and safety qualifications.

All GMO risk assessments were reviewed independently and externally by the Agentus (USA) EH&S manager to look for inconsistencies and to highlight potential risks.

Project Additional Information

Purposes of the contained use
The aim of this project is to use lentiviral delivery systems to introduce various mammalian DNA sequences into mammalian immune cells in culture. These sequences direct expression of either (i) RNA species (siRNAs or antisense RNAs) that interfere with the expression of various mammalian proteins or (ii) the corresponding mammalian proteins themselves; for in vitro use and for the generation of stable mammalian cell lines (and subsequent use of such stable lines in vitro).

Recipient or parental organism
Cloning, propagation and amplification of component plasmids for lenti-virus vector systems will take place in K12 and B strains of E. coli (with a history of safe use).
Mammalian cell lines (e.g. immortalized lines derived from human cancer tissues) fall into two types:

a) Packaging/helper cell lines into which plasmids containing lenti- or retroviral DNA will be introduced, and from which infectious virus will be secreted into the medium to high titre (e.g. HEK296 cells). The media from these cell lines poses a risk because of the high viral titre. As such this could provide a risk of infection to personnel working with the media.

b) Recipient cell lines in culture. These cells will initially be exposed to a high titre of virus to permit infection (virus derived from (a) above). However the infected cell lines will be incapable of themselves producing active virus and as such are no more dangerous than the parental cell lines, i.e. a negligible risk.

Host/vector system
The LENTIVIRAL vectors that will be used are derived from HIV-1, which is an ACDP Hazard Group 3 biological agent. However, second and third generation lentiviral vectors have several of the lentiviral accessory genes (required for pathogenesis only) deleted to increase biosafety and viral packaging is achieved by providing three helper constructs in trans containing gag, pol and rev sequences.
For example, second and third generation Lentiviral Expression Systems include the following key safety features:
In the second and successive generation lentiviral vectors several lentiviral accessory genes (vif, vpr, vpu and nef) are deleted from the transfer plasmid since they are not required for in vitro replication and the products they encode have cytotoxic activities.
In addition to this in the third generation lentiviral vectors:
- The Lenti expression vectors contain a deletion in the 3' L TR (LlU3) that does not affect generation of the viral genome in the producer cell line but instead results in "self-inactivation" of the lentivirus after transduction of the target cell (Yee et al., 1987; Yu et al., 1986; Zufferey et al., 1998). Once integrated into the transduced target cell, the lentiviral genome is no longer capable of producing a packageable viral genome.
- The number of genes from HIV-1 that are used in the system has been reduced to three (i.e. gag, pol, and rev).
- Genes encoding the structural and other components required for packaging the viral genome are separated onto four plasmids. All four plasmids have been engineered not to contain any regions of homology with each other to prevent undesirable recombination events that could lead to the generation of a replication-competent virus (Dull et al., 1998).
- Although the three packaging plasmids allow expression in trans of proteins required to produce viral progeny (e.g. gal, pol, rev, env) in the 293FT producer cell line, none of them contain L TRs or the 4J packaging sequence. This means that none of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. No new replication competent virus can be produced.
Despite the above safety features, use of these lentiviral vectors (which include WPRE) falls within SACGM 2
criteria due to the potential biohazard risk of possible recombination with endogenous viral sequences to form self-replicating
virus, or the possibility of insertional mutagenesis. Also, the virus will be packaged by transfecting
transfer vector into specific amphoteric 'helper' cell line (gag, pol and env stably incorporated into host
chromosome cells). NOTE: amphotropic packaging will widen the host range of the virus and allow it to infect a
wide range of mammalian species (including humans) and cell types.
This means that the viruses produced for this experiment could potentially infect a number of species, including
man.

Origin & function

Selectable markers - examples (but not restricted to);
- Ampicillin resistance: E.coli derived
- Neomycin resistance: bacteria derived aminoglycoside phosphotransferase gene
Puromycin resistance (PAC) : Puromycin acetyl transferase is derived from Streptomyces alboniger
Reporter proteins such as (but not restricted to);
- Fluorescent proteins as reporters;
- GFP derived from the jellyfish Aequorea victoria and variants of this
- Luciferase - class of oxidative enzymes used in bioluminescence
- renilla luciferase derived from the Sea pansy (Renilla reniformis)
- firefly luciferase derived from the firefly Photinus pyralis.
Open reading frames, cDNAs and gene sequences encoding potential drug targets or therapeutic proteins and / or
shRNAs (designed to knockdown the expression of Open reading frames, cDNAs and gene sequences encoding
potential drug targets or therapeutic proteins) - all human derived.
This could include the expression of potentially harmful genes e.g. encoding known proto-oncogenes or genes with
known oncogenic mutations that can contribute to cellular transformation.

Evaluation of foreseeable effects

All viral vectors employed in this protocol exhibit broad tropism and potential to infect human. Risks conferred
following infection are identified as:

i) genetic insertion of viral sequences with potentially deleterious effects on endogenous genes: we will employ
transgene promoters and other viral sequences that may affect host gene function in a wide range of cell types
(e.g. CMV promoter). We assess retro-, lenti- or adenovirus infection might induce permanent changes in infected
cells including a risk for tumorigenesis. Risks conferred are previously described and categorised under Class 2
risks [SACGM compendium of guidance part 2, page 121]: "The effects of integration upon the infected cell
should be considered. For instance, promoter sequences present in the provirus might activate genes adjacent to
the integration site or, alternatively, insertion may disrupt genes and prevent their expression."

ii) expression of human-derived or homologous transgenes with potentially deleterious effects: various transgenes
may be employed, wherein intrinsic function of the transgene confers potentially deleterious effects. For example,
expression human oncoproteins could induce transformation of infected cells. Beyond endogenous homeostatic
mechanisms that may lessen this risk (e.g. apoptosis and other host tumor suppression responses), we assess that
standard precautions under Class 2 risk mitigation procedures are adequate to address such risks.

iii) expression of exogenous transgenes directed to host genes with potentially deleterious effects: multiple
transgene technologies (antisense, RNAi, CRISPR or related gene conversion) may be employed to modify the
function of endogenous genes with potentially deleterious effects. For example, RNAi or antisense RNA could
reduce the function of genes necessary to control cell apoptosis, potentially resulting in tumorigenesis. As above,
we assess that Class 2 risk management procedures adequately address these risks.

iv) expression of heterologous genetic sequences with potentially deleterious effects: we will employ diverse
collections of non-human derived, exogenous transgene sequences that carry potential risks following infection.
Risks from expression of these collected transgene sequences are mitigated and attenuated through several
means. First, known pathogenic transgenes systemically removed, and other exogenous gene products are
fragmented or rearranged, such that potentially pathogenic or other biologically deleterious genetic functions are
not recapitulated in their complete endogenous configuration. Second, potentially deleterious transgenes in any
infectious viral preparation are highly titrated, such that any single deleterious sequence comprises less than 1 part
in 100,000 parts of an inoculum with infectious potential. In total, we assess these risks are adequately managed
via the same Class 2 risk precautions employed above.
We assess environmental hazards are adequately addressed through the proposed personnel risk management
measures. We employ multiple attenuation strategies and protocols to severely limit independent virus propagation
beyond the intended use, and therefore anticipate minimal risks of GMM release.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Instead of autoclaving waste in the building we propose to follow the procedure used by the Babraham Institute
described in their disposal notification GM105/4.1 (see also section 6 above for description). Reasons for adopting
this method of waste disposal are:
1. We do not have access to an autoclave within our area of the building
2. The waste disposal system used by the Babraham Research Campus is safe and has been running since
All liquid waste material will be inactivated by treatment with 1 % (w/v) Virkon solution prior to disposal. Solid waste
material will be placed in sealed bins and incinerated by an off-site incineration company (Vetspeed - Their GM
authorization is GM898) according to disposal notification GM1 05/4.1.
Waste from our GM work at Class 2 will be placed into suitably labelled hermetically sealable (red lid to distinguish
them from Class 1 waste) 60 litre UN approved (to Class 3) Type 3H21Y30/S/2003 bins. Sealed bins are placed
into secondary 210 litre yellow labelled "Eurobins". Contents of the bin are recorded and collections by the local
registered clinical/GM waste incinerator contractor will be made three times a week to prevent a build-up. The site
has 24/7 Security. The contractor uses solid bodied transport and carries portable disinfection equipment in case of
any spillage. Autoclave facilities will be available in an adjacent building, as required by the Regulations, in case of
loss of the contractor's facilities. The type of container and the secondary Euro container means that the risk of any
spillage of active GM waste on site is negligible. However, as active waste will leave the site, the risk to the
environment and health is possibly marginally higher than autoclaving prior to incineration. The only real risk of
release would be as a result of a major RTA, however, the containers are designed to withstand this.
This disposal method is expected to achieve 100% inactivation of the GMM

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste material will be inactivated by treatment with 1 % (w/v) Virkon solution prior to disposal. Solid waste
material will then be placed in sealed bins and incinerated by an off-site incineration company (see derogation
application above). Waste from our GM work at Class 2 will be placed into suitably labelled hermetically sealable
bins. They will be sealed by our staff and removed to a central collection point where they will be placed into 210
litre yellow labelled "Eurobins".
Collections for incineration will be made by the local registered clinical/GM waste incinerator contractor.
This disposal method is expected to achieve 100% inactivation of the GMM

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

Please enter comments on the GM safety committee on the risk assessment

The scope and particular aspects of safety risks described in the risk assessment were agreed upon, and satisfactory consensus was achieved regarding the adequacy of the IPPs and risk management planning protocols. Pending notification and acknowledgement by relevant authorities.

Give brief details of the genetic modification safety committee

All risk assessments for new work involving the use of genetically modified materials are submitted for review and approval by the Biosafety Committee.

The approval/rejection of a risk assessment by the Biosafety Committee is recorded by the Biological Safety Officer together with any comments applicable.

The members of the CDT Biosafety Committee are:

- Senior Executive responsible for work using genetically modified materials
- Biological Safety Officer
- Senior Advisor, Health, Safety and Environment

The Senior Executive responsible for work using genetically modified materials has over 15 years research experience, including the assessment and review of risk assessments.

A Scientist has been appointed to the role of Biological Safety Officer (BSO). The Scientist has a BSc and MSc in Medical Engineering, a PhD in the field of Biosensors and 5 years' work experience in the field of biosensors, including the assessment of risk and writing of risk assessments. The appointed BSO has attended a Biosafety Management and Practice training course, focusing on work at ACDP Containment Levels 1 and 2 and work with GMOs. The training course is approved by the Institution of Occupational Safety and Health.

The Senior Advisor, Health, Safety and Environment has also completed a Biosafety training course which was provided by the Medical Research Council and has over 15 years of work experience providing health and safety advice in healthcare and scientific research environments.

The requirements for inactivation of GMMs are considered and recorded in the risk assessments relevant to the work being carried out with those GMMs. The arrangements for waste disposal of GMMs are described in the local guidelines for work in the designated Biosafety Laboratory at CDT. All wastes containing GMMs are placed in sealed plastic containers and consigned as clinical waste to a licensed waste contractor for incineration. The following wastes are produced as a result of work with GMMs:
- contaminated solid wastes - pipette tips, wipes, petri dishes, tubes, t spreader and inoculation loop
- flammable solid wastes - alcohol wipes used to disinfect the work area
- aqueous waste - solutions containing microorganisms

Wherever it is possible only work with GMMs which are certified as inactive, and which therefore have a low risk of human infection, is carried out. The risk to human health and the environment from GMMs which are certified as inactive is negligible, and as such, wastes which are generated from the work with those materials are not subjected to a further inactivation process prior to consignment from site. Where work with active GMMs is carried out, then wastes from that work are subjected to a chemical inactivation process using a proprietary peroxygen compound (Virkon S) prior to consignment from site. Information from the manufacturer of the product that used to carry out the inactivation, or from a reliable source in the public domain, is used to substantiate a minimum 5-log reduction in viability and validate the inactivation of specific GMMs.

For activities involving GMMs, describe the waste management measures which will apply to the activity:

- contaminated solid wastes - pipette tips, wipes, petri dishes, tubes, t spreader and inoculation loop
- flammable solid wastes - alcohol wipes used to disinfect the work area

Information from the manufacturer of the product that used to carry out the inactivation, or from a reliable source in the public domain, is used to substantiate a minimum 5-log reduction in viability and validate the inactivation of specific GMMs.
The risk assessments completed for class 1 activities at CDT have been reviewed by the Biosafety Committee.
The arrangements in place for the storage, use and disposal of GMMs at CDT comply with the requirements of the legislation and the best practice described in the associated guidance for class 1 activities.
No additional arrangements were identified as necessary to control the risks to human health and the environment presented by the work specified in the assessments.
Approval of the risk assessments has been recorded.
The risk assessments are reviewed at least once a year or whenever it is required by changes in work conditions or procedures.

**Give brief details of the genetic modification safety committee**

BioAscent has formed a genetic modification safety committee comprising of a biological safety officer with over 20 years' GM and non-GM cell culture experience, two senior managers with experience of working in and managing GM cell culture facilities and one senior manager from a chemistry background with extensive knowledge of COSHH. The committee will meet regularly to review existing risk assessments and procedures and all new proposals to work with GMOs will be referred to the committee for review.

Liquid waste will be inactivated by addition of 1% Virkon in accordance with manufacturers instructions before being discharged to the drains. Contaminated solid waste will be placed in robust leak-proof and biohazard labelled plastic bins while sharps will be disposed of in desingated sharps bins and both will be destroyed by high temperature incineration by a licenced waste disposal contractor.

Outline Protocol for Disinfection Validation
The composition of the culture fluid, cell density, contact time and final concentration must be documented. 5-log reduction (99.999% kill) must be achieved.

• Grow up micro-organism under the typical experimental conditions.
• Add disinfectant to a known culture volume to give the desired final concentration.
• Incubate at room temperature for specified time period.
• Take a sample from the incubation mixture
• Eliminate traces of disinfectant by washing cells into fresh culture medium.
• Attempt to grow any surviving micro-organisms on plates or in liquid culture. Note – for viruses attempt to grow in host cell line.
• Count survivors and calculate % kill.

All waste disposal and spill procedures are captured in written standard operating procedures and compliance will be monitored via regular lab inspections and staff appraisal.

Please enter comments of the GM safety committee on the risk assessment

The risk assessment comprehensively details the characteristics of any new GM cell line that BioAscent aims to work on and provides a framework for capturing the associated risks and details the control measures required to mitigate those risks. The committee requires the risk assessments to be reviewed on a biennial basis.

Give brief details of the genetic modification safety committee

We have received advice from our director (of invitro biology at BioMedha), who has previously managed cell biology bioscience department with responsibility of Health and Safety/ GMO/ HTA/ Waste management internal policy design, risk assessments, implimenatation and training staff. He also received Health & safety training with respect to laboratory research activities. He has been instrumental in assessing, writing and implementation of Risk Assessments and SOPs for handling of biological and chemical materials, Class 1 and 2 containment safe practices, GMOs safe and clean environment and waste management. He is very experienced cellular and molecular biology scientist with over 15 years working across drug discovery, invitro cell biology, molecular biology, cell culture, transfection, cell line generation, class 1 and 2 containment ,GMOs and HTA safe and effective working practices. Has extensive working knowledge of complex research activities such as cell culture, cell isolation, transfection, stable cell line generation, PCR, Cryopreservation and thawing, passaging, centrifugation, cell counting, secondary containment sample handling, cell imaging and characterisation. He appreciates the significance of adhering to legislative demands and health & safety requirements. He understands the detrimental impact of non-compliance can have in relation to people, environment, tasks and project.

Laboratory

- Level 1 (GMMs) Yes
- Level 2 (GMMs) Yes
- Level 3 (GMMs)
- Level 4 (GMMs)
Liquid waste from all cell culture/GMO activities will be inactivated overnight by using 2% (v:v) Chemgene/bleach/virkon. Once inactivated, liquids should be decanted into the 10L plastic bottles (labelled “aqueous inactivated waste”. When full, liquid waste is collected by an external contractor for proper waste treatment.

Solid waste (tissue culture plastic waste) from cell culture/GMO Class 1 & 2 containment facilities, will be sprayed thoroughly with 2% (v/v) Chemgene/bleach and 70% ethanol before being placed yellow biohazard bins. Once filled, solid waste biohazard waste bins will be collected by external contractor for proper waste treatment.

Sharps waste will be disposed of via the sharps bins and will be collected by external contractor for treatment.

All contaminated glassware will be treated with fresh 2% (v/v) Chemgene/bleach/virkon solution, sprayed with 70% ethanol prior to washing with detergent.

All working surfaces are sprayed with 2% chemgene/ vircnon/ bleach and followed by 70% ethanol and wiped with tissue and will be disposed of into yellow biohazard solid waste bins.

Give brief details of the genetic modification safety committee

The Solent University GMSC has been established to provide guidance and advise on the use of GMMs. The inaugural meeting was held on 8th March 2019 and will subsequently meet at least annually or as required to discuss newly received GM risk assessments and to review existing assessments. The committee comprises four members, including academic and technical staff and the University Biological Safety Officer.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Liquid waste (spent media) will be inactivated either by autoclaving at 121°C for 15 minutes, or alternatively treated with chemical disinfectant (e.g., 1% Virkon) at contact times designated by the manufacturer to achieve complete inactivation. Liquid waste is discarded to the drain with copious water. Solid waste (including gloves, petri dishes, and pipettes) will be autoclaved for 15 minutes at 121°C, and then discarded via the clinical waste route. These methods achieve an effective 100% kill.

For autoclaving, the temperature and time of the process is monitored and logged digitally, and confirmed by indicator tape and commercial indicator vials, and the autoclave is subject to six monthly servicing.

Tick to confirm that you are attaching a summary of the risk assessment [Y]

Tick if you are claiming exemption from disclosure for sections of the risk assessment [ ]

Please enter comments of the GM safety committee on the risk assessment

The genetic modification safety committee reviewed the risk assessment and requested minor changes, which have now been incorporated, and the risk assessment has subsequently been approved by the committee.

The Jeffrey Cheah Biomedical Centre building management team will manage the building's waste streams. CL1 solid waste management: CL1 solid waste will be treated as GMO waste and includes CL1 contaminated plastic consumables, stripettes, pipette tips etc. CL1 solid waste will be placed in orange bags in orange bins. The CL1 waste bins will be placed throughout MTI (Milner Therapeutics Institute) laboratory areas. The CL1 orange waste bags will be closed with cable ties when 3/4 full and deposited in a central laboratory area for collection twice a day by building services. This waste will be removed from site by Novus Environmental as 'clinical waste'. CL1 liquid waste management: CL1 liquid waste will be treated with Chemgene before disposal down the drain. CL1 liquid waste will be treated with a final concentration of 10% v/v Chemgene with a minimum contact time of 30 minutes, before being disposed of down the sink/drain.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Comments of the senior scientific advisor (see section 3):
The attached risk assessment is fit for purpose and accurately describes a common GM process routinely conducted at CL1. The control measures and waste management streams stipulated are adequate to effectively manage the risks to humans and risks to the environment. This risk assessment, along with all other risk assessments issued in the institute, will be reviewed annually and updated/amended as required.
**Purposes of the contained use**

The purpose of this work is to modify mammalian cell lines (human and/or murine) with oncogenes, tumour suppressor genes and reporters in order to evaluate mouse models for paediatric high-grade gliomas.

**Recipient or parental organism**

Cells and cell lines:
- Hela, W12, S12, SiHa, CaSki, C33A derived from human cervix.
- U2OS, Saos-2 derived from human bone.
- FSK, NEK, HaCaT, NIKS, EF-1F derived from human skin.
- COS, CV-1, Vero derived from monkey epithelium.
- 293, 293T, 293TT, phoenix cells derived from human epithelium.
- RPTEC, ARPE19 commercially available primary human renal and retinal epithelial cells.
- U87-MG derived from human glioblastoma.
- J2 3T3, NIH 3T3, TK143 of mouse fibroblast origin.
- Neuro-2a of mouse neuroblastoma origin.
- Mouse cortical neurons.
- Mouse neural progenitors.
Cells will be routinely tested for microbiological and mycoplasma contamination.

**Host/vector system**

Vectors:
- TRIP-PGK-ATGm-MCS-WHV, PGIPZ or any second/third generation lentiviral expression vector.
- pMD.G or any second/third generation packaging system. Viral envelope (VSV-G) expression vector.
- pCMVdeltaR8.91 or any second/third generation packaging system. Gag and Pol expression vector.
- pcDNA3, pCMS-GFP, TOPO or any other commercially available backbone vectors commonly used for mammalian protein expression.

Bacterial strains:
Origin & function

Inserted sequences will be composed of either reporter genes such as GFP or Luciferase, or components of recombination systems that allow expression:
- PBase Piggybac transposase; A mammalian codon optimised version of the Piggybac transposase (Trichoplusia ni)
- Cre recombinase (P1-phage); A Type I topoisomerase that catalyzes the site-specific recombination of DNA between loxP sites.
- LoxP sequence (P1-phage); Target sequence for Cre recombinase which mediates the site-specific recombination of DNA.
- FRT sequence (Saccharomyces cerevisiae); Target sequence for Flp (flippase) catalyzes the site-specific recombination of DNA between FRT sites.
- CreERT2 ; Cre recombinase - estrogen receptor T2 fusion gene. Tamoxifen- inducible Cre recombinase.
- GFP and its derivatives (Aequorea victoria); Green fluorescent proteins.
- Firefly Luciferase (Lampyridae); A secreted reporter luciferase from firefly.
- Blasticidin resistance (Bacillus cereus); Blasticidin-S deaminase.
- Kanamycin resistance (Streptomyces kanamyceticus).
- Puromycin resistance (Streptomyces alboniger); puromycin N-acetyl-transferase.
- LacZ (Escherichia coli); β-galactosidase.

Reporter gene expression will be directed by:
- Human cytomegalovirus promoter (human cytomegalovirus)
- Mouse U6 Promoter (Mus musculus)
- TRE2 Promoter
- Lac promoter (Escherichia coli)

shRNA (small hairpin RNA) are small RNA molecules which form a hairpin structure. The hairpin structure will induce a normal cellular in vivo downstream sequence of processing events in response to foreign cellular single-stranded RNA intruder molecules that will result in the post-transcriptional downregulation of the gene to which the hairpin sequence is targeted.

PiggyBac vectors are non-viral/non-integrating expression vectors. PiggyBac vectors include two components expressed together in a cell; a vector containing a cassette of various genes that will be inserted into the genome at transposon sites, and a vector expressing transposase that will mediate the integration of the expression cassette at transposon sites.

H3.3 is a histone H3 variant that is expressed throughout the cell cycle.
DAXX and ATRX are both histone chaperones specific for H3.3.

Evaluation of foreseeable effects

Although recombinant Retro and Lentiviruses can infect humans, both are defective and unable to be propagated after infection because of the presence of self-inactivating deletions. Cell lines used for lenti/retrovirus packaging require the expression of replication genes from a separate cassette, which eliminates the possibility of autonomous virus production. In the unlikely event of infection, the viral particles will not be able to replicate as they lack the gene encoding the envelope protein, which is required for cell entry. The cell lines used as recipients of foreign genes are not hazardous, as they are unable to infect people or animals. Foreign genes will be expressed in mammalian cells from either the the CMV, TRE-tight, EF1F, CAG or TGK promoters, or from the Retro/Lenti virus promoter contained
within the viral LTR. Retro/Lentivirus production and infection will be carried out under containment level 2 conditions, and we will follow the standard code of practice for virus-handling.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

All animal work will be carried out off premises at the Cancer Research UK Cambridge Institute - Biological Resources Unit.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

| The Jeffrey Cheah Biomedical Centre building management team will manage two laboratory waste streams. One waste stream for CL1 waste and a second for all CL2 waste. CL2 solid waste management: CL2 solid waste includes items such as general tissue culture consumables used in CL2 (consumables having been in contact with or containing residual GM material) tissue culture plates, tissue culture flasks, tubes etc. Serological pipettes and pipette tips will be collected in Bio-bins initially. Once Bio-bins are full they will be sealed and placed into autoclave bags in clearly demarcated CL2 waste bins. When CL2 autoclave bags are 3/4 full, they will be closed using cable ties to reduce the risk of waste spillage. The 3/4 full cable tied bags will be removed from the laboratory and placed into red CL2 waste bins in a clearly demarcated collection area. When the red CL2 waste bins are full they will be closed with cable ties. The red CL2 waste bins will be collected at least once a day by the building services team who will transport them to the basement of the building to be autoclaved. The building's waste autoclaves will have maintenance schemes written by Bureau Veritas and will be inspected annually by Bureau Veritas and PSSR. Additionally, the buildings waste autoclaves will be serviced regularly and annually validated under a service contract. The autoclave will run at the pre-set guidelines for deactivation of CL2 waste, this will be validated on every run using indicator tape. Autoclaved waste will be transported off-site by Novus Environmental as 'offensive waste'. CL2 liquid waste, that is safe to dispose of down the drain after inactivation, including; used tissue culture media, PBS used to wash cells etc will be treated with Chemgene before disposal down the drain. Inactivation of liquid waste will be achieved by using a final concentration of 10% volume/volume Chemgene with a minimum contact time of 30 minutes, before being disposed of down the sink/drain. Chemical waste for disposal from CL2 tissue culture (that is not suitable for disposal down the drain) will be collected in bottles, treated with a final concentration of 10% volume/volume Chemgene for a minimum of 30 minutes. Bottles will be labelled with their contents and placed in the chemical fume hood for disposal by building services. All work surfaces shall be routinely disinfected by wiping with 5% Chemgene, left for 30 seconds before subsequently wiping with 70% ethanol. |

For activities involving GMMs, describe the waste management measures which will apply to the activity

All GMO's will be inactivated by autoclaving at 123 degrees centigrade for at least 15 minutes on a validated cycle, including all solid and liquid contaminated waste.

Post autoclaving; solid waste is disposed of into an offensive waste bag and sent off-site for incineration via the approved waste management company. Liquid waste is disposed of down the sink with copius amounts of water. This flows to the main foul drain and onto a waste water treatment facility owned by Thames Water.

Spills/surfaces in contact with GMO will be disinfected using 1:10 Distel spray (tested and approved as bactericidal, fungicidal and destroy DNA and RNA).

Based on the information provided and discussion around the work, the work described is GM Class 1 because it is working with a non-pathogenic bacteria already modified to express wild type human proteins. It poses no foreseeable hazard to human health and to the environment. The laboratory where the work will be conducted meets Containment Level 1 criteria and is suitable for the activities proposed in the GMRA.

Y

Give brief details of the genetic modification safety committee

Bioescalator GMO committee meets once per year, and on an ad hoc basis for new applications and is composed of several PhD-level Bioscientists with experience in Biological safety and genetic modification and risk assessments thereof. Specifically the committee comprises 2 Divisional Safety officers for Oxford University clinical departments. A Professor and company director who is a founding director of the British Society for Gene and Cell Therapies, The Bioescalator Lab manager, and three laboratory directors and project managers with several years of experience in GMO work. Three are staff representatives from companies at the Bioescalator.

For E.coli work
The containment and control measure that will be applied for work with these genetically modified micro-organisms are shown on Table 1 of the attached GMO risk assessment. Containment level 1 will be applied with Good Microbiological Practice and Good Occupational Health and Safety. Class 1.

For Virus work
The containment and control measure that will be applied for work with the genetically modified lentivirus or retrovirus and cell lines infected with lentivirus or retrovirus are shown on Tables 1 and 2 of the GMO risk assessment attached. Full containment level 2 will be applied with Good Microbiological Practice and Good Occupational Health and Safety. A microbiological safety cabinet and gloves will be used where appropriate. Class 2.

WASTE MANAGEMENT MEASURES
Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3,1993 (either 121-1250C for at least 15 minutes or 126-1300C for at least 10 minutes or 134-1380C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the Bioescalator clinical waste route.
Liquids (eg samples, culture supernatants, tissue culture media) - add Virkon to 1 % w/v for at least 1 hour and then discharge to drains or autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-1300°C for at least 10 minutes or 134-1380°C for at least 3 minutes) and discharge to drains. Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-1300°C for at least 10 minutes or 134-1380°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the bioescalator clinical waste route.

Degree of kill:
Autoclaving, effectively 100% kill (annual validation).
Incineration, effectively 100% kill (licensed incinerator).
Virkon disinfection, 99.99% kill. Virkon has been tested by independent laboratories and been proven to be effective against a total of 20 virus families (including HIV/AIDS)

Project Additional Information

Purposes of the contained use

The aim of this project is to use self-inactivating, replication incompetent lentivirus-based expression vectors to generate stable cell lines expressing TCR derived from tumour-specific cytotoxic T cells. For practical purposes (e.g., rapid isolation by FACS sorting of transduced cells) we will mostly use lentivirus-based vectors that express the green fluorescent protein or blue fluorescent protein (GFP, BFP) derived from jellyfish, as part of a bi-cistronic RNA. A development of these studies will concern the use of similar self-inactivating, replication incompetent lentivirus-based vectors for stable inactivation of genes of interest by small interfering (si) RNA in tumour cell lines and cultured primary tumour cells. Lentiviral particles expressing the transfer vector will be used with widely used packaging vectors, such as those described herein. A second approach to inhibition of target transcripts in tumour cells will be to use deactivated CAS9 lentiviral particles in association with lentiviral particles expressing target gene-specific "guideRNAs". The combination of the two vectors allows extremely specific transcriptional inhibition in the targeted cells.

Recipient or parental organism

K12 or B derivatives of E. coli will be used as bacterial cloning hosts to generate plasmid expression clones in readiness for expression within specified packaging cell lines. These are disabled hosts that cannot colonise the human gut and have a history of safe use. These hosts may be considered equivalent to ADCP hazard group 1. The packaging cell lines 293T, Jurkat-76 and Hut-78 are of human origin, which are well characterised and authenticated and is obtained from commercial sources. 293T, Jurkat-76 and Hut-78 can be regarded as low hazard for GM activities and as hosts are suitable for containment level 1 precaution. However, in our laboratory they are discarded as in containment level 2 via the Bioescalator clinical waste route. Human primary lymphoid cells (e.g CD4+ blasts and/or CD8+) can be considered as especially disabled hosts and as such may be considered to be equivalent to ADCP hazard group 1 however the cells have the potential to contain adventitious agents and as such will be handled at containment level 2 under COSHH.

Host/vector system

a) Lentiviral transfer vectors

a-1) cDNAs encoding proteins encoding CD8 TCRs will be cloned into pHRSIN-BX-IRES-Em, a slightly modified version (Appendix 1) of the lentiviral plasmid pHRSIN-CSGW (Demaison, Parsley et al. 2002; Ikeda, Takeuchi et al. 2003; Palmowski, Lopes et al. 2004) (provided by Dr. Mary Collins, University College London). The latter is a tailored version (Demaison, Parsley et al. 2002) of the original pHR'SIN-CE, described in 1997 by Trono and co-workers (Zufferey, Nagy et al. 1997). pHRSIN-CSGW and modified versions are last generation of widely used lentiviral vectors (Demaison, Parsley et al. 2002; Ikeda, Takeuchi et al. 2003; Palmowski, Lopes et al. 2004; Gruh, Schwanke et al. 2005; Clements, Godfrey et al. 2006). pHRSIN-BX-IRES-Em contains the 5' HIV LTR and an inactivated deletion mutant of the 3' HIV LTR which lacks a 400-nucleotide and L TR activity(Zufferey, Dull et al. 1998). This inactivation improves significantly biosafety because it reduces the possibility that replication-competent retroviruses will originate in the vector producer and target cell. Within the 5' and the 3'O/OU3 elements, pHRSIN-BX-IRES-Em contains a packaging sequence (0), a Rev responsive element (RRE), followed by a central purine tract cis-active sequence (cPPT)(Zennou, Petit et al. 2000) that improves transduction, and a central termination sequence (CTS) (Demaison, Parsley et al. 2002). The U3 part of the spleen focus forming virus (SFFV) strain P long terminal repeat (SFFV-U3L TR) follows that drives sustained and strong mRNA transcription in cells of haematopoietic origin of the gene of interest (in pHRSIN-BX-IRES-Em, a bicistronic mRNA containing the gene of interest cloned into a BAH-1 or Xho-1, restriction sites followed by an internal
ribosomal entry site (IRES) and the gene coding for eGFP (called Emerald GFP, a point mutant version of GFP that makes it 5 times brighter). A Woodchuck hepatitis virus Post-translational Regulatory Element (WPRE) (Zufferey, Donello et al. 1999) is inserted downstream of eGFP stop codon and allow enhanced gene expression. The HIV derived part of the vector is terminated by the defective HIV 3' LTR (3'/D U3).

pHR'SIN-BX-IRES-Em derives from pHR'SIN-cPPT-SE (Demaison, Parsley et al. 2002) modified into pHR'SINCSGW by Collins and co-workers (Ikeda, Takeuchi et al. 2003) by inserting an IRES eGFP element under the control of the SFFV promoter and the 3' WPRE sequence. pHR'SIN-BX-IRES-Em contains in addition a BAH-1 or Xho-1 restriction sites. This modification should not have introduced any substantial changes to cause safety concerns.

We intend to stably express by Lentivirus-based vectors short-hairpin (sh) DNA segments encoding a sequence generating an siRNA capable of inactivating mRNA of tumour transcripts of interest. The long-term silencing in a majority of cell lines can be achieved through the use of shRNAs in a lentiviral transduction fashion. For this purpose, we will use the pLKO.puro system.

The transfer vector pLKO.1-puro (see appendix 1 B) is a lentiviral (HIV)-based plasmid. pLKO.1-puro (used in combination with two other vectors (so-called *third generation lentivirus vector with a conditional packaging system (Zufferey, Dull et al. 1998) (see appendix 1 B), contains contains HIV-1 cis-acting sequences and an expression cassette with U6 Pol-III-driven promoter for expression of shDNA. It is the only portion transferred to the target cells and does not contain wild-type copies of the HIV L TR (e.g., elimination of the majority of lentiviral genes, Dvpr, vif, vpu and nef). The 5' L TR is chimeric, with the enhancer/promoter of RSV replacing the U3 region (RSV/5'L TR) to rescue the transcriptional dependence on Tat. The 3' L TR has an almost complete deletion of the U3 region (SIN/3'L TR), which includes the TATA box (from nucleotides -418 to -18 relative to the U3/R border). As the latter is the template used to generate both copies of the L TR in the integrated provirus, transduction of this vector results in transcriptional inactivation of both L TRs; thus, it is a self-inactivating vector (SIN generation). Moreover, pLKO.1-puro contains an RNA packaging sequence (0 ), a Rev responsive element (RRE), followed, after the expression cassette, by a central purine tract cis-active sequence (cPPT)(Zennou, Petit et al. 2000) that improves transduction, and a central termination sequence (CTS) (Demaison, Parsley et al. 2002). The human phosphoglycerate kinase (PGK) promoter drives the puromycin-resistance gene (to be used for stable transfection) and it is followed by SIN/3'L TR. The rest of the sequence is common to other bacterial plasmids (Amp-resistance gene for bacterial selection, f1 origin of replication and a pUC origin of replication). The vector is regarded as safe due to its modified features (deletion of a number of accessory genes implicated in the virulence of HIV, minimal genome of the viral particles, nonreplicating and self-inactivation features), making it incapable of producing virus once infected into the host cell.

a3). pHR-SFFV-dCAS9-BFP-KRAB and plentiguide Puro

The CRISPR (Clustered Regularly Interspaced Short Palindromic Repeats) system offers a general approach for RNA-guided regulation of transcription. Fusion of CRISPR-associated catalytically inactive dCas9 protein to distinct effector domains (e.g. p65AD or KRAB enables robust and efficient repression or activation of transcription in human cells, with the site of delivery determined solely by a co-expressed short guide RNA (sgRNA) which is encoded by a second lentiviral vector (Gilbert et al. 2013). Coupling of dCas9 to a transcriptional repressor domain can effectively silence expression of multiple endogenous genes, with no detectable off-targets as verified by RNA-seq analysis.

pHR-SFFV-dCAS9-BFP-KRAB like pHR'SIN-BX-IRES-Em is a third-generation lentiviral vector with self-inactivating 3' HIV-derived L TR (appendix 1 C). It encodes a human codon-optimized dCas9 from S. pyogenes fused to two copies of a nuclear localization sequence (NLS), an HA tag, and blue fluorescent protein (BFP). These are fused to the KRAB (Krlippel-associated box) domain of Kox1, which is a transcriptional repressor. These are cloned into the pHR vector backbone (Addgene).

pLentiguide-puro expresses S. pyogenes CRISPR chimeric RNA element with customizable synthetic guide RNA
(sgRNA) from U6 promoter and puromycin resistance from EF-1a promoter. Like the lentiviral vectors described above it has the safety features of the 3rd generation lentiviral backbone. The sgRNA expression plasmids are cloned by inserting annealed oligos into the lentiviral U6-based expression vector that was digested by BstXI and Xho1 (appendix 1 C). Cells to be targeted are transformed with two separate viruses; the dCAS9 vector and the lentiguide sgRNA vector.

Origin & function

In order to carry out these studies COB T cells which we identify as strong responders to the tumour antigens will be purified to the single cell level by flow cytometry and their T cell receptor (TCR) alpha and beta chain mRNA sequenced. The TCR sequences will then be constructed into cDNA and expressed in human T cell lines using the viral vectors described above. These T cell lines will then be used to characterise the efficiency and affinity of the purified TCRs.

Evaluation of foreseeable effects

i) For E.coli work
No significant hazards have been identified above. Insertion of the foreign sequences into these is not expected to result in harmful physiological or pharmacological properties or to affect the pathogenicity of the cloning host or normal human defence mechanisms. Gene transfer as described above is possible, but unlikely to be hazardous. The resulting GMO's are not expected to carry any additional risks compared to that of the un-modified recipients. Assignment to provisional containment: Containment level 1 with Good Microbiological Practice and Good Occupational Health and Safety.

ii) For viral work
For the transfected 293T cells there could be a significantly greater risk associated with the production of recombinant infectious Lentiviral particles. These therefore pose a risk to human health, but as they are self-inactivating replication deficient vectors, the risk is only from the insertion of the genetic material, described above. Although the two packaging plasmids allow expression in trans of proteins required to produce viral progeny (e.g. gal, pol, rev, tat, env) in the 293T producer cell line, none of them contain L TRs or the psi packaging sequence. This means that none of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target T cell lines. No new replication-competent virus can be produced. Finally, none of the genetic inserts are likely to cause significant effect on an individual. Therefore, as they are replication defective and in accordance with ACGM Guidelines, no additional containment and control measures are required. However, it is theoretically possible for these Lentiviruses to integrate into the genome of an individual on exposure. As they are self-inactivating, they are not capable of activating gene transcription from the inactivated viral L TR. However, they could in theory disrupt the function of a gene at the site of insertion. The worst-case scenario could be the chance integration of the virus into a tumour suppressor, thus disrupting that gene's function. Even so this single event is unlikely to cause any tumour formation and so the overall risk is still low. Therefore, taking into account all of the above, it would be appropriate to lower the overall level of containment for these types of vectors, but increase the containment level for the transfected cells and the virus containing supernatants from these cells. Assignment to provisional containment: Containment level 2.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-1300°C for at least 10 minutes or 134-1380°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the Bioescalator clinical waste route.

Liquids (eg samples, culture supernatants, tissue culture media) - add Virkon to 1% w/v for at least 1 hour and then discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-1300°C for at least 10 minutes or 134-1380°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the Bioescalator clinical waste route.

Degree of kill:
Autoclaving, effectively 100% kill (annual validation).
Incineration, effectively 100% kill (licensed incinerator).
Virkon disinfection, 99.99% kill. Virkon has been tested by independent laboratories and been proven to be effective against a total of 20 virus families (including HIV/AIDS).

Please enter comments on the GM safety committee on the risk assessment

1. Change the containment of vectors containing Woodchuck hepatitis virus post translational regulatory element (WPRE) from class1 to class-II in line with the 2014 regulations.
2. Review the Risk Assessment to ensure the waste management provisions are in line with the Bioescalator standard operating procedures.
3. Highlight table one to make clear where the justification for class II containment arises from.

### Project Additional Information

#### Purposes of the contained use

The aim of the project is to develop affinity ligands (known as aptamers) that are capable of specifically binding to surface epitopes on *Clostridium Difficile* spore. Spores which have had the surface proteins knocked out (GMO spore) will be used as controls to show the aptamer interaction is specific.

#### Recipient or parental organism

*Clostridium Difficile*

#### Host/vector system

The mutant spores were created using allelic exchange to delete most of the gene via homologous recombination. It is a clean deletion involving no antibiotic markers.

#### Origin & function

**Evaluation of foreseeable effects**

Native *Clostridium Difficile* have heightened risks to the following:

- Individuals on broad-spectrum antibiotics or several different antibiotics (which can include pregnant women).
- 65 years old
- Have underlying conditions such as IBD, cancer or kidney diseases
- Immunocompromised people (from diabetes, chemotherapy or steroid medication)
- Individuals on proton pump inhibitors (or similar)
- Individuals with digestive system related illness.

The vector system poses no risks, the *Clostridium Difficile* spores pose risks to anyone on proton pump inhibitors (or similar) or any stomach related illnesses, therefore by extension the knockout versions posing the same risk. The biological activity of the knockout spores is assumed to be the same as the native *Clostridium Difficile*.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

All work using the *Clostridium Difficile* spores (native or knockouts) is performed in a Class II microbiological safety cabinet, with all waste being treated with 1% Virkon (for 24 hours) and UV treated for 1 hour before being disposed of via clinical waste (and incineration). Cabinet is routinely cleaned with 1% Virkon and 70% IMS after each use.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All work using the *Clostridium Difficile* spores (native or knockouts) is performed in a Class II microbiological safety cabinet, with all waste being treated with 1% Virkon (for 24 hours) and UV treated for 1 hour before being disposed of via clinical waste (and incineration). Cabinet is routinely cleaned with 1% Virkon and 70% IMS after each use.

Give brief details of the genetic modification safety committee

An Intellectual Property and technology development professional at the University of Bradford; who has an undergraduate degree in Applied Biology with Biotechnology, and higher research degree in Biochemistry and Molecular Biology. The person has previously worked in drug development with Covance Laboratories, where they were the Biotechnology Gene Modification Risk Assessment Officer and member of the wider Gene Modification Safety Council within that organisation. Following this and prior to joining Bradford University, they have worked extensively developing early-stage biotechnologies and setting up the systems and procedures required for the delivery of these in a variety of positions, including acting as Chief Operating Officer of a biotechnology PLC.

Bacteriology Parasitology Transgenic Birds Microbiology Research
All reagents, consumable supplies, or materials that contain, or have come in contact with, the micro-organism C003 will be sterilized via steam autoclaving where possible or bleach addition prior to disposal in the regular waste stream. Steam autoclaving of waste is performed at 121°C for 60 min under 0.24 MPa, and results in no growth of cultures on agar plates after 48 h at 37°C. Moreover, sterilization efficacy of the autoclave is confirmed weekly using sterility indicator spore paper strips (Sigma-Aldrich, Cat No. 74041-25TESTS). Alternatively, bleach is added to the waste [to 10% (v/v)] and left to stand for 1 hour to ensure complete sterilization. No effluents are expected to be produced that would contain the viable C003 bacteria.

Use of a GM variant (C003) of the well known and highly attenuated E.coli strain DH5-alpha

For activities involving GMMs, describe the waste management measures which will apply to the activity

It was suggest that the CU risk assessment include a secondary protocol of and appropriate % bleach solution for disinfecting a contaminated area in the event that the surface cannot be excavated and extracted, and suggested a 10% solution should be adequate for the specific organism. These suggestions were addressed and the CU risk assessment was amended appropriately.

For activities involving GMMs, describe the waste management measures which will apply to the activity:

Waste management:
Solid waste will be autoclaved at 121°C for minimum of 30 min.
Liquid waste will go through an acid (pH 1-3) excursion before a caustic (pH 10-12) excursion for a min of 30 min each time before being neutralised and autoclaved. This is to inactivate the antibiotic present but also aids in killing the bacteria.
Autoclave will be tested to ensure a kill of a minimum of 10^116 organisms ml at scale (2 ltr volume) as part of process validation.

Please enter comments of the GM safety committee on the risk assessment:

Personson involved in risk assessment are all protak employees. Karyn Godden (HSE and HR Person) Kate Marshal (Research ASSOCiate) and Paul Shortland (BSO and Technical Production Manager) and Phill Godden (CEO)

Give brief details of the genetic modification safety committee

The genetic modification safety committee was formed as part of the process of establishing work with GMMs within Base4 Innovation Ltd.
The remit of the committee is to carry out risk assessments of all new processes/projects which utilise GMMs. A minimum of two committee meetings per year are to be held, or more frequently if required.
The genetic modification safety committee consists of:
- Base4 CEO
- Base4 H&S officer
- Base4 Biological Safety Officer
- Project lead(s) of the project(s) which use GMMs
- Employee(s) attached to the project(s) which use GMMs

Project Additional Information

Purposes of the contained use

To enable the generation and use of recombinant self-inactivating third generation lentiviral particles (by commercial research organisations or in house using commercially available 3rd generation lentivirus systems) encoding:
1. Open Reading Frames (ORFs), cDNAs, peptides
2. Specific gene sequences
3. Short hairpin RNAs (shRNAs) for the knockdown of Open Reading Frames (ORFs), cDNAs or specific gene sequences by RNA Interference (RNAi)

for in vitro use and for the generation of stable mammalian cell lines (and subsequent use of such stable lines in vitro) with the aim of:
1. Determining response to phenotyping reporters
2. Determining in-vitro immunomodulation responses
3. Efficiently generating cell models lines
4. Validating data from other experiments
5. Identifying and / or validating ORFs / cDNAs / or specific gene sequences as potential drug targets.

Recipient or parental organism

Recipient experimental systems are cells derived from mammalian organisms, predominantly in the form of immortalized cell lines derived from human cancer tissues.
The mammalian cell lines fall into two types:
a) A packaging/helper cell line into which plasmids containing lentiviral DNA will be introduced, and from which infectious virus will be secreted into the medium to high titre. The media from these cell-lines poses a risk because of the high viral titre. As such this could provide a risk of infection to personnel working with the media.
b) Recipient cell lines in culture. These cells will initially be exposed to a high titre of virus to permit infection (virus derived from (a) above). However the infected cell lines will be incapable of themselves producing active virus and as such are no more dangerous than the parental cell lines i.e. a negligible risk.

Host/vector system

The lentiviral vectors which will be used are derived from HIV-1, which is an ACDP Hazard Group 3 biological agent.
However, “Third Generation” lentiviral vectors have several of the lentiviral accessory genes (required for pathogenesis only) deleted to increase
biosafety. These include the vif, vpr, vpu and nef accessory genes which are not required for in vitro replication. The tat gene is also deleted and the Tat-responsive promoter present in the 5’ LTR is replaced with heterologous promoters, for example with the Rous sarcoma virus U3 region. An additional biosafety feature is achieved by deletion of the rev gene from the viral transfer vector. Viral packaging is achieved by providing three helper constructs in trans containing gag, pol and rev sequences. An additional biosafety feature is that these vectors are self-inactivating (SIN), whereby the U3 region of the 3’ LTR (which contains the major viral promoters and enhancers) is copied to the 5’ end of the provirus during reverse transcription. Deletion of enhancer and promoter elements from the 3’ U3 region in the vector construct will result in a provirus that is entirely devoid of U3 enhancer sequences, therefore reducing the potential for transactivation of cellular genes as a result of insertion. Furthermore, such vectors are not easily mobilisable as a result of a superinfection with wildtype virus.

Third generation Lentiviral Expression Systems include the following key safety features:
- The Lenti expression vectors contain a deletion in the 3’ LTR (ΔU3) that does not affect generation of the viral genome in the producer cell line, but results in “self-inactivation” of the lentivirus after transduction of the target cell (Yee et al., 1987; Yu et al., 1986; Zufferey et al., 1998). Once integrated into the transduced target cell, the lentiviral genome is no longer capable of producing packageable viral genome.
- The number of genes from HIV-1 that are used in the system has been reduced to three (i.e. gag, pol, and rev).
- Genes encoding the structural and other components required for packaging the viral genome are separated onto four plasmids. All four plasmids have been engineered not to contain any regions of homology with each other to prevent undesirable recombination events that could lead to the generation of a replication-competent virus (Dull et al., 1998). Although the three packaging plasmids allow expression in trans of proteins required to produce viral progeny (e.g. gal, pol, rev, env) in the 293FT producer cell line, none of them contain LTRs or the Ψ packaging sequence. This means that none of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. No new replication competent virus can be produced.

Despite the above safety features, use of these lentiviral vectors (which include WPRE) falls within SACGM 2 criteria due to the potential biohazard risk of possible recombination with endogenous viral sequences to form self-replicating virus, or the possibility of insertional mutagenesis. Also, the virus will be packaged by transfecting transfer vector into specific amphoteric ‘helper’ cell line (gag, pol and env stably incorporated into host chromosome.
cells). NOTE: amphotropic packaging will widen the host range of the virus and allow it to infect a wide range of mammalian species (including humans) and cell types. This means that the viruses produced for this experiment could potentially infect a number of species, including man.

Origin & function

Selectable markers – examples (but not restricted to);
- Ampicillin resistance: E. coli derived
- Neomycin resistance: bacteria derived aminoglycoside phosphotransferase gene
- Puromycin resistance (PAC): Puromycin acetyl transferase is derived from Streptomyces alboniger
- Reporter proteins such as (but not restricted to);
  - Fluorescent proteins as reporters;
  - GFP derived from the jellyfish Aequorea victoria and variants of this
  - Luciferase – class of oxidative enzymes used in bioluminescence
    renilla luciferase derived from the Sea pansy (Renilla reniformis)
    firefly luciferase derived from the firefly Photinus pyralis.

Open reading frames, cDNAs and gene sequences encoding potential drug targets or therapeutic proteins and/or shRNAs (designed to knockdown the expression of Open reading frames, cDNAs and gene sequences encoding potential drug targets or therapeutic proteins) – all human derived.

This could include the expression of potentially harmful genes e.g. encoding known proto-oncogenes or genes with known oncogenic mutations which can contribute to cellular transformation. Full length cDNA encoding wild type and disease relevant mutants of these types of genes will be expressed in third generation SIN lentiviral vectors. Any use of lentiviral particles encoding oncogenic inserts will require appropriate controls and operator training.

Evaluation of foreseeable effects

The lentiviruses are, at worst, amphotropic or pseudo typed with VSV G protein, either of which confers a broad host tropism including human cells. However, infectivity is unstable and infection is only obtained by co-cultivation of the packaged viruses with the recipient cells. The retrovirus is self-inactivating and there is thus no possibility of further transfer. Since some of the inserted DNA codes for potentially hazardous RNA or protein, the work is assessed as Class 2. This accords with HSE SACGM Compendium of Guidance for retroviruses (Part 2, para.18-20).

Even for the non oncogenic inserted DNA, there is a slight but non negligible risk due to the presence in the lentiviral vector of the Woodchuck Posttranscriptional Regulatory Element. The WPRE containing vector DNA will be treated as potentially oncogenic and is assigned to class 2 (see HSE SACGM Compendium of Guidance for retroviruses (Part 2, para.13)). However, bearing this in mind we should consider that the viruses that will be
used have been modified in a number of ways which will make them safer to handle:
- The genes encoding structural and other components of the viral genome have been separated. These genes have been engineered to minimise the risk of recombination that could lead to production of a replication-competent virus.
- The packaging cell lines allow expression of proteins, required to produce progeny virus: But the transfer vector is the only genetic material transferred to the target cells, consequently these cells cannot produce the proteins which are essential for viral assembly and infectivity.
Third generation or Self INactivating vectors retrovirus vectors will be used in all experiments
Procedures and controls measures will therefore follow HSE SACGM Compendium of Guidance for retroviruses (Part 2, para.30-36) i.e. using multiple plasmids with minimum sequence homology (e.g. 3rd generation SIN lentivirus vector system), gloves should be worn, use of class II safety cabinets, sharps avoided and all wastes be rendered harmless before disposal etc.
It is not thought that the modified virus would pose a serious risk to animals or plants in the environment. Although the VSV coat protein permits invasion of other mammalian cells, as in the case of humans, infection would be restricted to primary cells and productive virus would not be produced. In addition the control measures to protect human health will minimise release of virus to the environment. Therefore the environmental risk is low.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Instead of autoclaving waste in the building we propose to follow the procedure described below. The reason for adopting this method of waste disposal is that we do not have access to an autoclave of sufficient size within the premises.
All waste material will be inactivated by treatment with 2% (w/v) Virkon solution prior to disposal. Waste material will then be placed in sealed bins and incinerated by an off-site incineration company (Grundun – their GM authorization is GM782/01.1).
If at any time inactivation of waste from GM work at class 2 using Virkon is not possible, the off-site incineration company is permitted to dispose of noninactivated GM waste.
Waste from our GM work at Class2 will be placed into suitably labelled hermetically sealable 30/60L UN 3291 approved bins. Contents of the bin are recorded and collections by the local registered clinical/GM waste incinerator contractor will be made once every four weeks or more frequently if required to prevent build-up. The site has 24/7 security.
The contractor uses solid bodied transport and carries portable disinfection equipment in case of any spillage. Second containment is provided by 710L UN 3291 approved bins in which the 30/60L bins are placed during transport. In case of loss of the contractor's facilities, 4 weeks worth of waste can be stored on site. This is sufficient time to organise disposal through alternative contractor (Novus). The type of container means that the risk of any spillage of GM waste on site is negligible. However, as waste will leave the site, the risk to the environment and health is possibly marginally higher than autoclaving prior to incineration. The only real risk of release would be as a result of a major RTA, however, the containers are designed to withstand this.

This disposal method is expected to achieve 100% inactivation of the GMM.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste material will be inactivated by treatment with 2% (w/v) Virkon solution prior to disposal. Waste material will then be placed in sealed bins and incinerated by an off-site incineration company (see derogation application above). Waste from our GM work at Class 2 will be placed into suitably labelled hermetically sealable bins. Collections for incineration will be made by the local registered clinical/GM waste incinerator contractor.

This disposal method is expected to achieve 100% inactivation of the GMM.

Is an emergency plan required according to regulation 20?

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities  

Give brief details of the genetic modification safety committee

The Safety Committee meets at least yearly and is formed by a Safety Committee Chairman and three Biological Safety Officers (BSOs). The Safety Committee Chairman has extensive experience working with GMMs/GMOs during undergraduate, PhD, Post doc and industrial experience, as well as setting up new GMM/GMO procedures, including risk assessments. The BSOs have ample experience (more than 20 years altogether) working with CAT1/CAT2 GMMs/GMOs and as BSO at an academic and industrial institutions developing and reviewing CAT1/CAT2 biological and GMM/GMO risk assessments.

For activities involving GMMs, describe the waste management measures which will apply to the activity

GMO/GMM contaminated liquids must be placed into a container with sufficient Rely+On Virkon added (final concentration 1%, EPA Registration No. 39967-137; independent tests have shown Rely+On Virkon to have a broad spectrum of activity against viruses, some fungi and bacteria, including HIV and E. coli at dilution 1/100) to disinfect the waste. Leave for at least 12 hours before disposing using the drains with plenty of water.

GMO/GMM contaminated solid material or potentially contaminated material should either be bagged into autoclave bags (autoclave bags must be sealed at the top leaving sufficient air space for steam to penetrate, and autoclaved for 20 minutes at 121°C. Cycle records and autoclave tape will be checked to confirm sterilization) or disinfected with 1% Rely+On Virkon for at least 12 hours. Alternatively, containment level 1 contaminated material could be bagged into yellow sacks. The inactivated waste (or yellow sacks) will be removed from site by a professional specialised waste management company (e.g. Grundon) who performs high temperature incineration and disposal of the waste.

Tick to confirm that you are attaching a summary of the risk assessment  

Tick if you are claiming exemption from disclosure for sections of the risk assessment  

Please enter comments of the GM safety committee on the risk assessment
This work consists of growing bacteria for cloning purposes and the growth of mammalian cell lines for maintenance and transfection. Therefore this work is considered to be low hazard (class 1) to the environment and human health due to the following:

1. E. coli K12 derivatives are disabled, non-mobilisable and are not pathogenic to humans. They are unlikely to survive outside laboratory culture. They are assigned as ACDP hazard group 1. Mammalian sequences cloned into the bacteria are under the control of eukaryote promoters and thus will not be expressed through the bacteria culture and no potentially harmful proteins are produced. Inserts coding for RNAs and proteins that are physiologically expressed in mammals are to be found naturally in the environment from deceased bodies. Thus inserts are not expected to overcome disablement of the host organism, nor affect host specificity, tissue tropism or susceptibility to host defence mechanisms.

2. The inserts are not expected to alter the properties of the recipient. The environmental fitness will remain severely limited, thus it will be unable to survive. Resulting organisms are not harmful to the environment and the inserted sequences are non-mobilisable and offer no selective advantage to other organisms.

3. Mammalian cells will be transfected with plasmids (e.g. pUC-based plasmids, transposons, etc). Resulting transfected (non-viral) cell lines are not expected to gain selective advantage over other organisms. Additionally the inserts don't overcome disablement of the host organism, nor affect host specificity, pathogenicity, carcinogenicity, toxicity, tissue tropism, host range or susceptibility to host defence mechanisms.

4. Antibiotic resistance genes, for example Kan/AmpR, are not medically critical. Reporter genes including GFP, dsRED and Luciferase are thought to have no deleterious biological effect.

5. Cells containing oncogenes may be oncogenic but are incapable of colonising and causing disease. These cells could represent a genuine risk in the occurrence of accidental injection to an immuno deficient individual or to the corresponding primary cell donor but there will be no such opportunity for involved staff.

6. The transfected cells are not able to survive outside of the specific incubator environment (5% CO2, 37°C).

7. The risk to human health is minimised as no sharps are used, in addition all samples will be handled in a class 2 tissue culture hood to maintain experiment purity, thus further minimising risk to human health via aerosols.

8. All waste will be handled according to Mogrify Waste Management measures to minimise risk to the environment.

All the work mentioned above is to be carried out in containment level 1 laboratories. Future work at Mogrify Ltd. will require CAT2 premises and the CU2 application is being prepared. Therefore, the committee advises on applying for both level 1 and level 2 (GMMs) premises in the CU1 form.
**Project Additional Information**

**Purposes of the contained use**

Transcription factor mediated reprogramming of somatic cells to a pluripotent state showing key features of embryonic stem cells (e.g. induced pluripotent stem cells, iPSCs) is now well stablished. Based on this premise/technology, the overall goal of the research is to transdifferentiate cells from their origin cell type (e.g. hepatocyte, fibroblast, iPSC) to a desired cell type that can be then used in cell therapy or other applications. This will be achieved by a screening process using lentivirus, adenovirus (adenovirus and recombinant adeno-associated virus) and Sendai virus systems to discover which genes need to be overexpressed, downregulated or knocked out to allow such transdifferentiation. Transdifferentiated cells will be fully characterized to prove efficient transdifferentiation to the desired cell type (e.g. western blot, qPCR and flow cytometry of lineage specific markers; cell morphology and differentiation potential).

**Recipient or parental organism**

- GM E. coli K-12 derived: no insert expression due to eukaryotic promoters and transformed plasmid is non-mobilisable. Risk: effectively zero
- GM Mammalian cells in culture:
  - Packaging/helper cell line such as HEK/293, into which lentiviral/adenoviral transfer, packaging and envelope vectors will be introduced and from which infectious viruses will be secreted into the medium at high titre. This media possesses a risk because of the high viral titre. Risk: medium
  - Recipient cells such as cell lines, iPSC or primary cells will be used, depending on the project since transdifferentiation efficiency may be altered. Cells will be initially exposed to a high titre of virus to permit infection. Insert will be expressed, but vector is non replicative and mobilization is very unlikely and restricted. GM cells may be transformed/oncogenic but are still relatively fastidious and would be incapable of colonising and causing disease. These cells could represent a genuine risk to corresponding donor but such exposure would be unlikely. Risk: medium/low

**Host/vector system**

- Viral vectors (lentiviruses, adenoviruses and Sendai viruses): replication deficient vectors, amphotropes, viral infectious genes deleted, carry insert expression cassette, possible long term expression/insertional mutagenesis, transforming/oncogenic potential. Mobilization very unlikely (needs concomitant infection by similar wild type virus). Risk: medium

**Origin & function**

Several types of genetic material may be involved. Examples are listed below. Other inserts maybe used as required, which are similar to those discussed below.

1. Mammalian cDNA (+/- TAG sequences) coding for transcription factors, signal transducers, growth factors and surface receptors.
2. shRNA and miRNA sequences against cell endogenous coding sequences.
3. Reporter genes (e.g. GFP, LacZ, Luciferase, possibly fused to cDNA (type1 inserts)).
4. Selection genes (e.g. Ampicillin, NPT, PAC).
5. Functional non coding sequences (e.g. promoter, enhancer, insulators, IRES, WPRE, of mammalian or viral origin).
6. Neutral non coding sequences (such as introns, isolated exons, guides for CRISPR/Cas9 and similar genomic engineering techniques and tagging sequences).
7. Coding sequences of bacterial CAS9 and similar enzymes or alternatives (i.e. TALENs) with short sgRNA sequences will be used to express CRISPR systems. These systems are used for CRISPR gene editing techniques to knockout or knockdown gene sequences, to introduce specific sequences into the genome or to introduce point mutations. These modifications are expected to alter the development, differentiation, pluripotency, cell fate decision of the recipient host.

**Evaluation of foreseeable effects**

Work will be carried out in Class 2 containment laboratories in class II biological safety cabinets with routine disinfection of work surfaces. All staff working at Class 2 premises will be suitably trained to work in Class 2 containment laboratories, both in the experimental procedures undertaken for the study and in the case of accidental spillage or contamination. In addition, no glass or other sharps will be used, workers will be protected by PPE (a lab coat, gloves and eye protection) and skin lesions will be covered with a bandage in addition to the protective wear described above. Additionally, workers, contractors and visitors will be made aware of the risk assessments and
Control measures being applied in Mogrify Ltd. Consequently, risk of human infection with virus particles is very unlikely. In addition, no single plasmid contains all the genes necessary to produce packaged virus (lentiviruses, adenoviruses and Sendai viruses). Therefore, resultant particles are replication-incompetent and should the unlikely scenario of end-user infection occur, further virus production could not take place in infected cells.

Vectors/inserts are not expected to overcome disablement of the host organism, nor affect host specificity, toxicity, tissue tropism, host range or susceptibility to host defence mechanisms. Cells containing oncogenes may be oncogenic but are incapable of colonising and causing disease. These cells could represent a genuine risk in the occurrence of accidental injection to an immuno deficient individual or to the corresponding primary cell donor but this is most unlikely and additionally no glass or other sharps will be used, workers will be protected by PPE (a lab coat, gloves and eye protection) and skin lesions will be covered with a bandage in addition to the protective wear described above.

Control measures employed will minimise risks to the environment. These control measures include rendering all solid and liquid waste inactive within the laboratory by disinfection with Rely+On Virkon (final concentration 1%, EPA Registration No. 39967-137, independently proven to be effective against a wide range of viruses, bacteria and fungi including HIV and Escherichia coli at dilution 1/100). This waste will be disposed by a professional specialized waste management company who performs high temperature incineration. More detailed information on waste management procedures can be found on section 12.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All GM waste will be inactivated at the same site as the activity is taking place.

GMO/GMM contaminated liquids must be placed into a container and sufficient Rely+On Virkon added (final concentration 1%, EPA Registration No. 39967-137; independent tests have shown Rely+On Virkon to have a broad spectrum of activity against viruses, some fungi and bacteria, including HIV and E. coli at dilution 1/100) to disinfect the waste. Leave for at least 12 hours before disposing using the drains with plenty of water.

Pipette tips are to be disinfected with 1% Rely+On Virkon for at least 12 hours (EPA Registration No. 39967-137; independent tests have shown Virkon to be active at 1:100 for HIV and 1:1400 with Maedi and visna virus). After disinfection, material will be collected in burn bins (material used for viral work will be kept in closed containers). This inactivated solid waste will be then removed from site by a professional specialised waste management company (e.g. Grundon) who performs high temperature incineration and disposal of the waste.

Other solid waste such serological pipettes and culture plates will be disinfected with 1% Virkon and bagged into autoclave bags (autoclave bags must be sealed at the top leaving sufficient air space for steam to penetrate, and autoclaved for 20 minutes at 121°C. Cycle records and autoclave tape will be checked to confirm sterilization). This inactivated solid waste will be then bagged into offensive sacks to be removed from site by a professional specialised waste management company (e.g. Grundon) who performs high temperature incineration and disposal of the waste.

02/03/2022
The Genetic Modification Safety Committee (GMSC), formed by chair of the Committee, BSOs, confirmed the Risk Assessment as Containment Level 2. The risk to the human health and the environment was considered to be medium/low when applying the principles of Good Microbiological Practice and Good Occupational Safety and Hygiene. The project was classified as Class 2.

Give brief details of the genetic modification safety committee

The TRUCS Therapeutics Ltd GMSC will consist of the following four committee members:
Company Chief Scientific Officer responsible for Research and Development at TRuCs Therapeutics who has a degree and PhD in biological sciences followed by over 20 years of experience leading R&D activities.
Company Vice President of Process Development at TRuCs Therapeutics who has a degree in chemistry and PhD in biological sciences followed by over 20 years of experience leading GMO R&D activities.
Company Operations Manager UK responsible for operations at TRuCs Therapeutics UK who has a degree in Physiology, a Masters and Ph.D in Biomedical Science followed by over 15 years of experience working in operational roles supporting R&D activities within biotechnology companies and over 6 years with GMO production. The Operations Manager UK is also the nominated BSO and has received training in biosafety and Health and Safety.
Company Vice President of Manufacturing responsible for the implementation and running of manufacturing at TRuCs Therapeutics UK has over 25 years of manufacturing and quality experience working in regulated biotech, pharmaceutical and healthcare sectors.

The Safety Committee meets at least yearly and is formed by the Biological Safety Officer (BSO) who acts as Committee Chair, VP of Process development, head of viral vector process development, director of QA and virology expert. Others may be invited as necessary. The Safety Committee Chairman has experience working with GMMs/GMOs during undergraduate, PhD, and industrial experience, as well as setting up new GMM/GMO procedures, including risk assessments. The members of the committee collectively have over 20 years of experience working with Class 1/Class 2 GMMs/GMOs within academic and industrial institutions developing and reviewing biological risk assessments for handling Hazard Group 1/Hazard Group 2 microorganisms and Class 1/Class 2 GMM/GMOs.

The facility is designed to manufacture Advanced Therapy Medicinal Products under licence from the Medicines and Healthcare products Regulatory Authority (MHRA). The control measures listed below reflect the requirements of both Health and Safety legislation and the MHRA. CGTMC have designed and developed a range of control measures for the safe handling and inactivation of GM waste. TRUCS Therapeutics Ltd staff will be instructed and trained in these procedures and CGTMC staff will monitor and audit the collaborators to ensure compliance. Any near-miss or incidents will be reported to and assessed by the TRUCS Therapeutics BSO who will assign corrective and preventative actions.

Low Volume Liquid Waste (≤10L) and Solid Waste are inactivated by incineration using the following procedure:

Within the manufacturing module the operatives will contain low volume liquid waste (≤10L) within a sealed container in a leak free manner (via a screw cap or tubing seal or tie). The sealed liquid waste container and any solid waste will be placed in a secondary container (double biohazard bag or a biohazard bin) and then into a tertiary container (hard clinical waste bin) which will be sealed and labelled. They will then move the clinical waste bin through to the waste out section of the manufacturing module where the surface of the bin is cleaned using a spray and wipe technique with a broad spectrum biocide such as Virkon, Distel, IMS 70% and Klericide B. CGTMC technical support operatives will record the label details and transfer the clinical waste bins to the secure waste storage area located on the ground floor of the building where they will be stored until collected by CGTMCs approved waste disposal contractor (approved to handle GM waste). On the day of collection the CGTMC technical support team will transfer the clinical waste bins to the transport vehicle for transfer to the incineration facility and update the waste log.

Thames water trade effluent consent T.E. Case No: TRMD0BK2
The committee had no major concerns regarding the risk assessment. It was decided that the risk assessment should contain greater detail of our intended GM and so a greater depth of information on the modification has been added. The committee agreed there was minimal risk to human health or the environment and recommended that the material is classified as GM class 1, and our application will be made at GMO class 1.

Y

Give brief details of the genetic modification safety committee

The GM committee comprises of the company's Head of Research, two senior scientists, senior project manager, an external consultant and a Biological safety officer.  
The committee meets once a year to discuss safety measures in place in the laboratory and approve Genetic Modification Risk Assessments.  
When scientists plan to use a new genetically modified organism, the committee meets ad hoc when required to review new projects, otherwise they meet once a year.

All waste from E.coli class 1 activity (e.g., used agar plates) will be sealed and placed into sealed double bagged biohazard bags and placed into yellow bags sealed for incineration, then disposed of with clinical waste for incineration through an appointed specialist waste management company: Stericycle. All solutions containing E.coli or GM E.coli will be disinfected by treatment with including but not limited to Virkon, ChemGene or Trigene according to manufacturer's specifications. All glassware will be disinfected prior to washing and sterilisation in designated autoclave.

Please enter comments of the GM safety committee on the risk assessment

The risk assessment was reviewed by the GMO committee on 04/07/2019. It considered that the risk assessment contained sufficient risk management to justify classification of the project as class 1. It was therefore approved.

Project Ref 3491/19.1

Date Ackn'd 16/08/2019  
CU2 Project Title Use of lentivirus and lentiviral vectors for expression of novel molecules in both E.coli  
Class CultureVolClass2 CultureVolumeClass3-4

Class 2
To use Lentivirus transduction technology to generate cells or cell lines that can be used to develop tools to screen novel TCRs.

Disabled/non colonising E.coli K-12 derivatives including Stbl3 strain.
Fully characterised, widely used, commercially available cell lines.
Primary cells isolated from whole blood.

Commercially acquired 3rd generation Lenti-ArtTM virus packaging system in conjunction with a Lentiviral transfer plasmid (Creative Biolabs) containing the receptors insert to generate infectious replication incompetent lentivirus particles. The vectors are listed below:
- Packaging plasmid pHelp1, which encodes for gag and pol (HIV-1 structural viral proteins and enzymes) under control of a CMV promoter.
- pHelp2, which encodes for VSV-G (Vesicular Stomatitis Virus envelope protein VSV-G) in replacement of the HIV-1 envelope. This further reduces the chances of recombination with viral genome and is also driven also by the CMV promoter.
- pHelp3, which encodes for Rev (HIV-1 regulatory gene), under control of the RSV promoter. The expression of the gag-pol sequence (present in plasmid pHelp1) is Rev dependent, thus preventing the expression of gag-pol in the absence of Rev.

- Human Leukocyte antigens (HLAs), class I and class II. HLA is expressed by the majority of human cells and confers no harmful properties.
- Native TCR molecules.
- Variant TCR molecules including higher affinity versions of Native TCRs containing point mutations to increase the
affinity of binding to HLA peptide complexes on surface of target cells.

- Marker and Reporter genes such as GFP, RFP and luciferase (these have been used in various transgenic animal systems and have been shown not to cause any harmful effects), antibiotic resistance genes (such as Puromycin, Zeocin) and cell surface markers (such as Rat CD2) for monitoring and selection of transduced cells.

- Genome editing molecules such as CRISPR Cas 9 proteins and gRNA to target and knockout specific genes. In this Lenti transfer vector the transgene would comprise of a human U6 promoter to drive expression of a gRNA alongside sequence encoding a Cas9 protein or derivatives of (spCas9) driven by a mammalian promoter such as EFS or EF1-a.

**Evaluation of foreseeable effects**

### Lentivirus:
All the lentivirus plasmids used are non-mobilizable. The lentiviral vectors are well characterised, with a history of safe use, and inherently safe. These vectors will all be self-inactivating and replication-incompetent, that is, each lentiviral particle infects and gives genomic modification of one cell, and that cell will not (and indeed cannot) subsequently produce and release further viral particles. This is due to a deletion in the 3’ L TR (TAT A deletion) within the transfer vector, which prevents excision after genomic integration. Lentiviruses are highly susceptible to dehydration. However, they can survive for long periods in high protein media. Lentiviruses are rapidly inactivated outside the host, as illustrated by the fact that close contact is required for transmission. The lentivirus used for this study cannot replicate and so the consequences of escape are considered negligible.

### TCR inserts
The TCR gene inserts encode for proteins known to be functionally expressed by T cells only, as they require the presence of cellular CD3 proteins only found in T cells. Expression of TCRs by cells other than T cells renders the TCR non-functional. In the case of cancer specific TCR genes, their expression in T cells should only induce a response to cells expressing tumour antigens. TCR genes specific for self-antigens or auto antigens do present a hazard to the worker performing the work but only if the workers own T cells were transduced to express the genes, for this reason the use of self-cells is strictly prohibited.

### Mammalian cells:
Primary T cells are isolated from blood following standard gradient centrifugation protocol. These cells can only survive under specialised laboratory culture conditions. Any T cell transduced using the Lentivectors vectors could present a potential hazard to the original T cell donor for this reason no laboratory staff are allowed to work on their own cells. These donor cells will be HLA mismatched and therefore present no hazard to the individual user. Inclusion of any TCR to these donor cells will not change this and therefore the cells can be considered specially disabled.

Human Leukocyte Antigens (HLA)

HLA is expressed by the majority of human cells and confers no harmful properties. The HLA transduced human cells produced will have a HLA tissue type different from the laboratory staff and hence will be detected and efficiently eliminated by the immune systems of any inadvertently contaminated worker.

### CRISPR machinery:
There is a slight risk if all the components of are injected into the operator, especially in conjunction with a lentiviral vector delivery system. To minimise risk, avoid route of direct infection, e.g. needle sticks and/or spills onto open wounds. Take caution when dealing with CRISPR-Cas9 machinery, especially if lentiviral vector delivery system is used. Resulting cell lines should not pose an increased risk to the operator over their parental cell lines.
We do not have any work planned with larger GMOs.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

GM CL2 liquid waste is inactivated in freshly prepared 1 % Virkon (final concentration) or Chemgene for at least one hour contact time before being poured down the foul drain.
GM CL2 solid waste (eg. plastic tissue culture flasks or plates) will be treated with 1 % Virkon or Chemgene, then double-bagged in strong autoclave bags, placed in a leak-proof container with a lid on, then disposed with clinical waste for incineration through an appointed specialist waste management company: Stericycle.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

GM CL2 liquid waste is inactivated in freshly prepared 1 % Virkon (final concentration) or Chemgene for at least one hour contact time before being poured down the foul drain.
GM CL2 solid waste (eg. plastic tissue culture flasks or plates) will be treated with 1% Virkon or Chemgene, then double-bagged in strong autoclave bags, placed in a leak-proof container with a lid on, then disposed with clinical waste for incineration through an appointed specialist waste management company: Stericycle.

