The GMM's should be no more hazardous than the parent strains from which they were derived. Any excess risk is related to (a) the introduction of additional antimicrobial resistance genes that may impede the efficacy of antimicrobials if required, and (b) the inadvertent but rare genetic modification that results in unforeseen increase in virulence, for example in a regulatory gene. Hazards from antimicrobial resistance are minimised by use of antimicrobial markers that are not in clinical use. Mutations in regulatory genes can occur spontaneously in nature, and are selected for during invasive infection; as such the risk of such mutations arising in nature is possibly greater than the risk that they occur in the laboratory.

All strains are sensitive to penicillin (and its derivatives)

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration/dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) –autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), or inactivate by chemical means (following manufacturers guidelines), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration/dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration.

Animal bedding – EITHER autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), dispose via the industrial (black bag) waste stream for landfill OR dispose via clinical waste stream for incineration.

Animal carcasses - dispose via clinical waste stream for incineration.
Degree of kill:
- Autoclaving, effectively 100% kill (annual validation)
- Incineration, effectively 100% kill (licensed incinerator)
- Chemical, effectively 100% kill (following manufacturers guidelines)

## Project Additional Information

**Purposes of the contained use**

This project aims to produce replication incompetent fluorescent and non-fluorescent HIV-1 particles. These particles will be used for the superresolution microscopy studies of the distribution and dynamics of HIV proteins in the context of the free virus, initial virus-cell interactions during virus attachment and fusion as well as at the plasma membrane of HIV producing transfected cells.

**Recipient or parental organism**

- Mammalian cell line HEK293 is used for the production of the virus
- Mammalian cells to study the interaction of the virus

**Host/vector system**

- pCHIV (and derivatives there of) encode replication incompetent viral particle when placed in a permissive cell type such as HEK293 cells.

**Origin & function**

- pCHIV is based on the Human Immunodeficiency virus which is assiged to ACDP hazard group 3. The full DNA sequence of HIV-1 was placed into a plasmid vector pcDNA3.1 to create HIV-1NL4-3.

- pCHIV plasmid and all its derivatives encode for replication incompetent particles that express all HIV-1NL4-3 proteins but lacks Nef open reading frame as well as viral long terminal repeat regions (LTRs). These sequences are indispensable for initiation of reverse transcription as well as integration of resulting cDNA into the host genome. Nef is an important HIV accessory protein that is one of the first to be produced in HIV infected cells. It performs many numerous regulatory functions that are dispensable in vitro, but are essential for efficient virus spread and disease progression in vivo.

- A version pCHIV will also be used that lacks the env gene of HIV. This will subsequently be cotransfected with a second plasmid containing a different env gene, such as an env with a truncated C-terminal tail.

- Versions will also be created that have fluorescent marker genes, such as GFP or Cherry, added to Vpr

**Evaluation of foreseeable effects**

- Viral particles will be produced which are replication incompetent due to the lack of LTR genes and a functional Nef, they will however still be able to infect mammalian cells.

- To ensure that the plasmid preparations have not regained the LTR genes or a functional Nef (highly unlikely), the preparations will be tested by restriction digest and the results compared with the plasmid map to confirm there are no significant sequence changes.

- The likelihood of the virus gaining functional genes. This is unlikely as each viral preparation is created in a transient manner.

- As the LTR genes are required for integration it is unlikely that these viral particles will be able to integrate into the host genome and therefore insertional disruption of a
tumour suppressor gene is unlikely.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

### Project Additional Information

#### Purposes of the contained use

Use of replication defective lentiviral vectors to target and disrupt the interactions of the oncogenic proteins in mammalian cells

#### Recipient or parental organism

E. coli - K12 derivatives
mammalian cell lines
Primary mammalian cells
Packaging cell lines, such as HEK293

#### Host/vector system

Standard replication defective retro and lentiviral systems, such as MLV-ecotropic pCAG-Eco, pCNV-d8.2, pBabe, pMiG, pGIF/pFUW

Origin & function
Inserts code for engineered Variable Heavy (VH antibody domains or peptide aptamers, which are designed to be specific for various disease-causing proteins. They have no known oncogenic or other harmful effects, with a safe history of use. Other genes which may be implicated in leukaemias and other blood based diseases. Viruses may also encoding cas9 & gRNA for gene editing with the objective to knock in or knock out genes to assess their roles in leukaemias and other blood based diseases, such as CRISPR technology. Woodchuck hepatitis regulatory element for enhanced expression is present in the lentiviral vectors. Also standard marker/reporter genes such as lac Z, GFP, and localisation sequences etc. may be included and that also have a safe history of use. Standard antibiotic resistance genes, such as Kanamycin, Ampicillin etc.

Evaluation of foreseeable effects

Retrovirus and lentivirus particles are generated to transduce the mammalian cells. They are replication deficient as packaging elements necessary for their propagation are supplied by a packaging cell line or as additional helper plasmids, which lack packaging signals. Therefore, the resulting virus particle does not contain the structural genes required to produce replication-competent virus post-transduction, minimising hazard. The lentiviral vectors contain the Woodchuck hepatitis regulatory element (WPRE) for enhanced expression. This element may have oncogenic potential and as such work with these viruses is assigned to class 2.

Standard reporter genes and antibiotic resistance genes have a history of safe use and are not expected to increase the risk.

Inserts code for engineered variable heavy chain antibody domains or peptide aptamers which are designed to be specific for various disease causing proteins. They have no known oncogenic or other harmful effects.

Gene editing technologies, such as CRISPR allow targeted gene editing. They require sequence specific homology to allow specific point mutations which are user defined effectively causing a frameshift insertion/mutation. It is not expected that this mutation would be any more hazardous than that posed by insertional mutagenesis of the virus itself or the presence of the WPRE gene.

Use of Lentivirus to evaluate transgenes in cell types with poor transfection efficiency (e.g. cardiomyocytes)

Non-GMM Consent Granted

Project notified under transitional arrangements N

Withdrawn N

Tick if notifying a connected programme of work N
### Project Additional Information

#### Purposes of the contained use
Lentivirus will be used to transfect mammalian cells, such as cardiomyocytes or other excitable cells with genes linked to cardiovascular disease and/or genes useful for visualisation of cellular signals.

#### Recipient or parental organism
- **E. coli K12 derivatives**
- Primary and cell lines of mammalian cells.
- Packaging cell line, such as HEK293 cells.

#### Host/vector system
Standard vectors for the generation of lenti and retroviral particles such that the necessary genes are split onto a number of plasmids which have limited homology to prevent minimise recombination.

#### Origin & function
Genes of interest that will be useful in understanding how cardiomyocytes change their behaviour in response to disease causing mutation.

- Standard reporter genes, such as GFP etc
- Altersations to standard reporter genes which allow them to respond to second messengers, such as Ca++, ATP, cAMP and membrane potential etc.
- Light sensitive channels, such as Channel rhodopsin, and Halorhodopsin and derivatives there of.
- Standard antibiotic resistance genes, such as hygromycin and neomycin
- Genetic sequences that allow controlled gene expression, such as Tet etc
- Sequences that allow site specific recombination, such as Cre etc

#### Evaluation of foreseeable effects
The viral particles are infectious but cannot replicate. Therefore they are not transmissible from one individual to another. However, viral particles have the potential to integrate into the host genome which may cause intentional mutagenesis. In addition, viral particles contain WPRE which may have the potential to be oncogenic.
Inserts are genes thought to be involved in cardiovascular disease and may be either over expressed or knocked down. In addition genes that interact with these proteins may be altered.

Expression of reporter genes have a history of safe use and there is no indication that the alterations, such as calcium signalling sequence would affect this.

Genes of interest are not expected to be oncogenic and are unlikely to lead to a clinical significant event because:-
1) many of the genes we work with are only expressed in the heart, and cause disease by affecting the way other components of the heart cell behave. The same machinery does not exist in other cell types so the potential to adversely affect cell behaviour is diminished.
2) In the case of mutations in genes that cause multisystem disease (i.e. where targets are present in other tissues) skin and other epithelial defects are rarely associated with inherited cardiomyopathy or arrhythmia, even though all cells in the body are affected. Since it is impossible for the virus to infect more than all the cells in the body, it is unlikely that accidental exposure could lead to a more significant outcome than the natural history of the condition.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Appropriate containment and control measures have been assigned in accordance with the latest guidance issued by ACGM.
The focus of our research is the origin of the haemopoietic stem cells (HSCs) during mouse embryonic development Runx1 is absolutely required for HSCs generation. How Runx1 exerts its role in the onset of haemopoiesis is not known and is the focus of our studies.

Recipient or parental organism
E. coli K-12 and B derivatives - class 1
mammalian cell lines - class 1
HEK293 derived cells for packaging replication defective virus
### Host/vector system

Standard Replication defective recombinant Lentivirus and retrovirus which have the essential genes separated onto different plasmids. Some versions will be ecotropic and some will be amphotropic.

### Origin & function

Modulation of genes (overexpression or down regulate) or mutation using gene editing systems such as CRISPR and TALENS

- Runx1- regulated target genes (such as SPI1, Gfi1, Gfi1b)
- Genes encoding transcription factors directly or indirectly mediating Runx1 expression (such as Notch1, Hoxb4)
- Genes encoding Runx1-interacting proteins (such as Gata1, Cbfb)
- Other molecules such as cell cycle or gene expression regulators could be included

Woodchuck hepatitis virus post-transcription regulatory element (WPRE)

Standard antibiotic resistance genes

### Evaluation of foreseeable effects

Based on previous reports, expression of wild type and mutated Runx1, or other Runx genes, may affect the differentiation, maturation, and proliferation of mouse hematopoietic cells in vitro and in vivo. Expression of Runx1 target genes or upstream regulators (to be identified) may have an effect on in vitro and in vivo hematopoietic differentiation. In addition, we expect an alteration of the proliferation/differentiation balance or induction of apoptosis of the transduced cells and/or progeny.

Molecules identified as partners or targets or Rnx2, 2 and 3. These could involve other transcription factors, co-factors, chromatin remodelling factors, cell cycle regulators, apoptotic factors, structural proteins, members of the general transcription machinery and other regulators of gene expression. They are all expected to modify the proliferation/differentiation balance or induce apoptosis.

WPRE is a potential oncogene and as such could be hazardous in a viral system which integrates into the host genome.

CRISPR/TALENS allows for user defined genome editing (usually insertion or deletion) which results in a loss of function. Although, CRISPR/Cas vectors used are derived from the bacteria strains (S. pyogenes, S. thermophiles, T. denticola or N. meningitidis) they only contain small portions of the genome (similar to lentiviral vectors based on HIV) which has subsequently been codon optimised for expression in mammals. The genome sequences of many E. coli strains are not available so it is not known whether these strains contain intact Cas genes and/or CRISPR loci. However, introducing CRISPR vectors into these hosts is unlikely to cause any recombination due to the fact that all CRISPR and Cas-expressing genes within these vectors contain sequences that are codon-optimized for mammalian expression and thus do not have any sequence resemblance to their prokaryotic counterparts. The probability of DNA exchange between a vector and the host chromosomes can be further reduced (although not eliminated) by using a recA minus strain of E. coli, such as NEB Stable, DH5a and DH10b.

Standard antibiotic resistance genes and reporter genes have a history of safe use.

As a number of the genes have the potential to affect proliferation and differentiation their expression in lentiviral vectors which can integrate into the genome is potentially hazardous.

Primary cells and cell lines which have been infected with replication deficient lentiviral/retroviral particles are not expected to be hazardous after the particles have integrated into the genome and any residual particles removed by washing.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121°C-125°C, for a least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

### Project Additional Information

**Purposes of the contained use**

The creation of a replication defective lentivirus to study interferon induction both during viral infections and autoinflammatory diseases.

**Recipient or parental organism**

- E. coli - K12 or B derivatives Hazard Group 1
- Mammalian cells - standard cell lines and primary cells
- Producer cells - generally derived from HEK293 cells
- In vivo - direct inoculation of virus or of virus infected cells

**Host/vector system**

Use of full length HIV (pNK4-3 with a disrupted env gene (by the insertion of EGFP) on one plasmid (pNL4-3-deltaE-EGFP) and the env gene, such as VSV-G or THOV-G, on a second plasmid. Production of infectious but replication incompetent viruses occurs in producer cells, such as 293 cells.

Other similar systems may be used, such as pNL4-3.Luc. R-E- where the Luciferase gene has been inserted into the Nef gene and there are 2 frameshift mutations which render it Env- and Vpr-.

**Origin & function**
EGFP and Luciferase are standard reporter genes and have a history of safe use. Other standard reporter genes may also be used in similar vector systems.

The vector contains the genetic material for HIV-1 and as such produces virions which are infectious. The viral particles are replication defective due to either the deletion on the env gene or a frameshift mutation which inactivates the env gene. The addition of reporter genes is not expected to cause an increase in pathogenicity.

All these vectors are first generation there is the potential for recreation of a replication competent virus with either wild type env or the VSV-G or THOV-G envelope genes, however this is considered unlikely due to the following reasons.