Waste Disposal

- Presept is used as it is a validated disinfectant for transfected cells if used in the following way under manufacturers recommendations for 100% kill rate.
- Hard surfaces: A solution containing 2g/L for 1 hour contact time, 10mins for metal parts (longer can cause corrosion)
- Safety cabinets: 2g/L Presept (10mins)
- Supernatants/liquid waste: 2g/L Presept, for 1 hour, then flush down the drain with a lot of water.
- All solid waste is going to be incinerated.
- Full yellow euro bins (properly labelled and closed) are to be transported to the hazardous waste bins to the Babraham storage area by the state team. Howie type Lab coats, safety glasses and nitrile gloves will be used during the waste handling.
- The Babraham Research Campus has a derogation with the HSE so that clinical waste can be removed from site without being autoclaved. Waste is processed in accordance with the Babraham Institute disposal method according to notification GM 105.4.1.
- Bins are collected for off-site for incineration by Vetspeed Ltd._GM authorization number GM898.

Accidental Release:
In our laboratories the floor is sealed and the labs are built to CL2 level, all the MSC are Class 2.
In an uncontained area, all persons should evacuate the area to avoid contact with any potential aerosols formed.
Only after 1 hour the room might be entered (to allow any aerosols to settle) and the procedures should be the same as in a contained area.
In a contained area cover the spill with absorbent material, such as paper towels, and let the spill soak in. This helps prevent aerosolization of the contaminant.
Virkon powder should be applied all over the spill area. Allow 20 min contact time. The spillage is to be mopped up with damp towels, it must not be brushed. This solid waste is then to be incinerated as described before.

Tick to confirm that you are attaching a summary of the risk assessment  

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The BSO C MIOSH CBiol MRSB is the Director of Making Heath Safety Work Ltd.
The BSO has advised PolyProx Therapeutics on evaluating GMO handling and waste disposal risks and he is satisfied that we are acting appropriately, responsibly and with the best practice. The R&D does not contain anything exceptional that requires special consideration. The BSO approved the associated risk assessment and support this notification.

- Human embryonal carcinoma (NTERA-2)

#### Host/vector system

---

02/03/2022  Page 14679 of 15326
Set of plasmids for the Flp-In™ T-REx™ System, described on the attached RA, to induce expression the protein of interest with Tetracycline on the stable transfected cell lines. They are procured from ThermoFisher.
pCDNA3 plasmid to transiently express the proteins of interest. It is procured from Genscript.
The CRISPR/Cas9- dependent genome editing of cells does not involve viral vectors or plasmids. We will use it to tag the gene of interest with a reporter gene system (HiBiT) (described on the RA).

Origin & function

Evaluation of foreseeable effects

HEK293 LgBiT Stable Cell Line (commercially available at PROMEGA).
Further engineered HEK293 LgBiT Stable Cell Line to tag proteins of interest with HiBiT (generated by a third party using CRISPR).
Various commercially available cancer cell lines (listed in the RA) engineered to have HiBiT tagged proteins of interest using CRISPR.
Various commercially available cancer cell lines (listed in RA) engineered to express protein PROTACS under the tet-inducible system.
HEK-293 is commercially available, were generated in 1973 by transformation of cultures of normal human embryonic kidney cells with sheared adenovirus 5 DNA.
The transgenes (Protein PROTACS) do not encode for oncogenes, growth factor receptors or toxin molecules. The generation of all transgenes and cloning into expression vectors will be outsourced from commercial providers (e.g. Genscript). This includes all bacterial work.
The CRISPR/Cas9- dependent genome editing of cells does not involve any viral vector, nor plasmids.
The transfected HEK 293 and other cell lines used in this project pose minimal potential damage to the environment as they have been adapted to an artificial cell culture environment under laboratory conditions and so are unable to thrive in the external environment if released.

Control measures to be adopted:
• Records and tracking of materials used are kept as part of PolyProx Therapeutics’ good lab practice which involves up to date hard copies of lab books. All materials are clearly labelled and stored in specific safe storage areas within the facilities.
• PPE: lab coats, gloves and goggles to be worn always. This is to reduce the possibility of any physical contact with the transfected cells. Their handling will be conducted in biosafety Level 2 (BSL2) cabinets.
• No sharps to be used – removes the possibility of introduction into the blood stream
• All wastes treated to destroy GMO material (see disposal section below)
• HEK 293 and other cell lines (volumes less than 500ml) they should only be handled in closed containers or in the BSL2 cabinet.
• All experiments to take place in Building 580, which is on a secure site as part of the Babraham Research Campus. All areas where the cells are stored are only accessible by employees (via keycard or keypad). Visitors are supervised and wear badges to identify them.
• Training for use of the transfected cells will be conducted by users who have prior experience of handling them. The completion of training will involve the adding of the individuals name to this risk assessment. The signature will serve as a record of the training and be kept on file as part of the PolyProx Therapeutics training records.
• Where transfected cells are transported this will only be done while frozen, in sealed containers which are labelled and placed inside sealed plastic packaging. These in turn will be put into larger boxes, sealed and the box labelled with PolyProx’s name, address and contact details with the instruction not to open unless authorised.
There will be no lone, out of hours, work for this project.
The PolyProx Therapeutics Health and Safety Policy covering lab practice and use of COSHH is to be followed at all times.
Together the implementation of these control measures makes this project “LOW” risk
First Aid:
EYE EXPOSURE FROM SPLASH OR AEROSOLS: Rinse a minimum of 15 minutes in eye wash available at all sink hand wash areas or flush area with water. Seek medical attention.
CONTACT WITH SKIN: wash thoroughly with soap. Hand sinks available in all labs for washing.
INHALATION EXPOSURE FROM AEROSOLS: Seek medical attention.
NEEDLESTICK AND/OR SHARPS EXPOSURE: No sharps are to be used.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

<table>
<thead>
<tr>
<th>Waste Disposal</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Presept is used as it is a validated desinfectant for transfected cells if used in the following way under manufacturers recommendations for 100% kill rate.</td>
</tr>
<tr>
<td>• Hard surfaces: A solution containing 1g/L for 1 hour contact time, 10mins for metal parts (longer can cause corrosion)</td>
</tr>
<tr>
<td>• Safety cabinets: 2g/L Presept (10mins)</td>
</tr>
<tr>
<td>• Supernatants/liquid waste: 2g/L Presept, for 1 hour soaking, then flush down the drain with a lot of water.</td>
</tr>
<tr>
<td>• All solid waste is going to be incinerated.</td>
</tr>
<tr>
<td>• Full yellow euro bins (properly labelled and closed) are to be transported to the hazardous waste bins to the Babraham storage area by the state team. Howie type Lab coats, safety glasses and nitrile gloves will be used during the waste handling.</td>
</tr>
<tr>
<td>• The Babraham Research Campus has a derogation with the HSE so that clinical waste can be removed from site without being autoclaved. Waste is processed in accordance with the Babraham Institute disposal method according to notification GM 105.4.1.</td>
</tr>
<tr>
<td>• Bins are collected for off-site for incineration by Vetspeed Ltd _GM authorization number GM898.</td>
</tr>
</tbody>
</table>

Accidental Release:
In our laboratories, the floor is sealed and the labs are built to CL2 level, all the MSC are Class 2.
In an uncontained area, all persons should evacuate the area to avoid contact with any potential aerosols formed.
Only after 1 hour may the room be entered (to allow any aerosols to settle) and the procedures should be the same as in a contained area.
In a contained area cover the spill with absorbent material, such as paper towels, and let the spill soak in. This helps prevent aerosolization of the contaminant. Virkon powder should be applied all over the spill area. Allow 20 min contact time. The spillage is to be mopped up with damp towels, it must not be brushed. This solid waste is then to be incinerated as described before.

Give brief details of the genetic modification safety committee

BioEscalator GM Safety Committee:
The BioEscalator Innovation Building on Oxford University's Old Road Campus is home to a range of early stage life science companies. The GM Safety Committee is composed of representatives from these companies (Founders, research associates, and Designated Biological Safety Officers), the BioEscalator Laboratory Manager, and two Divisional Safety Officers from the Medical Sciences Division of the University of Oxford. Several of the committee members have extensive experience in the field of virology, and all have experience of working with or assessing the risk associated with working with GMM/GMO. The affiliation of the BioEscalator with the University of Oxford means that they adopt many of the practices of the University Safety Policy.
The committee meet annually. In the interim, when a new GM Risk Assessment is submitted to them for review, it is sent to each member of the committee for comments/approval. Their comments must be sent in writing to the assessor. Only once all committee members are satisfied that the Risk Assessment is appropriate for the containment class specified, can the HSE application be submitted.

### Project Additional Information

**Purposes of the contained use**

We will be using a lentiviral system to stably express immune cell surface receptors in recipient cell lines. The transduced cell lines will then be used in cell based assays to study immune response to modulating antibodies. The same lentivirus-based vector system will be used to express high titres of soluble forms of immune receptor proteins in a 293T cell line. These proteins will subsequently be purified from supernatant by affinity chromatography to be used in various assays required to characterise candidate antibodies (e.g. SPR and ELISA-based assays of antibody-receptor binding).

**Recipient or parental organism**

E.coli derivatives will be used to retransform lentiviral transfer plasmids. These cells are disabled such that they cannot colonise human gut. They are considered equivalent to ADCP hazard group 1.

HEK 293T cells will be transfected with a mixture of lentivirus transfer, packaging and envelope plasmids to produce the lentiviral particles.

The recipients are all cell lines of human or mouse origin. They include HEK 293T, Jurkat and BW5147. In some cases, the host Jurkat cell line may have already been genetically modified to contain a fluorescent reporter construct to report transcriptional activation via NFkB. The cell lines are all widely used and have a safe history of use. They are well characterised, authenticated, and are obtained from commercial sources. They are considered low hazard for GM activities and as such are considered Containment level 1 with good microbiological practice and good occupation hygiene.

**Host/vector system**

The vector system is a third generation HIV-1 based lentiviral system, using transfer plasmids pSF-Lenti-SFFV-EMCV-Blast-SV40ori and/or pSF-Lenti-SFFV-EMCV-Puro-SV40ori, along with ExceLenti LTX Lentivrus Packaging mix. The system is split over 4 plasmids, enhancing safety by reducing the likelihood that recombination events could produce replication competent virus. Several other features make this system incapable of producing replication competent virus; the system lacks the full complement of necessary genes to make replication competent virus, since the accessory proteins vpr, vif, vpu and nef are all absent, as is Tat; the transfer plasmid does not contain wild-type HIV-1 LTR, but has a mutated version which is self inactivating and uses a 5’ CMV rather than native promoter; HIV structural genes are provided in trans; LTR and psi packaging sequences are absent from the packaging plasmids containing these elements.

The transfer plasmid contains a WPRE sequence. This has a partial open reading frame for X Protein. Evidence suggest that this protein may play a role in promoting hepatocarcinogenesis in mice. Under the Genetically Modified Organisms Regulation 2014, work using vectors containing this sequence should be classified as Class 2.

**Origin & function**

The cDNA inserts will be ordered from commercial sources as gene strings and then cloned into the transfer plasmids using standard restriction cloning methods. These genes are all of mammalian immune cell origin and, along with the standard antibiotic resistance genes, have no oncogenic potential, and can be classified under Containment Class 1.
The transformed E.Coli confer no significant hazards. Expression of inserted genes does not present a hazard. The resulting GMO is no more hazardous to human health than the un-modified cells, since the changes do not alter the pathogenicity of the host. The resulting GMM would not survive outside laboratory conditions. Since it is non-colonising, and none of the inserted sequences would affect the level of risk, it would not be harmful to animals, plants or humans. Risk to the environment is effectively zero.

The inserts are manufactured synthetically as gene strings, so there is no risk associated with insert donor source.

The main risk to human health is from exposure to the lentiviral particles, which have wide tropism and are capable of infecting human cells. The transgenes are not toxic or oncogenic and therefore low GM risk, however there is a small oncogenic risk associated with the possibility that upon exposure to lentivirus, the transgene could potentially insert into a tumour suppressor gene, resulting in loss of function. The likelihood of this happening is extremely low. Good laboratory practice also minimises the risk of laboratory workers being exposed to virus.

Since the lentiviral system used produces replication incompetent vector, the resulting GMOs are incapable of producing replication competent virus and so genetic modifications cannot be transmitted from one individual to another or from one organism to another. As such, a combination of containment level 2 working and appropriate waste disposal methods (see below) means there is effectively zero risk to the environment from the resulting GMO. The lentiviral transfer plasmid contains a WPRE sequence that has not been mutated to scramble the open reading frame of the X protein, which may be oncogenic in nature. Under the Genetically Modified Organisms Regulation 2014, work using vectors containing this sequence should be classified as Class 2

Assignment to provisional containment: Containment Level 2

Evaluation of foreseeable effects

The transformed E.Coli confer no significant hazards. Expression of inserted genes does not present a hazard. The resulting GMO is no more hazardous to human health than the un-modified cells, since the changes do not alter the pathogenicity of the host. The resulting GMM would not survive outside laboratory conditions. Since it is non-colonising, and none of the inserted sequences would affect the level of risk, it would not be harmful to animals, plants or humans. Risk to the environment is effectively zero.

The inserts are manufactured synthetically as gene strings, so there is no risk associated with insert donor source.

The main risk to human health is from exposure to the lentiviral particles, which have wide tropism and are capable of infecting human cells. The transgenes are not toxic or oncogenic and therefore low GM risk, however there is a small oncogenic risk associated with the possibility that upon exposure to lentivirus, the transgene could potentially insert into a tumour suppressor gene, resulting in loss of function. The likelihood of this happening is extremely low. Good laboratory practice also minimises the risk of laboratory workers being exposed to virus.

Since the lentiviral system used produces replication incompetent vector, the resulting GMOs are incapable of producing replication competent virus and so genetic modifications cannot be transmitted from one individual to another or from one organism to another. As such, a combination of containment level 2 working and appropriate waste disposal methods (see below) means there is effectively zero risk to the environment from the resulting GMO. Under the Genetically Modified Organisms Regulation 2014, work using vectors containing this sequence should be classified as Class 2

Assignment to provisional containment: Containment Level 2

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumable waste (mainly plasticware eg. Pipettes, flasks, tubes, tips)
Autoclave using make safe cycle as specified in BS 2646 Prt 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the black bags (for incineration) waste route following autoclaving
Liquid waste (samples, tissue culture medium, supernatants, washings etc)
Add Virkon to 1% W/V for at least 1 hour and then discharge to drains.
Agar plate waste
Autoclave using make safe cycle as specified in BS 2646 Prt 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the black bags (for incineration) waste route following autoclaving

Please enter comments of the GM safety committee on the risk assessment

Reviewed by BSO only as contained use as per contained use Genetically Modified Organisms (Contained Use) Regulations 2014. The following comments were raised:
1) Confirmation of contained use of GM should be sought regarding likelihood of shedding of live, infectious GMO from patients.
2) Evidence should be provided for the GMO confirming limited viraemia and virulence of infection.
3) Confirmation that GMO is no more likely to persist in the environment compared to the attenuated vaccine strains of Yellow Fever and Japanese Encephalitis vaccine strains
Manufacturer risk assessment provided in response to above queries and attached to this application
Review by ATIMP committee requested further details regarding inactivation of vaccine and whether manufacturer had sought license in EU - responses provided by Sanofi.

Give brief details of the genetic modification safety committee

The Alloy Therapeutics Ltd genetic modification committee will consist of:
1. The head of the Cambridge site who will serve as the chair of the committee and has over 30 years of relevant research experience.
2. Five staff who have PhDs in various relevant fields of research and more than 10 years research experience including genetic modification and GMOs.
3. The external biosafety consultant (see section 8).

The Alloy Therapeutics Ltd GM committee agreed that the risk assessment included with this notification was suitable and sufficient. The committee will meet at least every 6 months to review risk assessments and GM procedures.

For activities involving GMMs, describe the waste management measures which will apply to the activity

All waste material will be inactivated by treatment with 1% (w/v) Virkon solution prior to disposal. Waste material will then be placed in sealed bins and incinerated by an off-site incineration company (see derogation application below). Waste from our GM work at Class1 will be placed into suitably labelled hermetically sealable bins. They will be sealed by our staff and removed to a central collection point where they will be placed into 210 litre yellow labelled “Eurobins”.

Collections for incineration will be made by the local registered clinical GM waste incinerator contractor.

This disposal method is expected to achieve 100% inactivation of the GMM. The data sheets describing inactivation by Virkon are attached.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment
The Alloy Therapeutics Ltd GMO committee reviewed the GMO risk assessment (see attached). The Alloy Therapeutics Ltd GMO committee consists of 6 people who have PhDs in different fields with at least 10 years research experience including genetic modification and GMOs. The GMO committee have previously written GMO risk assessments for similar work prior to joining AlloyTherapeutics and they understand the science around the work carried out.

The Health and safety consultant also reviewed the GMO risk assessment. The consultant has a B.Sc in Animal Sciences - Wye College (part of Imperial), London University, M Sc, Animal ParaSitology, Ph.D. The immunology and pathology of Sarcocystis ovicanis infections in sheep (both at U.C.N.W" University of Wales). Technical member of the Institution of occupational safety and health (Tech IOSH), NEBOSH National Diploma in Occupational Health and Safety (in progress), NEBOSH National General Certificate in Occupational Health and Safety, Member of the Institute of Safety in Technology and Research, MRC Biological Safety Officer Training Certificate. 1986 to 2010 at the Babraham Institute (Cambridge) where experience of handling pathogens and GMO obtained during research. 2006 made Babraham Research Campus Biological Safety Officer (part time plus research). 2009 onwards teach the genetic modification safety section of the One Nucleus 'Biological Safety: Management and Practice' course (IOSH approved).

2010 onwards Babraham Institute Health, Safety and Quality Assurance Manager and Babraham Bioscience Technologies (BBT) Biosafety Officer (Full time). 8 years experience in risk assessments and has health and safety qualifications.
### Purposes of the contained use

The aim of this project is to use MV, y-retrovirat and lentiviral delivery systems to introduce various mammalian DNA sequences into mammalian cells in culture. These sequences direct expression of either (i) RNA species (siRNAs or antisense RNAs) that interfere with the expression of various mammalian proteins or (ii) the corresponding mammalian proteins themselves; for in vitro use and for the generation of stable mammalian cell lines (and subsequent use of such stable lines in vitro) with the aim of generating stable cell lines expressing fluorescent proteins, potential drug targets or therapeutic proteins, etc.

### Recipient or parental organism

Cloning, propagation and amplification of component plasmids for MV, y-retro- and lenti-virus vector systems will take place in K12 strains of E. coli (with a history of safe use). Mammalian cell lines (e.g. immortalized lines derived from human cancer tissues) fall into two types:

a) Packaging/helper cell lines into which plasmids containing lenti- or retroviral DNA will be introduced, and from which infectious virus will be secreted into the medium to high titre. The media from these cell-lines poses a risk because of the high viral titre. As such this could provide a risk of infection to personnel working with the media.

b) Recipient cell lines in culture. These cells will initially be exposed to a high titre of virus to permit infection (virus derived from (a) above). However the infected cell lines will be incapable of themselves producing active virus and as such are no more dangerous than the parental cell lines, i.e. a negligible risk.

### Host/vector system

The AAV vector technology that we will use is based on a non-enveloped single-stranded DNA virus (Adeno Associated Virus - which are ACDP Hazard Group 1 biological agents) as vehicles to efficiently deliver and express genes in mammalian cells. MV viruses are taken up by endocytosis, released for transcription and expression following migration to the nucleus. Given the low pathogenicity of the recipient virus, the major hazards that will be posed by recombinant MV vectors will depend upon the properties of the inserted genetic material and any products that it may encode ..

The V-RETROVIRAL vectors which will be used are derived from either Moloney Murine sarcoma Virus (MoMLV), Mouse Mammary Tumour Virus (MMTV) or Feline Leukaemia Virus (FeLV), all of which are ACDP Hazard Group 1 biological agents. On the other hand, the virus will be packaged by transfecting transfer vector into specific amphoteric 'helper' cell line (gag, pol and env stably incorporated into host chromosome cells). NOTE: amphotropic packaging will widen the host range of the virus and allow it to infect a wide range if mammalian species (including humans) and cell types. This means that the viruses produced for this experiment could potentially infect a number of species, including man.

### Origin & function

Selectable markers - examples (but not restricted to);
- Ampicillin resistance: E.coli derived
- Neomycin resistance: bacteria derived aminoglycoside phosphotransferase gene

Puromycin resistance (PAC) : Puromycin acetyl transferase is derived from Streptomyces alboniger

Reporter proteins such as (but not restricted to);
- Fluorescent proteins as reporters;
- GFP derived from the jellyfish Aequorea victoria and variants of this
Luciferase - class of oxidative enzymes used in bioluminescence
  o renilla luciferase derived from the Sea pansy (Renilla reniformis)
  o firefly luciferase derived from the firefly Photinus pyralis.
Open reading frames, cDNAs and gene sequences encoding potential drug targets or therapeutic proteins and I or
shRNAs (designed to knockdown the expression of Open reading frames, cDNAs and gene sequences encoding
potential drug targets or therapeutic proteins) - all human derived.
This could include the expression of potentially harmful genes e.g., encoding known proto-oncogenes or genes with
known oncogenic mutations that can contribute to cellular transformation.

Evaluation of foreseeable effects

All viral vectors employed in this protocol exhibit broad tropism and potential to infect human. Risks conferred
following infection are identified as:

i) genetic insertion of viral sequences with potentially deleterious effects on endogenous genes: we will
employ transgene promoters and other viral sequences that may affect host gene function in a wide
range of cell types (e.g., CMV promoter). We assess retro-, lenti- or adenovirus infection might induce
permanent changes in infected cells including a risk for tumorigenesis. Risks conferred are previously
described and categorised under Class 2 risks [SACGM compendium of guidance part 2, page 121]:
  • ... The effects of integration upon the infected cell should be considered. For instance, promoter
sequences present in the provirus might activate genes adjacent to the integration site or,
alternatively, insertion may disrupt genes and prevent their expression."
ii) expression of human-derived or homologous transgenes with potentially deleterious effects: various
transgenes may be employed, wherein intrinsic function of the transgene confers potentially
deleterious effects. For example, expression human oncoproteins could induce transformation of
infected cells. Beyond endogenous homeostatic mechanisms that may lessen this risk (e.g., apoptosis
and other host tumor suppression responses), we assess that standard precautions under Class 2
risk mitigation procedures are adequate to address such risks.
iii) expression of exogenous transgenes directed to host genes with potentially deleterious effects: multiple
transgene technologies (antisense, RNAi, CRISPR or related gene conversion) may be employed to
modify the function of endogenous genes with potentially deleterious effects. For example, RNAi or
antisense RNA could reduce the function of genes necessary to control cell apoptosis, potentially
resulting in tumorigenesis. As above, we assess that Class 2 risk management procedures
adequately address these risks.
iv) expression of heterologous genetic sequences with potentially deleterious effects: we will employ diverse
collections of non-human derived, exogenous transgene sequences that carry potential risks
following infection. Risks from expression of these collected transgene sequences are mitigated and
attenuated through several means. First, known pathogenic transgenes systemically removed, and
other exogenous gene products are fragmented or rearranged, such that potentially pathogenic or
other biologically deleterious genetic functions are not recapitulated in their complete endogenous
configuration. Second, potentially deleterious transgenes in any infectious viral preparation are highly
titrated, such that any single deleterious sequence comprises less than 1 part in 100,000 parts of an inoculum with infectious potential. In total, we assess these risks are
adequately managed via the
same Class 2 risk precautions employed above.
We assess environmental hazards are adequately addressed through the proposed personnel risk management
measures. We employ multiple attenuation strategies and protocols to severely limit independent virus
propagation beyond the intended use, and therefore anticipate minimal risks of GMM release.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Instead of autoclaving waste in the building we propose to follow the procedure used by the Babraham Institute described in their disposal notification GM105/4.1 (see also section 6 above for description). Reasons for adopting this method of waste disposal are:
1. We do not have access to an autoclave within our area of the building
2. The waste disposal system used by the Babraham Research Campus is safe and has been running since October 2004.

All liquid waste material will be inactivated by treatment with 1% (w/v) Virkon solution prior to disposal. Solid waste material will be placed in sealed bins and incinerated by an off-site incineration company (Vetspeed - Their GM authorization is GM898) according to disposal notification GM105/4.1.

Waste from our GM work at Class 2 will be placed into suitably labelled hermetically sealable (red lid to distinguish them from Class 1 waste) 60 litre UN approved (to Class 3) Type 3H21Y30/SI2003 bins. Sealed bins are placed into secondary 210 litre yellow labelled "Eurobins". Contents of the bin are recorded and collections by the local registered clinical/GM waste incinerator contractor will be made three times a week to prevent a build-up. The site has 24h Security. The contractor uses solid bodied transport and carries portable disinfection equipment in case of any spillage. Autoclave facilities will be available in an adjacent building, as required by the Regulations, in case of loss of the contractor's facilities. The type of container and the secondary Euro container means that the risk of any spillage of active GM waste on site is negligible. However, as active waste will leave the site, the risk to the environment and health is possibly marginally higher than autoclaving prior to incineration. The only real risk of release would be as a result of a major RTA, however, the containers are designed to withstand this. This disposal method is expected to achieve 100% inactivation of the GMM.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste material will be inactivated by treatment with 1% (w/v) Virkon solution prior to disposal. Solid waste material will then be placed in sealed bins and incinerated by an off-site incineration company (see derogation application above). Waste from our GM work at Class1 will be placed into suitably labelled hermetically sealable bins. They will be sealed by our staff and removed to a central collection point where they will be placed into 210 litre yellow labelled "Eurobins". Collections for incineration will be made by the local registered clinical/GM waste incinerator contractor. This disposal method is expected to achieve 100% inactivation of the GMM.

The data sheets describing inactivation by Virkon are attached.

Y

Give brief details of the genetic modification safety committee

Responsible person for genetic modification safety is a qualified Microbiologist (B. Sc.) with a PhD in synthetic biology. This person (Chief Scientific Officer of the company) has extensive experience devising risk assessments for the genetic modification of bacteria, which will be the focus of this activity. This employee has created the risk assessments for the operations at the premises and is responsible for their implementation. All employees will meet with this person once a month to ensure continued compliance with existing SOPs and methods, and to assess operations for any further potential safety risks.

Our waste management procedures involve disposal of all GMM material in standard sealable yellow 60L eurobins. These bins will have ‘UN3245’ stickers (includes the biohazard triangle and Biohazardous class 1 waste) placed onto the box with the premises building and room numbers detailed, in accordance with the Babraham Institute (wider campus in which the laboratory is located) SOP 3 - disposal of GMM waste. When securely locked, the date will be applied to the bin and the bin transported for incineration using Babraham Institute approved waste disposal service contractors. Incineration will fully inactivate/kill the GMM waste.

The person responsible for biological safety (company CSO) will audit this procedure to ensure that all employees are disposing with GMM waste in accordance with this protocol, underpinned by the procedures described in the SOP.

Approved disinfectants (Chemgene and Virkon) will be used for disinfection (SOP1: Use of Disinfectants in the containment 1 lab). A standard spill procedure will be used (SOP 27: Dealing with Biological Spills at containment 1) (see attachments for the risk assessment). When needed, an autoclave will be used, at 121 degree C for 15 minutes. Reflection Therapeutics will use the standard sealable yellow 60l eurobin for all Biological lab waste, including GM class 1 micro-organism, GM animal material and other low risk Biological waste or contaminated material.

For activities involving GMMs, describe the waste management measures which will apply to the activity

"(…) needs to notify the HSE that she will be working with GM material (follow links) this is CLASS 1"

"HSE requires that human pathogens are handled in accordance with the classification as per http://www.hse.gov.uk/pubns/misc208.pdf . HEK293 cells are not listed on this list, therefore they themselves are not classified and do not require notification under COSHH (via a CBA1). Whilst they contains genes from viruses (e.g. adenovirus, SV40), if they do not produce that virus during passage, they do not need notifying via a COSHH route (i.e. 1st use of hazard group 2 agents). You should apply this logic to your assessment for other cell lines which you intend to use."

### Project Additional Information

#### Purposes of the contained use

The aim of this project is to use AAV, γ-retroviral and lentiviral delivery systems to introduce various mammalian DNA sequences into mammalian cells in culture. These sequences direct expression of either (i) RNA species (siRNAs or antisense RNAs) that interfere with the expression of various mammalian proteins or (ii) the corresponding mammalian proteins themselves; for in vitro use and for the generation of stable mammalian cell lines (and subsequent use of such stable lines in vitro) with the aim of generating stable cell lines expressing fluorescent proteins, potential drug targets or therapeutic proteins, etc.

#### Recipient or parental organism

Cloning, propagation and amplification of component plasmids for AAV, γ-retro- and lenti- virus vector systems will take place in K12 strains of E. coli (with a history of safe use). Mammalian cell lines (e.g. immortalized lines derived from human cancer tissues) fall into two types:

- **a)** Packaging/helper cell lines into which plasmids containing lenti- or retroviral DNA will be introduced, and from which infectious virus will be secreted into the medium to high titre. The media from these cell-lines poses a risk because of the high viral titre. As such this could provide a risk of infection to personnel working with the media.

- **b)** Recipient cell lines in culture. These cells will initially be exposed to a high titre of virus to permit infection (virus derived from (a) above). However the infected cell lines will be incapable of themselves producing active virus and as such are no more dangerous than the parental cell lines, i.e. a negligible risk.

#### Host/vector system

The AAV vector technology that we will use is based on a non-enveloped single-stranded DNA virus (Adeno Associated Virus - which are ACDP Hazard Group 1 biological agents) as vehicles to efficiently deliver and express genes in mammalian cells. AAV viruses are taken up by endocytosis, released for transcription and expression following migration to the nucleus. Given the low pathogenicity of the recipient virus, the major hazards that will be posed by recombinant AAV vectors will depend upon the properties of the inserted genetic material and any products that it may encode.

γ-RETO/ROVIRAL vectors which will be used are derived from either Moloney Murine sarcoma Virus (MoMLV), Mouse Mammary Tumour Virus (MMTV) or Feline Leukaemia Virus (FeLV), all of which are ACDP Hazard Group 1 biological agents. On the other hand, the virus will be packaged by transfecting transfer vector into specific...
amphoteric ‘helper’ cell line (gag, pol and env stably incorporated into host chromosome cells). NOTE: amphotropic packaging will widen the host range of the virus and allow it to infect a wide range if mammalian species (including humans) and cell types. This means that the viruses produced for this experiment could potentially infect a number of species, including man.

However, bearing this in mind we should consider that the viruses that will be used have been modified in a number of ways which will make them safer to handle:

• The genes encoding structural and other components of the viral genome have been separated. These genes have been engineered to minimise the risk of recombination that could lead to production of a replication-competent virus.

• The packaging cell lines allow expression of proteins, required to produce progeny virus: But the transfer vector is the only genetic material transferred to the target cells, consequently these cells cannot produce the proteins which are essential for viral assembly and infectivity.

• Second, third generation or Self INactivating vectors retrovirus vectors will be used in all experiments (see SACGM compendium of guidance part 2, section 2.11 (Retroviruses) pp117

The LENTIVIRAL vectors that will be used are derived from HIV-1, which is an ACDP Hazard Group 3 biological agent. However, second and third generation lentiviral vectors have several of the lentiviral accessory genes (required for pathogenesis only) deleted to increase biosafety and viral packaging is achieved by providing three helper constructs in trans containing gag, pol and rev sequences.

For example, second and third generation Lentiviral Expression Systems include the following key safety features:
In the second and successive generation lentiviral vectors several lentiviral accessory genes (vif, vpr, vpu and nef) are deleted from the transfer plasmid since they are not required for in vitro replication and the products they encode have cytotoxic activities.

In addition to this in the third generation lentiviral vectors:

• The Lenti expression vectors contain a deletion in the 3’ LTR (ΔU3) that does not affect generation of the viral genome in the producer cell line but instead results in “self-inactivation” of the lentivirus after transduction of the target cell (Yee et al., 1987; Yu et al., 1986; Zufferey et al., 1998). Once integrated into the transduced target cell, the lentiviral genome is no longer capable of producing a packageable viral genome.

• The number of genes from HIV-1 that are used in the system has been reduced to three (i.e. gag, pol, and rev).

• Genes encoding the structural and other components required for packaging the viral genome are separated onto four plasmids. All four plasmids have been engineered not to contain any regions of homology with each other to prevent undesirable recombination events that could lead to the generation of a replication-competent virus (Dull et al., 1998).

• Although the three packaging plasmids allow expression in trans of proteins required to produce viral progeny (e.g. gal, pol, rev, env) in the 293FT producer cell line, none of them contain LTRs or the Ψ packaging sequence. This means that none of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. No new replication competent virus can be produced.

Despite the above safety features, use of these lentiviral vectors (which include WPRE) falls within SACGM 2 criteria due to the potential biohazard risk of possible recombination with endogenous viral sequences to form self-replicating virus, or the possibility of insertional mutagenesis. In addition, the virus will be packaged by transfecting transfer vector into specific amphoteric ‘helper’ cell line (gag, pol and env stably incorporated into host chromosome cells). NOTE: amphotropic packaging will widen the host range of the virus and allow it to infect a wide range if mammalian species (including humans) and cell types. This means that the viruses produced for this experiment could potentially infect a number of species, including man

Selectable markers – examples (but not restricted to):
• Ampicillin resistance: E.coli derived
Neomycin resistance: bacteria derived aminoglycoside phosphotransferase gene
Puromycin resistance (PAC): Puromycin acetyl transferase is derived from Streptomyces alboniger

  - Luciferase – class of oxidative enzymes used in bioluminescence
    - renilla luciferase derived from the Sea pansy (Renilla reniformris)
    - firefly luciferase derived from the firefly Photinus pyralis.
Open reading frames, cDNAs and gene sequences encoding potential drug targets or therapeutic proteins and/or shRNAs (designed to knockdown the expression of
Open reading frames, cDNAs and gene sequences encoding potential drug targets or therapeutic proteins) – all human derived.
This could include the expression of potentially harmful genes e.g. encoding known proto-oncogenes or genes with known oncogenic mutations that can contribute to cellular transformation.

Evaluation of foreseeable effects

All viral vectors employed in this protocol exhibit broad tropism and potential to infect human. Risks conferred following infection are identified as:

i) genetic insertion of viral sequences with potentially deleterious effects on endogenous genes: we will employ transgene promoters and other viral sequences that may affect host gene function in a wide range of cell types (e.g. CMV promoter). We assess retro-, lenti- or adenovirus infection might induce permanent changes in infected cells including a risk for tumorigenesis. Risks conferred are previously described and categorised under Class 2 risks [SACGM compendium of guidance part 2, page 121]: “…The effects of integration upon the infected cell should be considered. For instance, promoter sequences present in the provirus might activate genes adjacent to the integration site or, alternatively, insertion may disrupt genes and prevent their expression.”

ii) expression of human-derived or homologous transgenes with potentially deleterious effects: various transgenes may be employed, wherein intrinsic function of the transgene confers potentially deleterious effects. For example, expression human oncogenes could induce transformation of infected cells. Beyond endogenous homeostatic mechanisms that may lessen this risk (e.g. apoptosis and other host tumour suppression responses), we assess that standard precautions under Class 2 risk mitigation procedures are adequate to address such risks.

iii) expression of exogenous transgenes directed to host genes with potentially deleterious effects: multiple transgene technologies (antisense, RNAi, CRISPR or related gene conversion) may be employed to modify the function of endogenous genes with potentially deleterious effects. For example, RNAi or antisense RNA could reduce the function of genes necessary to control cell apoptosis, potentially resulting in tumorigenesis. As above, we assess that Class 2 risk management procedures adequately address these risks.

iv) expression of heterologous genetic sequences with potentially deleterious effects: we will employ diverse collections of non-human derived, exogenous transgene sequences that carry potential risks following infection. Risks from expression of these collected transgene sequences are mitigated and attenuated through several means. First, known pathogenic transgenes systemically removed, and other exogenous gene products are fragmented or rearranged, such that potentially pathogenic or other biologically deleterious genetic functions are not recapitulated in their complete endogenous configuration. Second, potentially deleterious transgenes in any infectious viral preparation are highly titrated, such that any single deleterious sequence comprises less than 1 part in 100,000 parts of an inoculum with infectious potential. In total, we assess these risks are adequately managed via the same Class 2 risk precautions employed above.

We assess environmental hazards are adequately addressed through the proposed personnel risk management measures. We employ multiple attenuation strategies and protocols to severely limit independent virus propagation beyond the intended use, and therefore anticipate minimal risks of GMM release.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Instead of autoclaving waste in the building we propose to follow the procedure used by the Babraham Institute described in their disposal notification GM105/4.1 (see also section 6 above for description). Reasons for adopting this method of waste disposal are:
1. We do not have access to an autoclave within our area of the building.
2. The waste disposal system used by the Babraham Research Campus is safe and has been running since October 2004.

All liquid waste material will be inactivated by treatment with 1% (w/v) Virkon solution prior to disposal. Solid waste material will be placed in sealed bins and incinerated by an off-site incineration company (Vetspeed – Their GM authorization is GM898) according to disposal notification GM105/4.1.

Waste from our GM work at Class 2 will be placed into suitably labelled hermetically sealable (red lid to distinguish them from Class 1 waste) 60 litre UN approved (to Class 3) Type 3H21Y30/S/2003 bins. Sealed bins are placed into secondary 210 litre yellow labelled "Eurobins". Contents of the bin are recorded and collections by the local registered clinical/GM waste incinerator contractor will be made three times a week to prevent a build-up. The site has 24/7 Security. The contractor uses solid bodied transport and carries portable disinfection equipment in case of any spillage. Autoclave facilities will be available in an adjacent building, as required by the Regulations, in case of loss of the contractor's facilities. The type of container and the secondary Euro container means that the risk of any spillage of active GM waste on site is negligible. However, as active waste will leave the site, the risk to the environment and health is possibly marginally higher than autoclaving prior to incineration. The only real risk of release would be as a result of a major RTA, however, the containers are designed to withstand this.

This disposal method is expected to achieve 100% inactivation of the GMM.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste material will be inactivated by treatment with 1% (w/v) Virkon solution prior to disposal. Solid waste material will then be placed in sealed bins and incinerated by an off-site incineration company (see derogation application above). Waste from our GM work at Class 1 will be placed into suitably labelled hermetically sealable bins. They will be sealed by our staff and removed to a central collection point where they will be placed into 210 litre yellow labelled "Eurobins".

Collections for incineration will be made by the local registered clinical/GM waste incinerator contractor.

This disposal method is expected to achieve 100% inactivation of the GMM.

The data sheets describing inactivation by Virkon are attached.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The scope and particular aspects of safety risks described in the risk assessment were agreed upon, and satisfactory consensus was achieved regarding the adequacy of the SOPs, COPs and risk management planning protocols. Pending notification and acknowledgement by relevant authorities.

## Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Y

Give brief details of the genetic modification safety committee

The GMSC will be comprised of the Chief Scientific Officer/Safety Officer, two Scientific Officers. Note that we are a small company, and the Chief Executive Officer is also the Safety Officer. A quorum for the meeting is a minimum of two individuals.

The Committee will meet a minimum of once per year to discuss routine matters, review all existing risk assessments and audit the existing procedures. The GMSC will meet more frequently to discuss risk assessments etc. that require more urgent attention.

<table>
<thead>

</tbody>
</table>
All liquid waste from the GMMs will be aspirated into an appropriate disinfectant such as Virkon solution, such that the final concentration of Virkon remains above 1%, and is disinfected for at least 1 hour. The waste should then be disposed of down the sink with a copious amount of water. Contaminated solid waste such as plastic disposables, tissue paper and culture plates, etc will be disposed of in category 1 clinical waste disposal bins. The clinical waste disposal bins will be sealed, and disposed of together with other such material generated on the Babraham Research Campus by incineration off site. Sharps materials will be disposed of in yellow sharps containers, which are also disposed of by incineration off site.

The GMSC found that the risk assessment adequately stated the risks of carrying out the activities as described. The person responsible for supervision (in section 9 below) has confirmed the activity class of the work to be 1. FreeStyle 293-F will be used to express recombinant proteins. These are commercially available and are derived from HEK293 parental cells that have been adapted for suspension culture. The HEK293 lines are now well characterised with a history of safe use over several decades. They are an established host of choice for protein expression work. Work with the Freestyle 293-F cells are not believed to pose an increased hazardous risk compared to the parental line and containment within a cat 1 laboratory and good laboratory practice should be sufficient to minimise risk to health and the environment.

Use of genetically modified filamentous phage derived from well characterised parental phage strains

Give brief details of the genetic modification safety committee

The Alloy Therapeutics Ltd genetic modification committee will consist of:

1. The COO/researcher at Shift Biosciences will serve as the chair of the committee and has over 10 years of relevant research experience.
2. As the company (Shift Biosciences) currently has only one member of staff, four other committee members have been co-opted from Babraham Bioscience Technologies (BBT) and one a local biosafety consultant. The co-opted members from BBT have experience in various relevant fields of research and more than 10 years research experience including genetic modification and GMOs.
3. The local biosafety consultant (see section 8).

The Shift Biosciences Ltd GM committee agreed that the risk assessment included with this notification was suitable and sufficient. The committee will meet at least every 6 months to review risk assessments and GM procedures.

Please enter comments of the GM safety committee on the risk assessment
The Shift Bioscience Ltd GMO committee reviewed the GMO risk assessment (see attached). The Shift Bioscience Ltd GMO committee consists of 6 people who have at least 10 years research experience including genetic modification and GMOs. The GMO committee have previously written GMO risk assessments for similar work and they understand the science around the work carried out.

The biosafety consultant reviewed the GMOs. The consultant has a B.Sc in Animal Sciences - Wye College (part of Imperial), London University, M.Sc. Animal Parasitology, Ph.D. The immunology and pathology of Sarcocystis oviscanis infections in sheep (both at U.C.N.W., University of Wales). Technical member of the Institution of occupational safety and health (Tech IOSH), NEBOSH National Diploma in Occupational Health and Safety (in progress), NEBOSH National General Certificate in Occupational Health and Safety, Member of the Institute of Safety in Technology and Research, MRC Biological Safety Officer Training Certificate. 1986 to 2010 at the Babraham Institute (Cambridge) where experience of handling pathogens and GMO obtained during research. 2006 made Babraham Research Campus Biological Safety Officer (part time plus research). 2009 onwards teach the genetic modification safety section of the One Nucleus ‘Biological Safety: Management and Practice’ course (IOSH approved). 2010 onwards Babraham Institute Health, Safety and Quality Assurance Manager and Babraham Bioscience Technologies (BBT) Biosafety Officer (Full time). 8 years experience in risk assessments and has health and safety qualifications.

Purposes of the contained use

Analysis of anti-ageing genes and drugs.
### Host/vector system

- One retroviral parent vector pSRαMSU expressing mouse Cdk4 that was obtained from C S (Memphis, TN, USA).
- One pBABE-puro plasmid containing the hTERT sequence. The construct was created at the JS’s laboratory at the University of Texas Southwestern Medical Center, USA.

### Origin & function

**Origins:** Ker-CT CRL-4048TM cell lines are from ATCC®. The cell lines are immortalised keratinocytes, and originally obtained in J S laboratory at the University of Texas Southwestern Medical Center. This cell line was created by using the following steps:

1. Retroviral parent vector pSRαMSU expressing mouse Cdk4 obtained from C S (Memphis, TN, USA)
2. Plasmid DNA transfection into the ecotropic packaging cell line PE501, followed by infection into the amphotrophic packaging cell line PA137 (Miller And Rosman, 1989)
3. Selected clones generated from the amphotrophic packaging cell line were used to produce viral supernatant to infect normal epidermal keratinocytes
4. For double infections, keratinocytes were infected with a second construct Cdk4+hTERT
5. Keratinocytes were infected with pBABE containing hTERT in the presence of polybrene
6. Selection with 350 ng/ml of puromycin

**Intended Functions:** DNA sequence and cell culture. Overexpression of CDK4 and hTERT in neonatal foreskin keratinocyte induced a dramatic upregulation of p16INK4a and milder upregulation of p53 and p21WAF1, which became unresponsive to UV irradiation. Despite the high levels of these checkpoint factors, Ker-CT cells divide in an apparently normal regulated fashion, are able to respond to changes in calcium levels, retain the stem cell phenotype, and fully differentiate and stratify in organotypic culture.

### Evaluation of foreseeable effects

This cell line is not known to cause disease in healthy adult humans. The cells have NOT been screened for Hepatitis B, HIV, or other adventitious agents unless otherwise stated in Certificate of Analysis. The cell line contains one promoter of the full sequence of the SV40 virus, therefore the insert should not cause a problem. In addition, the plasmid contains the MMVL sequence (derived from Moloney murine leukemia virus) but lacks the genes required for viral packaging and
transduction (these genes are carried by helper plasmids or integrated into packaging cells instead). As a result, the vectors have the important safety feature of being replication incompetent (meaning that they can transduce target cells but cannot replicate in them).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Instead of autoclaving waste in the building we propose to follow the procedure used by the Babraham Institute described in their disposal notification GM105/4.1 (see also section 6 above for description). Reasons for adopting this method of waste disposal are:

1. We do not have access to an autoclave within our area of the building
2. The waste disposal system used by the Babraham Research Campus is safe and has been running since October 2004.

All liquid waste material will be inactivated by treatment with 1% (w/v) Virkon solution prior to disposal. Solid waste material will be placed in sealed bins and incinerated by an off-site incineration company (Vetspeed – Their GM authorization is GM898) according to disposal notification GM105/4.1.

Waste from our GM work at Class 2 will be placed into suitably labelled hermetically sealable (red lid to distinguish them from Class 1 waste) 60 litre UN approved (to Class 3) Type 3H21Y30/S/2003 bins. Sealed bins are placed into secondary 210 litre yellow labelled "Eurobins". Contents of the bin are recorded and collections by the local registered clinical/GM waste incinerator contractor will be made three times a week to prevent a build-up. The site has 24/7 Security. The contractor uses solid bodied transport and carries portable disinfection equipment in case of any spillage. Autoclave facilities will be available in an adjacent building, as required by the Regulations, in case of loss of the contractor’s facilities. The type of container and the secondary Euro container means that the risk of any spillage of active GM waste on site is negligible. However, as active waste will leave the site, the risk to the environment and health is possibly marginally higher than autoclaving prior to incineration. The only real risk of release would be as a result of a major RTA, however, the containers are designed to withstand this.

This disposal method is expected to achieve 100% inactivation of the GMM.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste material such as cell culture supernatant and medium will be rendered non-viable by overnight decontamination with Virkon (1%) and autoclaving prior to skin disposal. 2% or 3% solutions are used for buffered solutions. A minimal contact time of 1 hour is allowed prior disposal to sewers as per manufacturer’s’ recommendation.

Contaminated solid waste, e.g. Class 1 biological waste & GM waste, DNA and protein gels, contaminated paper, cardboard and towels used to mop spills, contaminated pipette tips and plastics and nitrile gloves) will be bagged in appropriate waste bins (yellow euro bins). Bins should be placed in the waste compound ready for collection and disposal as clinical waste.

Contaminated solid ACDP 2 waste (contaminated plastic ware, cell pellets, contaminated tubes and falcons, tips, gloves, etc.) should be placed in a red-topped bin. When bins are full, the bin is sealed tight and appropriately labels for collection and rendered inactive by autoclaving (100% kill) in a validate machine located within the same building. The autoclave is performance validated on an annual basis.

Plastic ware that can be effectively disinfected is treated with 1% Virkon for a minimum of 1 hour prior incineration. Any contaminated glassware is treated with 1% Virkon solution for a minimum of 1 hour prior to cleaning.

Solid surfaces are disinfected with 1% Virkon solution.

Chemical waste does not go down the drain with the exception of deactivated tissue culture supernatants and quantities of acids and alkalis of less than 100 mL. Chemical waste should be
decanted into a suitable container and labelled with the content and company name. Chemical waste must not be mixed. Chemical waste must be taken to the chemical store at the rear of the general store. Bottles should be transported using a bottle holder. Containers should be no spill and securely sealed.

Please enter comments on the GM safety committee on the risk assessment

All liquid waste material will be inactivated by treatment with 1% (w/v) Virkon solution prior to disposal. Solid waste material will then be placed in sealed bins and incinerated by an off-site incineration company (see derogation application above). Waste from our GM work at Class1 will be placed into suitably labelled hermetically sealable bins. They will be sealed by our staff and removed to a central collection point where they will be placed into 210 litre yellow labelled "Eurobins". Collections for incineration will be made by the local registered clinical/GM waste incinerator contractor.

This disposal method is expected to achieve 100% inactivation of the GMM.
The data sheets describing inactivation by Virkon are attached.

### Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities: Y

Give brief details of the genetic modification safety committee:

Phenotypeca's Biological Safety Officer and the University of Nottingham's Biological Safety Officer(s) for the Centre for Biomolecular Sciences and/or the School of Life Sciences have provided advice on GM risk assessments. All are scientists who have expertise in carrying out research using GMOs and are a good source of advice on risk assessment. Heads of Schools at the University of Nottingham where work with biological agents & GMOs is undertaken are required to appoint a person to act as Biological Safety Officer (BSO) to act as a local source of advice and support to researchers.

All solid waste and plastics exposed to GM material will be autoclaved prior to disposal. All liquid waste and glassware exposed to GM material will be autoclaved prior to disposal/wash up. Validated autoclaves are run at 126°C for 10 minutes (Centre for Biomolecular Sciences) and 128°C for 15 minutes (Life Sciences Building). Autoclaves are validated and serviced periodically with run cycle data recorded and retained, e.g. annual validation, 6-monthly service, annual insurance inspections and for each run a printout is obtained to validate the cycle, which is retained. Surfaces and spills will be disinfected (e.g. 2% Distel or 1% Virkon according to the manufacturers’ instructions) followed by disposal of cleaning materials by autoclaving.

For activities involving GMMs, describe the waste management measures which will apply to the activity

As reviewer of this application I am confident that the correct containment level has been determined for the work proposed. The yeast Saccharomyces cerevisiae is considered GRAS and QPS and the strains used in this proposal have been used safely for 10 years in numerous labs. They are disabled in that they have auxotrophies requiring nutrients making them unlikely to survive outside of the lab. They are benign except in cases of severe immune deficiencies or severe allergies which would be relevant to all yeast and not just these. The transient use of nonmobilisable vectors in disabled E. coli is also considered low risk. Any products made will be at small lab scale but should be assessed for potential toxicity or other detrimental effects. The scale of production in Phenotypewca is small and the risk of exposure is low. It is agreed that procedures within the company will ensure that containment at the required level is provided. All GM risk assessments, staff training, and GMO research will be compliant and aligned with the University of Nottingham policy.

10% bleach solution or commercial disinfectant (i.e. Virkon) will be used to disinfect any working surface or equipment used to handle the cells. In the event of a spill on a work surface, equipment (i.e. spill from a tube, etc) or floor, spilled material must be contained by covering with paper towels and decontaminated immediately. Manufacturer recommends a minimum of 10 minutes contact time for sufficient disinfection. This will be used followed by 70% ethanol/IPA wipe. Both methods have been validated against viruses, bacteria and some fungi activities. Further information on the safety and effectiveness of bleach is published by CDC (https://www.cdc.gov/infectioncontrol/guidelines/disinfection/disinfection-methods/chemical.html).

Virkon has been proven effective against 300 + strains/clinical isolates from 71 bacteria; 50 + strains/clinical isolates from 15 fungi; 70 + strains/clinical isolates from 33 viruses. Further detail on Virkon efficacy is provided in the following document: https://www.fishersci.co.uk/webfiles/uk/web-docs/SLSGD05.PDF

Waste solution from cell culture will be decontaminated using 10% bleach solution or commercial disinfectant (i.e. Virkon) with a minimum of 30 minutes contact time and is to be sluiced down the sink with warm water. Both bleach solution and Virkon are commonly used in laboratory environments for eliminating viable cells in cell culture and have been validated, as described above, to disrupt proteins and cell lipids, therefore can be used to effectively kill GMO cells (>99.9%) and denature proteins produced by them. The cell lines cannot survive outside the specialist cell culture environment. Solid waste, including plastic and gloves etc, will be disposed in a biohazard container. Once the container is full a lid will be placed to irreversibly seal the container, and a designated service (Stericycle) will collect them for disposal by incineration.

Spills and splashes on a work surface or equipment (i.e. spill from a tube, etc) must be contained by covering with paper towels and decontaminated immediately using the methods described above. In the event of a worker’s exposure to the GMO materials or waste via injuries, ingestion, or inhalation, treat immediately by making the site bleed (for cuts) and wash the exposed area for at least 15 minutes with water. Cover any small wounds with a waterproof dressing. Seek medical attention and contact Occupational Health if required. Uncontaminated personnel should be removed from the area while spills are dealt with by trained personnel wearing appropriate PPE with appropriate warning signs displayed throughout. Accidents must be reported following the company’s reporting procedure immediately and the appropriate Health and Safety body in the institution should also be informed.

For the use of a centrifuge, workers must follow the SOP to ensure a proper loading and use of appropriate lids. If a primary container has broken in a centrifuge without a closed rotor or bucket, immediately suspend use, notify lab staff and company head and request assistance from the company Biosafety Officer. For suspected or confirmed spills/breakage in any centrifuge, post a sign to indicate it cannot be used, wait at least 30 minutes after the centrifuge has stopped operating to allow aerosols to settle before initiating clean-up. If the spill is contained within a closed cup, bucket or rotor, spray the exterior with disinfectant and allow at least 10 minutes of contact time. Remove the carrier to the nearest biosafety cabinet (BSC). Carefully remove any unbroken tubes and place into a bin filled with disinfectant for 20 minutes. Wipe carrier/bucket with disinfectant. Spray the interior of the centrifuge chamber with a disinfectant, let sit for 20 minutes and then wipe down. In the event of a more significant failure (for example, a rotor failure) follow the above disinfection process and ensure equipment is clearly marked out of order until responsive maintenance by a qualified engineer.

Mammalian cell lines have stringent growth requirements and therefore are unlikely to survive outside the specialist cell culture environment posing minimal risk to both human health and the environment.
Genetic modification safety committee at The University of Birmingham had some minor comments which have been addressed within the body of the assessment. Examples of the comments are: 1) The assessment is generally well written but the significance of exposure to human health could be made clearer, ie. Effects on human health. 2) These types of modified cells are usually classed as Class 1 but handled at CL2. They are over classified. 3) Autoclaving is not used for waste inactivation and 30 minutes contact time with Virkon is deemed sufficient – there is a link to validation data but the relevant data about virkon could be pulled out.

Project Additional Information

Purposes of the contained use
Roylance storage is a storage only facility. GMO samples will be received on site via a courier, stored in the appropriate conditions and pulled and despatched at client request

Recipient or parental organism
Unknown - as we are storage oly this could vary between client requirements before we receive samples we ask for MSDS and as much information on the product as possible. Ensuring clients have the appropriate GMO clearance

Host/vector system
As above

Origin & function
As above

Evaluation of foreseeable effects
N/A

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
As a storage only facility the GMO products will be contained, controlled and treated as per MSDS and client instructions. If GMO products are deemed too hazardous or high risk, the samples will not be accepted for storage - only level 1 or 2 will be accepted for storage. Additional handling and spillage covered in risk assessment

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
As per risk assessment - likely only GMO's to be stored

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
As a storage only facility we do not offer disposal services. In the instance of spillages or primary packaging breakage our internal standard operating procedures will be followed for containment, cleaning, reporting and safety. This is performed with guidance from the MSDs and client instruction.
Products deemed too hazardous or high risk will be assessed before the study is accepted and storage rejected if applicable.

Please enter comments on the GM safety committee on the risk assessment

Iota Sciences follows site regulations on the disposal of GM material. All records are kept on site. All waste listed below will be disposed of as Clinical Waste (collected and incinerated by licensed waste contractors, Grundon):-
- Liquid waste (eg. culture, media etc. is first inactivated by treating with Virkon (final concentration of 2% for 12 hours, according to manufacturers instructions) and discarded into laboratory sink via excess water.
- Plastic ware (eg. petri dishes, pipette tips, Eppendorf tubes etc.) are collected into yellow plastic bags inside 60ltr burn bins with lids.
- Gloves, paper towels etc. which have potentially been in contact with GM material are disposed of in yellow bags inside 60ltr burn bins with lids.
- Surfaces are wiped with 70% Ethanol (100% kill).
Waste bins are not accessible to public and located only in the laboratory and carried down directly to Waste Contractors upon collection.

Tick to confirm that you are attaching a summary of the risk assessment Y

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment
The procedures outlined here are in accord with good laboratory practice (Good Microbial Practice, Good Occupational Health and Safety), and which are in use in the University of Oxford.

**Project Additional Information**

**Purposes of the contained use**

- The purpose of the contained use is to study the efficiency, cell survival and growth kinetics of expanding single induced-pluripotent stem cells (iPSCs) into populations of -20-500 cells.
- iPSCs are genetically reprogrammed somatic cells which exhibit a pluripotent stem cell-like state similar to embryonic stem cells. iPSCs can be derived by inducing selected gene expression via various methods including sendai virus-mediated gene transduction.
- The respective iPSCs will be obtained from commercial entities, for example, Public Health England (PHE) and EBiSC (European Bank for Induced Pluripotent Stem Cells), which are shown to be free of sendai-virus as per PCR-based detection (https://cells.ebisc.org/).

**Recipient or parental organism**

- Of note, iPSCs will be obtained from commercial entities, for example, Public Health England (PHE) and EBiSC (European Bank for Induced Pluripotent Stem Cells). The iPSC cell line(s) were originally generated by academic institutions, for example, the Institute for Neurophysiology, Medical Faculty, University of Cologne (UKK) Germany. The iPSC-cells were derived by reprogramming somatic cells, for example, fibroblasts of dermis (for example, cell line UKKI020-D) or Peripheral Blood Mononuclear Cell (PBMC) (for example, cell line UKKI026B) using Sendai Virus-mediated delivery of reprogramming factors.

**Host/vector system**

- Sendai-virus has been used to reprogram somatic cells into induced pluripotent stem cells (iPSCs). The Sendai virus is a non-integrating virus, which in principle means it does not integrate into the cells genomic DNA. It replicates in the cytoplasm and delivers key genetic elements that produce proteins to reprogram mammalian cells (for example, fibroblasts) into iPSCs.
- Sendai-virus can infect mammalian cells, including human cells in petri dishes and respective laboratory conditions. Upon infection, cells are not capable of producing infectious particles.
Sendai-virus has been used to reprogram somatic cells into induced pluripotent stem cells (iPSCs). The Sendai virus is a non-integrating virus, which in principle means it does not integrate into the cells genomic DNA. It replicates in the cytoplasm and delivers key genetic elements that produce proteins to reprogram mammalian cells (for example, fibroblasts) into iPSCs.

- Sendai-virus can infect mammalian cells, including human cells in petri dishes and respective laboratory conditions. Upon infection, cells are not capable of producing infectious particles.

**Evaluation of foreseeable effects**

SeV (Sendai Virus) vectors used consist of viral proteins NP, P, M, F (activated), HN, and L, and the SeV genome RNA, from which the F gene is deleted.

- Because SeV infects cells by attaching itself to cell surface receptor sialic acid, present on the surface of many cell types of different species, the vectors are able to transduce a wide range of cells. However, they are no longer capable of producing infectious particles from infected cells, because the viral genome lacks the F-gene.

- Therefore, cells infected with SeV are not capable of producing infectious particles.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

- Liquid waste will be collected in a sealed container, and discarded into yellow Biohazard plastic bags inside 60L burn bins and sent for incineration.
- Solid and plastic ware (eg. petri dishes, pipette tips, tubes etc.) that have been in contact with cell culture biohazard waste will be collected into yellow biohazard plastic bags inside approved 60L burn bins with lids and sent for incineration.
- Other waste material that have been in contact with Biohazard materials (eg: tissue, gloves and other non-sharp items that will not puncture the bag) will also be collected into yellow biohazard plastic bags in 60L burn bins. The bag will be tied and carried inside the bin, and the bag handed directly to the Waste contractor for incineration.
- All waste will be packaged according to ADR regulations to minimise risk to human and/or animal health and the environment. All bins will be kept in the lab and handed directly to the Waste Management contractor upon collection.
- All waste will be incinerated through the Clinical Waste! GMO System provided by our Waste Management Contractor, Grundon (GM Authorization Number GM78201.1) that is permitted to accept Class 2 GMM that is noninactivated. Incineration Degree of kill: 100%.
- For routine sterility control of work surfaces: Wipe clean before and after use with 70% ethanol and/or ChemGene High level disinfectant. Degree of Kill: 100%.

**Is an emergency plan required according to regulation 20?**

No

**If yes, tick to confirm that it is attached to this form**

No

**Tick to confirm that you have attached a risk assessment to this form**

Yes
Iota Sciences Ltd. is a spin-out company from the Sir William Dunn School of Pathology, University of Oxford. We have applied procedures outlined here in accordance with good laboratory practice (Good Microbial Practice, Good Occupational Health and Safety), and which are also in use in the University of Oxford.

We have received advice from a Professor at the University of Oxford. Now retired, the Professor is an expert in cell biology, and has a 40 years experience in risk assessment of working with various cells, in particular genetically modified cells, and microorganisms. The Professor is still actively engaged in research as an 'Honorary Researcher' at Oxford University.

Y

Give brief details of the genetic modification safety committee

The South Tyneside and Sunderland NHS Foundation Trust has appointed an internal Biological Safety Officer (BSO) to advise management on contained use activities and provide approval for the risk assessments which are of GM Class 1 risk level as permitted under the contained use regulations. The BSO has been trained by external providers. The Queen Mary University of London (QMUL) GM Safety Committee and the QMUL BSO under contractual agreement provide expert peer review of risk assessments where risk level is deemed greater than Class 1 or contentious issues arise. The Sunderland Trust BSO is a co-opted member of the QMUL GM safety committee and participates in relevant meetings either in person or via video conferencing. The QMUL GMSC meets at least three times a year and conducts its activities under the terms of reference drawn up according to the contained use regulations and can be viewed at a specific webpage at http://www.hsd.qmul.ac.uk/

Solid GM Class 1 non-sharp waste is either inactivated by an effective disinfection method (noted below) or directly placed into eco-lock bins for uplift and offsite high temperature incineration (900 deg C) by an authorised upper-tier clinical waste contractor (currently Sharp Smart; incinerator location CliniPower, Avonmouth, Bristol). Sharps waste is deposited directly into sharpsafe bins, sealed and uplifted for offsite high temperature incineration by the same clinical waste contractor / incinerator. High temperature incineration achieves 100% kill of the GMM.

Liquid waste (or as necessary, for solid waste) is disinfected by an effective disinfectant shown to give > 5 log kill of the GMM. Virkon (final concentration 1% w/v) is the current effective disinfectant shown by the supplier under defined ‘suspension’ standards for liquid samples to give 5 log kill of the viral GMMs proposed for use. Liquid waste will then be disposed with copious tap water down designated sluice / lab sinks, in line with the local Water Authority effluent permit conditions. Any new disinfectant to be used will be shown to provide 5 log kill or greater before authorised use.

Surface decontamination (e.g. lab / ward benches) is to be conducted with virkon (1% w/v). Emergency spillages will also be treated with virkon to a final concentration of 1% w/v.

Disinfection protocols are being set up and applicable personal protective equipment donned / worn during handling. Training of GM users / workers in the use of disinfection procedures is recorded and refreshed according to local policy.

For activities involving GMMs, describe the waste management measures which will apply to the activity

The attached risk assessment for Class 1 work has been peer reviewed by the QMUL BSO and approved for submission. Future risk assessments and any amendment required to this notification will be peer reviewed by the QMUL BSO and where relevant, the QMUL GM safety committee (as per contractual arrangements noted in section 3).

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Yes

Give brief details of the genetic modification safety committee

As this is the first (and currently only) GMAC2 project at this premise, the GMSC has been constituted specifically for this project. The committee consists of:
- Health and Safety Manager (MSci, CMIOSH), who leads the compliance efforts in this area
- Member of PA's management team, with responsibility for quality and compliance in the group
- 3 members of the project team specialising in microbiology, biomaterials and physics
- Project team lead ('assignment manager') with direct responsibility for safety
- Microbiologist with PhD and BSO training independent from the project
- Independent member (group Head of Operations)

If further GM work is to be undertaken, the GMSC membership will be reviewed and it will be reconstituted as appropriate.

02/03/2022
Liquid wastes will be chemically deactivated using a disinfectant with validated efficacy against the microorganism, typically Virkon. The deactivated waste will then be disposed of via clinical waste. Solid wastes will be sealed in a medibin in the laboratory then incinerated as clinical waste.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Project Additional Information

Purposes of the contained use

Functional testing of prototype designs and the final production system. GMMs only to be used when components/prototypes have been fully tested with surrogate materials.

Recipient or parental organism

Jurkat Clone E6-1 T-cells, or similar non-hazardous T-cell lines [commercially purchased]

Host/vector system

rLV.EF1.ZsGreen1-9, or similar lentiviral vectors encoding non-hazardous proteins [commercially purchased]

Origin & function

GFP marker protein

Evaluation of foreseeable effects

No foreseeable adverse effects in-vivo, however notification reflects the unlikely potential for re-acquisition of capsid genes, in line with the classification of the vector supplier.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid wastes will be chemically deactivated prior to incineration as clinical waste
Solids will be incinerated as clinical waste

The comments of the GMSC have been incorporated into the risk assessment

### Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

- **Yes**

Give brief details of the genetic modification safety committee

GM committee comprises of members of staff at various levels in the company. Head of Research and Development, Head of Laboratory Operations who is the Biological Safety Officer, Senior Scientists.

Other members of the committee have worked with GM material and also have carried out the work in the past with viral vectors. We have a wide range of Knowledge working with biological materials from an academic research environment, industry and the NHS.

The biological safety committee will meet on a 6 monthly basis and will produce a report and send minutes to the main safety committee. This then in turn will be submitted to the board of directors.

Any risk assessments for review prior to committee meeting, a meeting will be set up to discuss.

### For activities involving GMMs, describe the waste management measures which will apply to the activity

All the waste generated will be handled by the Babraham Institute and with accordance to the regulations set out by Babraham Institute, and will seek derogation, however this is an outline:

- **Usual chloride containing disinfectant (e.g. 1% solution of Virkon) or other chemical disinfectant (e.g. Chemgene 2%) overnight, Autoclaving/incineration of contaminated labware or laboratory coats. Effectively 100% inactivation of virus.**
  - Autoclaves regularly serviced, temperature validated and calibrated
- **All disposable culture/labware from the CL2 laboratory decontaminated with 2% Chemgene or 1% Virkon prior to being placed in yellow Eurobin (red lid) before leaving the building for off-site incineration.**
- **All highly contaminated material i.e. all items that have been in contact with viruses (pipettes, tips, culture plates) will be separately decontaminated (2%**
Chemgene. 1% Virkon) before placing in red lid yellow Eurobin.

- Liquid waste capture bottles have 1% Virkon added overnight before autoclaving. This then to be discarded to drain flush with copious amounts of water.
- Small spills will be removed after surface soaking with 2% Chemgene, left to deactivate for at least 10 minutes, followed by further decontamination with 70% ethanol.
- Large accidental spills will be sprinkled with neat Virkon powder before cleaning after 10 minutes.
- Bench and cabinet surfaces will be wiped down with 2% Chemgene and 70% Ethanol.
- Large spill outside of MSCII will be covered up with Virkon powder and the room then evacuated and entry be restricted for 1 hour to allow for 6 air changes to remove any aerosols.
- All GM modified cell cultures will be destroyed (soaking with 1% Virkon overnight and the placed in Red Lid Yellow Eurobin for incineration) or chemically fixed (e.g. 1-4% Formaldehyde, guanidine isothyocianate, RIPA) before leaving containment.

Historical Significant Changes
### Purposes of the contained use

Our main objective is to understand the molecular mechanisms controlling lineage differentiation from pluripotent stem cells in order to develop cells relevant to basic and medical research and applications. The research projects will include transduction of a variety of genes with expected biological effects into mammalian cell lines and primary cells by the means of replication deficient recombinant viral vectors episomal or other DNA plasmids.

Use of recombinant viral vectors, episomal and DNA plasmid vectors to introduce genetic material into mammalian cell lines, including primary and iPSCs. The cells are derived from human tissue expanded outside of the body and also various mammalian species including bovine, porcine and rodent.

Our main objective is to understand the molecular mechanisms controlling lineage differentiation from pluripotent stem cells. The research projects will include transduction of a variety of genes with expected biological effects into mammalian cell lines and primary cells by the means of replication deficient recombinant viral vectors (including lentiviral, Sendai viral vectors) and also episomal and DNA plasmid vectors.

By identifying and understanding fundamental development processes, our projects should allow us to better control in ex vivo differentiation protocols and improve the production of therapeutically relevant cell types, for example neurons, muscle cells and blood platelets.

After the R&D processes the final iPSC lines will be made commercially available for use in research, drug discovery and eventually therapeutically. These cells will be free from viral vectors however they will be genetically modified.

### Recipient or parental organism

- Escherichia coli, K12 derived strains
- Mammalian cells: iPSC (human and other mammals)
- Mammalian cells: Primary Human origin (Skin fibroblasts, blood cells, immortalised cell lines)
- Mammalian cells: Bovine/porcine Primary Inhouse

### Host/vector system

- Vector (1): replication deficient recombinant lentiviral vectors
- Vector (2): Sendai: F temperature sensitive derived vectors. (Cytotune, SeV-hNanog)
Origin & function

- cDNA (Type1 inserts) will code for transcription factors, signal transducers, growth factors and receptors which are expected to play a role in pluripotency, cell fate decision and differentiation from pluripotent stem cells (PSCs).
- shRNA (Type2 inserts) will produce non-coding RNA sequences targeting endogenous mRNA from above mentioned families (Type1 list). Expression of both insert types may enhance/block commitment and differentiation of PSCs towards one of the three primitive germ layers and further differentiated progeny.
- Reporter genes (Type3 inserts) will code for proteins with fluorescent or enzymatic properties allowing easy identification of genetically modified (GM) cells. They are thought to have no deleterious biological effect on expressing cells (for example EGFP, ECFP, EBFZ, EYFP, dTomato, LSSorange, LacZ, Luciferase, possibly fused to cDNA (type1 inserts)).
- Selection genes (Type4 inserts) will produce enzymatic proteins able to inactivate specific antibiotic families allowing selection of GM cells. They are thought to have no deleterious biological effect on expressing cells (for example NPT, PAC, Puro, Neo, Hygro, Blast).
- Functional non-coding sequences (Type5 inserts) will act as promoters of transcription (promoters and enhancers), local chromatin structure modifiers (enhancers and insulators), RNA transcript stabilizers (WPRE) or translation regulators (IRES). They will be used (independently or in combination) into viral expression cassettes to achieve best control of transgene expression depending on targeted cells (for example promoter, enhancer, insulators, IRES, WPRE, of mammalian or viral origin).
- Neutral non-coding sequences (Type6 inserts) will be used in particular for gene targeting projects to promote homologous recombination at defined genomic loci (intrinsic/exonic genomic sequences). They should not have biological effect by themselves.
- Expression cassettes for guide RNA and CAS9 DNA nucleases (Type 7 inserts) variants of the CAS9 system, eg, dCAS9, dCAS9-KRAB

Evaluation of foreseeable effects

TYPE1, cDNA Type1 inserts will code for transcription factors, signal transducers, growth factors and receptors which are expected to play a role in pluripotency, cell fate decision and differentiation from pluripotent stem cells (PSCs). It is difficult to predict in vivo consequences of ectopic expression of all these genes on human health. However, since they are key regulator of cell identity, their overexpression could lead to pathological modifications of cell phenotype/function. Moreover, several of these genes have been involved in oncogenic processes and uncontrolled expression could subsequently initiate tumoral transformation. However, malignancy is a complex multistep process which involves multiple genomic alterations and a single "hit" is unlikely to trigger alone the oncogenic process. Experiments involving co-transduction or even co-expression by the same vector of several inserts should consequently be considered at higher risk for the worker. Notably, reprogramming experiments of somatic cells toward pluripotency (co-transduction with the 4 factors OCT4, SOX2, MYC, KLF4) could imply a specific risk since accidental genetic modification of worker cell could theoretically lead to teratoma formation.

TYPE2, shRNA/miRNA Type2 inserts will produce non-coding RNA sequences able to inhibit protein expression from the group of genes mentioned as Type1 insert. As for Type1 insert, it is difficult to predict in vivo consequences of ectopic expression of these sequences on human health. However, since they target key regulators of cell identity, their expression could lead to pathological modifications of cell phenotype/function. Notably, several miRNA have been implied in oncogenic processes.

TYPE3, reporter gene Type3 inserts will code for proteins with fluorescent or enzymatic properties allowing easy identification of genetically modified (GM) cells. They are thought to have no deleterious biological effect on expressing cells excepted acute toxicity at very high concentration.

TYPE4, selection gene Type4 inserts will code for enzymatic proteins able to inactivate specific antibiotic families allowing selection of GM cells. They are thought to have no pathological effect on expressing cells excepted acute toxicity at very high concentration.

TYPE5, functional non-coding sequence Type5 inserts will act as promoters of transcription (promoters and enhancers), local chromatin structure modifiers (enhancers and insulators), RNA transcript stabilizers (WPRE) or translation regulators (IRES). They will be used (independently or in combination) into the expression cassette to achieve best control of insert expression depending on the targeted cell. No direct pathological effect is expected for these sequences. However, indirect deleterious effects should be considered for promoter and enhancer sequences through retrovirus mediated genomic integration in the host cell and potential insertional mutagenesis. Indeed, strong
promoter/enhancer could lead to ectopic activation of neighbour endogene expression. Moreover, the WPRE sequence has been shown to have oncogenic properties by itself.

TYPE6, neutral non coding sequence Type6 inserts do not have any foreseeable deleterious biological effect. They will be used in particular for gene targeting projects to promote homologous recombination at defined genomic loci.

Type 7 inserts expression cassettes for guideRNA and CAS9 DNA nickase (and variants of the CAS9 system, eg, dCAS9, dCAS9-KRAB). The coded proteins have nuclease or epigenetic remodelling activities which might create DNA double strand breaks and mutagenesis, or impact on cell gene expression profile respectively, possibly leading to biological perturbations.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

The hazardous waste is managed by the Babraham Institute which has a derogation see below. If bit bio operates at a separate site in the future the derogation below will only apply to bit bio facilities located on the Babraham Institute site.

Instead of autoclaving waste in the building we propose to follow the procedure used by the Babraham Institute described in their disposal notification GM 105/4.1 (see also section 6 above for description). Reasons for adopting this method of waste disposal are:

1. We do not have access to an autoclave within our area of the building

2. The waste disposal system used by the Babraham Research Campus is safe and has been running since October 2004. All waste material will be inactivated by treatment with 1 % (w/v) Virkon solution prior to disposal. Waste material will then be placed in sealed bins and incinerated by an off-site incineration company (Vetspeed -Their GM authorization is GM898) according to disposal notification GM105/4.1. Waste from our GM work at Class1 will be placed into suitably labelled hermetically sealable 60 litre UN approved (to Class 3) Type 3H21Y30/S/2003 bins. Sealed bins are placed into secondary 210 litre yellow labelled "Eurobins". Collections by the local registered clinical/GM waste incinerator contractor will be made three times a week to prevent a build-up. The site has 24/7 Security.