Possibility for homologous recombination in E. coli:
- HIV-1 does not infect E. coli;
- all plasmid manipulations will be carried out in a laboratory where wt HIV-1 is not present;
- recombination deficient E. coli strains are used for all recombinant DNA procedures to minimize spontaneous losses of genetic information;
- plasmids with partial or full env genes are not used in the laboratory;
- there are no flanking homology regions between the VSV-G or THOV-G gene-containing plasmids and the lentivectors and homologous recombination is therefore impossible;
- and d) wt HIV-1 cannot infect 293T cells so all wt HIV-1 would be generated only from the cell(s) in which the recombination took place and therefore the amount of wt HIV-1 would be small.

Possibility for homologous recombination in target cells:
- a) wt HIV-1 would need to be present in the same target cells, but this is impossible as we are working in a Class 2 facility where HIV-1 is absent;
- b) we are not using unscreened human cells (such as cells from blood) that may contain HIV-1 if the donor of these cells is HIV-1 positive;
- c) VSV-G or THOV-G gene sequences are not present in infected target cells.

Possibility of homologous recombination in the mouse:
- a) HIV-1 does not infect mice;
- b) there is no HIV-1 present in Animal Facility, unless the personnel were infected with HIV-1, which would cause greater risk of HIV-1 infection itself than theoretical recombination;
- c) the lentivectors and wt HIV would have to infect the same cells within a given mouse for recombination to occur;
- d) wt HIV-1 cannot infect mouse cells so all wt HIV-1 would be generated only from the cell(s) in which the recombination took place and therefore the amount of wt HIV-1 would be small;
- e) VSV-G or THOV-G gene sequences are not present in infected target cells.

Possibility of homologous recombination in humans accidentally exposed to vectors:
- a) the vectors do not produce infectious progeny particles;
- b) if the wt HIV-1 were present in humans, it would cause the disease without the need for recombination;
- c) VSV-G or THOV-G gene sequences are not present in humans.

Possibility of cross-contamination of vectors with wt HIV-1:
Purified plasmid DNA will be transfected into 293T cells. Contaminating wt HIVV-1 does not infect 293T cells and thus would not be amplified. Theoretically, plasmid DNA might also be contaminated by plasmid carrying a molecular clone of wt HIV-1, but the likelihood is very small as such molecular clones are not used in the laboratory. Vector stocks will be grown exclusively in a LEVEL-2 laboratory, in a dedicated incubator, in which the risk of accidental exposure to HIV-1 is zero.

As the virus integrates into the host genome there is a potential risk should the virus integrate into a region containing a tumour suppressor gene.

Transmission and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
N/A

Use of self-inactivating lentiviral vectors for the study of degenerative diseases

The laboratory is interested in understanding the mechanisms underlying neurodegeneration in a wide range of diseases, such as Parkinson's Disease, Alzheimer's Disease, Friedrich's Ataxia, Amyotrophic Lateral Sclerosis and Familial Hypercholesterolaemia. The use of recombinant replication defective lentiviral particles is required due to their ability to infect quiescent cells.

Recipient or parental organism

- E. coli K12 and B derivatives - class 1
- Mammalian cell lines and primary cells - class 1
- Packaging cell lines such as HEK293 cells used for generating replication defective lentiviral particles

Host/vector system

Standard replication defective lentiviral vectors which have the essential genes separated onto different plasmids or stably expressed from the packaging cell line

Origin & function

- Reporter genes (e.g. GFP, Luciferase, B-galactosidase)
- Standard antibiotic resistance (e.g. Neomycin, Hygromycin, Puromycin and ampicillin)
- shRNAs, μRNAs.
- Genome editing tools (e.g. TALENs, Cas9-CRISPR).
- Tet repressor/activator systems.
- Neurotrophic/neuroprotective factors (e.g. BDNF, CNTF, GDNF and NGF).
Factors involved in neural reprogramming (e.g. SOX2, MASH1, GATA3),
- Neurodegenerative susceptibility genes (e.g. SNCA-1, GBA and MAPT).
- Susceptibility genes for familial hypercholesterolaemia (e.g. LDLR)
- Genes involved in the mechanisms of neurodegenerative (e.g. LC3, P62, TFEB, DRP1, DLP1)

Woodchuck post transcriptional regulatory element may be present in the replication defective lentiviral vectors

### Evaluation of foreseeable effects

Reporter genes and standard antibiotic resistance genes have a history of safe use and are not expected to increase the risk of the viral particles.

The protein products of the genes to be studied (over expressed, mutated or knocked down) are not expected to be toxic or oncogenic but some of the genes of interest may modulate immune function.

Initially, the RNAs, TALENs or Cas9-CRISPR systems to be used are not targeting known tumour suppressors. However, there is potential for off-target effects with, which could potentially have tumorigenic effects. This will be minimised by careful design with as little sequence homology as possible to off-target genes, including BLAST searches against genome databases. In the immediate future the experiments will target individual genes, it is possible however that genome-wide screening will be performed using shRNA technology with out iPS derived disease models. In this case the risk of the shRNAs will be greater, as shRNAs against all possible genes would be employed, including tumour suppressors.

Gene transfer is possible, significantly from the transfected producer cell lines, as the resulting Lentiviral/Retroviral vector will be able to infect a wide range of cells, including human cells, as the VSV-G or Rabies-G envelope enable amphotropic infection. However, dissemination in the environment is limited due to the viruses being replication defective.

Some concern has been raised with regards to the potential oncogenic activity of the post-transcriptional regulatory element from the woodchuck hepatitis virus (WPRE) which is present in mainly lentiviral vectors, including the lentiviral backbones that we will use here.

The main risks from in vivo work are associated with the method of viral delivery itself which usually involves localised injections and, therefore, the use of needles and sharps. However, with proper supervision and training of new personnel, ensuring the use of gloves, awareness of the needle position during injection, no re-shafting of needles and proper disposal directly into a sharps bin, the risk is considered to be low. Additionally, to minimise the generation of aerosols during the loading/unloading of the injecting device, viral suspensions will be prepared in dedicated Class 2 Microbiological Safety Cabinets. Once the gene is stably inserted into the target host the risk is minimal due to the replication defective nature of the virus and no additional containment is required compared to other genetically modified animals.

Project Ref 553/14.8

Date Ackn'd 13/06/2014
CU2 Project Title Vaccinia Viruses for cancer gene therapy, enhanced tumour delivery using mechanical
Class
CultureVolClass2 CultureVolumeClass3-4
Vaccinia virus has a natural tropism for tumourous cells and can accommodate large amounts of foreign DNA making them useful tools in the treatment of cancer and other diseases. They also elicit immune responses to the expressed antigens.

**Recipient or parental organism**

Vaccinia Virus, strains such as Copenhagen, Western Reserve, Wyeth

Modified vaccinia ankara

**Host/vector system**

Homologous recombination between shuttle plasmids and the viral genome

**Origin & function**

Reporter genes such as luciferase GFP etc.

Enzymes such as cytosine deaminase-phosphoribosyl transferease fusion enzyme which converts a prodrug to an active drug.

**Evaluation of foreseeable effects**

Humans are not the natural hosts for Vaccinia but injection into the skin leads to a brief and limited subcutaneous infection that stimulates an immune response. It was used world wide to eradicate smallpox and was generally well tolerated.

Inserts are placed into the Thymidine kinase gene resulting in disruption of the gene and reducing virulence in normal tissue. However, they have inherent tumour tropism thought to be due to the overexpression of cellular TK in cancer cells supplying the TK in trans.

Some strains also have ribonucleotide reductase deletions are also significantly attenuated with respect to the wild type as the gene catalyzes the formulation of deoxyribonucleotides from ribonucleotides. Deoxyribonucleotides are required for the synthesis of the vaccinia DNA genome.

Luciferase and other standard reporter genes have a history of safe use.
FUC1 converts a prodrug into an active metabolite and therefore cytotoxicity is dependent on the presence of the prodrug. Other prodrug/enzyme combinations may be used.

Ligand and retargeted and polymer coated viruses are expected to have reduced tropism and therefore less pathogenic to the wild type strains. Initially the tropism will be for cancer cells by the addition of ligands that target specific receptors on cancer cells. Other diseases may be looked at in the future.

**Purposes of the contained use**

Rhomboid proteases play a critical role in regulation of the EGF receptor signalling in the fruit fly Drosophila melanogaster. Notably, deregulated EGF receptor activity contributes to cancer in humans; however the role of Rhomboids in this process has not yet been investigated. Therefore, we propose to investigate the role played by mammalian rhomboid proteases and rhomboid-like proteins in human disease(s), including cancer using replication defective lentivirus.
Recipient or parental organism
E. coli K-12 and B derivatives - Class 1
mammalian cells - Class 1
Packaging cell lines, such as HEK293 cells, used for packaging replication defective lentiviral particles

Host/vector system
Standard replication defective lentiviral vectors which have the essential genes separated onto different plasmids or stably expressed from the packaging cell line.

Origin & function
Standard reporter genes, such as Neomycin, puromycin and kanamycin
shRNA or mir30-based shRNA-mirs
Silencing or overexpression of Rhomboid proteases, related proteins and their putative substrates. Silencing or overexpression of common housekeeping genes, such as GAPDH.
CRISPR or similar technology will be used to allow loss of function mutations at specific site within human and murine genomes.
WPRE may be present in some of the lentiviral vectors.

Evaluation of foreseeable effects
Rhomboids are intramembrane serine proteases that cleave membrane proteins within the bilayer and are involved in a wide range of biological processes. Mammalian rhomboid targets include thrombomodulin, ephrinB4 and EGF but Rhomboids are generally highly specific with a limited number of substrates.

iRhom molecules lack intramembrane protease activity but are required for activation of Tumour Necrosis Factor α Converting Enzyme (TACE) and thus secretion of TNFα and various EGFR ligands.

EGFR ligands, such as EGF, amphiregulin and HB-EGF will lead to activation of downstream signalling cascades such as the MAPK and JNK pathways leading to processes such as migration or proliferation. As such a precautionary approach will be taken.

The diversity of biological functions already known to depend on rhomboids is reflected in evidence that rhomboids play a role in a variety of diseases including cancer, parasite infection, Parkinsons disease and diabetes.

Standard fluorescent protein reporter genes, such as enhanced green fluorescent protein (EGFP), will be transduced into cells using lentiviral vectors, to provide positive controls with which to assess the efficiency of lentiviral transfer. Fluorescent proteins are a common investigative tool and no hazards are associated with their use.

The silencing of rhomboid and rhomboid related genes can be achieved using a Cas9 VRISPR-associated nucleae expressed under a EFS promoter which is guided to specific sites within the host genomes of human and mouse cells by a customizable stRNA (synthetic single-guide RNA), under a U6 promoter. DNA double strand breaks, catalysed by Cas9, create frame shift insertion/deletion (indel) mutations that result in a loss-of-function allele.

Some concern has been raised with regards to the potential oncogenic

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

02/03/2022
Project Additional Information

Purposes of the contained use

Viruses are intracellular parasites that rely on the cellular resources to complete their biological cycle. In the context of virus infection, RNA represents a key molecule because it can function as a messenger and, in some instances, also as genome. Thus, the interaction between host proteins and viral RNA represents a central theme in modern virology. This project will explore the dynamics of RNA-binding proteins in response to infection as well as the composition and plasticity of viral ribonucleoproteins throughout the infection.

Recipient or parental organism

A number of different viruses will be utilised during this project including both hazard group 2 and 3 viruses. Examples include:
- Hazard group 2
  - Encephalomyocarditis virus
  - Influenza virus
  - Vaccinia virus
  - Sindbis virus
- HIV replicons and single-round replication viruses
- EcoHIV which replicates in mice
- Replication defective lentiviral vectors (3rd or 411 generation)
Hazard group 3
human immunodeficiency virus

Host/vector system

- Standard E. coli K-12 or B derivative
- Standard plasmids
- Standard packaging cell lines
- Flp-in and Flp-oul expression system
- CRISPRiCas 9 cloning systems
- Standard mammalian cell lines including CD4 lymphocytes and monocytes
- Primary murine CD4 cells

Origin & function

- Standard reporter genes, such as eGFP, mCherry, luciferase and standard antibiotic resistance genes are not expected to alter the virulence of the viruses.
- MS2 loops or b-boxes - RNA elements which are recognised by specific RNA binding proteins
- Point mutations within the virus to assess viral interaction with host RNA
- Expression of individual viral genes in cell lines and over-expression/knockdown of host cellular genes has been deemed class 1 and this work is covered by a separate risk assessment. These cell lines will be used in combination with the viruses listed in this risk assessment and handled at a level according to the viral work.

Evaluation of foreseeable effects

- HIV replicons are based on standard HJV molecular clones (e.g. NL4-3), which lack the glycoproteins (env) as well as either of the accessory genes vpr or rev. These constructs can replicate efficiently within the cell but cannot give rise to infectious particles due to the lack of structural proteins which are essential for viral particle formation. Replicons are generated by transfecting constructs into cells which express the env and vpr (or rev) in trans. These viral particles will be handled at containment level 2 as they require 2 competent and independent recombination event to acquire full infectivity. Test for replication competent virus will be done by simple re-infection assays.
- In EcoHIV, the tropism determinant gp120 is replace by the MIV glycoprotein gp80 which directs HIV to its natural range of target cells but restricts the infection to rodents. Although this virus doesn't infect humans only one recombination step with wild type gp is required and as such will be handled at containment level 2 and never used along side wt env expressing cells.
- Encephalomyocarditis virus (ECMV) is a virus that can infect pigs, however the strain to be used has adapted to being grown in cultured cells and is thus attenuated for cultured cells. It will be handled at containment level 2.
- Sindbis virus is passed to humans via a bite from an infected mosquito and is designated hazard group 2 by ADCP. It will be handled at containment level 2.
- Influenza virus (FLU) is generally transmitted through aerosols and vaccinations are available and is designated to hazard group 2 by ADCP. It will be handled at containment level 2.
- Vaccinia Virus (W) is the active constituent of the vaccine used to eradicate smallpox and is assigned to hazard group 2 by ADCP. It will be handled at containment level 2.
- Replication defective lentiviral vectors will be used in some experiments. These will be based on 3rd or 4th generation vectors which have a number of safety feature but which may contain the WPRE fragment and as such may pose a minimal risk. They will be handled at containment level 2.
- Hazard group 2 viruses may be used for in vivo work. Infection with EcoHIV will be through intravenous injection (tail vein). In the case of EMCV, FIU and W the infection can be performed following intravenous or by intranasal
inoculation. HIV is a hazard group 3 virus which causes AIDS and as such work with this virus will require handling in a dedicated containment level 3 suite.

Most of the viruses will just be modified to contain a reporter gene which will allow the tracking of the virus and infective cells. In addition, MS2 loops or b-boxes can be inserted in the viral genome. These RNA elements are recognised by specific RNA-binding proteins (MS2 and lambda, respectively) that will fuse to a fluorescent reporter or to a purification tag to allow RNA localisation assays (fluorescent version) or RNA purification (using the tagged version. e.g MBP, GST, FLAG or His).

Single point mutations of RNA binding sites of host and viral factors will be utilised maintaining amino acid sequence in the glycoproteins but may alter amino acid sequences in accessory proteins.

The lentiviral vectors will be used to employ CRISPR technology and expression of siRNA but may also be used when required for expression of individual genes linked to this project within mammalian cells.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

### Project Additional Information
**Purposes of the contained use**

This programme of work will use amphotropic lentiviruses to help study the functions of cellular genes that affect the regulation of cellular stress, proliferation and survival, and that may be involved in the generation of phenotypic heterogeneity in cancer. The principal aim of this work is to create human cell lines that either enhance or attenuate an endogenous gene of interest related to cellular stress for subsequent biochemical analyses.

**Recipient or parental organism**

</tr>
<tr>
<td>Replication defective lentiviral particles some of which may include the WPRE sequence</td>
</tr>
</tbody>
</table>

**Origin & function**

The cDNAs carried by the lentivirus vectors will be used to express genes with roles in maintenance of endoplasmic reticulum (ER) homeostasis. This may include genes linked with: protein folding, protein degradation, lipid biosynthesis, calcium regulation, protein translation, stress response, protein secretion, protein trafficking and any secretory cargo.

Examples of genes involved in cellular stress are Hrd1, SEL 1L, FAM8A1, EMC1-10, UBXD8, HERPUD1

Although not anticipated, some genes may promote cell proliferation and/or decrease apoptosis - such genes are generally, but not exclusively, oncogenes. Conversely, cellular and viral genes encoding proteins that inhibit cell proliferation and/or promote apoptosis - such genes are generally, but not exclusively, tumour suppressor genes.

Also shRNA will be used to knock down expression of gene families listed above.

Standard reporter genes, such as GFP.

Standard antibiotic resistance genes, such as Neomycin

**Evaluation of foreseeable effects**

No risk from E. coli work (class 1)

Executive

Contained Use Notification

Packaging cell lines will produce replication defective viral particles which are capable of a single round of infection in a variety of mammalian cells, including humans. They also have the ability to integrate into the host genome. Genes required for viral production are separated onto 3 plasmids that have minimal homology and as such there is limited potential for recombination to create replication competent viral particles. In some cases, genes such as gag, pol and env are stably integrated into the genome of the packaging cell lines decreasing the risk of RCVs even further.

Once mammalian cells have been transduced and the virus has integrated into the host genome the cells pose minimal risk as the virus is unable to replicate.

The group are not specifically planning to work with oncogenes or knocking out tumour suppressor genes, however as they are looking at a number of genes in pathways involved in proliferation and cell survival there is a potential that they may inadvertently work with such genes. Therefore a precautionary approach is being taken.
WPRE may be present in a number of the lentiviral vectors. As this is a potential oncogene a precautionary approach is being taken. Genes involved in cellular stress are not predicted to be oncogenes or tumour suppressor genes however a number of genes to be looked at have unknown function. It is unlikely that over expression or knock down of a single gene would have major effects on cell growth and survival.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250C for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250C for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), or inactivate by chemical means (following manufacturers guidelines), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250C for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps - Sharps will not be used

Degree of kill:
- Autoclaving, effectively 100% kill (annual validation)
- Incineration, effectively 100% kill (licensed incinerator)
- Chemical, effectively 99.998% kill (following manufacturers guidelines)

CU2 Project Title Use of genetically modified salmonella typhimurium and escherichia coli expressing antigen in assays assessing functionality of antibodies against the bacterial antigens

Class 2

CultureVol Class 2 < 1 Litre

Consent Granted

Project notified under transitional arrangements

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

Project Additional Information

Purposes of the contained use

Bactericidal assays allow the assessment of functional antibodies against a number of bacteria. In vitro assays developed in-house allow the assessment of functional antibodies against a superfamily of enzymes common to Gram-negative bacteria. One in vitro assay measures susceptibility of bacteria to antibiotics and the other measures enzymatic breakdown of beta-lactams by beta-lactamase enzymes.

Recipient or parental organism

Hazard Group 2 gram negative bacteria such as Salmonella Typhimurium and Escherichia coli.

Host/vector system

Standard E. coli strains such as K-12 and B derivatives
Individual antigens from other bacterial species such as the Vi antigen from Salmonella typhi and the beta-lactamase antigen from Klebsiella pneumoniae or Pseudomonas aeruginosa.

Evaluation of foreseeable effects

Salmonella Typhimurium constitutively expressing the Vi antigen from Salmonella Typhi is not expected to have increased pathogenicity. This modification will allow the group to study the efficacy of vaccines against Salmonella Typhi without having to work with a hazard group 3 pathogen. Beta lactamases are enzymes that produce antibiotic resistance to B-lactam antibiotics (such as penicillin, cephemycins and carbapenems) in gram negative bacteria. There are a number of different types of beta lactamases some of which are specific (i.e. against penicillin) other are have broad spectrum activity. Antibiotic resistant strains of E. coli are present in the population, however most of the strains used in this project will be based on strains with limited pathogenicity.

### Project Ref 553/15.2

- **Date Ackn’d**: 25/02/2015
- **CU2 Project Title**: Investigating Neurological disorders using improved cell and animal models
- **Class**: Class 2
- **CultureVolumeClass2**: < 1 Litre
- **Consen Granted**: Consent Granted
- **Project notified under transitional arrangements**: N

#### Project Additional Information

- **Purposes of the contained use**
  - Use' of Sendai virus to generate induced pluripotent stem cells
  - Use of Replication defective Lentivirus
  - Use of Adenovirus and AdenoAssociated virus
### Recipient or parental organism

- E. coli K12 or B derivatives
- Primary mammalian cells
- Mammalian cell lines

### Host/vector system

- Standard replication defective lentiviral, adenoviral, Adeno associated virus and sendal viral vectors in E. coli cells and packaging cell lines such as HEK293

### Origin & function

**Oct4, Sox2, Klf4, Myc** are 4 genes required for the reprogramming of cells to generate induced pluripotent stem cells.

- Wild-type ion channel and neuronal function genes such as CACNA1A, TRESK, SCN1A, Tau, Cluslerin
- Mutated versions of above with deletions, insertions and/or point mutations.
- Selective modifications of any/all of the above.
- Short hairpin RNA interference sequences against the above mentioned genes (or other genes).
- Standard reporter genes, such as, Beta-galactosidase (lacZ), Jellyfish green fluorescent protein (GFP and derivatives), Td tomato and nerve growth factor.
- Standard antibiotic resistance genes, such as, puromycin and neomycin (puroR and neaR).

**WPRE** present in viral vectors

### Evaluation of foreseeable effects

**Myc** is a known human oncogene, and will be under the control of constitutively active mammalian promotors. As such it poses the risk of cell transformation if it is accidentally administered. Klf4 is also associated with cellular transformation in some scenarios, so should be assigned a similar level of risk.

The four genes (Oct4, Sox2, Klf4 and Mye) together, either in tandem in one vector, or together as pooled virus preps, are capable of reprogramming cells to become pluripotent. As such they pose a greater risk in combination than individually. The risk of induction of pluripotency in the event of ingestion, inhalation or injection is very low, as even if the genetic material is successfully introduced into the genome of cells within the body, reprogramming is an inherently very inefficient process (~0.01% efficiency) even in defined tissue culture conditions, and the environment in which a reprogramming cell would find itself would not be conducive to the reprogramming process (other signalling events induced by the local environment would be likely to override the reprogramming process). If, despite this low level of risk, reprogramming does occur within a laboratory worker, then it is possible that a teratoma could result, as is the case when iPS cells are injected into immunosuppressed mice.

**OCT4, Sox2, Klf4 and Myc** will only be expressed in Sendai virus using a kit available from invitrogen (or other similar available source). The kit uses vectors based on a modified, non-transmissible form of Sendai virus (SeV) to safely and effectively deliver and express key genetic factors necessary for reprogramming somatic cells into iPSCs. This vector is non-integrating and remains in the cytoplasm. The Fusion protein (F gene) has been deleted from the vectors rendering the virus incapable of producing infectious particles from infected cells. In addition, the presence of functional mutations such as temperature sensitivity in the amino acid sequence of several SeV proteins (SeVFTS.6..F, SeVFTS 12..6..F, and SeVrrS15ll.F) renders the vectors easily removable from transduced cells.

Replication defective lentiviral vectors will be employed to overexpress or knock down genes thought to be involved in neuronal function. None of the genes are expected to be hazardous however the lentiviral vectors may contain the...
WPRE gene which may have the potential to be oncogenic. As such, these viruses will be handled at containment level 2.
Replication defective Adenoassociated vectors also contain WPRE and although these vectors (and adenovirus vectors) are non-interacting a precautionary approach is being taken with them being handled the same as replication defective lentiviral vectors.
In addition, these viral particles will be used in vivo however the risks are minimal due to the use of anaesthesia and a stereotaxic frame.

- **Class Volume Culture**: Class 3-4
- **Non-GMM Consent Granted**: Not Applicable
- **Project notified under transitional arrangements**: N

**Project Additional Information**

- **Purposes of the contained use**
  1. to describe and understand basic mechanisms of EBV virology, particularly the mechanisms by which EBV influences cell polarity and cell differentiation status
  2. to investigate whether natural variation in EBV genomes might have a consequence for the basic virology and...
tropism of the virus
3. to examine the impact of Helicobacter p)1ofi infection on the EBV reproductive state and the general influence of both pathogens on the Infectious abilities of one another
4. to investigate the contribution to of EBV to disease

**Recipient or parental organism**

Eppstein Barr Virus· human herpes virus that infects the lymphocytes and some epithelial cens of humans and a few closely related primates to which most of the POPUlation has be exposed to in early childhood.

**Host/vector system**

Addition of reporter gene performed in collaborators lab
HEK293 cells will be used as producer ceNs after transfection with pBZLF1 or pBalF4 which contain the GFP gene

**Origin & function**

GFP 0( other similar reporter genes that have a history of safe use.

**Evaluation of foreseeable effects**

The addition of a reporter gene is not expected to have any effect on the virulence of the virus and will be handled in the same manner as wild type.
Wild type virus often causes asymptomatic infections or are undisguishable from other acute viral infections.
Infections in adolescence causes glandular fever. EBV infections are linked to a number of cancers where It is thought 10 contribute to the diseases by supplementing cell genetic changes.
The group will work with ceDs that are derived from EBV infected cancers where infection is latent and little virus is produced. They will also Infect cells with w~d type and GFP versions of EBV

Historical Significant Changes

02/03/2022 Page 9171 of 15326
Replication defective lentiviral vectors are a well-established system for the long term and stable expression of a gene of interest which is routinely used in laboratories world-wide. These vectors are an excellent way to introduce fluorescent markers and genetic modifications and have significant advantages over other delivery methods such as transfection. Transient transfection is inefficient, especially in terminally differentiated cells such as those derived from IPS cells and primary cultures. Lentiviral vectors provide the opportunity to transduce high percentages of cells in these models and have the added advantage that they can be used to produce long-term and stable expression due to their ability to integrate into the target genome.

Recipient or parental organism

Mammalian cell lines, such as primary cells, induced pluripotent stem cells and tissue samples.

Host/vector system

HEK293 cells (and derivatives) are used as a producer cell line. Second and third generation lentiviral vectors will be used where the gene of interest, the Gag-Pol genes and envelope genes are on separate plasmids such as pHR-SIN and lentilox.