The contractor uses solid bodied transport and carries portable disinfection equipment in case of any spillage. Autoclave facilities will be available in an adjacent building, as required by the Regulations, in case of loss of the contractor's facilities. The type of container and the secondary Euro container means that the risk of any spillage of active GM waste on site is negligible. However, as active waste will leave the site, the risk to the environment and health is possibly marginally higher than autoclaving prior to incineration. The only real risk of release would be as a result of a major RTA, however, the containers are designed to withstand this. This disposal method is expected to achieve 100% inactivation of the GMM.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Please see information in section 11 as all the waste generated will be handled by the Babraham Institute and with accordance to the regulations set out by Babraham Institute.

- Usual chloride containing disinfectant (e.g. 1% solution of Virkon) or other chemical disinfectant (e.g. Chemgene 2%) overnight, Autoclaving/incineration of contaminated labware or laboratory coats. Effectively 100% inactivation of virus.

Autoclaves regularly serviced, temperature validated and calibrated
- All disposable culture/labware from the CL2 laboratory decontaminated with 2% Chemgene or 1% Virkon prior to being placed in yellow Eurobin (red lid) before leaving the building for off-site incineration.

- All highly contaminated material i.e. all items that have been in contact with viruses (pipettes, tips, culture plates) will be separately decontaminated (2% Chemgene, 1% Virkon) before placing in red lid yellow Eurobin.

- Liquid waste capture bottles have 1% Virkon added overnight before autoclaving. This then to be discarded to drain flush with copious amounts of water.

- Small spills will be removed after surface soaking with 2% Chemgene, left to deactivate for at least 10 minutes, followed by further decontamination with 70% ethanol.

- Large spills will be sprinkled with neat Virkon powder before cleaning after 10 minutes.

- Bench and cabinet surfaces will be wiped down with 2% Chemgene and 70% Ethanol.

- Large spill outside of MSCII will be covered up with Virkon powder and the room then evacuated and entry be restricted for 1 hour to allow for 6 air changes to remove any aerosols.

- All GM modified cell cultures will be destroyed (soaking with 1% Virkon overnight and the placed in Red Lid Yellow Eurobin for incineration) or chemically fixed (e.g. 1-4% Formaldehyde, guanidine isothiocyanate, RIPA) before leaving containment.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form  

Tick to confirm that you have attached a risk assessment to this form  

Tick if you are claiming exemption from disclosure for section of the risk assessment  

Please enter comments on the GM safety committee on the risk assessment
Q1. How should the tubes be handled before moving to storage? Chemgene and ethanol?

All tubes should be wiped with 2% chemgene before moving in to storage as per RA justification to move out of containment.

Q2. How are the cells generated from vector batches tested for RCR? and how do you know they are free from RCR?

This is carried out by quality testing by transducing Supp-T1 cell lines with 5% of the vector batch, leave to grow for 14 days and monitor P24 levels in supernatant at day 7+14. The P24 levels are detected by ELISA.

Q3. Final handling of GM at containment level 1 or 2 needs to be explained further.

This has now been addressed in the RA by the following statement:

"The final handling of the resultant GM cell line must then revert back to the containment level that the cell line assigned due to and other biological factors, set out in the subsequent biological risk assessment that is summarised in the table on page 19. Therefor if the resultant GM handling can subsequently be moved from CL2 to CL1 and the biological risk assessment has assigned the cell line to containment level 2 then the cell line must be used at the containment level originally designated."

Q4. Justification of removal of material from containment for imaging?

The committee would like this to be reduced to a minimum and that imaging system in the CL2 lab may reduce the risk. This has been addressed in the risk assessment as follows:

Removal form CL2 is to be reduced to minimum, possibly by having imaging systems in CL2 labs. Ideally, this should not happen with culture recently exposed to viral vectors where viral load in medium is still significant. If necessary, additional measures like not opening the secondary container for >5min to protect from any aerosols generated, and ensuring no spills happened during transport should be considered.

An emergency procedure for spillage at CL1 should also be in place.

For activities involving GMMs, describe the waste management measures which will apply to the activity

All biological waste is treated and properly disposed of.
For liquid waste, inactivation is done with Virkon (1% solution stored away from direct sunlight and changed weekly or once colour is lost; if it is not pink, it does not work).
Surfaces and spills can be cleaned with 70% Ethanol.
Appropriately labelled red bins are present in the labs for Autoclave waste and incineration with an external contractor Novus Environmental.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

All biological work is in compliance with the Department of Chemistry and Wren Therapeutics safety instructions.

All contaminated solid waste (plasticware e.g. pipettes, flasks, tubes) inactivate by autoclave using a make safe cycle at 134°C for at least 3 minutes and then collected by Waste contractor for incineration.

All contaminated Liquid waste (e.g. samples, culture supernatants, tissue culture media) inactivated with Virkon to 2% w/v for at least 60 minutes and then discharge to drains.

For the GMO risk assessment all materials are classified as class I, however the laboratories meet the standard for Containment Level 2 due to other laboratory work. All work performed with good laboratory practices and observation of established health and safety local rules for containment and disposal of GMOs.

Tick to confirm that you are attaching a summary of the risk assessment: Yes

Tick if you are claiming exemption from disclosure for sections of the risk assessment: No

### Please enter comments of the GM safety committee on the risk assessment

The Bioescalator GMSC concluded the proposed work present low risk work using commercially available materials and that the use of Containment Level 1 measures would be adequate to reduce the risks to negligible. Therefore the GMSC thought that the proposed work with genetically modified micro-organisms should be classified as Class 1. Further, it was noted the laboratories in the Bioescalator Innovation building exceed the requirements and meet containment level 2.

For activities involving GMMs, describe the waste management measures which will apply to the activity

All contaminated materials, including waste destined for incineration, will be inactivated by onsite autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be calibrated and serviced annually by an approved supplier and each run will be monitored using TST (Time, Steam, and Temperature) test strips (Rodwell, TST class 6 emulating indicator 121°C for 20 min). Autoclaving will be carried out using the autoclave located in the room adjacent to the Microbiology laboratory and all waste will be placed in autoclave bags and sealed before transfer between the two rooms.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

Assessment was reviewed and comments made. The reviewer agreed with the classification of the activity as a Class 1 GMM.

For activities involving GMMs, describe the waste management measures which will apply to the activity

GMM contaminated material and all liquid waste will be deactivated by 5000ppm Presept solution. All solid waste will be autoclaved in the same laboratory as GMM handling. Autoclave designed to operate at 121 °C for 28 minutes, for the sterilization of glassware and consumables used with GMM's. Non-autoclavable materials, and laboratory consumables contaminated with cell culture material, shall be disposed of in a solution of 5000ppm Presept solution and soaked overnight. Presept disinfectant will be made up fresh just prior to use. Waste decontaminated materials should be double bagged in yellow hazardous waste bags and sent for incineration. Appropriate process testing carried out on deactivated material to validate safe waste management.

Give brief details of the genetic modification safety committee

The Mote Research Ltd genetic modification committee will consist of:

1. The biosafety officer who has extensive experience of genetic modification issues, being currently in charge of biosafety for a large research institute. The biosafety officer will chair all genetic modification committee meetings.
2. The Chief Executive Officer has 30+ years experience of genetic modification and previously ran research groups in academia. His function on the committee is to advise and provide the necessary resources for the actions of the committee to be implemented. He will write the minutes of the meetings.
3. Postdoctoral scientist who has >10 years experience of genetic modification in E. coli and mammalian cells. He will provide advice and ensure the actions arising from the committee meetings are implemented.

The committee will meet every 6 months to review biosafety and whenever a new risk assessment is required. The first meeting will review the existing risk assessments.

In addition animal cell culture will be performed using the immortal cell line….

For activities involving GMMs, describe the waste management measures which will apply to the activity

All waste material will be inactivated by treatment with 1 % (w/v) Virkon solution prior to disposal. Waste material will then be placed in sealed bins and incinerated by an off-site incineration company (see derogation application below). Waste from our GM work at Class1 will be placed into suitably labelled hermetically sealable bins. They will be sealed by our staff and removed to a central collection point where they will be placed into 210 litre yellow labelled "Eurobins". Collections for incineration will be made by the local registered clinical/GM waste incinerator contractor. This disposal method is expected to achieve 100% inactivation of the GMM. The data sheets describing inactivation by Virkon are attached.

Tick to confirm that you are attaching a summary of the risk assessment  Y

Project Ref  3520/20.1

Date Ackn'd  02/03/2022  

CU2 Project Title  Class  CultureVolClass2  CultureVolumeClass3-4
The culture and use of mammalian cells believed to harbour Epstein Barr Virus (EBV)

Purposes of the contained use
Part of our work is aimed at selectively killing EBV-containing cells. For this reason, we need to be able to grow such cells so that we can study them.

Recipient or parental organism
The mammalian cell lines include human-derived lines such as Daudi (ATCC® CCL-213), a well-known and widely used B lymphoblast cell line. This cell line is known to harbour EBV.

Host/vector system
In the first instance, we will not be using any viral (replicable) vectors with these cells. Instead, they will be transfected with plasmids not capable of replicating in mammalian cells.

Origin & function
Selectable markers – examples (but not restricted to);
Ampicillin resistance: E. coli derived, and not expected to be expressed in mammalian cells (this is a selectable marker used for preparing plasmids in E. coli).
Green Fluorescent Protein: this is a fluorescent protein, expected to be expressed in mammalian cells, and serving (by fluorescence) to confirm that the plasmid has entered the mammalian cell.

Evaluation of foreseeable effects
The only foreseeable effects arise from the Epstein Barr Virus (EBV) present in this cell line, rather than from any modification or work done on the cell line. EBV is an extremely common virus (approximately 90% of adults worldwide have had EBV) which usually causes no or mild symptoms (fever, fatigue) in adults contracting it for the first time; symptoms normally resolve without treatment. Individuals who have already had EBV are not susceptible.
Given the abundance of the virus in the general population, working with EBV-infected cells does not create a risk to
the wider population.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Instead of autoclaving waste in the building we propose to follow the procedure used by the Babraham Institute described in their disposal notification GM105/4.1 (see also section 6 above for description). Reasons for adopting this method of waste disposal are:

1. We do not have access to an autoclave within our area of the building
2. The waste disposal system used by the Babraham Research Campus is safe and has been running since October 2004.

All waste material will be inactivated by treatment with 1% (w/v) Virkon solution prior to disposal. Waste material will then be placed in sealed bins and incinerated by an off-site incineration company (Vetspeed – Their GM authorization is GM898) according to disposal notification GM105/4.1.

Waste from our GM work at Class2 will be placed into suitably labelled hermetically sealable (red lid to distinguish them from class 1 waste) 60 litre UN approved (to Class 3) Type 3H21Y30/S/2003 bins. Sealed bins are placed into secondary 210 litre yellow labelled "Eurobins". Contents of the bin are recorded and collections by the local registered clinical/GM waste incinerator contractor will be made three times a week to prevent a buildup. The site has 24/7 Security. The contractor uses solid bodied transport and carries portable disinfection equipment in case of any spillage. Autoclave facilities will be available in an adjacent building, as required by the Regulations, in case of loss of the contractor's facilities. The type of container and the secondary Euro container means that the risk of any spillage of active GM waste on site is negligible. However, as active waste will leave the site, the risk to the environment and health is possibly marginally higher than autoclaving prior to incineration. The only real risk of release would be as a result of a major RTA, however, the containers are designed to withstand this.

This disposal method is expected to achieve 100% inactivation of the GMM.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All waste material will be inactivated by treatment with 1% (w/v) Virkon solution prior to disposal. Waste material will then be placed in sealed bins and incinerated by an off-site incineration company (see derogation application above). Waste from our GM work at Class1 will be placed into suitably labelled hermetically sealable bins. They will be sealed by our staff and removed to a central collection point where they will be placed into 210 litre yellow labelled "Eurobins". Collections for incineration will be made by the local registered clinical/GM waste incinerator contractor.

This disposal method is expected to achieve 100% inactivation of the GMM.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
The safety committee was convened on 15 December 2019. The scope and particular aspects of safety risks described in the risk assessment were agreed upon, and satisfactory consensus was achieved regarding the adequacy of the SOPs, COPs and risk management planning protocols. Pending notification and acknowledgement by relevant authorities, the risk assessment and related work activities were deemed suitable.

Y

Give brief details of the genetic modification safety committee

Lecturer and Principle Investigator and at the Centre for Synthetic Biology, Imperial College London with more than 10 years of lab experience working with genetically modified organisms. He heads a lab group composed of 15 scientists where he is responsible for the genetically modified organisms and conducts a thorough risk assessment for their use every year. Collectively his experience allows him to understand the risks to both human health and the environment arising from the proposed contained use activity and should any uncertainty arise from the activity, he has sufficient experience to be able to judge the adequacy of the risk assessment and the controls that are being put in place and have recourse to external expertise if required. As CorNatural is based in the Imperial I-Hub, access to advice from the Imperial College GM committee (HSE reference GM31) is permitted if required.

For activities involving GMMs, describe the waste management measures which will apply to the activity

For Liquid waste - Virkon is added to 1% final solution. Incubated for 20 minutes for E coli cultures and 30 minutes for yeast.
For Solid waste - Dispose of solid waste in the autoclave bins provided. The bins will be changed when 3/4 full. The bag will be gathered at the top, sealed loosely to allow steam penetration, and placed in a plastic box before transportation to the autoclave facility. The autoclave is calibrated and then validated annually by a UKAS accredited service engineer with a worst case representative waste load to check that it achieves 121 degrees for 15 minutes throughout the chamber during a waste cycle.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

During the development of the risk assessment, the following recommendations were made, which were subsequently implemented:

2.14. - Mention the boundaries of the work - That we will not introduce any genes that would make the host organisms pathogenic, alter their host / environmental range, increase their ability to survive in the environment or in any other way make them more harmful to human health or the environment than the original host organisms.

2.18 - Add that no frontline therapeutic antibiotics will be used.

7.1 - Solid waste. Also state that the autoclave is calibrated and then validated annually by a UKAS accredited service engineer with a worst case representative waste load to check that it achieves 121 degrees for 15 minutes throughout the chamber during a waste cycle.

7.6 - Elaborate on proper disposal and how waste is dealt with.

Besides this no further comments agreed GM Class 1.

Solid waste contaminated with GM Class 1 material will be segregated from other non-GMO waste generated in the laboratory.

Class 1 GMO waste will be sealed in autoclavable waste bags and inactivated by autoclaving at 134degC and 15 psi for 15 minutes; after which the solid waste will be placed in clinical waste bins.

Liquid waste will be inactivated by the addition of sodium hypochlorite to a final concentration of 1% and minimum contact time of 1 hour (resulting in a six order-of-magnitude reduction in cell viability), after which the deactivated waste will be placed in clinical waste bins.

Sealed clinical waste bins will be collected by a licenced waste carrier.

Please enter comments of the GM safety committee on the risk assessment

Bacterial strains have been administered to human volunteers and were well tolerated (Hindle et al. 2002 Inf Imm. Vol. 70-7 pg 3457–3467; Tennant & Levine 2015 Vaccine C36-C41; Hien et al. 2010 Plos One 5: e11778; Darton et al. 2016 Plos NTD 10: e0004926) and severely immunocompromised adults chronically infected with hepatitis B virus (He 2007, Trends Biopharma Ind 3: 40-45). These direct evidences in humans enable these mutants to be classified as GM Class 1.

Give brief details of the genetic modification safety committee

There is a genetic modification safety committee in place with 4 members comprised of the COO, Laboratory Manager, the department head and a member of the laboratory staff. They meet quarterly to discuss the use and containment of GMs within the lab. The committee members collectively have significant experience in microbiology, cell biology and virology, including but not limited to the proper handling, storage and disposal of GMMs and associated materials. All risk assessments are reviewed to ensure they are up to date along with ensuring personnel training is up to date for the safe handling of GMs within the lab.

Liquid decontamination - once the GMs have been used and are no longer required, they are decontaminated in 1 %
virkon for 60 minutes as per manufacturers instructions and flushed down the sink along with excess cold water.
Waste Procedure - the contaminated labware is placed in an orange ridged sided box so it cannot pierce through and
is sent to our waste management firm for disposal. Contaminated personal protective equipment is placed into
orange clinical bags for pick up by the same waste management firm.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

The Genetic Modification Safety Committee have> 25 years combined experience handling various GMOs, up to
biosafety category 3, and have written risk assessments on each of these organisms.

Date Ackn’d
CU2 Project Title
07/08/2020
Genetically modified mammalian cells for drug discovery research
Class CultureVol
Class2 CultureVolume
Consent Granted
Non-GMM < 1 Litre

Project notified under transitional arrangements
### Purposes of the contained use

The purpose is to generate, maintain and characterise stably transfected or CRISPR-engineered mammalian cells that express proteins of interest to our drug discovery work. Additional work may involve the knockdown of proteins of interest using shRNA. These all include proteins that are directly relevant to therapeutic development as well as those that would be considered tool proteins required for specific experiments.

### Recipient or parental organism

Genetic modifications will be carried out on frequently used immortalised mammalian cell-lines relevant to drug discovery and specific therapeutic indications. This will include cell-lines derived from myeloid cells, colorectal, lung, pancreas, prostate, liver, and breast cancers, and the HEK293T cell-line. In some cases, these cell-lines will have already undergone genetic modification by a commercial supplier using the CRISPR/Cas9, and then procured prior to subsequent in-house modification of the form discussed in this document. Infected cells will be selected for using culture medium supplemented with appropriate antibiotics (such as neomycin, puromycin, hygromycin or blasticidin).

### Host/vector system

Lentiviral particles carrying cDNA or shRNA constructs will be procured from commercial suppliers (e.g. SMARTvector Lentiviral Non-targeting control shRNA, Horizon VSC7078) and the obtained lentiviral vectors are self-inactivating, making them replication deficient. When procurement is not possible, a Trans-Lentiviral ORF Packaging System from Dharmacon will be utilised, according to manufacturer guidelines. This is a multicomponent, 4th generation system that minimises the possibility of producing replication competent viruses. In this system, constructs of interest will be cloned into commonly used lentiviral vectors (i.e. pLenti7), which will then be transfected alongside plasmids encoding lentiviral packaging genes, representing 4th generation technology. As a safety precaution, viral packaging components are separated onto five plasmids and expression of gag-pro and tat-rev are under the control of the conditional tetracycline-responsive promoter element (TRE), limiting expression of these viral components strictly to cells expressing the tetracycline transactivator. The HEK293T cell-line will be used for viral packaging.

### Origin & function

The genetic material will be cDNA constructs (designed either for gene expression or shRNA-mediated gene silencing) encoding a number of human genes. These genes are well studied and characterised, with information on them available in the public domain. These genes will typically be either relevant to clinical disease (i.e. oncogenes) or significant to our specific drug discovery work. In some cases, commercially available, proprietary cDNA constructs from Promega's NanoLuc system will be used.
These constructs are originally from the shrimp Oplophorus gracilirostris but have since undergone significant modification by Promega. Such genetic material will, once introduced into immortalised cell-lines, act as ‘tool proteins’ and aid in our drug discovery work.

### Evaluation of foreseeable effects

The introduction of gene-expressing cDNA or gene-silencing shRNA constructs is not expected to cause any hazards to human health. These modifications could change the phenotype of the modified cell, potentially turning a normal cell into a cancerous one. However, these modifications are being made in already immortalised mammalian cells predominantly derived from cancers. These cell-lines are, by default, not capable of colonising healthy individuals nor are the genetic modifications likely to change this.

Cells modified using Lentiviral transfection are not expected to release infectious viral particles. Commercially sourced Lentiviral vectors will be acquired in a replication deficient state. Lentivirus vectors produced in-house will have been prepared using a commercially used 4th generation packaging system which encodes the required helper, structural and scaffolding genes into 5 separate pTLA1 plasmids lacking homology with the pLenti7 vector. This system also places the necessary gag-pro and tat-rev genes under tetracycline control (preventing expression in cells lacking the tetracycline transactivator gene). This packaging system has been tested for virus production with negative results.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable for this project

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

M8 - There is an autoclave available in the same building, but does not possess sufficient capabilities to meet our waste output. Contaminated labware and PPE is placed in yellow ridged sided boxes or orange clinical bags so it cannot pierce through for pick up by and off-site incineration by our waste management firm.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid decontamination - once the GMs have been used and are no longer required, they are decontaminated in 2% virkon for 60 minutes as per manufacturers instructions and discarded into liquid waste.

Waste Procedure - the contaminated labware is placed in a yellow ridged sided box so it cannot pierce through and is sent to our waste supplier for disposal. Contaminated personal protective equipment is placed into orange clinical bags for pick up by the same waste management firm.

### Is an emergency plan required according to regulation 20?

Please enter comments on the GM safety committee on the risk assessment
The Genetic Modification Safety Committee have > 25 years combined experience handling various GMs, up to biosafety category 3, and have written risk assessments on a large variety of organisms.

The risk assessments are prepared by proposers according to HSE and SACGM guidelines. Together with the appropriate GM Notification/assessment form, the proposals are then circulated to all members of the GMSC who return their comments to the proposers for their response and possible amendment of the proposals or risk assessments. The final submissions are discussed by the GMSC members and the required containment level is agreed.

For the proposal herein, agree to Class 2, Containment Level 2. Notifiable to the HSE.

For activities involving GMMs, describe the waste management measures which will apply to the activity

- Media & broths - 1/50 or 2 % concentration of approved disinfectant (Distel/Chemgene) to media/broth with a contact time of 60 minutes, then disposal down laboratory sink.

- Plastics, agar plates and cell pellets - deposit in clinical waste bins which are double bagged prior to sterilisation by autoclave using discard program (130 °C for 10 minutes).

- Tips & sharps - Deposit in yellow sharps bins, then sterilise in autoclave using discard program (130 °C for 10 minutes).

- Serological pipettes - Deposit in 'Biobins', then sterilise in autoclave using discard program (130 °C for 10 minutes).

- Flasks and glassware - 1/50 or 2 % concentration of approved disinfectant (Distel/Chemgene) to empty flasks, contact time of 60 minutes, then sterilise in autoclave.
using equipment programme (121 °C for 15 minutes).

Autoclave: Automated built in jacketed vacuum autoclave (Astell ASB300) for use by Oncimmune staff (following training & SOP) in Oncimmune service laboratory. Two cycles (discard & equipment) will be validated prior to use (externally by installation engineers using thermocouple) to determine degree of kill >5 log. Programmes will also be re-validated annually. Autoclave will also be serviced annually. Each run will be verified (print out record stored) to ensure each cycle has met the required criteria for successful sterilisation of each load. All loads will then be transported off site for incineration (service provider to be confirmed).

Disinfectant: Distel or chemgene will be used to inactivate GMMs and DNA/RNA from media/liquid, glassware and spillages. The disinfectant concentrations quoted are at or higher than the recommended concentration by the manufacturer/supplier of both disinfectants to result in 5 log reduction/ degree of kill in the timescales quoted. The websites below detail the studies carried out to determine contact times but none have not been verified in house, this is deemed to be acceptable considering the low containment level (s) of the GMMs used.

distel-high-level-disinfectant_PF-SL-154479.html?gclid=Cj0KCQiA89vzBRDoARtASOlPgEy19_GbHUE8e9_6LAL92pzejwzNvmMckjDa2KB462z8r2cHkfcaAjyyEALw_wcB#tab=downloads

Give brief details of the genetic modification safety committee

The GMSC for Adaptate Biotherapeutics Ltd was established in January 2020 and consists of the following committee members:
- Company Chief Scientific Officer responsible for Research and Development at Adaptate Biotherapeutics who has a degree and PhD in Biological Sciences followed by over 15 years of experience leading R&D activities in companies.
- Company Scientist & lab manager who has a degree in biological sciences, has received training in biosafety and Health and Safety and has 5 years experience in initiating and maintaining start-up company health and safety programmes.
- An external Safety Advisor who is laboratory based and a chartered member of the Institution of Occupational Safety and Health (over 12 years). They are a member of a University GMSC.

Level 1 (GMMs)  
Level 2 (GMMs)  
Level 3 (GMMs)  
Level 4 (GMMs)  
Non-microbial
For activities involving GMMs, describe the waste management measures which will apply to the activity

- Any surface/equipment which is known or thought to be contaminated with GMOs will be disinfected using 2% Chemgene spray solution. A contact time of at least 5 minutes is required. After contact time, any residue is wiped away using absorbent tissue, which is then disposed of via clinical waste bags. Liquid wastes are to be inactivated by adding Chemgene to a final concentration of 5% (contact time in solution of at least 2 hours). After contact time, liquid wastes are disposed of via a designated laboratory sink, flushing with plenty of water.
- At a concentration of 5%, Chemgene solution has a greater than 4 log degree of kill on a range of bacterial, fungal and viral strains.
- Consumables or re-usable equipment (e.g. forceps, spatulas) contaminated with GMO waste will be autoclaved with a holding time of 15 minutes at 121 degrees celsius. The autoclave is 12-point thermocouple and load tested annually. Inactivated bagged waste will be transported inside a sealed wheelie bin designated for use of clinical waste only. The autoclave is present in the GammaDelta Therapeutics (HSE Centre GM Number 3363) facility which directly adjoins the Adaptate Biotherapeutics laboratory on the same corridor.
- Untreated waste is stored securely until autoclaved by GammaDelta staff under a contract with Adaptate Biotherapeutics.
- After waste is autoclaved by Adaptate staff it is sent for incineration at a site certified to deal with clinical waste.

Tick to confirm that you are attaching a summary of the risk assessment  
Y

Tick if you are claiming exemption from disclosure for sections of the risk assessment  

Please enter comments of the GM safety committee on the risk assessment
With regards to the associated risk assessment:

The GMSC requested clarification on:

2.1- Additional information on downstream processes
2.2- Remove use of other cell lines
2.8 – Risk to environment
3.1c – Antibiotics and cell lines
4.1 – When aerosols are generated
4.3 & 4.4 – Waste and disinfection procedures

Also – in section 4.6 to add the UN number that GMOs will be transported under.

Further clarification was provided and the risk assessment was amended appropriately. The GMSC had no further comments.

Give brief details of the genetic modification safety committee

Endocrin has received advice from a chartered member of the Institute of Occupational Safety and Health and the Institute of Safety in Technology and Research, with significant in-depth knowledge of Health and Safety systems which are relevant to working at high biological containment. This member currently has experience serving with the Biosafety Steering Group of the ISTR.

The chartered member's experience has been gained and developed over 20 years and includes periods of time spent as Head of Health and Safety at the Institute for Animal Health, Head of Risk & Assurance and Biological Safety Officer at The Pirbright Institute and as a Specialist Inspector within the Biological Agents Unit of the Health and Safety Executive. The member has also worked with BBSRC supporting all of their Institutes.

Prior to this the member worked at the Health Protection Agency (HPA), Porton Down, initially as a scientist working predominately at Containment Level 3 (CL3) then as a Safety Advisor where the member took the role of Biological Safety Officer (BSO) and was responsible for the Research Division which included the high containment animal facility and the TSE, CL3 and CL4 facilities.

For activities involving GMMs, describe the waste management measures which will apply to the activity

All waste material will be inactivated in a decontamination autoclave, which has previously been validated (outsourced, independent validation) for each material load. We will maintain the waste loading to the maximum validation set point (e.g., validation of 5 L, will see no more than 5 L of material autoclaved at one time). Solid waste will be routinely separated from liquid waste and both will be autoclaved separately before being disposed of. We will treat all waste whether solid or liquid, as a potential biohazard. Once autoclaved it will be considered non-hazardous and disposed of as offensive waste, however, to ensure IP protection and uphold company reputation, an external contractor will be consulted to dispose of it through incineration. Chemical waste (e.g., acids, metals) will be neutralised, if possible, according to the COSHH assessment, and then disposed of via an external chemical waste contractor or as specified in the chemical’s COSHH. We will write into the lab policy/code of conduct that no liquid waste will disposed of into any sink, compliance will be mandatory for all workers. For routine cleaning and inactivation of microorganisms we will use a sporicidal (e.g., Klercide or similar) chemical to disinfect work areas before and after experimentation and an appraisal in the way of a report, on the efficacy of this sporicide (complete killing of a highly dense culture representative of any routine fermentations, 0 0 600 >200) will be conducted on all Endocryne strains. To test sterilisation, killing and other sterility checks, we will routinely assess the growth of cultures (plating, turbidity checks) prior and post-inactivation to confirm decontamination has been successfully performed.

Tick to confirm that you are attaching a summary of the risk assessment

Give brief details of the genetic modification safety committee

Guidance has been taken from a Safety Consultant working for a major London academic institution specifically experienced in the use of GMOs. In addition, a Genetic Modification Safety Committee has been formed for Quell Therapeutics Limited consisting of the Biological Safety Officer, VP Product Delivery, Office Representative and Scientific Lab Representative (note that the GMSC also acts as the internal Health and Safety Committee). The Committee will meet four times per year (as a minimum) to review the work of Quell Therapeutics. This will include periodic review of the GM risk assessment. Ad hoc meetings will be scheduled should more frequent risk assessment updates be required.

All members of the Committee have significant experience in the field of GM research with the exception of the Office Representative who acts as the lay person.

For activities involving GMMs, describe the waste management measures which will apply to the activity

No waste treatment is required but live cells will be inactivated with 1% Virkon and all solid waste will be disposed of as clinical waste (yellow bags) in line with standard lab practice. Clinical waste bags will be stored/transported in designated leak proof containers and be collected by the approved clinical waste contractor appointed by the building landlord, Imperial College London ThinkSpace.

Waste Management Plan

WASTE DISPOSAL Waste disposal procedures were specified for all work carried out in the ONI laboratory in the lab safety policy (which can be provided on request)

Biological waste
Any waste containing or exposed to biological materials, such as microorganisms and tissue culture, will be treated with procedures that are appropriate to their containment level prior to disposal.

Procedures planned to follow
Autoclaving (121°C, 13psi and 30 minutes duration), or a one-hour soaking in Decon 90. Using Vikron solutions to clean up the work benches which are used for blood products and body fluid samples Using Chemgene to disinfect tissue culture area 70% ethanol for general disinfection

Waste containers
Yellow bins Chemically contaminated, hazardous solid wastes will be disposed in clinical waste bins provided by our approved waste management service providers

Blue bins
Empty solvent bottles are discarded after evaporating the residual substances in fume hood overnight. Large broken glass bottles can also be discarded in the blue bins

Sharp bins
Glass slides, Needles, Coverslips, etc. will be discarded in these bins

General waste bins
Non-hazardous, household waste

Recycling bins
Recycling bins will be kept away from the lab work area and will be categorised as plastic waste, electrical waste and cardboard recycling waste

Refill racks recycling
Designated for recycling pipette tips refill racks

Jerry cans
Three different Jerry cans will be kept for disposing:
Non halogenated solvents
Halogenated solvents
Aqueous waste

Jerry cans will be stored in the fume hood

For activities involving GMMs, describe the waste management measures which will apply to the activity

### Project Additional Information

#### Purposes of the contained use
All the GMOs, tissue samples, cell lines and body fluids are used exclusively for research purpose only. There are no clinical trials, animal studies or sales from the R&D department.

#### Recipient or parental organism
The GMO which will be used at ONI Ltd, is only a low risk source of any infection. This strain of E. Coli is not a pathogen, and was developed for laboratory cloning use. This strain was developed by D. Hanahan as a cloning strain with multiple mutations that enable high-efficiency transformations. The mutations that the DH5-Alpha strain has are: dlacZ Delta M15 Delta(lacZYA-argF) U169 recA1 endA1 hsdR17(rK-mK+) supE44 thi-1 gyrA96 relA 1. These mutations correspond to the distinct characteristics that make the DH5-Alpha strain excel in laboratory cloning procedures.

lacZ Delta M15 mutation: Allows for blue-white screening for recombinant cells.
endA 1 mutation: Allows for lower endonuclease degradation which ensures higher plasmid transfer rates.
recA 1 mutation: reduces homologous recombination for a more stable insert.

**Host/vector system**

- **GMO**: Escherichia coli - DH5 alpha competent cells
- **Body fluids**:
  - Cerebrospinal fluid (CSF) - These are samples of neurological origin which may contain disease forming prion proteins
  - Saliva
  - Blood and blood products - Risk of viral infections
  - Human tissue samples - Samples have high chance of containing blood and therefore is considered infectious for the risk of HIV, HBV, HCV and other smaller group of viruses such as HTLV1 and paravirus B19
- **Commercially purchased cell lines from ATCC**:
  - Jurkat: Source - Human Cell type - T lymphocytes
  - HaCAT: Source - Human Cell Type - Keratinocytes
  - HEK Cells: Source - Human Cell Type - Kidney cells
  - Risk - Contains adenoviral DNA sequences
  - COS-7 Cells: Source - Monkey Cell Type - Kidney cells
  - Risk - Contains SV40 viral sequences
  - 3T3 Cells: Source - Mouse Cell Type - Fibroblast
  - N2ACells Source - Mouse Cell Type - Neuroblastoma
  - Exosomes - will be purchased from Fujifilm COL021
  - Mesenchymal placental exosomes in saline - will be purchased from Kimera
  - From academic collaborators CT26 - colorectal tumour samples from mouse and human

**Origin & function**

Research purposes only.

**Evaluation of foreseeable effects**

- Risk of HIV, HBV, HCB, and other viruses from bodily fluids and tissue samples.
- Exposure to blood-borne pathogens.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

No large GMOs are used.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

- High-level disinfectants such as Chemgene and Virkon will be used to clean the work benches and other surfaces/equipment that has come into contact with possibly infectious agents.
- Appropriate sodium hypochlorite bleach (Clorox) and hydrogen peroxide (Virox) solutions will be used to kill bloodborne pathogens.
- All bodily fluid will be dispose in a biohazard bag and sterilised prior to disposal in a chemical wast bin, collected by our hazardous materials collection service provided, Grundon.

Give brief details of the genetic modification safety committee

The Biological Safety Committee of Virology Research Services Ltd (VRS) is comprised of the company Directors, Health & Safety and Facilities Manager and other staff members. Most committee members have post-graduate degrees in a biological sciences discipline (virology, molecular cell biology and imaging sciences), and each has over a decade of experience of working with human pathogens and genetically modified microorganisms in containment level 1- 3 facilities. Furthermore, in their previous employment at University College London and King's College London, committee members were active participants in matters of health and safety, particularly those pertaining to biological and GM safety, training, compiling risk assessments, and writing codes of practice and standard operating procedures.

02/03/2022
For inactivation of Class 1 GMMs we will use an aqueous solution containing 10% Distel high level laboratory disinfectant for equipment, surfaces, solid and liquid waste.

All solid waste items that have been in contact with GMMs will be soaked overnight in 10% Distel. Solid waste will be placed into a rigid clinical waste container and sent for incineration. For this purpose we use Stericycle Waste Management.

For liquid waste Distel will be added to containers before use, such that the final volume will result in a 10% solution of disinfectant. When containers are 2/3 full they will be sealed and left overnight to ensure inactivation of GMMs. Waste will then be poured down a general waste sink and flushed with copious amounts of water.

Using the parental MDCK cell line, we have previously shown that 1 hour incubation in a solution of 10% Distel renders all cells non-viable by Trypan Blue exclusion. We will confirm this with MDCK-SIAT1 cells after we receive authorisation for GM work from the HSE.

**For activities involving GMMs, describe the waste management measures which will apply to the activity**

Representatives of Virology Research Services Ltd, Biological Safety Committee are satisfied that the attached risk assessment "Use of MDCK SIAT1 Cells for Producing Human Influenza Viruses" and the work proposed therein comply with the provisions of The Genetically Modified Organisms (Contained Use) Regulations 2014, and that notification should be given to the Health and Safety Executive. Work must not commence until receipt of notification is acknowledged.

Furthermore, we are satisfied with the information provided in the risk assessment and agree that it is suitable and sufficient for the proposed work.

Give brief details of the genetic modification safety committee

The University of Nottingham Health Service (UNHS) Genetic Modification Safety Committee has been formed as part of the process for initiating a study to determine the efficacy, safety and immunogenicity of a candidate COVID-19 vaccine in healthy adult volunteers. The inaugural meeting was held on May 4th 2020. The initial remit of the committee was to review the risk assessment of the GMM-based trial vaccine, and going forward, is to review risk assessments relating to any additional GMMs which may be used at the premises. Membership of the committee, which is chaired by the organisation's Research Lead, includes, amongst others, a Consultant Microbiologist, the Senior Nurse Manager, a general practitioner representative and a trial nurse representative. A PhD-level qualified, laboratory-based, external advisor with 20+ years of practical GMO and University Safety Committee membership experience also provided external expert review and attended the UNHS GMSC. Further committee meetings are to be held on an annual basis (or more frequently, if required). Reporting arrangements are to the Chief Operating Officer with copy to UNHS Safety Committee for information.

The GMM is incapable of surviving outside a host cell and is susceptible to common disinfectants. All surfaces to be disinfected with Clinell single-use spill wipes (which generate peracetic acid once wet) to disinfect non-soiled surfaces/small spills, and large spillages using Haz-tab granules/solution (granules to soak up the spill and tablets which when dissolved provide chlorine solution to clean the area; manufacturers validation >5 log10 reduction). Spillages will be reported as per local SOPs. All solid GMO waste will be collected and stored in designated leak-proof containers and autoclaved as specified in BS2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes; 100% kill), prior to incineration by validated means through a licensed waste contractor (Sharpsmart Ltd). Backup autoclave facilities are available onsite at the University of Nottingham, if required.

Please enter comments of the GM safety committee on the risk assessment

The UNHS GMSC met to review the submitted GM risk assessment (and related SOPs) at their meeting on 04 May 2020. It was noted that the GMM had been previously assessed and classified as Class I by a GMSC at the GMM manufacturers.

After recommending that the GMM be transported from the storage freezer to clinical areas in a sealed rigid container to ensure that, in the unlikely event of being dropped, the GMM would be contained, category 1 work involving the GMM on the premises was approved.

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities: Y

Give brief details of the genetic modification safety committee:

- The London Vision Clinic has appointed an internal designated GMO individual to advise management on contained use activities and provide approval for the risk assessments which are of GM Class 1 risk level as permitted under the contained use regulations. The GMO individual holds a BSc in Biomedical Sciences and previous experience in cell and molecular biology. The genetic modification safety committee (GMSC) comprises of this designated GMO individual, a staff nurse and a member of clinic management, and meets on an ad hoc basis to review all risk assessments and conducts its activities under the terms of reference drawn up according to the contained use regulations. The GMO individual and GMSC have received additional training and advice from external providers.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Solid GM Class 1 non-sharp waste directly placed into eco-lock bins for uplift and offsite high temperature incineration (900 deg C) by an authorised upper-tier clinical waste contractor (currently Medisort; incinerator location CliniPower, Avonmouth, Bristol).

Sharps waste is deposited directly into sharpsafe bins, sealed and uplifted for offsite high temperature incineration by the same clinical waste contractor/incinerator. High temperature incineration achieves 100% kill of the GMM.

Liquid waste (or as necessary, solid waste) on site is disinfected by Klericide CR Sterile Biocide E which is an effective disinfectant shown to have broad spectrum virucidal activity. Liquid waste will then be disposed with copious tap water down designated sluice/lab sinks, in line with the local Water Authority effluent permit conditions.

Any new disinfectant to be used will be shown to provide effectiveness against GMM before authorised use.

Surface decontamination (e.g. lab/ward benches on site) is to be conducted with Klericide CR Sterile Biocide E.

Emergency spillages will also be treated with Klericide CR Sterile Biocide E.

Disinfection protocols are being set up and applicable personal protective equipment donned/worn during handling.

Training of GM users/workers in the use of disinfection procedures is recorded and refreshed according to local policy.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

GMSC felt there was minimal risk to human health or the environment and recommended that the material is classified as GM class 1
GM Centre Number: 3537

There will be three routes of disposal. All organisms will either be:
1. Autoclaved using a standard laboratory autoclave with recording to confirm sterilisation conditions, and disposed of via normal waste
2. Liquid cultures will be exposed to bleach overnight and washed down the sink
3. Disposed of via a clinical waste route.

This risk assessment is essentially identical to that approved by the Durham University Health and GMO committee.

For activities involving GMMs, describe the waste management measures which will apply to the activity

**Page 14820 of 15326**
**Project Additional Information**

**Purposes of the contained use**

Examples include, but are not limited to use of GM lab strains of Pseudomonas aeruginosa, E.coli and other bacteria to investigate biofilm formation and infection in C. elegans. GM bacteria carrying fluorescent markers will be used to monitor the formation of biofilm during infection of C. elegans as an alternative to cell or mammal based assays.

**Recipient or parental organism**

Pseudomonas aeruginosa is an aerobic, class 2 bacterium. Escherichia coli will include class 1 or class 2 strains.

**Host/vector system**

The bacteria is modified by transforming with plasmids for the expression of GFP or RFP (fluorescent proteins) under bacterial promoters. These plasmids are derived from commonly used plasmids and sequences and also confer resistance to an antibiotic such as kanamycin or ampicillin.

**Origin & function**

**Evaluation of foreseeable effects**

Genetic modification of the bacteria will not increase risk. The bacteria will express fluorescent proteins so they can be imaged under a fluorescent microscope.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

C. elegans are kept in agar plates or liquid media. If they manage to crawl out of their containers they are quickly killed by desiccation. All animals not killed in experiments will be killed by autoclaving or by soaking overnight in bleach or through a clinical waste route.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

There will be three routes of disposal. All organisms will either be:
1. Autoclaved using a standard laboratory autoclave with recording to confirm sterilisation conditions, and disposed of via normal waste
2. Liquid cultures will be exposed to bleach overnight and washed down the sink
3. Disposed of via a clinical waste route.

**Y**

**Give brief details of the genetic modification safety committee**

Advice was obtained from an external biological safety officer (BSO) with >10 years experience of managing the health and safety of several academic groups actively involved in the genetic modification of micro-organisms, and the preparation of risk assessments for such processes in a university setting. The RA was prepared, with help from the external BSO, by the company BSO, who has >15 years post-doctoral practical experience of the genetic modification of micro-organisms up to CL2, including writing GM risk assessments for such work.

Tick if confidential |
Solid biological waste is sequestered from waste of non-biological origin, by placing into biohazard labelled yellow autoclave bags. Bags are folded in such a way as to allow steam to enter during autoclaving. Solid waste is then sterilised by autoclaving (20 minutes at 121°C), using an autoclave sited within the laboratory. This cycle is expected to result in essentially complete kill of the types of microbe cultured in the laboratory (E. coli DH5α and BL21(DE3)). The sterilised waste is then collected for incineration by an approved contractor. Autoclave function will be tested monthly by including a glass vial containing E. coli DH5α cells at a concentration of 10^8 CFU/ml in a representative sterilisation run, and streaking the suspension after the autoclaving cycle is complete on an LB agar plate. If any colonies grow on the test plate, the autoclave should be repaired and the run repeated before waste is sent for disposal.

Liquid waste is inactivated within the vessel in which the organisms were cultured or their waste products collected, by treatment with Distel disinfectant at a final concentration of 1% for at least 12 hours before disposal to drain with copious water flushing. This treatment is expected to result in at least a 5-log reduction in viable E. coli within 5 minutes, according to the manufacturer’s information.

Tick to confirm that you are attaching a summary of the risk assessment  Y

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The external advisor's comments were as follows:
The risk assessment is adequate for the planned activities, which are appropriately classified as class 1 contained use. The outlined containment measures are also appropriate to the level of risk. However, the risk assessment could benefit from further clarification with respect to the following items:
• Include further information with respect to the rationale for the assumption that E. coli expressing the proteins of interest will not be more likely to cause infection than the unmodified cloning strain
• Give an estimate of the expected efficiency of sterilisation of the E. coli cloning strains by the disinfectant to be used for liquid waste
• Indicate the maximum culture volumes
• Provide a list of target genes to be cloned

02/03/2022
All cell lines and primary cells will be deactivated in 2% virkon for 20 minutes, such that all GMOs will be destroyed, before disposal in wastewater. It is expected that this will kill 99.98% (as per the manufacturer's validation) of mammalian cells. Testing can be done by measuring remaining viable cells by trypan blue exclusion assay after virkon treatment.

All plastic ware will be autoclaved in a BS 2646, Part 3, 1993 (either 121-125°C for a minimum of 15 minutes, or 126-130°C for a minimum of 10 minutes, or 130-136°C for a minimum of 3 minutes). Excess liquids will be discharged to the drains, solid wastes will be disposed of via the clinical waste stream for incineration/disposal. Any sharps used will be disposed of via clinical waste stream for incineration. Autoclave and incineration will deliver a degree of killing of 100%.

The University of Oxford, Innovation Buildings Biological safety committee was pleased to approve our risk assessments with no modifications.

The University of Oxford, Innovation Buildings Biological safety committee was pleased to approve our risk assessments with no modifications.
Purposes of the contained use

The risk assessments to human health and the environment show that the genetic material to be generated during this project has a relatively low risk, warranting using containment level 2.
The final GM activity class is containment level 2.

Recipient or parental organism

GMO will be standard cancer model cell lines (available from the ATCC) that have been genetically modified to overexpress specific natural receptors of interest. Working in vitro, typically cells will include human and murine cancer cell lines (e.g., human breast cancer cell lines such as MB-MDA-268 or human colorectal cancer cell lines such as HT29, HCT116 or murine colorectal CT26 and MC38 cell lines).

Host/vector system

We will use transfection reagents, such as lipofectamine, or electroporation to generate GM target cell lines

Origin & function

Transgenes to be expressed include:

• Reporter genes: Photinus (firefly) and renilla luciferase, Beta-galactosidase, Secreted Alkaline Phosphatase, Chloramphenicol acetyltransferase, fluorescent proteins from marine organisms (CFP, EGFP and YFP). These naturally fluorescent proteins emit light when excited by high-intensity light of specific wavelengths. Several variants of natural genes have been produced that encode a protein with modified adsorption/emission characteristics and which have been optimised for higher level expression, e.g., the “EGFP”. GFPs are widely used and no hazardous properties have been reported. Other proteins have been isolated from other organisms, however, each of these proteins has no cellular toxicity in normal cells, otherwise, they would not function as a successful reporter gene. Luciferase from Firefly and Sea Pansy are widely used as reporter genes and not considered to have harmful properties. No hazardous effects are anticipated because all the parent proteins are without harmful properties.

• Mammalian selectable markers: Hygromycin resistance, Puromycin resistance, Zeomycin resistance, Neomycin resistance, Blasticidin resistance, and Geneticin resistance. Never shall any vector contain more than one of these markers. They do not function in bacteria. The promoter of the mammalian antibiotic resistance or selectable marker is recognised by the mammalian RNA polymerase and allows transcription of the gene of the mammalian antibiotic
resistance or selectable marker in mammalian cells.

Evaluation of foreseeable effects

As above, typically cells (as described above) will be transduced using the procedures described in the attached risk assessment. The transduced cells will be selected by treatment with puromycin, sorted by flow cytometry or subject to at least three media changes and used as a mixed preparation of transduced and untransduced cells.

Transgenes and their potential risks

Transgenes will include only reporter genes, naturally occurring human receptors (such as PD-1, CTLA4, TIGIT, LAG-3, or TIM3) receptor, and/or selectable markers. No other proteins will be encoded, for example there will be no toxins, super-antigens or oncogenes.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

We will use full containment class 2, with no derogation.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

<table>
<thead>
<tr>
<th>The containment and control measure that will be applied for work with the genetically modified cell lines and the infectious vector preparations are shown on Tables 1. Give brief details of the genetic modification safety committee

Exonate has established a local genetic modification safety committee who have reviewed and approved this notification and GM risk assessment. The committee is comprised of a Senior Scientist with expertise in GM work in Universities and Exonate, a Principal Scientist with experience in reviewing risk assessments in Universities and Exonate and a Professor with extensive expertise in risk assessments relating to genetically modified organisms who is Head of Department and Director of a Research Centre at the University of Nottingham.

Laboratory | Animal Unit | Growth Room | Glass House | Large Scale |

- Transgenic Animals: Yes
- Transgenic Fish: Yes
- Gene Therapy: Yes

Tick if confidential

02/03/2022
All cultures and infected liquids will be sterilised by incubation in 1% Distel for at least 2 hours and disposed of through designated sinks. Validated data supplied by the manufacturer indicates that this will result in inactivation of all organisms Exonate uses in class 1 activities.

Contaminated glassware and solid waste, including plastics, tubes, pipettes, agar plates will be decontaminated by the addition of 1% Distel (final concentration) and incubated at room temperature for 2 hour. This will give 100% kill. Objects which are likely to puncture the bags will be placed in a BioBin or similar container. The inactivated waste will be stored in a sealed and labelled wheele bin with biohazard symbols displayed until removal by a registered waste contractor (Stericycle) for incineration.

Work surfaces will be wiped down with 70% ethanol after use.

Sharps material is not required, and it will be avoided.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Tick to confirm that you are attaching a summary of the risk assessment Y

Tick if you are claiming exemption from disclosure for sections of the risk assessment Y

Exonate were working in University GM approved laboratories and have recently moved to new laboratories at MediCity. The new labs meet all criteria for containment level 2 but will initially be used for class 1 activities upon acknowledgement of this premises notification followed by class 2 activities upon notification and approval from HSE. The risk assessment for the initial class 1 activities meets our approval for containment of low risk activities.
Project Additional Information

Purposes of the contained use

The GMM originated in this project will be used in R&D and small molecules screening for kinase inhibitors discovery and development.

Recipient or parental organism

Primary RPE cells, iPS-derived RPE cells, RPE cell line (ARPE19), embryonic kidney cell line (HEK-293T) and other immortalized or cancer cell lines detailed in section 17. The recipient for plasmids transformation and amplification will be E. coli DH5alpha.

Host/vector system

Vector system: mammalian expressing plasmids (chemical transfection and nucleofection), transduction of replication-defective lentivirus, Nucleofection of ribonucleoprotein complex. More detailed information in following section.

Origin & function

1. For knock-in modifications
For integration of the tags sequences in the genome, cells will be nucleofected with Cas9 protein and gRNA ribonucleoproteins (RNP) purchased from Sigma or ThermoScientific and the HDR (homology directed repair) donor plasmid with homology arms and tag coding sequences (in vitro synthesised by GeneScript). HDR-plasmids are pUC-based vectors and are non-mobilisable. They contain bacterial origin of replication and selection gene for ampicillin resistance. They do not contain markers of mammalian selection. As donor template for small knock-ins or point-mutations, single-stranded oligo DNA nucleotides will be used instead of plasmid.

2. For knock-out modifications
Knock-out cell lines will be generated by chemical transfection of dual-vector plasmids based on commercially available construct pSpCas9(BB)-2A-Puro (PX459). These are non-mobilisable plasmids that express both Cas9 endonuclease and guide RNA (gRNA) sequences targeting SRSF1, "Target X (detailed in section 17)" or SRPK1 genes and the antibiotic selection markers ampicillin and puromycin.pSpCas9(BB)-2A-Puro (PX459) plasmid was purchased from GeneScript and gRNA were cloned in house.

Mammalian expressing plasmids (detailed in Section 17) are develop by the Custom Assay Services team within Promega. The vectors are non-mobilisable. They contain bacterial origin of replication and bacterial selection genes such as Kanamycin and Chloramphenicol resistance. They also contain markers of mammalian selection such as Neomycin and Blasticidin resistance. Transfection of mammalian cells will be accomplished using chemical reagents or by nucleofection. None of the mammalian vector systems can be used to generate viruses.

02/03/2022
4. For shRNA mediated knock-down
Mammalian cells will be infected with shRNA Lentiviral Transduction Particles targeting SRPK1, Target X or SRSF1. Commercially available self-inactivating recombinant lentiviral vectors with enhanced biosafety will be used.

**Evaluation of foreseeable effects**

1. Overview of the different types of GMM that will be constructed (detailed list in section 17).
   - Knock-in Stable Cell Lines (by CRISPR)
     Stable cell line expressing tagged-SRPK1 + tagged-SRSF1 OR tagged-TargetX + tagged-SRSF1.
     Cells: HEK-293T, ARPE19 and others (section 17).
   - Knock-out Stable Cell Lines (by CRISPR)
     Modification: SRPK1 or “Target X” or SRSF1 knock-out.
     Cells: HEK-293T, ARPE19, and others (Section 17).
   - Kinase-dead mutant cell lines (by CRISPR)
     Modification: kinase-dead point mutations in catalytic domain of SRPK1 or “Target X”.
     Cells: HEK-293T, ARPE19, and others (Section 17).
   - Knock-down cell lines (by shRNA-lentiviral infection)
     Modification: SRPK1, “Target X” or SRSF1 shRNA.
     Cells: HEK-293T, ARPE19, primary RPE cells, iPS-derived RPE cells and others (section 17).
   - Human cells transiently transfected with tagged SRPK1, SRSF1, “Target X”
     Cells: ARPE19, HEK-293T, primary RPE cells and iPS-RPE cells.
   - Human cells stably expressing transfected tagged SRPK1, SRSF1, “Target X”
     Cells: (section 17).
   - E. coli DH5α cells transformed with plasmids for amplification and cryopreservation

2. Function of inserted sequences and knock-out genes (complete list in Section 17)
   - SRPK1
     Serine–arginine protein kinase 1 phosphorylates proteins containing serine–arginine rich (SR) domains which are involved in the regulation of several mRNA processing pathways, including alternative splicing.
   - SRSF1
     Serine/Arginine Splicing Factor 1 regulates key aspects of mRNA metabolism, such as mRNA splicing, stability, and translation, as well as other mRNA-independent processes, such as miRNA processing, protein sumoylation, and the nucleolar-stress response. SRSF1 is a proto-oncogene that appears to exert its tumorigenic effects via a number of mechanisms, particularly alternative pre-mRNA splicing (8).
   - Cas9 endonuclease
     Guided by a guide RNA, the Cas9 endonuclease breaks DNA at a target sequence. Imprecise repair of the double strand break can result in insertion or deletion mutations, while repair pathways can be engineered to introduce specific point mutations or insertions.

3. Nature of the risks
The work involves the genetic modification of human cell lines, primary cell cultures and bacteria, manipulation of naked DNA encoding CRISPR machinery components, the handling of Cas9 purified protein complexed with gRNA and overexpression of proteins with oncogenic properties. Therefore, risk assessment for human health and
environment is necessary.

4. Risk assessment for human health

4.1 Mechanisms by which the GMM might pose a hazard to health

4.1.1 What are the hazards associated with the vectors?

- shRNA Lentiviral Transduction Particles targeting SRPK1, Target X (Section 17) or SRSF1. Commercial viral particles developed by 3rd-generation of lentiviral vector system (Sigma MISSION®) will be purchased. Particles are replication-incompetent and deletion in the U3 portion of the 3' LTR eliminates the promoter-enhancer region, further negating the possibility of viral replication and they lack of virulence genes which are not necessary for shRNA packaging. These features combined have improved biosafety and handling. Nevertheless and, though there are no known incidents of third generation systems producing replication competent virus, it is advisable to handle replication-incompetent lentiviral particles as Risk Group-Level 2.

Lentiviruses are generally transmitted via exposure to contaminated material or percutaneous inoculation and generally not transmitted via the airbone route. Therefore, accidental piercing of the skin or other surface tissues with virus containing objects represents the main potential route by which accidental infection could occur. Appropriate risk reduction measures will be implemented to reduce the likelihood of this occurring.

DNA Plasmids

Dual Cas9-gRNA plasmids. The vectors are non-mobilisable and are unable to generate viral particles. Cas9 and gRNA will not be expressed in bacteria as they are under regulation of a eukaryotic promoter.

Mammalian expression vectors. The vectors are non-mobilisable and are unable to generate viral particles. "Target X", SRSF1 and SRPK1 will not be expressed in bacteria as they are under regulation of a eukaryotic promoter.

Antibiotic resistance markers expressed in E. coli: These cassettes have been widely utilised for research purposes and these antibiotics are not used for treatment of natural infections by the recipient organisms. Besides, they will be expressed only transitory during the amplification of the plasmids, rather than in the final GMO product and it does not constitute any risk to human or animal health.

4.1.2 What are the hazards associated with the recipient cells?

- Primary human RPE cells developed in house. Human ocular (choroid/iris/retina) endothelial cells will be isolated from posterior segments. Despite donor tissues being submitted to stringent health screens for transplant suitability and negative for Hepatitis B and VIH, this organism would be considered class II due to the potential risk of infection.

- iPS-RPE. Retinal Pigment Epithelial cells developed from human induced pluripotent stem cells purchased to Phenocell. This product should be treated as potentially infectious and only used in biological safety level 2 premises and conditions.

- HEK-293T cell line is classified as ACDP Hazard Group 2 because it was originally initiated by the transformation and culturing of normal HEK-293 cells with sheared adenovirus 5 DNA. A portion of human adenovirus 5, nucleotides 1-4344, is integrated into chromosome 19 but they do not contain the complete viral genome and therefore, the risk of generation of these viruses by these cells is extremely low. However, the possibility that wild-type virus might recombine and mobilize these viral genes into infective particles can't be excluded. HEK-293T cells also contain Simian Virus 40 large T antigen (SV40LT).

- Immortalized cell line detailed in section 17. The cells were immortalized by transduction with human papilloma virus 16 (HPV-16) E6/E7 genes and contain papilloma viral DNA sequences, therefore it will be considered as biosafety level 2.

- All the other cells mention in section 17 except one, are well characterized human cells and do not represent any hazard to human health or the environment and are categorised as Biosafety level 1:

  - E. coli DH5 alpha cells are avirulent and considered to be ACDP biological agents hazard group 1 because they have an established record of safety in the laboratory with no adverse effects on human, animal or plant health or the environment. Furthermore E. coli DH5alpha is incapable of survival outside the laboratory.

4.1.3 What hazards are associated with the inserted genetic material or genetic modifications?

Knock-ins: The genetic insertions generated by HDR are stable in the genome and plasmid maintenance is not required. Knock-ins tags are not pathogenic and have no direct effect on cellular processes. The resistance markers encoded in the backbone of the HDR-donor will not be permanently integrated in the genome, as no selection will be used. While the risk of random integration of fragments of the plasmids in the genome of the human cell lines is very low, this cannot be completely excluded. SRPK1, "Target X" and SRSF1 Knock-out/knock-down: Depletion or nonsense mutations in SRSF1, "Target X" and SRPK1 are unlikely to induce oncogenic transformation or pathogenicity of the cell lines, or to suppose a risk for the worker. Nevertheless, SRSF1 is classified as proto-oncogene(8) and Wang et al. (9) report that SRPK1 can function as both an oncogene and a tumour suppressor in mouse embryonic fibroblasts. "Target X" can act as a tumour suppressor or its amplification can contribute to carcinogenesis depending on cellular context(10). The greatest risk would be associated with accidental infection of someone during handling of the shRNA viral particles.
and therefore, viral particles will be handled at containment level 2. Also, Cas9-mediated editing can generate coding mutations with undescribed phenotype but cells carrying those mutations won’t be amplified or stored.

4.4 What hazards are associated with the mutations in SRPK1, "Target X" and SRSF1 genes?

Whilst the risks of the knock-ins generating a transformed phenotype seem very low, this cannot be completely excluded as the effect of tagging these proteins to SRPK1, "Target X" and SRSF1 has never been investigated. SRSF1 is a proto-oncogene and both, oncogenic and tumour-suppressor characteristics have been attributed to SRPK1 and "Target X". Therefore, even though tumorigenesis is a multistep process, genetic modification of these genes could induce transformation of the cell lines. However, with the precautions in place and the use of Class II Microbiological safety cabinet, the GM cell lines will not present a hazard for humans.

4.5 What hazards are associated with the stable overexpression of SRPK1, "Target X" and SRSF1 in human cell lines?

SRPK1 is a proto-oncogene and both, oncogenic and tumour-suppressor characteristics have been attributed to SRPK1 and "Target X". While development of a cancer is acknowledged to be a multistep process requiring a number of genetic lesions to generate a malignant tumorigenic cell, expression of some genes can allow proliferation or confer an extended life span upon primary cells. This may predispose a cell to accumulating oncogenic lesions and might be one step nearer to forming a cancer. For this reason, all the primary cells used in this study will be handled as class 2 organisms after being stably transfected with SRPK1, "Target X" or SRSF1 expressing vectors. The stable overexpression of oncoproteins in already cancerous cell lines is not expected to significantly increase its safety characteristics, however class 2 safety guides are advisable to handle these cells.

4.6 What hazards are associated with the potential off-targets effects?

There is the potential of off-target DNA double strand breaks following transduction with Cas9 and gRNA, which could potentially alter the cell phenotype, however the reported incidence of this is extremely low. This will be minimised by careful gRNA selection with as little sequence homology as possible to off-target genes. This risk is lower when transfecting Cas9-gRNA RNP complex instead of plasmids because Cas9-gRNA RNP complex is rapidly cleared from the cell, minimizing the chance of off-target cleavage events.

Similarly, shRNA potential off targets will be minimised by careful design with as little sequence homology as possible to off-target genes, including BLAST searches against genome databases.

4.7 Likelihood of genetic transfer to other GMM or organisms

Gene transfer is possible as the commercial lentiviral vector will be able to infect a wide range of animal cells, including human cells. However, after transduction and integration into genomic DNA of the target cells, gene transfer possibility is insignificant due to the viruses being replication defective.

4.2 Containment level needed to sufficiently protect human health

HEK-293T, iPS-RPE and the cell line immortalized with HPV (Section 17) require biosafety level 2. CRISPR-Cas9 resulting modifications could have the effect of deletion, repression or upregulation on the target gene. This could potentially alter the cell phenotype, for instance increasing the ability to survive or proliferate. There is also the potential of off-target DNA double strand breaks, however the reported incidence of this is extremely low. Biosafety level 2 containment is also advisable when working with or handling any lentiviral vector particles and when stably expressing proto-oncogenes in human cells. Consequently, appropriate containment level 2 control measures will be used to minimize exposure.

Hazard evaluation of the activities and measures to follow are summarized in Table 1 in the attached risk assessment.

4.3 Likelihood that the GMM will be a risk to human health and safety

With all the precautions in place and following good laboratory practices the likelihood that the GMM will be a risk to human health and safety is close to negligible for the following reasons:

The CRISPR-Cas9 plasmids, E. coli cells and all the human cells used in this project except HEK-293T, are not able to infect humans or survive in the environment. HEK-293T cells do not contain the complete adenoviral genome and therefore, the risk of generation of these viruses by these cells is extremely low. HEK-293T cells have been widely used in research labs during years and to the best of our knowledge, no infections have been described in humans. Following proper microbiological techniques will avoid wild-type virus to infect HEK-293T cells, recombine and mobilize their viral genes into infective particles.

Third generation lentiviral particles are self-inactivating recombinant lentiviral vectors with enhanced biosafety. The greatest risk would be associated with accidental infection of staff during handling of the shRNA viral particles and therefore, viral particles will be handled at containment level 2.

5. Risk assessment for the environment

5.1 Likelihood that the GMM will be a risk to the environment

Risk associated with these activities to the environment is deemed low. First, the cells will not be cultured on a large scale, there will be no risk of any large spillages.
Consequently, it is highly unlikely that either cells or viruses would be released into the environment. In the unlikely event of escape, neither the GMM nor the lentivirus are capable of surviving outside of the laboratory environment since they require supplementation with growth factors and specific temperature and atmospheric conditions. The virus does not replicate so will not amplify in the cells. Secondly, neither the DNA, encoded proteins, bacterial or mammalian transfectants are likely to have any deleterious effect on the environment.

5.2 Containment level needed to protect the environment
Containment level 1 is sufficient to prevent release and protect the environment. A higher level of containment has been assigned to protect human health, but the environmental risk is essentially effectively zero.

6. Review procedures and control measures
Human infection/colonisation by cultured cells is mitigated by the use of microbiological safety cabinets class II, secondary containment during transport, and appropriate centrifuge spill/leak protocols. Proper microbiological techniques will be used so as not to contaminate HEK-293T and HK-2 cells with wild-type virus that might recombine and mobilize their viral genes into infective particles. Handling of lentiviral particles must be done in Class 2 cabinets and sharps/glass will not be used in the procedure. Environmental exposure of all GMMs will be limited. Any waste generated must be inactivated by validated disinfection before being sent for incineration.
A more detail review of the procedures and measures implemented can be found in Table 1 in the attached risk assessment.

6.1 Record staff training
End user will be required to read, understand and sign the SOPs involved in this activity, the risk assessments related with the reagents, assays and genetic modifications involved and Exonate's Code of Practice for work with Biological Agents and Genetically Modified Micro-Organisms.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All cultures and infected liquids will be sterilised by incubation in 1% Distel for at least 2 hours before disposed of through designated sinks. Validated data supplied by the manufacturer indites that this will result in inactivation of all organisms used or generated in this project. Contaminated glassware and solid waste, including plastics, tubes, pipettes, agar plates will be submerge in 1% Distel (final concentration) and incubated at room temperature for 2 hours. This will give 100% kill. Objects which are likely to puncture the bags will be placed in a BioBin or similar container. The inactivated waste will be stored in a sealed and labeled wheeble bin with biohazard symbols displayed until removal by a registered waste contractor (Stericycle) for incineration. When Distel is not suitable for inactivation, for instance for the decontamination of agar plates, contaminated items will be autoclaved. Exonate has access to an autoclave on site, where items will be transported to in labeled and sealed bags. Spillages will be immediately absorbed into paper towels soaked in undiluted Distel, surface wiped down with Distel 1%. The use of 70% ethanol is not recommended for spill clean-up due to evaporation. As the cells will not be cultured on a large scale, there will be no risk of any large spills. Work surfaces will be wiped down pre and post carrying out GMO work use using 70% ethanol or 1% Distel, except when working with lentiviral particles, in which case ethanol should not be used to avoid evaporation. Sharps material is not required and must be avoided during GMO work.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  Y
Exonate were working in University GM approved laboratories and have recently moved to new laboratories at MediCity. The new labs meet all criteria for containment level 2 and we have already notified the premises to carry class 1 activities and are waiting for the confirmation letter and HSE reference number. We are submitting now an application to additionally execute class 2 activities. The risk assessment for this class 2 activity meets our approval for containment of medium risk activities.

Y

Give brief details of the genetic modification safety committee

The person performing the risk assessments is a senior scientist within the organisation, who has used GMMs during their PhD and two post-doctoral positions. This individual has written previous risk assessments for Class 1 GMM work for internal approval at a previous employer, and was the post-doctoral representative on a GMO safety committee at a previous employer. This individual has worked as a post-doctoral scientist in derogated Category 3 conditions with genetically modified organisms covered by a SAPO license at a previous employer.

Yes
All liquid waste will be treated with an appropriate disinfectant (CHEMGENE HLD4L; final dilution of 1:100, Virkon; final concentration of 1%, or equivalent). This will be left at room temperature for a minimum of 2 hours to ensure full deactivation of the GMMs. Deactivated liquid waste can then be disposed of down the sink with plenty of water. Solid waste will be autoclaved (121°C, 20 minutes) in an autoclavable biohazard bag. This is then subsequently bagged in black bin liners and sent to landfill. The autoclave is serviced annually, but the success of each run is monitored by integrated sensors, and TST (time, steam and temperature) test strips. Spillages can be safely contained within the laboratory and treated with either concentrated CHEMGENE HLD4L or 70% ethanol. These will be mopped with blue roll, placed in autoclave bags and then deactivated as contaminated waste, as detailed above.

For activities involving GMMs, describe the waste management measures which will apply to the activity

All waste potentially contaminated with GM material will be autoclaved at 126°C for 10 minutes using the biodiscovery institute (formerly centre for biomolecular sciences) building system. Autoclaves are validated and serviced and each run cycle data is recorded and analysed. Autoclave servicing is performed 6-monthly, inspections occur annually. Laboratory surfaces and equipment will be cleaned and disinfected using for instance 2% distel of 1% virkon.

Tick to confirm that you are attaching a summary of the risk assessment  

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

All of the bacteria intended to be modified are considered ACDP HG1.

Manchester Institute of Biotechnology Safety and Risk Manager and assistant biological safety advisor.

02/03/2022
All contaminated biological waste will be fully inactivated (sterilised) prior to disposal through standard drainage systems. Sterilisation will be performed by either on site autoclaving or chemical treatment (1% Virkon).

The fermenter will have 100% liquid external containment capability in the case of a spillage or leak. Gaseous emissions will be filtered (0.2 um) to eliminate the risk of accidental GMM aerosol exposure to the air. Equipment that has been in contact with GMMs will be sanitised by treatment with 1% Virkon and/or dairy hypochlorite. Confirmation of effective sterilisation/sanitisation will be performed by periodic test swabbing the laboratory equipment and culturing on GMM-specific agar plates.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Give brief details of the genetic modification safety committee

BiologIC is currently a small startup so has a BSO on the executive committee rather than a full GM safety committee. The BSO has 15+ years hands on experience in the handling of GMOs and infectious diseases, and has headed up commercial laboratories up to BSL3 including with safety and biosecurity remit.

All waste is treated to ensure 100% kill prior to disposal. For class 1 activities, the primary inactivation is by disinfectant as per the suppliers instructions e.g. Virkon. All contaminated materials that cannot be suitably disinfected will be inactivated by autoclaving (100% kill) at 121°C or 134°C prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Each run will be monitored using chemical indicators e.g. steam sterilisation indicator tape.

Class 1 GM waste will be separated from non-GM waste and inactivated on site by means of autoclave sterilisation (i.e., 134°C for 30 minutes), then sent off site for incineration. A record of autoclave run reports will be kept as proof of effective sterilisation. Autoclaves are regularly maintained by the Estate Department of Cardiff and Vale University Health Board and serviced by a third party company.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Purposes of the contained use

Chimeric Antigen Receptor (CAR) -T cells are engineered T cells that specifically express a T cell receptor to a defined antigen, allowing for the activation of the cells by this target antigen. Engineering of Treg in this manner has implications in the treatment of autoimmune and inflammatory indications. The lentiviral and retroviral vectors provided by the client for this project will allow the generation of test CAR-T regulatory cells (Treg) that target MOG antigen. The activity of these T cells will then be verified in vitro (human cells) or in vivo (murine cells).

Recipient or parental organism

Each virus stock solution contains a pure recombinant, replication-defective lentivirus/retrovirus population. Virus constructs contain a chimeric antigen receptor to enable T cells to recognise a specified antigen (constructs outlined in attached RA).

Host/vector system

Host cells will be purified murine or human T cells. These cells have a regulatory phenotype, therefore any inadvertent exposure or entry of these cells into a human or other vertebrate should not instigate any aberrant immune responses. Lentivirus and retrovirus constructs are well characterised vectors that enable insertion of genetic material into host cell genomes. Third generation construct vectors are not considered harmful as they are replication incompetent.

Origin & function

The inserted gene product is not in itself harmful and encodes T cell receptors that can recognise a peptide sequence within MOG protein. T cell receptors are ordinarily expressed on T cells and therefore, no adverse biological activity should be present. Activation of the receptor in the model T cells would require exposure to the specific antigen.
Evaluation of foreseeable effects

Sequence will be stably transduced into target cells and so there should be no risk of sequence being transferred from transduced CAR-T cells. Supernatants from transduced T cells, and any excess viral vector solutions, will be inactivated (by addition to Virkon) prior to disposal and so there should be no further risk of accidental transfer of sequence. Each virus stock solution is a replication-defective, well characterised vector and so is unlikely to cause any harm to human health. The chimeric antigen receptor that will be inserted into the host T cells is specific for protein expressed within the central nervous system which is not normally visible to the mammalian immune system (due to the blood brain barrier). Therefore, even if lab workers were accidentally exposed to these transduced T cells, these would provide no harm to human health in immunocompetent people (with an intact blood brain barrier). Murine CAR-T cells generated in this project will provide no additional risk to human health. In terms of oncogenic potential, the vectors used in this study pose no additional harm over standard vectors. Pregnant women, new mothers and/or immunocompromised employees must not handle class 2 lentiviral and retroviral vectors.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste from sample processing will be disinfected with 2% Virkon for at least 15 minutes before disposal to the drain with copious volumes of water. All potentially contaminated solid materials will be inactivated by autoclaving prior to disposal of waste. This will include any material used for handling leakages, spills or breakages. Project Ref 3547/20.2

Date Ackn'd: 23/07/2020

CU2 Project Title: Handling live genetically modified Mycobacterium bovis

Class: Class 2

CultureVolClass2: < 1 Litre

Consent Granted

Withdrawn: N

Tick if notifying a connected programme of work: N

Historical Significant Changes

Project notified under transitional arrangements: N

Project Additional Information

Purposes of the contained use:

Genetically modified mycobacterium will be supplied by the client: VPM1002BC is a live genetically modified Mycobacterium bovis (M. bovis) BCG strain, generated in order to direct mycobacterial
antigens to the major histocompatibility complex (MHC) class I pathway. The project will utilise cancer
cell lines and PBMC to understand whether genetically modified material can alter the immune
responses and directed killing of cancer cells by BCG-activated PBMC.

Recipient or parental organism

VPM1002BC is a genetically modified version of BCG-medac, that has been
categorised by the suppliers as biological substance risk group 1. Nonmodified
BCG-medac belongs to biological substance risk group 2, which
can lead to disease in humans and pose a danger to employees. Both
substances will be handled with the same precautions, making the overall
activity class 2.

Host/vector system

Client will provide stably modified VPM1002BC (and control BCG-medac).
No genetic modification will take place within Concept Life Sciences, just
stimulation of primary (human) cells in vitro with these mycobacterium
preparations.

Origin & function

VPM1002BC is a live, attenuated BCG strain that has been modified in order
to direct mycobacterial antigens to the major histocompatibility complex
(MHC) class I pathway. This should provide no additional risk to human
health.

Evaluation of foreseeable effects

The genetic modification of BCG-medac to produce VPM1002BC reduces its
pathogenicity by improving any resultant immune response upon accidental
exposure.
Exposure to VPM1002BC and BCG-medac can lead to disease in humans
and pose a danger to employees. If the following precautions are followed by
trained personnel, then risk to human health is low:
• Persons handling BCG-medac and VPM1002BC must use BSCs and
should additionally wear gloves and lab coats. This will protect users from
any hazard posed by the mycobacterium and ensure sterility of cellular
samples is maintained.
• After work, all waste and surfaces must be disinfected with Virkon solution
(or a similar suitable disinfectant).
• After completion of work, PPE must be removed and hands thoroughly
cleaned before users leave the laboratory area.
Pregnant women, new mothers and/or immunocompromised employees
must not handle VPM1002BC or BCG-Medac product.

Project Ref 3547/20.3

Date Ackn’d CU2 Project Title Class CultureVolClass2 CultureVolumeClass3-4

02/03/2022
Transduction of cell lines using genetically modified adenovirus

Replication deficient adenoviruses will be used to transduce human urinary bladder transitional cell papilloma RT4 cells. The project will use these transduced cells and HLA-1 matched PBMCs to understand IFN alpha expression can increase tumour antigen-specific T cell responses using a series of in vitro cell based assays.