Origin & function

- Standard Reporter genes (e.g. GFP, YFP, RFP)
- Standard antibiotic resistance (e.g. Neomycin, Hygromycin, Puromycin and ampicillin).
- shRNAs, siRNAs.
- Genome editing tools (e.g. TALENs, Cas9-CRISPR).
- Tet repressor/activator systems.
- Neurotrophic/neuroprotective factors (e.g. BDNF, CNTF, GDNF and NGF).
- Neurodegenerative susceptibility genes (e.g. C9orf72, TOP-43).
- Optogenetics/calcium sensors (e.g. ChR2, ChR1, GaMP)
- pH sensitive vesicular endo/exocytosis fluorescent reporters (e.g. Synapto-pHluorin, SynpH)
- Ral GTPases (e.g. RALA, RALB)
- Factors involved in neuronal differentiation (e.g. Bm3a, Ngn1, Ngn2)
- Designer receptors exclusively activated by designer drugs (DREAODs) for specific neuronal silencing (e.g. GluC1, hM4D)

Evaluation of foreseeable effects

The protein products of the genes to be studied are not expected to be toxic or cancer inducing in any way. However, the H1V receptors are also receptors for chemokines and as such the genes could modulate immune function, especially chemotaxis, in target cells. This could provide a growth/invasion advantage to cells. Initially, the shRNAs, TALENs or Cas9-CRISPR systems to be used are not targeting known tumour suppressors.
However, there is potential for off-target effects with, which could potentially have tumorigenic effects. This will be
minimised by careful design with as little sequence homology as possible to off-target genes, including BLAST
searches against genome databases.
Gene transfer is possible, significantly from the transfected producer cell lines, as the resulting LentiviralRetroviral
vector will be able to infect a wide range of cells, including human cells, as the VSV-G or Rabies-G envelope enable
amphotropic infection. However dissemination in the environment is limited due to the viruses being replication
defective.
Some of the vectors may contain the woodchuck hepatitis virus regulatory element (WPRE) and there is some limited
evidence of its oncogenic potential.
Some of the genes of interest may modulate immune function.
Once the virus has integrated into the genome of the host cell it poses minimal risk and the cells can be handled at
containment level 1 after a given period of time.

Date of Significant Change

**Project Additional Information**

**Purposes of the contained use**

The group develops new approaches to study signalling networks in cancer cells and to uncover specific weaknesses, particularly in breast and lung cancer and other tumour types that can be used for developing more effective targeted drugs and for guiding treatment decisions. We develop and employ high-throughput chemical and genetic screening.
approaches and haploid genetics to engineer isogenic human cancer cells and tease out drug-gene interactions that could be therapeutically exploited.

**Recipient or parental organism**
- E. coli K12 or B derivatives
- Mammalian cell lines
- Primary mammalian cells

**Host/vector system**
- Standard plasmids
- Standard non-replicating retro and lentiviruses

**Origin & function**
- Standard reporter genes, such as GFP
- Standard antibiotic resistance genes, such as ampicillin
- shRNA to knock down a variety of genes involved in signalling pathways
- cDNA libraries involved in signalling pathways
- Genes from oncogenic viruses, such as Adenovirus E1A gene or SV40 large T antigen
- Element designed to modify the host DNA sequence, such as CRISPR, TALENS and genetrap

**Evaluation of foreseeable effects**

No increased risk is expected from genes in E. coli as they will be driven by mammalian promoters. Class 1.

No increased risk from cell lines and primary cells is expected other than those covered under CoSHH (presence of adventitious agents) as the viral vectors are non-replicating and not infectious once integrated into the host genome. Cells are likely to be detected as foreign and removed by the immune system and have strict nutritional requirements which renders their persistence in the environment negligible. Class 1.

Viral producer cells will be handled at containment level 2 as will all procedures with infectious virus. Class 2.

Standard antibiotic resistance genes and reporter genes have a history of safe use and are not expected to increase the risk.

shRNA libraries will knock down gene expression. As these are libraries of genes there is the potential to knock down the expression of tumour suppressor genes especially given that some of the libraries are related to tumourogenesis there is potentially an increased risk.

cDNA libraries will over express genes. As these libraries are related to tumourogenesis there is potentially an increased risk.

Genes from oncogenic viruses are often used to immortalise cells and are therefore potentially there is an increased risk.

The use of CRISPR targets modification to specific sites and therefore minimises random integration effects.

The inserted material may intentionally or accidentally affect the host DNA and/or gene expression and thereby stimulate oncogenic transformation of eukaryotic cells. Likewise, the random insertion of lentiviral or retroviral vectors (which may be used to transfer the sequences above into the host cells) can result in the altered expression of cancer driver genes. As such, these vectors and inserts pose the risk of cell transformation when accidentally administered to the scientists working with these vectors and this represents the greatest health and safety hazard. However, these risks are strongly mitigated by the Biosafety Features of the Vectors (see below) as well as the Risk Reduction for lenti- and retroviral transductions.

The viral vectors used are second or third generation and create non-replicating viruses which integrate into the host
genome. There are a number of different safety features depending on the system used. Only the minimal number of viral genes are used, genes are often separated onto 3 of 4 different plasmids and they contain L TR regions which self inactivate the virus.

In the event that a person will be in direct contact with a lentivirus or retrovirus carrying an oncogene the chance that this will result in transduction of cells and induction of a tumor is very small. The infection efficiency of these viruses into primary human cells is very low, particularly in those terminally differentiated and not proliferating cells lining the skin and mucosa or present in the bloodstream. Furthermore, even if such cells would be transduced they would be shed/disposed from the body within days and thus could not result in tumorigenesis. Furthermore, tumorigenesis is a multi step process, requiring several genetic events and these viruses would only carry single cancer genes.

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), or inactivate by chemical means (following manufacturers guidelines), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration. Sharps will not be used for viral work.

Degree of kill:

Autoclaving, effectively 100% kill (annual validation)

Incineration, effectively 100% kill (licensed incinerator)

Chemical, effectively 100% kill (following manufacturers guidelines)

Is an emergency plan required according to regulation 20? N

**Purposes of the contained use**

This project involves modulating (overexpress or down-regulate) the expression of genes involved in the promotion or inhibition of T cell activation, proliferation, differentiation and polyfunction survival, genes encoding transcription factors directly or indirectly mediating their expression, and genes encoding their interacting proteins in human cell lines and primary cells. In the course of the study, other molecules such as cell cycle or gene expression regulators.
Recipient or parental organism

Primary mammalian cells, including those from HIV patients and other patients

Host/vector system

Standard replication defective retro and lentivirus systems
E-coli K-12 and B derivatives and standard vectors will be used for cloning purposes

Origin & function

Genes involved in:
- T cell activation, such as CD28 and CD69
- T cell proliferation and inhibition, such as MAL and DNMT1
- T cell differentiation, such as CD28 and CD69
- Polyfunction survival, such as BCL2 and PRF1
- Transcription factors, such as NFkB 1 and ST AT3
- Cell cycle regulators, such as MCM2 and E2F1
- Immune regulators, such as TYROBP and FCRL3
- WPRE is present in numerous lentiviral systems and some studies have shown this to be a potential oncogene
- Genes in which expression is expected to be dependent upon the genome editing technology
- Genes such as those listed above that are already expressed in the genome editing technology

Evaluation of foreseeable effects

CRISPR/Cas system (and similar systems) allows targeted gene editing on endogenous genes. It has been isolated from the bacterium Streptococcus pyogenes. The SpCas9 has been human codon-optimized. Although it has been isolated from a hazard group 2 micro-organism the risks are limited due to only the necessary genes being used, the fact that these genes have been codon optimised for expression in human cells and the fact that the editing is limited to specific genes within the genome rather than random integration.

Standard replication defective lentiviral vector systems can integrate into the genome

Before infecting recipient cells with replication defective lentivirus, all the cells isolated from HIV-1 infected patients are tested by nested PCR and confirmed free of HIV-1 genes (especially viral packaging genes: gag-capsid and polreverse transcriptase-integrase genes) within genome. In this case, there is also minimal possibility of undesirable recombination events occurring which could contribute to the generation of replication-competent virus.

In addition work with primary cells from patients positive for HIV, HepB and HepC will be carried out in a containment level 3 laboratory due to the requirements of the CoSHH regulations.

The ability of the virus to infect human cells, the potentially oncogenic nature of some of the inserted genetic material, and the likelihood that expression will lead to changes in the proliferation of infected cells and in some cases possibly contribute to oncogenic transformation, increases the risk to human health. However the use of sharps is minimal and the likelihood of exposure is low.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Appropriate containment and control measures have been assigned in accordance with the latest guidance issued by ACGM.

Project Ref 553/15.7
The objective of this project is to determine the role of autophagy in the mechanism behind artemisinin-resistant Plasmodium falciparum.

Recipient or parental organism

Plasmodium falciparum - hazard group 3

Host/vector system

replication defective retro / lentiviral vectors

Origin & function

Reporter genes, such as eGFP or m-cherry.

Executive

Knock down I knock out or specific mutations of parasite genes thought to be involved in autophagy such as the Atg genes.

Evaluation of foreseeable effects

Plasmodium is a protozoa which is transmitted to humans via mosquitos and may cause serious disease. The Plasmodium which is modified to express reporter genes is not expected to be any more hazardous than the wild type versions. There is no report in the literature of increased virulence following addition of reporter genes. The Plasmodium in which certain proteins have been edited (either knocked down or SNP inserted) are not expected to have increased virulence however they may be involved with the resistance to artemisinin. In the event of accidental exposure any infection would be treated with a partner drug such as chloroquine which have different
mechanisms of action and are therefore unlikely to share the same resistance mechanisms. This work does not involve mosquitos and these insects are not present in the UK therefore the risk to the environment is minimal as without a host I vector the protozoa have limited ability to survive. The only sharps present are glass slides necessary for the creation of blood smears which will be disposed of immediately into a sharps bin. Replication defective Lentiviral particles will be used to modify the plasmodium, some of which may contain the WPRE sequence which is a potential oncogene and are therefore considered to be class 2. The addition of reporter genes and plasmodium genes is not expected to increase the hazard of the lentiviral particles. However should accidental exposure occur there is the potential for integration into the genome at random sites which may alter expression of genes at that site.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Laboratory not sealed for fumigation. There is no foreseeable need to fumigate the laboratory. In the event of a major spillage, the bulk of material would be soaked up on absorbent paper towels then autoclaved, killing any parasites. The area would be wiped down with disinfectant. Any aerosols created that were not cleaned in this initial effort would dry out, killing both host cell and parasite. The area of the laboratory would be left isolated for a period to ensure effective drying. Effective parasite transmission is only possible via direct inoculation of viable parasites. No negative pressure, HEPA filtered extract, microbiological safety cabinet or specified measures to control aerosol dissemination. The organism presents no hazard of infection by the airborne route. Class II microbiological safety cabinets are in use in the dedicated laboratory, they are necessary for sterile culture of the organism; they are not required for operator safety. Activities involve small scale, standard laboratory techniques with no aerosol generating procedures. Autoclave and some other equipment not within the laboratory

Although the laboratory contains most of the necessary equipment for the work, some activities use specialist equipment that cannot reasonably be accommodated within the dedicated facility. In all cases a safe system of transport involving secondary containment is in use, any equipment used is cleaned and disinfected immediately on completion of the work and any contaminated items either returned to the dedicated laboratory or removed for disposal as waste. The following activities are undertaken outside the dedicated laboratory:

i) Fluorescence microscopy: a fluorescent microscope is located within the same building; there is a second fluorescent microscope in the Weatherall Institute of Molecular Medicine, which is connected

ii) Storage: transfected parasite stocks are frozen and stored at -800C or in liquid nitrogen within the same building. The freezers are locked and accessed only by authorised personnel.

ii i) Autoclaving: an autoclave validated for disposal of waste is located within the same building.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (e.g. plasticware) All plastic ware used in the procedure is treated with 2-4% Virkon before being disposed of according to the CL3 CoP. All waste from the Containment Level 3 laboratory must be immediately placed in a suitable receptacle, e.g. sharps into a sharps box; plastic, gloves and tissues into a hazard waste bag. Plastic ware or human tissue that has been in contact with hazard group 3 organisms must first be disinfected in 2% Virkon. They are then treated as normal clinical waste. Disinfected items must immediately be placed in a yellow clinical waste burn bin. When each bin is either full or filled to the line indicated on the side, seal the lid down. Ensure all
the locator tabs are secure. The person locking the bin must label it with a waste reconciliation sticker and complete waste reconciliation form accordingly. Sealed and labelled bins are placed in corridor outside the lab for removal by cleaning staff in Facilities.

Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-1300°C for at least 10 minutes or 134-1380°C for at least 3 minutes), or inactivate by chemical means (following manufacturers guidelines), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-1300°C for at least 10 minutes or 134-1380°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via clinical waste stream for incineration.

Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration.

Degree of kill:
Autoclaving, effectively 100% kill (annual validation)
Incineration, effectively 100% kill (licensed incinerator)
Chemical, effectively 100% kill (following manufacturers guidelines)

Project Ref 553/15.8

Date Ackn'd CU2 Project Title Class CultureVolClass2 CultureVolumeClass3-4

02/03/2022
The purpose of this project is to genetically modify yeast genes involved in chromosome segregation to understand their function.

Yeast strains such as Candida glabrata

Standard E coli K-12 or B derivatives will be used for the cloning stages of this project.