VQAd EMPTY-eGFP is a recombinant adenovirus type 5 encoding eGFP.
VQAd hIFNa2.GFP is a recombinant adenovirus type 5 encoding human IFNa2 and eGFP.

Host cells will be RT4 cells which are Biosafety level 1.

Adenoviridae are non-enveloped, icosahedral virions, 75-80 nm diameter, doubled stranded, linear DNA genome. The recombinant viruses are based on human adenoviral backbone (dl309) which is deleted in the essential E1 gene as well as the E3 gene. The viruses produced are replication deficient. Vectors were produced by ViraQuest, Inc. Both vectors have tested negative for E1 detection and RCA titre.

Both vectors contain GFP expressing gene while one of the vectors also contains an IFNa expressing gene. IFNa is involved in the innate immune
response to viral infections. As IFNα is immunomodulatory, exposure to the recombinant adenovirus expressing IFNα could result in an immune response. Danger can be caused by penetration through injured or unprotected softened skin, spraying over the eye and mucous membranes and/or swallowing.

Each virus stock solution is a replication-defective, well characterised vector and so is unlikely to cause a large infection risk. However, the risk from infection by defective recombinant adenoviral vectors depends both on the dose of virus and on the nature of the transgene. Infection can vary in clinical manifestation and severity; symptoms can include fever, rhinitis, pharyngitis, cough and conjunctivitis. Adenovirus does not integrate into the host cell genome but can produce a strong immune response.

Purposes of the contained use

Genetically modified lentivirus, retrovirus or adenovirus will be supplied by our clients and will be used to transduce human or rodent cells. These will either be primary cells (from healthy human donors or WT animals) or stable cell lines. Engineering of cells in this manner has implications in the treatment of autoimmune and inflammatory indications and will allow us to use a range of in vitro assays to further elucidate the function of the molecules being targeted by our clients in health, and in disease.

Recipient or parental organism
Each virus stock solution will be provided by our clients and will contain a pure recombinant, replication-defective lentivirus, retrovirus or adenovirus population.

### Host/vector system

Host cells will be purified primary human (isolated from PBMCs from healthy blood donors), or rodent (isolated ex vivo from wild-type mice or rats) immune cells; or established cell lines. These cells are not considered harmful and therefore any inadvertent exposure or entry of these cells into a human, or other vertebrate, should not instigate any aberrant immune responses.

### Origin & function

Each virus stock solution will be provided by our clients and will contain a pure recombinant, replication-defective lentivirus, retrovirus or adenovirus population. The inserted gene product will not in itself be harmful and will not include allergens, oncogenes or cytokines.

### Evaluation of foreseeable effects

Sequence will be stably transduced into target cells and so there should be no risk of sequence being transferred from transduced cells. Supernatants from transduced cells, and any excess viral vector solutions, will be inactivated (by addition to Virkon) prior to disposal and so there should be no further risk of accidental transfer of sequence. Each virus stock solution is a replication-defective, well characterised vector and so is unlikely to cause any harm to human health. In terms of oncogenic potential, the vectors used in these studies pose no additional harm over standard vectors.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste from sample processing will be disinfected with 2% Virkon for at least 15 minutes before disposal to the drain with copious volumes of water. All potentially contaminated solid materials will be inactivated by autoclaving prior to disposal of waste. This will include any material used for handling leakages, spills or breakages. Autoclaves will be validated by annual (at least) thermocouple mapping and each run will be monitored by continuous chart or digital recording of the temperature / time profile. Surfaces will disinfected with 1% Virkon spray after use, and tissue discarded into autoclave waste. Spillages will be absorbed onto paper towels and disposed of after autoclaving. The area will then be
disinfected with 1% Virkon as above.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Project Ref 3547/21.2

Handling genetically modified Herpes Simplex Virus-1 (HSV-1)

Date Ackn'd 04/03/2021

Date Project Ceased 04/03/2021

Class 2

< 1 Litre

Non-GMM Consent Granted
Purposes of the contained use

Genetically modified Herpes Simplex Virus-1 (HSV-1 - KGα2 -4 E6-B hKt) will be supplied by the client. The virus is an IL13Rα2-targeted oncolytic virus (OV) with eGFP. This virus will be used to infect A375 and A549 cell lines, investigating the effect of this construct upon immunogenic cell death in vitro.

Recipient or parental organism

An IL13Rα2-targeted oncolytic virus expressing eGFP will be provided by our client.

Host/vector system

Host cells will be established A375 and A549 human cell lines (class 1). These cells are not considered harmful and therefore any inadvertent exposure or entry of these cells into a human, or other vertebrate, should not instigate any aberrant immune responses.

Herpes simplex virus-1 (HSV-1) belongs to the sub family Alphaherpesviridae in the family Herpesviridae, genus Simplexvirus. It is 120-300 nm in diameter and consist of a linear, double stranded DNA genome (152 Kb) enclosed within an icosahedral capsid, surrounded by a phospholipid rich envelope.

Origin & function

The GM HSV-1 used in this project (HSV-1 - KGα2 -4 E6-B hKt) has genetically modified glycoproteins gD, gB, and gK. The mode of infection, and transmission capabilities, are considered to be more limited than that of wild-type HSV-1.

gD is essential for HSV-1 entry into cells. Amino acid 2 to 24 of gD are deleted and a point mutation Y38C is introduced to eliminate its ability to bind to its natural receptors HVEM and nectin-1. A single-chain variable fragment (scFv) targeting a human cancer-testis antigen IL13Rα2 is inserted into the deletion region of gD. These gD modifications enable the GM HSV-1 to enter only cells actively expressing human IL13Rα2.
Two point mutations (D285N, A549T; refers to as NT mutations) are introduced in gB to enhance the entry of the GM HSV-1 into target cells. Syncytial mutations (point mutations R858H in gB and A40T in gK; refers to as BhKt mutations) are introduced to confer hyperfusogenicity to the GM HSV-1, resulting in enhancement of the cytopathic effect in IL13Ra2-positive cells.

The coding sequence for enhanced green fluorescent protein (eGFP) under the CMV promoter is inserted between UL3 and UL4 genes. eGFP has no known hazards and is not a dangerous substance according to GHS classification.

Evaluation of foreseeable effects

Infection with WT HSV-1 can lead to Herpes labialis/ cold sores; Herpetic whitlow; infections of the eye and encephalitis in children and adolescents. The GM HSV-1 used in this project (HSV-1 - KGNα2 -4 E6-B hKt) has genetically modified glycoproteins gD, gB, and gK. The mode of infection, and transmission capabilities, are considered to be more limited than that of wild-type HSV-1.

NT and BhKt mutations may enhance the virulence of the GM HSV-1; however, this effect is limited to infection of IL13Ra2-positive cells. Considering that virus entry and replication of the GM HSV-1 are strictly limited to cells expressing IL13Ra2, which is known as a cancer-testis antigen and is not expressed in normal tissues except for the testis, the potential for harm to human health is considered low.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Yes

Give brief details of the genetic modification safety committee

Site has a safety committee structure. Departmental reviews take place. This activity will form part of the existing governance overview. Regular vaccine task force meetings have been taking place between Wokhardt, AstraZeneca and Oxford's Jenner Institute, where collaboration has taken place, including discussion of health and safety matters, e.g the risk assessment was developed using data from the Jenner Institute at Oxford University.

**PREMISES IS NOT USED FOR GENETIC MODIFICATION - Storage of substance only.**
The potential to generate waste would result only as a consequence of a spill. This outcome has been assessed as being highly unlikely due to the method of packaging of the substance (an article), The substance itself is defined in the SDS as not being hazardous in terms of exposure. The safety data sheet advises that the adenovirus vector has no risk of pathogenicity and virulence in the case of occupational exposure. It is not classified as being harmful to the environment. Wockhardt has procedures to deal with spills for hazardous substances and materials (HSOP-029-2874) and waste disposal (ENV-007-04-1857). These procedures would allow for any risk of contamination that could potentially render the substance to become hazardous to be safely managed- the risk assessment for the defined activities also identifies that such a scenario is also highly unlikely. Hazardous, non-hazardous and clinical waste is disposed of via approved licensed contractors.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Inactivation of GMMs in waste and subsequent disposal:
Plasticware, gloves and tissues etc. will be disposed into autoclave bags (double-bagged), autoclaved (121°C for 15 minutes; programmed and validated on the Biohub autoclave which reports that the cycle has passed or failed [if a cycle fails, the fault would be rectified and the contents treated as hazardous and the load run again successfully]; this autoclave is serviced every 6 months with annual UKAS calibration and supported by a rolling service contract) and disposed of as clinical waste by incineration. Expected degree of kill 100%.

Liquid waste will be incubated in 1% Chemgene or 1% Virkon or PreSept tablets before solidification with vernagel and disposed of in clinical waste for incineration. Expected degree of kill 100%.

The cell lines are not expected to survive outside the specialist cell culture environment.

Monitoring of waste inactivation methods:
As cell lines are so fragile and cannot survive outside specialist cell culture environment growth is not expected following inactivation. The autoclave waste cycle used for inactivation has been validated and reports a ‘pass’ or ‘fail’. The autoclave is serviced every 6 months with annual UKAS calibration and supported by a rolling service contract along with regular monitoring by Biohub staff.

 Tick to confirm that you are attaching a summary of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The GM safety committee commented on the disinfection process for plasticware. We will decontaminate plasticware by disposal into autoclave bags (double-bagged), autoclaving (121°C for 15 minutes; programmed and validated on the Biohub autoclave which reports that the cycle has passed or failed [if a cycle fails, the fault would be rectified and the contents treated as hazardous and the load run again successfully]; this autoclave is serviced every 6 months with annual UKAS calibration and supported by a rolling service contract) and disposed of as clinical waste by incineration. Expected degree of kill 100%. This information has been updated within the risk assessment.

In addition, they asked:
"Mention autoclave and how its runs are monitored."

We have added details of the autoclave waste cycle, how it is serviced, and how runs are monitored into the risk assessment (121°C for 15 minutes; programmed and validated on the Biohub autoclave which reports that the cycle has passed or failed [if a cycle fails, the fault would be rectified and the contents treated as hazardous and the load run again successfully]; this autoclave is serviced every 6 months with annual UKAS calibration and supported by a rolling service contract).

Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Give brief details of the genetic modification safety committee

An earlier version of the Risk Assessment associated with this application was reviewed by a previous member of the University Genetic Modification and Biological Agents Committee, based in the School of Biosciences at Cardiff University. Cellesce is a small, independent, start-up company (SME) originating from Cardiff and Bath Universities. Cellesce has offices and labs in a Cardiff University-run facility that supports new biotechnology businesses. The “Lead Scientist” has more than 15 years experience in the assessment of risk related to academic and commercial use of GMOs. The senior staff members of the company also have many years of experience working with GMOs. As required by the Safety Representatives and Safety Committees Regulations 1977, Cellesce employees who are not covered by trade union safety representatives have been consulted, according to the Health and Safety (Consultation with Employees) Regulations 1996. This application has been reviewed and approved by Cellesce’s “Genetic Modification Safety Committee” GMSC. This comprises Cellesce’s Lead Scientist, the Lab Operations Manager and a Professor at Cardiff University who is Deputy Head of Molecular Biosciences, Director of organoid biology at Cellesce, and has been working with GMOs for more than 20 years.

Level 1 (GMMs)  
Yes

Level 2 (GMMs)

Level 3 (GMMs)

Level 4 (GMMs)
Procedures for waste management are based on the principles of Good Microbiological Practice, COSHH regulations, and the British Standard (BS EN 12740: 1999 Biotechnology. Laboratories for research, development and analysis. Guidance for handling, inactivating and testing of waste). The SACGM guidance on risk assessment (part 2) and waste inactivation before disposal (part 3, section 3.5) was also considered. The waste management system is appropriate to the overall management of the waste produced as part of the laboratory's activities.

Commercially available cell-lines are negative for mycoplasma. Cells are transported into the lab, contained within suitable packaging and stored at the appropriate temperature (depending on whether they are cryopreserved or live), humidification and carbon dioxide as necessary. Personal Protective Equipment; lab coat, gloves and safety glasses, are worn at all times in the laboratory area.

All staff working within the laboratory are competent, properly trained and informed. Training records are kept and updated regularly. Hands will be washed in the event of a suspected contamination and on leaving the laboratory. Lone working is not permitted. All accidents and incidents are recorded and reviewed regularly.

The handling of the cell cultures is performed in Class II Biological Safety Cabinets. Cabinets are serviced annually.

02/03/2022
Surfaces are decontaminated with 70% ethanol before use and the insides of the cabinet are disinfected weekly using "Virkon" (Du Pont), a high-level surface disinfectant proven to effectively tackle all known pathogens; fungi, viruses and bacteria. Equipment within the hoods such as pipettes, are decontaminated regularly with 70% ethanol. Equipment is decontaminated thoroughly with 70% ethanol before repair or servicing. Manual culture materials are single-use. All contaminated solids, such as used plastics, single-use pipettes and paper (used for decontamination of work surfaces and equipment with 70% ethanol) are treated as hazardous and placed in designated, clearly labelled, biohazard waste bins, double-lined with brightly coloured, clearly labelled, biohazard waste bags. The partially filled bags are removed regularly and double sealed with tape. They are removed to a large, locked container at the back and exterior of the building, where all of the waste is stored. Media from tissue culture is aspirated into sealed, impermeable, rigid cannisters, containing a gelling agent to solidify the liquid. This container is sealed when full, to maintain the required impermeability and integrity. It is then placed in a biohazard bag and sealed at the top with tape. The bag is placed in the bin at the back of the building with the rest of the bio-hazard waste. Keys for the container are held by Cellesce and by the commercial waste disposal company, Greener Options Ltd, who collect the rubbish on a monthly basis for incineration. This is the recommended method for solids and is 100% effective. The use of sharps is not normally necessary for this procedure. If absolutely necessary, these are placed in commercially available "sharps bins" that are sealed when full and stored with the biohazardous waste, for collection and incineration. Non-contaminated material, for example cardboard or packaging from sterile tissue culture plastics, is classified as non-hazardous waste and placed in clear bags for recycling where possible or in in black bags in designated black bins, for removal to the household waste facility at the rear of the building. The recycling and nonhazardous waste is collected twice weekly by the local council.

This project does not require an emergency action plan as the risk to people and to the environment is negligible.

Y

Give brief details of the genetic modification safety committee

The team is currently located in Cambridge, where a local Sub-Committee holds Biological Safety Team Meetings four times a year. There are currently three members on the committee, which cover EH&S requirements, Nagoya compliance, Biological safety, Material received/sent inspections.

Our procedures are captured in the internal Biological Safety Handbook, which collects all the information required to work with:

- Working with and keeping live organisms (plants, bacteria, yeast, cell cultures etc.)
- Biological compounds such as certain DNA plasmids or viral RNAs that can act as biological agents.
- Importing biological material into R&D Cambridge
- Exporting biological material from R&D Cambridge
- Disposal of biological material

We also have a Risk assessment for "Working with Biological Materials including Class 1 GMOs", and SOPs for the different procedures.

The person responsible for Biological Safety is a Senior Scientist in R&D New Sciences. They have expertise in microbiology, molecular biology, biotechnology and agronomy. They have worked for over 10 years with plants, microbes, and GM material in laboratory controlled environment condition and greenhouses (up to BSL2)."
For activities involving GMMs, describe the waste management measures which will apply to the activity

Waste containing plant material, including greenhouse waste and waste from growth chambers, and plant growth medium are disposed of in the sealable, rigid clinical waste bins. These are sealed when full and stored in the waste chemical store for licensed special waste disposal.

Waste material and laboratory glassware, plastic-ware or other materials contaminated with GMMs are to be inactivated by validated means: Domestos bleach to be used at a final concentration of 10% solution (needs to be made up fresh daily) or freshly made 1% Hypochlorite (final concentration) for disinfecting liquid cultures, cleaning benches, surfaces and floors. Laboratory sharps (scalpel blades, syringe needles, glass pipettes etc.) are all to be collected in labelled clinical sharps containers and disposed of as clinical waste by incineration, whether likely to be contaminated or not. Alternatively, they can be autoclaved with a discard cycle (121C at 15psi for 30min), after which they can be safely disposed of.

Simple spills are to IMMEDIATELY be covered with a paper towel. Wear disposable gloves and use paper towels to absorb all free liquid. Finally, decontaminate surfaces with undiluted disinfectant. All infected towels and gloves must be put into an autoclave bag for autoclaving or in a yellow labwaste bin for incineration.

When infected materials in bottles, flasks or petri-dishes are dropped and broken, the debris is be IMMEDIATELY covered with a paper towel soaked in undiluted disinfectant. Avoid bringing the face into contact with the aerosol cloud. Absorb any free liquid with paper towels (DO NOT use sweeping brushes because these can cause an aerosol). Use the dustpan and plastic scoop or forceps to collect the debris and place in a container to be autoclaved or yellow labwaste bin for incineration. Broken glass must NOT be placed in autoclave bags. It has to be placed in a yellow labwaste bin for incineration. The area is to thoroughly with undiluted disinfectant. All debris, used towels and gloves are then to be autoclaved before discarding.

Working surfaces are disinfected after each use, staff is to inspect each laboratory for accidental spills before start of work and clean those as stated above. Incidents are to be tracked and reported immediately.

Additionally, the general rules for working in laboratory environment apply.

Y

Give brief details of the genetic modification safety committee

The London Clinic has appointed an internal Biological Safety Officer (BSO) to advise management on contained use activities and provide approval for the risk assessments which are of GM Class 1 risk level as permitted under the contained use regulations. The BSO has been trained by external providers. The Queen Mary University of London (QMUL) GM Safety Committee and the QMUL BSO under contractual agreement provide expert peer review of risk assessments where risk level is deemed greater than Class 1 or contentious issues arise. The QMUL GMSC meets at least three times a year and conducts its activities under the terms of reference drawn up according to the contained use regulations and can be viewed at a specific webpage at http://www.hsd.qmul.ac.uk/

Solid GM Class 1 non-sharp waste is either inactivated by an effective disinfection method (noted below) or directly placed into yellow, sealable UN approved containers for uplift and offsite high temperature incineration (900 deg C) by an authorised upper-tier clinical waste contractor Harrison Benn. High temperature incineration achieves 100% kill of the GMO. The clinical waste contractor's quarterly returns for certification of solid waste destruction by incineration will be held for 3 years at the site, in accordance with UK environmental legislation. Sharps waste is not expected since no needles will be used during the product administration procedure. Liquid waste (or as necessary, for solid waste) is disinfected by an effective disinfectant. Chlor-Clean for inactivation of the GMO is proposed for use. Chlor-Clean contains triclosene sodium, which is a strong oxidant and chlorating agent. Liquid waste will then be disposed with copious tap water down designated sluice / lab sinks, in line with the local Water Authority effluent permit conditions. Surface decontamination (e.g. lab / ward benches) is to be conducted using Clinell Universal Wipes (in didecyl dimethyl ammonium chloride which is an antiseptic/disinfectant and polyhexamethylene biguanide which has antiviral and antibacterial properties). Emergency spillages will be treated using Chlor-Clean. Disinfection protocols are being set up and applicable personal protective equipment donned / worn during handling. Training of GM users / workers in the use of disinfection procedures is to be recorded and refreshed according to local policy. Any residual GMO cell stocks will be disposed into clinical waste sharp bins (yellow or white lid) for high temperature incineration by the authorised upper-tier clinical waste contractor Harrison Benn. Autoclaving of waste is not required at this risk level, although in case of emergencies, an autoclave at The London Clinic for waste inactivation by autoclaving at 121 deg C for 15 min holding time is available. All waste bags and containers are to be transported from clinical area to waste collection bin location in robust closed leak proof containers (on trolley if bulky or heavy).

**For activities involving GMMs, describe the waste management measures which will apply to the activity**

For activities involving GMMs, describe the waste management measures which will apply to the activity

Primary containment of solid and liquid waste containing GMMs in clear plastic sack marked "Autoclave Waste Only" containing absorbent material held in appropriate bag stand. Deactivation of contents is achieved by closing the bag loosely with Autoclave Indicator Tape prior to sterilisation and autoclaving (121°C for 60 minutes) before disposal as non-infectious clinical waste through laboratory waste management contractor (e.g. Grundon).

Spillages treated with standard cleaning materials (e.g. absorbent towels) and surface cleaned with appropriate disinfectant such as Distel Trigene (or similar commercial reagent). Any contaminated cleaning materials (e.g. paper towels) will be disposed of according to procedure for disposal of solid and liquid waste containing GMMs.

**Y**

Give brief details of the genetic modification safety committee

The Alchemab Ltd genetic modification committee will consist of:

1. **GMO Supervisor** - The Head of Research has extensive experience of genetic modification, having 20 years+ experience of working in a biotechnology/pharmaceutical industry setting, working in antibody and protein engineering research, involving phage display and protein expression/modification in mammalian cells and E.Coli, with management oversight for a research group.

2. **Biological Safety Officer** - The Head of Translational and Clinical Science who has who has 20+ years experience of working in a biotechnology/pharmaceutical industry setting working in pre-clinical bioscience, translational biology and early clinical settings, including use of mammalian cell culture, primary cells and human samples, and management of a research group. The biosafety officer will chair all genetic modification committee meetings.

3. **The Chief Scientific Officer** has 20+ years experience of genetic modification and was previously site lead for a large multinational pharmaceutical company. Her function on the committee is to advise and provide the necessary resources for the actions of the committee to be implemented.

4. **2x Senior Research Scientists** who are either specialists in mammalian cell culture or molecular biology, both with 5+ years experience in an academic/pharmaceutical industry/biotechnology setting. These members will provide advice and will rotate writing the minutes of the meeting between them.

The committee will meet every 6 months to review biosafety and whenever a new risk assessment is required. The first meeting will review the existing risk assessments.

At Illumina Accelerator:
All waste material will be inactivated by treatment with 1 % (w/v) Virkon solution prior to disposal, and autoclaved onsite before being placed in sealed bins and removed by registered waste specialists. Liquid waste (Virkon inactivated) will be decanted into suitably labelled liquid waste vessels before being removed from the site by registered waste specialists. (Veolia)

At Babraham Meditrina premises:
All waste material will be inactivated by treatment with 1 % (w/v) Virkon solution prior to disposal. Waste material will then be placed in sealed bins and incinerated by an off-site incineration company (see derogation application below). Waste from our GM work at Class 1 will be placed into suitably labeled sealable bins. They will be sealed by our staff and removed to a central collection point where they will be placed into 210 litre yellow labelled "Eurobins". Collections for incineration will be made by the local registered clinical GM waste incinerator contractor.
Both of these disposal methods are expected to achieve 100% inactivation of the GMM. The data sheets describing inactivation by Virkon are attached.

 Tick to confirm that you are attaching a summary of the risk assessment

 Tick if you are claiming exemption from disclosure for sections of the risk assessment
Given the lack of mechanism for transmission to, or expression in, human hosts there is effectively zero likelihood of harm to human health even in the event of exposure.
- Hosts are standard, non-pathogenic E.coli lab strains, such as TG-1 and BL-21, which are hazard group 1
- the genes are human-derived and therefore normally expressed and tolerated in human hosts
- no vector capable of transmitting DNA into humans is involved in the work described
- the human genes are under the control of a bacterial promoter (not a mammalian promoter) so even if plasmids were present in a human host the genes would not be expressed

There is minimal risk to environment.
If the GM microorganism (GMMO) were to leave the lab environment, it would be expected to lose the plasmid encoding the foreign gene within a few cell divisions unless maintained on antibiotic selection. Only in the scenario where the foreign gene confers a growth advantage would the GM microorganism be able to survive and potentially displace other organisms. The only organisms likely to receive the DNA vectors and express the gene inserts are closely related bacterial species so no harm to animals or plants is anticipated. Bacterial expression vectors are designed for optimal function within lab strains of E.coli but expression of the human gene products in related gram negative bacteria eg other strains of E.coli or Salmonella species is possible. If the human gene products are toxic to the recipient bacteria then these bacteria will rapidly self-eliminate without passing the vector any further. Even if the gene products are not toxic but change bacterial biology in some other way, they will not be maintained over multiple cell divisions in the absence of the antibiotic used to maintain the plasmid so the vector's persistence would be expected to be short-lived. Only if the gene product confers a selective advantage to the bacterial recipient will it be maintained and potentially passed to other bacterial hosts.
**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

The contained use purpose covers the generation and use of third generation lentivirus particles that encode individual open reading frames (ORFs), gene sequences, cDNAs and/or shRNAs, and their subsequent use to generate cell lines for in vitro studies. These studies will assist with understanding disease biology, and the role of specific target proteins by generating cell lines for in vitro screens. Such screens can include: (i) Binding assays and flow cytometry (ii) Pull down and Immunoprecipitation studies (iii) Imaging assays (iv) Proliferation assays (v) Phenotypic screens (vi) Generation of cell lines with constitutive reporter proteins or inducible signalling reporter cell lines. This work will assist in the validation and discovery of novel antigenic targets relevant to human health. The overall purpose is to develop antibody therapeutics.

**Recipient or parental organism**

Mammalian cell lines from Hazard group 1 & 2 and Activity Class 1 & 2 genetically modified cells. All mammalian cells will be covered by appropriate risk assessments prior to their use for this project.

**Host/vector system**

For successful viral production, the third-generation lentiviral system requires 4 separate plasmids to be co-transfected into a host mammalian cell line (e.g. HEK293T). HEK293T, is a subclone of the transformed human embryonic kidney cell line, HEK 293, which is highly transfectable and supports high levels of viral protein expression. The cell line also constitutively expresses the simian virus 40 (SV40) large T antigen.

The plasmids required for lentiviral production are:
- The transfer plasmid (encoding the genetic insert)
- Two packaging plasmids (one encoding Gag and Pol and another encoding Rev)
- One envelope plasmid encoding VSV-G

Commercial packaging and envelope plasmids will be used, for example pPACKH1 HIV Lentivector Packaging Kit 200ul (Systems Biosciences #LV500A-1).

The lentiviral vector together with the packaging plasmids comprise the third generation lentiviral expression system. The HIV-based lentivectors are based on the vectors developed for gene therapy applications by Dr. J. G. Sodroski (US patent #5,665,577 and # 5,981,276).

The HIV-based lentivector systems are designed to maximize their biosafety features, which include:
- A deletion in the enhancer of the U3 region of 3’LTR ensures self-inactivation of the lentiviral construct after transduction and integration into genomic DNA of the target cells.
- The RSV promoter (in HIV-based vectors) upstream of 5’LTR in the lentivector allow efficient Tat-independent production of viral RNA, reducing the number of genes from HIV-1 that are used in this system.
- Number of lentiviral genes necessary for packaging, replication and transduction is reduced to three (gag, pol, rev), and the corresponding proteins are expressed from different plasmids (for HIV-based packaging plasmids) lacking packaging signals and share no significant homology to any of the expression lentivectors, pVSV-G expression vector, or any other vector, to prevent generation of recombinant replication-competent virus.
- None of the HIV-1 genes (gag, pol, rev) will be present in the packaged viral genome, as they are expressed from packaging plasmids lacking packaging signal—therefore, the lentiviral particles generated are replication-incompetent.
- Third generation lentiviral vectors are also not readily mobilizable as a result of a superinfection with a wild-type virus.

**Origin & function**

Open reading frames (ORFs), cDNAs and gene sequences encoding potential drug targets or therapeutic proteins and / or shRNAs (designed to knockdown the expression selected gene products) will be expressed in third generation, self-inactivating, lentiviral expression vectors. ORFs could include DNA encoding potentially ‘harmful inserts’, which can be defined as a sequence that may have harmful biological activity such as oncogenes, toxins,
cytokines, transcription factors, receptor tyrosine kinases, growth factors and immunomodulatory proteins. For example, the expression of an oncogene, proto-oncogene, or sequence with oncogenic mutations may result in cellular transformation. In addition, the use of shRNAs to knockdown tumour suppressor gene expression could also result in cellular transformation.

Lentiviral particles will also include selectable markers which may include (but are not restricted to):
- Ampicillin resistance: derived from E.coli
- Neomycin resistance: aminoglycoside phosphotransferase gene derived from bacteria
- Puromycin resistance (PAC): Puromycin acetyl transferase is derived from Streptomyces alboniger

### Evaluation of foreseeable effects

In lentivirus transfer plasmids, the encoded genetic insert sequence is flanked by long terminal repeat (LTR) sequences, which facilitate integration of the transfer plasmid sequences into the host genome. Typically, it is the sequences between and including the LTRs that is integrated into the host genome upon viral transduction.

3rd-generation transfer plasmids have chimeric 5'LTR that includes an RSV promoter and are self-inactivating (SIN) vectors. SIN vectors have a deletion in the 3'LTR of the viral genome that is transferred into the 5'LTR after one round of reverse transcription. This deletion abolishes transcription of the full-length virus after it has incorporated into a host cell.

Examples of elements found in the vector system include, but are not limited to, the following:

<table>
<thead>
<tr>
<th>Lentiviral elements</th>

<td></td>
</tr>
<tr>
<td>Selection marker e.g. AmpR Bacterial selectable marker</td>
<td></td>
</tr>
</tbody>
</table>

Two potential safety concerns for use of Lentivirus are:
1. Potential for generation of replication-competent lentivirus (RCL)
2. Potential for oncogenesis.

Replication-defective lentiviral vectors, such as the 3rd generation vector, are not known to cause any diseases in humans or animals. Non-essential viral accessory genes have been removed and the remaining ones split across 4 plasmids so that 4 separate recombination events would have to occur simultaneously to generate replication competent lentiviruses.

In addition, lentivirus particles pose some risks because they can transduce primary human cells and can integrate into the host cell genome, thus still posing some small risk of insertional mutagenesis if able to transduce cells of the user. Genome-wide studies of viral integration have shown that lentiviruses most often integrate into actively transcribed genes, and that this preference is conserved across target species. For this reason, the product should be handled at containment level 2.

Open reading frames (ORFs), cDNAs and gene sequences encoding potential drug targets or therapeutic proteins and / or shRNAs (designed to knockdown the expression selected gene products) will be expressed in third generation, self-inactivating, lentiviral expression vectors.

ORFs could include DNA encoding potentially 'harmful inserts', which can be defined as a sequence that may have harmful biological activity such as oncogenes, toxins, cytokines, transcription factors, receptor tyrosine kinases, growth factors and immunomodulatory proteins. For example, the expression of an oncogene, proto-oncogene, or sequence with oncogenic mutations may result in cellular transformation. In addition, the use of shRNAs to knockdown tumour suppressor gene expression could also result in cellular transformation.

The expression of lentiviral encoded transgenes is controlled by a promoter. Some promoters, such as human cytomegalovirus (CMV) promoter, are considered strong mammalian expression promoters. Hence, the expression levels of 'harmful inserts' could be reasonably high in the transduced cells. An example of this is high expression of growth factors or transcription factors (e.g. myc) resulting in induced cell proliferation. Uncontrolled proliferation of cells in a human host can result in cancer.

Overexpression of cytokines in human hosts could result in autoimmunity or cytokine storm.

Random integration of the lentivirus encoded genetic insert (or transgene) into the human genome can be hazardous irrespective of the transgene as it may disrupt essential genes or inactivate tumour suppressor genes.

There is also the risk of transfer of the lentivirus to other cell lines used for in vitro work, if they are exposed to the lentiviral particles. This could impact experimental work using these cells are they may not behave as parental lines.
Lentivirus transfer plasmids that encode genetic inserts/transgenes are designed for optimal function within lab strains of E.coli and in mammalian cells in combination with co-transfection with packaging and envelope plasmids to produce lentivirus. If the plasmids were transferred to related microorganisms, for example, related gram negative bacteria eg other strains of E.coli or Salmonella species, they will not be maintained over multiple cell divisions in the absence of Ampicillin antibiotic. Antibiotic selection is used to maintain the plasmid so the vector’s persistence would be expected to be short-lived. Only if the gene product confers a selective advantage to the bacterial recipient will it be maintained and potentially passed to other bacterial hosts.

Within mammalian cells, once a 3rd generation lentivirus has transduced the cell and integrated within the host genome, it is incapable of generating more lentivirus particles due to the safety mechanisms used. The lentiviral particles produced by third generation lentivirus systems are replication incompetent. A deletion in the 3’ LTR (U3) results in “self-inactivation” (SIN) of the lentivirus after transduction and genomic integration of the target cell (Yee et al., 1987; Yu et al., 1986; Zufferey et al., 1998). This alteration renders the lentiviral genome incapable of producing packageable virus following host integration.

Transduced cell line pools or stable cell lines generated will be treated as hazard group 2 (especially when the nature of the inserted transgene or location of insertion is unknown).

If a ‘hazardous insert’ was transferred to an immunocompromised individual or pregnant female host, and the insert was correctly incorporated into the host genome and subsequently expressed at high levels, or resulted in insertional mutagenesis, these individuals may be more susceptible to its downstream effects; however, the likelihood of this is very low using containment level 2 practices. The initial bacterial strain encoding the lentiviral transfer plasmid (with a genetic insert/transgene) is unlikely to transfer the genetic material to other organisms. Once a mammalian cell has been transduced with a third-generation lentiviral system it is unable to generate lentivirus particles. Therefore, it will not be able to transfer genetic material to other organisms.

Lentivirus particle encoded inserts can integrate into the genome of a host cell. This poses a risk of insertional mutagenesis if the cells of a user were to be transduced with lentivirus. There is a risk that the integration of the encoded insert may disrupt, or mutate, essential genes or tumour suppressor genes. Genome-wide studies of viral integration have shown that lentiviruses most often integrate into actively transcribed genes, and that this preference is conserved across target species. Following containment level 2 practices, the likelihood of transduction of cells of a user is low and therefore the risk of genetic instability is also low.

The NIH guidance ‘Biosafety Considerations for Research with Lentiviral Vectors’ states that ‘laboratory scale’ use of lentivirus (as opposed to mass production scale used in cell therapies or commercial production) pose a low risk. Replication-defective lentiviral vectors, such as the 3rd generation vectors, are not known to have ever caused any diseases in humans or animals.

If the GM microorganism (GMMO) E.coli host were to leave the lab environment, it would be expected to lose the plasmid encoding the foreign gene within a few cell divisions unless maintained on antibiotic selection. Only in the scenario where the foreign gene confers a growth advantage would the GM microorganism be able to survive and potentially displace other organisms.

Human hosts may be infected by lentivirus through injection, or direct contact with mucous membranes, such as inhaling airborne droplets/aerosols. The initial bacterial strain encoding the lentiviral transfer plasmid (with a genetic insert/transgene) is unlikely to transfer the genetic material to other organisms.

The potential for the transfer of genetic material between organisms is greatest during the production of lentiviral particles and transduction of mammalian cell lines where airborne droplets may be produced. To minimise this risk, segregation of the lentiviral work from standard cell culture work should be in place (e.g. strip cleaning class II MBSC hoods with distel and 70% ethanol after working with lentivirus). HEK293T cells transfected with lentiviral plasmids and host cells initially transduced with lentiviral particles should also be separated from standard cell culture cell lines (e.g. in a separate incubator). Once transduced cells have been washed with PBS, subjected to a media change and passed into new plastic flasks or plates, they can be moved back to an incubator with standard cell culture stocks, as the risk of transfer of lentiviral particles are low. In addition, all serological pipettes used with lentivirus particles should be deactivated with 1% Virkon (final concentration) in the class II MSC to reduce the spread of particles outside the hood and reduce aerosol/droplet transmission. Pipette tips which cannot be easily disinfected with 1% Virkon will be collected inside the MBSC hood inside a BioBin container. The BioBin will then be sealed inside the MSC hood and placed in a sealed plastic yellow CL2 waste bin, with a category 2 sticker (includes UN 3373 diamond sign). The bin will then be collected for incineration. Laboratory costs will be autoclaved prior to laundry.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Lentiviruses have been identified to infect humans and other primates, cats, cattle, sheep, goats and horses. Genetic inserts may include human ORFs and therefore the expression of human genes in the animals may result in harmful immune reactions. Moreover, similar to humans, overexpression of ‘harmful inserts’ and/or insertional
mutagenesis could also cause harm. The experimental work outlined utilises third generation vectors with no known history of causing harm in animals, will adhere to containment level 2 procedures and no animals will be present in the environment where this work will be carried out. The risk of generation of unanticipated genetic modification of animals and subsequent harms are therefore extremely unlikely. As lentivirus is unable to infect plant cells, there is no mechanism for transmission of the lentivirus plasmid to plant hosts.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Instead of autoclaving waste in the building we propose to follow the procedure used by the Babraham Institute described in their disposal notification GM 105/4.1 (see also section 6 above for description). Reasons for adopting this method of waste disposal are:
1. We do not have access to an autoclave within our area of the building
2. The waste disposal system used by the Babraham Research Campus is safe and has been running since October 2004.
All waste material will be inactivated by treatment with 1 % (w/v) Virkon solution prior to disposal. Waste material will then be placed in sealed bins and incinerated by an off-site incineration company (Vetspeed - Their GM authorization is GM898) according to disposal notification GM105/4.1.
Waste from our GM work at Class1 will be placed into suitably labelled hermetically sealable 60 litre UN approved (to Class 3) Type 3H21Y30/S/2003 bins. Sealed bins are placed into secondary 210 litre yellow labelled "Eurobins".
Collections by the local registered clinical/GM waste incinerator contractor will be made three times a week to prevent a build-up. The site has 24/7 Security. The contractor uses solid bodied transport and carries portable disinfection equipment in case of any spillage. Autoclave facilities will be available in an adjacent building, as required by the Regulations, in case of loss of the contractor's facilities. The type of container and the secondary Euro container means that the risk of any spillage of active GM waste on site is negligible. However, as active waste will leave the site, the risk to the environment and health is possibly marginally higher than autoclaving prior to incineration. The only real risk of release would be as a result of a major RTA, however, the containers are designed to withstand this. This disposal method is expected to achieve 100% inactivation of the GMM.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste material will be inactivated by treatment with 1 % (w/v) Virkon solution inside a Class 2 microbial safety cabinet prior to disposal. Waste material will then be placed in sealed bins and incinerated by an off-site incineration company (see derogation application below).
Waste from our GM work at Class 2 will be placed into suitably labeled sealable bins. They will be sealed by our staff, notified on a central electronic logging systen and removed to a central collection point where they will be placed into 210 litre yellow labelled "Eurobins".
Collections for incineration will be made by the local registered clinical/GM waste incinerator contractor.
Laboratory coats will be autoclaved prior to laundry.
All of these disposal methods are expected to achieve 100% inactivation of the GMM. The data sheets describing inactivation by Virkon were attached at notification of premises (CU1).

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

Please enter comments on the GM safety committee on the risk assessment
The Risk Assessment was approved after the following comments had been addressed:
- Remove reference to use of generated cell lines for in vivo use as this is not currently planned
- Remove reference to 'Generic' in Risk Assessment as this RA applies to specific packages of work
- Insert additional description of the in vitro assays that will use the generated cell lines (in particular, the use of generation cell lines with constitutive reporters and inducible signaling reporters)
- Use 'serological pipettes' to remove confusion between disposable stripettes and pipetting equipment
- Lab coats should be autoclaved prior to laundry
- Include risks of random integration to Section 3.2.6 in Risk Assessment
- Add descriptors of harm to Risk Matrix

Bacteriology | Parasitology | Transgenic Birds | Transgenic Animals | Transgenic Fish | Microbiology Research | Gene Therapy
| Yes         |             |                |                  |              |                    |            |
For activities involving GMMs, describe the waste management measures which will apply to the activity

All plates or tubes containing the genetically modified bacteriophage will be soaked in virkon. All waste will then be transferred into theatre bins which are collected by a commercial waste management company. No genetic modification work is being performed at the Solus lab. The genetically modified bacteriophage used in this diagnostic technique are supplied by the manufacturer of the diagnostic assay.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

Experienced UK University professor who has years of experience working with bacteriophages and their risk assessment. He was clear that this work is low risk work as these phages pose no risk to humans, animals or plants and correlates with Levell (GMM's).

**Historical Significant Changes**

**Historical Date of Additional Info**
Recipient or parental organism
Salmonella Typhimurium Bioball Luminate is a commercial product manufactured and sold by Biomerieux.

Host/vector system
Bioball Luminate is a commercial product manufactured and sold by Biomerieux.

Origin & function
Commercially available Salmonella Typhimurium which is tagged with a Green Fluorescent Protein (GFP) marker used as a QC control strain in food testing labs as it is easy to distinguish from external contaminants.

Evaluation of foreseeable effects
The genetic modification is not expected to effect the growth of Salmonella Typhimurium and poses no greater risk than working with Salmonella Typhimurium (Class 2 organism with class 2 containment measures)

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
No derogation from Class 2 containment

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All waste will be placed in theatre bins and be collected by a waste management company. Treatment involves sterilising and shredding the waste, heat penetrating treatment and more shredding so the end product is not distinguishable as waste, it's more like fluff which is then sent for deep burial.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
The genetic modification is not expected to effect the growth of Salmonella typhimurium and poses no greater risk than working with Salmonella typhimurium (Class 2 organism with class 2 containment measures)

02/03/2022
Small scale culture (<10 litres): All wild type and GMM organisms in culture will be autoclaved or chemically inactivated prior to disposal. Standard autoclaving for cycle should be 121°C for at least 30 minutes by using saturated steam under at least 15 psi of pressure. Chemical inactivation will take place using validated disinfectants according to the manufacturer’s instructions. Large scale culture: Validated inactivation methods that have been shown to prevent release of the GMO to protect human health and the environment will be used. As part of the industrial process the culture mixture is heated to 80 °C for at least 30 seconds. Internal validation has demonstrated this to be an effective inactivation step. Annual validation of the process is required and monitoring of the waste takes place after production of 1000 L of material. Subsequently the material is treated with a chlorination step. Chlorination is by far the most common method of wastewater disinfection and is used worldwide for the disinfection of pathogens before discharge into receiving streams, rivers or oceans. Chlorine is known to be effective in destroying a variety of bacteria, viruses and protozoa, as well as effectively destroying DNA contamination.

Monitoring
Monitoring of process organisms in the waste water is required to ensure compliance with procedures to protect human health and the environment and to ensure that containment is maintained. The monitoring protocol for process organisms is performed according to ISO standard 9308-1 (membrane filtration method). This is a standard monitoring method used across the pharmaceutical, food and beverage industry to measure bioburden. Briefly; a sample of the spent dye liquor is filtered through a membrane designed to retain microorganisms. The membrane collects cellular debris as well as any intact microorganisms. This is then placed onto a selective media which promotes the growth of our process organisms and incubated at optimal temperatures to allow their growth. If any process organisms remain intact and are collected by the membrane they will form growth colonies on the media. Monitoring frequency is dependent on volumes of dye liquor being produced and so will take place after every 1000 L volume of fermentation dye liquor produced rather than on a weekly or monthly basis.

The biological safety committee accepted the risk assessment of the activity to be complete. The risk assessment has carefully considered the risks that the project may pose to both human health and the environment and the controls indicated by the risk assessment as sufficient to protect human health and the environment.

Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Level 1 (GMMs)

Level 2 (GMMs)

Laboratory

Animal Unit

Growth Room

Glass House

Large Scale

The TranSINE Therapeutics Ltd genetic modification committee will consist of:

- Vice President of Research and Operations: Has 22 years experience working with mammalian cell culture projects, including the use of GMMs. She has lead and managed groups of scientists and advised on biosafety matters. Her function on the committee is to advise and provide the necessary resources for the actions of the committee to be implemented.

- Research Director: Will chair the TranSINE H&S committee. Has 20 years experience working with mammalian cell cultures, including genetically modified cell lines and bacteriological work, in both academia and industry. He has managed teams of lab scientists and advised on safety aspects of work. His role on the biosafety committee is to provide advice and ensure that actions arising from the committee are implemented.

- Senior Scientist: Is an expert in mammalian cell culture and molecular biology, with 8 years of experience. She will provide advice and implement the outcomes of the Biosafety Committee in the laboratory.

The committee will meet every 6 months to review biosafety and ad hoc whenever a new risk assessment is required.
All waste material will be inactivated by treatment with 1% (w/v) Virkon solution prior to disposal. Waste material will then be placed in sealed bins and incinerated by an off-site incineration company (see derogation application below).

Waste from our GM work at Class1 will be placed into suitably labelled hermetically sealable bins. They will be sealed by our staff and removed to a central collection point where they will be placed into 210 litre yellow labelled "Eurobins".

Collections for incineration will be made by the local registered clinical/GM waste incinerator contractor. This disposal method is expected to achieve 100% inactivation of the GMM. The data sheets describing inactivation by Virkon are attached.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Use of adeno-associated virus or lentivirus in hazard group 1 and 2 cell lines to investigate the therapeutic potential of natural or synthetic long non-coding RNA molecules

SINEUPs are natural or synthetic long non-coding (Inc) RNA molecules that can upregulate the protein synthesis of target genes in mammalian cells without altering the endogenous mRNA levels of the target gene. As such these could have therapeutic applications in diseases associated with decreased expression of key proteins.

A standard SINEUP project takes the following format:

SINEUPs versus a specific cellular target gene are designed in silico and synthesised.

In certain instances adeno-associated virus (AAV) or lentivirus containing vectors to express SINEUPs will be obtained from 3rd party vendors in small aliquots and used to transduce hazard group 1 or 2 mammalian cells.

The effects of SINEUP transcription upon protein expression will be monitored for 1-28 days.

SINEUP-transduced cells will be used for a range of biochemical, cell biology and cell-based assay experiments including, but not limited to, lysis for western blot and quantitative PCR, fluorescence microscopy and immunocytochemistry on live and fixed cells, cell death quantification, luciferase assays, GFP assays, ATP assays, mitochondrial membrane potential assays and other functional readouts.

To facilitate a full understanding of the biology around the activity of SINEUPs, there will also be the need to use AAV or lentivirus to generate in vitro cellular models which may have:

- Stable overexpression of exogenous genetic sequence
- Reduced expression of target genes by expressing shRNA
- Knockout or modification of endogenous genes using CRISPR/Cas9 or related methodologies to:
  - introduce specific amino acid changes
  - add a tag such as but not limited to GFP, luciferase, FLAG & HA
- Introduction of reporter gene systems to allow the measurement of functional effects on key cellular signalling
Recipient or parental organism

Well characterised immortalised cell lines.
A number of immortalised cell lines are available that can be used as model systems for validating and initial assessment of target activity. Due to the nature of the work cell lines known to support the propagation and production of replication competent lentivirus particles (RCLs) will not be used. The Biosafety level 1 or 2 cell lines will be obtained from reliable sources (commercial and academic) with a clear history of safe use and a well understood mechanism of immortalisation to remove the risk of recombination events leading to production of RCLs.

Primary human cells
The main risk is the presence of adventitious pathogens.
Ideally, cells will have been screened for major human pathogens with the potential to harm health and shown to be negative.
In some instances however, consent to screen for major human pathogens is not sought at the time of cell donation. Screening the cells for major human pathogens would have potentially significant clinical health implications for patients (e.g. HIV), for which explicit consent has not been given at the time of donation. As such, for cells where consent has not been given, these cannot be screened for human pathogens and must therefore be handled at Biological Safety Level 2. All donors however, must have no previous known history of infectious disease and will be from epidemiologically low-risk populations.

These mutations are naturally occurring in the genome of these individuals, they are not mobile genetic elements and thus present a very low biosafety risk.

hiPSC derived from primary human cells, most commonly fibroblasts.
The hiPSC that will be used may have been either generated using 3rd or 4th generation self-inactivating (SIN) non-mobilisable integrating retroviral systems based on , but not limited to, mouse Maloney murine leukaemia virus (MMLV), Maloney murine sarcoma virus (MMSV), myeloproliferative sarcoma virus (MPSV), or human HIV. Some of the original donor material will not have been screened for human pathogens but donors will have a known medical history and will be classified as being low risk for retroviral pathogens. As such the hiPSC are highly unlikely to be producing RCLs.

Reprogramming of the hiPSC is achieved using a variety of factors, that are integrated into the cell genome by the retroviral vectors, that induce pluripotency in the donor cells. A combination of the following factors may be present in the supplied hiPSCs:

- **SOX2**: is a transcription factor that is essential for maintaining the pluripotency of undifferentiated embryonic stem cells.
- **KLF4**: is a transcription factor that regulates proliferation, differentiation, apoptosis and somatic cell reprogramming. KLF4 may also act as a tumour suppressor gene.
- **OCT4**: is a homeodomain transcription factor of the POU family. This protein is critically involved in the selfrenewal of undifferentiated embryonic stem cells and is used as a marker for undifferentiated stem cells. It is indispensable for generating iPSC.
- **CMYC**: is a transcription factor that plays a role in cell cycle progression, apoptosis and cellular transformation. Mutated c-Myc is found in many cancers, where it is constitutively expressed, leading to the unregulated expression of many genes, some of which are involved in cell proliferation leading to oncogenesis. This factor poses a risk if mobilised into RCL.
- **NANOG**: is a transcription factor critically involved with self-renewal of undifferentiated embryonic stem cells.
- **LIN28**: encodes a microRNA-binding protein; overexpression of which in mice, can cause gigantism and a
delay in the onset of puberty. Human GWAS studies indicate the LIN28B gene to be associated with human height and the timing of puberty. The biosafety risk is low for adults.

- GLIS1: is a highly promiscuous transcription factor, positively or negatively regulating the expression of a number of genes.
- shp53: short hairpin RNA that suppresses expression of p53. P53 is a known tumour suppressor gene and binds to DNA where it regulates the expression of anti-mutagenesis genes. Mutations in the p53 gene leading to a loss of activity are the most commonly found single mutation in human cancer.
- Mir302/367 cluster: microRNAs are a subclass of small non-coding RNAs that fine-tune the regulation of gene expression at the post-transcriptional level, with a particular role in establishing cellular pluripotency.

HiPSCs can also be generated using episomal approaches and if suitable will be used preferentially. Where cells are reprogrammed using non-viral episomes, there is no integration of genetic material into the resulting hiPSC genome and no viral sequences are introduced into the cells. Episomes are lost as the reprogrammed hiPSC proliferate, at an approximate rate of 5% per generation. Therefore by approximately 12-13 proliferation cycles, the episomal transgenes have been entirely lost. This eventually results, at the time of use, in “footprint-free” cells that do not contain the original reprogramming sequences. In this respect the hiPSC are not genetically modified but do have a changed gene expression profile and a pluripotent phenotype.

**Host/vector system**

In the case of hiPSC generated using integrated retrovirus the factors and vectors used will be fully described prior to receipt and be reviewed by the Biological Safety Committee (BSC) at TranSINE Therapeutics Ltd (TTX) which also has the responsibility for any work involving genetic modification. In this case subsequent lentiviral vectors will be non-homologous with the integrated sequences to mitigate the small risk of a recombination event leading to mobilisation of genetic material, such as the myc oncogene or immunomodulatory genes, that might pose a risk to human health. The integrated murine-based lentivirus pose no additional risk to the environment. It is also planned to transduce immortalised cell lines, primary cells and episomally generated hiPSCs with lentiviral vectors. The recipient cells will not be known to harbour viral material that could be mobilised by introduction of lentiviral vectors and where viral material is present it will not support the production of RCLs.

Secondary transduction would either transiently modulate the protein expression of a target protein at the translational level, modify the cells to explore the underlying disease process or to generate tools for drug discovery. To this end the following could be used based upon the needs of drug discovery programs:

- Integration of shRNA constructs to ‘knock down’ expression of a gene of interest
- The over-expression of particular genes
- Reporter genes under the control of selected transcriptional regulatory sequences to study effects on cellular pathways.
- The lentivirus used will be obtained from commercial sources and generated using third of fourth generation vector systems. The vector backbone and promoters used to drive vector generation in these systems will be consistent. Due to the nature of the work, genes may be selected that will include growth factors, tropic factors, quiescence factors, confirmed oncogenes, tumour suppressors and proteins known to be involved in neurological disorders. The vectors will be generated using a non replication-competent HIV based lentiviral system that upon integration into the host genome loses part of its long terminal repeat (LTR) preventing excision at a later time point. Such self-inactivating (SIN) vectors are designed to produce stable gene expression in target mammalian cells. The viral particles can only be generated upon co-transfection of a packaging cell line (usually HEK-293T) with at least four
separate plasmids, three of which provide the minimal set of genes required for viral production (gag-pol, rev and env). The env gene used is from the vesicular stomatitis virus (VSV-G) to increase tropism. The final plasmid provides the genetic material to be supplied to the target cell and as such contains packaging sequences directing it to be incorporated into nascent viral particles. Only the minimum amount of lentiviral genome is used in the system and all of the plasmids lack homologous sequences to minimise any chance of recombination. The resultant lentiviral particles are VSV-G pseudotyped, SIN and replication incompetent in mammalian cells. Small aliquots of no more than 1x10^8 viral particles in 5 to 10 microlitres will be used at anytime, further reducing the risk.

Third Generation Systems use 4 standard bacterial plasmid vectors. Three plasmids encode for proteins required for production and packaging of full length viral RNA (for example: pCgpV, pRSV-Rev and pCMV-VSVG). The gene of interest is contained in a fourth plasmid (e.g., pSMPUW). This is the only plasmid that contains the packaging sequence for incorporation into the virus particle.

Fourth Generation Systems use 6 standard bacterial plasmid vectors. The system uses tetracycline to control when viral particles are produced adding yet another level of control to production. For example, pTRE-gag-pro, LTR HIV2-vpr-pol, penv(VSV-G), pTet-Off and ptat-IRES-rev contain the sequences that code for proteins that are responsible for the tetracycline control and packaging of the viral genetic material. As above the last plasmid (e.g., pSMPUW) only contains the genetic material to be packaged into the vector and no other lentiviral gene sequence. An integrase deficient version of the fourth generation system is available which contains a mutation in the sequence encoding the viral integrase.

In some cases the broad tropism of MV vectors will be utilised to transiently introduce genetic material of interest into hiPSC cell lines, primary cells or immortalised cell lines. MV vectors are replication incompetent. The vectors used will be incapable of integration into the host genome as they will not contain the rep or cap genetic sequence. The genetic material will remain epichromosomal and will be progressively lost as cell continue to divide until essentially no introduced genetic material remains. These vectors pose negligible risk to human health. These vectors will be obtained from third party sources.

### Origin & function

As mentioned above there may be a requirement to look at genes encoding growth factors, their receptors, tropic factors, putative oncogenes, confirmed oncogenes, tumour suppressors and proteins associated with neurological disorders. Any target gene will need the approval of the TranSINE Therapeutics BSC and the vectors used will have their sequence checked to ensure lack of homology.

- **a-Vector containing SINEUP** - each vector will encode a sequence expressing a SINEUP that is designed to enhance the translation of a specific protein. This will be under the control of a polymerase II or III promoter.

- **b-Vector containing shRNA** - each vector will code for one shRNA transcript that will be designed to target one mRNA/protein of interest (or a scrambled shRNA in the case of negative control). This will be under the control of a polymerase II or III promoter.

- **c-Vector containing CRISPR nucleases** - Programmable nucleases function by binding to, and cleaving, user-defined target DNA sequences. This instigates a robust DNA repair response which can either be used to disrupt the target sequence by deletion at the cleavage site or to introduce user-supplied genetic material via recombination with a vector containing complementary sequences to the target gene.

For Cas9/CRISPR; nuclease target specificity is determined by a guide RNA, which consists of a short (18-20 nucleotide) sequence homologous to the target gene and an additional short sequence that forms a complex with the Cas9 enzyme. The vector will encode Cas9/CRISPR plus a guide RNA under the control of a Polymerase III promoter.

Zinc finger nuclease target specificity is dependent upon the zinc finger protein sequence which will be under the
control of a polymerase II promoter. A fluorescent protein or enzyme under the control of a polymerase II promoter or the promoter of a gene of interest may be included. Control vectors only expressing fluorescent protein/enzyme will also be used.

d-Reporter or overexpression gene vector - The vector will contain either sequence coding for a reporter protein, a protein to be overexpressed under the control of regulatory elements of a promoter of a gene of interest or a polymerase II promoter. An appropriate selection marker i.e.; neomycin could also be included to allow the selection of cells stably containing the introduced genetic material. The efficacy of lentiviral vectors will be assessed first using cell lines that routinely require biosafety level 1 containment (BSL 1). Application of lentiviral particles will be done at Biosafety Level 2 containment. At least 24 hours post transduction the cells will be washed three times to remove any residual viral particles and then treated as BSL 1 as the potential risk will have been minimised. The efficacy of the genome manipulation will be assessed using in vitro assays. AAV vectors will be tested in a similar manner but only require BSL 1 containment and will look at the effect of the expression of the introduced genetic material upon the cell phenotype within several cell generations before the proportion of the cell population still containing the episomal vector becomes too small. hiPSC will be transduced with validated lentivirus. All procedures will be conducted at BSL2. Stable cell lines will be documented. Resultant cells will be studied to further understand disease processes or used for drug discovery efforts. This will be done by phenotypic analysis using a range of common in vitro assays, including but not limited to RT-PCR, Western blotting, immunocytochemistry and imaging, cellular bioenergetics or electrophysiology. All culturing of viable BSL2 cell lines will be conducted at Biosafety Level 2. Cells that are rendered non-viable (i.e., fixed, lysed etc.) will not pose a risk. This material does not need Biosafety Level 2 containment.

Evaluation of foreseeable effects

hiPSC are pluripotent and are capable of uncontrolled proliferation. Lentiviruses belong to the Retroviridae virus family and are capable of infecting both human and animal species. The lentiviral vector system that will be used is based on HIV-1. Retroviruses are generally transmitted via exposure to contaminated body fluids or percutaneous inoculation and generally not transmitted via the airborne route. Piercing of the skin represents the main potential route by which material could be accidentally introduced into an individual. Appropriate risk reduction measures will be implemented to reduce the likelihood of this occurring. Accidental introduction of iPSC into healthy individuals should not lead to the formation of teratomas because the immune system will rapidly destroy these cells. As mentioned above the pathogen status of some cells is not known. However the material will not be derived from high-risk clinical patients and procedures are in place to deal with needle stick incidents (although no sharps will be used). Individuals with compromised immune systems are not permitted to work with this material. The genetic material to be incorporated into the viral particles is flanked by non-coding retroviral LTRs. No retroviral genes are encoded on this plasmid, minimising the chance any will be packaged into viral particles. As the system requires the co-transfection of three to five additional separate plasmids into a permissive cell line the chance of recombination occurring that leads to the incorporation of any or all of the retroviral genes necessary for the production of a RCL is very low and the risk is therefore low. The lentiviral Expression System includes the following key safety features:

- Only the vector containing the genetic sequence of interest includes LTRs and the packaging signal sequence required for incorporation into viral particles and integration into the genome of a transduced cell. A hybrid 3’LTR is used that does not affect generation of the viral genome in the producer cell line, but upon integration into the genome of a target cell, the 3’LTR SIN which prevents production of viral genomic material that can be packaged and reduces the chance of mobilisation due to secondary infection with wild-type lentivirus. No transcriptionally active LTRs are present in the system and an SV40 polyA sequence is included after the hybrid 3’LTR to reduce the potential for transactivation of cellular genes due to an insertion event that might promote inappropriate gene expression.
expression leading to oncogenic effects.

* The LTR has been modified to enable lentiviral production independent of Tat expression. HIV-1 devoid of Tat is known to be replication incompetent. This decreases the risk of RCL occurring.

* The essential genes encoding the proteins required for packaging of the viral genome are separated onto three to five different plasmids. These express the proteins (gag, pol, rev, env) required to generate viral particles transiently in a permissive packaging cell line (e.g. HEK-293T). Other retroviral structural genes are not present in the system. None of the plasmids have regions of homology which will prevent undesirable recombination. As multiple recombination events would be required to generate a RCL the risk of this happening is very low and has so far not been observed in large-scale production and testing of lentiviral vectors.

* In most systems expression of the gag and pol genes has been rendered Rev-dependent by virtue of the HIV-1 RRE (Rev Responsive Element) in the gag/pol mRNA transcript. Expression requires the presence of rev, which is supplied by a separate plasmid. The Rev/RRE system is highly conserved among lentiviruses and loss of the RRE sequence and associated splice donor/acceptor sequences results in a loss of transduction efficiency.

* Lentiviral vectors have a very low potential to cause immunogenicity.

* The central poly purine tract (cPPT), from the pol ORF, is included in all of the viral vectors that will be used to improve the nuclear import of the proviral DNA and hence accelerate transduction of target cells. Whilst pseudotyped VSV-G is used as the envelop protein to increase the cell types that can be infected this increase in risk is mitigated by the SIN non-replication nature of the viral vectors generated. Due to the random nature of integration into the genome insertional events that disrupt gene function could occur and, in some instances, might lead to undesirable effects which could be oncogenic.

The resultant lentiviral vectors contain about 20% of the original HIV-1 genome. Recombination with wild-type HIV-1 is still potentially possible and could result in mobilisation of the transgene. This is highly unlikely because:

1. Wild-type HIV-1 is not used with in the laboratory environment.
2. Primary cells or hiPSC are not derived from donors either known to be HIV positive or from a high-risk population; so HIV contamination is highly unlikely.
3. Wild type HIV-1 cannot rescue a SIN HIV-1 based lentivirus once integrated into the host genome.
4. It is likely that any recombination would actually decrease the ability of HIV-1 to infect other cells or to replicate.
5. Even if a worker was already or became HIV-1 positive and was accidentally infected with lentiviral vector any recombination would require infection of the same cells. Generation of RCL would require homologous recombination to be in the right regions to enable mobilisation and incorporation to the HIV-1 genome without loss of replication ability. If such a rare event were to occur it is likely to be self limiting and the HIV-1 infection itself is of greater concern to the worker.

The use of lentiviral vectors is an efficient manner with which to deliver genetic material to, and integrate into, the genome of numerous cell types. This stable integration is of great benefit in scientific research. The design of the vectors minimised the chance for subsequent mobilisation of transgenes and inappropriate activation of endogenous oncogenes. Insertional events can lead to harmful side effects but are still very unlikely. As such the greatest risk from these vectors comes with their production where much larger volumes and numbers of vectors are being generated. The risk here is mitigated by the correct use of containment measures and the absence of sharps. Lentiviral vectors are susceptible to dehydration and loss of viability if they are not stored in high protein conditions which reduces the risk to workers and the wider environment.

MV expression system has the following safety features:

1. The vector lacks the rep and cap sequences preventing integration at the specific MVS1 integration site in the human genome.
2. The vector is replication incompetent and only forms epichromosomal double stranded DNA (dsDNA)
concatemers in the nucleus of a transduced cell.

3- In dividing cells this epichromosomal dsDNA is not replicated and gets progressively lost/diluted out in the daughter cells until eventually it is effectively not present in the cell population. In this way the expression system is transient and self limiting.

4- Recombination is highly unlikely as the dsDNA is not replicated and even if it was to occur all of the structural genes have been removed (contained in the cap sequence) and replication is also reliant upon co-infection with another virus that could support this process (e.g., adenovirus). This is a highly unlikely event in the laboratory setting.

The use of MV vectors is an efficient manner with which to transiently deliver genetic material to a wide range of dividing and quiescent cells and in a self limiting manner. There is negligible risk from insertional events. Even if the vector was introduced into a worker the effect would be localised and self limiting. There is negligible risk even if the co-worker had a co-infection with a permissive virus as this would need to be in the same cell and the AAV vector lacks the necessary gene sequence to support capsid generation and hence formation of new virus particles. Additionally wild-type MV is not known to be pathogenic.

Transgenes to be delivered to target cells:

Additional hazards could arise from the properties of the genetic material that will be inserted into the viral vectors and expressed in transfected cell lines, primary cells or hiPSCs.

The introduced SINEUP sequence is aimed to increase the translation of a target gene and can be viewed as potentially the same as introducing the equivalent genetic code (though whether the effect is equivalent is not yet known). As such SINEUPs to growth factors, their receptors oncogenes and proteins associated with disease all carry an increase in risk and must be approved by the SSC before work can commence.

Gene products to be overexpressed may include growth factors, oncogenes and proteins associated with disease. The risk that these represent is minimised by the use of single use aliquots of MV and lentiviral vectors in a controlled biosafety level 2 environment. Any protein to be expressed will require justification to and gain SSC approval before work can commence.

The 'knock-down' of specific gene expression using shRNA can lead to off-target and immunomodulatory responses in vivo. shRNA sequences will be screened against databases of known mammalian/mRNA sequences during the design stage to avoid such complications. Control vectors will also be used that contain a sequence of interest that has been scrambled (scrambled shRNA), and which is not complementary to and therefore does not target any known mammalian sequences. Such sequences are unlikely to pose any safety risks for the environment or human health.

Programmable nucleases: Cas9/CRISPR will be directed against genes of therapeutic interest. In isolation, these sequences are unlikely to pose any safety risks for the environment or human health. Programmable nucleases may be used to generate isogenic controls lines by correcting disease causing mutations back to wildtype sequence. This is low risk because the sequence is aimed to revert back to non-disease forms of the gene. In the case of adding a tag to monitor/follow gene expression there is no anticipated change to the function of the gene and the risk is low.

Reporter genes: Commonly used fluorescent proteins or enzymes under the regulatory control of promoters of interest may be used to monitor effects on cellular pathways. Such proteins are not known to cause any human or animal disease and pose no-risk.

In all cases justification for any target must be submitted to the TranSINE Therapeutics SSC for approval prior to any work commencing.

Summary

Primary human cells and hiPSC will be derived from low risk patient populations but may not be screened for
human pathogens. Only well characterised immortalised cell lines will be used. The lentiviral systems are replication incompetent and SIN, minimising the potential for transgene mobilisation and propagation. The AAV system is transient, non-integrating and replication incompetent, having a negligible potential for transgene mobilisation. The transgenes that will be selected will on their own have a low risk to human health. Infection of mucosal cells may occur via aerosols but is highly unlikely due to the use of microbiological safety cabinets and secondary containment. Such infection is self limiting due to the natural shedding of epithelial cells coupled with the replication incompetent nature of the vectors. The most likely route of accidental infection with an AA V, lentivirus or with an hiPSC line will be via inadvertent percutaneous inoculation via stick injury or open wound. The likelihood of this occurring will be minimised by following standard BSL2 containment practices. Infection of the community and environment with AA V or lentivirus particles is highly unlikely due to the small quantities used, their intrinsic instability and rapid loss of viability with time. hiPSC can not survive outside of the laboratory environment so pose no wider risk. Therefore the risks towards workers, co-workers, the public and the environment associated with the use of these AA V and lentiviral vectors with hiPSC will be low and BSL2 containment is sufficient.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Instead of autoclaving waste in the building we propose to follow the procedure used by the Babraham Institute described in their disposal notification GM1 05/4.1. Reasons for adopting this method of waste disposal are:
1. We do not have access to an autoclave within our area of the building
2. The waste disposal system used by the Babraham Research Campus is safe and has been running since October 2004.

All waste material will be inactivated by treatment with 1 % (w/v) Virkon solution prior to disposal. Waste material will then be placed in sealed bins and incinerated by an off-site incineration company (Vets peed - Their GM authorization is GM898) according to disposal notification GM105/4.1. Waste from our GM work at Class 2 will be placed into suitably labelled hermetically sealable (red lid to distinguish them from class 1 waste) 60 litre UN approved (to Class 3) Type 3H21Y30/S/2003 bins. Sealed bins are placed into secondary 210 litre yellow labelled "Eurobins". Contents of the bin are recorded and collections by the local registered clinical/GM waste incinerator contractor will be made three times a week to prevent a buildup. The site has 24/7 Security. The contractor uses solid bodied transport and carries portable disinfection equipment in case of any spillage. Autoclave facilities will be available in an adjacent building, as required by the Regulations, in case of loss of the contractor's facilities. The type of container and the secondary Euro container means that the risk of any spillage of active GM waste on site is negligible. However, as active waste will leave the site, the risk to the environment and health is possibly marginally higher than autoclaving prior to incineration. The only real risk of release would be as a result of a major RTA, however, the containers are designed to withstand this. This disposal method is expected to achieve 100% inactivation of the GMM.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste Handling
Solid waste will be chemically inactivated by treatment with a 1 % Virkon solution, after which the material will be placed in suitable hermatically sealed bins. These bins are collected from a central point and sent off-site for incineration via a registered waste disposal company. All liquid waste will be inactivated for at least 6 h with a 1 % (final concentration) Virkon solution prior to disposal to drains via a designated sink. These disposal methods
achieve 100% inactivation of the GMM. Virkon is a synergised oxidising system that works by physical destruction of pathogens by acting on proteins. It is resistant to inactivation by organic material. Shown to be effective against bacteria, viruses and fungi including all major human pathogens. Recommended to be used at 1% concentration for all activities. Chemgene HLD4L is formulated as a micelle cleaning technology that enables the active molecules in the product to be carried rapidly through the cell walls or micro-organisms. Swift penetration of the cell walls ensures cell death is equally rapid. Chemgene HLD4L has been reported to be bactericidal, fungicidal as well as virucidal (HIV, hepatitis B, Herpex Simplex, Norovirus and Coronavirus) and sporidical. It is recommended to be used at a 1:100 dilution (1%) for general purposes, 1:20 dilution (5%) for high risk areas, and for disinfection of blood and biohazard spillages.

General cleaning procedures
Surfaces will be thoroughly cleaned with a 5% Chemgene solution (or an equivalent product) at the end of each experiment or after the occurrence of an accidental spillage of infectious material. Application of these antimicrobial agents will totally inactivate any viral vectors that might be present. According to the biosafety literature, all the viruses to be used are susceptible to these disinfectants. Anything that might have potentially come into contact with the virus will be treated with 5% Chemgene before being incinerated.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
It is noted that the primary human cell lines used for the generation of hiPSCs will be taken from patient populations with a known medical history meaning that there is a low risk of material containing harmful human pathogens. This does not rule out the presence of latent viral infection but the use of third or fourth generation integrating lentiviral systems that are self-inactivating and essentially non-mobilisable makes it highly unlikely that infective replication competent virus will be generated. This is important due to the presence of the potentially oncogenic MYC sequence. Additional rounds of lentiviral transduction should not be able to mobilise any genetic elements because self-inactivating systems will be used that lack the necessary genes for viral replication and packaging. As an additional measure the GMSC will have a clear understanding of how each cell line was generated and steps will be taken to ensure overlapping, therefore potential sites for recombination are not present in lentiviral vectors. These vectors are for the introduction of further modifications. Those aimed at correcting disease mutations do not pose a risk to health. The introduction of non-disease causing genetic material for exogenous expression is not seen as a risk either. In the instance where immune-modulators may be targeted the risk, although increased, is well contained by the avoidance of sharps during transduction procedures. Once cells are transduced and virus is removed the risk posed here is very low. The use of iPSC derived from primary human cells and integrating lentiviral vectors dictates propagation, differentiation and further transduction of cell lines at BSL2. Subsequent testing of the cells will also continue at BSL2 although the genetic modification of the cells is of very low risk.

All waste GMM material e.g. cellular material pellets in plastic tubes from centrifugation, will be autoclaved. The procedure to be used will be autoclaving at at least 121 degrees centigrade for 15 minutes. This method has been validated by the manufacturer and the machine itself is serviced by the manufacturer on a regular basis as organised by the BioHub management. When carried out correctly the degree of kill is expected to be 100%. Glassware: Soaked in 1% VIRKON solution overnight and then washed with washing up liquid the next day. Plasticware e.g. tips, will be soaked in 1% VIRKON solution overnight then disposed of in the laboratory waste which is sent for incineration. Effective use of VIRKON is monitored using the scientifically determined standards and protocols (see the VIRKON background information Report, AMTEC 1994). The autoclave is maintained by the manufacturer via 6-monthly maintenance visits where cycles are tested and calibrated. The machine is self-reporting if any errors occur during the cycle and will alert the user if the sterilization was unsuccessful. In the event of an error, the waste will be treated as contaminated until the error is fixed and then run again.

### Please enter comments of the GM safety committee on the risk assessment

**Reviewer 1**

"Emergency procedures
I don’t think the detail is really necessary – what are the chances of the culture being ingested?"

Actions taken by LD: In the section ‘Emergency procedures - Is an emergency plan required?’ The text has been modified to reflect a more practical approach to any spillage which more accurately reflects the risks involved.

"Final containment section
I think there is some confusion about the conclusions as its come out as GM Class 1, but the guidance on the form is clear"

Actions taken by LD: In the section 'Assign your final containment level/GMM Class (1/2)' the risk was correctly assessed as GM class 1 but due to the requirement from the Biohub facility, Containment Level 2 procedures will be implemented at all times. This has been clarified in the text.

**Reviewer 2**

"Soaking pipette tips in Virkon prior to disposal is usually only performed when working with class 2 viral vectors because it can be difficult to safely separate the tips from Virkon. Is the method used in this procedure considered straightforward and safe?"

Actions taken by LD: 'In the section Inactivation of GMMs in waste, and subsequent disposal ' we have clarified the reasons and process for decontaminating tips.

**THE COMPANY DEVELOPS GENE THERAPIES FOR NEUROLOGICAL DISORDERS.**

For activities involving GMMs, describe the waste management measures which will apply to the activity

All solid waste is placed into a double yellow bag and taken offsite for incineration (by Rentokil Initial). Rentokil Initial disposes GM class 1 waste under through Tradebe Healthcare National Limited (at the Rochester Clinical Waste Treatment Facility) under the permit number EPR/WP3036ZR.

Liquid waste will be treated with 1% Chemgene. Supernatants must be siphoned via a pump into a flask containing 1% Chemgene. After finishing work, Chemgene will be added to the flask to 1% and left for at least 60 min prior to disposal. All treated liquid waste is emptied down laboratory sink with excess water.

All experiments using viral particles will be carried out in a Class 2 microbiological safety cabinet, where applicable aerosol-resistant tips will be used.

## Premises Conditions

**Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities**

Yes

**Give brief details of the genetic modification safety committee**

For the purposes of this initial Class 1 application, the guidance of our appointed BSO has been sought to review and approve the Risk Assessment. She is a Chartered member of the Institute of Occupational Safety and Health and a Member of the Institute of Safety in Technology and Research, and previously Chair of the Biosafety Steering Group of ISTR for 4 years.

Recommendations and actions from the Risk Assessment are conveyed direct to staff.

For potential future Class 2 activities, the organisation shall join the on site genetic modification safety committee covering Diamond Light Source (DLS), Research Complex at Harwell (RCaH) and Rutherford Appleton Laboratory (RAL).

For activities involving GMMs, describe the waste management measures which will apply to the activity

All personnel will be trained in the activity. All personnel working in the laboratories are required to wear protective clothing (gloves, lab coat and safety glasses) when working and observe good laboratory practice. No contaminated material will leave the lab other than as waste, including protective clothing, and all surfaces and equipment will be decontaminated after use.

For contaminated equipment that can be reused such as bacterial culture flask, spatula and centrifuge tube will be decontaminated by Virkon solution and then washed with detergent and water.

For disposal of cells & contaminated material/equipment such as bacterial culture dish, pipette tips and one-off culture tubes will be decontaminated with Virkon solution to ensure no risk of live cells remains, then dispose to bio-hazard waste bag/bin for removal to secure local storage, and sent for incineration via a licenced waste carrier. Alternatively, waste is collected into autoclaveable bags, autoclaved and disposed of as non hazardous waste.

Sharps will be placed into a labelled sharps bin, sealed after use and sent for disposal via a licensed waste carrier.

For used culture media, it will be decontaminated by Virkon first to ensure no risk of live cells remains, then pour into the sink.

For maintenance of a clean working environment, free from bacterial contamination, all working surfaces (bench, table, centrifuge, balance) will be regularly decontaminated by Virkon disinfectant. Wash hands before leaving the lab.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment
Webster’s Biosafety Ltd have reviewed and commented on the risk assessment. Webster’s Biosafety has over 20 years experience in reviewing GM and Wild type risk assessments.

#### Project Additional Information

**Purposes of the contained use**

The Rosalind Franklin Institute is a scientific research organisation for the public good. It is primarily funded by the UK research council (UKRI) and Wellcome Trust. The organisation is a charity (regulated by the charity commission) and a company limited by guarantee. The Trustees are drawn from the Industry and Academia. Its researchers are predominantly post PhD with some PhD students. The Franklin has a strict code of safety covering all activity.

The purpose of the contained use is for the Franklin’s work with Hazard Group 2 (HG2) organisms which include those that may be genetically modified. The work would involve the generation, growth, imaging and storage of material. Expression of the material (i.e. protein) will be in either prokayotic or eukaryotic organisms which will be no greater than HG2 and maybe GM material. The expressed material is to be prepared at RFI for usage, primarily imaging. Samples will be generated, stored, imaged and disposed of at the RFI. Assessment will be completed at a local level for every sample. This assessment will detail the experiment to be completed, including details of hosts, vectors, inserts and mutations to be used.

This completed assessment will be submitted to the Genetic Modification Safety (GMS) management committee. This committee is already in operation for all organisations on the "STFC" campus, ISIS, Diamond, Research Complex at Harwell and Central Laser Facility. The attached risk assessment identifies these organisations.
By functioning as part of the established campus system, we will ensure that our procedures meet or exceed these already in operation and approved.

The GMS management committee will review and make a recommendation to the Director of the Rosalind Franklin for proposed organism/sample and work. The Director will then make a final determination as to whether to allow the work by Franklin staff (employees, secondees or students) subject to the correct safety assessments being in place.

No organism or sample that is NOT approved by the GMS management committee will be considered by the Director and no such organism or sample allowed in the Franklin or be permitted to be handled by Franklin staff.

The samples that we be submitted for approval could be any of the following:

- Non-hazardous proteins genetically modified with a tag for structural and bio-chemical characterisation
- Non-hazardous proteins originating in higher than Hazard Group 2 agents classification
- Prokaryotic material from no greater than HG2 classification
- Eukaryotic material from no greater than HG2 classification
- Virus no greater than HG2 classification

The assessment by GMS will include all the proposed work in addition to organism. Only work approved by GMS will be considered by the Director and no other work will be allowed.

Any and all work involving the following will be rejected:

- Any biological agent to be used is classified as HG3 or HG4
- Any biological agent to be used is a SAPO agent
- Any biological agent is listed on ATCSA Schedule 5
- In the case of experiment using multiple live bio-material, there should not have more than one biological agent from the same domain carrying a genetic modification (i.e. the experiment will be rejected where a GM virus is used in co-infection with non-GM/GM virus but will be accepted where an experiment using a GM virus infected a GM mammalian cell line).
- If the genetic modification confers potentially harmful biological activity (e.g. virulence factor, toxin, determinant of immune evasion)
- If the genetic modification increases the pathogenicity and/or fitness of the sample.

Material which is no longer the subject of active study will be destroyed by steam autoclave and disposed of according current regulation.

**Recipient or parental organism**

Any prokaryotic or eukaryotic organisms

**Host/vector system**

Any prokaryotic or eukaryotic organism.

Vector systems used will include vectors from prokaryotic or viral sources. All vectors used will be commercially available and include a replication origin and a drug-resistance gene. All vectors will be avirulent and have a good safety profile (e.g. has a long documented history of safe use) both of which will be evidenced in the GM assessment required to be completed prior to starting any work. For example, bacterial vectors will be non-mobilisable. Viral vectors will be disabled and incapable of establishing a transmissible infection in humans.

A list of prohibitions for the insert is detailed in the CU2 notification.

Work will be prohibited if the parental strain of the GMO is a human HG3 or HG4, even where the modification attenuates the strain.

**Origin & function**
The genetic material will originate from either a prokaryotic or eukaryotic organism. The inserted genetic material will be expressed in either a prokaryotic and eukaryotic system and will not be permitted if it can

- Confer potentially harmful biological activity (e.g. a virulence factor, a toxin, an allergen or determinant of immune evasion)
- Increase its pathogenicity and/or fitness.
- Alter the host range
- Alter the susceptibility to prophylaxis
- Confer potentially harmful activity to the environment
- Increase its survival fitness.

Any work to be completed must not increase the virulence, pathogenicity or robustness of the recipient host (classification up to HG2 prokaryotic or eukaryotic organism)

Manipulation using sharps will be minimised wherever possible, however the use of sharps is unavoidable in some cases (e.g. some imaging tools) Sharps must be handled only by members of staff with experience in and trained for using these tools

Any manipulation of an organism that can cause harm by the airborne route must be able to be handled in a microbiological safety cabinet or the proposed work will be rejected. The Franklin has 12 Class II safety cabinets and these are inspected as per the manufacturers requirements.

If an antibiotic is an option for the treatment of any infection with that organism, it must not be used in the work. (i.e. antibiotic resistance selection cannot use the same antibiotic that could be used for any treatment of an infection with that organism).

**Evaluation of foreseeable effects**

Access to the laboratory is tightly controlled to authorised personnel (managed by photo card swipe). All those entering the labs to work must have completed mandatory training, must have personal protective equipment and completed appropriate risk assessments.

Visitors to the lab areas are only permitted when escorted and must also wear personal protective equipment. All visits are risk assessed and in the event of grant of CU2 permission is given, notices will be displayed prominently at all lab entry points.

The labs are well maintained and regularly cleaned. All biological waste is autoclaved in the laboratory. We do not see any prospect of accidental release outside the lab area. Lab cleaning protocols ensure that any spill inside the lab area is dealt with properly, including disinfection where required.

Exposure to aerosols will be avoided by using sealed flasks, handling in class II safety cabinets, using lysis buffer rather than mechanical lysis methods wherever possible (where this not possible any such mechanical lysis will be inside the safety cabinet).

No specific additional hazards are foreseen to arise from our work since we are not creating new pathogenic traits as any mutation must not confer any pathogenic traits or alter the host range.

No specific hazards are envisaged as the inserted material will have been scrutinised to ensure it does not encode any hazardous products.

Finally to avoid transfer of genetic material, in the case of experiment using multiple live bio-material, there will not be more than one biological agent from the same domain of life carrying a genetic modification as part of the experiment. All material no longer subject to study will be destroyed. Any material that is stored will be kept to the absolute minimum required for further experiments.
No use of larger GMOs will take place

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation measures required

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

<table>
<thead>
<tr>
<th>The work will produce both solid waste and liquid waste. Solid waste: Will be treated by disposal of into autoclave bags or bins and autoclaved in a cycle validated by a 12 point thermocouple test prior to either off site incineration or disposal to landfill. In the case of lab coats, they will be treated by autoclaving in a validated cycle followed by washing in the general laundry route. Autoclaves are serviced and validated annually. Liquid waste: Will be treated in one of the following ways depending on the concentration and organism in use.</th>

Please enter comments on the GM safety committee on the risk assessment
The enclosed risk assessment is broad overview that can be used to guide future individual assessments. It is based upon a previous CU2 application accepted by HSE on the 4/09/2019 with the reference GM972/19.1. The GM972/19.1 application was accepted on the basis of future support and review to be provided by the site GMS management committee of which the RFI has become a member. As such, all future work will first be reviewed through the site GMS management committee a well established GM and BioSafety committee supporting work on the Rutherford Appleton Laboratory Site. The committee is composed of representatives from Diamond Light Source (DLS), ISIS, Research Complex at Harwell (RCaH), Central Laser Facility (CLF), STFC, partner companies, universities and RFI with support from our consultant BioSafety Officer, Sharon Webster. Some of these representatives are also members of the onsite safety, health and the environment (SHE) group (https://staff.she.stfc.ac.uk/pages/staff/home.aspx). All work will have an individual supporting GM/bioCOSH assessment that requires approval from the aforementioned GMS management committee before it can take place. This will enable a consistent and coordinated approach to all notifications and risk assessments completed by staff in the member institutes.

Solid waste will be inactivated with overnight soaking in 10% Distel solution, before being placed in sharps bins and biohazard-marked bags, which will be sealed and collected by Initial Medical Services for incineration. Liquid waste will be sterilised by the addition of Virkon tablets or 10% Distel solution in leak-proof containers. This will be left to stand overnight before discharge to drain. Expected degree of kill is 100%.

CU2 Project Title Use of retroviral and lentiviral vectors to transduce murine and human cells

Class 2

CultureVolClass2 < 1 Litre

Class VolumeClass3-4 Non-GMM Consent Granted
**Project Additional Information**

**Purposes of the contained use**

The overall aim of this project is to generate genetically modified murine and human cells in vitro, for example but not limited to Chimeric Antigen Receptor (CAR)-T and CAR-NK cells, which will be used in combination with CytoSeek’s technology for in vitro and in vivo pre-clinical studies. All genetic modifications will involve the addition of a targeting receptor for a tumour antigen, and will not involve inserting any known oncogenes. CytoSeek’s technology, which consists in adding artificial membrane-binding proteins on the GM cells, will not alter the potential risks of the generated GMOs. In adoptive cell therapy, immune cells are genetically engineered to express a receptor targeting a defined antigen, allowing the activation of the cells by this target antigen. Engineering of T cells and other immune cells in this manner has implications in the treatment of liquid and solid tumours. The use of viral vectors will allow the generation of engineered immune cells that target tumour associated antigens. Genetically modified immune cells will be combined with CytoSeek's technology and their safety and efficacy will be tested in vitro and in vivo using mouse models of cancer. It would not be possible to effectively assess the functionality of the technology in vitro or in vivo without using GM cells in this way. This study will generate data relevant to clinical application. The work is significant as the technology being developed by CytoSeek is the first of its kind and may be useful in medicinal therapies that use genetically altered immune cells.

**Recipient or parental organism**

We will genetically modify three types of cells:

1. **Bacteria**: standard laboratory strain of E. coli will be transformed with recombinant plasmids, containing genes that encode for tumour antigen-specific receptors (CARs), and/or retroviral/lentiviral genes, as well as genes providing antibiotic resistance genes to the bacteria to aid selection. This will facilitate molecular cloning and allow us to grow up sufficient quantities of plasmids for transfection of packaging cells (e.g. 293T cells). The competent bacteria used are commercially available.

2. **Retroviral and Lentiviral packaging cell lines** such as the human HEK293T cell line and its derivatives (e.g. Phoenix Amphi cell line, Phoenix-Eco cell line containing chromosomally integrated helper functions and encoding amphotropic or ecotropic envelope proteins respectively, and 293FT cells for co-transfection with helper plasmids in lentivirus rescue).

3. **Human and mouse immune cells** (eg T and NK cells) and mammalian cell lines (eg Jurkat) will be transduced with the above recombinant retroviral/lentiviral vectors.

**Host/vector system**

Replication-defective, genetically modified retroviruses (MoMuLV- or derived), with amphotropic or ecotropic envelopes, and 3rd generation self-inactivating (SIN) lentivirus vectors.

The retrovirus system uses two plasmids, the pMP71 retroviral expression plasmid that carries the CAR transgene, and a pCL Amphi or Eco packaging vector to increase expression of the appropriate envelope protein in the packaging cell line. These plasmids are transfected into the Phoenix packaging cell line. The Phoenix Amphi cell line is a high titre amphotropic retrovirus-producing cell line that was generated by stable transfection of 293T cells with a Moloney GagPol-IREs-Lyt2 construct with a Rous sarcoma virus (RSV) promoter and a pPGK hygro selectable marker. 293T cells are human embryonic kidney cells transformed with the E1 region of adenovirus type 5;
and subsequently also stably transfected with SV40 T-antigen. These cells were then stably transfected with the Moloney amphotropic envelope gene (Phoenix-Ampho) or ecotropic envelope gene (Phoenix-Eco) driven by a CMV promoter and coselected with a diphtheria toxin resistance gene (pHED-7). The separation of the gag-pol and the env plasmids within the Phoenix cells is designed to ensure a very low likelihood of generating replication-competent retrovirus.

The lentiviral system uses four plasmids, where Rev and Gag/pol genes have been separated on two separate plasmids, with the third plasmid encoding envelope proteins. The Tat gene has been deleted. The transfer plasmid will contain the transgene of interest (eg CAR gene) driven by a promoter (eg human elongation factor 1 alpha promoter (EF1alpha)). The plasmids are as described in the attached risk assessment.

These split packaging systems are designed to minimise the chance of recombination events that could incorporate the helper functions to generate a replication-competent virus. For lentivirus, only “self-inactivating” (SIN) vectors will be used; these have a deletion within the U3 region of the 3’LTR, which removes enhancer and promoter sequences. Upon completion of one life-cycle from the RNA genome of the virus particle, via reverse transcription to integration into chromosomal DNA, the deleted U3 region is copied to the 5’LTR. As a result, the 5’LTR becomes incapable of transcribing full length viral genomes. This further reduces the possibility of onward viral transmission. Lentiviruses will generally be pseudo-typed using the VSV-G envelope glycoprotein; this is widely used as it permits efficient transduction of a wide variety of cell types and makes the virus particles relatively resistant to shear stress, facilitating their concentration by centrifugation if required to increase the titre.

Origin & function

The sequences that will be inserted into recipient eukaryotic cells will include chimeric antigen receptors (CAR) as described in the attached risk assessment. In general, the CAR constructs will contain:

- a sequence encoding a receptor able to specifically recognise a tumour-associated antigen (eg a single chain variable fragment (scFv) constructed from a tumour antigen-specific mouse antibody). Other examples are in the attached risk assessment;
- a hinge region (eg from CD8);
- a transmembrane region (eg from CD8 or CD28);
- a series of intracellular signalling moieties, including costimulatory domains (eg from CD28 and/or 41BB), followed by CD3ζ.

The plasmids containing the tumour-targeting construct and the retro/lentiviral genes will be expanded in competent bacteria and purified to transfect packaging cells that will allow the formation of the viral particles.

Viral particles will be harvested from the supernatant fraction of the packaging cell cultures and may be concentrated to transduce human and murine immune cells.

Human and murine immune cells, for example but not limited to primary T and NK cells from peripheral blood of healthy human donors or murine models, and mammalian cell lines, will be transduced with the viral stock solution containing a pure recombinant, replication-defective lentivirus/retrovirus population. The integration of the tumour-targeting construct in the genome of human and murine cells will enable these cells to stably express this receptor and thereby respond to a specific tumour-associated antigen.

Evaluation of foreseeable effects

None of the proposed genetic alterations are expected to cause a significant increase in the risk to human health or to the environment. As with any retroviral vector, there is the potential hazard of generating a replication competent virus by recombination with helper sequences in the packaging cells. However this risk has been minimised by the design of the “split” packaging cells used, and by the use of equivalent split helper functions, and SIN vectors, for lentivirus vectors.

Retrovirus and lentivirus infection also carries an associated risk of insertional mutagenesis. Such insertional mutagenesis has resulted in oncogene activation and leukaemia in some patients in a gene therapy clinical trial for X-SCID, however this was in the context of deliberate administration of very high doses of virus expressing the cytokine receptor gamma chain to haematopoietic stem cells. The lack of such adverse effects in the vast majority of other gene therapy trials including a large number of CAR T cell therapy trials using retroviral or lentiviral systems and involving hundreds of patients, indicates that the chromosomal insertion of replication-defective forms of these viruses is generally unlikely to cause overt harm.
The retroviruses or lentiviruses will be used in vitro to transduce human or mouse immune cells or cell lines (e.g. Jurkat) which are not known to carry any other virus and which are not expected to complement the replication-deficiency of the vectors. The Phoenix cells are widely used and any adventitious retrovirus contamination of these cells would have been widely publicised if the problem had arisen. There is a substantial history of safe use of such vectors in these and other human cells, with no apparent interaction with the endogenous, ancestral, degenerate retrovirus-like sequences in the human genome. If the vectors or cells transduced with the vectors are used in mice, there is also a theoretical risk of complementation/recombination with endogenous viruses, but again there is a substantial history of safe use of such vectors.

The introduction of CAR genes into T lymphocytes should result in expression of the CAR at the cell surface and could potentially result in activation of the T cell if it encounters the target antigen. The CARs used are specific for tumour-associated antigens, so activation is more likely to be beneficial to the host rather than harmful, although if the target antigen is expressed on healthy cells this could result in immune-mediated pathology in the host.

In all cases, cells derived from the operator will not be used in these studies and therefore should the operator be accidentally inoculated with any of these genetically modified cells they will be identified as “foreign” cells and eliminated by the host’s immune system. For the same reason any murine genetically modified cells generated in this project will provide no additional risk to human health. Pregnant women, new mothers and/or immunocompromised employees will not handle lentiviral and retroviral vectors.

If the viral vectors were introduced directly into the host by accidental exposure and transduce T cells in situ this could result in autologous T cells with auto-reactive potential. Although transduction in this manner is likely to be very inefficient, it is important that sharps are avoided when handling the virus vectors to control the risk of injecting yourself. The main hazard with these viral vectors is the possibility of oncogene activation at the site of integration. Consideration of the experiences from human gene therapy clinical trials suggests this risk is particularly low when using T cells as the host, and any accidental exposure of humans to recombinant virus is likely to involve many logs fewer virus particles. Nevertheless precautions to avoid exposure are appropriate.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N.A.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None. CytoSeek has access to an autoclave on site at Unit Dx and the University of Bristol if needed.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Contaminated pipette tips, serological pipettes, cell culture plates, flasks, tubes and similar plasticware will be collected in a class II cabinet within a category 2 laboratory, where it will be inactivated with overnight soaking in 1% Virkon solution. After overnight soaking, disinfected plasticware will be rinsed and disposed of within biohazard-marked 60L sharp bins. Sharps will be contained within the same sharp bins. Sharp bins will be sealed and collected by a specialised clinical waste licensed contractor for incineration. Soft waste, such as hand towels and gloves, will be collected in hazard-marked bags which will be disposed of by incineration off-site after collection by a licenced contractor. If any soft waste is known to be contaminated with virus (e.g after a spill), this will be soaked overnight in 1% Virkon before disposal in hazard-marked bags. Liquid waste will be collected in 1L sealed buckets in a class II cabinet within a category 2 laboratory and inactivated overnight by the addition of Virkon to make up 1% solutions. Deactivated liquid waste will be then discharged to drain.

The manufacturer’s information indicates efficacy of Virkon against HIV (at dilutions from 1:100 – 1:1400), and against the oncovirus Avian Leukosis Virus (at 1:200). CytoSeek has access to an autoclave on site at Unit Dx. Autoclaving achieves effectively 100% kill of all GMMs.

**Is an emergency plan required according to regulation 20?** N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

02/03/2022  Page 14954 of 15326
Our biosafety committee has reviewed the attached risk assessment and concluded that the measures outlined should adequately control the hazards in this project, which is suitable for assignment to class 2.

02/03/2022
The GMO is a Recombinant Adeno-Associated Virus.

Inactivation Methods:
1) Trained staff will use a specific GMO spill kit and wear appropriate PPE. This includes: Safety Glasses, FPP2 Face Mask, Labcoat, and Shoe Covers.
2) In the event of a breakage, any broken glass will be collected using a disposable scoop and placed into clinical waste bags.
3) Absorbent paper will be used to soak up any liquid. This will be repeated until there is no liquid in the contaminated area. Contaminated absorbant paper will be placed into clinical waste bags.
4) Hypochlorite/chlorine bleach will be poured over the contaminated area and left for 20 minutes.
5) The area will then be thoroughly wiped with water to remove any traces of disinfectant.
6) Any wipes or other cleaning materials which came into contact with the spill will be placed into clinical waste bags ready for destruction.*
7) Items from the GMO spill kit which are used during clean-up will be replaced to ensure the contents of the kit are appropriate for next use.
   * Xerimis Ltd. have a service agreement with a destruction company who are able to dispose/destroy infectious clinical waste.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Receipt, Storage and Distribution of a GMO to UK clinical sites on behalf of a sponsor company.

3) Packaging Room Supervisor.
4) Distribution Support Coordinator, Dangerous Goods trained (IATA)

The GMSC group worked through a Failure Mode and Effects Analysis (FMEA) risk assessment process, identified risks were scored and mitigating actions identified, in review of the residual risks post implementation of the mitigating actions, no high risks remained. The remaining risks were for the majority to be determined low, with a few medium risks, with the controls in place these remaining risks were deemed by the committee to be acceptable.

The GMO is a Recombinant Adeno-Associated Virus which is pre-packed before entering the facility. The sponsor company anticipates less than 50 active patient kits will be supplied to Xerimis UK.

☐
1. Waste such pipettes, stripettes, falcon tubes, eppendorfs etc. are treated as "biologically hazardous" and collected and incinerated off-site by a waste disposal company accredited to manage hazardous material.

2. Sharps used for the dissection of tissues are disposed of in the assigned sharps disposal container. Plus their use is reduced by the usage of scissors.

3. Live cells and culture media waste is decontaminated with 3% Virkon for more than 2 hours and washed down the sink under running water.

For activities involving GMMs, describe the waste management measures which will apply to the activity

- Sendai virus reprogramming kit CytoTune is class 1 GMO organism. This kit has been developed to reprogram somatic cells into induced pluripotent stem cells ad it is available from Thermo Fisher Scientific and has been widely use for cell biology research. The kit and lines produced have been used for several years and are also though to be safe.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Effective inactivation and disposal of waste containing genetically modified organisms will be done as follows:

-Solid waste: All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored by continuous chart or digital recording of the temperature/time profile. Waste will be transported in sealed containers and following autoclaving, the resulting non-hazardous waste will be packaged into "Biohazard"-labelled bags and be sent for incineration following local regulations.

-Liquid waste: All liquid waste generated will be aspirated into a bottle containing Virkon, a peroxygen based disinfectant, which will be used according to the manufacturer's instructions. Following a 24-hour chemical inactivation, the resulting non-hazardous waste will be disposed of in an excess of water.

Tick to confirm that you are attaching a summary of the risk assessment  Y

Solid wastes and small volumes of liquid are disposed of in dedicated lined yellow plastic snap-top 60L bins that are treated by autoclaving at 121 degrees C for 15 minutes in the contained use laboratory. An indicator strip is included with each autoclave run to monitor peak temperature of each run. Bins are numbered and collected by a third party waste disposal company for incineration off-site. Paperwork is signed off upon collection of designated, autoclaved laboratory waste. Liquid wastes including microbiological cultures are inactivated by contact with 1% bleach (working final concentration) for 1 hour before disposal down the designated laboratory sink. Laboratory surfaces are wiped down at least daily with chempgene first followed by 70% ethanol. Swabs will be taken from designated locations/surfaces of the laboratory twice a year with growth on agar and agar supplemented with the antibiotics ampicillin and kanamycin (swabs on two separate plates). Results from these swabs to be documented with any mitigation requirements noted for areas that are identified as having a detectable level of contamination with presumed GMM organisms.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

All experiments to be conducted on site involving GMMs are considered to fall under Class I. As such, standard good laboratory practice applies with a defined waste disposal methodology and safe methods of work documented within the companies risk assessment and SOPs.

**Project Additional Information**
The proposed work will identify gene modifiers of dysregulated processes that result in poor outcome of steatotic liver transplants. This will involve interrogation of gene candidates utilising standard overexpression and knockdown viral vectors, e.g. lentiviral vectors encoding the gene of interest or vectors expressing CRISPR systems that target genes for inactivation. The impact of these genetic edits will then be assessed using in vitro and ex vivo systems.

Recipient or parental organism

The recipients include

(a) bacterial cultures to enable growth of the DNA required to produce the viral vectors. E.coli (K12 or B derivatives) are disabled and unable to colonise the human gut and have a history of safe use and can be assigned to ADC hazard group 1. The vectors are non-mobilisable. The inserted genetic material does not increase the level of risk for the GMMs.

(b) mammalian cell cultures (e.g. human hepatoma cell lines) These are are well characterised, continuous cell lines that have an established history of safe use (regarded as low hazard for GM activities and are suitable for use under containment level 1, though are handled at containment level 2 for CoSHH regulations), and additional modification are not considered capable to increasing the risk of these cells lines.

(c) primary human cells (e.g. hepatocytes) These are less well characterised but are considered especially disabled hosts under the Genetic Modification Regulations and are therefore of minimal risk (considered to be ADCP hazard group 1). However, due to the potential presence of adventious agents they are handled at containment level 2 under CoSHH regulations and additional control measures are included (e.g. the requirement of HepB vaccination and records of training) - this risk is reduced through the use of prescreened donors negative for HIV, HBV and HCV.

Host/vector system

For this work self-inactivating, third generation lentiviral system will be used, generated by transient transfection of the human 293T cell line. Although this vector system is based on the pathogenic human immunodeficiency virus, it has an excellent safety rating due to the removal of accessory genes, the lack of expression of any viral genes in transduced cells, the split production plasmids with no homology to prevent the recreation of replication competent retroviruses and reduced insertional mutagenesis though mutation of the viral U3 promoter. However, the vector does incorporate the WPRE, elevating its potential for tumourogenesis due to the presence of a truncated HBV X protein, is pseudotyped with VSV-g to increase its tropism, and the transgenes used in this proposal (human genes and components of the CRISPR system) increase the risks of altered cellular behavior (both cell death and tumourogenesis) if exposed and transduced by these vectors.

Origin & function

Genes for overexpression will be of human origin generated from cDNA, and as such will not be toxins but do have the potential to act as oncogenes or other modifiers of cellular behaviour in cells that are transduced by the vector.

CRISPR components (e.g. Cas9 and sgRNA) are of bacterial origin and are designed to introduce a mutagenic double stranded break in the human genome. Gene targets could include tumor suppressor genes, thereby increasing the risk of tumourogenesis associated with the vector. However, the two components will be separated into two vectors in order to reduce the likelihood of this event (i.e. it would require dual exposure to result in this event).

Evaluation of foreseeable effects

The bacterial used in this proposal are disabled and introduction of additional plasmids for their upgrowth does not alter their risk to the environment or human health.

The use of third generation lentivirus systems has many advantages, notably all accessory genes are removed and the essential viral proteins, gag, pol, and rev are provided in trans by additional plasmids (optimised to harbour no homology) and the envelope gene is replaced with VSV-g, all of which reduce the likelihood of producing replication competent or infectious virus effectively to zero (and there is no documented evidence of this occurring in third-generation systems). However, upon transduction of a cell the genetic vector is integrated at random into the host genome, which has the potential to disrupt the expression of a host gene or to enhance the expression of neighbouring genes through insertional mutagenesis, and the use of the VSV-g envelope expands the cell types that the vector can access. Additionally some vectors harbour the WPRE to enhance transgene expression. The WPRE may result in the expression of the HBV X protein, which as been associated with tumourogenesis in
certain models. The impact of these insertional mutagenic events is reduced through the use of self-inactivating vectors in which the viral promoter is mutated, and standard laboratory safety measures (class II safety cabinets, PPE etc), not producing large quantities (>1l) of virus or concentrating viral stocks to very high titre (not >100 fold), and not using sharps in any procedure involved with vectors makes the use of these vectors of negligible risk on their own. Finally, they are self-inactivating so do not increase the risk of cells transduced by them, so such cells/cell lines can be considered of the same category of risk as the parental cells (generally class 1 for cell lines and class 2 for primary cells).

That said the transgenic inserts that are carried to the recipient cells using lentiviral vectors do increase the potential risk to human health. The overexpression of human genes can have numerous impacts but importantly could act as oncogenes, immunomodulators, apoptotic regulators etc, all of which can enhance the potential for tumourogenesis. Additionally the use of the CRISPR system to target gene inactivation not only has the potential to eliminate important tumour suppressor control elements of the cell but also act as a general mutagen through off-target double strand break induction. However these risks would only be realised through self-inoculation through percutaneous or mucosal routes that are minimised through the elimination of sharps usage during vector procedures, use of good laboratory practice and PPE, and ensuring adequate documented training.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste i.e. consumables such as plasticware eg pipettes, flasks, tubes are rinsed in 5% chemgene or 10% distel prior to being autoclaved using a make safe cycle as specified in BS 2646, Part 3, 1993 (134-138oC for at least 15 minutes). Any excess sterilised liquids will be discharged to drains and the resultant sterile waste is disposed via the industrial (black bag) waste stream for incineration to produce electricity (Select environment Ltd) or clinical waste stream for incineration.

Liquids (eg samples, culture supernatants, tissue culture media) are exposed to a final concentration of 2% Virkon/ 10% distel/ or 2% chemgene for 30 minutes at room temperature prior to discharge to drains.

Agar plates are autoclaved using a make safe cycle as specified in BS 2646, Part 3, 1993 (see above), excess liquid discharged to drains, and solids discarded via the black bag waste stream for landfill.

All GM containing material must be deactivated or decontaminated before leaving the premises. Sharps bins containing GM material, that has not been decontaminated prior to being placed in a sharps bin, must be autoclaved before being placed in clinical waste.

Degree of kill
Autoclaving, effectively 100% kill (annual validation)
Incineration, effectively 100% kill (licensed incinerator)
Chemical, effectively 100% kill (following manufacturer’s guidelines)

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form  

Tick to confirm that you have attached a risk assessment to this form  

02/03/2022  
Page 14973 of 15326
We don't use 10% distel or 5% chemgene or 2% trigene as disinfectant in TC lab, its % Virkon and 70% ethanol. The autoclave waste discard cycle here is 134C for 15 minutes not 5 minutes mentioned in the RA. The black bags are collected by Select environmental Ltd and are not landfill but incinerated to produce electricity.

All GM containing material must be deactivated or decontaminated before leaving the premises. Sharps bins containing GM material, that has not been decontaminated prior to being placed in a sharps bin, must be autoclaved before being placed in clinical waste. This should be written in the waste procedures.

02/03/2022
For activities involving GMMs, describe the waste management measures which will apply to the activity

1. RVC will arrange for collection and disposal of Domestic and Hazardous Waste Disposal via appropriate licensed contractors. Axovia are responsible for sorting their waste into the correct waste stream (hazardous/offensive/domestic) to comply with local RVC rules. RVC will provide training on identification of appropriate waste streams.

2. Solid waste - Treatments used Autoclave, Chemical and Incineration
   Disposables used in aliquotting the vector (ependorphs, pipette tips) and injecting the vector (glass micropipettes, needles). Animal carcasses will be disposed of via incineration.
   Any materials that contain or have come into contact with viral particles will be decontaminated by soaking in the DEFRA-approved virucide TriGene Advance 10% for 5 minutes and then subjected to autoclaving. Autoclaving (132 degrees celsius, 15 minutes holding time) will give 100% kill at this temperature and time. Animal carcasses will be disposed of via incineration.

3. Liquid Waste - Treatments Used Autoclave, Chemical.
   The vector will be aliquoted into 10 ul volumes and stored at -80 degrees celcius. Between 5-10 ul will be injected in vivo. Any spare vector will be disposed.
   Any materials that contain or have come into contact with viral particles will be decontaminated by soaking in the DEFRA-approved virucide TriGene Advance 10% for 5 minutes and then subjected to autoclaving. Autoclaving (132 degrees celsius, 15 minutes holding time) will give 100% kill at this temperature and time.

Tick to confirm that you are attaching a summary of the risk assessment [ ]

Tick if you are claiming exemption from disclosure for sections of the risk assessment [ ]
In accordance with regulation 3 of the Management Regulations 1999, risk assessments are required for all Axovia Activities.

Axovia shall be responsible for:
• Providing risk assessments for all of Axovia activities.
• Circulating copies of all authorized Risk Assessments to the RVC Area Safety Supervisor.
• Ensuring RVC staff involved in Axovia activity have received appropriate risk assessment training.

RVC shall be responsible for:
• Providing risk assessments associated with husbandry of standard rodents
• Providing risk assessments associated with BSU shared areas

Purposes of the contained use

Bardet-Biedl Syndrome (BBS) is a rare genetic condition that presents complex clinical manifestations, where multiple systems are affected; polydactyly, retinal degeneration, cystic kidneys, obesity, auditory deficiencies and. Perhaps the most clinically relevant feature is the retinal degeneration that appears progressively starting as night blindness and progressing to complete loss of sight and registered blind usually before puberty. So far 18 genes have been linked with BBS and most of them form complex known as BBS that is involved in the function of the cilium.
The particular and molecular mechanism of how and why the retina degenerates progressively still remains unclear. So far all knock-down mouse models lacking complete BBS gene function, reproduce the same pattern of the human progressive degeneration. In this project we have aim to a new gene therapy approach to for the study and treat the loss of sight. We have to our disposition a new knock-in BBS1 M390R knock-out mouse lines both replicating the human retinal phenotype. To pin point how the retinal function improves with gene therapy we propose to use to treat them with intravenous injections of adeno-associated virus (AAV), as vectors containing a human wild-type copies.

Viral vectors also often incorporate reporter proteins that allow us to determine the success and extent of expression, as well as offering the possibility to trace the anatomy of retinal cells affected by experimental perturbations. Two main questions will be answered by this project; first, which are the molecular functions involve in the death of retinal cells and how good is our gene therapy restoring the photoreceptors and the different layers of the retina.

The assessment should review for the first time the future use of AAV as a genetic vector in the Procedure rooms at the Biological services, located at LBIC and RVC. The new activity risk assessment will include the perinatal injections on GM mice and the cleaning and disposal of bench, material, tools and animal carcasses.

Recipient or parental organism

Adeno-associated virus (pAAV). Note that vectors will not be handled, as the already-packaged virus particles (replication-deficient).

Genetic modified mice with gene modificaton to mimic ciliopathies and BBS.

Host/vector system

The host are the genetic modified mice and the vector system will be the adeno-associated virus (AAV).

Origin & function

H.sapiens cDNAs will be cloned or purchased with the aim to replace mutated gene expression in the GM mouse models.

Evaluation of foreseeable effects

None of these are hazardous as they are replication deficient virus particles. The donor organism is not pathological or pathogenic. While AAVs can survive in the environment for protracted periods of time (they are resistant to dehydration). However, they would not be able to replicate in the absence of helper viruses (which are not used in the process of virus packaging - see above) or other helper functions.

Insertion of the gene sequences listed above will not affect the pathogenicity or toxicity of the AAVs. Transmission of AAV can occur through ingestion, inhalation of aerosol droplets, mucous membrane contact and accidental injection. However, for all of the above reasons, the AAV will be unable to replicate.

The infected cells (which might be in the epithelia or lung) will only express the recombinant protein transiently.

When transduced secondary cells divide, the expressed protein is diluted and quickly lost. We are also highly trained in the use of 'sharps' under aseptic conditions.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Mouse Handling-

All animal handling is performed according to Home Office guidelines and local area safety codes. Suitable training in the form of a Home Office approved animal handling
course is provided for all individuals working with animals. Protective clothing, masks and gloves are worn. Additional respiratory protection is available for allergic individuals to reduce exposure. Western labs/UCL Central facility users will have the standard six monthly health check. Regular lung function tests are monitored by Occupational Health. Occupational Health advice and protocols will be followed in the event of sensitisation. If an individual is significantly sensitised, all contact with live animals/ animal dander will be avoided and a substitute person will undertake parts of the research requiring direct animal contact.

Use of Mouse Tissues-

Mouse tissues will be collected by a personal licence holder or staff once they have attended the Home Office approved animal handling course and passed to staff, in order that exposure to allergen is minimized. Use of needles and other sharps will be minimized. Gloves, lab coat and protective eye wear will be worn at all times whilst handling specimens. Any cuts or abrasions will be covered with Elastoplast or similar material. Additional respiratory protection is available for allergic individuals to reduce exposure. Facility users will have the standard six monthly health check. Regular lung function tests are monitored by Occupational Health. Occupational Health advice and protocols will be followed in the event of sensitisation. If an individual is significantly sensitised, all contact with live animals/ animal dander will be avoided and a substitute person will undertake parts of the research requiring direct animal contact. Solid waste material will be disposed of into designated waste bags and then autoclaved before being incinerated. Any liquid waste will be treated with sodium hypochlorite solution before disposal.

Other personnel: Hazardous waste will be properly bagged, labelled and removed from the labs to allow safe disposal by cleaning staff. Maintenance staff and visitors may enter the lab only by appointment with the lab manager and will be accompanied by trained personnel of the facility.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

1. RVC will arrange for collection and disposal of Domestic and Hazardous Waste Disposal via appropriate licensed contractors
   Axovia are responsible for sorting their waste into the correct waste stream (hazardous/ offensive/ domestic) to comply with local RVC rules.
   RVC will provide training on identification of appropriate waste streams.

2. Solid waste- Treatments used Autoclave, Chemical and Incineration
   Disposables used in aliquoting the vector (ependorphs, pipette tips) and injecting the vector (glass micropipettes, needles). Animal carcasses will be disposed of via incineration.
   Any materials that contain or have come into contact with viral particles will be decontaminated by soaking in the DEFRA-approved virucide TriGene Advance 10% for 5 minutes and then subjected to autoclaving. Autoclaving (132 degrees celsius, 15 minutes holding time) will give 100% kill at this temperature and time. Animal carcasses will be disposed of via incineration.

3. Liquid Waste- Treatments Used Autoclave, Chemical.
   The vector will be aliquoted into 10 ul volumes and stored at -80 degrees celsius. Between 5-10 ul will be injected in vivo. Any spare vector will be disposed.
   Any materials that contain or have come into contact with viral particles will be decontaminated by soaking in the DEFRA-approved virucide TriGene Advance 10% for 5 minutes and then subjected to autoclaving. Autoclaving (132 degrees celsius, 15 minutes holding time) will give 100% kill at this temperature and time.
In accordance with regulation 3 of the Management Regulations 1999, risk assessments are required for all Axovia Activities. Axovia shall be responsible for:

- Providing risk assessments for all of Axovia activities.
- Circulating copies of all authorized Risk Assessments to the RVC Area Safety Supervisor.
- Ensuring RVC staff involved in Axovia activity have received appropriate risk assessment training.

RVC shall be responsible for:

- Providing risk assessments associated with husbandry of standard rodents.
- Providing risk assessments associated with BSU shared areas.

Please enter comments on the GM safety committee on the risk assessment

Give brief details of the genetic modification safety committee

Mellizyme have sought advice from GMBSC Ltd Biosafety consultancy who will act as our GMSC. Our Advisor was a former Principal Specialist Inspector of Biological Agents for HSE and a University BSO and so is well equipped to advise our biological health and safety needs. GMBSC Ltd will work with two of our Lead Scientists to develop comprehensive GM Risk assessments which will be reviewed on a quarterly basis (or more frequently if the need arises).

Page 14983 of 1532
Autoclaving is the preferred route for inactivation of GMMs and where possible, cultures will be inactivated in the autoclave located in LSP wash up room at 121°C for 20 minutes. The autoclave is serviced, calibrated and validated once a year by Select Engineering Services, 13 Hurst Close, Over Hulton, Bolton BL5 1DT. Inactivated cultures will be poured down the laboratory sink and flushing copiously with water.

Where autoclaving is not possible, Virkon disinfectant will be added to final concentration of 1% w/v and left for at least 8 hours before being poured down the laboratory sink and flushing copiously with water.

Contaminated single use pipette tips are placed into yellow "Bio-Bins" for incineration. These are labelled and sealed before they leave the laboratory.

Contaminated plates and single use tubes are disposed of via yellow incineration bags, labelled and sealed with a cable tie. These are transported to the appropriate clinical waste bins in IC1, Liverpool Science Park in a clearly marked UN-compliant CL2 transport container.

Glassware will be disinfected with 1% w/v Virkon disinfectant and left for at least 8 hours before being poured down the laboratory sink and flushing copiously with water. The empty glassware will then be sterilised by autoclave.

Virkon is a safe and effective decontaminant shown to be active against 300 + strains/clinical isolates from 71 bacteria and resulting in >5-log reduction in viable organisms when used as a 1% dilution (Hernandez et al., 2000 [J. Hosp. Inf. 46(3)203-209], ‘Virkon Background Information’ https://www.fishersci.co.uk/webfiles/uk/webdocs/SLSGD05.PDF).

Chemgene will be used as an alternative to Virkon. It is a high-level laboratory surface disinfectant combines enhanced active ingredient molecules with micelle cleaning technology to provide swift penetration of the cell walls to ensure rapid cell death. The synergistic blend of technology and active ingredients enables Chemgene to work quicker than most disinfectants and ensure that apoptosis (cell death) is achieved rather than merely suspending activity. Chemgene is a safe and effective decontaminant shown to be active against E. coli K-12 cloning strains when using a 2% solution (Technical details can be obtained here: http://medimark.co.uk/industry/product/chemgene-hld4l-laboratory-disinfectant)

I have reviewed the proposed work and conclude that class 1 is appropriate. The initial proposed work involves using disabled E.coli strains transformed with fluorescent protein markers, which is of no or negligible risk to human health or the environment. I have requested that the users include information on the mobilisation status of the plasmid vectors to be used.

As this is the first genetic modification project to be undertaken by the company, this risk assessment should be submitted to HSE along with a CU1 notification form to register the premises for GM work.

Once KTE-X19 is administered to the patient, empty bags and the used delivery system components (e.g., guide tube, cannula, injection needles and syringes), gauzes, personal protective equipment (e.g. gloves etc.) and any other components that have been in contact with the product before and during administration will be disposed of as medical waste. Spillage of product will be treated with 10000ppm free chlorine solution as per local biological product spillage guidance. Unused product will be returned to the manufacturer in the shipper.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Staff will wear appropriate PPE, including glasses, plastic gown and gloves. Patients are in single rooms and current waste management and spillage guidance is satisfactory. The product presents a negligible risk to staff, patients and the environment based on the Gilead risk assessment and the current practices and control measures are sufficient.

For activities involving GMMs, describe the waste management measures which will apply to the activity:

- Disinfectant solutions (Presept, Virkon and alcohols) will be used to clean work areas and deal with any spillages.
- An autoclave is available within the same building.
- Solid waste will be bagged as offensive waste and incinerated using a licensed waste disposal firm.
- Sharps or pipettes will be disposed of via sharps bins and incinerated using a licensed waste disposal firm.

Tick to confirm that you are attaching a summary of the risk assessment: Y

Tick if you are claiming exemption from disclosure for sections of the risk assessment: 

Please enter comments of the GM safety committee on the risk assessment:

The BSO has assisted with, and agreed the final draft of the attached risk assessment.

Bacteriology Parasitology Transgenic Birds Microbiology Research
Bacterial cells in suspension will either be lysed using detergents (SDS) and strong base solutions (e.g. during the process of plasmid DNA extraction) or inactivated by treatment with Virkon with a final concentration of at least 1% Virkon solution for at least 1h. Bacterial cultures growing on solid media will be autoclaved. Mammalian cells and tissue cultures will be treated Virkon solution with a final concentration of at least 1% for at least 1h. These methods of treatment provide virtually 100% inactivation of GMMs. Following inactivation, solid waste will be disposed using a professional waste management firm (registered contractor.) Liquid waste will be disposed of via a sink following inactivation with Virkon with a final concentration of at least 1% Virkon. Drains, sinks etc. do not pose a mode of transmission to the environment, as liquid waste has been inactivated.

All personnel who intend to undertake activities involving the use of GMMs, will be required to demonstrate the knowledge of the rules for work under containment and if necessary the relevant training will be provided.

The risk assessment has been reviewed by an independent Biological Safety Officer who agrees that the work outlined within falls within the brackets of level 1 GMM work.

Give brief details of the genetic modification safety committee

The safety committee comprises of three experienced scientists that each have held/hold positions of responsibility leading laboratory activities at academic and industrial sites. Each have expertise in virology and GMM. The chair has previously held responsibility as CSO for biological safety for a company with over 20 bench scientists. Stratosvir's safety committee for genetic modification reviews codes of practice, COSHH and risk assessments and meets regularly (every quarter or as necessary) to review policies, procedures and conduct audits to ensure this is integral to the company's health and safety systems.

For activities involving GMMs, describe the waste management measures which will apply to the activity

**Solid waste:**
Contaminated general Class I waste will be disposed of in yellow autoclave bags. This includes plasticware (except stripettes) and soiled tissues/packaging which have been contaminated with biological/GM agents. The bags will be sealed with a cable tie when no more than 3/4 full and sent for incineration through a recognised clinical waste disposal provider.
Glass and sharps (including stripettes) which will be disposed of in rigid plastic containers which will be sealed and incinerated when full.

**Liquid waste:**
Liquid waste will be disposed of in the following manner: Biological liquid waste (not exceeding Class I) should be properly treated before disposal down the sink. Bacterial cultures/supernatants will be treated by adding Virkon to a final concentration of 1% and left for 1 hour followed by discarded down sink and rinsed with cold water. Cell cultures (Class I) will be treated with be treated with 1% Virkon for at least 1 hour and discard down sink with cold water.
Animal fluids (Class I) will be treated with 1% Virkon for at least 1 hour. Discard down sink with cold water.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

The risks have been assessed and can be sufficiently managed using the procedures outlined in this document.

Project Ref    3583/21.1
**Project Additional Information**

**Purposes of the contained use**

Please see section 17. We do not wish to publicly disclose this information because of intellectual property rights.

**Recipient or parental organism**

The parental organism is the vaccine strains of vaccinia virus, Western Reserve, IHD-J, Copenhagen, Lister and Modified Vaccinia Ankara. These strains have been widely used to eradicate smallpox and are considered safe in terms of their pathogenicity, infectivity, toxicity, virulence, allergenicity. Attenuated strains such as MVA, Copenhagen, Wyeth and Lister strains are considered ACDP hazard group 1 (SACGM Compendium Table 2.10.2) whereas wild type vaccinia virus strains are considered ACDP hazard group 2. Western Reserve and IHD-J are more virulent and will be considered ACDP hazard group 2 unless further attenuated through TK deletion. MVA MVA is widely used as recombinant vector for vaccination or gene therapy. MVA corresponds to an attenuated laboratory virus developed by Professor Anton Mayr. It is derived from the Chorioallantois Vaccine Ankara (CVA) strain of the vaccinia virus. The attenuated strain was renamed MVA after the 516th passage of CVA strain on primary chicken embryo fibroblasts (CEF). Genomic studies have revealed that, as a consequence of these longterm passages, the resulting virus lost approximately 15% of its genome compared to the parental CVA strain. As a result of these deletions and disruptions, MVA no longer encodes many of the known poxviral immune...
evasion and virulence factors, making the virus defective for replication in human cells and avirulent in test animals. MVA growth is restricted to a few cell lines in vitro and doesn’t replicate in vitro due to the deletions. (Verheust 2012 Vaccine 30, 2623-2632)

Lister Lister or Lister/Elstree strain was developed at the Lister Institute in the United Kingdom. From 1968 to 1971, the Lister strain became the most widely used vaccine throughout the world. Lister was deposited to ATCC ® by Dr. James H. Nakano at the Centers for Disease Control in 1978, after isolation from the skin of a sheep. The Lister (Elstree) strain was widely used during the World Health Organization (WHO) program on the eradication of smallpox, but this can induce rare but severe adverse effects.

Western Reserve This strain is derived from serial passage of the original smallpox vaccine strain New York City Board of Health (NYCBH) through 50 rounds of intracerebral infection in mice. Although WR was never used as a human vaccine, its parental strain (NYCBH) had the lowest rate of complications among vaccine strains. WR is pathogenic in mice replicating in nose, lungs, brain, ovaries, and skin. It can provide immunization in mice by scarification. WR has been adopted as the laboratory strain of VACV, it is the standard used in most poxvirus laboratories and the vast majority of mutants in laboratories and the field at large have been generated in this background.

IHD-J IHD-J: This strain is also derived from passage of the VACV NYCBH strain through 51 rounds of intracerebral infection in mice followed by four passages on egg chorioallantoic membranes. Like WR IHD-J was never used in humans as a vaccine but is pathogenic in mice replicating in nose, lungs, brain, ovaries, and skin and can provide immunization by scarification. This strain is commonly used in laboratories for comparative studies with WR.

Copenhagen This is the original smallpox vaccine used in Denmark. It led to intermediate adverse affects. Cop replicates poorly in mice, but provides immunization by scarification. This strain is commonly used in laboratories for comparative studies with WR.

Further modifications are detailed in section 17 as we do not wish to disclose these publicly for reasons of intellectual property rights.

**Host/vector system**

DNA plasmids derived from pUC (e.g. pUC18, pUC119, pBluescriptIIKS) with ampicillin resistance and neomycin resistance/kanamycin resistance will be used to shuttle gene sequences into the viral genome. Flanking regions will allow recombination of the gene with sites in the virus which have been deleted or replaced with marker genes.

Plasmids will be amplified in E. coli K-12 derivatives such as Novablue,
which are recognised as non-colonising and disabled, and may be considered to be equivalent ACDP hazard group 1. They are not considered pathogenic to humans or animals. They are expected to have limited survivability in the environment and have auxotrophic requirements, which are unlikely to be satisfied outside of laboratory culture.

Mammalian cell lines permissive to viral infection will be used. As a precaution, cell culture will be performed in a BSL2 laboratory. These cell lines include the following: HeLa (Human: ECACC 93021013; ATCC CCL 2) - HeLa cell lines were derived from cervical cancer cells taken in 1951 from Henrietta Lacks. The cells are characterized to contain human papillomavirus type 18 (HPV-18) and BSL2 requirements are recommended.

Vero cells (Monkey: ECACC 88020401; ATCC CCL 81) - Established from the kidney of a normal adult African Green monkey. Susceptible to a wide range of viruses including polio, rubella, arboviruses and reoviruses. BSL1.

MRC-5 (Human: ATCC CCL-171) – normal lung fibroblast. BSL1

RK13 (Rabbit: ECACC 00021715, ATCC CCL-37) – Rabbit kidney cells. RK13 has been derived from kidney cells of a 5 week old rabbit. Cells contain Bovine Viral Diarrhea Virus (BVDV) therefore BSL2 requirements are recommended.

HEK293T - (Human ECACC 12022001) - Human embryonic kidney SV40 transformed, genetically modified. BSL1

Origin & function

Please see section 17 for further details. We do not wish to publicly disclose this information because of intellectual property rights.

Evaluation of foreseeable effects

These are detailed in section 17 as we do not wish to disclose these publicly for reasons of intellectual property rights.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All vaccinia stocks are stored in a locked -80C freezer within a biosafety level 2 facility for designated personnel only.

Routine infection work will occur in biological safety class II safety cabinets. Disposable polystyrene aspirating pipets will be utilized for aspirating virus containing media into proper disposal containers containing 1% Distel (final volume). All aspiration will be followed by disinfection of Disposable polystyrene aspirating pipettes through aspiration of 5% Virkon which results in a degree of killing of 100% (Butcher and Uleato 2005, Contact inactivation of orthopoxviruses by house hold disinfectants). All disposable polystyrene aspirating pipettes will then be autoclaved.
All hard plasticware waste will be placed in an autoclave bag inside a rigid plastic bin which will be collected and placed directly in the autoclave (121°C, 15 PSI, 35 minutes). Following autoclaving they are disposed of via the clinical waste route of incineration. Contaminated tips are placed in standard plastic screw-top containers, which are autoclaved when full and then incinerated. Pipettes and pastettes will be flushed with 5% Virkon which has 100% kill on contact.

Liquid cultures are sterilised by addition of 1% v/v Distel followed by autoclaving. Vaccinia virus can be 100% inactivated upon autoclaving occurs at 15 PSI for 15 min therefore standard conditions (121C, 15 PSI, 35 minutes) can be used (Espy M.J. et al. 2002: Detection of vaccinia virus by LightCycler by PCR after autoclaving: implications for biosafety of bioterrorism agents).

Autoclaves in the Centre are serviced twice yearly, inspected and validated annually. Should a load fail it is reautoclaved in a different machine and the cause of the failure investigated and rectified. In case of spillage, the area of the laboratory in which the spill has occurred will be blocked off. Virkon powder can be used to soak up the spilled liquid and absorbent disposable material (paper roll) containing in 5% Virkon, which has 100% killing activity upon contact, will be applied to the spill to soak up any remaining visible spillage. The area of the spill and its reasonable surrounding area will then be thoroughly wiped a second time with absorbent material containing in 5% Virkon. The area will be wiped dry and all absorbent material used for clean-up will then be disposed of in autoclave bags for inactivation.

In case of personal injury, the wound will be treated by decontamination of wounded area with 70% EtOH, followed by bandaging of area and transport of the injured person to the Queen Elizabeth Emergency Department. Cidofovir and ST246 are USDA approved prophylactic agents available for post-exposure treatment of VACV infection or vaccination.

The risks have been assessed and can be sufficiently managed using the procedures outlined in this document. The main risk from the activity would be through piercing of the skin and subsequent viral infection. This is minimised by the lack of any procedure using sharps. Biological safety level 2 activity.

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Give brief details of the genetic modification safety committee

Advice has been received from the Health and Safety Operations Manager in the Institute. A genetic modification risk assessment has been written (Ref: FAETH_GM_01v1), along with a procedural risk assessment (Ref: FAETH_01v1_CL2) for this work. These risk assessments have been reviewed and approved by the CRUK Cambridge Institute's Biological Safety Committee. The Committee is composed of:
1. Chairperson - Senior Scientist
2. Scientific Advisors
3. Biological Safety Officer
4. Occupational Health Physician
5. Members of: Management Team, Scientific Technical Staff and Staff Representatives.

The committee will meet as required but at least annually to review current projects.

All liquid waste shall be mixed with no less than an equal volume of a 2% solution of the peroxygen chemical inactivation agent DuPont RelyOn Virkon, for at least 60 minutes, prior to disposal to drain via a sink designated for this purpose (as per the manufacturer’s recommendation) within a GM lab. This procedure will inactivate all cells and other biological agents present (100% kill). Any spills shall be treated with an equal volume of 2% Virkon for at least 10 minutes. Work surfaces shall be routinely disinfected with 1% Virkon for at least 10 minutes.

Bags will be placed in a GM-labelled leak-proof rigid container, then autoclaved on site to inactivate all biological agents (100% kill). This is then disposed of by incineration as hazardous ‘clinical’ waste by a licensed contractor (SRCL) at a licensed site.

The efficacy of the autoclaving procedure will be monitored as follows:
1. Monitoring of the autoclave parameters (temperature, time etc.) displayed by the autoclave, to ensure successful completion of the autoclave cycle on each occasion.
2. Autoclave print outs are produced on each occasion, documenting the details of the autoclave run, and maintained on site by the Laboratory Management Facility.
3. Autoclave indicator strips are added to the run in 2 places (for example top/bottom or front/back) to provide a visual confirmation the run had sterilised, on each occasion.

The autoclaves are serviced quarterly and thermometric tested every 6 months.
The genetic modification risk assessment (Reference: FAETH_GM_01v1) and procedural risk assessment (Reference: FAETH_01_v1_CL2) were assessed by the CRUK Cambridge Institute Biological Safety Committee. The Committee suggested to include the reference number of the genetic modification risk assessment (FAETH_GM_01v1) in the procedural risk assessment. The Committee subsequently approved the risk assessments.

Project Additional Information

Purposes of the contained use

This project aims to uncover factors that govern the energy metabolism of cancer cells. The long term aims of the project are to define novel therapeutic targets which will inform the development new anticancer medicines and strategies. The project will make use of a number of standard cancer cell lines together with gene modulation by CRISPR/Cas9 approaches. These modulations will be achieved by using lentiviral vectors and subsequently characterised in vitro.

Recipient or parental organism

Commonly used immortalised cancer cell lines (for example HeLa, Jurkat, etc).

Host/vector system

Commercially available recombinant 2nd or 3rd generation lentiviral vectors (e.g. pC-Pack2), pseudotyped with VSV-G envelopes, will be used. All vectors are non-mobilisable and the transfer vector contains a self-inactivating (SIN) unit. Furthermore, the lentiviral vectors used in this project are non-functional outside of the producer cells (e.g. 293T cells). This ‘split genome’ conditional packaging acts as an inherent safeguard against generation of productive recombinants. An example of a second generation vector system is described in Naldini L et al (1996) Science 272, 263-267.

Origin & function

The genetic material will be sets of CRISPR guide RNAs constructs computationally designed to disrupt target genes. cDNA encoding Cas9 will need to be introduced into the cell lines, to enable target gene disruption. Cas9 originates from bacterial species such as S. pyogenes, and has no known virulence and is not toxic. cDNAs encoding selection markers such as GFP or puromycin resistance may need to be used. Furthermore, vectors encoding different selection markers such as RFP, BFP, mCherry or blasticidin may have to be used. None of these components are known to induce oncogenic effects in cells.

Evaluation of foreseeable effects

The CRISPR constructs are designed to disrupt target genes. The foreseeable effect of this will be the removal of the corresponding protein from the cells transduced with the virus. In most cases, it is anticipated that the disruption of a component of a pathway will impair the ability of that pathway to function. In other cases, it is likely that disruption of certain genes may have no overall effect on a pathway. In rare cases, it is possible that disruption of certain genes may lead to activation of a pathway, for example, if a negative regulator of a pathway is disrupted. However, these effects are likely to be deleterious to the cell's ability to grow and it is not anticipated that cells transduced with the viruses will achieve a selective advantage relative to their parent cells. Indeed, the genes of interest in this work, are largely comprised of metabolic genes and enzymes. It is therefore very much predicted that disruption of such genes will impair pathways and lead to a selective disadvantage to cell growth and survival. An example of this phenomenon is outlined by Arroyo ey al (2016), Cell Metabolism, 24, 875-885. Consequently, the potential risks to human health and the environment are not increased as a result of these modifications, and are likely to be decreased. Furthermore, the viral vectors described in this assessment are self-inactivating, replication incompetent and non-mobilisable. They require two or three different vectors for packaging (that cannot themselves be packaged), and in the case of third generation vectors require upstream elements and in trans complementation. They cannot survive outside of closed controlled cell culture conditions, are rapidly inactivated by dehydration or other environmental insults. Spread to the wider human
and/or animal populations is thus very unlikely, and the risks to the environment and human health are extremely low. The GM cells themselves are similarly rapidly inactivated by any environmental insult, and are unable to survive outside of a closely controlled cell culture setting. A fuller description can be found in the attached Genetic Modification risk assessment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste shall be mixed with no less than an equal volume of a 2% solution of the peroxygen chemical inactivation agent DuPont RelyOn Virkon, for at least 60 minutes, prior to disposal to drain via a sink designated for this purpose (as per the manufacturer's recommendation) within a GM lab. This procedure will inactivate all cells and other biological agents present (100% kill). Any spills shall be treated with an equal volume of 2% Virkon for at least 10 minutes. Work surfaces shall be routinely disinfected with 1% Virkon for at least 10 minutes.

All solid waste shall be collected in double autoclave bags, which are sealed by autoclave tape. These bags will be placed in a GM-labelled leak-proof rigid container, then autoclaved on site to inactivate all biological agents (100% kill). This is then disposed of by incineration as hazardous 'clinical' waste by a licensed contractor (SRCL) at a licensed site.

The efficacy of the autoclaving procedure will be monitored as follows:
1. Monitoring of the autoclave parameters (temperature, time etc.) displayed by the autoclave, to ensure successful completion of the autoclave cycle on each occasion.
2. Autoclave print outs are produced on each occasion, documenting the details of the autoclave run, and maintained on site by the Laboratory Management Facility.
3. Autoclave indicator strips are added to the run in 2 places (for example top/bottom or front/back) to provide a visual confirmation the run had sterilised, on each occasion.

The autoclaves are serviced quarterly and thermometric tested every 6 months.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
All liquid waste shall be mixed with no less than an equal volume of a 2% solution of the peroxygen chemical inactivation agent DuPont RelyOn Virkon, for at least 60 minutes, prior to disposal to drain via a sink designated for this purpose (as per the manufacturer's recommendation) within a GM lab. This procedure will inactivate all cells and other biological agents present (100% kill). Any spills shall be treated with an equal volume of 2% Virkon for at least 10 minutes. Work surfaces shall be routinely disinfected with 1% Virkon for at least 10 minutes.

All solid waste shall be collected in double autoclave bags, which are sealed by autoclave tape. These bags will be placed in a GM-labelled leak-proof rigid container, then autoclaved on site to inactivate all biological agents (100% kill). This is then disposed of by incineration as hazardous 'clinical' waste by a licensed contractor (SRCL) at a licensed site.

The efficacy of the autoclaving procedure will be monitored as follows:
1. Monitoring of the autoclave parameters (temperature, time etc.) displayed by the autoclave, to ensure successful completion of the autoclave cycle on each occasion.
2. Autoclave print outs are produced on each occasion, documenting the details of the autoclave run, and maintained on site by the Laboratory Management Facility.
3. Autoclave indicator strips are added to the run in 2 places (for example top/bottom or front/back) to provide a visual confirmation the run had sterilised, on each occasion.

The autoclaves are serviced quarterly and thermometric tested every 6 months.

Give brief details of the genetic modification safety committee

Pneumagen Ltd operates on a site within the University of St Andrews Biomedical Sciences Research Centre (BSRC) and complies with the health and safety procedures of the University. All GM work in the BSRC is assessed by the building Health and Safety Committee. This committee is comprised of the building Safety Coordinator and the Director of the BSRC facility. After initial approval, GM projects are submitted to the Chemical and Biological Hazards Sub-committee (which acts as the Genetic Modification Safety Committee for the University) for ratification, before work commences.

E. coli waste medium will be autoclaved at 121°C for 30 min. If this is not possible, the waste will be treated with 1% (w/v) Virkon for a minimum of 1 h prior, to disposal via the drain with excess water. Glassware/plasticware will be soaked in 1% (w/v) Virkon and washed out with to the drain with excess water.

Please enter comments of the GM safety committee on the risk assessment

The risk assessment is very straightforward. The project involves expressing carbohydrate binding domains from a number of bacterial proteins in E. coli using standard cloning and expression systems that are well documented and have a long history of use. The protein subdomains being expressed are isolated modules with no enzymatic activity. As such, and taking into account the decontamination and handling procedures that will be used, I am content that this is a level 1 activity as indicated.

Give brief details of the genetic modification safety committee

- Chief Scientific Officer - 32 years experience of managing commercial laboratories conducting GM work including the use of bacterial, mammalian, retroviral, lentiviral and baculoviral vectors for protein expression.
- Chief Operating Officer - 11 years experience of managing business operations
- Director, Biology - 9 years experience of academic and 3 commercial laboratory work/management including the use of mammalian primary and cell lines
- Director, Drug Discovery - 20 years experience of generating GMO’s in commercial laboratories including the use of bacterial, mammalian, retroviral, lentiviral and baculoviral vectors for protein expression.
- Director, Oncology - 21 years experience of academic laboratory work/management including the use of baculoviral, adenoviral and lentiviral vectors for protein expression and functional genomics.
- Laboratory Manager - 6 years experience of health and safety and risk assessments in academic laboratories
- Director of Safety Services - >39 years’ experience in healthcare, >29 years’ experience in health and safety / biosafety, 18 years working in microbiology laboratories (diagnostic microbiology and microbiological research at CL2 and CL3)

PPE (lab coat, gloves and goggles) will be used at all times as according to Engitix Laboratory Standard Operating Procedures. The standard procedures for mammalian cell culture will be appropriate for handling the GMM (all cell culture is carried out inside a Biological Safety Cabinet). Sharps and glassware will not be used within this project. Solid waste materials (e.g. gloves, plastic ware, cell pellets etc) that have come in contact with GMOs are segregated from other tissue culture waste and are autoclaved (100% kill) using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes) in a validated machine located in room 4.04 (Utility room). Excess liquids (culture and medium) are discharged to drains following disinfection by the addition of Virkon to give a 3% final working concentration. A minimal contact time of 1 hour is allowed prior to disposal to sewers (as per manufacturer’s recommendation). Alternatively, a 10% bleach solution in place of Virkon may be used. Solid waste is disposed via the clinical waste route in yellow bags and goes for incineration. The autoclave is performance validated by 12-point thermocouple tests on an annual basis. Records are kept on site.

Virkon is routinely used as per the manufacturer’s recommendations: Solid surfaces are disinfected with 1% Virkon solution. Plastic ware that can be effectively disinfected is treated with 1% Virkon for a minimum of 1 hour prior to placing in yellow bags for incineration.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The Biosafety Committee discussed the project and agreed that the control measures were appropriate, and that it could be approved as Class 1, Containment Level 1. Points highlighted were:

a) waste management and the clinical waste route - this was confirmed with the waste contractor.
b) the numbering system for GM Risk Assessments – change to make a clear separation between GM and non-GM work.

Other(s)
To permit the generation of DNA vectors and use them in mammalian cell lines
**Project Additional Information**

**Purposes of the contained use**
To permit the generation of lentiviral vectors and use them in mammalian cell lines for the expression of:
1) Open reading frame (ORFs), including but not limited to oncogenes, tumor suppressor genes, Cas9 proteins, cDNA, peptides and other gene sequences.
2) synthetic RNA sequences for gene expression regulation, including but limited to microRNA, short hairpin RNA, and short interfering RNA.
3) synthetic RNA for gene editing, including but not limited to synthetic guide RNAs for CRISPR/Cas9 technologies, template for gene editing.

**Recipient or parental organism**
The recipient organism will be of 2 types which may be classified as ACDP hazard group 2 or below:
1) cell line used for virus production, such as HEK293T and into which the different plasmids for virus production (encoding viral vector proteins and genome) will be transiently co-transfected for the transient production of viral particles that will be released into the cell growth media. These viral particle suspensions could provide a risk for infection for the personnel handling them.
2) recipient cell line in culture that will be infected with the viral particles produced as described above. This includes (but is not limited to): immortalised cell lines, cancer cell lines, and other previously established cell lines and long term culture of human and animal origin, classed as ACDP hazard group 1. For the first few days after contact with virus, the infected cultures could provide a potential risk for infections for the personnel handling them.
Lentivirus parental organism – Human Immunodeficiency virus (HIV-1) is classified as ACDP hazard group 3.

**Host/vector system**
The lentiviral vectors used are multi-attenuated meaning they are devoid of all potentially pathogenic HIV-1 encoded functions. In addition, they are replication-defective which means that the vector cannot multiply on its own unless supplied by certain proteins in trans. These are provided on at least two separate plasmids to limit the risk of unintended viral replication. They are self-inactivating which means that the viral promoter in the U3 region of the 5’ LTR has been disabled by genetic manipulation. Only a very unlikely event of multiple recombinations during the process of generation of the viral vector can expose the person to a wild type HIV-1. The probability of such an event is extremely low.

Origin & function

The mammalian cell lines used herein are from commercial suppliers (ATCC, DSMZ, RIKEN, CLS). The genetic material is obtained from commercial suppliers eg. tetracycline-inducible lentiviral expression vector pTMONB-TRE-MCS-12-RFP-EFS-rtTA-2A-Blast, lentiviral packaging plasmids pS Pax2 and pMD2.G, sgRNA expression vectors such as pSF-Lenti-U6-guide-Puro. Overexpression studies may utilise similar lentiviral expression systems from other suppliers. cDNAs/ORFs for genes of interest will be purchased from commercial suppliers.

The lentiviral vectors are derived from HIV-1 virus. All the viral vectors that we will generate and use are devoid of the proteins required for virus replication and pathogenicity, and as so, they are replication-incompetent vectors that after integration into the host cell genome cannot propagate nor replicate.

Additional safety features of the lentiviral vectors that we will use are:
- viral vectors are devoid of pathogenic accessory genes (vif, vpr, vpu and nef) required for viral replication and the genes from the parental virus strain contained in the viral vector is reduced to just the structural proteins: gag, pol, env.
- genes encoding the structural and other components required for packaging the viral genome are separated onto 2 or more plasmids. All plasmids have been engineered to limit the regions of homology with each other so that undesirable recombination events that could lead to the generation of a replication-competent virus are minimised.
- none of the packaging plasmids that allow expression in trans of proteins required to produce viral progeny, nor the constructs stably expressing the viral proteins in packaging cell lines, contain LTRs or the 5’ packaging sequence. This means that none of the virus structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. No new replication-competent virus can be produced.
- whenever possible, we will use viral vector constructs that are "self-inactivating": those vectors contain a deletion in the 3’ LTR that does not affect generation of the viral genome in the producer cell line, but results in "self-inactivation"of the viral vector after transduction of the target cell. Once integrated into the transduced target cell, the viral genome is unable to transcribe a packageable viral genome, further reducing the possibility of production of any infectious viral progeny. Despite the above safety features, use of these viral vectors (which include WPRE sequence) falls within Class 2 criteria due to the potential biohazard risk of possible recombination with endogenous viral sequences to form self-replicating virus, the possibility of insertional mutagenesis, and the expression of potentially oncogenic genes. Also, the virus will be packaged with envelope proteins (including but not limited to VSV-G) that allow the transduction of a wide variety of animal species and cell types. This means that these viruses could potentially infect a number of species, including human beings. Despite this, the viral vectors will not be able to propagate nor produce in any way an infective progeny, due to the safety measures applied as described above.

Evaluation of foreseeable effects

The viral vectors that we will produce will be pseudo typed with VSV-G protein, which confers a broad host tropism including human cells. However, all the viral particles will be replication-incompetent and, when possible, self-inactivating, therefore there is no possibility of viral replication nor propagation further. Since some of the inserted DNA could code for potentially hazardous RNA or protein, the work is assessed as Class 2. Even for the non-oncogenic inserted DNA, there is a slight but non negligible risk due to the presence in some of the viral vectors of the Woodchuck Post-transcriptional Regulatory Element. This sequence has been linked to liver tumours in mice in a pre-clinical study using lentiviral vectors. Under the Genetically Modified Organisms Regulations 2014, work using vectors containing this sequence should be classified as Class 2.

However, the viruses that will be used have been modified in a number of ways which will make them safer to handle:
- The genes encoding structural and other components of the viral genome have been separated. These genes and the plasmids encoding them have been engineered to minimise the risk of recombination that could lead to production of a replication-competent virus.
- The packaging cell lines allow expression of proteins, required to produce progeny virus, but the transfer vector (not encoding the structural viral proteins) is the only
genetic material transferred to the target cells, consequently these recipient cells cannot produce the proteins which are essential for viral assembly and infectivity.

- The viral vector production in helper/packaging cell line will be transient, i.e. the component for the assembly of infective viral particles will be co-expressed exclusively for the few days of persistance of the transiently transfected plasmid encoding the viral genome.

Procedures and controls measures will therefore follow HSE SACGM Compendium of Guidance for retroviruses (Part 2, para. 30-36) i.e. using multiple plasmids with minimum sequence homology (e.g. 2nd or 3rd generation lentiviral vector systems), lab coats, eye protection and gloves will be worn, use of class II safety cabinets, sharps avoided and all wastes will be rendered harmless before disposal etc.

It is not thought that the modified virus would pose a serious risk to animals or plants in the environment. Although the VSV coat protein permits transduction of other mammalian cells, as in the case of humans, infection would be restricted to primary cells and productive virus would not be produced. In addition the control measures to protect human health will minimise release of virus to the environment. Therefore the environmental risk is low.

The viral vectors will be used to generate a cell population stably expressing the gene or RNA sequence(s) of interest.

For the first week after infection, or until at least both 3 replications and 3 media changes have occurred, the cell population infected with the viral particle will be treated as potentially infective. After this period, these cell cultures and the derivative products will be considered as Class I since the viral particles will be cleared from the culture.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste materials that have come in contact with GMOs (e.g. gloves, plastic ware, cell pellets etc) are segregated from other tissue culture waste and autoclaved (100% kill) in a validated machine located within the same building using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes). Subsequently the solid waste enters the yellow bag clinical waste route and goes for incineration. The autoclave performance is validated by 12-point thermocouple tests on an annual basis. Records are kept on site.

Virkon is routinely used as per the manufacturer’s recommendations: Solid surfaces are disinfected with 1% Virkon solution. Plastic ware that can be effectively disinfected is treated with 1% Virkon for a minimum of 1 hour prior to incineration. Contaminated glassware is treated with 1% Virkon solution for a minimum of 1 hour prior to cleaning. Liquid waste (culture and medium) is disinfected by the addition of Virkon to give a 3% final working concentration. 2% or 3% solutions of Virkon are used for buffered solutions. A minimal contact time of 1 hour is allowed prior to disposal to sewers (as per manufacturer’s recommendation). Alternatively 10% bleach solution in place of Virkon may be used.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
The GM Committee agreed that the control measures were appropriate and that the work can be approved as Class 2, Containment Level 2. Points highlighted by the committee:

a) Plasmid maps to aid understanding

Waste media and contaminated lab ware (plastics & consumables) will be decontaminated / sterilised using either the addition of Virkon (as manufacturer's instructions) or via autoclaving. The kill will be 100%. Viability testing to ensure efficacy of the killing / sterilisation process will be carried out. Autoclave validation, testing the ability of the autoclave to decontaminate a typical load, will be performed at least annually by a competent engineer using calibrated equipment in accordance with the relevant British Standard. Autoclave operation will be monitored while in use via chart recordings to ensure correct performance (pressure / temperature / cycle time) as measured via integral thermocouple and they will be operated such that they reach and maintain a temperature of 121°C for at least 30 minutes by using saturated steam under at least 15 psi of pressure. Following autoclaving, solid materials will be packaged in yellow laboratory waste bags and enter the waste stream for incineration. Sterilised liquids will be disposed via the drain. In the event of both main and auxiliary autoclaves failing simultaneously any waste which is normally autoclaved will be packaged in accordance with the approved requirements and incinerated.

All sharps will be discarded into appropriate sharps boxes meeting the requirements of BS 7320 and the boxes will be incinerated.

Give brief details of the genetic modification safety committee

We have received approval for our risk assessments from the Sitryx GMO safety committee. Committee comprises of head of biology, Biology group lead, 2 senior scientist, operations director, and operations manager. Combined the is over 50 years’ experience working in research in CU1 and CU2 laboratories.

02/03/2022
For routine culturing of genetically modified cells either purchased commercially or produced in-house using non-viral vectors, all contaminated solid waste will be double-bagged and then sealed in leak-proof solid, rigid 60L bins; hard plastic waste that may puncture bags such as pipette tips and stripettes are first sealed in a cardboard Bio-Bin® or dispo-jar before being placed in bags/plastic bins. Plastic bins will be collected from site on a regular basis by a Certified Waste Management company, Grundon Waste Management Ltd (GM Centre 782), and disposed of under EWC classification 18 01 03*.

All solid waste will be collected live (without prior inactivation) and transported directly for high temperature incineration, providing 100% kill as monitored by Grundon (Certificates of Destruction are available on request). Alternatively, solid waste may first be autoclaved using make safe cycles (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes) before being double bagged and stored in a lockable container within the lab until collection by a Certified Waste Management company, such as Grundon Waste Management Ltd. (GM Centre 782), and disposed of under EWC classification 18 01 03 (Human) or 18 02 02 (murine). All solid waste will be collected live (without prior inactivation) and transported directly for high temperature incineration, providing 100% kill as monitored by Grundon (Certificates of Destruction are available on request).