Standard antibiotic resistance genes such as ampicillin, gentomycin and hygromycin

Auxotrophic marker genes such as ADE, HIS, LEU, LYS, MET, TRP, URA

Epitope tags such as Flag, HA, His, Myc, PK

Marker genes such as kan, nat and hph

Cohesin complex subunits: such as Smc1, Smc3, Scc1, Scc3, Pds5

Cohesin complex regulatory proteins: such as Scc2, Scc4, Wapi, Eco1

Cohesin confers both intrachromatid and interchromatid cohesion through formation of a tripartite ring within which DNA is thought to be entrapped. Cohesin loading onto chromosomes is catalysed by the Scc2/Scc4 complex, whereas dissociation is catalysed by Wapi and several other cohesin subunits like Scc3 and Pds5. Establishment of cohesion during S phase involves neutralization of the dissociation activity through Eco1-mediated acetylation of Smc3. This locks rings shut until opened irreversibly by Scc1 cleavage through the action of separase, an event that triggers the metaphase to anaphase transition.
The anticipated effect of the changes are chromosome segregation defects, cell cycle arrest and changes in cohesin ring formation. Addition of standard reporter genes and epitope tags is not expected to increase the hazard of this micro-organism. Switching the promoter sequences with those from other yeast species to alter the expression level is also not expected to have an adverse effect.

Appropriate containment and control measures have been assigned in accordance with the latest guidance issued by ACGM.

Project Containment
The overall aim of work under this risk assessment is to better understand bacteriocin uptake pathways leading to their antibiotic activity, allowing their exploitation to produce novel antibiotics. Bacteriocins are potent narrow spectrum protein antibiotics, produced by Gram negative bacteria to kill closely related bacteria. Many Gram negative bacteria produce bacteriocins, but with the exception of the colicins of Escherichia coli, little is known about their receptors and uptakes routes.

Recipient or parental organism

Hazard group 2 bacteria such as Escherichia coli, Pseudomonas aeruginosa and Klebsiella pneumonia

E. coli K-12 or B derivatives

Host/vector system

**Project Additional Information**
Standard plasmids

Origin & function

Bacteriocins, bacteriocin immunity proteins, bacteriocin receptors or proteins involved in bacteriocin uptake from hazard group 2 bacteria such as Escherichia coli, Pseudomonas spp. or Klebsiella spp., along with standard resistance markers which are not generally used for treatment.

Evaluation of foreseeable effects

Bacteriocins, bacteriocin immunity proteins, bacteriocin receptors or proteins involved in bacteriocin uptake from hazard group 2 bacteria, along with resistance markers, will be individually cloned into standard plasmids and expressed in E. coli K-12 or B derivatives such as BL-21. Whilst bacteriocins are potent toxins, their activity is narrow-spectrum, acting against their specific target bacterial species. Bacteriocin receptors are often nutrient receptors sometimes classified as virulence factors, analogous pathways exist in the host strain and without other components of the uptake pathway the inserted genetic material should not increase the level of risk for the GMMs. Class 1.

Addition of WbbL to E. coli K-12 strains. The inability of K-12 to colonise the GI tract in animal models is likely due to their phenotypically rough LPS, lacking O-antigen due to disruption of the wbbL gene by an insertion sequence. Restoration of the wbbL gene, and hence the rhamnose transferase it encodes, resulting in the production of 016 serotype LPS. Whilst the ability of O-antigen restored K-12 to colonise the GI tract has not been studied in animal models it is likely to be greater than that of K-12 carrying the wbbL gene disruption, most likely comparable to the ancestral commensal E. coli K-12. Class 2.

Work with Hazard group 2 bacteria, such as Uropathogenic E. coli, Pseudomonas aeruginosa, and Klebsiella pneumonia. The inserted genetic material should not increase the level of risk for the GMMs. The insertions will be (i) chromosomal and lead to gene inactivation and are likely to attenuate the host, (ii) plasmids allowing the expression of wild-type or mutated components of the bacteriocin uptake pathways from hazard group 2 bacteria such as E. coli, P. aeruginosa or K. pneumonia or (iii) plasmids encoding bacteriocin immunity proteins and should not promote the survivability of the GMM. The inserted material will contain resistance markers for agents not usually used to treat humans with infections with these bacteria. Class 2.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Date Project Ceased

Project notified under transitional arrangements

02/03/2022
The main focus of this research is on cerebral cortical development. Topics covered range from neural progenitor fate specification to early thalamocortical and corticothalamic anatomy and connectivity. Replication defective viruses will be used to assist in this research.

Recipient or parental organism
- Mammalian cells
- In vivo neurons

Host/vector system
- Replication defective lentiviruses second or third generation
- Replication defective adenoviruses, such as E1 or E1 and E3 deleted
- Producer cell lines such as HEK 293 cells
- E. coli K-12 or B derivatives

Origin & function
- Standard reporter genes such as GFP, Luciferase and B-gal
- Standard antibiotic resistance genes
- WPRE element from Woodchuck Hepatitis virus
- Mammalian genes thought to be involved in cortical development or neuroprotective roles, such as Serpini1 gene

Evaluation of foreseeable effects
- No adverse effect are expected with the generation of plasmids in E. coli as the genes are driven by mammalian promoter and as such the work is considered to be class 1.
- Standard reporter genes and standard antibiotic resistance genes have a history of safe use and are not expected to increase the hazard of the viruses. Overexpression of fluorescent proteins in transgenic mice had shown no adverse effect.
- Genes which are involved in cortical development or neuroprotective roles are not expected to increase the hazard of the virus. Overexpression of serpini in transgenic mice shown slight anxiety
- The replication defective viruses are standardly used in research, however some versions of both the lentivirus and the adenovirus contain the WPRE element that has been shown to be a potential oncogene and a such a precautionary approach is being taken.
- In vivo work will involve sharps however the risks will be minimised by using anaesthetic or stereotaxic equipment and...
the sharps will be very fine pulled glass capillaries. Sharps will be disposed of immediately. Due to the location of innoculation and the replication defective nature of the viruses there is minimal risk of transmission post innoculation.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

  - Executive
  - Contained Use Notification
- CRISPR (Clustered regularly interspaced short palindromic repeats) system which is an RNA guided endonuclease technology for genome editing
- Cre recombinase - Lox P system
- Extracellular vesicle markers, such as CD9, CD63 and CD81 of the Tetraspanin family
- Extracellular vesicle targeting sequence
- Transcriptional activators such as VP64, VP160 and VPR
- Transcription of RNA to induce or abolish expression of reporter genes
- WPRE element

**Evaluation of foreseeable effects**

Second and third generation lentiviral vectors will be used which means that all the components required for lentiviral replication (e.g. gag, pol, rev, env, vif, vpr, tat, vpu and nef) are on two separate plasmids and do not contain the packaging sequences. A third plasmid supplies the transgene and a packaging signal. This generates viral particles that are able to enter cells and integrate within the host genome but are unable to replicate.

- WPRE is present in many of the lentiviral vectors and is a potential oncogene. As such a precautionary approach is being taken with the viral work being done at Class 2.
- Standard reporter genes and antibiotic resistance genes have a history of safe use and are not expected to increase the hazard of the lentiviral particles.
- Cre recombinase - Lox P system allows for either the inversion, deletion or translocation of genes. This system has been in use for a number of years without any obvious adverse effects. The genes to be targeted are standard reporter genes which are not normally present in mammalian cells nor are the Lox P sites.
- Although CRISPR and Cas9 are originally of bacterial origin they are not expected to increase the hazard of the E. coli due to the fact that they are driven by mammalian promoters which are not active in bacterial cells. Therefore this work can remain at class 1. In addition the guide RNA is targeted to a specific genomic sequence in mammalian cells and would thus limit off target effects.
- Extracellular vesicle markers have not been noted to cause any harmful effects and tagging with reporter genes is not expected to alter that.
- Transcriptional activators when fused to an inactive Cas9 are capable of up-regulating gene transcription of targeted genes to enhance expression.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), or inactivate by chemical means (following manufacturers guidelines), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Degree of kill:
Autoclaving, effectively 100% kill (annual validation)
Incineration, effectively 100% kill (licensed incinerator)
Chemical, effectively 100% kill (following manufacturers guidelines)

### Project Additional Information

**Purposes of the contained use**

The project will utilise lentiviral vectors expressing shRNA, or marker proteins, and host proteins to transfect immortalised cell lines. By transfecting relevant cells with lentiviral vectors expressing host restriction factors and/or their variants, the effect of their genetic variation on protein expression can also be investigated.

**Recipient or parental organism**

Mammalian cell lines such as C8166, U937 etc
Mammalian primary cells

**Host/vector system**

HEK293 cells or similar virus producer cells
Second and third generation replication defective retro/lentiviral systems derived from HIV, SIV, FIV, EIAV or similar VSV-G pseudotyped viruses

**Origin & function**

- shRNA to knock down the expression of genes of host proteins
- Standard antibiotic resistance genes such as carbencillin and puromycin
- Standard reporter genes such as GFP
- Woodchuck hepatitis post transcriptional regulatory element (WPRE)
- Host proteins such as restriction factors from the TRIM family of proteins, and eventually other restriction factors such as SAMHD1, APOBEC, and Tetherin,

**Evaluation of foreseeable effects**

Standard antibiotic resistance genes and standard reporter genes have a history of safe use and are not expected to pose an issue over that posed by replication defective lentiviral particles.
Replication defective retro/lentiviruses have non-essential genes removed and the remaining genes split onto separate plasmids with minimal homology to reduce the risk of homologous recombination. As the gag, pol, and env plasmids do not contain the packaging sequence none of the genes are present in the package viral genome. The likelihood of these viral particles obtaining the missing genes is very low and therefore the risk of replication competent viruses being created is minimal.

WPRE may be present in the vectors and a precautionary approach is taken with this potential oncogene. One of the hallmarks of restriction factors is a significant decrease in retroviral activity during their overexpression, or a significant increase in retroviral activity during their attenuation. However it is highly unlikely that there would be adverse effects in the event of accidental exposure due to the low tranfection efficiency of viral vectors and their inability to replicate.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

</tr>
<tr>
<td>Virus producer cell lines, such as HEK293 (and derivatives)</td>
</tr>
</tbody>
</table>

### Host/vector system

Standard replication defective lentiviral vectors

### Origin & function

- Standard reporter genes such as Green Fluorescent Protein (GFP)
- Standard antibiotic resistance genes such as ampicillin

**Health and Safety**

- Executive signalling protein, cell surface protein, and other proteins, such as APRATAxin, CRN1 and DRP from mammalian sources such as human and mice
- CRISPR/Cas9 system
- shRNA
- Woodchuck hepatitis virus regulatory element (WPRE)

### Evaluation of foreseeable effects

Standard reporter genes and standard antibiotic resistance genes have a history of safe use and are not expected to alter the hazard of the viral particles.

- Cas9 has been codon optimised for expression in mammalian genes and is not expected to alter the hazard when expressed in E. coli. Use in the viral particles is expected to increase specificity in the targeting of gene mutation and therefore can be considered the same as non CAS viral particles.
- The genes to be either over-expressed or knocked down are signalling proteins, cell surface proteins and other proteins. None of the genes are expected to be oncogenic when over expressed, knocked down or mutated.

- Standard replication defective lentiviral particles can infect mammalian cells however they lack the essential genes required for replication. Lentiviral particles integrate into the host cell genome and this integration could in theory knock down a tumour suppressor gene. Most modern lentiviral systems contain self inactivating features which reduce the likelihood of activating genes within the host genome. Minimising the use of sharps will reduce the likelihood of accidental exposure.
- The lentiviral particles may contain a version of the WPRE which may have oncogenic potential therefore a precautionary approach will be taken with these viral particles.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The waste disposal routes vary for the locations as one is embedded within the hospital and follows their waste stream.
On WIMM site

i) Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-1300°C for at least 10 minutes or 134-1380°C for at least 3 minutes).

ii) Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-1300°C for at least 10 minutes or 134-1380°C for at least 3 minutes), discharge to drains.

iii) Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-1300°C for at least 10 minutes or 134-1380°C for at least 3 minutes).

iv) Sharps (eg needles, syringes, scalpels) - No sharps should be used in the course of the work. However, if applicable for any reason they will be disposed via clinical waste stream for incineration.

On John Radcliffe hospital site

i) Consumables (mainly plastic ware eg pipettes, flasks, tubes)

All disposables will go into the Clinical Waste Stream. Disposables will be placed in clinical waste limb bins designated for incineration.

ii) Liquids (eg samples, culture supernatants, tissue culture media)

Liquid waste will be subjected to Virkon or Chemgene-decontamination or incinerated. A prolonged exposure to 1% Virkon or Chemgene will be utilised after which waste can be discharged to drains. For any applicable liquid waste, it will be placed in clinical waste limb bins designated for incineration.

iii) Agar plates

Agar plates will be disposed of in clinical waste limb bins designated for incineration.

iv) Sharps (eg needles, syringes, scalpels)

No sharps should be used in the course of this work. However, if applicable for any reason, they will be disposed of via clinical waste stream for incineration.

Degree of kill:

- Autoclaving, effectively 100% kill (annual validation)
- Incineration, effectively 100% kill (licensed incinerator)
- Chemical, effectively 100% kill (following manufacturers guidelines)

Project Additional Information

Purposes of the contained use
To study the effect of bacterial fermentation products, such as short chain fatty acids, on the regulation of the immune system within the gastrointestinal tract and prevention of inappropriate immune responses.