Mammalian cells and liquid waste will first be deactivated by treatment with 2% Virkon for 60 minutes prior to either disposal to wastewater via lab sinks with copious amounts of water in accordance with trade effluent license limits, or solidified using LabSorb or similar absorbent material before disposal as solid waste by a certified Waste Management company (Grundons see details above). Alternatively, liquid waste may first be autoclaved using make safe cycles (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes) before being discharged to waste and monitored.

Contaminated laboratory glass or plasticware for re-use will be soaked in 2% Virkon for 1 hour then rinsed in water before passing through dishwasher. Virkon, when used according to manufacturers’ instructions under standard conditions, has been validated to deliver 99.998% kill. Disposal of Virkon via laboratory sinks is recorded and full training, supervision and regular safety checks ensure compliance with the Sitryx Waste Management SOP.

Please enter comments of the GM safety committee on the risk assessment

The Sitryx Therapeutics Biological Safety Committee was consulted, and risk assessments were reviewed. The Committee had no additional comments on any of the final risk assessments submitted.
Developing therapeutics targeting immunometabolism, autoimmunity, cancer and metabolic disorders using mammalian cell systems expressing reporter genes or overexpression/silencing of normal mammalian genes

Sitryx is a pharmaceutical company focused on developing novel therapeutics targeting immunometabolism across therapeutic areas such as autoimmunity and cancer. GMMs will be used to ascertain the effects of known and novel compounds on the immunometabolism and phenotypic profile of the cells of interest.

Recipient or parental organism

A list of cells to be used can be found in Appendix I of the attached "Contained use of GMMs (stably transfected cell lines, and transiently transfected primary tissues arising from transgenic mice and humans)" risk assessment. Commercially available and pre-characterized cells from collaborators will be used to ascertain the effects of known and novel compounds on the immunometabolism and profile of the cells for use in therapeutic areas such as cancer and autoimmunity. Typical examples of cells to be used include human and mouse cancer cell lines such as THP1 (myeloid leukaemia), Jurkats (lymphoid leukaemia), A549 (adenocarcinoma) and HEK 293 (embryonic kidney). Some cells from collaborators may also have been altered to overexpress specific mammalian genes of interest or reporter genes such as LacZ, GFP or luciferase; these may be maintained under the control of antibiotic genes. Primary murine cells arising from blood or tissues such as bone marrow and spleens, from wildtype or genetically modified mice to overexpress or knock out mammalian genes typically related to immunometabolism, may be cultured ex-vivo. Some cells may also express reporter genes such as LacZ, fluorescent constructs or luciferase. These cells will be obtained from external sources and no in-house work involving animals will take place within the Sitryx laboratories. Primary human blood cells and tumour samples and tissues may be cultured ex-vivo and may have been altered to overexpress certain mammalian genes or reporter genes such as LacZ, GFP or luciferase. These cells will be obtained from external sources. All cells to be used have strict in vitro growth requirements and are therefore incapable of growth outside normal laboratory conditions.

Host/vector system

GMMs purchased as commercially available stably transfected cell line/tissues or provided by collaborators may contain standard replication deficient/incompetent viral vectors, which are unlikely to be hazardous. Non-viral vectors Non-vector systems (e.g. CRISPR-Cas9 mediated targeted deletion of endogenous genes) or non-hazardous standard plasmid or phage vector systems will be used for in-house modification in Sitryx laboratories.
Viral vectors
To properly interrogate relevant biology and the effects of compound treatment, cells may have to be modified to differentially express certain mammalian genes; this may be done using retro/lentiviral vectors. Should this work occur, cells would be incubated with the replication incompetent virus overnight, at an MOI of 1-100 infectious virus particles per cell. Cells would then be washed to remove free uninternalized and unbound virus (media to be treated with Virkon), and cells would then be allowed to recover for a few days before being evaluated for transgene expression or markers determined by FACS or plate reader assays. Cells may be grown as single cell clones to allow for characterization of expression in subpopulations, by copy number and integration assays.
Replication incompetent viruses are generated by transfecting producer cells (commonly HEK293 cells or derivatives) with multiple plasmids which together provide the required genes for packaging the gene of interest (be it reporter or transgene) into infectious replication defective viral particles. The viral vectors are derived from numerous wild type viruses, such as MoMLV, HIV, SIV and EIAV. However, all non-essential genes are removed from the vectors with the remaining genes split onto separate plasmids with minimal homology thus reducing the risk of homologous recombination. For example, lentiviral vectors derived from HIV are devoid of tat, vif, vpu, vpr nef and the envelope gene has been replaced by VSV-G envelope. Gag, pol and rev are generally on one plasmid, env on a second and the gene of interest is on a third and fourth plasmids along with cis-acting signals required for reverse transcription and integration. As the gag, pol, rev and env plasmids do not contain the packaging sequence none of the genes are present in the package viral genome. The probability of these viral particles obtaining the missing genes is very low and therefore the risk of replication competent viruses being created is minimal.
In addition, some of the later generation viral vectors also include a self-inactivating feature, a deletion within the 3’ LTR, which is transferred to the 5’ LTR after reverse transcription and integration in infected cells. This results in the transcriptional inactivation of the LTR in the provirus and reduces the risk of transactivating genes around the site of insertion. Some concern has been raised with regards to the potential oncogenic activity of the post-transcriptional regulatory element from the woodchuck hepatitis virus (WPRE) which is frequently included in lentiviral systems. Following the guidance from the Health and Safety Executive these systems must be handled at Containment Level 2. Retro/lentiviral particles will be pseudotyped with common glycoproteins such as RD114 or Vesicular Stomatitis Virus glycoprotein G (VSV-G), which allow efficient gene transfer to a broad array of cell types and species. Producer cells are especially disabled hosts having strict nutritional and environmental requirements for survival. The modifications are not expected to increase their survival in the environment, nor increase their ability to evade the immune system. Therefore, the only risk is from the viral particles themselves. No genetic alterations will be made to the retroviral/lentiviral packaging plasmids or retro/lentiviral backbone transfer vector plasmids.

Origin & function
Our primary focus is on genes reported in the literature or implicated by collaborative research to be involved in human immunometabolism and related processes. Therefore, inserts typically code for normal mammalian genes, selective alterations of those genes (including targeted editing of endogenous genes e.g. CRISPR/Cas9 mediated gene targeting), or targeted inhibition of endogenous gene expression (e.g. miRNA and shRNA) or viral vectors. In addition to these, typical genetic inserts to facilitate include:
• Standard reporter genes such as lac Z/beta-galactosidase, secreted alkaline phosphatase, and chloramphenicol acetyltransferase, fluorescent proteins from marine organisms (e.g. CFP, EGFP, RFP and YFP), and Photinus (firefly) and renilla luciferase. These naturally occurring fluorescent or luminescent proteins either emit light when excited by high-intensity light of specific wavelengths, or generate light from catalysis. Each of these reporters is widely used and no cellular toxicity in normal cells or harmful properties have been reported. Therefore, no hazardous effects are anticipated.
• Mammalian selectable antibiotic markers such as Hygromycin resistance, Puromycin resistance, Zeomycin resistance, Neomycin resistance, Blasticidin resistance, and Geneticin resistance may be present in altered cells to maintain gene expression. The promoter of the mammalian antibiotic resistance or selectable marker is recognised by the mammalian RNA polymerase and allows transcription of the gene of the mammalian antibiotic resistance or selectable marker in mammalian cells. These resistance markers are not functional in bacteria.
• Various promoters may be used to regulate gene expression in order to achieve different levels of expression. Typical examples of these promoters include CMV, SFFV, SV40 and EF1α promoters, as well as synthetic promoters. We will also include mammalian promoters associated with cell types of interest in specific states, such as the promoters for CD60, CD206, iNOS, IL-10 in differentiated macrophages. There are no risks associated with these promoters, as they do not themselves encode any proteins; they merely influence the level of transgene expression achieved.
• Overall, these genetic inserts are not expected to have harmful physiological or pharmacological properties or to affect the pathogenicity of cloning host or normal human defence mechanisms. Gene transfer is possible, but unlikely to be hazardous.

Evaluation of foreseeable effects
Risk assessments (attached) have determined that the resulting GMMs used and generated during this project carry no additional hazards compared with those already.
present in the environment and are of a relatively low risk to human health and the environment, warranting the use of containment level 2. All cells will be cultured and propagated in fully serviced Class II Microbiological Safety Cabinets and incubators accordance with good microbiological practice and good occupational safety and hygiene, and in accordance to SACGM Compendium of guidance part 3 p18-21 and any additional advice referred to in the relevant Material Safety Data Sheets (e.g. US Dept Labor Universal Precautions 29 CFR 1910.1030). Resulting GMMs have strict in vitro growth requirements and are therefore incapable of growth outside normal laboratory conditions. Any transfer of genetic material to other organisms would be of minimal hazard.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

We request a derogation for the Class 2 Containment requirement for use of an autoclave. Mammalian cells and liquid waste will first be deactivated by treatment with Virkon for 60 minutes prior to either disposal to waste water via lab sinks with copious amounts of water in accordance with trade effluent license limits. Alternatively it will be solidified using LabSorb or similar absorbent material before disposal as solid waste by a certified Waste Management company (Grundons see details below). All contaminated solid waste will be double-bagged and then sealed in leak-proof solid, rigid 60L bins; hard plastic waste that may puncture bags such as pipette tips and stripettes are first sealed in a cardboard Bio-Bin® or dispo-jar before being placed in bags/plastic bins. Plastic bins will be collected from site on a regular basis by a Certified Waste Management company, Grundon Waste Management Ltd (GM Centre 782), and disposed of under EWC classification 18 01 03 (Human) or 18 02 02 (murine). All solid waste will be collected live (without prior inactivation) and transported directly for high temperature incineration, providing 100% kill as monitored by Grundon (Certificates of Destruction are available on request).

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

For routine culturing of genetically modified cells either purchased commercially or produced in-house using non-viral vectors, all contaminated solid waste will be double-bagged and then sealed in leak-proof solid, rigid 60L bins; hard plastic waste that may puncture bags such as pipette tips and stripettes are first sealed in a cardboard Bio-Bin® or dispo-jar before being placed in bags/plastic bins. Plastic bins will be collected from site on a regular basis by a Certified Waste Management company, Grundon Waste Management Ltd (GM Centre 782), and disposed of under EWC classification 18 01 03* and 18 02 02. All solid waste will be collected live (without prior inactivation) and transported directly for high temperature incineration, providing 100% kill as monitored by Grundon (Certificates of Destruction are available on request).

Solid waste that has been used for viral work will be first be inactivated by treatment with Virkon (2% final concentration for 1 hour) prior to being disposed of as mentioned above. Alternatively, solid waste may first be autoclaved using make safe cycles (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes) before being double bagged and stored in a lockable container within the lab until collection by a Certified Waste Management company, such as Grundon Waste Management Ltd. Liquid waste will first be deactivated by treatment with Virkon for 60 minutes prior to either disposal to waste water via lab sinks with copious amounts of water in accordance with trade effluent license limits. Alternatively it will be solidified using LabSorb or similar absorbent material before disposal as solid waste by a certified Waste Management company (Grundons as previously described). Contaminated laboratory glass or plasticware for re-use will be soaked in 2% Virkon for 1 hour then rinsed in water before passing through dishwasher. Virkon, when used according to manufacturers’ instructions under standard conditions, has been validated to deliver 99.998% kill. Disposal of Virkon via laboratory sinks is recorded and full training, supervision and regular safety checks ensure compliance with the Sitryx Waste Management SOP.

**Is an emergency plan required according to regulation 20?**

Give brief details of the genetic modification safety committee

The person that provided us with expert advice has been working in the GM field for 10+ years. He advised several academic research groups and small companies on matters related to risk assess (RA), use and contain genetically modified organisms.

He will keep working with us as a consultant to ensure we have appropriate RA, training and recall/revision system in place.

Disinfection:
The liquid waste will be chemically disinfected by soaking in 1% w/v Virkon or 1,000ppm Presept (four 0.5g tablets into 1L of liquid) for 24h before discharging via drains.

Autoclaving:
All contaminated materials will be inactivated by autoclaving (100% kill) at 121C or 134C prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autocalves will be validated by annual (at least) thermocouple mapping and each run will be monitored using thermal indicators (e.g. Browne TST indicator test strip).

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment
The risk assessment (RA) has been conducted in a thorough fashion, considering:
- effect of the genetic modification on the environment
- effect of the genetic modification on human health

Here below is a brief sum-up of the main considerations behind the risk assessment.

The risk for the environment is low because:
- the genetically modified mice will be bought in from a commercial partner and not produced in-house
- the bacteria used for plasmid propagation are derivatives of E.coli K-12 and B-strains, which have been demonstrated to be non-pathogenic, incapable of colonising mammalian hosts, and auxotrophic, so dependent on nutrients in the media for survival
- the genes inserted in the plasmid are under a human promoter, therefore unable to be expressed by bacteria
- sequences will be checked carefully to avoid the unintentional introduction of a cryptic bacterial promoter

The risks for human health are minor because:
- the genetically modified mice cannot pass any disease or genetic modification as a consequence of being genetically modified themselves and they will be humanely culled at the end of each experiment
- the transfected genes will be expressed in a transient and non-integrating manner, so it is highly unlikely that any transfected gene product will cause long term harm upon occasional contact
- no oncogene or tumour-suppressor gene will be targeted during the project
- the material will be appropriately inactivated and disposed of after the end of the experiments as described above, and it will therefore not be hazardous

More details on the transfected targets are provided in section 12.

Other(s)  
To confirm: there shall be absolutely no work undertaken at the premises....

For activities involving GMMs, describe the waste management measures which will apply to the activity

Taking cognisance of note 6:
The proposed work shall, I understand from GMO (CU) Regs, involve non-notifiable work involving larger GMOs.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Comments on the person with expertise on the risk assessment process is that the responsible person at the organisation receives advice from an individual whom has knowledge in, among other things, risk assessments relating to confined use to the level, as required in these matters, regarding CU Level 1. This knowledge was acquired while employed with a Govt Agency working with animals. Among other abilities, training, knowledge and experiences possessed by this individual there are various supporting qualifications e.g. an MSc distinction in Safety & Risk Management together with being a current member of a professional safety body with designation CMIOSH.

### Project Additional Information

#### Purposes of the contained use

**Recipient or parental organism**

The parental organisms are viral vectors.

**Host/vector system**

The host vector system is a Marek's disease virus, such as Rispens or Herpes Virus, which has been modified to express one or more transgenes.

**Origin & function**

The parental viral vectors have been supplied by a UK research institute. The transgenes to be evaluated were synthesised by a commercial gene synthesis company using Gibson assembly and were then integrated into the viral vector by the UK research institute.

**Evaluation of foreseeable effects**

Avian herpesviruses have a tropism to avian species. It is highly unlikely that avian herpesviruses can be transferred into humans. Thus, it is not expected that the GMM described in this document could be hazardous to the human. Avian herpesviruses are strictly restricted to the avian species and expected to be either attenuated relative to wildtype, or at worst no more hazardous than wildtype, and thus pose no risk to the environment. Furthermore, cellassociated nature of HVT restricts its chances for transmission. The modified viruses, as is the case with wild type avian herpesviruses, are strictly avian pathogens, with infection and replication restricted to avian cells. Moreover, HVT is cell associated, making any exposure unlikely. These characteristics including their strict host restriction, coupled with the likely disabling mutations in gene knock out constructs make them extremely low risk to human health.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

HVT-contaminated materials (e.g. glassware, plastics, tips, flasks, media and cultures) will be inactivated (e.g. exposure to at least 1% virkon for a minimum of 30 minutes or autoclaving). Testing and monitoring methods will include quantitative PCR.

Please enter comments of the GM safety committee on the risk assessment

In our laboratory we handle non-pathogenic E. coli (strain K-12), which we use to make preparations of plasmids. We use these E. coli to produce plasmids which are subsequently used for the expression of non-pathogenic monoclonal antibodies. None of the components of these plasmids are derived from any infectious pathogen, and none of them contain any known oncogenes. The genetic modifications do not contribute to pathogenicity of the host E. coli, or to any other environmental micro-organisms.

Appropriate disinfection and disposal procedures have been put in to place to minimise the risk of any accidental release of GMO organism in to the environment.

Appropriate PPE and training is available to protect laboratory staff from the host species itself, which while non-pathogenic (BSL 1) should be handled with care.

Introduction and knock-down of cell surface proteins into mammalian cell lines or

**Class**

Class 1

**CultureVol**

1-50 Litres

02/03/2022

Page 15047 of 15326
The purpose of the project is to use lentiviral vector expression systems for the expression of cell surface proteins in order to determine the functional characteristics of purified monoclonal antibodies. The use of this vector system would also allow the use of a more extensive array of cells for screening, allowing the modification of cell lines without established transfection tools. It would also further allow the use of shRNA to allow for the modulation of existing cell surface proteins.

Recipient or parental organism

Lentiviruses are complex retroviruses that cause the transmissible immunodeficiency syndromes.

Host/vector system

Mammalian cells/Lentivirus vectors

Origin & function

Lentivirus: The origin of the lentiviral vector requested in this application is HIV-1. Modern Lentivirus systems which would be used are attenuated so as to reduce the risk of infection or oncogenesis should an employee be exposed. These mechanisms of attenuation include: Deletion of the enhancer region of the 3' U3 of LTR. This results in a transcriptionally inactive vector that cannot be converted into a full length RNA. The deletion also reduces the risk of tumorigenesis via promoter insertion. In addition to loss of the regulatory/accessory genes (tat, vpr, vpu, vif and nef), pLKO.1 is also deficient for the gag, pol, rev, and env genes of HIV-1, which must be provided on three non-homologous plasmids expressed in a packaging cell-line. These highly attenuated lentiviral vectors have shown sufficient biosafety for their insertion in ongoing human clinical trials as therapeutic vectors.

Evaluation of foreseeable effects

The generation of replication competent virus has to be viewed as a potential major safety issue. However, the probability of the lentiviral vectors reverting to wild-type is extremely low. Therefore, although these viral vectors can potentially infect a wide range of cell types there is a minimal risk of viral replication in infected cells. The only potential safety concern for retroviral-based vectors is insertional mutagenesis of essential genes. Retroviral integration can lead to oncogenesis but appears restricted to stem cells additionally inherent characteristics of LVs and safety modifications considerably reduce the risk of genotoxicity with no reports of genotoxicity-related adverse effects to date in any of the LV-based gene and cell therapies (Munis A., 2020). Although the cell surface proteins themselves do not cause a major risk due to their natural presence on mammalian cells, their modification may in the worst case scenario induce autoimmune disease.
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

- Virkon is a synergised oxidising system that works by physical destruction of pathogens by acting on proteins. It is resistant to inactivation by organic material. Shown to be effective against bacteria, viruses and fungi including all major human pathogens. Recommended to be used at 1% concentration for all activities.
- Chemgene HLD4L is a commercial validated disinfectant. It is formulated as a micelle cleaning technology that enables the active molecules in the product to be carried rapidly through the cell walls or micro-organisms. Swift penetration of the cell walls ensures cell death is equally rapid. Chemgene HLD4L has been reported to be bactericidal, fungicidal as well as virucidal (HIV, hepatitis B, Herpex Simplex, Norovirus and Coronavirus) and sporicidal. It is recommended to be used at a 1:100 dilution (1%) for general purposes, 1:20 dilution (5%) for high-risk areas.
- Following all work solid waste (including tips, pipettes, and flasks) will be bagged into an autoclavable bag as the waste is generated. After work has been completed it will then be double bagged before being sealed and immediately then autoclaved prior to being bagged and sent into the clinical waste stream for incineration with a registered waste contractor.
- It will be routine practise that all liquid waste material be neutralised before disposal, and for the neutralised waste to be transported in leak-proof containers to prevent spillages. Liquid waste will be inactivated with Virkon for 24 hours prior to disposal. In some instances, the liquid waste will be disposed to sewers via a designated laboratory sink or solidified with Labsorb (or equivalent product) and disposed of as solid waste as above.
- Surfaces will be thoroughly cleaned with Chemgene HLD4L 5%* (or an equivalent product) at the end of each experiment or after the occurrence of an accidental spillage of infectious material. Application of these anti-microbial agents will totally inactivate any viral vectors that might be present. According to the biosafety literature, all the viruses to be used are susceptible to these disinfectants. Anything that might have potentially come into contact with the virus will be treated with Chemgene HLD4L before being incinerated.

The Biological Safety Committee (BSC) agrees with the assessment that this work can be conducted at BSL2. The BSC notes that any work with primary cell lines should be taken from population with a known medical history to minimise risk of the presence of harmful human pathogens. The BSC agrees that the use of the latest generation of lentiviral systems, which are self-inactivating and in effect non-mobilisable reduces the risk of potential infection to near zero, however they have stressed the need to follow the procedures set forth in the risk assessment to prevent an exposure as there is still a potential risk of oncogenesis which cannot be completely ablated. Lentiviral transduction into immortalised cell lines should not be able to mobilise any genetic elements because self-inactivating systems will be used that lack the necessary genes for viral replication and packaging. The BSC agrees the requirement for each new piece of work to have an individual risk assessment completed prior to commencement to ensure the safety of the work. Where new vectors or hosts are to be used this risk assessment must assess the potential sites for recombination and ensuring they are not present in the lentiviral vector. Once cells are transduced and virus removed the risk posed here is very low. Due to some cell lines already requiring biosafety level 2 containment and the use of integrating lentiviral vectors this dictates continued use at BSL2. BSL1 cell lines once transduced, and lentivirus removed at BSL2 could be used at BSL1, however it is the opinion of the BSC that they should be maintained at BSL2.

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Give brief details of the genetic modification safety committee

GMSC includes the SVP Research and Early Development, Cellular and Molecular Biologists and Cell Culture Scientists, all with experience of working at activity class 1 and 2. Collectively many decades worth of experience in similar organisations undertaking preclinical research and development. Where additional support is required the staff needed will be added/adapted to allow for the most relevant expertise and input. External advice from H&S Consultant/Biosafety Practitioner Level1 (ISTR) is contracted and used where necessary. The GMSC meet to review risk assessments and discuss GM matters, these are minuted and also GM is a standing item on the H&S committee agenda.

At the conclusion of an experiment, cells and culture media will be inactivated by 1% Virkon
(final concentration) disinfectant for 30 minutes as per the manufacturer’s instructions. This
protocol has been shown to reduce organisms by 5 log. Solid waste will be decontaminated by
the submersion in 1% virkon final concentration for 30 mins, drained and collected in waste
bags for incineration with a licensed waste contractor as infectious waste.

Please enter comments of the GM safety committee on the risk assessment

The GMSC met to review this assessment 05/Feb/2021.
The GMSC agreed to the application of activity class 1. This was concluded after discussion of
the project, hazards and risk. The need for CL2 controls were discussed and it was concluded
they would be unnecessary to protect human health or the environment. This was based on
the low risk due to use of hosts that are pre-screened and inactivated, inactive 2nd generation
lentivirus, low oncogenic risk and use of electroporation techniques for modification at the
premises.
It was agreed that this risk assessment would form the supporting evidence so the HSE GM

**Project Additional Information**

**Purposes of the contained use**

O2 Healthcare is seeking to develop novel therapeutics focused on human disease. To facilitate a full understanding of the biology of disease it is anticipated that, there will be the need to generate in vitro cellular models which may have:

- Stable overexpression of exogenous genetic sequence.
- Reduced expression of target genes by expressing short hairpin RNA (shRNA).
- Knockout or modification of endogenous genes using CRISPR/Cas9 or related methodologies to:
  - Introduce specific amino acid changes.
  - Add a tag such as but not limited to GFP, luciferase, FLAG & HA.
- Introduction of reporter gene systems to allow the measurement of functional effects on key cellular signalling pathways.
- The target mammalian cell lines may be categorised as hazard group 1 & 2.
- These modifications maybe introduced into cells using expression plasmids and standard non-viral transfection methodologies.
- In some circumstances the nature of the enquiry will be better addressed by transducing the most appropriate cell line using lentivirus. Where possible these will be obtained from 3rd party vendors in ready to use aliquots but there will be instances where the lentiviral material will need to be generated on site.

**Recipient or parental organism**

**Cell lines for packaging lentivirus**

Where lentivirus cannot be reasonable obtained from commercial sources it will need to be produced internally using a packaging cell line, such as HEK-293T capable of supporting the production of lentiviral particles. Packaging cell lines are only used for the production of lentiviral particles and are not used to develop cellular models.

Well characterised immortalised cell lines for in vitro cellular models

A number of immortalised cell lines are available that can be used as model systems for validating and assessment of target activity and used subsequently in developing molecules to modify that activity. Due to the nature of the work cell lines known to support the propagation and production of replication competent lentivirus particles (RCLs) will not be used in this area of the work. The Biosafety level 1 or 2 cell lines will be obtained from reliable sources (commercial and academic) with a clear history of safe use and a well understood mechanism of immortalisation to remove the risk of recombination events leading to production of RCLs.

**Primary human cells**

The main risk is the presence of adventitious pathogens.

Ideally, cells will have been screened for major human pathogens with the potential to harm health and shown to be negative.

In some instances, however, consent to screen for major human pathogens is not sought at the time of cell donation. Screening the cells for major human pathogens would have potentially significant clinical health implications for patients (e.g., HIV), for which explicit consent has not been given at the time of donation. As such, for cells where consent has not been given, they cannot be screened for human pathogens and must therefore be handled at Biological Safety Level 2. All donors, however, must have no previous known history of infectious disease and will be from epidemiologically low-risk populations.

Recipient cells will be from healthy individuals, or from patients with a disease caused by genomic mutations. As these mutations are naturally occurring in the genome of these individuals, they are not mobile genetic elements and
thus present a very low biosafety risk.

HiPSC derived from primary human cells, most commonly fibroblasts. The hiPSC that will be used may have been either generated using 3rd or 4th generation self-inactivating (SIN) nonmobilisable integrating retroviral systems based on, but not limited to, mouse Maloney murine leukaemia virus (MMLV), Maloney murine sarcoma virus (MMSV), myeloproliferative sarcoma virus (MPSV), or human HIV. Some of the original donor material will not have been screened for human pathogens but donors will have a known medical history and will be classified as being low risk for retroviral pathogens. As such the hiPSC are highly unlikely to be producing RCLs.

Reprogramming of the hiPSC is achieved using a variety of factors, that are integrated into the cell genome by the retroviral vectors, that induce pluripotency in the donor cells. A combination of the following factors may be present in the supplied hiPSCs:

- **SOX2**: is a transcription factor that is essential for maintaining the pluripotency of undifferentiated embryonic stem cells.
- **KLF4**: is a transcription factor that regulates proliferation, differentiation, apoptosis, and somatic cell reprogramming. KLF4 may also act as a tumour suppressor gene.
- **OCT4**: is a homeodomain transcription factor of the POU family. This protein is critically involved in the self-renewal of undifferentiated embryonic stem cells and is used as a marker for undifferentiated stem cells. It is indispensable for generating iPSC.
- **CMYC**: is a transcription factor that plays a role in cell cycle progression, apoptosis, and cellular transformation. Mutated c-Myc is found in many cancers, where it is constitutively expressed, leading to the unregulated expression of many genes, some of which are involved in cell proliferation leading to oncogenesis. This factor poses a risk if mobilised into RCL.
- **NANOG**: is a transcription factor critically involved with self-renewal of undifferentiated embryonic stem cells.
- **LIN28**: encodes a microRNA-binding protein; overexpression of which in mice, can cause gigantism and a delay in the onset of puberty. Human GWAS studies indicate the LIN28B gene to be associated with human height and the timing of puberty. The biosafety risk is low for adults.
- **GLIS1**: is a highly promiscuous transcription factor, positively or negatively regulating the expression of a number of genes.
- **shp53**: short hairpin RNA that suppresses expression of p53. P53 is a known tumour suppressor gene and binds to DNA where it regulates the expression of anti-mutagenesis genes. Mutations in the p53 gene leading to a loss of activity are the most commonly found single mutation in human cancer.
- **Mir302/367 cluster**: microRNAs are a subclass of small non-coding RNAs that fine-tune the regulation of gene expression at the post-transcriptional level, with a particular role in establishing cellular pluripotency. HiPSCs can also be generated using episomal approaches and if suitable will be used preferentially. The cells are reprogrammed using non-viral episomes, there is no integration of genetic material into the resulting hiPSC genome, and no viral sequences are introduced into the cells. Episomes are lost as the reprogrammed hiPSC proliferate, at an approximate rate of 5% per generation. Therefore, by approximately 12-13 proliferation cycles, the episomal transgenes have been entirely lost. This eventually results, at the time of use, in “footprint-free” cells that do not contain the original reprogramming sequences. In this respect the hiPSC are not genetically modified but do have a changed gene expression profile and a pluripotent phenotype.

**Host/vector system**

In the case of hiPSC generated using integrated retrovirus the factors and vectors used will be fully described prior to receipt and be reviewed by the Biological Safety Committee (BSC) at O2 Healthcare (O2H) which also has the responsibility for any work involving genetic modification. In this case subsequent lentiviral vectors will be nonhomologous.
with the integrated sequences to mitigate the small risk of a recombination event leading to mobilisation of genetic material, such as the myc oncogene or immunomodulatory genes, that might pose a risk to human health. The integrated murine based lentivirus poses no additional risk to the environment. It is also planned to transduce immortalised cell lines, primary cells and episomally generated hiPSCs with lentiviral vectors. The recipient cells will not be known to harbour viral material that could be mobilised by introduction of lentiviral vectors and where viral material is present will not support the production of RCLs. Secondary transduction would either transiently modulate the protein expression of a target protein at the translational level, modify the cells to explore the underlying disease process or to generate tools for drug discovery. To this end the following could be used based upon the needs of drug discovery programs:

- Integration of shRNA constructs to ‘knock down’ expression of a gene of interest
- The over-expression of particular genes
- Specific modification of the host genome using programmable nucleases:
  - Cas9/CRISPR
  - Reporter genes under the control of selected transcriptional regulatory sequences to study effects on cellular pathways.

Introduction of genetic material on expression plasmids using chemical or physical transfection methods has a negligible risk of introducing such material into humans or the wider environment. The main risk is associated with the host cell line and its altered form. Cell lines will be used in accordance with their biosafety level status. As lentivirus have a much greater ability to transduce cells this risk assessment will focus on their use. The lentivirus obtained from commercial sources will have been generated using third of fourth generation vector systems. The vector backbone and promoters used to drive vector generation in these systems will be consistent. Due to the nature of the work, genes may be selected that will include growth factors, tropic factors, quiescence factors, confirmed oncogenes, tumour suppressors and proteins known to be involved in neurological disorders. The vectors will be generated using a non-replication-competent HIV based lentiviral system that upon integration into the host genome loses part of its long terminal repeat (LTR) preventing excision at a later time point. Such self-inactivating (SIN) vectors are designed to produce stable gene expression in target mammalian cells. The viral particles can only be generated upon co-transfection of a packaging cell line (usually HEK-293T) with at least four separate plasmids. Three of which provide the minimal set of genes required for viral production (gag-pol, rev and env). The env gene used is from the vesicular stomatitis virus (VSV-G) to increase tropism. The final plasmid provides the genetic material to be supplied to the target cell and as such contains packaging sequences directing it to be incorporated into nascent viral particles. Only the minimum amount of lentiviral genome is used in the system and all of the plasmids lack homologous sequences to minimise any chance of recombination. The resultant lentiviral particles are VSV-G pseudotyped, SIN and replication incompetent in mammalian cells. Small aliquots of no more than 1x10e8 viral particles in 5 to 10 microlitres will, further reducing the risk.

Third Generation Systems use 4 standard bacterial plasmid vectors. Three plasmids encode for proteins required for production and packaging of full-length viral RNA (for example: pCgpV, pRSV-Rev and pCMV-VSVG). The gene of interest is contained in a fourth plasmid (e.g., pSMPUW). This is the only plasmid that contains the packaging sequence for incorporation into the virus particle.

Fourth Generation Systems use 6 standard bacterial plasmid vectors. The system uses tetracycline to control when viral particles are produced adding yet another level of control to production. For example, pTRE-gag-pro, LTRHIV2-vpr-pol, penv(VSV-G), pTet-Off and ptat-IRES-rev contain the sequences that code for proteins that are responsible for the tetracycline control and packaging of the viral genetic material. As above the last plasmid (e.g., pSMPUW) only contains the genetic material to be packaged into the vector and no other lentiviral gene sequence. An integrase
deficient version of the fourth-generation system is available which contains a mutation in the sequence encoding the viral integrase.

Lentiviral Vector Expression System

If lentiviral particles do need to be generated internally either a 3rd or 4th generation system will be used as above and purified using either commercially available kits, or well-established methods (detailed below). Lentiviruses belong to the Retroviridae virus family which are capable of infecting both human and animal species. As the lentiviral vector system that will be used in these studies is based on HIV-1, a theoretical risk to human health exists. However, retroviruses are generally transmitted via exposure to contaminated body fluids or percutaneous inoculation and generally not transmitted via the airborne route. Therefore, accidental piercing of the skin or other surface tissues with virus containing objects represents the main potential route by which accidental infection could occur. Appropriate risk reduction measures will be implemented to reduce the likelihood of this occurring.

In all of the modified pSMPUW plasmids (containing protein-coding sequences, miRNA, shRNA, or programmable nucleases or reporter gene sequences), the sequences inserted are flanked by non-coding retroviral LTRs, and no retroviral genes are encoded on the modified pSMPUW plasmids. Therefore, no retroviral genes will be transferred into generated viral particles. This construct is packaged into particles using a HEK293T cell based packaging system, which requires the co-transfection of these cells with three to five additional separate plasmids (as detailed above). The additional plasmids express the envelope protein from VSVg and the non-structural proteins of the virion, and, importantly, none of these genes will be transferred into the assembled viral vectors, since they lack the packaging signal (Psi), which is only present on the modified pSMPUW plasmids.

The lentiviral Expression System what will be used include the following key safety features:

- All of the pSMPUW contain a hybrid 3’LTR that does not affect generation of the viral genome in the producer cell line, but results in “self-inactivation” (SIN) of the vector after transduction of target cells. Once integrated into a transfected target cell, the lentiviral genome is no longer capable of producing viral genomic material that can be packaged. Moreover, presence of an SV40 polyA after the hybrid 3’LTR in the vector construct will result in a provirus which should reduce the potential for transactivation of cellular genes due to an insertion event. Furthermore, the development of self-inactivating vectors improves the biosafety of vectors, as they are less likely to be mobilised following a superinfection with wild-type virus (HIV).
- The VSV-G gene from Vesicular Stomatitis Virus is used in place of the HIV-1 or other retroviral envelope genes. Heterologous envelopes, like VSV-G, typically broaden the tropism and allow gene transfer into a broad variety of cells. The risk will mitigated by the use of self-inactivating virus and limiting the number of viral particles that will be handled at any one time.
- Sequences encoding the proteins required for packaging of the viral genome are separated onto three to five plasmids, and all of the 4-6 plasmids used in the system have been engineered not to contain any regions of homology with each other so as to prevent undesirable recombination events that could lead to the generation of a replication-competent lentivirus (RCL), which could potentially be harmful to humans. It is important to note that no such RCL has ever been observed despite large-scale production and testing of lentiviral vectors.
- All of the pSMPUW containing plasmids/vectors will be used are devoid of all viral sequences apart from essential cis-acting sequences, including the LTRs and the packaging signal Psi. Although the packaging plasmids used in these systems allows for the expression in trans of protein required to produce viral progeny (e.g. gal, pol, rev, env) in the HEK293T producer cell lines, none of them contain LTRs or the Psi packaging sequence. Several of the lentiviral accessory genes (vif, vpr, vpu and nef) that are dispensable for lentiviral vector production/transduction have been deleted from the packaged construct. Therefore, none of the retrovirus structural genes will actually be present in the packaged viral genome, and they will never be expressed in the transduced target cells, which means that no new
RCL can be produced.

- The lentiviral particles produced in this system are replication-incompetent, only carry the sequences of interest, and no other viral species are produced.
- Expression of the gag and pol genes from pgag-pol-RRE has been rendered Rev-dependent by virtue of the HIV-1 RRE (Rev Responsive Element) in the gag/pol mRNA transcript. Addition of the RRE in these plasmids prevents gag and pol expression in the absence of rev, which is contained in the pRSV-REV plasmid only. The Rev/RRE system is highly conserved among lentiviruses, and removal of the RRE sequence and associated splice donor/acceptor sequences result in a loss of transduction efficiency.
- LTR has been modified so as to increase lentiviral vector production, and also to allow lentiviral vector production to be independent of tat expression. It is known that Tat-deleted mutants of wild-type HIV-1 are not replication competent. Therefore, the deletion of Tat should decrease the risk of generating a putative RCL.
- Lentiviral vectors have a very low potential to cause immunogenicity.
- The central poly purine tract (cPPT), from the pol ORF, is included in all of the viral vectors that will be used to improve the nuclear import of the proviral DNA and hence accelerate transduction.

While the lentiviral vectors that are produced using this system contain only about 20% of the original genome of HIV-1, there is a very small risk that subsequent infection of cells already infected with the lentiviral genome of HIV-1 could lead to a rare recombination event in which the transgene is transferred to a replication-competent virus. Thus, the sequences in the vector that will be expressed could potentially be transferred to surrounding cells. This event is, however, extremely unlikely to occur for a number of reasons:

1- The lentiviral vector is replication-incompetent and self-inactivating. In the case of a subsequent HIV-contamination, wild-type HIV-1 cannot rescue a self-inactivating HIV-1 based lentivirus once integrated into the host genome, although non-self-inactivating vectors can be.
2- In order for the spread of the gene of interest to occur following accidental infection (assuming that this has lead to viral integration), a series of unlikely events have to occur:
   a- The worker would have to become infected with HIV-1 or to be already infected with the virus.
   b- The viral and lentiviral genomes would have to integrate into the host worker’s genome in the same cells and in a position where they could interact to effect homologous recombination (point 1 above)
   c- Recombination would have to occur in just the right regions to allow for transfer of the gene of interest from the lentivirus to the HIV-1 genome, which could also involve the transfer of the HIV-1 genes to the lentiviral genome. In that case, it is conceivable that a non-self-inactivating HIV could be generated that contained the gene of interest but not the rest of the genome it requires. The other gene products could be provided in trans from the lentiviral genome that may now contain the HIV-1 genes or from other HIV-1 integrants.
   d- The situation in c could conceivably lead to the production of an infectious particle containing the gene of interest, but again no genes necessary for subsequent replication. In order for another round of infection to occur, the process would have to begin again.

In these circumstances, the effects of lentiviral infection are likely to be minor in comparison to the effects of the HIV-1 infection, which would be required to affect the spread of the gene of interest. In addition, the scenario described is essentially equivalent to the rescue of the lentiviral genome from the host, which has already been shown not to occur.

3- It is extremely unlikely that any worker would infect themselves with a significant dose of lentivirus as the volumes that are used in transduction experiments are small (aliquots contain a maximum of 10 μl of vector solution).
4- Moreover, insertional mutagenesis into the host genome may be considered as an oncogenic risk. We cannot rule out the possibility that, when the lentiviral genome integrates into the host genome, it will not lead to the activation of
an endogeneous oncogene. However, all transcriptionally active long-terminal repeats (LTRs) have been removed as well as all promoter-like elements that required to drive expression of the transgene. This should prevent unforeseen activation of such genes. It is noted that deletion of retroviral enhancer in self-inactivating systems reduces the risk of activation but not of disruption, therefore, retroviral infection might still have permanent effects upon a cell (including oncogenic effects).

Importantly, we do not consider that the use of these lentiviral vectors will result in a significant increased risk of oncogenic activation compared to the risk possessed by any other viral delivery system. Moreover, the risk of transduction leading to tumourigenesis or other untoward harm following exposure is related in part to the titre of the viral vectors; exposure of workers to quantities of virus high enough to cause such effects would be unlikely during standard laboratory-based manipulations of lentiviral vectors.

For both commercial and internally generated lentivirus the fourth plasmid (e.g., pSMPUW) will contain the sequences that code for protein, miRNA, shRNA, or programmable nuclease sequence, or reporter gene sequence under the promoter of the gene of interest. These may include growth factors, tropic factors, quiescence factors, confirmed oncogenes or tumour suppressors.

Origin & function

• Gene overexpression
Some genes/proteins may be overexpressed in order to investigate their cellular function and role in disease mechanisms. The genes/proteins that will be overexpressed may include any growth factors, confirmed oncogenes, tumor suppressors, immunomodulators or proteins known to be involved in disease. The BSC will be informed of the full nature of, and justification for, any proposed gene/protein overexpression, and have final say on whether it is acceptable to proceed with the proposed modification.

• shRNA
With the use of shRNA-expressing viral vector systems, the expression of specific mammalian genes/proteins can be knocked-down, in order to study their functions. Potential deleterious effects such as off-target and immunomodulatory responses can be minimised through screening designed shRNA sequences against databases of known mammalian/mRNA sequences during the design stage. The genes/proteins of interest that will be targeted by shRNA may include growth factors, tropic factors, quiescence factors, confirmed oncogenes, or tumor suppressors. Some of the viral vectors that will be used contain a sequence of interest that has been scrambled (scrambled shRNA), and which is not complementary to any known mammalian sequences. This sequence will adopt a hairpin structure as with any shRNA, but it should not target any mRNA of human, mouse or rat origin. Consequently, these sequences are unlikely to pose any safety risks for the environment or human health. The BSC will be informed of the full nature of and justification for, any proposed shRNA in cell line in order to seek approval and will have final say on whether it is acceptable to proceed with the proposed modification.

• Programmable nucleases: zinc fingers or Cas9/CRISPR
CRISPR/Cas9 gene editing will be directed against genes of therapeutic interest. Since the purpose of programmable nucleases is to cause mutations in defined DNA sequences the primary hazard is that such a mutation would lead to deleterious cellular effects. The genes/proteins that will be targeted may include growth, trophic factors, confirmed oncogenes, tumor suppressors or immunomodulators. In isolation, these sequences are unlikely to pose any safety risks for the environment or human health. Programmable nucleases may also be used to generate isogenic controls lines, whereby mutations are reverted to the common wild-type sequence. Generation of isogenic lines poses a low risk to human health as the sequences being targeted are the rare mutated sequences and they are being reverted back to the normal, functional version of the gene. The BSC will be informed of the full nature of and justification for, any proposed programmable nuclease-based modifications in cell lines in order to seek approval and will have final say on whether it is acceptable to proceed with the proposed modification.
Reporter genes: Fluorescent protein or enzymes

The reporter gene could be a fluorescent protein or an enzyme. Fluorescent proteins, for example GFP or dsRed, are not known to cause any diseases in human or animals and have no direct effect on cellular processes. Enzymes used frequently in reporter gene assay ie luciferase of beta-galactosidase are not known to cause any diseases in humans or animals and as no direct effect on cellular processes. The expression of fluorescent protein or enzymes under control of a promoter of a gene of interest is unlikely to pose any safety risks for the environment or human health. The BSC will be informed of the full nature of, and justification any proposed reporter gene expression in cell lines in order to seek approval and will have final say on whether it is acceptable to proceed with the proposed modification.

Evaluation of foreseeable effects

HiPSC are pluripotent and are capable of uncontrolled proliferation. Lentiviruses belong to the Retroviridae virus family are capable of infecting both human and animal species. The lentiviral vector system that will be used is based on HIV-1. Retroviruses are generally transmitted via exposure to contaminated body fluids or percutaneous inoculation and generally not transmitted via the airborne route. Piercing of the skin represents the main potential route by which material could be accidentally introduced into an individual. Appropriate risk reduction measures will be implemented to reduce the likelihood of this occurring.

Accidental introduction of hiPSC into healthy individuals should not lead to the formation of teratomas because the immune system will rapidly destroy these cells. As mentioned above the pathogen status of some cells is not known. However the material will not be derived from high-risk clinical patients and procedures are in place to deal with needle stick incidents (although no sharps will be used). Individuals with compromised immune systems are not permitted to work with this material.

The genetic material to be incorporate into the viral particles is flanked by non-coding retroviral LTRs. No retroviral genes are encoded on this plasmid minimising the chance any will be packaged into viral particles. As the system requires the co-transfection of three to five additional separate plasmids into a permissive cell line the chance of recombination occurring that leads to the incorporation of any or all of the retroviral genes necessary for the production of a RCL is very low and the risk is therefore low.

The lentiviral Expression System includes the following key safety features:

* Only the vector containing the genetic sequence of interest includes LTRs and the packaging signal sequence required for incorporation into viral particles and integration into the genome of a transduced cell. A hybrid 3’LTR is used that does not affect generation of the viral genome in the producer cell line, but upon integration into the genome of a target cell, the 3’LTR SIN which prevents production of viral genomic material that can be packaged and reduces the chance of mobilisation due to secondary infection with wild-type lentivirus. No transcriptionally active LTRs are present in the system and an SV40 polyA sequence is included after the hybrid 3’LTR to reduce the potential for transactivation of cellular genes due to an insertion event that might promote inappropriate gene expression leading to oncogenic effects.

* The LTR has been modified to enable lentiviral production independent of Tat expression. HIV-1 devoid of Tat is known to be replication incompetent. This decreases the risk of RCL occurring.

* The essential genes encoding the proteins required for packaging of the viral genome are separated onto three to five different plasmids. These express the proteins (gag, pol, rev, env) required to generate viral particles transiently in a permissive packaging cell line (e.g. HEK-292T). Other retroviral structural genes are not present in the system. None of the plasmids have regions of homology which will prevent undesirable recombination. As multiple recombination events would be required to generate a RCL the risk of this happening is very low and has so far not been observed in large-scale production and testing of lentiviral vectors.

* In most systems expression of the gag and pol genes has been rendered Rev-dependent by virtue of the HIV-1 RRE (Rev Responsive Element) in the gag/pol mRNA transcript. Expression requires the presence of rev, which is supplied...
by a separate plasmid. The Rev/RRE system is highly conserved among lentiviruses and loss of the RRE sequence and associated splice donor/acceptor sequences results in a loss of transduction efficiency.

- Lentiviral vectors have a very low potential to cause immunogenicity.
- The central poly purine tract (cPPT), from the pol ORF, is included in all of the viral vectors that will be used to improve the nuclear import of the proviral DNA and hence accelerate transduction of target cells.

Whilst pseudotyped VSV-G is used as the envelop protein to increase the cell types that can be infected this increase in risk is mitigated by the SIN non-replication nature of the viral vectors generated. Due to the random nature of integration into the genome insertional events that disrupt gene function could occur and, in some instances might lead to undesirable effects which could be oncogenic.

The resultant lentiviral vectors contain about 20% of the original HIV-1 genome. Recombination with wild-type HIV-1 is still potentially possible and could result in mobilisation of the transgene. This is highly unlikely because:

1. Wild-type HIV-1 is not used with in the laboratory environment.
2. Primary cells or hiPSC are not derived from donors either known to be HIV positive or from a high-risk population; so HIV contamination is highly unlikely.
3. Wild type HIV-1 cannot rescue a SIN HIV-1 based lentivirus once integrated into the host genome.
4. It is likely that any recombination would actually decrease the ability of HIV-1 to infect other cells or to replicate.
5. Even if a worker was already or became HIV-1 positive and was accidentally infected with lentiviral vector any recombination would require infection of the same cells. Generation of RCL would require homologous recombination to be in the right regions to enable mobilisation and incorporation to the HIV-1 genome without loss of replication ability. If such a rare event were to occur it is likely to be self limiting and the HIV-1 infection itself is of greater concern to the worker.

The use of lentiviral vectors is an efficient manner with which to deliver genetic material to and integrate into the genome of numerous cell types. This stable integration is of great benefit in scientific research. The design of the vectors minimises the chance for subsequent mobilisation of transgenes and inappropriate activation of endogenous oncogenes. Insertional events can lead to harmful side effects but are still very unlikely. As such the greatest risk from these vectors comes with their production where much larger volumes and numbers of vectors are being generated.

The risk here is mitigated by the correct use of containment measures and the absence of sharps. Lentiviral vectors are susceptible to dehydration and loss of viability if they are not stored in high protein conditions which reduces the risk to workers and the wider environment.

Transgenes to be delivered to target cells:

Additional hazards could arise from the properties of the genetic material that will be inserted into the viral vectors and expressed in transfected cell lines, primary cells or hiPSCs.

- Gene products to be overexpressed may include growth factors, oncogenes and proteins associated with disease. The risk that these represent is minimised by the use of single use aliquots of AAV and lentiviral vectors in a controlled biosafety level 2 environment. Any protein to be expressed will require justification to and gain BSC approval before work can commence.

- The 'knock-down' of specific gene expression using shRNA can lead to off-target and immunomodulatory responses in vivo. shRNA sequences will be screened against databases of known mammalian/mRNA sequences during the design stage to avoid such complications. Control vectors will also be used that contain a sequence of interest that has been scrambled (scrambled shRNA), and which is not complementary to and therefore does not target any known mammalian sequences. Such sequences are unlikely to pose any safety risks for the environment or human health.

- Programmable nucleases: Cas9/CRISPR will be directed against genes of therapeutic interest. In isolation, these sequences are unlikely to pose any safety risks for the environment or human health. Programmable nucleases may...
be used to generate isogenic controls lines by correcting disease causing mutations back to wild-type sequence. This is low risk because the sequence is aimed to revert back to non-disease forms of the gene. In the case of adding a tag to monitor/follow gene expression there is no anticipated change to the function of the gene and the risk is low.

- Reporter genes: Commonly used fluorescent proteins or enzymes under the regulatory control of promoters of interest may be used to monitor effects on cellular pathways. Such proteins are not known to cause any human or animal disease and pose no-risk.

In all cases justification for any target must be submitted to the BSC for approval prior to any work commencing.

Summary

Primary human cells and hiPSC will be derived from low risk patient populations but may not be screened for human pathogens. Only well characterised immortalised cell lines will be used. The lentiviral systems are replication incompetent and SIN minimising the potential for transgene mobilisation and propagation. The AAV system is transient, non-integrating and replication incompetent having a negligible potential for transgene mobilisation. The transgenes that will be selected will on their own have a low risk to human health. Infection of mucosal cells may occur via aerosols but is highly unlikely due to the use of microbiological safety cabinets and secondary containment. Such infection is self limiting due to the natural shedding of epithelial cells coupled with the replication incompetent nature of the vectors. The most likely route of accidental infection with lentivirus or with an hiPSC line will be via inadvertent percutaneous inoculation via stick injury or open wound. The likelihood of this occurring will be minimised by following standard BSL2 containment practices. Infection of the community and environment with lentivirus particles is highly unlikely due to the small quantities used, their intrinsic instability and rapid loss of viability with time. hiPSC can not survive outside of the laboratory environment so pose no wider risk. Therefore the risks towards workers, co-workers, the public and the environment associated with the use of these lentiviral vectors with hiPSC will be low and BSL2 containment is sufficient.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMOs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Instead of autoclaving waste in the building as per the guidance we wish to chemically inactivate all of our waste and then send it for disposal off site via a registered waste contractor.

All waste material will be inactivated by treatment with a validated disinfectant prior to disposal. For example 5% (v/v) Chemgene solution or 2% final Virkon concentration in the case of material with a high protein concentration such as waste liquid media. Liquid waste will be inactivated for 24 hours prior to either disposal to sewers via a designated laboratory sink or being solidified and treated as solid waste. Solid waste material will then be placed in sealed bins and incinerated by an off-site incineration company.

Waste from our GM work at Class 2 will be double bagged and placed into suitably labelled hermetically sealable (yellow lid to distinguish them from class 1 waste) 60 litre UN approved (to Class 3) bins. Sealed bins are placed into secondary 210 litre yellow labelled “Eurobins”. Contents of the bin are recorded and collections by the local registered clinical/GM waste incinerator contractor will be routinely be made to prevent a buildup. The site has 24/7 Security. The contractor uses solid bodied transport and carries portable disinfection equipment in case of any spillage. The type of container and the secondary Euro container means that the risk of any spillage of active GM waste on site is negligible. However, as active waste will leave the site, the risk to the environment and health is possibly marginally higher than autoclaving prior to incineration. The only real risk of release would be as a result of a major road traffic accident, however, the containers are designed to withstand this.

This disposal method is expected to achieve 100% inactivation of the GMM.
### Waste Handling

- Following all work requiring biosafety level 2 containment solid waste will be neutralised by soaking in a validated disinfectant solution for at least 20 minutes, after which the material will be “double bagged”, and, ultimately placed in hermetically sealed burn bins for incineration offsite with a registered waste contractor. It will be routine practise that all liquid waste material be neutralised before disposal, and for the neutralised waste to be transported in leak-proof containers to prevent spillages. Liquid waste will be inactivated with Chemgene HLD4L* (or equivalent product, i.e. Virkon) for 24 hours prior to disposal. In some instances, the liquid waste will be disposed to sewers via a designated laboratory sink or can be solidified with Labsorb (or equivalent product) and disposed of as solid waste as above.

- Virkon is a synergised oxidising system that works by physical destruction of pathogens by acting on proteins. It is resistant to inactivation by organic material. Shown to be effective against bacteria, viruses and fungi including all major human pathogens. Recommended to be used at 1% concentration for all activities.

- Chemgene HLD4L is a commercial validated disinfectant. It is formulated as a micelle cleaning technology that enables the active molecules in the product to be carried rapidly through the cell walls or micro-organisms. Swift penetration of the cell walls ensures cell death is equally rapid. Chemgene HLD4L has been reported to be bactericidal, fungicidal as well as virucidal (HIV, hepatitis B, Herpex Simplex, Norovirus and Coronavirus) and sporicidal. It is recommended to be used at a 1:100 dilution (1%) for general purposes, 1:20 dilution (5%) for high-risk areas, and for disinfection of blood and bio-hazard spillages.

### General cleaning procedures

- Surfaces will be thoroughly cleaned with Chemgene HLD4L 5%* (or an equivalent product) at the end of each experiment or after the occurrence of an accidental spillage of infectious material. Application of these anti-microbial agents will totally inactivate any viral vectors that might be present. According to the biosafety literature, all the viruses to be used are susceptible to these disinfectants. Anything that might have potentially come into contact with the virus will be treated with Chemgene HLD4L* before being incinerated.

*Page 15066 of 15326*
The Biological Safety Committee (BSC) agrees with the assessment that this work can be conducted at BSL2. It is noted that the primary human cell lines used will be taken from patient populations with a known medical history meaning that there is a low risk of material containing harmful human pathogens. This does not rule out the presence of latent viral infection but the use of third or fourth generation integrating lentiviral systems that are self-inactivating and essentially non-mobilisable makes it highly unlikely that infective replication competent virus will be generated. Important due to the potential use of oncogenic sequences. Lentiviral transduction into hiPSC or immortalised cell line should not be able to mobilise any genetic elements because self-inactivating systems will be used that lack the necessary genes for viral replication and packaging. As an additional measure the BSC will have a clear understanding of how each cell line was generated and steps will be taken to ensure overlapping and therefore potential sites for recombination are not present in lentiviral vectors. These vectors are for the introduction of further modifications. Those aimed at correcting disease mutations do not pose a risk to health. The introduction of nondisease-causing genetic material for exogenous expression is not seen as a risk either. In the instance where oncogenic or immune modulators may be targeted the risk although increased is well contained by the avoidance of sharps during and subsequent to the transduction procedure. Once cells are transduced and virus removed the risk posed here is very low. Due to the use of iPSC derived from primary human cells, cell lines already requiring biosafety level 2 containment and the use of integrating lentiviral vectors this dictates propagation, differentiation of cell lines at BSL2. BSL1 cell lines once transduced, and lentivirus removed at BSL2 could be used at BSL1.

The work will be carried out in compliance with good laboratory practice and local safety rules for GM work in a containment class 2 facility.

Solid media will be autoclaved at 121 degrees C and 15 psi for 30S mins to achieve 100% inactivation. Autoclave is present in the laboratory.

Print outs from the autoclave and autoclave indicator tape will be monitored and recorded for successful runs. All autoclave cycles have been validated for the actual load types used. Successful completion of every load will be checked prior to disposal.

Decontaminated solid media will be placed into lab waste bags, cable tied and stored in lidded carts and stored in a separate dedicated waste storage room prior to collection from site by professional waste removal subcontractor.

Liquid media will be treated with 1% solution of Virkon for minimum of 30 mins as per Virkon manufacturer instructions to achieve 100% inactivation. Decontamination will occur on a dedicated lab bench distinct from the rest of the lab to ensure safe working procedures. Virkon provides a colourmetric identification to ensure successful and correct usage. Decontaminated liquid media will be safely disposed through the lab sink drain. Any accidental spillage of liquid waste will be cleaned with 2% virkon and paper towels, followed by 70% ethanol.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

The risk assessment provided is comprehensive and adequate for use of class 1 contained GMM usage. Appropriate risks have been identified and counter measures have been placed to ensure safe working and avoid any contamination risk to human health of users, staff and also risk to the building and local environment.

Project Ref 3596/21.1
Bacterial and fungal strains isolated from soil will be cultured alongside bioluminescent reporter strains for novel metabolite production.

**Project Additional Information**

**Purposes of the contained use**

Novel non GM biological agents isolated from soil are screened against class 1 reporter stains and cultured in laboratory on a small scale (0-1 OOmL volume) to extract primary and secondary metabolites. Bioluminescent reporter strains (currently all class 1) have had the lux operon integrated into genome to produce luminescence. The reporter strain is transferred to a 96-well plate containing the novel bacterial species in a BSC level II safety cabinet. The plate is then sealed and luminescence is measured over a period of 24 - 72 hrs in a sealed TECAN cryoSPARK plate reader.

**Recipient or parental organism**

No class 2 GMOs currently present.

**Host/vector system**

No class 2 GMOs currently present.

**Origin & function**

No class 2 GMOs currently present.

**Evaluation of foreseeable effects**

No class 2 GMOs currently present.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

No larger GMO work will be conducted at the premises.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**
No derogation from full containment is requested

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The work will be carried out in compliance with good laboratory practise and local safety rules for GM work in a containment class 2 facility.
Solid media will be autoclaved at 121 degrees C and 30 psi for 15 mins to achieve 100% inactivation
Autoclave is present in the laboratory.
Print outs from the autoclave and autoclave indicator tape will be monitored and recorded for successful runs.

Standard organism decontamination procedure used at our laboratory site is to use Virkon disinfectant as a 1-2% solution to be subsequently disposed of in the laboratory sink. Virkon is validated against a number of typical lab and hospital pathogens with extremely high killing capability (greater than 99.999% kill) and is one of the most reliable and commonly used disinfectants on the market. Random periodic sampling and plating of disinfected surfaces, equipment and culture flasks will be performed to monitor and demonstrate total cell death. After disinfecting with Virkon, culture flasks will be autoclaved.

The Maxion Therapeutics Ltd genetic modification committee will consist of:

1. The biosafety officer who has extensive experience of genetic modification issues, being currently in charge of biosafety for a large research institute. The biosafety officer will chair all genetic modification committee meetings.
2. The Chief Executive Officer has 30 years experience of genetic modification and previously ran research groups both in industry and academia. His function on the committee is to advise and provide the necessary resources for the actions of the committee to be implemented.
3. The Chief Scientific Officer who has 11 years experience of genetic modification in E. coli and mammalian cells. He will provide advice and ensure the actions arising from the committee meetings are implemented.
4. Senior Research Scientist who is a specialist in mammalian cell culture has 7 years experience. He will provide advice and write the minutes of the meetings.

The committee will meet every 6 months to review biosafety and whenever a new risk assessment is required. The first meeting will review the existing risk assessments.
All waste material will be inactivated by treatment with 1% (w/v) Virkon solution prior to disposal. Waste material will then be placed in sealed bins and incinerated by an off-site incineration company (see derogation application below).

Waste from our GM work at Class1 will be placed into suitably labelled hermetically sealable bins. They will be sealed by our staff and removed to a central collection point where they will be placed into 210 litre yellow labelled "Eurobins".

Collections for incineration will be made by the local registered clinical/GM waste incinerator contractor. This disposal method is expected to achieve 100% inactivation of the GMM. The data sheets describing inactivation by Virkon are attached.

Tick to confirm that you are attaching a summary of the risk assessment  

Tick if you are claiming exemption from disclosure for sections of the risk assessment  

The scope and particular aspects of safety risks described in the risk assessment were agreed upon, and satisfactory consensus was achieved regarding the adequacy of the SOPs, COPs and risk management planning protocols. Pending notification and acknowledgement by relevant authorities.

Give brief details of the genetic modification safety committee

The ArkVax Ltd genetic modification committee will consist of:
1. The CEO and biosafety officer who has extensive experience of genetic modification issues, having worked at a University and being the academic in charge of a category 3 laboratory. He has over 20 years of experience of genetic modification of E. coli and other bacterial cells. The biosafety officer will chair all genetic modification committee meetings.
2. The Co-founder has 20 years experience of genetic modification and previously ran research groups in academia. His function on the committee is to advise and provide the necessary resources for the actions of the committee to be implemented.

The committee will meet every 6 months to review biosafety and whenever a new risk assessment is required. The first meeting will review the existing risk assessments.

Project Ref 3599/21.1

Date Ackn’d 25/02/2021

CU2 Project Title Engineering of veterinary vaccine candidates targeting bacterial diseases

Class CultureVol

Class 2 < 1 Litre

Consent Granted

Non-GMM
Purposes of the contained use

To genetically modify strains of E. coli K-12 derivatives or ACDP category 2 pathogens in order to create attenuated vaccine candidates. The mutation target site will generally render the organism unable to establish an infection (example, removal of O antigen or capsular polysaccharide) in a host in addition to disabling growth outside of rich culture medium (such as the removal of Aro genes, responsible for creating aromatic amino acids). These live weakened bacteria will also be modified to carry vaccine immunodominant antigens such as capsular polysaccharide or protein antigen that have been demonstrated to be efficacious immune system stimulants. Vaccine candidates will be cloned into pathogens such as (i) immunodominant antigens such as surface proteins (ii) the O (LPS) antigen from several bacteria, (iii) the capsule from several bacteria. These will be introduced into the host bacteria on their chromosomes or on plasmids for initial proof of concept studies. The cloned antigens will be tested by whole cell western blotting but also purified for further analysis. None of the cloned antigens are classified as active toxins.

Recipient or parental organism

Subproject 1: Vaccine candidates will be cloned into E. coli K12 such as (a) immunodominant antigens (eg AcrA and OmphH1 from Campylobacter jejuni, sortase and sorted proteins from Clostridium spp. and detoxified proteins (b) adherence proteins such RsCC from Yersinia pseudotuberculosis and PEB3 from Campylobacter jejuni (c) the O (LPS) antigen from several bacteria, (d) the K (capsule) antigen from several bacteria. The nucleic acid sequences of the genes to be cloned from disease causing bacteria such as Campylobacter spp., Salmonella spp., Streptococcus spp., Staphylococcus spp., Actinobacillus spp., Haemophilus spp., Brucella spp., Yersinia spp. Edwardsiella spp. Pseudomonas spp. E. coli.

Subproject 2: Construction of attenuated mutants in (Yersinia pseudotuberculosis, Yersinia enterocolitica, Yersinia ruckeri, Salmonella spp., Shigella spp. Actinobacillus pleuropneumoniae, Streptococcus suis, Haemophilus parasuis, Pasteurella spp. Mycoplasma hyopneumoniae, Edwardsiella spp. and wild type E. coli). These are all category 2 organisms. Of note, no category 3 members of the genus will be worked on such as Y. pestis.

Vectors with the following specified origins of replication will be employed in this work: pMB1/ColE1, p15A, pSC101/R100/FII, incW, pBBR1, RK2/ori/IncP and carrying the following antibiotic resistance markers: Tetracycline/kanamycin/ampicillin/chloramphenicol/Zeocin/trimethoprim. The majority of the vaccine assembly work such as cloning and protein expression will first be carried out in E. coli K12 category 1 laboratory strains. However when working on direct attenuation of a live organism we will carry out as follows:

**Origin & function**

For the construction of defined mutants, in Gram positive organisms, the pMTL and pSET low copy shuttle vectors will be used to introduce DNA into test pathogens such as Streptococcus suis. No high copy number vectors are required to introduce DNA into the test pathogens. Low copy number plasmid pBBR1MCS3, pACYC and pWKS will be used to introduce DNA into competent E. coli K12 derivative cells. Selection will be through tetracycline, trimethoprim, ampicillin, chloramphenicol, zeocin, kanamycin resistance. Low copy number plasmids such as pUOA18 will be used to introduce DNA in the attenuated S. typhimurium and other Salmonella strains (Wyszynska A, et al., Vaccine. 2004 Mar 29;22(11-12):1379-89). The Salmonella typhimurium crp-, cya-, asdA1 mutant, is a lethal-balance vector-host system, in which the asd deletion introduced to the chromosome of the host is complemented by the asd gene present on the plasmid, that enables cloning of foreign genes without antibiotic selection.

**Evaluation of foreseeable effects**

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Instead of autoclaving waste in the building we propose to follow the procedure used by the Babraham Institute described in their disposal notification GM 105/4.1 (see also section 6 above for description). Reasons for adopting this method of waste disposal are:

1. We do not have access to an autoclave within our area of the building
2. The waste disposal system used by the Babraham Research Campus is safe and has been running since October 2004.

All waste material will be inactivated by treatment with 1 % (w/v) Virkon solution prior to disposal. Waste material will then be placed in sealed bins and incinerated by an off-site incineration company (Vetspeed - Their GM authorization Is GM898) according to disposal notification GM105/4.1. Waste from our GM work at Class1 will be placed into suitably labelled hermetically sealable 60 litre UN approved (to Class 3) Type 3H21Y30/S/2003 bins. Sealed bins are placed into secondary 210 litre yellow labelled "Eurobins". Collections by the local registered clinical/GM waste incinerator contractor will be made three times a week to prevent a build-up. The site has 24/7 Security. The contractor uses solid bodied transport and carries portable disinfection equipment in case of any spillage. Autoclave facilities will be available in an adjacent building, as required by the Regulations, in case of loss of the contractor's facilities. The type of container and the secondary Euro container means that the risk of any spillage of active GM waste on site is negligible. However, as active waste will leave the site, the risk to the environment and health is possibly marginally higher than autoclaving prior to incineration. The
only real risk of release would be as a result of a major RT A, however, the containers are designed to withstand this.  
This disposal method is expected to achieve 100% inactivation of the GMM.  
ArkVax is applying for its own derogation.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All waste material will be inactivated by treatment with 1% (w/v) Virkon solution prior to disposal. Waste material will then be placed in sealed bins and incinerated by an off-site incineration company (see derogation application above). Waste from our GM work at Class1 will be placed into suitably labelled hermetically sealable bins. They will be sealed by our staff and removed to a central collection point where they will be placed into 210 litre yellow labelled “Eurobins”.  
Collections for incineration will be made by the local registered clinical/GM waste incinerator contractor. 
This disposal method is expected to achieve 100% inactivation of the GMM. 
The data sheets describing inactivation by Virkon are attached under SOP2 'use of disinfectants in containment level 2 laboratories'.

Please enter comments on the GM safety committee on the risk assessment
In the very improbable event that the GMOs should be outside the ACDP category 2 designated area, they are unlikely persist, disseminate and cause disease for the following reasons.

1. Invariably modifications will result in an attenuated less virulent strain.
2. The transmission of these organisms is usually dependent upon an animal host. For example, Y. enterocolitica, Y. pseudotuberculosis and S. typhmurium are transmitted through the consumption of meat products. Attenuated strains are less likely to have the same level of transmissibility as the wild type strain.
3. Y. enterocolitica and Y. pseudotuberculosis require several nutrients to grow outside the host, have a slow growth phase compared with most enterobactericiae (eg E. coli) and generally do not persist. In addition, Y. enterocolitica, Y. pseudotuberculosis, S. typhmurium, Edwardsiella ictaluri, Mycoplasma hyopneumoniae, Actinobacillus pleuropneumonia, Streptococcus suis and Haemophilus parasuis are not spore formers and all are unlikely to survive well outside a nutrient rich environment. Again attenuated strains are less likely to survive than the wildtype strain.
4. The wildtype/parent strains used for allele replacement are passaged through several in vitro rounds of growth. Invariably the wild type strain will have lost properties to allow it to persist, transmit and cause disease compared with fresh clinical isolates. Thus even the wild type strain is unlikely to be as pathogenic as strains causing disease.
5. Actinobacillus pleuropneumonia, avian pathogenic E. coli, Mycoplasma hyopneumoniae, Streptococcus suis, Pasteurella multocida and Haemophilus parasuis are invariably pathogens associated with pigs, and not a direct threat to humans.

Undertaking good laboratory practice and waste disposal in ACDP 2 lab conditions will minimize the risk to humans and the environment. Taking all of these factors into consideration, we consider that there is a negligible consequence of environmental contamination and the estimation of risk is effectively zero.

Y. ruckeri, Yersinia pseudotuberculosis, Yersinia enterocolitica, Salmonella typhimurium cause gastroenteritis that is either self-limiting or can be treated with a range of antibiotics. None of the pathogens are transmitted by aerosol delivery.

For activities involving GMMs, describe the waste management measures which will apply to the activity

A validated disinfectant, for example; 1% Virkon for 10 minutes or 10% Distel for 10 minutes, 2% Oettol30 minutes.
1 :100 FAM30 30 minutes) will be used to disinfect any exposed surfaces including equipment.
Absorbent material (Blue roll or similar) will be used to stem the spread of spills.
Accidental spillages of liquid waste will be deactivated with a double strength concentration of a validated disinfectant.
Contaminated dothing and shoes should be removed and advice sort on its decontamination from the Biological safety officer
All liquid waste will be inactivated by a validated disinfectant and contact time and then disposed to drain or autoclaved on a validated cycle. Users are trained in waste disposal prior to starting work.
All solid waste will be placed into double bagged autoclave bags and placed directly into a metal autoclave tin before being transported directly for autoclaving. Following autoclave the waste is incinerated.

Y

Give brief details of the genetic modification safety committee

Purespring Therapeutics is a new gene therapy company which has resulted from work currently being carried out at the University of Bristol by the investigators cited in the risk assessment. The Scientific Officer of Purespring Therapeutics is also currently a member of their University of Bristol GMSC and has been the Deputy Biological Safety Officer for the Bristol Medical School for over 10 years. The Scientific Officer has reviewed and advised on this class 1 risk assessment as the competent person to do so for the company. When required, the duties of a GMSC will be undertaken by a Safety Committee being established by Purespring Therapeutics, chaired by the Scientific Officer, with relevant experience represented, including the lab manager and representatives from both the research and technical staff.

Laboratory | Animal Unit | Growth Room | Glass House | Large Scale
---|---|---|---|---
Level 1 (GMMs) | Yes |
Level 2 (GMMs) |
Level 3 (GMMs) |
Level 4 (GMMs) |
All solid waste will initially be inactivated by exposure to 1% Virkon for at least 30 minutes. All solid waste (pipette tips, animal tissues, including slides with sections) will be placed in autoclavable bags or an appropriate CinBin, sealed, collected and disposed of appropriately by Novus-Environmental (registration number is GMGM898). Liquids (e.g. samples, culture supernatants, tissue culture media) should made safe by 1% Virkon (for at least 30 minutes) and discharged to drains. Autoclaving effectively 100% kill (annual validation). Incineration effectively 100% kill (licensed incinerator). Chemical disinfection with Virkon, used according to manufacturer's instructions under standard conditions, manufacturers validation (e.g. 99.998 % kill). Animal waste – carcasses will be disposed of by incineration following the RVC Animal Services Unit rules.

Purespring Therapeutics is a new gene therapy company which has resulted from work currently being carried out at the University of Bristol by the investigators cited in the risk assessment. The original risk assessment has been reviewed by the University of Bristol Genetic Modification Safety Committee for work carried out on University of Bristol premises. The attached risk assessment has now been reviewed and updated by the Purespring Therapeutics Scientific Officer so that it is relevant to the processes and procedures being implemented at Purespring Therapeutics premises. The scope, risks and control measures have not changed from those reviewed by the University GMSC because of this review and remain appropriate for work undertaken by Purespring Therapeutics.
Purespring are developing novel gene therapy tools for the kidney. This includes using Lentiviral expression in kidney cell lines to validate our tools.

Recipient or parental organism

AAV, Ad5 & Lentivirus
Species Organ Tissue or cell Source
Human Kidney HEK 293T Cells Commercial
Human Cervix HeLa cells Commercial
Human and Mouse Kidney Podocytes Isolated from kidney tissue
Human and Mouse Kidney Glomerular Endothelial Cells Isolated from kidney tissue
Human and Mouse Kidney Mesangial cells Isolated from kidney tissue
Human and Mouse Kidney Proximal Tubular Epithelial Cells Isolated from kidney tissue
Human and Mouse Kidney Glomeruli Isolated from kidney tissue
AAV and Ad5 will be administered to mice by systemic injection or targeted kidney injection

Host/vector system

Other vector components Description of safety features, control sequences (e.g. promoters), antibiotic resistances
Human NPHS1 promoter Podocyte-specific promoter
Mouse NPHS1 promoter Podocyte-specific promoter
CMV promoter Constitutive promoter
WPRE (Woodchuck Hepatitis Virus Posttranscriptional regulatory element) Shown to improve gene expression.
MSCV promoter (Murine Stem Cell Virus) Constitutive promoter, effective in most mammalian cell lines, optimal for pluripotent cell lines

Origin & function
The lentiviral constructs are all 3rd/4th generation and have been purchased from Addgene. AAV and Ad5 are also from commercial sources. Promotors have been designed in house and proprietary to Purespring.

Evaluation of foreseeable effects

Lentivirus
The 3rd generation Lentivirus is recombinant deficient but can integrate into the human host. The lack of such adverse effects in most other gene therapy trials using retroviruses indicates that the chromosomal insertion of replication-defective retroviruses is generally unlikely to cause overt harm. There will be no change to other properties of the GMMs after modification, and they will be unable to engraft in a normal immunocompetent human host. Some of the vectors will encode standard reporter genes (GFP, LacZ, Luciferase), which are routinely used without safety issues. Other vectors will express proteins important in kidney diseases under a podocyte-specific promoter. It is unlikely to have any toxic effects. Potential to express within a human but should have no detrimental effect.

AAV
The recombinant AAV vectors are replication defective and have none of the wild type AAV genes. They are replication defective and incapable of propagating in a human host. There will be no change to other properties of the GMMs after modification, and they will be unable to engraft in a normal immunocompetent human host. Some of the vectors will encode standard reporter genes (GFP, LacZ, Luciferase), which are routinely used without safety issues. Other vectors will express proteins important in kidney diseases under a podocyte-specific promoter. It is unlikely to have any toxic effects. Potential to express within a human, but should have no detrimental effect.