Recipient or parental organism
Hazard group 2 bacteria involved in gastrointestinal illnesses such as Salmonella typhimurium

Host/vector system
Standard vector systems

Origin & function
Standard reporter genes such as GFP and Luciferase
Standard antibiotic resistance genes such as ampicillin and Kanamycin.
Deletion of genes or insertion of antibiotic resistance into gene to knock them out which may attenuate the bacteria

Evaluation of foreseeable effects
Salmonella typhimurium can cause diarrhoea, vomiting and gastrointestinal symptoms, recovery is usually within a week. It is potentially more hazardous to pregnant women due to complications being more common in pregnant women and the antibiotic of choice for treatment being associated with birth defects. The route of infection is generally oral and therefore good hygiene must be adhered to.
Addition of standard reporter genes and standard antibiotic resistance genes is unlikely to have any adverse effects.
Deletion of aroA attenuates the Salmonella as strains with mutations in the aromatic pathway require p-aminobenzoic acid (PABA), which is lacking in mammalian tissues. However they will be handled the same at the parental strain.
Other similarly attenuated strains may be modified. Again they will be handled the same as the parental strain.
Bacteria will be used in in-vivo experiments however as this is via oral gavage there is minimal risk from sharps.
Other strains of bacteria which cause gastrointestinal illness, such as Helicobacter pylori, Campylobacter and E. coli may be modified by either attenuation and I or addition of reporter genes. These bacteria have similar risks and routes of exposure to Salmonella and will be handled in the same manner.

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

02/03/2022
### Project Additional Information

#### Purposes of the contained use

The overall aim of our research is to determine the steps at which specific gene products influence metastasis. Replication defective lentiviral particles will be used to alter expression of genes affecting survival, angiogenesis, and some proteases that have previously been shown to alter metastatic behaviour.

#### Recipient or parental organism

- E. coli K12 or B derivatives: class 1
- Hek293 cells (or similar) lentiviral producer cell lines
- Mammalian cell lines including tumour cells

#### Host/vector system

- Standard replication defective lentiviral systems

#### Origin & function

- Genes such as mcp-1, pn1, mmp9, FGF-2, PAD4, STING, Interferon V etc that are involved in tumour cell metastatic behaviour, including cell survival, proliferation and vascular remodelling, will be either knockdown by Lentiviral particles expressing shRNA, overexpressed or mutated. Some of these genes may have oncogenic potential or be tumour supressor genes.
- WPRE - Woodchuck Hepatitis Virus Post-translational regulatory element. Is commonly found in replication defective lentiviral systems but may be a potential oncogene.
- Standard reporter genes such as GFP, DsRed and Luciferase
- Standard antibiotic resistance genes such as hygromycin and puromycin

#### Evaluation of foreseeable effects

Standard replication defective lentiviral particles are infectious for mammalian cells however their replication defective nature means that they are only capable of a single round of infection. As they integrate into the genome in a random manner there is a potential for adverse effects should accidental exposure occur. However, laboratory procedures which minimise the use of sharps reduce the likelihood of this happening.

Standard reporter genes and standard antibiotic resistance genes have a history of safe use and are not expected to increase the risk over that posed by empty lentiviral particles.

Some of the lentiviral particles may contain WPRE which may be a potential oncogene.

Some of the genes being overexpressed, mutated or knockdown may be involved in pathways regulating cell survival, cell proliferation, vascular remodelling and metastasis and as such may have detrimental effects should accidental exposure occur.

Cells transduced with replication defective virus may be used invivo, however as the virus is replication defective these cells are deemed to be of no greater risk that the untransformed cells after 2 days post transfection and multiple washing / media changes and as such are assigned to class 1.

Individual plasmids transfected into E. coli are not expected to pose a risk as the genes are driven by mammalian promotors and will not be expressed within E. coli.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

Project Additional Information

Purposes of the contained use
To study the structure and mechanism of secretion systems within Porphyromonas gingivalis or other similar microorganisms within the Bacteroides-Cytophaga-Flavobacterium phylum.

Recipient or parental organism
Hazard group 2 micro-organisms from the Bacteroides-Cytophaga-Flavobacterium phylum such as Porphyromonas gingivalis.

Host/vector system
Standard plasmids or shuttle vectors derived from other BCF group micro-organisms such as Capnocytophaga canimorsus.
Standard plasmids will be constructed in E. coli for recombination in P. gingivalis by electroporation.
Conjugation from E. coli may be required if electroporation fails.

Origin & function
Most of the work will involve knocking down, over expressing or mutation of normal P. gingivalis genes. Overexpression will be achieved using plasmids with an origin of replication that is functional in P. gingivalis. Affinity tagging will involve standardly available affinity tags. Expression will be driven by either native P. gingivalis promoters, consensus P. gingivalis promoters or promoters from antibiotic resistance genes that express in P. gingivalis. Antibiotic resistance genes, such as erythromycin, tetracyclin, chloramphenicol and cephalaxin. Counterselectable marker genes, such as sacB, codA, upp and pyre.

**Evaluation of foreseeable effects**

P. gingivalis can cause periodontal disease. Where possible work will be done using a strain that is considered less virulent, however on occasion other strains may be required for comparative studies. The P. gingivalis host organism already possesses functional copies of all genes to be introduced or modified in this study and the T9SS in the host organism is already evolutionarily optimised for function. Our genetic modifications of T9SS or substrate genes (e.g. affinity tagging or fusion to reporter proteins) are expected to reduce the functionality of the T9SS and therefore reduce the fitness and potential pathogenicity of the recombinant strains. Some of the T9SS proteins contribute to P. gingivalis pathogenicity however it is not expected that expression of single components of the T9SS pathway in E. coli K-12 will increase the hazard or overcome the disabled nature of the strain. The antibiotic resistance genes to be used are widely distributed in the BCF phylum and so are unlikely to increase the pathogenicity above that of natural populations. We will not be introducing resistance genes against the antibiotics that are most commonly used in the treatment of advanced P. gingivalis-associated periodontal disease: metronidazole, doxycycline, amoxicillin, and azithromycin. Reporter genes, affinity tags and counter selectable markers are all standardly used in biotechnological systems and have a history of safe use.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

### Project Additional Information

**Purposes of the contained use**

Use of replication defective lentiviral particles to investigate lysosomal storage and related diseases.

**Recipient or parental organism**

- **E. coli - Class 1**
- Hek293 (and derivatives) - viral production cell lines
- Mammalian cell lines
- Primary cells

**Host/vector system**

- Standard replication defective lentiviral systems
- Hek 293 (and derivatives) producer cells

**Origin & function**

- Standard reporter genes, such as GFP.
- Standard antibiotic resistance genes, such as amp.
- Health and Safety Executive
- Proteins thought to be involved in normal lysosomal function or implicated in lysosomal disease such as Cathpsin D, NPC1, Prosaposin, ATPB1-B4, and TFEB.
- siRNA / shRNA for achieving knock out of genes implicated in lysosomal disease.
- CRiPSR / CAS 9 gene elements to allow targeted gene mutation.
- WPRE is standardly used in lentiviral vectors.

**Evaluation of foreseeable effects**

Standard replication defective lentiviral systems are commonly used in molecular biology. Second and third generation systems have a number of safety features which prevent the generation of replication competent viruses.
but they do still pose a risk of insertional mutagenesis. In-vitro work will limit the risk by reducing the use of sharps
however for in-vivo work sharps will be required. Risks will be mitigated by training and procedures including no
resheathing of sharps and immediate disposal into a sharps bin.
Over-expression or knock-out of genes implicated in lysosomal disease is not expected to pose an increased risk over
and above that posed by lentiviral vectors.
Expression of standard antibiotic resistance genes and reporter genes is not expected to pose an increased risk over
and above that posed by the lentiviral vectors.
Use of the CRISPR system allows for targetted mutation or knocking out of genes and as such will reduce the risk of
off target integration.
WPRE is commonly used in replication defective lentiviral particles however there has been some concern raised with
regards the potential oncogenic nature of this gene. As such a precautionary approach will be taken with these
particles.
Once the viral particles have integrated into the host genome the host cells pose minimal risk and therefore can be
handled at Class 1.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS
2646, Part 3, 1993 (either 121-1250C for at least 15 minutes or 126-1300C for at least 10m inutes or 134-1380C for at
least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream
for landfill.
Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in
BS 2646, Part 3,1993 (either 121-1250C for at least 15 minutes or 126-1300C for at least 10 minutes or 134-1380C
for at least 3 minutes), or inactivate by chemical means (following manufacturers guidelines), discharge to drains.
Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3,1993 (either 121-1250C for at least
15 minutes or 126-1300C for at least 10 minutes or 134-1380C for at least 3 minutes), discharge any excess liquids to
drains, dispose of solids via the industrial (black bag) waste stream for landfill.
Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration.
Animal bedding - EITHER autoclave using a make safe cycle as specified in BS 2646, Part 3,1993 (either 121-
1250C for at least 15 minutes or 126-1300C for at least 10 minutes or 134-1380C for at least 3 minutes), discharge any excess liquids to
drains, dispose of solids via the industrial (black bag) waste stream for landfill.
Animal carcasses - dispose via clinical waste stream for incineration.
Degree of kill:
Autoclaving, effectively 100% kill (annual validation)
Incineration, effectively 100% kill (licensed incinerator)
Chemical, effectively 100% kill (following manufacturers guidelines)

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

02/03/2022

**Project Additional Information**

**Purposes of the contained use**

The project aims to use replication defective lentiviral particles to help elucidate immunological pathways in response to infections and tumour development.

**Recipient or parental organism**

Mammalian cell lines: such as THP1, C1 Rand Hap1 cell line.  
Cell lines, such as HEK293 (or derivatives of) for the production of replication defective lentivirus.

**Host/vector system**

Disabled E. coli, K12: such as DH10b, DH5a, XL 10, Stabl2, Stabl3, TOP10, as well as commercially available class I - approved dam-/dcm- strains. Additionally, Pir+ expressing strains for propagation of pir-based replication origins may be used.  
Standard non-mobilisable or mobilisation defective vectors will be used.

**Origin & function**

Mammalian genes implicated in immune responses will be over-expressed, knocked down or mutated.  
CRISPR/CAS 9 (or similar) and guide RNA will be used for mutation of genes.  
Standard antibiotic resistance genes, such as Puromycin and Neomycin.  
Standard reporter genes, such as GFP and Luciferase.  
shRNA for knock down of genes.  
WPRE may be present in some of the vectors.

**Evaluation of foreseeable effects**

Inserts code for either normal mammalian genes, selective alterations of those genes, codon-optimized Cas9 and a single guide RNA targeting a mammalian gene, or an shRNA targeting a mammalian RNA. The target genes do not include known oncogenes but may be antigens expressed by tumour and/or normal cells, genes involved in the processing and presentation of antigens, genes involved in immune responses, genes involved in intracellular trafficking and genes involved in the unfolded protein response. Some genes have been found to be associated with hereditary diseases, expressed on tumour cells or involved with immune response. Since human sequences are targeted, modification of cellular DNA is theoretically possible upon gene transfer, but risk of gene transfer is minimal and unlikely to be hazardous.

Standard marker genes such as lacZ, eGFP, dsRed, or mCherry, and standard antibiotic resistance genes have a history of safe use and are not expected to have harmful physiological or pharmacological properties or to affect pathogenicity of the cloning host.

WPRE is commonly present in lentiviral vector systems and could be potentially oncogenic.  
Where possible sharps will not be used with lentiviruses. Where required e.g. for in vivo work, adequate training will be provided and training records maintained. Sharps will be disposed of immediately, not resheathed and the needle will not be removed from the syringe prior to disposal.

As the viruses are replication defective, shedding is not expected to be an issue and therefore minimal risk from in vivo work subsequent to inoculation. Inoculation of transduced cells is also not expected to pose a risk as the cells
should be recognised as foreign and cleared by the immune system.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

| N/A |

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

| N/A |

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

| Consumables (mainly plasticware eg pipettes, flasks, tubes): autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250C for at least 15 minutes or 126-1300C for at least 10 minutes or 134-1380C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) -autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250C for at least 15 minutes or 126-1300C for at least 10 minutes or 134-1380C for at least 3 minutes), or inactivate by chemical means (following manufacturers guidelines) then discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3,1993 (either 121-1250C for at least 15 minutes or 126-1300C for at least 10 minutes or 134-1380C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration.

Animal bedding - Dispose via the industrial waste stream for landfill OR dispose via clinical waste stream for incineration.

Animal carcasses - Dispose via clinical waste stream for incineration.

Degree of kill

- Autoclaving, effectively 100% kill (annual validation)
- Incineration, effectively 100% kill (licensed incinerator)
- Chemical disinfection, used according to manufacturers instructions under standard conditions, manufacturers validation [eg4.79] log reduction ([eg99.998]% kill).

Collective T cell differentiation and T cell responses

Use of hazard group 2 micro-organisms to study the signals controlling T cell immune responses to pathogens. Generating the right balance between effector and memory subsets is crucial to insure both short- and long-term protection, and we are studying how this balance is determined. In particular, we are studying:

- The signals regulating T cell fate
- The spatio-temporal T cell response and commitment
- T cell collective responses

Recipient or parental organism

- Hazard group 2 micro-organisms, such as Listeria monocytogenes.
- Influenza strains, such as A/HKx31
Host/vector system

Immunogens have been fused to signal sequence and promoter of hly gene and reintroduced into listeria. The bacteria are created elsewhere.
Immunogens have been inserted after the HA gene in influenza. These stains have been created elsewhere.

Origin & function

Immunogens, such as Ovalbumin, introduced into micro-organisms.