Adenovirus Type 5
The recombinant Ad5 vectors are 3rd generation and are recombinant deficient. There will be no change to other properties of the GMMs after modification, and they will be unable to engraft in a normal immunocompetent human host. Some of the vectors will encode standard reporter genes (GFP, LacZ, Luciferase), which are routinely used without safety issues. Other vectors will express proteins important in kidney diseases under a podocyte-specific promoter. It is unlikely to have any toxic effects. Potential to express within a human but should have no detrimental effect.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

• Handling mice that have been infected with recombinant viral vectors poses no extra risk to staff at the BSU.
• Where appropriate, an animal restrainer will be used.
• Only experienced and licensed staff will undertake any regulated procedures required for this part of the project.
• All solid waste will initially be inactivated by exposure to 1% Virkon or a suitable, validated alternative for at least
30 minutes. All solid waste (pipette tips, animal tissues, including slides with sections) will be placed in autoclavable bags or an appropriate CinBin, sealed, collected and disposed of appropriately by Novus-Environmental (registration number is GMGM898).

- Gloves and PPE will be disposed via standard clinical waste routes. No autoclaving or disinfection is required prior to disposal.
- Animal bedding is considered minimal risk and will be disposed as normal landfill. No autoclaving or disinfection is required prior to disposal.
- Animals carcasses will be disposed by incineration.
- Animals will not pose additional health risks if released into the environment as the recombinant viral vectors are replication deficient and cannot be passed down through reproduction as it does not integrate.
- The animal house is a high security facility with many measures in place to prevent escape of mice into the environment.
- Mice are housed in secure cages in rooms designated to one individual research group per room.
- Rodent barriers exist to prevent mice from escaping and travelling between rooms and exits.
- Animal bait traps are placed throughout the facility and regular checks are made to ensure that if any cracks/holes in walls, doors etc appear they are repaired immediately.
- Mice will only be injected with viral vectors by appropriately trained staff.
- The doses of recombinant viral vectors being used for mouse transduction are several orders of magnitude lower than that required for human transduction even in the event of inadvertent intravenous puncture.
- Only appropriately trained personnel will use sharps.
- Sharps will never be re-sheathed.
- Sharps will be appropriately disposed of in a sharps bin that will never exceed being ¾ full, which is then disposed via normal waste routes.
- Health surveillance is conducted on all staff that conduct work within the BSU (e.g. annual lung function test).
- The BSU will ensure adequate ventilation.
- Where appropriate local exhaust ventilation is used.
- If an operator experiences any negative reactions, e.g. an allergic reaction, they report this immediately.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste will initially be inactivated by exposure to 1% Virkon for at least 30 minutes. All other solid waste (pipette tips, animal tissues, including slides with sections) will be placed in autoclavable bags or an appropriate CinBin, sealed, collected and disposed of appropriately by Novus-Environmental (registration number is GMGM898).

Liquids (e.g. samples, culture supernatants, tissue culture media) should made safe by 1% Virkon (for at least 30 minutes) and discharged to drains. Autoclaving effectively 100% kill (annual validation). Incineration effectively 100% kill (licensed incinerator) Chemical disinfection with Virkon, used according to manufacturer's instructions under standard conditions, manufacturers validation (e.g. 99.998 % kill). Animal waste –carcasses will be disposed of by incineration following the RVC Animal Services Unit rules.

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities: Y

Give brief details of the genetic modification safety committee:

The advisor has over ten years experience as a Biological Safety Officer, having previous served as the BSO to two biotechnology companies: the contract manufacturing organisation Cobra Biologics Ltd, and most recently the vaccine and cancer therapy development company Prokarium Ltd (BSO for six years). The advisor has reviewed numerous risk assessments at GM Class 1 and 2 for various species of bacteria (including modified pathogens), viruses and cell lines.

Accidental spillages will be dealt with by swabbing with 70% IPA spray which is bactericidal.

Contaminated, solid, bacteria waste such as plastic disposables, tissue paper, culture plates, etc., are bagged in autoclave bin bag and closed with autoclave bin bag. The bag is autoclaved at 121°C for 20 mins, 1 bar pressure. The autoclave tape has to turn black before being placed into a yellow bin bag and tied up. The bags are finally placed in large yellow waste bin.

Approximately 2L of liquid culture medium is treated by adding to Virkon or bleach to achieve a final concentration of 10% and left to stand overnight before discharge to the sewer.

Contaminated solid waste is autoclaved at 128 celcius and 15 PSI for 20 mins, under these conditions sterilisation will be achieved, thus ensuring inactivation of the the micro organisms. The autoclave is calibrated annually and serviced every 6 months, during the service the cycle is tested to ensure sterilisation is achieved.

Liquid waste is inactivated by treatment with 5% solution of chlorine. For example, the waste is treated with 5% virkon for 48 hours before disposal. The manufacturer has verified that a 10 min contact time with a 1% solution is sufficient contact time to inactivate 99.999% of the micro-organisms.

Saccharomyces cerevisiae solid cell pellet waste from 10 litre fermentation is inactivated by treatment with 5% Janitol solution for 48 hours before disposal. This has been tested in house and no growth of S. cerevisiae was observed after treatment (R&D/R-0345).

Give brief details of the genetic modification safety committee

Head of CMC at NovalGen has over 15 years of contained use experience in the industry. They served on Health and Safety committees in manufacturing and development sites in biopharma as well as sitting on a GMO safety committee. Their experience covers the use of viral vectors, microbial and mammalian cells, some of which required the use of negative pressure isolators to protect the operators and environment from the expresssed compounds of interest.

02/03/2022
Yes

All waste containing viable GMM is to be inactivated by validated means prior to leaving site for incineration. Solid waste, including contaminated materials like plasticware, pipette tips, gloves and tissue paper, is to be rendered safe by autoclaving. Contaminated sharps will be placed in sealed sharps bins and disposed of by incineration. The autoclave will be available within the same building as the laboratory. The autoclave is to be validated and checked annually. Given the thermal sensitivity of the organisms which will be used on site a 6-log kill cycle will be used, its performance monitored on each use (e.g. with indicator tape or probes) and the inactivation documented. Autoclaved inactivated GMM waste still be treated as hazardous waste (180103) and will be collected by an approved contractor for incineration. Liquid waste containing viable GMM (including spent culture media) is to be inactivated chemically with Distel 1:20, Virkon or Precept before discarding to achieve 6 log kill. As with the solid waste this will be sent off site for incineration. Inactivation of GMM waste and subsequent disposal will be detailed in the Waste Management SOP.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The current NovalGen laboratories location gives us access to the risk assessments and GMO safety committee of our landlord. Consequently, NovalGen staff are familiar with the relevant procedures for working with GMMs and have access to risk assessments performed and reviewed by the GMO safety committee. The GMMs we propose to use are a subset of those detailed in these risk assessments.
Project Additional Information

Purposes of the contained use

Research, development and analysis of antibodies or antibody-like molecules with biopharmaceutical potential (e.g. bispecific antibody T-cell engager for targeting hematological cancers such as Chronic Lymphocytic Leukemia and Mantle Cell Lymphoma, and for targeting solid tumors). Research and development of Chimeric Antigen Receptor (CAR) T cell therapeutic solutions by lentiviral or retroviral vector transduction of human T cells in culture. Research and development of AAV vectors for gene transfer. The contained use includes molecular biology techniques using recombinant bacteria, phage display, yeast display, and cell culture techniques for expression of recombinant proteins and for biological assays.

Recipient or parental organism

The microorganisms used are standard, well characterised, strains commonly used the area of molecular biology (e.g. DH5alpha, K1 and L21 disabled E.coli strains, bacteriophage M13, yeast strain EBY100). Standard, well characterised and widely used mammalian cell lines will also be used (e.g. human HEK293 or HEK293T cells, animal cells such as hamster CHO and other immortalised cell lines). The intended function of the lentiv- and retroviral vectors is CAR T cell engineering for development of adoptive immunotherapy for blood cancer and/or solid tumour cancers, or engineering of standard mammalian cell lines as research tools. AAV viral vectors would be used for gene transfer. Hybridoma cells (fusions of mouse B cells and the well known SP2/0 cells) are cultured for expression of monoclonal antibodies.

Host/vector system

Standard DNA cloning vectors (e.g. pUC derivatives) and mammalian expression vectors for production of antibodylike molecules in cell culture. All cloning will be performed using commercial bacterial strains which are disabled. The inserted sequences may originate from human, mouse, or other mammalian genomic DNA or cDNA and encode engineered antibody binding arms. For example, the bispecific antibody NVG-111 has two "arms", one arm binds ROR1 molecule on cancer cells, and the other arm binds body's immune cells directing them to kill the cancer cells. The NVG-111 drug has been approved for clinical trial. Antibody gene libraries for phage and/or yeast display of antibody fragments allowing for discovery of molecules with therapeutic potential. Hybridoma cells cultured for the
production of monoclonal antibodies are a well known and established technology. Standard lentiviral vectors will be used for engineering of CAR T cells, including packaging plasmid pCMVR8.74 and VSV-G envelope plasmid pMD-G. The lentivirus is a 3rd generation (or safer, 4th generation) HIV vector and 2nd generation FIV vector with virulence genes deleted, on split plasmids. Recombinant AAV (rAAV) vectors are the gold standard for studying in vivo gene function. It is forceable that AAV vector engineering and virus generation may be performed on site. However, the “use” of the virus would be restricted to an authorised external animal facility only. The vector capsid and backbone are derived from wild type AAV. Such plasmids have type AAV genes replaced with a transgenic cassette with an inserted sequence encoding the molecule of interest or a reporter transgene like GFP or luciferase. For virus production helper plasmids are required such as pHelper (HGTI), rep/cap, Ad5Rep2G (adenoviral functions), AAV cap/rep expressing plasmids - 2/8, 2/5 LKO3, AA3L, transgene plasmids with transgene flanked by AAV inverted terminal repeat sequences, such as pAV plasmids.

**Origin & function**

| N/A |

**Evaluation of foreseeable effects**

As the bacterial strains are disabled, they are not harmful to health and environment. The strains are widely used in academic and commercial laboratories. Following transformation with plasmids the bacteria gain resistance to antibiotics. The release of such a microorganism may mean that it spreads to the environment. Such bacteria should have no environmental advantage over wild type bacteria. However, due to the possibility of bacterial recombination and DNA transfer to recipient strains, all cultures are to be inactivated by validated means prior to discarding. Peripheral blood and isolated peripheral blood mononuclear cells from normal human donors and patients with haematological malignancies can harbour potentially unknown pathogens. Samples and cultures of animal or human cells are handled in biosafety class II A1/A2 microbiological safety cabinets with class H14 HEPA/ULPA filters to protect the operators and are inactivated by validated means prior to discarding. Operators must not work with their own blood cells as autologous cells could potentially pose a major risk in the unlikely event of infected or otherwise modified cells reaching their blood streams through injuries. The viral vectors are not pathogenic as they have all virulence genes deleted. These vectors can potentially integrate into human DNA which poses a low risk of impact on health of a laboratory operator directly handling the virus. However, there are no such cases known. The lentiviral vector particles include a vesicular stomatitis virus G (VSV-G) viral fusion protein, which results in broad host specificity and may increase susceptibility of different cells. However, lentiviral vectors insert preferentially into the coding regions of DNA rather than into more risky promoter or control regions. The risk of insertional mutagenesis is reduced by the use of self-inactivating (SIN) vectors. Overall, the lentiviral vectors are considered low risk. The AAV viruses are not known to cause disease and are a known platform for gene therapy. Chimeric antigen receptors (CARs) are artificial receptors consisting of an antibody specific to a tumour target, fused to T cell receptor signalling domains. Autologous T cells can be isolated from patients and modified to express a CAR directing the T cell response against tumour cells with a specific marker. Such cells have therapeutic potential when readministered to the patient and need to be studied in vitro and potentially in vivo to determine the safety and efficacy.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

| N/A |

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All biological waste produced will be inactivated in a 2% Virkon soln (where necessary) for at least 10 min. Solid biological waste (for example the bacterial pellet) will then be disposed of in the biohazard waste. Liquid waste will be disposed of down the sink with copious amounts of running water.

## Project Additional Information

### Purposes of the contained use

- Bacterial transformation and plasmid DNA prep & generic retrovirus work

### Recipient or parental organism

- Continuous human cell lines (i.e. Hela, HEK293, tumour-derived cell lines)
- Continuous rodent cell lines (i.e. 3T3, CHO)
- Primary mouse tissue (from animals hosted in the Biological Resource Unit and devoid of pathogens)
- Patient-derived xenografts (passed in rodent after initial transplantation)

### Host/vector system

- Retrovirus, standard (a plasmid containing the viral genome, in a self-inhibiting cassette, is transfected into a packaging cell line (i.e. PlatA, Phoenix) containing the viral capsid, polymerase and accessory proteins. Optionally, the VSV-G envelope protein can also be added through a separate plasmid. The insert can contain the WPRE transcriptional element.

### Origin & function

The vectors used will all be self-inactivating and replication-incompetent, that is, each retroviral vector particle infects and gives genomic modification of one cell, and that cell will not, and indeed cannot, subsequently produce and release further viral particles.

### Evaluation of foreseeable effects

Retroviruses give infection of, and stable genomic integration into, dividing cells of a wide variety of tissue types with relatively high efficiency, including human and mouse. These vectors derived from retroviruses provide an excellent vehicle of achieving the required genomic modifications and will be useful tools with which to carry out the genetic manipulation of cells.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All cell lines, human and mouse, are considered GM Class 1 before the packaging/infection. While the GM classification of the infected cells is creased to GM Class 2 during the described process, these cells can return to containment level 1 after they have been washed or passaged 4 times after the infection. The rationale behind this 'demotion' is that the retroviral GM construct is self-inactivating and non-replicative, and therefore infected cells lack the ability to produce new virus. The virus originally used for infection is diluted at every subsequent wash, and rigorous testing has shown that no virus remains after 4 passages.

GM Class 2 agents and GMOs shall only be handled and stored in Containment Level 2 laboratory, set up and operated according to the appropriate laws and requirements.

Routine CL2 control measures include but are not limited to: restricted access, occupational health clearance of workers, training and supervision requirements, no sharps, no vortex mixing, use of Class II microbiological safety cabinets conforming to the appropriate standards, closed rotor/bucket centrifuges opened in the safety cabinet, disposable nitrile gloves conform to appropriate standards, CL2 dedicated lab equipment, separate lab coats for CL2, hands washed before leaving CL2 lab, and emergency and contingency arrangements.

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste shall be mixed with not less than an equal volume of a 2% solution of the peroxygen disinfectant DuPont Rely On Virkon for at least 10 minutes prior to disposal to drain via a sink designated for this purpose, and this shall all be done within the CL2 lab. This will inactivate all viral particles, cells and other biological agents.
liable to be present. All solid waste shall be collected in double autoclave bags in an appropriately labelled leak-proof rigid container, then autoclaved on site (within the premises of the Cambridge Institute but not within the laboratories) to deactivate all biological agents, and this then disposed by incineration as hazardous 'clinical' waste by a licensed contractor at the licensed site. The only exceptions are any sharps and pipettes, which shall be collected in appropriately labelled rigid sharps bins designed to collect such articles, and thence autoclaved and incinerated as for the other solid waste. Any spills shall be treated with an equal volume of 2% Virkon for at least 10 minutes. Work surfaces shall be routinely disinfected with 1% Virkon for at least 10 minutes.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Attached are procedural and GM risk assessments to cover work to be carried out on bacterial transformation and plasmid DNA prep & generic retrovirus work.

For activities involving GMMs, describe the waste management measures which will apply to the activity

The GMM in our case will be mammalian cells transfected with plasmid DNA. To kill cells, Virkon solution (1 tablet of Virkon=1% solution when diluted in 500ml of water) will be added to the cells (1:1 v/v to medium). The liquid waste will be kept in contact with Virkon for at least 30 minutes before disposing it down the sink.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The procedures suggested should be enough to minimise the risk of conducting the GMM work.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Bison, contained on the farm on the Rhug Estate will be inoculated by a veterinary surgeon experienced with handling bison with MVA recombinant(s) expressing OvHV-2 glycoproteins. The bison will be handled by the farm staff using purpose built handling pens feeding onto a curved chute terminating in a Warwick cattle crush (squeeze type). This crush can safely restrain bison of all sizes being easily adjusted by the operator.

Inoculation will take place to deliver up to 1 x 10^9 PFU of recombinant MVA into the neck of bison via the intramuscular route. The bison will be accessed through a door in the side of the crush safely permitting access to the neck whilst restraining the bison. We will use a sterimatic gun for inoculation e.g. http://www.molevalleyfarmers.comlmvf/storeJproducts/molecare-injector-gun-2ml This consists of a high quality Simcro syringe with metalluer-lock and selectable dose in 0.2ml increments. The Sterimatic system automatically protects and cleans the needle with 2.5% glutaraldehyde, this helps provide user safety and reduces potential injection site abscesses and disease transmission between animals. Injection site will be swabbed after vaccination with alcohol. After individual vaccination each bison will be released into the handling pens before being housed in a shed adjacent to the handling system. Housing will take place for one week after vaccination with forage supplied to the bison from outside the pen via a feed passageway.

Solid waste: Steeping overnight in a solution of 2% w/v virkon. Virkon has been validated as an effective decontaminant for MVA. Disposable PPE will be incinerated. Decontaminated glass vials and other sharps will be disposed of in sharps waste. Non-disposable PPE e.g. overalls, wellingtons will be washed after decontamination.

Liquid waste: Steeping overnight in a solution of 2% w/v Virkon. Virkon has been validated as an effective decontaminant for MVA. Accidental spills of vaccine will be either soaked up with absorbent material and the area decontaminated with 2% Virkon or by covering in virkon powder prior to wiping up with absorbent material.

All equipment and protective clothing will remain overnight in the crush area being soaked in Virkon for 24 hours. The vaccine vial will be immersed in Virkon together with the injection gun and the needles. The crush area will be sealed off from the rest of the farm for 24 hours. Following removal of the equipment the crush area will be cleaned and disinfected with Virkon and sealed off from the rest of the farm for a further 24 hours.

We will also perform environmental sampling to detect MVA DNA in bison secretions and in the containment environment. To do this, samples will be collected using boot socks and then analysed for the presence of MVA using a peR assay for virus DNA.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment
This work was risk assessed by the Dept of Infection Biology, University of Liverpool GMSC on 21/1/20 and approved for use as a class I activity. The virus is based on modified vaccinia Ankara (MVA; ACDP 1) with the insertion of coding sequences for the green fluorescent protein and glycoprotein B from ovine herpesvirus 2 neither of which were deemed likely to increase the pathogenicity or tropism of the virus. Given the extensive knowledge and use of MVA and recombinant derivatives there are therefore negligible risks to either the vaccinated animals, humans or the environment. The premises and procedures for vaccination and waste disposal were inspected by members of the GMSC and deemed appropriate for contained use for the purposes of vaccination with the MVA recombinant.

02/03/2022
Solid biological laboratory waste (e.g. bacterial agar plates, plastics, gloves) from our class 1 GM work is collected in laboratory waste bins (Eurobins) which are sealed and labelled by our staff. The sealed bins are then removed by the Babraham campus waste team to a central collection point where they will be placed into labelled 210 litre yellow Eurobins. The 210 litre bins are then collected by a registered clinical/GM waste company and incinerated (see derogation application below).

Liquid class 1 GM culture waste (e.g. cultures and spent media after isolation of cells) is inactivated by treatment with Virkon. After full inactivation (1% Virkon treatment overnight), liquid waste is disposed of into the waste water supply. Associated plastics will then be disposed of as the solid waste. Surfaces will be routinely cleaned and decontaminated with 2% Chemgene.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Comments of the Safety Officer: proposed work is low risk and risks and control measures adequately identified in the risk assessment. As a tenant of BBT Ltd we have all of our risk assessments approved by the Babraham Biosafety Committee prior to any laboratory work and this covers correct procedures for genetic modification as well as contained use.

Project Ref 3618/21.1

Date Ackn'd 26/05/2021

Date Project Ceased

Genetic Modification of cell lines using lentiviral vectors

Class CultureVol

Consent Granted

Project notified under transitional arrangements
The objective of this project is the modification of mammalian cell lines (human and/or murine) or avian cell lines with transgenes expressing a short hairpin RNA (shRNA), or specific proteins involved in the cellular RNA silencing mechanism to allow high-throughput RNAi screening. A broad range of our projects are aimed at the investigation of the cellular processes regulating the biogenesis and function of small and long non-coding RNAs in mammals. Such projects often require the production of genetically modified cells in which a) key components of the physiological pathways (i.e., small RNA biogenesis, long non-coding RNAs, piRNA clusters) are knocked down by means of RNA interference, or removed by disruptive mutation) components of the pathway are overexpressed or modified, or c) components of the pathway are modified by fusing them with a protein reporter or tag, allowing their detection by imaging and/or their purification for further biochemical studies.

Categories of gene inserts / gene modifications:
- Selection cassettes (e.g. neomycin, hygromycin, puromycin, thymidine kinase)
- Reporter genes and tags (i.e. EFGP, Discosoma fluorescent proteins, and their variants. Hemagglutinin tag, FLAG tag, myc-tag, SNAP-tag, HALO-tag, His-tag)
- Genes coding for small RNAs (i.e. shRNAs, miRNAs, piRNAs).

Recipient or parental organism
Mammalian cell lines including commercially available primary cells and well characterised cell lines (immortalised) of human origin. All without a significant risk of transmitting pathogens to human.

Host/vector system
LENTIVIRUS, THIRD GENERATION - Four plasmids are co-transfected on 293T / 293FT cells or similar. The plasmids contain: 1) The gag and pol genes, plus other accessory viral genes 2) The rev gene, 3) an envelope protein gene (i.e. VSV-G), 4) the viral genome and insert, in a self-inactivating (SIN) unit. The insert can contain the WPRE transcriptional element.
LENTIVIRUS, SECOND GENERATION - Three plasmids are co-transfected on 293T/293FT cells or similar. The plasmids contain: 1) The gag, pol and rev genes, together with other viral accessory genes, 2) an envelope protein gene (i.e. VSV-G), 4) the viral genome and insert, in a self inactivating (SIN) unit. The insert can contain the WPRE transcriptional element.
RETOVIRUS - A plasmid containing the viral genome, in a self-inhibiting cassette, is transfected into a packaging cell line (i.e. PlatA, Phoenix) containing the viral capsid, polymerase and accessory proteins. Optionally, the VSV-G envelope protein can also be added through a separate plasmid. The insert can contain the WPRE.
Origin & function

We will use PCR amplification to amplify approximately 10 regions across the viral genome in separate reactions. These regions will include the 5'UTR, the entire Orf1_ab segment, Spike, Orf7, Orf8, the Nucleocapsid region and the 3'UTR. In addition, we will create a GFP/Luciferase reporter construct under the control of the 'E' 5'UTR of the SARS-CoV-2 genome. The left primer for the 5'UTR will include a T7 promoter sequence. The final product will have the SARS-CoV-2 genome with two important differences: (i) the E (Envelope) and the M (Membrane) genes will be totally absent from the replicon and the Spike protein will have multiple loss of function mutations to prevent its expression and a full deletion of the Furion Cleavage site that is required for pathogenicity. These two genes are essential for particle assembly and therefore the virus will be deleterious (ii) Instead of the 'E' gene, the replicon will have a reporter construct.

T7 RNA polymerase will be used for transcription of the replicon in vitro.

RNA from the T7 polymerase reaction will be transfected into recipient cells using RNA transfection reagents (e.g lipofectamine)

Evaluation of foreseeable effects

CELL CULTURE

This project will make use of commercially available primary cell or continuous mammalian cell cell lines, all with a history of safe use and where possible screened as free from HepB, HepC and HIV. Some examples of such lines are A549, 293, HeLA, etc. In such cells, adventitious pathogens are unlikely to be present, and even if present originally, are likely to have been deactivated or diluted away. The chances of such cells, on entering the body, evading immune surveillance and giving colonisation etc are remote.

LENTIVIRAL / RETROVIRAL VECTORS

The lentiviral and retroviral vectors used will all be well characterised, and with a history of safe use.

These vectors will all be self-inactivating and replication-incompetent, that is, each lentiviral/retroviral vector particle infects and gives genomic modification of one cell, and that cell will not (and indeed cannot) subsequently produce and release further viral particles. This is due to a deletion in the 3' LTR (TATA deletion) which prevents excision after genomic integration.

The genetic material inserted in the destination cell line through the GM modification here proposed include selection cassettes (producing genes that confer selective immunity to cytotoxic agents), reporter genes (i.e. fluorescent proteins), regulatory sequences (promoters, enhancers, etc) and other accessory sequences.

These inserts do not present any significant hazard to human health in the form and amounts in which they are used, either when expressed alone or fused to endogenous proteins.

The hazards arising from an inserted transgene can be divided into two categories: hazards due to the insertion of the transgene(s) directly into the human genome and hazards due to cultured cells that have been genetically modified by the insertion of the transgene(s).

Direct insertion of the transgene in the human genome would require a contact between the original lentivirus/retrovirus stock and a human host. The presence of the VSV-G envelope protein on the viral particles described in this assessment results in an increased tropism, and therefore enhances this hazard.

While the transgenes described in this document would NOT result, if integrated, in nocive effect, the insertion itself could result in the inactivation of an endogenous genes (insertional mutagenesis), with potential harmful consequences.

While extremely unlikely, this could, in a worst-case scenario, result in the inactivation of a tumour-suppressor gene and in the production of tumorigenic cells. It has to be noted, however, that in most cases a single mutation is not sufficient to result in tumorigenesis, and that such aberrant cells would most likely be cleared by the immune system.

Since the viral genome used in this project is “inactivated”, and not able to replicate past a first round of infection, any infected cell would not be able to propagate the infection. Indeed, the insertion of any transgene in a human host would require a direct contact with the original viral stock, during its manipulation. The risk of such an event can be minimised by adequate control measures.

A second category of hazard is the hazard due to cultured cells that have received the transgene via the lentivirus/retrovirus. As mentioned above, the transgenes used in this study do not result in any significant hazard.

As for the case of a direct infection of a human host, the insertion of the transgene in cultured cells could increase their proliferative potential due to insertional mutagenesis. However, these GM cells, even if made tumorigenic in nature, would not be able to colonize the human body due to the activity of the immune system.

02/03/2022
All the inserts used in this project could include the WPRE element, which can result in an increase of the expression level of other transgenes present in it. This could potentially exacerbate transgene-related hazards.

Cell lines expressing biologically active proteins could lead to accumulation of molecules in the media. However, experiments are small scale and short term and not designed to produce large amounts of active proteins. Again, the risk is low and can be minimised by adequate control measures.

This project makes use of genetic inserts that might be hazardous in nature, including short hairpins targeting onco-suppressor genes. Examples of onco-suppressor genes include BRCA1, TP53, RB1 etc.

The insertion of these transgenes in human cells via a primary infection could result in potentially serious health hazards: a worst-case scenario is that the virus might insert a dominant acting oncogene under the control of an active promoter, activate an endogenous oncogene, or knock-down a tumour suppressor, thus contributing to the genesis of human cancers. However, this would require penetration of the human body, cellular uptake and integration into the genome of the relevant tissue. The risk is fairly low, since the transgenes themselves are unable to mobilize from the GM cells once inserted. The risk can be further minimised by adequate control measures (Good Microbiological Practice, avoid work if having an open wound, avoiding aerosols and sharps and wear personal protective clothing.)

The insertion of these transgenes in cultured cells would increase their tumorigenic potential if these cells invade a human host. This even, however, is extremely remote due to the activity of the immune system, that would recognise and destroy the invading cells.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Biological waste – inactivate with an equal volume of 2% Virkon for a minimum contact time of 10 minutes. Discard the Virkon solution down the sink. Solid waste like used agar plates, TC flasks, falcon tubes and other plastic ware (excluding pipettes) will be placed in yellow waste disposal bags and incinerated by a licensed contractor.

Chemical waste: discard allowed substances (pbs, salts, non-hazardous substances) down the sink with plenty of water. Discard regulated or hazardous chemicals in an appropriate chemical waste bottle for proper disposal. If the chemical is contained in cell culture medium, inactivate with an equal volume of 2% virkon first, and then dispose as chemical waste.

Solid waste – cell pellets, extracted tissues, including gels, eppendorfs, placed in yellow waste bins for incineration.

Tips – dispose of in plastic jars or in white cardboard waste containers. When full, dispose of the containers in yellow waste bags for incineration.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Copies of the GM project and risk assessments were circulated to members of the CRUK biological safety committee for consideration prior a meeting on the 16th of March 2021.

The project was subsequently approved by the committee and signed by the chair.
**Project Additional Information**

**Purposes of the contained use**

A SARS-COV-2 replicon system provides a safe alternative to study the virus and examine anti-viral therapies. We aim to use the replicon system to test the effect of our novel therapy strategies on viral replication.

**Recipient or parental organism**

The starting material is extracted RNA of a SARS-CoV-2 virus. E coli host will be E coli K12 derivatives (e.g. HB101, XL1B, DH5a, Y1088, 1089, 1090, C600) Mammalian cell lines including commercially available primary cells and well characterised cell lines (immortalised), all without a significant risk of transmitting pathogens to
**Host/vector system**

We will use PCR to amplify 10 regions across the viral genome in separate reactions. The final product will be cloned into pUC based plasmid backbones which are non-mobilised. This includes pUC 12, 18, 19, pSP65, pBSBluescript and pTOPO-PCR. Transfection of mammalian cells will be accomplished by RNA mediated transfection.

**Origin & function**

We will use PCR amplification to amplify approximately 10 regions across the viral genome in separate reactions. These regions will include the 5'UTR, the entire Orf1_ab segment, Spike, Orf7, Orf8, the Nucleocapsid region and the 3'UTR. In addition, we will create a GFP/Luciferase reporter construct under the control of the ‘E’ 5'UTR of the SARS-CoV-2 genome. The left primer for the 5'UTR will include a T7 promoter sequence.

The final product will have the SARS-CoV-2 genome with two important differences: (i) the E (Envelope) and the M (Membrane) genes will be totally absent from the replicon and the Spike protein will have multiple loss of function mutations to prevent its expression and a full deletion of the Furion Cleavage site that is required for pathogenicity. These two genes are essential for particle assembly and therefore the virus will be deleterious (ii) Instead of the “E” gene, the replicon will have a reporter construct.

T7 RNA polymerase will be used for transcription of the replicon in-vitro.

RNA from the T7 polymerase reaction will be transfected into recipient cells using RNA transfection reagents (e.g lipofectamine)

**Evaluation of foreseeable effects**

This work will make use of an extracted/inactivated RNA of a positive sample for SARS-CoV-2. This material will arrive at the CI from external collaborators already inactive, and won’t be inactivated on the premises. Purified SARS-CoV-2 RNA is non hazardous and is routinely processed at CL1 in the institute (i.e. to perform qPCR).

As part of our replicon construction, we will delete the E (Envelope) and M (Membrane) genes from the SARS-CoV-2 genome and will introduce loss of function mutations to the Spike gene.

The M gene is the most abundant protein structural protein in coronaviruses and exists in all branches of Coronavirinae (Masters and Perlman, Fields Virology, 2013). A segment of its transmembrane domain is highly conserved and even found in torovirus, the closet outer group to Coronavirinae (Masters and Perlman, Fields Virology, 2013). The protein is required for virion production in coronavirus (Schoeman and Fielding, Virology, 2019).

The E gene is less conserved but required to maintain pathogenesis of the virus (Masters and Perlman, Fields Virology, 2013). Studies with SARS-CoV have shown that a deletion of the E gene resulted with highly attenuated virus (Schoeman and Fielding, Virology, 2019). Moreover, studies with viral-like particles in SARS-CoV have demonstrated that both E and M are necessary for the formation of virus like replicons and a single expression of each does not produce any viral particles (Mortola and Roy, FASEB, 2004). Taken together, these lines of evidence show that these genes are highly essential for the viability of SARS-CoV-2.

The Spike protein is essential for receptor binding cellular entry (Masters and Perlman, Fields Virology, 2013). We will create a premature stop codon within the first 10 aminoacids of the ~1000aa of this protein and will also introduce a premature stop codon. Moreover, we will remove the Furion Cleavage Site. A recent Nature paper showed that without this site the SARS-CoV-2 virus is substantially attenuated and does not create any pathology in an hamster model (Johnson et al., Nature, 2021).

To further demonstrate the deleterious effects of these two genes, we analyzed the mutation profile of over 26,000 SARS-CoV-2 genomes in GISAID. We calculated the probability to observe a nonsense mutation in each gene adjusted to its length. Our analysis shows that E and M and among the top three structural proteins with the smallest number of nonsense mutations. Other proteins such as ORF8, ORF6, and N exhibited 4x to 5x fold increase in these loss of function mutations. Again, this shows that deleterious effects and the importance of these genes for viral survival.

As stated above, a replicon system have no ability to produce viral particles and therefore become infectious. One extremely unlikely and theoretical event is that the replicon system will undergo a recombination with a coronavirus that somehow infected the cells to acquire the missing proteins. This scenario is partially impossible. The specific SARS-CoV-2 Spike protein is absolutely essential for its increased pathogenicity compared other coronaviruses (Xia et al., Signal Transaction and Targeted Therapy, 2020). The replicon system has no Furion Cleavage Site and its Spike has two loss of function mutations. Thus, even if somehow a low pathogenicity coronavirus (“common cold”) infects the cells, it lacks the SARS-CoV-2 Spike protein and any recombinant product

As stated above, a replicon system have no ability to produce viral particles and therefore become infectious. One extremely unlikely and theoretical event is that the replicon system will undergo a recombination with a coronavirus that somehow infected the cells to acquire the missing proteins. This scenario is partially impossible. The specific SARS-CoV-2 Spike protein is absolutely essential for its increased pathogenicity compared other coronaviruses (Xia et al., Signal Transaction and Targeted Therapy, 2020). The replicon system has no Furion Cleavage Site and its Spike has two loss of function mutations. Thus, even if somehow a low pathogenicity coronavirus (“common cold”) infects the cells, it lacks the SARS-CoV-2 Spike protein and any recombinant product
will not be able to produce back the SARS-CoV-2 spike. The only way for the replicon to acquire this protein is a recombination with SARS-CoV-2. However, that means that the cells were exposed to SARS-CoV-2, which creates a hazardous condition regardless of the replicon system. Moreover, as we are working in a CL2 conditions, the personal protective equipment and the hoods should prevent human-to-cell transmission of any coronavirus.

Finally, before T7 transcription, we are going to evaluate to deeply sequence the DNA of the replicon system in order to ensure that all the changes above were made. Only after verification, we will transcribe and transfect the cells.

### Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities  

Give brief details of the genetic modification safety committee  

Y
The Division of Biomedical Science GMO safety committee (GMOSC) oversees all GMO projects within the Division. The GMOSC will provide a review and advice on the following issues:

- All genetically modified organism risk assessments.
- Biological agent risk assessments for COSHH notifiable projects.
- Any other relevant hazardous work that the GMOSC determines is needed to be reviewed and approved by the committee.

The GMOSC will check that all documents and procedures required at a local level within the Division have been completed prior to commencement of the project and reported. The GMOSC will also investigate and report accidents and incidents, when required.

It is anticipated that the number of GMO projects within the Division will be small (less than 3 per annum) therefore the GMOSC will meet on an ad hoc basis when required. There will be at least one physical meeting of the GMOSC per annum to review relevant documents and procedures. All meeting agendas and minutes will be issued at least 2 days before every meeting and minutes reviewed for accuracy prior to approval, electronic copies will be kept. The committee will report regularly to the School of Health research committee and the University Executive Office Health and Safety committee.

The GMOSC consists of:

**Chair (academic representative):**
This position is filled by a Reader in the Genetics and Immunology Department. This individual has a PhD and 20 years' experience in academic bioscience research laboratories. This individual has substantial practical experience of working at containment level 2, cell and tissue culture and GMO projects in human cell lines and micro-organisms. This individual has considerable experience of health and safety and risk assessment in a research laboratory.

**Head of Division (management representative):**
This position is filled by a Professor in the Free Radical Research Facility. The individual has a PhD and over 30 years experience in academic research laboratories in several HEIs in the UK. A proportion of his research has involved human and mammalian cell culture and treatment and he has overall responsibility for Health and Safety in the Division. This individual has considerable experience of health and safety and risk assessment in a research laboratory.

**Staff (technical) representative:**
The staff representative position is filled by the Genetics and Immunology research technician. This individual has a BSc (Hons) in Life Sciences with more than 20 years experience in academic research labs and 5 years' experience in industry in quality control. This individual has substantial experience in molecular biology techniques and in working at containment level 2 cell culture with several different cell types including human and trypanosomatid cell lines. GMO experience includes working with microorganisms and trypanosomatid cell lines. This individual has considerable experience of health and safety and risk assessment in a research laboratory.

**GMO safety officer (Divisional health and safety officer):**
This position is filled by the laboratory manager. This individual has a PhD and over 25 years experience in academic bioscience research labs and is currently responsible for health and safety in the Division. This individual has considerable previous hands-on experience of working at containment level 2, cell culture and GMO projects in mammalian cell lines and microorganisms with responsibility for many aspects of the projects including health and safety, waste disposal and record keeping. This individual has considerable experience of health and safety and risk assessment in a research laboratory.
Committee member:
This individual is a senior scientist with a PhD and more than 30 years experience of working in biomedical sciences research. This person has extensive experience of tissue culture working with cell lines, primary cells and tissues at containment level 2, as well as some experience of GMO work using mammalian cells and microorganisms. This individual also has additional responsibility for research governance and compliance. This individual has considerable experience of health and safety and risk assessment in a research laboratory.

For activities involving GMMs, describe the waste management measures which will apply to the activity

All plasticware and solid lab waste used in GMO projects will be autoclaved (100% kill) at 121C and 15 psi for 30 minutes, prior to disposal. The autoclave servicing and temperature validation will be completed annually by suitably qualified external contractors. A printed record with time and date will be kept for each autoclave run for GMO waste.

Liquid waste will be inactivated with 2% Rely-On+ Virkon solution for 24 hours and then be discarded to drain with water.

Solid waste will be disposed of via a licensed waste contractor to be incinerated as clinical waste. Accidental spillages of GMO waste will be inactivated with 2% Rely-On+ Virkon solution. Benches and the immediate will be cleaned using 2% virkon solution after each use.

Tick to confirm that you are attaching a summary of the risk assessment  

02/03/2022
The GMO safety committee had some comments regarding transport, the procedure for spillages and clarity around stating that the project uses commercially purchased GMO cell lines. These concerns have been addressed in the risk assessment to satisfaction of the GMO safety committee.

We will make use of Chemgene and Virkon to sterilize and kill any live material. Chemgene 2% spray will be used for the sterilization of surfaces by spraying, and replaced after 1 month. It will be applied to surfaces for >5 minutes to ensure biological material killing. Virkon 1% will be used to treat cultures, pipette tips, and any cultureware that comes into contact with cells. Appropriately treated waste (i.e. Virkon 1%) will be disposed of in standard sealable yellow 60L eurobins. A UN3245 sticker will be placed on the bin, including biohazardous symbol. The bin will not be overfilled and will be replaced after 1 month. The bin will be marked with date sealed. The sealed bin will be placed in the building's clinical waste bin area, where it will be removed and taken to the incinerator by central Babraham Research Campus services.

Tick to confirm that you are attaching a summary of the risk assessment Y

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

This CU1 notification along with the attached risk assessment have been reviewed by the Rockend biological safety officer (BSO), Rockend's head of discovery, Rockend's Chief Scientific Officer (together - Rockend's genetic modification safety committee) as well as the BBT Biosafety committee.
Our objective is to understand the molecular mechanisms involved in blood cell formation (haematopoiesis) from different stem cell sources (haematopoietic stem cells, pluripotent stem cells). The research projects will include transduction of genes with expected biological effects into mammalian cell lines and primary cells by the means of CRISPR based editing.

By identifying and understanding fundamental development processes, our projects should allow us to better control in ex vivo differentiation protocols and improve the production of therapeutically relevant cell types, for example haematopoietic stem cells.

The recipient microorganism is especially disabled, non-colonising and unlikely to survive outside laboratory culture. The hosts can be assigned to ACDP hazard group 1. iPSCs are considered especially disabled, unable to survive outside the laboratory environment. However, they have been derived from human primary tissue with associated low risk of pathogen contamination. Their culture has been assigned CL2.

- Mammalian primary cells are considered especially disabled, unable to survive outside the laboratory environment. However, they have been derived from primary tissue with associated low risk of pathogen contamination. Their culture has been assigned CL2.
- Mammalian cell lines are considered especially disabled.

The vector system will be purified CRISPR components and guide RNAs. These vector systems are completely inert and incapable of further replication. They will be transduced into cells by nucleofection in a dedicated apparatus. In the absence of these apparatus, the CRISPR components are unable to edit or self propagate (and are just purified protein and RNA components). Where transgenes are integrated into the host, the code for these genes will be present on naked plasmids only, and also delivered to the hosts by nucleofection.

Type 1 inserts

None of the inserted sequence will generate product presenting acute toxicity (e.g. toxin).
cDNA will code for genes, for example transcription factors, signal transducers, growth factors and receptors which are expected to have a biological role in transduced recipient cells (cell growth, death, differentiation).

Type 2 inserts
shRNA will produce non-coding RNA sequences targeting cell endogenous mRNA in the recipient host. Downregulation of these genes are expected to have a biological role in transduced recipient cells (cell growth, death, differentiation).

Type 3 inserts
Reporter genes will code for proteins with fluorescent or enzymatic properties allowing for easy identification of genetically modified (GM) cells. These are thought to have no deleterious biological effect on expressing cells.

Type 4 inserts
Selection genes will produce enzymatic proteins able to inactivate specific antibiotic families allowing for selection of GM cells. These are thought to have no deleterious biological effect on expressing cells.

Type 5 inserts
Functional non-coding sequences will act as promoters of transcription (promoters and enhancers), local chromatin structure modifiers (enhancers and insulators), RNA transcript stabilizers (WPRE) or translation regulators (IRES, 2A). They will be used (independently or in combination) with viral expression cassettes to provide control of transgene expression, type used depending on targeted cells. Type 5 inserts are not expected to have a biological effect separately from their associated coding sequence (type 1-3). There remains the unlikely exception of genomic integration events which could lead to endogene dysregulation.

Type 6 inserts
Neutral non-coding sequences will be used in particular for gene targeting projects to promote homologous recombination at defined genomic loci (intron/exon genomic sequences). Use of type 6 inserts should not have biological effect on the recipient host by themselves.

**Evaluation of foreseeable effects**

The GMOs themselves are not capable of surviving outside of the tissue culture environment and thus there is little to no risk of environmental contamination.

As we do not plan on using viral GM methods there is no risk of our approach producing any propagative particles. GM cells may be transformed/oncogenic but are incapable of colonising and causing disease. These cells could represent a genuine risk in the occurrence of accidental injection to an immune-deficient individual or to the corresponding primary cell donor but there will be no such opportunity for involved staff.

We do not expect any harmful products resulting from the increased transcribed/translated genes.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The Jeffrey Cheah Biomedical Centre building management team manages two waste streams. One waste stream for CL1 waste and a second for all CL2 waste.

CL2 solid waste management:
CL2 solid waste includes items such as general tissue culture consumables used in CL2 (consumables having been in contact with or containing residual GM material) tissue culture plates, tissue culture flasks, tubes etc. Serological
pipettes and pipette tips will be collected in Bio-bins initially. Once Bio-bins are full they will be sealed and placed into autoclave bags in clearly demarcated CL2 waste bins. When CL2 autoclave bags are 3/4 full, they will be loosely closed with autoclave tape to reduce the risk of waste spillage. The 3/4 full cable tied bags will be placed into red CL2 waste bins and lids secured with cable ties. The red CL2 waste bins will be collected at least once a day by the building services team who will transport them to the basement of the building to be autoclaved. The building's waste autoclaves will have maintenance schemes written by Bureau Veritas and will be inspected annually by Bureau Veritas and PSSR. Additionally, the buildings waste autoclaves will be serviced regularly and annually validated under a service contract. The autoclave will run at the pre-set guidelines for deactivation of CL2 waste, this will be validated on every run using indicator tape. Autoclaved waste will be transported off-site by Novus Environmental as ‘offensive waste’. CL2 liquid waste, that is safe to dispose of down the drain after inactivation, including; used tissue culture media, PBS used to wash cells etc will be treated with Chemgene before disposal down the drain. Inactivation of liquid waste will be achieved by using a final concentration of 10% volume/volume Chemgene with a minimum contact time of 30 minutes, before being disposed of down the sink/drain. Chemical waste for disposal from CL2 tissue culture (that is not suitable for disposal down the drain) will be collected in bottles, treated with a final concentration of 10% volume/volume Chemgene for a minimum of 30 minutes. Bottles will be labelled with their contents and placed in the chemical fume hood for disposal by building services. All work surfaces shall be left for 30 seconds before subsequently wiping with 70% ethanol.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

This CU2 notification along with the attached risk assessment have been reviewed by the MTI biological safety officer (BSO), and MTI Drug Discovery and Onco-Innovation Programme Manager. This CU2 application will be noted at the next MTI Safety Committee Meeting, which includes our biological/genetic modification safety committee function.

Give brief details of the genetic modification safety committee

CSO, Biological Safety Officer and GMSC chair of Phenotypeca Ltd  
Professor of Genetics with the following relevant experience:  
Served on the Genetic Modification Sub Committee (2001-2005) for the University of Leicester and chaired the subcommittee from 2003-2005. Currently serves on the EFSA microorganism working group and is familiar with the current EU regulations. Extensive experience modifying yeast (S. cerevisiae) and E. coli for 30 years under GMM approval at the Universities of Oxford, Leicester and Nottingham

Bacteriology | Parasitology | Transgenic Birds | Microbiology Research | Yes

02/03/2022
We sub-let laboratory space within the Strathclyde Institute of Pharmacy and Biomedical Sciences (SIPBS). As such, our rental agreement gives us access to the building’s waste disposal and sterilisation facilities. Therefore, all waste generated through project activities will be disposed of in accordance with practice enforced by SIPBS. All biological and GMM waste is treated as clinical waste; therefore any waste derived from our work processes that involve GMM will be processed as clinical waste. Solid waste such as agar plates, non-recyclable plastic, paper towel, absorbent powder, nitrile gloves placed into autoclave bags within yellow clinical waste bins. Small volumes of contaminated liquid waste (<50 mL) can also be placed into autoclave bags. Each bag of clinical waste contained in autoclave bags will be sterilised by use of a validated autoclave. Each bag of autoclavable clinical waste must have a yellow label with the name and floor number of the person generating the waste. This is to ensure that the waste can be traced back to the user in case of any problems.

Large volumes of contaminated or spent media will decanted into dedicated rigid containers marked waste and autoclaved (using validated autoclave) prior to disposal as clinical waste.

Control measures such as the use of autoclave tape and temperature charts (to track autoclave temperature and hold times) will be used to ensure waste is correctly sterilised.

Autoclave operating conditions for sterilisation of waste: 126 degrees centigrade, 15 psi, hold time 30 minutes

Disinfection of reusable items will be achieved by soaking the items in high level disinfectant such as Virkon or Chemgene HLD4 (prepared and used as directed by the manufacturer) for a sufficient time. Monitoring of this (to ensure thorough disinfection) will involve taking samples from the process and plating out onto non-selective agar plates in order to detect re-growth and therefore failed disinfection.

For activities involving GMMs, describe the waste management measures which will apply to the activity

As reviewer of this application, I am confident that the correct containment level has been determined for the work proposed. The yeasts Saccharomyces cerevisiae and Pichia pastoris and the specific E. coli strains are considered GRAS and QPS and the strains used in this proposal have been used safely for decades in numerous labs. They are disabled in that they have auxotrophies requiring nutrients making them unlikely to survive outside of the lab. The yeast are benign except in cases of severe immune deficiencies or severe allergies which would be relevant to all yeast and not just these. The use of non-mobilisable vectors in disabled E. coli is also considered low risk. Any products made will be at small lab scale but should be assessed for potential toxicity or other detrimental effects. The scale of production in Xias Bio Limited is small and the risk of exposure is low. It is agreed that procedures within the company will ensure that containment at the required level is provided. All GM risk assessments, staff training, and GMO research will be compliant and aligned with the University of Strathclyde policy.

Give brief details of the genetic modification safety committee

The Biological Safety Officer, The James Hutton Institute, Invergowrie, 002 5DA. The BSO has more than thirty years of experience working with GMMs, principally GM plant pathogens. The BSO has been in position for more than five years, was a deputy BSO for ten years and served on the institute's GMSC prior to that. The BSO has qualified as a Biosafety Practitioner Level 1 on an ISTR approved course.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Waste is inactivated in the building by autoclaving at 123°C for sixty minutes to give 100% kill of laboratory E. coli strains. A load probe is used as appropriate. Waste runs are monitored using 3M™ Comply™ Thermalog™ Steam Chemical Integrator Strips and/or an independent temperature logger and/or a biological indicator. Autoclaved solid waste is passed to a contractor for incineration.

Please enter comments of the GM safety committee on the risk assessment

The adviser considered the proposed activities as commonplace low risk work. The adviser thought that the cloning of low-risk mammalian antibody fragment sequences and their expression using phage display systems, with a long history of use, and vectors based on commercial expression vector systems as chimeric antibody sequences in disabled E. coli K12 derived strains presented a low risk to human health and the environment. The adviser thought that using containment level 1 measures would reduce the risks to human health and the environment to negligible levels. Therefore, the adviser thought that the work should be classified as Class 1.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Biological waste. The volumes of biological samples used are very small (below 200μl). The typical experiment will require volumes of 1-10μl of the biological material (depending on titer). Most of the contaminated material will be small volumes of diluted sample contained in Eppendorf tubes or equivalent tubes, glass coverslips and pipette tips.

- Liquid waste: due to the small amounts of liquid used and the nature of the biological material. Contaminated material will be disposed into appropriate bins for biological waste, identified for the purpose.
- Spills will be cleaned using inactivating chemical agents, such as bleach or other appropriate liquid for decontamination.
- Sharps, such as glass coverslips, will be discarded into puncture-resistant containers designed for the purpose of sharps disposal.

Biological waste bins and sharps are disposed using a 3rd party specialised in biological waste.

Modified vaccinia virus Ankara (MVA) is a replication deficient virus. It has lost its ability to replicate in most mammalian cells and cannot revert to virulence, even in irradiated animals that are otherwise immunocompromised. Antigens expressed by MVA are not expected to alter the ability of the attenuated vectors to infect or replicate in mammalian cells or their ability to survive in the environment. The trial will not amplify or modify the GMM, it will apply and ultimately destroy it. Any items in contact with the substance (vials, syringes, needles) will be disposed of as clinical waste for incineration.

Bacteriology Parasitology Transgenic Birds Microbiology Research
All waste liquids are collected in two 20,000 litre treatment tanks and heat inactivated prior to release to public sewer or to contracted registered road haulier waste disposal company.

Laboratory solid waste is collected in airtight sealable containers for disposal via a registered waste management company. Laboratory liquid aqueous waste is chemically inactivated prior to entering the building liquid waste streams. Liquid organic waste is collected and disposed using a registered waste management company.

Manufacturing solid waste is either autoclaved onsite prior to being bagged and disposed in landfill or double bagged and removed for incineration by a registered waste management company.

The VMIC production facility consists of both laboratory research and development and large scale vaccine manufacturing activities using GMMs. The classification of GMO's handled within the facility is limited to biological safety level 2 and contained accordingly. The traceability of all GMMs within the facility is achieved from receipt to disposal using electronic systems (manufacturing activites using a Laboratory Information Management System and research and development using an Electronic Laboratory Notebook system). GMM storage is in secured cold storage with controlled access.

Mechanical segregation of the GMMs from staff is maintained during use using biological safety cabinets and closed systems with onsite air-quality monitoring for the manufacturing areas. Liquid waste stream treatment is built into the building design via two 20,000 litre treatment tanks prior to release to public sewer or collection by contracted registered specialist waste company. A rotational disinfectant program is used throughout the facility to control microorganism contamination, with manufacturing areas being maintained as clean rooms with air quality between class B and class D. Solid contaminated waste is autoclaved prior to disposal or collected by a registered commercial waste operator for incineration.

It is the conclusion of the VMIC Biological Safety Committee that the VMIC facility is designed to control all the potential risks from working with genetically modified organisms to a classification of category 1.

Give brief details of the genetic modification safety committee

The work to be carried out is a continuation of many years (20+) R&D by the organisation albeit when we were based within an academic collaboration and worked within University departments (this work has previously been agreed as class 1 activity at the level of University GMSC). The ADAS research team are now in premises of their own and are looking to continue similar research using the same techniques. The person with overall responsibility for the research team is the director of the business, trained to the level of PhD and has been working in scientific research for the last 25 years. Previously this individual was involved in the writing and maintenance of the GMO RAs within academic departments and has also been involved in a consultancy role for a CRO that has periodically had to notify HSE of studies where clients have wanted them to test products containing GMOs. For this contained used application the GM risk assessment has been based on a similar form that we had used within a department of the University of Nottingham. In this application the GMO RA has been updated and discussed within the ADAS research team. At present this has been discussed with the person acting as GMSC meeting chair and the site BSO (who is also the proposer of the GMRA). In this instance-and because the class 1 use has been assessed before, it has was agreed that further staff involvement for the activity was not necessary on this occasion. Between the BSO and the chair there is 40+ years experience of working with GMOs and specifically phage display technology- the subject of the RA that supports this notification of premises. It is anticipated that the GMO RA will be reviewed on a 6 monthly basis with the same two individuals plus a ADAS senior research scientist, to ensure that the RA is still valid, up to date and within scope for the R&D activities that are being carried out. To ensure that these are not missed they will be an agenda item to be added to the 6 monthly quality meetings that we currently have planned.

02/03/2022
The decontamination and disposal routes set out below have been used by our laboratory personnel (when working within an academic department) for over 20 years. We have discussed this again within our internal GMSC and see no reason to change this approach.

All contaminated disposable plasticware will be collected in appropriately labelled containers with a disposable liner. Once the container is full, the liner will be removed and placed in an autoclave bag closed with autoclave tape for autoclave sterilisation. These items will be inactivated on an autoclave cycle at 121°C for 15 mins, demonstration that the cycle had been successful would be by the autoclave cycle report and the visual indicator check of the autoclave tape. Inactivated waste will be disposed of via the laboratory waste stream (bagged waste to landfill).

Liquid cultures (phage and E.coli) and including spent media supernatants will be inactivated by the addition of the halogenated tertiary amine solution Trigene to the manufacturers recommended concentration. Inactivated solutions will be disposed of via liquid waste using copious flushing with fresh water.

Glassware and any reusable plasticware will initially be treated with Trigene to the manufacturers recommended dilution before extensive washing and then sterilisation by autoclaving.

Benches, cabinets and incubator surfaces will be periodically surface sterilised by wiping down with 70% alcohol solution, any spills will be treated by addition of Trigene to the spill, before mopping up with a spill kit and its disposal after autoclave.

Tick to confirm that you are attaching a summary of the risk assessment

All GMM work undertaken by NanoSyrinx Ltd at the University of Warwick premises will be done in compliance with existing long-standing biosafety compliance. Measures for the management of waste include:
1. Non-biological waste (e.g. used gloves, tissue, labware not used for culture etc) is disposed of in to hazardous waste bins which are clearly demarcated (red bins with yellow liners). This waste is collected in to a secure compound and removed by a University approved 3rd party contractor.
2. Contaminated biological waste is autoclaved on-site. Waste is added to metal autoclave tins which are double lined with autoclave bags. University central technical support actions the disposal of waste after autoclaving in line with established protocols.
3. All other routine waste (such as paper towels from handwashing, office waste etc) is disposed off in the institutes regular waste.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Risk assessments are due to be carried over from previous academic lab work based at the University, of which this research is a continuation. The existing risk assessments have been approved by the University HSE and biosafety committee for academic work. We have not yet formally adopted the risk assessments via approval from the University of Warwick HSE, but as the research we are conducting is a direct continuation of academic research, within the same containment facility, we expect the existing risk assessments to be appropriate for our research activity and acceptable by the committee.
We are awaiting final approvals/revisions for the risk assessments at the present time, and so will provide these in a follow-up email.

All liquid waste arising from/contaminated with cell cultures (of E.coli and cyanobacteria) will be made unviable/inactive by 1-2% Virkon disinfectant for 30 minutes. All solid waste arising from/contaminated with cell cultures will be made unviable/inactive by use of autoclave at 121-125°C for 15-30 minutes (as per manufacturer's instructions). All waste to be collected in biohazard bins to be disposed of by a specialized, licenced contractor.

For further details on the following, please see attached risk assessment:

[All E. coli strains and all cyanobacteria strains to be used are classified as ACDP Hazard Group 1 (low hazard). The transformed (genetically engineered) cyanobacteria strains have no additional harmful properties in comparison the wild-type strains. As such, according to guidelines of “The Genetically Modified Organisms (Contained Use) Regulations 2014”, transformed cyanobacteria strains have Risk Classification Class 1 with only Containment Level 1 required.]

Please enter comments of the GM safety committee on the risk assessment

Comments from Biological Safety Officer at a UK academic institution:

"The nature of the experiments justifies the classification of containment level and biohazardous group."

"For good practice, the risk assessment should be assessed case by case, meaning that if the inserted genetic material to be expressed results in higher pathogenicity or toxicity (however unlikely), the biohazardous group and containment level would proportionally increase. In such a scenario, further notification to HSE would be required"

### Premises Conditions

**Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities**

- **Yes**

**Give brief details of the genetic modification safety committee**

Hoxton Farms has a genetic modification safety committee consisting of two experts: a company director who holds a DPhil (PhD) degree in molecular biology and has ten years' experience conducting genetic modification experiments and associated risk assessments in industrial and academic laboratory settings; and (2) an external advisor who is the facilities manager at a 450-person university molecular biology department in England. The committee meets on a quarterly basis (or more frequently if the need arises) to develop and review comprehensive GM risk assessments.

Autoclaving is the preferred route for inactivation of GMMs. Cultures will be sterilized in the autoclave located in the Hoxton Farms laboratory at 121°C for 20 minutes. The autoclave is serviced, calibrated and validated once a year by Astell Scientific Ltd., 19 - 21 Powerscroft Road, Sidcup, Kent DA14 5DT. Inactivated cultures will be poured down the laboratory sink while flushing copiously with water.

Where autoclaving is not possible, Virkon disinfectant will be added to a final concentration of 1% w/v and left for at least 8 hours before being poured down the laboratory sink and flushing copiously with water.

Contaminated single use pipette tips, serological pipettes, flasks and other single-use plasticware are placed into yellow “Bio-Bins”. These are labelled and sealed before they leave the laboratory. Waste is collected weekly by Initial Medical Services for incineration as offensive clinical waste.

Glassware will be disinfected with 1% w/v Virkon disinfectant and left for at least 8 hours before being poured down the laboratory sink and flushing copiously with water. The empty glassware will then be sterilised by autoclave.

Virkon is a safe and effective decontaminant shown to be active against 300 + strains/clinical isolates from 71 bacteria and resulting in >5-log reduction in viable organisms when used as a 1% dilution (Hernandez et al., 2000 [J. Hosp. Inf. 46(3)203-209], ‘Virkon Background Information’ https://www.fishersci.co.uk/webfiles/uk/webdocs/SLSGD05.PDF).

For activities involving GMMs, describe the waste management measures which will apply to the activity

Spillages will be dealt with by swabbing with 70% alcohol spray which is fungicidal.

Contaminated, solid waste such as plastic disposables, tissue paper, culture plates, etc., are bagged in autoclave bin bag. The bag is autoclaved at 121°C for 20 mins, 1 bar pressure. The autoclave tape has to turn black before being placed into a yellow bin bag and tied up. The bags are finally placed in large yellow waste bin.

Liquid culture medium is treated by adding to Virkon or bleach to achieve a final concentration of 10% and left to stand overnight before discharge to the sewer.

Tick to confirm that you are attaching a summary of the risk assessment  Y

Tick if you are claiming exemption from disclosure for sections of the risk assessment  

Please enter comments of the GM safety committee on the risk assessment

The advisor has reviewed the accompanying risk assessment and regards the proposed work as GM Class 1 requiring Containment Level 1.

The waste management measures include use of chemical disinfectant and autoclave (steam based decontamination) in the lab, where the work is conducted. Solid bio-wastes will be autoclaved and given to a licensed company for disposal. Liquid wastes will be collected and autoclaved using the decontamination cycle described below. Alternatively, appropriate amount of disinfectant will be added and allow sufficient time to be effective before disposing.

Examples of chemical disinfectants:
- Virkon (peroxygen): Effective against a range of bacteria, fungi and viruses. To be used at 1% w/v, i.e. 10 g Virkon in 1L liquid waste for at least 30 mins.
- Methylated spirits (alcohols): Effective against bacteria, and fungi (but not bacterial spores). To be used at 70% v/v for at least 10 mins.
- Bleach (not household) (chlorine): Effective against vegetative bacteria, virus, fungi. To be used at 2500-5000 ppm (or 0.25-0.5% v/v) for at least 30 mins.

Autoclave decontamination cycle:
The decontamination (waste treatment) cycle will include 121-124°C for 15 mins, followed by 134°C for 3 mins. Autoclaves is fitted with chart recorders or alternative devices for recording run-time parameters (temperature, time, pressure etc). These will be checked and kept for each sterilisation run to ensure that the autoclave continues to perform satisfactorily. Use of autoclave tape is an indicator that the desired temperature has been reached.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment:
The strains that will be used have been demonstrated to be avirulent, have a long history of safe use and the genetic lesions are well understood. The genetic material involved includes genes from bacteria that translate specific proteins. These proteins do not have any harmful biological activity and thus it is unlikely that they will give rise to any harm.

As the range of proteins expressed in our lab will increase, the nature and biological activity of every new protein will be reviewed and appropriate safety measures will be followed.

## Project Additional Information

### Purposes of the contained use

Overexpression of recombinant proteins in bacterial or yeasts hosts. Cells will be homogenised and the lysate will be used directly or purified to afford the protein of interest, which then will be used to catalyse chemical reactions.

### Recipient or parental organism

**Escherichia coli, Bacillus subtilis, Saccharomyces cerevisiae, Kluyveromyces lactis, Pichia pastoris, Streptomyces coelicolor**

### Host/vector system

**Host:** Escherichia coli, Bacillus subtilis, Saccharomyces cerevisiae, Kluyveromyces lactis, Pichia pastoris, Streptomyces coelicolor  
**Vector:** Plasmids for expression in bacteria (such as pET) and in yeasts (such as Ylp, YEp, YCp)

### Origin & function

The genetic material involved includes genes from bacteria that translate specific proteins. These proteins do not have any harmful biological activity (e.g. toxins, cytokins, growth factors, allergens, hormones or oncogenes) and thus it is unlikely that they will give rise to any harm. The intended function includes utilizing these proteins for biocatalytic reactions in vitro.

### Evaluation of foreseeable effects

Variants of E. coli strains K-12 and B will be used. The strains that will be used have been demonstrated to be avirulent, have a long history of safe use and the genetic lesions are well understood. The gene inserts that will be used do not have harmful biological activity (e.g. toxins, cytokins, growth factors, allergens, hormones or oncogenes). Thus, it is very unlikely that the gene products will give rise to any harm.  
As the range of proteins expressed in our lab will increase, the nature and biological activity of every new protein will be reviewed and appropriate safety measures will be followed.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

No larger GMOs will be used.

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The waste management measures include use of chemical disinfectant and autoclave (steam based decontamination) in the lab, where the work is conducted. Solid bio-wastes will be autoclaved and given to a licensed company for disposal. Liquid wastes will be collected and autoclaved using the decontamination cycle described below. Alternatively, appropriate amount of disinfectant will be added and allow sufficient time to be effective before disposing.

Examples of chemical disinfectants

Virkon (peroxygen): Effective against a range of bacteria, fungi and viruses. To be used at 1% w/v, i.e. 10 g Virkon in 1L liquid waste for at least 30 mins

Methylated spirits (alcohols): Effective against bacteria, and fungi (but not bacterial spores). To be used at 70% v/v for at least 10 mins

Bleach (not household) (chlorine): Effective against vegetative bacteria, virus, fungi. To be used at 2500-5000 ppm (or 0.25-0.5% v/v) for at least 30 mins

Autoclave decontamination cycle:

The decontamination (waste treatment) cycle will include 121-124°C for 15 mins, followed by 134°C for 3 mins.

Autoclaves is fitted with chart recorders or alternative devices for recording run-time parameters (temperature, time, pressure etc). These will be checked and kept for each sterilisation run to ensure that the autoclave continues to perform satisfactorily. Use of autoclave tape is an indicator that the desired temperature has been reached.

Solid waste will be placed in bags for autoclaving. Pipettes will be placed in yellow bio bins before placing in the bags. Liquid waste will be inactivated with 2% virkon for a minimum of 30 minutes before disposing either down the laboratory sink and flushing thoroughly or collected into a waste container and taken off-site for disposal by a licensed waste contractor. Waste bags will be sealed and labelled as GM waste. Bags will be autoclaved using the autoclave in the building before they are collected for disposal by the authorised hazardous waste disposal company, Albus Environmental.

Well characterised laboratory strains of E. coli and commercially obtained mammalian expression cells (related to CHO cells) will be used in this study.

Biohazard group 1:

Non-pathogenic E. coli (such as BL21, Rosetta, TOP10, DH5a, K12)

ExpiCHO-S™ Cells

All liquid waste material will be inactivated by treatment with 1% (w/v) Virkon solution prior to disposal. Solid waste material will be placed in sealed bins and incinerated by an off-site incineration company. Waste from our GM work at Class1 will be placed into suitably labelled hermetically sealable bins. They will be sealed by our staff and removed to a central collection point where they will be placed into 210 litre yellow labelled "Eurobins". Collections for incineration will be made by the local registered clinical/GM waste incinerator contractor. This disposal method is expected to achieve 100% inactivation of the genetically modified entities. The biocidal and viricidal activity of Virkon can be reviewed here: https://virkon.us/#downloads

Virkon solution will be prepared fresh to maximise biocidal activity.

For activities involving GMMs, describe the waste management measures which will apply to the activity

The chosen E. coli strains and ExpiCHO cell lines are considered non-harmful to human health or the environment. They both have exacting growth requirements and would rapidly perish outside of controlled laboratory conditions. The gene inserts confer no pathogenic traits to the recipient cells.

Give brief details of the genetic modification safety committee

GMO safety committee is formed of the following members:
1) BSO - individual with extensive experience of genetic modification issues (>20 years), fully certified and trained by completing the full Biosafety Practitioner course "Biological Safety Officer's Workshop", accredited by the ISTR Biosafety Accreditation Scheme. The BSO is external to the applicant organisation and will provide advice to the committee.
2) Committee chair - non-executive director of the applicant organisation, currently holds a full Professorship in a reputed academic institution. Has extensive experience of genetic modification procedures (>30 years) and currently runs an academic research group.
3) Research scientists - one Scientist and one Senior scientist with >12 years of combined experience in genetic modification procedures in microorganisms (e.g. E. coli and S. cerevisiae) and human cells. These members will draft and implement Risk Assessments to carry out Level I and Level II GMO research activities.

The committee will meet (in person or via videocall) every 6 months or whenever a new Risk Assessment is required, to review existing procedures. In case face-to-face meetings are not possible or not-advised due to COVID restrictions, an email-based review and approval system will be established.

For activities involving GMMs, describe the waste management measures which will apply to the activity

To minimise the risk of escape of GMO’s to the environment, all contaminated waste streams generated during the course of this work will be decontaminated within the laboratory block. Cultures will be grown within leak proof vessels. Teknon™ Biocleanse disinfectant will be added to liquid waste and allowed to stand for 24 hours prior to disposal. Solid waste will be autoclaved prior to incineration. This will achieve 100% inactivation of the lentiviral particles as well as all the materials, reagents and biological samples in contact with them.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

Risk assessment by the BSO and genetically modified organisms safety committee supports the use of CL1 containment.

02/03/2022
The waste proposal will strictly follow the COSHH procedures and genetically modified organism regulations. We have submitted a waste disposal form to the BioEscalator, which has been approved already.

For contamination level 1 waste, the waste will be decontaminated using chemical disinfectant, such as Virkon. The validation of decontamination will rely on the manufacturer's data and standard protocols for chemical disinfection. Infected liquid cultures will be decontaminated with Virkon (2-5%) for at least 2 hours and then dispose of in sink.

The safety committee has approved our GMO work and there are no further comments/concerns.
**Project Additional Information**

**Purposes of the contained use**

The aim of the project is to build up a novel AI model to accelerate T cell receptor (TCR) discovery with better specificity and accuracy. As training the AI model requires a large amount of data, we will adopt high-throughput methods mainly for TCR discovery. This involves the use of well-established methods for TCR discovery, including soluble expression of proteins and surface expression of proteins on mammalian cells (mammalian display). DNA plasmids will be transfected into mammalian expression systems for soluble expression of proteins of interest. Lentivectors will be transfected into mammalian cells to produce non-replicating lentiviral particles which will in turn be transduced into mammalian cells for stable surface expression.

**Recipient or parental organism**

1. Expi293F cells (derived from 293, immortalised human embryo kidney cell line)
2. HEK293T cells (derived from 293, immortalised human embryo kidney cell line)
3. Jurkat cells (immortalised T cell line)

**Host/vector system**

DNA plasmids and non-replicating lentivirus particles. An example of DNA plasmids used include:

1. pD649 - a expression vector plasmid used in expression vectors such as HEK and CHO, contains CMV promoter and puromycin resistance for selection in mammalian cells
2. pHR-SFFV - a lentivector used for cloning in gene of interest, contains SFFV promoter
3. pRSV-Rev or similar - a packaging lentivector plasmid that encodes for Rev
4. pMDLg/pRRE or similar - a packaging plasmid that encodes for Gag and Pol
5. pMD2.G or similar - a packaging plasmid that encodes Env

Vectors 2-5 combine to produce a non-replicating lentivirus.

**Origin & function**

DNA plasmid vectors and gene fragments have either been purchased commercially or obtained via Material Transfers Agreement from scientific collaborators. For transient protein expression, DNA plasmids containing genes of interest will be transfected into Expi293F cells to produce soluble proteins. The proteins will be used as reagent tools for functional assays. For stable protein expression, DNA plasmids containing genes of interest will be transfected into HEK293T cells, along with lentiviral packaging vectors to produce lentivirus particles. Lentiviral particles will be transduced into Jurkat cells for stable protein expression on cell surface. These proteins will be used for high-throughput screening of binders against a specific target (mammalian display).

All proteins produced are of human origin and non-toxic to humans.

**Evaluation of foreseeable effects**

The human cell lines described above are classified as risk group 2. 293-derived cell lines are known to contain DNA derived from adenoviruses which are pathogenic to humans. However, due to the viral genome being incomplete, the risk of viral generation is extremely low. The Jurkat cell line is not known to contain any DNA that could cause
pathogenesis to humans. Regardless, all cell cultures have the potential to carry as yet unidentified adventitious agents and thus, any cell culture work will only be performed in a class II biosafety cabinet by an experienced, fully-trained scientist.

Most of the lentiviruses used are derived from HIV. They have the ability to integrate into host chromosomes, infect dividing and non-dividing cells and have high mutation rates. The major risks associated with lentiviruses are:

- Potential for generation of replication-competent lentivirus (RCL)
- Potential for oncogenesis

To circumvent this, we will be using 3rd generation production protocols for lentiviruses that are developed with enhanced safety by eliminating virulence genes and splitting key genes among different vectors and will also be taking extra precautions when handling the lentiviruses (namely extra PPE and double-containment).

More information can be found in our risk assessment which has been written and has been signed off by the institutional health and safety committee.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

| N/A |

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

| No derogations applied for. |

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

For lentiviral work and mammalian cell culture, liquid waste will be chemically inactivated by incubating with 2% Virkon for 2 hours and disposed of in the sink.

Contaminated solid waste will be double-bagged and autoclaved at 134°C using GMO option and then disposed of in black bag (general waste route) which will be collected by Select Environmental Ltd for incineration.

**Degree of kill:**
- **Autoclaving:** effectively 100% kill (annual validation)
- **Chemical disinfection,** used according to manufacturer’s protocols under standard condition: manufacturer's validation of 99.99% kill

### Is an emergency plan required according to regulation 20?  

| N |

If yes, tick to confirm that it is attached to this form

| N |

Tick to confirm that you have attached a risk assessment to this form

| Y |

Tick if you are claiming exemption from disclosure for section of the risk assessment

| N |

### Please enter comments on the GM safety committee on the risk assessment

The BioEscalator GMO safety committee has approved our risk assessment of class II work, including risk assessment, containment facilities and disposal route.

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities  

Give brief details of the genetic modification safety committee

The advisor has over ten years experience as a Biological Safety Officer, having previous served as the BSO to two biotechnology companies: the contract manufacturing organisation Cobra Biologics Ltd, and most recently the vaccine and cancer therapy development company Prokarium Ltd (BSO for six years). The advisor has reviewed numerous risk assessments at GM Class 1 and 2 for various species of bacteria (including modified pathogens), viruses and cell lines.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Solid waste contaminated with GM Class 1 material will be sealed in autoclavable clinical waste bags, autoclaved and collected by a licensed waste contractor. Liquid waste will be inactivated by the addition of sodium hypochlorite to a final concentration of 1% and minimum incubation time of 1 hour, resulting in a six order-of-magnitude reduction in viability, and disposed to drains. Spills will be treated with sodium hypochlorite or 70% ethanol, adsorbed with paper towels and disposed via the solid waste route.

Tick to confirm that you are attaching a summary of the risk assessment  

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The advisor has reviewed the accompanying risk assessment and regards the proposed work as GM Class 1 requiring Containment Level 1.

The work involves use of standard molecular biology E.coli strains and extracts for micro-scale expression of recombinant enzymes.

All spent cultures will be autoclaved and disposed of via the waste sluice. All smaller volumes (<1ml) will be diluted with bleach and disposed of following site regulations. The largest volume of cultures used will not exceed 1 litre and will typically be 1-5ml.

For activities involving GMMs, describe the waste management measures which will apply to the activity

The applicant has recently retired from running a research laboratory in the area of molecular genetics at the University of Sheffield. He previously held the position of Head of the Department of Molecular Biology and Biotechnology and was a member of the University over-arching Health and Safety Committee. He has considerable experience of managing work in this area in both academic and commercial sectors.

The Daresbury campus has an exemplary track record of supporting Health and Safety and Recombinant DNA technology in this general area.

02/03/2022
Solid waste will be collected in autoclave bags and liquid waste in clearly marked glass bottles for autoclaving. Lab waste is inactivated by autoclaving at 121 degrees C for 30 minutes to kill 100% of E.coli and Agrobacterium strains. A load probe is used as appropriate. Waste runs are monitored using 3M Comply Thermalog Steam Chemical Integrator Strips. All waste is contained and autoclaved within the GM containment building (AN). Autoclaves are thermometrically tested. Following autoclaving, all incinerable material is collected for incineration offside.