Evaluation of foreseeable effects

Wild type listeria is a hazaard group 2 micro-organism and the introduction of immunogens is not expected to increase or decrease the risks from this pathogen.
Strains of influenza used are attenuated strains however X31 still has low pathogenicity in humans although it cannot invade lung epithelium. Due to this a precautionary approach is being taken and containment level 2 requirements will be used. PR8 strain has been shown to be non infectious to humans however it causes illness in mice and as such containment level 2 will be required in BMS facilities.
Ovalbumin is the main immunogen in eggs but has been used in research for many years without any reports of induction of egg allergy.
These engineered strains of Listeria and influenza allow us to study, for example, the function of T cell affinity for the peptide or the spatio-temporal T cell response following infection.
Infection of mice and analysis post infection by immunological assay, imaging or phenotyping. Infection of mice will be done by intravenous injection for Listeria and intranasal inoculation for influenza. Needles will be single used and disposed of directly in sharps bin. Strictly no re-sheathing of needles. The volume will most commonly be 100-200jll. Infected mice will be handled in a Class II micro-biological safety cabinet and housed in IVCs. Generation of single cell suspensions from tissues will be done in an MSC. Cages will be clearly labelled.
Listeria monocytogenes cannot naturally infect mice, as it is unable to interact with mouse E-Cadherin and therefore invade the gut. Therefore, natural Listeria transmission to other mice is limited. Listeria will be cleared in mice after around 10 days post infection.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Project Additional Information

**Purposes of the contained use**
The design and generation of lentiviral particles, in particular siRNA, shRNA and guide RNA for customised library screens but also viral particles for over expression of genes.

**Recipient or parental organism**
- E. coli K12 and B derivatives - class 1
- Viral producer cells, such as HEK293 cells or derivatives
- Mammlian cells

**Host/vector system**
Standard replication defective retro- or lenti-viral particles based on viruses such as MoMLV, HIV, EIAV
- Viral producer cells, such as HEK293 cells or derivatives.

**Origin & function**
As the nature of the work is generating library screens it is difficult to predict what the intended functions will be and there is the potential to express oncogenes or to knock-down tumour supressor genes. As such all viral particles will be handled with a precautionary approach.
WPRE may be present in some of the viral vector plasmids.

**Evaluation of foreseeable effects**
As the overall aims of the service is to generate sgRNA and shRNA libraries for customised library screens. Therefore there is the potential that the sgRNA I shRNA could target tumour supressor genes or other essential genes which could have a deleterious effect. The control measures in place should reduce the potential for exposure to occur. Occasionally genes may be expressed from the lentivirus however these are not expected to increase the hazard over that posed by the presence of WPRE, which is potentially an oncogene.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

This aim of this project is to assess mouse cytomegalovirus as a vaccine vector for its ability to induce long and durable immune responses, both cell mediated and humoral, against an antigen of interest.

Recipient or parental organism

Producer cell lines, such as NIH 3T3
Standard mammalian cells lines
Primary cells
Mice

Host/vector system

Standard E. coli transfected with a bacterial artificial chromosome (BAC) containing the whole MCMV genome

Origin & function

Inserted genetic material will be a gene of interest from numerous infectious pathogens with the aim of triggering an immune response to the pathogen. Examples include antigens from Plasmodium, Influenza and Mycobacterium etc
Other inserts will be model antigens such as Ovalbumin or Hen Egg Lysozyme
Standard reporter genes such as GFP, mCherry or Luciferase

contained
**Evaluation of foreseeable effects**

MCMV has been shown to infect human cells in vitro, but infection leads to an abortive cycle and is not thought to induce any disease. It can however infect murine samples and the prevalence in the wild population is estimated to be 65-90%. It leads to an asymptomatic infection and is likely to persist in the environment however control measures are in place to prevent accidental release into the environment. MCMV is an enveloped virus and therefore has poor survival in the environment. MCMV transmission is thought to require direct contact with contaminated excretion/secretions. Cross protection between wild type and recombinant strains is expected.

The inserts are not expected to alter the pathogenicity of the virus nor is it expected to alter the host range. It is expected that exposure to the virus would induce immunity to the transgenes and subsequently the pathogens from which they are obtained.

Animal Units

Large Scale Activities

Human Clinical Applications
The aim of the research is to study how changes in intracellular and extracellular pH affect cellular or tissue physiology and pathophysiology.

Recipient or parental organism

Primary mammalian cells
Mammalian cell lines
Lentiviral producer cell lines such as HEK293

Host/vector system

Standard replication defective lentiviral systems

Origin & function

Enzymes that synthesise and degrade mobile H+ carriers (such as CARN1, CARNMT1, CDNP).
Proteins that form cell-to-cell connexin channels (such as mainly Cx43 isoform).
Genes involved in the regulation of extracellular acidity (such as SLC4A2 (coding for AE2)).
Genes coding for membrane transporters, such as SLC superfamily members coding for NHE and NBC proteins. Genes involved in changes to the pH regulatory apparatus, including nuclear NHE1, as well as genes coding for proteins that synthesise and breakdown histidyl-based mobile buffers. Standard reporter genes such as GFP and luciferase. Standard antibiotic resistance genes such as puromycin and neomycin. Woodchuck hepatitis virus post transcriptional regulatory element. CRISPR / Cas 9 and sgRNA system.

**Evaluation of foreseeable effects**

Lentiviral particles can enter mammalian cells and, in case of successful transduction, integrate into the genome. There is therefore potential for the inadvertent disruption of tumour supressor genes, however this will be mitigated by not using sharps. The lentiviral particles are replication defective and should they enter the cell they will not be able to generate more infectious virus. The WPRE gene fragment is present, which may have oncogenic potential. Genes will be knocked down using lentiviral delivery of shRNA, overexpressed by lentiviral delivery of genes or mutated using CRISPR / Cas 9. CRISPR sgRNA and the Cas9 genes are on separate lentiviral plamids and therefore the possibility of gene drive is minimised. Knock down or over expression of the genes is likely to affect the pH of the intra / extracellular environment resulting in a change of cellular or tissue physiology and pathophysiology.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

| Consumables (mainly plasticware eg pipettes, flasks, tubes) | - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250C for at least 15 minutes or 126-1300C for at least 10 minutes or 134-1380C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill. 
Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250C for at least 15 minutes or 126-1300C for at least 10 minutes or 134-1380C for at least 3 minutes), or inactivate by chemical means (following manufacturers guidelines), discharge to drains. 
Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250C for at least 15 minutes or 126-1300C for at least 10 minutes or 134-1380C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

**Project Additional Information**

**Purposes of the contained use**

A replication defective lenti-viral system will be used to produce large quantities of both secreted and membranebound recombinant proteins in order to determine their structure and function.

**Recipient or parental organism**

- E. coli K-12 - class 1
  - Standard eukaryotic cell lines, primary cells, iPS cells, immortalized cells and secondary cells.

**Host/vector system**

- Standard replication defective Lentivirus
  - HEK293 (or derivatives / similar) producer cells

**Origin & function**

This program of work will investigate proteins involved in development and neurology. Typically neuronal proteins required for signal transduction and cell adhesion and also proteins involved in cell adhesion and signalling that are important in development and disease. we plan to express peptides, proteins, naturally occurring genes (or mutants thereof), synthetic oligonucleotides (designed to create mRNA in eukaryotic cells for recombinant protein expression) and short synthetic genes (for example, codon optimised genes). Examples include the Wnt signalling pathway, FLRT family, semaphorins and nanobodies.

Standard antibiotic resistance genes and standard reporter genes, such as GFP, Luc, amp and Kan.

Woodchuck Hepatitis Virus Posttranscriptional Regulatory Element (WPRE) is also present in many of the lentiviral constructs.

The constructs may also include genes to allow for an inducible system of gene expression, such as Tet-on.

**Evaluation of foreseeable effects**

The lentivirus to be used are replication defective however they do have the ability to integrate into the host genome and pose a risk of insertional mutagenesis. The worst-case scenarios are: i) expression of oncogenes, ii) the chance integration of the virus into a tumour suppressor disrupting that gene’s function and/or iii) reprogramming of cells and subsequent teratoma formation. However, in all cases, the virus particle would be incapable of infecting more than one cell and would not self-replicate. In-vitro work will limit the risk by reducing the use of sharps. Risks will be mitigated by training and procedures.

Many of the inserts are not expected to pose a hazard however a number of them are linked to stem-cell replication and are implicated in some cancers. As such a precautionary approach will be taken with these genes.

WPRE is commonly used in replication defective lentiviral particles however there has been some concern raised with regards the potential oncogenic nature of this gene. As such a precautionary approach will be taken with these particles.

Expression of standard antibiotic resistance genes and reporter genes is not expected to pose an increased risk over and above that posed by the lentiviral vectors.

Once the viral particles have integrated into the host genome the host cells pose minimal risk and therefore can be handled at Class 1.

Project Additional Information

Purposes of the contained use
Use of HIV infectious molecular clones to look at antigen processing and presentation in HIV-1 infected cells and to develop assays used to determine efficacy of vaccines.

Recipient or parental organism
Human immunodeficiency virus (HIV)

Host/vector system
The viruses are created elsewhere however they will be expanded in vitro within the department to generate viral stocks using human PBMC.

Origin & function
Standard reporter genes such as those based on Luciferase, Renilla and GFP,
Various strains of HIV isolates will be used which originate in different parts of the world and have different clades.

Evaluation of foreseeable effects
The LucR, GFP and RFP inserts are commonly used reporter genes and are not expected to alter the virulence of the
viruses.
The HIV isolates are all found in the natural population with different strains being more prevalent in different parts of the world.

#### Historical Significant Changes
- Notification transferred to GM20

### Project Additional Information

#### Purposes of the contained use
The aims of the project are to understand how adhesion of bacteria to surfaces, followed by defined cell-cell interactions between bacteria, lead to the formation of macroscopic three-dimensional bacterial communities called biofilms.

#### Recipient or parental organism
- Hazard Group 2 bacteria such as Pseudomonas aeruginosa
- Hazard group 1 bacteria such as Pseudomonas fluorescens and disabled strains of E. coli (K-12 and B derivatives)

#### Host/vector system
- E. coli K-12 or B derivatives and non-mobilisable vectors

#### Origin & function
Standard reporter genes such as GFP and Luciferase
Standard antibiotic resistance genes such as Amp and Kan
Over expression or knockdown of genes proposed to be involved in the bacterial adhesion process, such as fimbriae genes, Ag43, Pel and PsI.
Over expression or knockdown of genes identified from bacterial samples from Cystic fibrosis patients to be involved in biofilm formation.

Evaluation of foreseeable effects

Addition of standard reporter genes has a history of safe use and is not expected to alter the pathogenicity of the host.
Standard antibiotic resistance genes are not used to treat the disease and therefore will not alter the ability to treat infections.
Over expression of proteins in disabled E. coli K-12 or B derivatives to enable production of proteins for study is not expected to overcome the disabled nature of the strains.
Overexpression of genes involved in biofilm formation in P. aeruginosa is not expected to increase virulence. Where there may be potential for affecting virulence the work will be done in strains which are Type IV pili negative.
Deletion mutants are likely to have a reduced ability to form biofilms and consequently are less likely to cause infection.
Parallel work in P. fluorescens and E. coli will be done to the same standards as P. aeruginosa to ensure consistency.

Project notified under transitional arrangements
Purposes of the contained use

We wish to use a replication-incompetent 'deltaG' rabies virus system as a laboratory tool. This will be used for in vitro studies of the structure of the rabies glycoprotein and for virological assays (such as antibody neutralization assays). Plasmids encoding a rabies genome lacking the essential gene for the virion glycoprotein (G), and helper plasmids will be transfected into cell lines which express the rabies G protein or an alternative G protein which results in rabies virions that cannot propagate due to lack of G protein in their genome. This system has been used in the USA, Switzerland and other UK Universities.

In addition as a connected part of this work we wish to use standard replication defective lentiviral systems.

Recipient or parental organism

SAD B19 strain of rabies (vaccine strain used to immunize wild animals in Europe and other locations).

Also standard replication defective strains of Lentivirus

Host/vector system

E. coli K12 and B derivatives will be used to propagate plasmids.

Plasmids used are non-mobilisable.

Plasmids containing the deltaG rabies genome will be transfected into packaging cell lines such as HEK and BHK.

Plasmids containing the genes for replication defective lentivirus will be transfected into packaging cell lines such as HEK.

Origin & function

TEV protease, rabies glycoprotein, modified rabies glycoproteins or other modified glycoproteins. The modifications to the rabies glycoprotein typically entail introduction of affinity purification and protease cleavage tags within the glycoprotein sequence. The genes are to be introduced into the packaging cells lines using replication defective lentivirus.

delta G rabies sequence may also contain standard reporter genes such as mCherry and GFP.

CRISPR guide RNAs and Cas 9. The primary genes of interest for the work to be undertaken here will be those encoding cell-surface receptors. There are however thousands of such genes and it is often more economical/practical to use a pre-existing genome wide gRNA library than to design and synthesize a custom gRNA library targeting a subset of genes. This risk assessment thus includes and addresses the likelihood of using gRNAs targeting any gene in the human or mouse genome.

In the case of CRISPR-Cas9 work, cell lines will then be screened for a phenotype of interest, for example flow cytometric assays of binding of a protein.