For activities involving GMMs, describe the waste management measures which will apply to the activity

The GMSC thought the proposed cloning of plant DNA fragments, that do not encode known toxins or allergens, into plasmid vectors for sequencing and subsequent manipulation for expression and silencing (RNAi) in transgenic plants as routine, low risk work. The GMSC thought that as disabled Escherichia coli laboratory strains and disarmed strains of Agrobacterium tumefasciens, which are not pathogenic to humans, would be used and the introduced sequences would be under the control of eukaryotic, not prokaryotic, regulatory sequences with the plant derived sequences containing introns to prevent expression in bacteria the risk to human health was minimal and that the use of Containment Level 1 measures would be adequate to reduce the risks to negligible. Therefore the GMSC thought that the proposed work with genetically modified micro-organisms should be classified as Class 1. Further, as the cloned genes do not encode known toxic or allergenic proteins and the introduced genes are not predicted to increase the levels of toxic or allergenic compounds in the transformed plants, the GMSC thought that the transgenic plants produced would present no greater risk to human health than the untransformed, progenitor plants.

Give brief details of the genetic modification safety committee

Prior to this notification we have not used GMOs and therefore have not had a GMSC. Our new GMSC will consist of:
Venomtech CEO, CSO, operations manager, post doctoral researcher and senior technician
The CSO has relevant expertise in health and safety and will chair the committee
The GMSC convened to complete and approve this CU1 (including risk assessment) and will meet formally once every three months and also ad hoc.

All waste cell culture media is denatured in 2% DEFRA approved quaternary amine detergent and then disposed of to waste water treatment. Live cells will be Autoclaved by registered waste handler prior to incineration.

Early stage drug discovery, using transiently and stably transfected mammalian cell lines

Tick to confirm that you are attaching a summary of the risk assessment  Y

Tick if you are claiming exemption from disclosure for sections of the risk assessment  

We have reviewed the risks associated with working with established cell lines including genetic modification and we feel they are adequately controlled. We routinely carry out non GM cell work and thus have proven containment and safe systems of work, so we feel the addition of genetic modification to these cells will pose no measurable extra risk to our staff or the environment in which they work.

Give brief details of the genetic modification safety committee

The Biological Safety Committee includes its chair (Head of Biology) and Senior Scientists within Samsara Therapeutics. It meets quarterly to approve new scheme of works and to review associated risk assessments, which involve genetically modified organisms. The committee is also tasked with auditing compliance to all risk mitigation strategies. Samsara Therapeutics consult with an individual with Health and Safety and Risk Management expertise, particularly within biosafety and biosecurity. The consultant is a director in safety training and an non-executive director in governance, strategic planning and risk management and works with a variety of small to medium biotechnology companies within the UK.

Other(s) Basic DNA cloning using bacterial and tissue culture procedures with mammalian cells.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Plastic Consumables (e.g. pipettes, flasks, tubes, agar plates) - incineration (licensed incinerator). Plastic wear is sealed within BioBins before disposal and incineration.

Liquids (e.g. samples, culture supernatants, tissue culture media) - inactivate by chemical means (e.g. Virkon following manufacturers guidelines 1-2 % final concentration for 30 minutes.) Virkon will be added to liquid in class II hood to minimise risk of aerosol exposure.

Sharps (e.g. needles, syringes, scalpels) - dispose via clinical waste stream for incineration in sharps bin.

All waste will be appropriately labelled. Solid waste will be placed in double bio-hazard plastic bags for incineration.

Degree of kill:

Incineration, effectively 100% kill (licensed Incinerator)

Chemical, effectively 100% kill (following manufacturers guidelines)

Tick to confirm that you are attaching a summary of the risk assessment Y

Bacteriology | Parasitology | Transgenic Birds | Microbiology Research

Yes
Spillages will be dealt with by swabbing with 70% alcohol spray and diluted bleach spray which are microbiocidal. Contaminated, solid waste such as plastic disposables, tissue paper, culture plates, etc., are bagged in autoclave bin bag. The bag is autoclaved at 121°C for 20 mins, 1.5 bar pressure. The autoclave tape has to turn black before being placed into a yellow bin bag and tied up. The bags are finally placed in large yellow waste bin. Liquid culture medium is treated by adding to Virkon or bleach to achieve a final concentration of 10% and left to stand overnight before discharge to the sewer.

Yes

Give brief details of the genetic modification safety committee

Health and Safety Committee is responsible for H&S Strategy at the Milner Therapeutics Institute (MTI) and consists of Chair of Safety Committee, School Biology Sciences Representative, Department Safety Officer, Biological Safety Officer, Building Services Manager, Functional Genomics Centre Representative and MTI Senior Scientific Advisor. Risk assessments are reviewed and approved by the biological safety committee (BSO, DSO and Senior Scientific Advisor) and reported to the H&S Committee. Members of the biological safety committee have experience working with GMM's in academic laboratories at a postdoctoral level. They also have experience working with GMM's in the biomedical/pharmaceutical industry in the UK and abroad. Roles in academia/industry include, Team Leader, Group Leader and Project Manager.

The Jeffrey Cheah Biomedical Centre building management team will manage the building's waste streams. Surfaces used for GMM work will be disinfected using 70% EtOH and 5% Chemgene. Care is taken to assure correct concentration of the chemicals used as disinfectants. Agar plates with bacterial colonies will be autoclaved for disposal. Degree of kill is sterilisation. Waste management personnel is fully trained in waste handling. Autoclaves are periodically serviced.

CL1 solid waste will be treated as GMO waste and includes CL1 contaminated plastic consumables, stripettes, pipette tips etc. CL1 solid waste will be placed in orange bags in orange bins. The CL1 waste bins will be placed throughout MTI (Milner Therapeutics Institute) laboratory areas. The CL1 orange waste bags will be closed with cable ties when 3/4 full and deposited in a central laboratory area for collection twice a day by building services. This waste will be removed from site by Novus Environmental as 'clinical waste'.

CL1 liquid waste will be treated with Virkon 2% or Chemgene 10% for at least 30 min before disposal down the sink/drain.

**Tick to confirm that you are attaching a summary of the risk assessment**

Y

**Tick if you are claiming exemption from disclosure for sections of the risk assessment**

N

**Please enter comments of the GM safety committee on the risk assessment**

The attached risk assessment is fit for purpose and accurately describes a common GM process routinely conducted at CL1. The control measures and waste management streams stipulated are adequate to effectively manage the risks to humans and risks to the environment. This risk assessment, along with all other risk assessments issued in the institute, will be reviewed annually and updated/amended as required.
Protein coding gene inactivation in human brain tumour cells via lentiviral transduction of inducible gRNA/Cas9 (CRISPR) and shRNA. Gene down-regulation will be confirmed by quantitative PCR.

**Project Additional Information**

**Purposes of the contained use**
The purpose is to test the effect of gene down-regulation on viability and proliferation of human brain tumour cells.

**Recipient or parental organism**
Cultured mammalian cells, usually human brain tumour cells.

**Host/vector system**
The oligos (shRNA or gRNA) complementary to protein coding gene of interest are cloned into existing retroviral vectors (i.e., pLV[gRNA]-EGFP/Puro-U6 or Tet-pLKO-puro) that are based on HIV lentivirus (3rd generation). The pLV vector is a self-inactivated vector carrying a deletion in the U3 region of the 3' LTR, which eliminates the promoter activity of LTR. The vectors lack the viral gag, pol and env genes. The viruses will be packaged into replication incompetent particles using HEK 292T cells. The infected cells will be selected using puromycin.

**Origin & function**
The genetic material will be oligonucleotide sequences (guide-RNA or short hairpin RNA) complementary to known protein coding genes.

**Evaluation of foreseeable effects**
We expect expression of the doxycycline inducible sgRNA/Cas9 constructs or shRNA in human brain tumour cells to down-regulate a protein coding gene of interest, which in turn should result in reduced proliferation or cancer cell death. The cells are not expected to release infectious viral particles. The retroviral particles are incapable of replication due to removal of the viral pol, gag and env genes. The virus particles are capable of infecting human cells, but will not replicate. The expression of Cas9 and shRNA is doxycycline dependent. The primary concerns are formation of aerosols and use of sharps. We will carry out all manipulations in Class II microbiological safety cabinet.
and will not use sharps or sonication of solutions containing virus. The cancer cell-lines are not viable outside tissue culture conditions.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The Jeffrey Cheah Biomedical Centre building management team has an established CL2 waste stream: CL2 solid waste includes items such as general tissue culture consumables used in CL2 (consumables having been in contact with or containing residual GM material) tissue culture plates, tissue culture flasks, tubes etc. Serological pipettes and pipette tips will be collected in Bio-bins initially. Once Bio-bins are full they will be sealed and placed into autoclave bags in clearly demarcated CL2 waste bins. When CL2 autoclave bags are 3/4 full, they will be closed using cable ties to reduce the risk of waste spillage. The 3/4 full cable tied bags will be removed from the laboratory and placed into red CL2 waste bins in a clearly demarcated collection area. When the red CL2 waste bins are full they will be closed with cable ties. The red CL2 waste bins will be collected at least once a day by the building services team who will transport them to the basement of the building to be autoclaved. The building’s waste autoclaves will have maintenance schemes written by Bureau Veritas and will be inspected annually by Bureau Veritas and PSSR. Additionally, the buildings waste autoclaves will be serviced regularly and annually validated under a service contract. The autoclave will run at the pre-set guidelines for deactivation of CL2 waste, this will be validated on every run using indicator tape. Autoclaved waste will be transported off-site by Novus Environmental as ‘offensive waste’. CL2 liquid waste, that is safe to dispose of down the drain after inactivation, including; used tissue culture media, PBS used to wash cells etc will be treated with Chemgene before disposal down the drain. Inactivation of liquid waste will be achieved by using a final concentration of 10% volume/volume Chemgene with a minimum contact time of 30 minutes, before being disposed of down the sink/drain. Chemical waste for disposal from CL2 tissue culture (that is not suitable for disposal down the drain) will be collected in bottles, treated with a final concentration of 10% volume/volume Chemgene for a minimum of 30 minutes. Bottles will be labelled with their contents and placed in the chemical fume hood for disposal by building services. All work surfaces shall be routinely disinfected by wiping with 5% Chemgene, left for 30 seconds before subsequently wiping with 70% ethanol.

Is an emergency plan required according to regulation 20?  

Y

If yes, tick to confirm that it is attached to this form

Project Ref 3648/21.1

Date Ackn’d: 03/11/2021
CU2 Project Title: Development of novel methods for the diagnosis and control of intestinal and skin pathogens

Class: Class 2
Culture Vol: 1-50 Litres

Consent Granted
Project notified under transitional arrangements

Withdrawn: No
Tick if notifying a connected programme of work: No
## Purposes of the contained use

The overall aim of this project is to inform the development of gene-targeted therapeutic agents for the control of bacterial diseases. In the initial stages of this work, this will entail identification of gene targets by knockout and complementation within an individual bacterium and also expression of the target genes in a second bacterial species, usually the common expression vector E. coli. In order to develop diagnostic tests for the particular target bacteria and genes expression of partial and full length proteins is also necessary. This will enable the calibration of protein sequencing tests and ELISAs for the target pathogens, and identify cross-reactivity, sensitivity and specificity of such tests.

The significance of this work is that it is developing agents which can replace antibiotics in food animal production, as a response to the antibiotic resistance now commonly found in these bacteria. It is necessary to use GMMs as targets for the various therapeutics under test target individual genes, and without producing GMMs the target cannot be verified.

Specifically for this individual project, the aim is to establish the validity of such an approach across multiple bacterial species which are known to be animal and zoonotic pathogens. This is a key enabling step in informing the future design of gene-targeted agents.

## Recipient or parental organism

- Salmonella (non-typhoidal serotypes)
- E. coli serotypes (non-toxigenic)
- Streptococcus spp.
- Staphylococcus spp.
- Campylobacter spp.
- Clostridium spp.
- Edwardsiella spp.
- Klebsiella spp.
- Enterobacter spp.
- Enterococcus spp.
- Listeria spp.
- Pseudomonas spp.
- Providencia spp.
- Yersinia spp. (intestinal strains, not pestis)
- Vibrio spp. (not cholerae)

## Host/vector system

Standard antibiotic resistance cassettes will be used for gene disruption, eg ApR (ampicillin), KnR (kanamycin), Sm/SpcR (spectinomycin), TcR (tetracycline), CmR (chloramphenicol). Also, a range of standard plasmids (all nonconjugative) conferring antibiotic-resistance will be employed for cloning purposes.

Crispr-Cas systems derived from ACDP group 1 bacteria, or components of these, systems will be introduced on plasmids.

All routine cloning will be in E. coli K-12 using standard plasmids (pUC series and derivatives) and will include strains such as E. coli K-12 (BW25113, TOP10, DH5α, MC4100, W3110, MG1655, S17::pRP4), E. coli B (BL21/DE3). Gene expression will use standard commercially available backbones such as pOPIN-E/F, pBAD, pCDF-duet and may be
under the control of inducible promoters such as arabinose and tetracycline. Green fluorescent and other FPs will be cloned in to assess expression in model systems. The commercial source is Clontech pGFPuv Vector.

### Origin & function

Crispr-Cas sequences from ACDP group 1 bacteria targetted to bacteria. Bacetrially-sourced or synthetic resistance genes. Genes encoding toxins, or that enhance virulence, will be specifically excluded from the work. For expression outside E. coli, vectors may be altered by modifying the promoter and ribosome binding site and/or origin of replication by inserting artificially synthesised gene fragments.

### Evaluation of foreseeable effects

Expression of target genes in bacteria would not increase the virulence of any organisms containing them, Crispr-Cas genes will be on plasmids and large size of construct will render the created strains less fit than wild type. Created strains would be either as virulent or less virulent as the parent organism, and would likely be less fit in terms of survival and competition in the environment. Forseeable effects would be as for the parental organisms. Plasmid carriage or knockout will render them less fit than the wild type, limiting their ability to compete and survive.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**None**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Highly contaminated material - tips and loops, and similar plasticware will be collected in the laboratory within small benchtop containers (waxed card waste bins, not biohazard marked). This waste will be combined with agar plates and larger volume plasticware and sterilised by autoclaving. Transport to autoclave will be in a leakproof container on a trolley. Following confirmation of autoclave cycle using TST strips waste will be disposed of to landfill by a licenced contractor. Failure of cycle as indicated by either autoclave or TST strips will mean waste is autoclaved again.

Autoclaves are inspected and tested for temperature and time conformance annually. TST indicators are used as a failsafe.

Sharps will be contained within an autoclavable sharps bin, autoclaved as above, then collected by a licenced contractor for incineration.

Liquid waste will be sterilised by the addition of Virkon from stocks made up weekly. This will be added to a concentration of 2%, the mixture left to stand for 60 minutes before discharge to drain. Glassware will be autoclaved as above.

Low risk material - hand towels and gloves will be collected in yellow bags disposed of by incineration off site after collection by a licenced contractor.

**Is an emergency plan required according to regulation 20?**  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form
Lab users should use PPE — lab coat with elasticated cuffs and high neck, and gloves at all times. Coats must not be worn outside of the laboratory. When transporting waste to autoclave this must be on a trolley. TST indicators should be used in autoclave loads and these ensured to be specific to 121°C for 15 min at 15 PSI. These have been incorporated into the risk assessment.

For activities involving GMMs, describe the waste management measures which will apply to the activity

02/03/2022
Note: the first contained use is to be for a “non-notifiable activity involving larger GMOs” not GMMs. However Note 6 says that section 6-8 should be completed. Inactivation of the GMOs will be carried out by freezing them at -20 °C in a dedicated freezer for 72 hours. This will attain a near 100% kill percentage. After inactivation by freezing the GMOs will be placed for 48 hours into a sodium hypochlorite solution with a minimum of 13 % sodium hypochlorite by weight (i.e. 13 g of sodium hypochlorite for every 100 g of solution) to ensure destruction of the GMOs. The waste produced after inactivation and destruction will be category 3 waste under Regulation (EC) 1069/2009 and will be stored at betabugs limited until disposal in an authorised landfill in line with regulations.

Other(s) Cell biology- To access cell function and phenotype through the analysis of various cellular markers

For activities involving GMMs, describe the waste management measures which will apply to the activity
**Disinfection**

The disinfectant of choice (Virkon) is used in strict accordance with the manufacturer's (Antec's) guidelines to inactivate liquid and solid waste.
- Liquid waste is treated with 1% Virkon solution overnight and disposed of to drain with copious amounts of water.
- Surfaces and equipment will be decontaminated with Virkon (1% w/v).
- Emergency spillages will also be treated with Virkon to a final concentration of 1% w/v.

Virkon has been validated as being effective within 10 minutes at this concentration and Virkon stocks are routinely tested by the manufacturer ([http://www.antecint.co.uk/go.htm](http://www.antecint.co.uk/go.htm)).

**Waste disposal**

**Solid waste:** All solid waste will be collected live on a weekly basis and transported directly for high temperature incineration (HTI), providing 100% kill as monitored by Grundon (Certificates of Destruction are available on request).
- Solid waste will be double-bagged and then sealed in leak-proof solid, rigid 30L burn bins.
- Hard plastic waste that may puncture bags such as pipette tips and stripettes are first sealed in a Bio-Bin® before being placed in sharp bins (Volumes available 5L, 11.5L, and 22L).
- Biological samples (containing blood samples without prior inactivation) will be disposed into burn bins (30L) containing vermiculite granulates and sealed before reaching 20kg – Such bins will be separated from the rest of the lab waste and labelled as GMO Class 1 – A certificate of destruction can be provided for waste sent via Grundon.

*Alternatively, solid and liquid contaminated waste can be treated by autoclaving for 30 minutes at 121°C on a validated cycle resulting in 100% kill. This is not the preferred route as the autoclave is small/medium size and the waste could be accumulated during long periods resulting more hazardous to the people and it is unnecessary as the samples are classified as GMO 1. The autoclave is serviced, calibrated, and validated once a year by Astell Scientific Ltd.*

**Liquid waste:** liquid waste will first be deactivated by treatment with 1% Virkon overnight at room temperature prior to disposal to wastewater via lab sinks with copious amounts of water in accordance with trade effluent license limits.

---

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

---

Please enter comments of the GM safety committee on the risk assessment

The risks from the GMMs potentially present in the clinical samples (from trials using Class 1 GMMs) is low to negligible, so the work can be approved as a Class 1 activity and carried out at Containment Level 1. It is noted that all clinical samples are routinely handled at Containment Level 2.

Give brief details of the genetic modification safety committee

The MTI Health and Safety Committee has delegated the GMO Risk Assessment responsibilities to the MTI-BSO since it has the expertise to advise the committee in the review and approval of not only biological and chemical but also GMO risk assessments. The committee is also supported by the Safety Officer in the School of Biological Sciences at the University of Cambridge. The committee will receive the advise and will in turn make the decision on approving or make suggestion for modifications in the risk assessment.

Production and use of genetically modified of non-pathogenic E. coli and derivatives

For activities involving GMMs, describe the waste management measures which will apply to the activity
All GM waste is inactivated at the same site as the activity is taking place. Liquid waste will be inactivated with 2% Virkon or similar for at least 1 h (or overnight) before disposal to sink. All contaminated labware (pipettes, tips and culture plates) are separately decontaminated using Virkon 2% or ChemGen 5% before being disposed in clinical waste bins for incineration. All GM modified cell cultures (flasks with cells and no media) will be chemically inactivated by soaking with Virkon 2% for at least 1h (or overnight). Once inactivated this waste will be placed in clinical waste bins for disposal by incineration. Small spills will be removed immediately by surface soaking with Virkon 2% and further decontamination using 70% Ethanol. Large accidental spills will be sprinkled with Virkon powder before cleaning and immediately reported to the Biological Safety Officer. Bench and cabinet surfaces will be wiped down with Distel/Chemgene/Virkon 2% and further decontamination using 70% Ethanol.

The attached risk assessment is fit for purpose and accurately describes a common GM process routinely conducted at CL1. The control measures and waste management streams stipulated are adequate to effectively manage the risks to humans and risks to the environment. This risk assessment, along with all other risk assessments issued in the institute, will be reviewed annually and updated/amended as required.

### Purposes of the contained use

Our research aims at understanding the molecular signalling pathways underlying the communication between the lymphoma microenvironment and primary CLL cells and how this affects the selection of drug resistant clones. HEK293T cells are being used to produce recombinant amphotropic/VSV-G pseudotyped recombinant lentivirus and retrovirus particles containing specific transgenes. These particles may then be used for transduction of primary cells, cultures, cell lines.

### Recipient or parental organism

**Mammalian cells: primary cells and cell lines (including haematopoietic progenitor cells, leukemic cell lines, skin fibroblasts)**

In vitro cultured mammalian cells are considered especially disabled and unable to survive outside the lab environment.

### Host/vector system

<table>
<thead>
<tr>
<th>Retrovirus</th>
<th>Lentivirus:</th>
</tr>
</thead>
<tbody>
<tr>
<td>2nd generation systems</td>
<td>3rd generation systems</td>
</tr>
<tr>
<td>Vector containing insert:</td>
<td></td>
</tr>
</tbody>
</table>

Vectors contain coding sequences for antibiotic resistance genes and reporter genes that are used for selection. Antibiotic resistance genes used, for example Kan/AmpR, are not medically critical. Reporter genes, for example GFP, dsRED, Luciferase, are thought to have no deleterious biological effect.

**Inserts**

Several types of inserts may be used:

- **Type 1** - Human, murine, xенopus cDNA (+/- tag sequences) coding for genes including, but not restricted to, transcription factors, signal transducers, growth factors, oncogenes and surface receptors
- **Type 2** - shRNA and miRNA sequences against endogenous coding sequences of the recipient host
- **Type 3** - Reporter genes (i.e. EGFP, ECFP, EBFB, EYFP, LacZ, Luciferase, possibly fused to cDNA (type1 inserts))
- **Type 4** - Selection genes (i.e. NPT, PAC, Puromycin, Neomycin, Hygromycin, Blasticidin)
- **Type 5** - Functional non-coding sequences (promoters, enhancers, insulators, IRES, WPRE, of mammalian or viral origin)
- **Type 6** - Neutral non-coding sequences (introns, isolated exons)
- **Type 7** - expression cassettes for guide-RNA and CAS9 DNA nickase (and variants of the CAS9 system, e.g. dCAS9, dCAS9-KRAB)

### Origin & function

**Transient transfection of HEK293T** with these plasmids will result in the production of recombinant lentiviral or retroviral particles containing transgenes of interest that will be harvested from the cell culture media for subsequent over-expression, knock-down or knock-out experiments.

### Evaluation of foreseeable effects

The modification is not expected to overcome disablement of the host organism, not affect host specificity, tissue tropism or susceptibility to host defence mechanisms. Co-transfected HEK293T cells will produce amphotrope/ VSV-G pseudotyped recombinant lentiviral or retroviral particles containing the transgene of interest, which will be secreted into the culture medium.

Insert expression, non -replicative vector, vector mobilization very unlikely and restricted

Generation of replication competent lentiviral particles (RCL) in a host cell is a theoretical possibility. Oncogenes (or potential oncogenes) altered through insertional mutagenesis could potentially lead to pathological modifications of mammalian cell phenotype/function which may be oncogenic.

The use of 3rd generation lentivirus systems has decreased this risk to a negligible level. However, if oncogenes or genes of unknown function are being inserted into hosts using 2nd generation lentivirus systems this risk is increased.
To decrease the likelihood of infection of an individual, standard measures to decrease percutaneous as well as aerosolised transmission of the virus, such as no use of sharps and work to be performed within a Class 2 microbiological safety cabinet, will be used. Lentiviral and retroviral virulence genes (e.g. vpr, vpu, vif and nef) have been deleted. The derived vectors are therefore unable to replicate once they have transduced a target cell. In addition, third generation lentivirus production systems are deleted for the tat gene and carry a SIN deletion of the 3’ LTR (ΔU3). This results in “self-inactivation” of the lentivirus following the transduction of the target cell.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The Jeffrey Cheah Biomedical Centre building management team will manage two laboratory waste streams. One waste stream for CL1 waste and a second for all CL2 waste.

CL2 solid waste includes items such as general tissue culture consumables used in CL2 (consumables having been in contact with or containing residual GM material) tissue culture plates, tissue culture flasks, tubes etc. Serological pipettes and pipette tips will be collected in Bio-bins initially. Once Bio-bins are full they will be sealed and placed into autoclave bags in clearly demarcated CL2 waste bins. When CL2 autoclave bags are 3/4 full, they will be closed using cable ties to reduce the risk of waste spillage. The cable tied bags will be removed from the laboratory and placed into red CL2 waste bins in a clearly demarcated collection area. CL2 waste bins will be collected everyday by the building services team who will transport them to the basement of the building to be autoclaved. The building’s waste autoclaves will have maintenance schemes written by Bureau Veritas and will be inspected annually by Bureau Veritas and PSSR. Additionally, the building’s waste autoclaves will be serviced regularly and annually validated under a service contract. The autoclave will run at the pre-set guidelines for deactivation of CL2 waste, this will be validated on every run using indicator tape. Autoclaved waste will be transported off-site by Novus Environmental as ‘offensive waste’.

CL2 liquid waste, that is safe to dispose of down the drain after inactivation (i.e. used tissue culture media, PBS used to wash cells) will be treated with 2% Virkon for at least 30 min for inactivation before disposal down the drain.

Chemical waste for disposal from CL2 tissue culture (that is not suitable for disposal down the drain) will be collected in bottles labelled with their contents/concentrations, and will be placed in the chemical fume hood for disposal by building services. All work surfaces shall be routinely disinfected by wiping with 5% Chemgene, left for 30 seconds before subsequently thoroughly wiping with 70% ethanol.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form  

Tick to confirm that you have attached a risk assessment to this form  

Tick if you are claiming exemption from disclosure for section of the risk assessment

This CU2 application along with the attached risk assessments (Biological and GMM) have been reviewed and approved by the MTI biological safety officer (BSO) and presented it to the safety committee. The risk assessment supporting this CU2 application covers the specific containment measures needed at this particular level (CL2) and all work with GMMs apply the principles of good microbiological practice (GMP) and good occupational safety and hygiene (GOSH).

For activities involving GMMs, describe the waste management measures which will apply to the activity:

Bacteria cultures will be in the order of 2 to 4L on a weekly basis or less often.
Bacterial waste and utensils that come into contact with it will be inactivated by soaking in 1% Virkon for at least 30min. This will include:
- media and flasks used for growth (2 to 4L approximately) - dissolve Virkon tablets to 1%
- utensils used to collect and purify cell pellets and the supernant waste (5-50ml) from cell lysis
- small culture aliquotes used for analysis (1-2ml), or small scale cultures (50ml) will be poured into a container with 200ml of final concentration of 1% Virkon.
Small disposable containers (1 to 50ml tubes, plates) that have come into contact with bacteria or bacteria lysis waste will be autoclaved for 20mins at 121 degree Celsius (15psi) and disposed via waste contractor holding a GM waste carriers licence.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The risk assessment has been reviewed and as the risks for human health and the environment are minimal the work can be classified as a Class 1 activity.

Give brief details of the genetic modification safety committee

Accession Therapeutics Ltd is a biotechnology company focussed on developing treatments for cancer. The technology and basis for the work originates from work registered previously (GM130/15.2) and will continue at Accession Therapeutics Ltd.

Accession Therapeutics Ltd has established a Biological and Genetic Modification Safety Committee with membership comprised of corporate and scientific leadership, scientific operations and bench science, documentation and operations personnel, and is chaired by the Head of Preclinical Development who is a member of the company leadership team and reports directly into the CEO. Members of the committee represent all functional areas of the company and facilities.

The Committee meets on a quarter-year basis or as required more frequently, with agenda and minutes and documentation managed through a Quality Management System.

The scientific leadership team have extensive expertise in genetic modification and virology, with the lead projects coming from 15 years of GMO committee-approved research at a leading University from which the Chief Investigator is also a member of this scientific leadership team and on this GMO committee. Other leadership team members also have previous experience with attending and leading GMO and general health and safety committees.

</tbody>
</table>
The first notification will be for class 2 GMM work, detailed in the accompanying cu2 notification. Class 1 and 2 work will be carried out in fit-for-purpose laboratories adhering to appropriate risk assessments and following our SOP for waste management which outlines waste management routes including Accession's contracted waste removal firms.

Commercially available human and animal cell lines (class 1 or 2), primary human blood and tissues, and viruses (class 2) will be maintained in an environment designed to prevent aerosol spread (biosafety level 2 tissue culture hoods, under negative pressure). All used plastics shall be kept sealed/closed except when decanting and pipetting which will be conducted in tested class II safety cabinets, and virus containing waste media will be treated immediately using sodium dichloroisocyanurate (HAZ-TABS).

The use of sharps in the process of purifying viral vectors from Caesium gradients is unavoidable, and is essential to the procedure, but will be kept to minimum use possible. Initial disinfection will be with HAZ-TABS then disposed of through commercial sharps bins.

Liquid waste will be disinfected with HAZ-TABS. Expected degree of kill 100%. Haz-Tab Tablets have been proven through independent EN Standard testing to have broad spectrum biocidal activity, including against viruses.

Solid waste will be autoclaved unless involving human tissue, which would then be disposed of through clinical waste routes by Accession's commercial clinical waste partner.

Details of any other control measures to be used:

Recombinant viruses will at all times be maintained in an environment designed to prevent aerosol spread. All flasks containing the virus shall be kept closed except when decanting and pipetting which will be conducted in tested class II safety cabinets. Centrifugation steps shall be performed in sealed buckets that will be opened only in safety cabinets.

Contaminated pipettes will be immersed in Sodium Dichloroisocyanurate for a minimum of 4hr prior to transferring to a container for autoclaving. The tissue culture cabinet and any potentially contaminated area will be disinfected with chlorine-based disinfectant or Virkon (1%) according to an approved protocol. Access to laboratories employed for virus work will be restricted.
The first notification is for a class 2 activity, therefore no risk assessment for a class 1 activity is attached. Please see accompanying cu2 form for class 2 activity and risk assessment.

## Project Additional Information

### Purposes of the contained use

The purpose of the proposed project is to use the existing Ad5-Null-A20 platform (described in GM130/15.2) to express therapeutic genes that may be beneficial for cancer treatment.

We have previously modified the tropism of both oncolytic and replication-deficient adenoviruses to more selectively target cancer cells (See GM130/15.2). We now propose to use these viruses to express therapeutic genes.

### Recipient or parental organism

We have previously generated oncolytic Ad5-Null virus (this form of the virus does not infect, or replicate in, healthy...
cells) by standard modifications of the Ad5 genome. These include the delta 24 mutation in the E1A protein (1) and the potency enhancing T1 mutation (2). We have also modified the tropism of both oncolytic and replication deficient virus to more selectively target cancer cells using the A20 peptide, from foot and mouth disease, so that the Ad5-Null-A20 form of the virus is only able to infect cells that express αvβ6 integrin (a cancer selective marker). We now propose to use these viruses to express therapeutic genes (please see box 17 for non-disclosure).

Host/vector system

Preliminary vector manipulations will be performed in disabled E.coli strains (DH5a, JM109, XL-1 blue, BJ5813, SW102).

Viruses will be grown in mammalian helper cell lines where required (e.g. 293 cells), or non-helper cell lines where viral replication can occur without complementation (using e.g. A549 cells, HeLa cells).

The viruses will be used to infect various αvβ6 integrin positive and negative cells, including cancer cell lines, cell lines representing healthy tissues and primary blood cells from healthy volunteers.

Origin & function

Evaluation of foreseeable effects

The envisaged worst-case scenario would be that a worker would inadvertently self-inoculate with a large dose of conditionally replicating virus that expresses a biologically active gene that may have benefit in cancer treatment. “Leaky” expression of this gene (which should be minimal due to the inability to infect non-αvβ6 expressing cells) may result in expression of immune modulators in off target tissues, and potentially transient autoimmune responses. However, due to the altered tropism of Ad5-Null-A20 (8), and the very limited expression of its ligand, αvβ6 integrin, in healthy tissues (9), it is very unlikely that the Ad5-Null-A20 virus with the intended encoded transgene would infect any cells in a healthy person. Additionally, the Ad5-Null-A20 virus has been modified to be conditionally replicative by incorporation of a DL24 mutation in E1A (1). Thus, even if a low level of the virus was able to infect healthy cells, it would not be able to replicate in the presence of pRB (a tumour suppressor gene). Finally, even if the virus was to infect αvβ6 integrin positive tumour cells, the expression of the transgene would be highly localised, and would be very unlikely to reach the serum levels associated with dose limiting toxicity as observed when these therapeutic proteins have been administered clinically.

Mitigation:

To minimise the potential for infection, all work will be conducted under containment level 2 conditions, including the use of class 2 level biosafety cabinets.

References:
3-7 can be found in box 17 for non-disclosure
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Will a safety cabinet be used? Yes
Will any procedures use sharps? Yes
The use of sharps in the process of purifying viral vectors from Caesium gradients is unavoidable, and is essential to the procedure. Initial disinfection will be with sodium dichloroisocyanurate then sent for autoclaving in a sealed container.
Will liquid waste be autoclaved or disinfected? Liquid waste will be disinfected:
Product Name: HAZ-TABS
Generic Chemical Name: Sodium Dichloroisocyanurate
Expected degree of kill 100%. Haz-Tab Tablets have been proven through independent EN Standard testing to have broad spectrum biocidal activity, including against viruses.
Will solid waste be autoclaved or disposed of as clinical waste? Solid waste will be autoclaved unless involving human tissue, which would then be disposed of through clinical waste routes by Accession's commercial clinical waste partner.
Details of any other control measures to be used:
Recombinant viruses will at all times be maintained in an environment designed to prevent aerosol spread. All flasks containing the virus shall be kept closed except when decanting and pipetting which will be conducted in tested class II safety cabinets. Centrifugation steps shall be performed in sealed buckets that will be opened only in safety cabinets.
The use of sharps when handling virus preparations will be minimised.
Contaminated pipettes will be immersed in Sodium Dichloroisocyanurate for a minimum of 4hr prior to transferring to a container for autoclaving. The tissue culture cabinet and any potentially contaminated area will be disinfected with chlorine-based disinfectant or Virkon according to an approved protocol. Access to laboratories employed for virus work will be restricted.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment Y

Please enter comments on the GM safety committee on the risk assessment
The risk assessment has been reviewed and deemed appropriate by the Accession Therapeutics Biological and Genetic Modification Safety Committee. The work here at Accession Therapeutics will follow biosafety level 2 processes, waste routes and controls the same as the previous lab as the linked program GM130/15.2. The work will be carried out by, under the supervision of, or trained by the same investigator and scientist as GM130/15.2.

Give brief details of the genetic modification safety committee

The Hull University Teaching Hospitals NHS (Castle Hill Hospital) recently established a dedicated GMSC for the initial purpose of clinical trials with GMO-based vaccines and the approval of corresponding risk assessments. Upon risk assessment, the proposed vaccine clinical trials are considered to be ‘contained Use’ which falls within the remit of the GMO (Contained Use) Regulations 2014.

The HUTHGMSC includes representatives from different departments within the local hospital Trust with various levels of expertise of working with GMOs. In addition, an honorary Biosafety Advisor has been appointed, who is part of the GMSC. The Biosafety Advisor has extensive work experience (competency) with GMOs and is currently the University Biological Safety Officer and Chair of Genetic Modification Committee of the University of Hull.

The composition of the GMSC is as follows: Chair and vice-Chair, Biosafety Advisor, Director of Infection Prevention and Control, Clinical Trials Pharmacist, R&D Quality Manager, Trust Safety Manager, different consultant clinicians for Infectious Diseases including a Virologist, and Employee Union representatives from Unison, Unite, RCN and BMA. The GMSC is chaired by infectious diseases consultant clinician who has recent experience with GMO-based clinical trials and laboratory research.

The HUTH Trust GMSC will meet a minimum of annually with more frequent meetings when required. The GMSC reports to the Trust Patient Safety and Effectiveness Committee, which sits under the Quality Committee, which reports to the Trust Board.

Risk assessments will be reviewed and approved by the GMSC on an annual basis or earlier when proposed change(s) affect the risk level and classification of the GM work.

</tbody>
</table>
Following risk assessment, current work with GMOs at the HUTH Trust has been classified as Class I genetic modification work. Following the requirements of the GMO (Contained Use) Regulations 2014 and the SACGM Compendium of Guidance on the use of genetically modified organisms within clinical settings (part 6), all GMO-containing waste must be inactivated before entering the clinical waste stream and leaving the hospital premises as (accumulated) infectious clinical waste (incineration route, appointed contractor).

Main method of biological inactivation of the current GMOs is the use of chemical disinfectants, in this case the chlorine-dioxide based disinfectants Tristel FUSE and Tristel DUO. These are the recommended disinfectants to be used within the clinical settings of the HUTH NHS Trust. According to the manufacturer’s specifications, both formulations of Tristel have a confirmed high efficacy against Adenovirus and Vaccinia virus of which disabled/non-replicative versions are used as vectors for the GMO-based vaccines.

Non-sharps solid waste will be inactivated by submerging in the by the manufacturer prescribed working concentration of Tristel FUSE (50 ml sodium chlorite activator combined with 50ml citric acid base and diluted in 5 litres of water for a final concentration of chlorine dioxide of up to 125ppm) for at least the recommended contact time of 5 minutes. Following inactivation, the disinfectant phase is disposed of via a sluice and the remaining solid waste will be disposed of

</table>

For activities involving GMMs, describe the waste management measures which will apply to the activity
via the clinical waste stream (accumulated infectious clinical waste, incineration route).

Sharps containing waste will be submerged in Tristel FUSE for an extended time (longer than recommended by the manufacturer) as for example needles are/can be less accessible to disinfectants. For practical reasons, this incubation will be overnight (minimum of 8 hours) before the disinfectant phase is disposed of via a sluice and the sharps bin containing the disinfected sharps is disposed of via the cytotoxic waste route.

Laboratory surfaces are disinfected by using Tristel DUO (sodium chlorite activator and citric acid base combined at the time of use in a foam by a dispenser for a final concentration of chlorine dioxide of 200-600ppm) for at least the manufacturer recommended contact time of 1 minute.

Accidental spills will be inactivated with an excess of Tristel FUSE at the minimum recommended contact time of 5 minutes before disposal of the materials/used paper towels via the clinical waste route. It is further standard practice to disinfect (wipe down) the external surface of waste bags with Tristel FUSE before disposal via the clinical waste stream.

Dedicated SOPs for all waste and spill management processes are in place. All staff handling GMOs will confirm they have read and understood the risk assessment and waste management measures (SOPs) before they can commence GMO work.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

A risk assessment was conducted as set out under the GMO (Contained Use) Regulations 2014 and the SACGM Compendium of Guidance (part 6, working with GMMs in clinical settings). The GMSC and Biosafety Advisor agreed that the risk assessment (attached) is satisfactory, that all regulatory requirements have been fulfilled and that the proposed work is to be considered as a Class 1 genetic modification work activity with no risk to humans, animals or the environment. A copy of the respective risk assessment is attached.

The Panthera BSO & GMSC can confirm, after review of the EU approved Application form for the use of the vector in humans, the likelihood that the Ad26.RSV.preF clinical vector is shed to the environment in relevant quantities upon administration, beyond its initial potential presence at the injection site (injection site leakage) is negligible, taking into account:

• vector DNA is only infrequently detected, and if so, is only found at very low levels and does not contain infectious virus particles.

• the potential for shedding is considered to be independent of the transgene insert, as the transgene insert does not have an impact on the vector particle, and thus does not change cell tropism.

• the same routes (i.e. intramuscular injection) and dose (1 × 1011 VP or below) of inoculation will be used for vaccination as have been used for previous shedding studies.

Give brief details of the genetic modification safety committee

The Enplas Europe Ltd., Lifescience Lab genetic modification committee will consist of:
1. One member of staff who has a PhD in a relevant field of research and more than 25 years research experience including genetic modification and GMOs, and will act as chair. This person has IOSH Biosafety Officer training.
2. Two other employees with approximately 2 years each experience of generating and handling GMOs.
3. The external biosafety consultant (see section 8).

The Enplas Europe Ltd., Lifescience Lab GM committee agreed that the risk assessment included with this notification was suitable and sufficient. The committee will meet at least every 6 months to review risk assessments and GM procedures.

For activities involving GMMs, describe the waste management measures which will apply to the activity

All waste material will be inactivated by treatment with 1% (w/v) Virkon solution prior to disposal. Waste material will then be placed in sealed bins and incinerated by an off-site incineration company (see derogation application below). Waste from our GM work at Class 1 will be placed into suitably labelled hermetically sealable bins. They will be sealed by our staff and removed to a central collection point where they will be placed into 210 litre yellow labelled "Eurobins". Collections for incineration will be made by the local registered clinical/GM waste incinerator contractor. This disposal method is expected to achieve 100% inactivation of the GMM. The data sheets describing inactivation by Virkon are attached.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The Enplas Europe Ltd., Lifescience Lab GMO committee reviewed the GMO risk assessment (see attached). The Enplas Europe Ltd GMO committee consists of one person who has a PhD in a relevant field with more than 25 years research experience including genetic modification and GMOs together with IOSH Biological Safety Officer training, plus two others with 2 years experience with GMOs each. The GMO committee have previously written GMO risk assessments for similar work prior to joining Enplas Europe Ltd., and they understand the science around the work carried out.

The Health and safety consultant reviewed the GMOs. The consultant has a B.Sc in Animal Sciences - Wye College (part of Imperial), London University, M.Sc. Animal Parasitology, Ph.D. The immunology and pathology of Sarcocystis ovicanis infections in sheep (both at U.C.N.W., University of Wales). Technical member of the Institution of occupational safety and health (Tech IOSH), NEBOSH National Diploma in Occupational Health and Safety (in progress), NEBOSH National General Certificate in Occupational Health and Safety, Member of the Institute of Safety in Technology and Research, MRC Biological Safety Officer Training Certificate. 1986 to 2010 at the Babraham Institute (Cambridge) where experience of handling pathogens and GMO obtained during research. 2006 made Babraham Research Campus Biological Safety Officer (part time plus research). 2009 onwards teach the genetic modification safety section of the One Nucleus ‘Biological Safety: Management and Practice’ course (IOSH approved).

2010 onwards Babraham Institute Health, Safety and Quality Assurance Manager and Babraham Bioscience Technologies (BBT) Biosafety Officer (Full time). 10 years experience in risk assessments and has health and safety qualifications.
The generation and use of AAV, Adenoviral, Baculoviral, HSV-1 viral, Retroviral and Lentiviral particles for knock-in/knock-out of oncogenes and other potential cancer therapeutic targets to study and confirm mechanisms of action, and efficacy of anti-cancer agents.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

All liquid waste material will be inactivated by treatment with 1% (w/v) Virkon solution then autoclaved prior to disposal. Solid waste material will be placed in sealed bins.
and incinerated by an off-site incineration company (Stericycle – Their GM authorization is GM779) according to disposal notification GM.779/01.1. Waste from our GM work at Class 2 will be placed into suitably labelled hermetically sealable (red lid to distinguish them from Class 1 waste) 60 litre UN approved (to Class 3) Type 3H21Y30/S/2003 bins. Sealed bins are placed into secondary 210 litre yellow labelled "Eurobins". Contents of the bin are recorded and collections by the local registered clinical/GM waste incinerator contractor will be made three times a week to prevent a build-up. The site has 24/7 Security. The contractor uses solid bodied transport and carries portable disinfection equipment in case of any spillage. Autoclave facilities will be available in an adjacent building, as required by the Regulations, in case of loss of the contractor's facilities. The type of container and the secondary Euro container means that the risk of any spillage of active GM waste on site is negligible. However, as active waste will leave the site, the risk to the environment and health is possibly marginally higher than autoclaving prior to incineration. The only real risk of release would be as a result of a major RTA, however, the containers are designed to withstand this. This disposal method is expected to achieve 100% inactivation of the GMM.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste material will be inactivated by treatment with 1% (w/v) Virkon solution prior to disposal. Solid waste material will then be placed in sealed bins and incinerated by an off-site incineration company (see derogation application above). Waste from our GM work at Class 1 will be placed into suitably labelled hermetically sealable bins. They will be sealed by our staff and removed to a central collection point where they will be placed into 210 litre yellow labelled "Eurobins". Collections for incineration will be made by the local registered clinical/GM waste incinerator contractor.

This disposal method is expected to achieve 100% inactivation of the GMM.

The data sheets describing inactivation by Virkon are attached.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment Y

The scope and particular aspects of safety risks described in the risk assessment were agreed upon, and satisfactory consensus was achieved regarding the adequacy of the SOPs, COPs and risk management planning protocols. Pending notification and acknowledgement by relevant authorities.

Y

Give brief details of the genetic modification safety committee

Advent Bioservices has a GMSC consisting of members of the Senior Management Team, including the Quality Department, a contracted Safety Consultant and the H&S lead for the company. This committee meets quarterly, with additional meetings as required if a new client is interested in the service.

Yes

For disposal, all materials are sealed into yellow hazard bins (which are hermetically sealed) and sent for incineration (FCT-SOP-4). Any spills of materials would be managed as per standard procedure (FCT-SOP-7) which requires that any spills involving biological materials are treated with a suitable disinfectant to ensure inactivation of the biological material. Incineration is outsourced to Stericycle (GM Centre Number 779). We are applying for derogation as Advent Bioservices does not have a waste autoclave.

**For activities involving GMMs, describe the waste management measures which will apply to the activity**

For disposal, all materials are sealed into yellow hazard bins (which are hermetically sealed) and sent for incineration (FCT-SOP-4). Any spills of materials would be managed as per standard procedure (FCT-SOP-7) which requires that any spills involving biological materials are treated with a suitable disinfectant to ensure inactivation of the biological material. Incineration is outsourced to Stericycle (GM Centre Number 779). We are applying for derogation as Advent Bioservices does not have a waste autoclave.

**Is an emergency plan required according to regulation 20?**

N

**If yes, tick to confirm that it is attached to this form**

N
The Genetic Modification Safety Committee (GMSC) have affirmed that Advent Bioservices is equipped with the appropriate facilities and systems to store and distribute external clients GMO material(s). These include appropriate waste and spill procedures. No manipulations will be performed. To undertake this work we are required to notify the HSE using the CU2 form. All clients must have their own risk assessment and Notification to the HSE prior to commencement of contracted work. This work is deemed low risk, please see attached Risk Assessment.

We will use commercially available prostate cancer cell lines (LNCaP) to knock-out two genes.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Leftover cells not used in experiments will be detached from their respective flasks/containers and aspirated to a sealed reservoir containing pure cold sterilant solution (actril), according to the manufacturer's specifications, which achieves a kill percentage of 100%. Once inactive has been achieved, this solution can be safely disposed of via the main drain pipes in the lab.

Any flask/container where cells were present will be sealed and placed in appropriate biohazard bags, which will be autoclaved prior to disposal.

Any potential spills will be cleaned with appropriate wipes plus sprayed with 70% ethanol solution. These wipes will be also sprayed with ethanol and left under the microbial safety cabinet, exposed to UV light overnight, to further inactivate any potential leftover cells. These wipes will then be placed in appropriate biohazard bags and autoclaved prior to their disposal.

Cells used in terminal experiments will be actively lysed and destroyed according to the experimental protocol.

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Tick to confirm that you are attaching a summary of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

It is expected by both the Biosafety officer of the department of Radiology as well as an external Safety officer that this genetic modification will not pose any danger. In fact, the expectation is that knockdown of these genes would probably lead to a decrease in cell viability and proliferation, making these cells even less dangerous than normal.

Y

Give brief details of the genetic modification safety committee

The Skylark Therapeutics Ltd Genetic Modification Safety Committee will consist of

1. The CSO who has 15 years+ experience working in basic and translational research, including use of mammalian cell culture/primary samples and management of research teams.
2. The COO who has 15 years+ experience working in the biotechnology industry, managing teams focused on genetic engineering/synthetic biology across microbial and mammalian systems, and working with viral vector engineering and manufacture
3. External Consultant - Currently a Safety Advisor (CMIOSH) at a UK Research University with > 20 years experience in Biological and GM Safety.

The Committee will meet quarterly to review GM biosafety and whenever a new GM risk assessment is submitted

Laboratory | Animal Unit | Growth Room | Glass House | Large Scale

Other (please specify) | Tick if confidential |
Solid Waste disinfection and disposal
- All solid waste (i.e., tissue culture plates, stripettes, tips etc) will be double bagged in clear plastic autoclave bags at the end of each session.
- At designated daily time slots, autoclave bags will be taken to the autoclave room in the communal lab (F35) by the individual TC user (trained by competent person) where they will be processed immediately. The TC user is responsible for the loading and unloading of the autoclave.
- A backup autoclave is located in the adjacent Accelerator building in cases when the primary autoclave is not in use.
- Autoclave settings: 121°C, (holding time 20mins). Autoclaves will be validated by annual (at least) thermocouple mapping and each run will be monitored by continuous chart or digital recording of the temperature / time profile.
- Waste will be removed from site and incinerated by Grundon CWI, Clinical waste incinerator, Lakeside road, Colnbrook, Slough, SL3 0EG (who are licensed to handle clinical waste).

Liquid Waste disinfection and disposal
- Liquid will be collected in an autoclavable screw top plastic container.
- The container will be labelled with the date and company name. The liquid waste will be chemically disinfected by adding to 1:20 diluted Chemgene HLD4L for 1 hour before discharging via the drains with excess water in the lab sink within the TC suite. (see https://www.starlabgroup.com/Documents/eng/339784.pdf). The containers are reusable and should be rinsed with excess water and left to dry on the sink within the TC suite. Labelling will be removed at point of waste disposal.

Waste disposal routes
- All solid and liquid waste will be decontaminated/disposed of by the user at the end of every TC session. Liquid waste will be disinfected as described above.
- Solid waste will be autoclaved before final disposal by incineration.
- Waste will be removed from site and incinerated by Grundon CWI, Clinical waste incinerator, Lakeside road, Colnbrook, Slough, SL3 0EG (who are licensed to handle clinical waste).

Inactivation Controls
1. Autoclaving is a validated method and provides 100% cell kill.
2. All solid waste will be double bagged at the end of each session, prior to autoclaving.
3. All liquid waste will be decontaminated/disposed of by the user at the end of every TC session.
4. Surfaces will be sprayed 1% Trigene/1:20 Chemgene HLD4L followed by 70% Ethanol after use.

**For activities involving GMMs, describe the waste management measures which will apply to the activity**

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment
This project has now been approved by Skylark GMSC as a Class 1 project subject to the following amendments:
- Clarification on downstream analysis;
- Source of iPSCs and continuous cell lines;
- Statement on health hazard of transient gene expression;
- Clarification on loading and removal of waste in the autoclave;
GM Centre Number: 3664

02/03/2022
Liquid GM class 1 waste is treated with 1% virkon for a minimum of 30 minutes before disposal to the drains as per manufacturer's instructions. Virkon is known to be an effective against viruses, bacteria and mycoplasma under these conditions (manufacturer's data) in the case of any infection that has contaminated the cell culture. Cultures are mycoplasma tested regularly. All solid waste (contaminated plastics, gloves etc) that has been in contact with GM class 1 material is either submerged in 1% Virkon for at least 30 minutes, or autoclaved at 121 degrees for a minimum holding time of 15 minutes before final disposal into yellow sacs as biohazard waste which is taken for incineration off-site by a licenced waste carrier. All waste is double contained. This should give a 100% kill, as established by Collins, CH (1993), Laboratory Acquired Infections, 3rd edition. Autoclaves undergo annual service and calibration and inspections. Small volume spillages will be cleaned up using 1% virkon. Due to the nature of the work there is no likelihood of large volume spillages. Benches are cleaned after use with 70% denatured ethanol or isopropyl alcohol.

Solid GM waste will be inactivated via autoclave (136°C for 4 minutes, 100% kill) prior to disposal via waste disposal contractor. The autoclaves are tested and calibrated annually and shown to hold temperature during the runs.

Liquid waste will be chemically inactivated using 1-5% Virkon for 60 minutes (or other approved disinfectand according to manufacturer's instructions).

The contingency procedure (for example in the event of autoclave malfunction) is the removal of biohazard waste for external incineration.

This work will be carried out within the Physics of Medicine building, Department of Physics, University of Cambridge. As such, the Department is responsible for waste management, the steps outlined above are the same as departmental requirements.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

We have received guidance from a health and safety consultant in the preparation of relevant risk assessment documentation and procedures. The risk assessment has been approved by an internal biological safety committee. One item of feedback from the committee was that the autoclave run time should be clarified to be four minutes, rather than forty as was originally stated. The safety committee comprises the biological safety officer, scientific director and chief operating officer of the company and which meets on a bimonthly basis.

The biological safety officer is an experienced biological scientist with >20 years experience working in and being responsible for risk assessment within CL1 and CL2 laboratories. The BSO will be attending an IOSH-approved programme in biological safety, management and practice.

Bacteriology  Parasitology  Transgenic  Microbiology
Birds  Research
All potentially contaminated GMM waste material (needles, syringes, wipes/swabs, PPE) and waste vaccine product will be placed into suitable clinical waste containers for collection by our GMO accredited/licenced clinical waste disposal contractor. In the unlikely event of a small spill, this will be absorbed onto an absorbent pad and disposed of as above. The area of the spill will then be cleaned using either sodium hypochlorite or Virkon™ disinfecant at the appropriate concentration as set out in the relevant SOP and risk assessment. Surfaces will then be cleaned using standard cleaning procedures.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Please enter comments of the GM safety committee on the risk assessment

I am satisfied that risk class 1 is appropriate for this work and that the control measures set out in the risk assessment should ensure that exposure of persons and the environment is minimized so far as is reasonably practicable consistent with the Principles of Good Microbiological Practice and Good Occupational Safety and Health.

### Premises Conditions

**Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities**

- Yes

**Give brief details of the genetic modification safety committee**

Advice was sought from the Health and Safety and QA manager, Babraham Institute, Babraham Research Campus. Somaserve GMO committee is composed of non-technical staff, and experienced scientific staff including members of the senior management team. The Health and Safety manager, provides both administrative and management support to the committee.

For class 1 contained use involving the propagation and transfection (with plasmid DNA or RNA) of mammalian cells; liquid waste from mammalian cell culture will be treated with Chemgene high level biodegradable, non-corrosive surface detergent, to a final concentration of 10% for a minimum of 10 minutes, as per manufacturers recommendations. Liquid waste will then be disposed of into the waste water system. Tissue culture flasks will be decontaminated with 10% solution of Chemgene detergent, as recommended by the manufacturer. Chemgene high level laboratory surface disinfectant combines enhanced active ingredient molecules with micelle cleaning technology to provide swift penetration of the cell walls to ensure rapid cell death. 'Treated, decontaminated' plastic waste will be rinsed with tap water and placed in waste bins reserved for 'treated decontaminated' plastic waste, and will be processed as recycled plastic. This procedure is applicable to large tissue culture flasks and is in line with current policies on plastic recycling and clinical waste reduction measures. Contaminated sharps will be placed in 'sharps bins', which are clearly labeled and disposed of according to Somaserve (POL003) and site waste handling policies (SOP BIO3). Benches, Microbiological Safety Cabinets (MSC) and other surfaces will be cleaned with 1% Chemgene solution and if required, 70% ethanol/water mix. Contaminated plastic consumables, for example serological pipettes and disposable tips, not suitable for recycling will be placed in autoclave bags and transferred to yellow 60L, leak proof eurobins, designated for 'clinical waste'. Bins are clearly labeled with biohazard symbols (UN3245 label), location and company name. Sealed yellow bins are surface decontaminated with 1% Chemgene detergent prior to removal from the containment facility for off-site incineration, according to Somaserve (POL003) and site waste handling policies (SOP B1O3). Autoclaves are not available for disposal of clinical waste on the Babraham Research Campus. A derogation from full containment has been granted to Babraham Research Campus. All clinical waste is incinerated in an off site facility. Off site incinerated site: Novus Environmental - Specialist Waste Management Experts (novus-environmental.co.uk)

Purposes of the contained use

Routine culture and cell banking of continuous mammalian cell lines (human and mouse), which have been transformed with known oncogenic sequences. Preparation and culture of primary murine glial cells from tissue and short term culture. Primary cells have an increased risk of carrying endogenous pathogens. Mice are obtained from 'pathogen free' colonies.

Cells will be transfected with plasmid DNA, here described as the cargo, in order to evaluate the expression of selected genes in vitro. Cells will be transfected using a novel technology, Polynaut (https://somaserve.com/polynaut-technology), vesicles, prepared from biodegradable or stable polymers. Polynaut will be evaluated alongside more traditional transfection protocols eg Lipofectamine and Electroporation.

Recipient or parental organism

GMO Cell Lines: Human endothelial kidney (HEK293T) cells, although a frequently used laboratory cell line are derived from HEK293 cells and result from sequential transformation events with viral genetic material: human adenovirus (Ad5) DNA and SV40 virus large T antigen. This modification allows continuous growth in culture and plasmids carrying the SV40 virus origin of replication to replicate to high copy in the transfected cell. BV-2 is a murine microglial cell line obtained from the C57/BL6 mouse strain. The BV2 cells are transformed by vraf/v-myc. BV2 express nuclear v-myc and the cytoplasmic v-raf oncogene products as well as the env gp70 antigen.
(J2 retrovirus) at the surface level. BV2 microglia cell line retains microglia morphological and functional characteristics. Cell lines transformed with known oncogenic sequences carry increased hazard of causing harm. Primary murine glial cells. Primary cell lines carry additional hazards, primary cell lines are more likely to carry adventitious agents, mycoplasma, and virus pathogens. Primary cells will be sourced from 'pathogen free' animals from established colonies.

### Host/vector system

Cell lines and primary cells will be transfected with 'reporter plasmids' pcDNA3.1 NL which carries the nano luciferase gene, amp and neo resistance markers and CMV promoter. The plasmid is non-mobilisable.

R-pre-GFP which carries the green fluorescent protein, kan and neo resistance markers and CMV promoter. The plasmid is non-mobilisable.

### Origin & function

The reporter plasmids have been prepared in an Ecoli host system, but it is not intended that this document includes the preparation of the reporter plasmids. Reporter plasmids are sourced from commercial/contractual suppliers.

- GFP reporter protein is from the species Aequorea victoria
- Nano luciferase (nanoLuc) reporter protein is from the species Oplophorus gracilirostris.

The GFP protein has been modified to locate to the cell surface. No additional hazard is anticipated with this modification.

The reporter plasmid will allow the efficiency of 'transfection' to be measured. Luciferase expression in transfected cells will be measured using the "luminol" assay. GFP expression will be measured by microscopy and western blot.

### Evaluation of foreseeable effects

Expression of the inserted reporter genes will be transient and therefore limited. It is not anticipated that expression of the GFP or nanoLuc protein will modify the tropism of the cell or change/increase the underlying hazard of working with a transformed cell line.

The GMO cell line requires specialised growth media and can not survive out side the laboratory environment.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

- **For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**
  - Class 2 waste is disposed of as described in policy documents Somaserve POL003 and BRC SOP BIO3. Briefly, class 2 waste (solid) is placed in EURO bins which are sealed with a red lid and surface cleaned and incinerated off site. Off site incineration is managed by on site contractors, Babraham Research Campus. Autoclaves are not available for disposal of clinical waste on the Babraham Research Campus. A derogation from full containment has been granted to Babraham Research Campus. All clinical waste is incinerated in an off site facility. Off site incinerated site: Novus Environmental - Specialist Waste Management Experts (novus-environmental.co.uk) GMGM898

- **Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**
  - For class 2 contained use involving the propagation and transfection (with plasmid DNA or RNA) of BSL2 mammalian cells; liquid waste from mammalian cell culture will be treated with Chemgene high level biodegradable, non-corrosive surface detergent, to a final concentration of 10% for a minimum of 10 minutes, as per manufacturers
recommendations. Liquid waste will then be disposed of into the waste water system. Chemgene high level laboratory surface disinfectant combines enhanced active ingredient molecules with micelle cleaning technology to provide swift penetration of the cell walls to ensure rapid cell death. Chemgene detergent is biodegradable. Tissue culture plastics (solid waste) and other contaminated plastic waste will be placed directly in yellow EURO bins and sealed with a red lid and designated as class 2 'clinical waste'. Contaminated plastic consumables, (solid waste) for example serological pipettes and disposable tips, not suitable for recycling will be placed in autoclave bags and transferred to yellow 60L, leak proof EURO bins, and sealed with a red lid, and designated as 'class 2 clinical waste'. Bins are clearly labelled with biohazard symbols (UN3245 label), location and company name. Sealed yellow EURO bins are surface decontaminated with 1% Chemgene detergent prior to removal from the containment facility for offsite incineration, according to Somaserve (POL003) and site waste handling policies (SOP B1O3). Large tissue culture vessels, may be treated with 10% chemgene solution. 'Treated', decontaminated plastic waste will be rinsed with tap water and placed in waste bins reserved for 'treated decontaminated' plastic waste, and will be processed as recycled plastic. This procedure is applicable to large tissue culture flasks and is in line with current policies on plastic recycling and clinical waste reduction measures. Contaminated sharps will be placed in leak proof 'sharps bins', which are clearly labelled and disposed of according to Somaserve (POL003) and site waste handling policies (SOP BIO3). Sharps bins are incinerated at the offsite facility, Novus Environmental. Benches, Microbiological Safety Cabinets (MSC) and other surfaces will be cleaned with 1% Chemgene solution and if required, 70% ethanol/water mix.

### Purposes of the contained use

Vectors and plasmid DNA generated will be used to characterise novel chromatography adsorbents for vector purification. To assess the purification of vectors for use in gene therapy.

### Recipient or parental organism

Lentivirus is a retrovirus and may be infective:

[https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5152689](https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5152689)

AAV used will be non competent and therefore will not be infective.

The E. coli host will be E. coli K12 derivatives - DH5 alpha, ER2738 (F+) for phage display and BL21-Gold (DE3) for subcloning and protein expression (F-).

### Host/vector system

Mammalian cell lines will include a number of well characterised (immortalised) cell lines of human or murine origin. Transgenes/ reporter genes will be expressed in HT 1080, for example, and limited to GFP/ Luciferase for infectivity testing purposes to limit possibility of harm.

Mammalian cell lines will include a number of well characterised (immortalised) cell lines of human or murine origin. Transgenes/ reporter genes will be expressed in HT 1080, for example, and limited to GFP/ Luciferase for infectivity testing purposes to limit possibility of harm.

### Origin & function

Cell lines will be purchased from commercial vendors.

### Evaluation of foreseeable effects

The recombinant viral vectors are disabled vectors. They have had regulatory and accessory genes deleted, ensuring that viral particles produced in packaging cell lines
are replication incompetent. As a result, whilst they pose an infection risk they are unable to initiate further rounds of replication/infection cycles. The probability of seroconversion is minimal.

Whilst the VSV-G envelope extends the cellular tropism and confers greater stability and environmental survivability, it is thought there is NO significant increase in the likelihood of transfection via the airborne route of exposure. Control measures utilised are appropriate to guard against the associated residual risks.

The target genes do not encode viral specific protein, nor do they interfere with known activities of the virus and so are unlikely to have any effect upon the basic nature of the virus.

Whilst the VSV-G envelope confers greater stability and environmental survivability, control measures employed will minimise risks to the environment. These control measures include - (1) rendering all solid or liquid waste inactive within the building (either by autoclaving or use of Virkon), (2) work will be carried out in Containment level 2 laboratories, (3) work will be conducted within Class 2 microbiological safety cabinets, (4) routine disinfection of work surfaces and (5) all staff are suitably trained in GM work and employing the necessary risk control measures.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

NA

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

n/a

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

**Solid waste (i.e. gloves, plastic consumables, tissue) -**

Will be collected in labelled autoclavable biohazard bags in leak proof containers.
Waste will be autoclaved at 121°C for an appropriate time then placed into heavy duty biohazard bags and sealed.
Waste will then be placed into a locked incineration waste bin to be collected by an approved waste management company (i.e. Grundons) and incinerated accordingly.

**Solid waste (i.e. sharps) -**

Will be collected in dedicated autoclavable approved sharps containers.
Waste will be autoclaved at 121°C for an appropriate time then sealed and placed into heavy duty biohazard bags and sealed.
Waste will then be placed into a locked incineration waste bin to be collected by an approved waste management company (i.e. Grundons) and incinerated accordingly.

**Liquid waste -**

Will be treated via a suitable chemiclal process (i.e. 1% Virkon for a minimum of 15 minutes) prior to disposal down the sink; flushed with plenty of water.
Spillages will be contained and treated via a suitable chemical process (i.e. ChemGene).

Purposes of the contained use

As a result of intellectual property implications, the identity of the vector and the inserts will need to remain confidential. The wild-type agent from which the replication-deficient viral vectors are derived is classed as ADCP Group 2, with low propensity for mutation, recombination or integration. The natural route of infection for the wild-type replicating agent is via the oral, mucosal and inhalation route. The wild-type agent is attenuated by removal of key viral replication genes and can only replicate in cell lines that express the complementary viral genes. It is therefore not capable of causing an infection in humans or animals, although it will transduce human and animal cells (i.e. the virus will enter a cell and express the insert, but no infectious viral particles can be produced). There are no reports of shedding of the constructs into the environment upon in vivo administration and it has been reported to be deactivated by chlorinated drinking water.

Plasmids containing the truncated viral genome (destination vectors) will be recombined in vitro with entry vectors containing the genetic sequence of interest to generate plasmids containing the viral genome and the genetic sequence of interest. These will be transfected into cell lines expressing the complementary viral genes to produce viral particles that also express the recombinant protein of interest. These recombinant, replication-deficient viruses will be tested in vitro and in vivo in appropriate animal facilities.

Recipient or parental organism

Standard packaging cell lines (eg PerC6 or 293) from commercial sources. These are recombinant human cells with part of the virus genome integrated, so that the missing viral proteins are expressed.

Host/vector system

Destination vectors:
- p-Dest
- plasmid with recombinant replication deficient viral genome (See Appendix 1a for p-Dest vector map)

Entry vectors:
- p-Entry
- A plasmid with appropriate promoter, multiple cloning site to insert immunogen sequence of interest and polyA signal sequence (See Appendix 1b for pEntry vector map)

Origin & function

Transcription in the recipient cell line expressing the complementary viral proteins allow formation of infectious recombinant viral particles. These can be purified for use in other experiments. The recombinant virus particle lacks key viral genes, so that replication is only possible in the recipient cell line. None of the products of the introduced genetic sequence will increase the required containment level above BSL2.

The generated viral particles will transduce animal cells and express the recombinant genetic material. If injected into animals, an immune response will be generated against the recombinant genetic sequence. However no further infectious particles can be formed.

Evaluation of foreseeable effects

Evaluation of the foreseeable effects of

i) the recipient micro-organism: No hazard identified from recipient human cells

ii) the inserted (donated) genetic material: The inserted genetic material will be typically manufactured as a synthetic sequence; these will consist of DNA sequences derived from human genes or genes from other mammalian or micro-organisms. There is no risk associated with the inserted donor source. Likewise, the products of these sequences would not be toxic or oncogenic to animals or humans.
iii) the vector: The recombinant viral genome can only form infectious particles in the recipient cells, which contain the missing viral genes, not in other human or animal cells, and cannot therefore cause a disseminated infection or disease.

iv) the resulting genetically modified micro-organism: The recombinant replication deficient virus would contain the inserted gene. Expression of the genetic sequence is driven by the CMV promoter. This does not generate additional hazards.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

1. Used consumables (plasticware eg. Pipettes, flasks, tubes, tips)
   Autoclave using make safe cycle as specified in BS 2646 Prt 3, 1993 (134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the black bags (for incineration) waste route following autoclaving.

2. Culture fluids (tissue culture medium, bacterial growth medium, washing etc) will be inactivated with virkon solution (Virkon concentration 2% W/V) for at least 60 mins and then discharged to drains.

3. Agar plates are autoclaved using make safe cycle as specified in BS 2646 Prt 3, 1993 (134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the black bags (for incineration) waste route following autoclaving.

4. Spillage: In the event of a spill of culture fluid, virkon granules should be added to the spill. Mop up using tissue and autoclave all contaminated waste.

Degree of kill:
   Autoclaving, effectively 100% (annual validation)
   Incineration, effectively 100% (licensed incinerator)
   Virkon disinfection, 99.99% kill. Virkon has been tested by independent laboratories and been proven to be effective against 58 viruses including the virus family of the vector.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
Please note that as a result of the comments of the committee below we have modified the containment level to BSL2.

Happy with the revisions

While it is stated that the agent is class 2, the form is still listed as class 1 and this line "None of the products of the introduced genetic sequence will increase the required containment level above BSL1" reads as though the work will be performed at BSL1. My understanding is that if an agent is class 2 then it needs to be handled under BSL2 conditions. Additionally, human cells lines like 293 cells are also required to be handled/manipulated under BSL2 conditions. Hope this makes sense.

Thanks for this. It seems a little bit strange they are reluctant to name their type of virus (particularly when they say they are using 293 and PerC6 cell to package, which implies it's an adenovirus; and the genome size in the plasmid supports that). Nevertheless the risk assessment appears reasonable to me - except the university used to have a guideline that 293 and PerC6 cells (because they harbour a known oncogene) have to be handled at category 2.

Looks good to me except the virus name and the usual route of infection for the virus used (inhalation, oral, skin contact) is not described. This is useful to know to show safety methods in place are sufficient to prevent exposure or clean up after an incident. Though the risk assessment does clearly show even if someone was exposed its highly likely to be extremely harmless.

The rest of the members had no comments.

Y

Give brief details of the genetic modification safety committee

- UK SDW BioSafety Officer / UK SDW Deputy BioSafety Officer / UK SDW HSE Manager / UK SDW Director of Technology / US SDI Chief Scientist, BioTechnology / US SDI Senior Microbiologist
- The committee comprises the following skills:
  - 4 members of the committee hold degrees in biological sciences
  - 1 is a professional safety manager
  - 1 is a senior manager with experience in managing safety critical systems and materials.
- All have multiple years experience in their respective fields of work.
- Initial review held, quarterly meetings scheduled

Liquid wastes will be treated with bleach (1% sodium hypochlorite) and left for 24 hours prior to disposal via laboratory sinks into waste water management systems. Used pipette tips and vessels such as bottles and beakers will be soaked for 24 hours in 1% hypochlorite prior to rinsing in water: i) The single use items, such as disposable pipette tips, will be placed in sharpsafe canisters and sealed prior to disposal as hazardous waste for incineration. ii) The re-usable items, such as glass bottles and beakers, will, after treatment with 1% sodium hypochlorite for 24 hours, be placed in a laboratory dish washer for cleaning prior to re-use. Spills will be sprayed with 1% hypochlorite and wiped up with tissues which will then be placed in an autoclave bag for subsequent autoclaving prior to disposal as hazardous waste for incineration. Other solid wastes, such as tissues used to wipe up spills, will be autoclaved prior to disposal as hazardous waste for incineration.

Please enter comments of the GM safety committee on the risk assessment

The GM Committee reviewed the CU1 form and risk assessment and the cells used, E. coli K12 and immortalised lymphocytes, are both confirmed low risk Containment Level 1 materials and the inserted sequences for aequorin, coelenterazine and antibodies are Class 1 GM modifications with the final modified material presenting negligible risk to humans and the environment. Further the control measures and decontamination methods used are suitable for the selected materials.

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment:

All bioagents are Biosafety Level 1 and the GMMs produced lead to modifications that do not lead to any functional advantages of biological significance.

Transfection of protein/DNA or RNA encoding Cas9, Cas9 nickases or our in-house genomic editing tool with BSL 1 agents, that target endogenous genes producing either knock in or knock out GMMs. Genes targeted do not lead to any functional advantages of biological significance.

Inserts are not expected to have harmful physiological or pharmacological properties or to affect pathogenicity of cloning host or normal human defence mechanisms.

The GMMs pose no threat to humans or the environment and are unable to survive outside of a laboratory environment.

All GMMs will be inactivated by autoclave before disposal and hand over to waste management at Alderely Park.

Risk Assessments are attached for more details.
Our studies are carried out by transfecting RNP (Ribonucleoprotein)/RNA or plasmid DNA insertions that target and edit a selected endogenous gene producing either a tag or knock in/out GMM. No known loss or gain of function is expected to cause an effect of any biological significance. Recombinant DNA methods are used to analyse gene characteristics, for example by subcloning and sequencing DNA obtained from screening libraries or by PCR. Recombinant methods are also used to make constructs to express normal or mutant proteins in tissue culture.

Recipient or parental organism
Gibco® Episomal Human iPSC line
& Human iPS Cell Line
Although the cell lines are not known to contain any agents capable of harm to humans the possibility of a contaminant, adventitious virus can rarely be excluded. Therefore, these are recommended as a BioSafety Level 2 agent

Host/vector system
For DNA inserts delivery is via standard commerical-based plasmid expression vectors. DNA inserts from vectors are integrated through transient expression.

Origin & function
The insertion is either the protein/plasmid DNA/mRNA inserts that encode for proteins that are known (Cas9 and Cas9 nickases) or supposed (our in-house tool) to function as a genomic editing tool. These include enzymes that target and modify a selected endogenous gene. Either short nucleic acid/amino acid or dsDNA templates are introduced to aid the restoration or disruption of the targeted gene. Inserts are not expected to have harmful physiological or pharmacological properties or to affect pathogenicity of cloning host or normal human defence mechanisms.

Evaluation of foreseeable effects
The delivery of the DNA inserts produce either knock in or knock out of a pre-selected endogenous gene. This will not lead to any advantageous gain in function compared to the orginal host cells. The resulting GMMs are unable to survive beyond the laboratory environment and after appropriate heat inactivation or disinfection pose no risk to the environment. Therefore they remain a BioSafety Level 2 agent and will be contained as such.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
GMO includes Biosafety level 2 agents (iPSC) cell lines only. All cell lines are fixed, all work to be carried out using a Class II Biosafety cabinet. This level of containment is sufficient for these cells. Cells once transfected are grown for 1-2 days and then sacrificed and the gDNA extracted using general molecular biology techniques.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Specified disinfection procedures in place, inactivation of liquid waste by autoclave or 1% vikron, solid waste disposal in clear biological waste bags for autoclave by waste management at Alderley Park.

Standard molecular biology techniques. Sonicator or chemical lysis used for breaking cells and centrifuge for pelleting cells. Maximum culture volumes - cell culture/plasmid preps - less than 0.1 L

Standard molecular biology analysis and processing such as PCR or DNA sequencing.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

iPSC cell lines are designated Biosafety Level 2. Mostly to protect both user and cells. Therefore Level 2 biosafety hood required to handle the cell line. Genetic modifications to be carried out on the cell lines produce knock in/knock out GMMs with no advantageous functionality of biological significance.

Endogenous gene target have been specifically selected (gene PD1) to be deleted or restored resulting in a GMM that are not harmful to the environment or humans. These GMMs are unable to survive outside of the laboratory environment.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Standard GMO clinical waste disposal will apply. As per the R&I COP, any material that has been in contact with the product will be disposed/packaged by the team undertaking the trial, in yellow Econix bins (for soft waste) and/or yellow sharps bins (for sharps waste) as appropriate.

The disposal of waste following administration will follow the waste stream for non-infectious waste. A UN 3245 label and a GMO label should be placed on these bins. Two copies of the GMO Waste Disposal Record Sheet will be maintained by the research team with a copy given to waste disposal team so tracking to external disposal/inactivation is possible.

Level 1 waste stream will be adopted at pharmacy during handling of the IMP.

GM waste will not be inactivated on site. They will be incinerated offsite by an external contractor.