Selectable drug resistance markers (such as puromycin and Olasticidin resistance)

Evaluation of foreseeable effects

Wild type Rabies is a group A pathogen on schedule 5, is a hazard group 3 pathogen under ADCP and is a specified animal pathogen. However no wild type will be handled, the work is restricted to a replication defect version of the vaccine strain used widely in Europe to control rabies in wild animals but not in the UK.

The strain of Rabies Virus that has been modified is the vaccine strain SAD 819 which has been routinely distributed.
within the environment of Europe in an effort to vaccinate wild animals and has contributed to a reduction in wild type rabies cases across Europe. SAD 819 is a highly attenuated rabies virus derivative, generated by serial passage of an original 1935 field isolate first in mouse brain cells then in two in vitro cell lines. SAD 819 is licensed in Europe as a live-attenuated veterinary vaccine against rabies ("Fuchsoral", IDT Biologika, Germany; License Number 479/a/91). Millions of doses have been distributed in the environment for wildlife vaccination; there has never been a report of human disease due to SAD 819. Safety studies have found that SAD 819 is incapable of causing disease in any of 16 tested species including baboons and chimpanzees, with the exception of highly attenuated pathogenicity (without further transmission) in certain experimental rodents.

Key biosafety features of this system are as follows:

1. The principal safeguard is that the nucleic acid genome carried by ~GR virions lacks the essential glycoprotein gene and are thus unable to replicate in cells other than the packaging cell line. The risk of recombination reconstituting a G-containing genome is generally regarded negligible due to the absence of any regions of homology between the backbone of the glycoprotein expression vectors and the ~GR genomic sequence. The system has been used in multiple laboratories since 1996 and recombination has never been reported, despite the fact that it would be very readily detected in the course of routine experiments in vitro or in vivo.

2. The G-deleted genome of the ~GR virions is that of the Street Alabama Dufferin 819 strain (SAD 819) of rabies. SAD 819 is highly attenuated, to the extent that it has been extensively and deliberately released into the environment as live vaccine for immunisation of foxes in Europe and has been shown not to be transmitted between wildlife.

3. Where possible, we will use a recently described ~GR-variant known as ‘self-inactivating rabies’ (SiR). In addition to lacking the gene for G, the viral nucleocapsid (N) protein-coding gene in the SiR genome carries a proteasome-targeting tag. This results in destabilisation of the essential N protein in any cells other than the packaging cell line (which expresses a protease mediating removal of the tag). An additional recombination event would thus be required to reconstitute replication-competent virus from the SiR genome.

Reconstitution of an infective virion would require recombination of the ~GR genome with the G protein gene present in the packaging cell line; the risk of recombination reconstituting a fully infection-competent virus is widely regarded as negligible for the following two reasons:

- Firstly, there are no regions of homology between the backbone of Glycoprotein expression vectors and the genomic sequence of the ~GR, making RNA recombination extremely improbable.
- Secondly, rabies is a negative strand RNA virus replicating in the cytoplasm. It does not enter the nucleus or have a DNA intermediate stage, let alone one which integrates in the genome. There is therefore effectively no chance of recombination between the ~GR rabies genome and the genomically-integrated G-coding DNA present in the packaging cell lines.

Accordingly, in more than 300 rounds of production in other laboratories over the last decade not a single case of recombination has been detected (Marco Tripodi, personal communication). Had they occurred, these events would have been readily identifiable during routine studies as they would confer a large selective advantage to those particles, dramatically changing their behaviour.

The risk of recombination of the Gvar-coding nucleic acid in the pseudotype packaging cell lines with the ~GR genome is negligible for the same reasons outlined above.

Infection of humans with wild-type rabies requires percutaneous or mucosal contact with the virus. Containment Level 2 measures and the prohibition of use of any sharps with ~GR virus will reduce the opportunity for such contact to a minimum.

The SAD B19 vaccine strain of rabies safety has been extensively evaluated in multiple animal species; it does not cause disease in any of 16 tested species (except after parenteral administration in mice). Potential for transmission between animals has been specifically examined and ruled out. The risk of environmental harm would therefore be
negligible even if intact SAD B19 was used; risk pertaining to this work is even lower because no intact SAD B19
genomes will be involved. Risk of environmental harm is therefore assessed as effectively zero.
Addition of standard reporter genes is not expected to increase the hazard of the replication defective virus.
The packaging cells lines are generally based on HEK and BHK cells which are both widely used laboratory cells
lines. Expression of the TEV or the glycoproteins is not expected to increase the risks from the cells. Replication
defective lentiviruses will be used that may contain WPRE and as such these will also be handled at containment
level 2.
Both the lentivirus itself and the lipofectamine-plasmid mixtures used in lentiviral production have the potential to
transduce mammalian cells. The following events of concern might occur after such transduction events:
1. Insertional mutagenesis
2. Oncogenesis as a result of the use of the WPRE post-transcriptional regulatory element.
3. Mutagenesis as a result of the CRISPR-Cas9 system.
Insertional mutagenesis and WPRE-driven oncogenesis are considered to be improbable, even should skin contact
with lentivirus occur. Use of gloves and standard Containment Level 2 measures is assessed to reduce these risks to
a negligible level, as has been widely accepted for such work elsewhere.
Mutagenesis in a worker's cells by the CRISPR-Cas9 system could potentially lead to activation, inactivation or
mutation of any gene (in the case of use of a genome-wide gRNA library, and dependent upon the Cas9 variant in use
[nuclease active, trans-activating or transcriptionally-repressing]). However, any such effects would require
transduction of the same cell with both a guide RNA and the Cas9 nuclease; either constituent on its own is inactive.
Potential for such effects will thus be avoided by the use of systems in which these elements are supplied by different
vectors during different cell-transduction steps. This work will not use bicistronic vectors carrying both Cas9 and
gRNA, and nor will these be handled simultaneously at any point. The combination of this measure with the use of
gloves and standard Containment Level 2 measures is thus assessed to reduce to a negligible level the risk to the
worker of CRISPR-Cas9-driven mutagenesis.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

Appropriate containment and control measures have been assigned in accordance with the latest guidance issued by ACGM.
Consideration has been given to the appropriateness of mandatory pre-exposure rabies vaccination of workers using t.GR virus. It has been decided that this would not be appropriate because the work will not involve any replication-competent rabies virus and additional safeguards against harmful exposure are in place (use of the SAD 819 backbone, containment level 2 measures and prohibition of sharps).
The delta G strains has already been approved for work at class 2 (GM53/13.4) in another Department within the University and is also worked on as a class 2 at another UK University. Advice from DEFRA at that time was that it would fall outside the scope of SAPO due to the replication defective nature. We also feel it falls outside of ATCSA.
**Project Additional Information**

**Purposes of the contained use**

Use of replication defective retrovirus and lentivirus to study how chromatin structure is established and how it is stably inherited epigenetically.

**Recipient or parental organism**

E. coli K-12 and B derivatives
Mammalian cells lines including human primary cells, immortalized cells and cancer cell lines

**Host/vector system**

Non-mobilisable plasmids
Standard replication defective retrovirus and lentivirus systems

**Origin & function**

Standard reporter genes such as SNAP, HALO, other fluorescent proteins.
Standard epitope tags such as HA, FLAG and Myc.
CRISPR-Cas9 system using guide RNA to knock out genes mentioned below.
Housekeeping genes involved in the functioning of the centromere such as CENP-A, CENP-C and CENP-T.
Genes involved in interferon signalling such as STAT and IRF transcription factors.
WPRE - Woodchuck Hepatitis Virus (WHP) Posttranscriptional Regulatory Element.

**Evaluation of foreseeable effects**

Viral particles are non-replicating and non-lytic, however they do have the capacity to enter human cells and integrate within the host DNA. This could potentially cause random insertional mutagenesis.
Standard reporter genes and epitope tags have a history of safe use and are not likely to increase the risk over that posed by the viral vectors themselves.
Cas 9 nuclease along with its guide RNA will be delivered into target cells via lipofectamine or viral delivery. The purpose is to create targetted double stranded breaks to disrupt the gene of interest or to insert a reporter gene at a specific location. The genes to be disrupted are not associated with major pathologies and are not known as major cancer drivers.
WPRE is commonly found in lentiviral systems and may be a potential oncogene. As such a precautionary approach is being taken and work with viral particles will be done in a micro-biological safety cabinet.
Genes will not be expressed in E. coli as they are driven by mammalian promoters, therefore this work can be assigned to class 1. Mammalian cells transduced with the virus pose minimal risk as the viral particles are non-replicating, therefore this work can be assigned to class 1 after the media has been changed. Producer cells will produce viral particles capable of one round of infection once they have been transfected with the plasmids and will therefore be handled at containment level 2 along with viral preparation for subsequent transductions.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

| N/A |

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

| N/A |

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

| Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-1300°C for at least 10 minutes or 134-1380°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill. Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-1300°C for at least 10 minutes or 134-1380°C for at least 3 minutes), or inactivate by chemical means (following manufacturers guidelines), discharge to drains. Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-1300°C for at least 10 minutes or 134-1380°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill. **Degree of kill:** Autoclaving, effectively 100% kill (annual validation) Incineration, effectively 100% kill (licensed incinerator) Chemical, effectively 100% kill (following manufacturers guidelines) |

**Significant Change ID**

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

Use of replication defective lentivirus to assist in the studies performed in this department. Examples of the studies include cancer metabolism and hypoxia, the role of mitochondria in ME/CFS, investigating the role of mitophagy in patients with mitochondrial diseases and also investigative studies on pre-eclampsia and endometriosis.

**Recipient or parental organism**

Standard E. coli K-12 and B derivatives.
Standard mammalian cells including primary and immortalized cells.
Standard viral producer cells, such as HEK293 derivatives.

**Host/vector system**

02/03/2022
Standard replication defective lentivirus, second generation or higher, where the genes required are separated on to at least 2 different plasmids.

**Origin & function**

cDNA sequences of mammalian origin and/or shRNA sequences.
Standard reporter genes (eg GFP, mCherry) and standard antibiotic resistance genes (eg Amp, Kan, Neo).
Genes / shRNA will be cloned into the lentiviral vectors including partial/entire gene sequences or mutant forms of genes under the control of constitutive promoters.
Some of the genes will have unknown function and as a result may include oncogenes or tumour suppressors.
WPRESS may be present in some of the vectors used. As this may have a potential oncogenic effect a precautionary approach will be taken.

**Evaluation of foreseeable effects**

Standard reporter genes and standard antibiotic resistance genes have been used for many years with no adverse effects being reported.
Replication defective lentiviral particles have the potential to infect cells and integrate into the host cell DNA. As this integration is random there is the potential for insertional mutagenesis. The risks of this occurring are minimised by the fact that sharps will not be require for the experimental procedures.
WPRESS may be a potential oncogene and as such a precautionary approach is being taken.
Some of the projects may involve work with tumour supressors or genes involved in oncogenesis. In addition many of the genes have an unknown function as such a precautionary approach is being taken.
Work with lentiviral particles will be considered Class 2.
Once cell lines have been transfected and the viral particles integrated (approx 5 media changes) cells will be considered low risk (excluding any CoSHH issues) and may be handled at containment level 1.
Genes are not expected to increase the risk of E. coli K-12 I B derivatives and can be considered class 1.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Project Ref** 553/18.3

- **Date Ackn’d**: 08/02/2018
- **CU2 Project Title**: Molecular engineering for bacterial vaccine development
- **Class CultureVolClass2 CultureVolumeClass3-4**: Class 2 ≤ 1 Litre
- **Historical Significant Changes**: N
- **Historical Date of Additional Info**: N
- **Significant Change ID**: N
Purposes of the contained use

The project will exploit the ease with which bacteria can be genetically manipulated to advance vaccine development. Bacterial diseases are responsible for a huge burden of morbidity and mortality and with increasing global levels of antimicrobial resistance, vaccination is an attractive option for combatting the public health problem presented by such diseases. Bacteria will be genetically modified to engineer candidate vaccines. Vaccines will consist of whole cell killed vaccines, live attenuated vaccines, vesicle vaccines and subunit vaccines.

Recipient or parental organism

Hazard group 2 bacteria, such as Neisseria and Salmonella (nontyphoidal) or similar bacteria.

Host/vector system

Standard E.coli K-12 and B derivatives for manipulation of standard plasmids (e.g. pUC based), Use of lambda-red recombinase to delete and insert targeted genes into the bacterial chromosome.

Origin & function

In the main, genes will be from the hazard group 2 bacteria being assessed. Standard reporter genes and standard antibiotic resistance genes may also be utilized.

Health and Safety

Executive

Examples of genes are included below but other genes, which have potential to be good antigens will be assessed as the research progresses.

Genes targeted for deletion will include those required for essential metabolic process e.g. aroA, aroD, htrA - mutations likely to render bacteria non-pathogenic for synthesis of lipopolysaccharide and e.g. msbB, htrB, pagP, galE, wbaP - mutation markedly reduces reactogenicity of bacteria maintaining integrity of linkage between inner and outer membrane e.g. Rmp, tolR, gna33 - mutation upregulates release of vesicles from the bacterial surface

Genes targeted for upregulation will include those encoding key antigens that are potential targets of protective immunity e.g. fHbp, nadA* mtrE, sseB, ompD.

Upregulation will enhance the immune response directed against such molecules.

Evaluation of foreseeable effects

Alteration of individual or multiple genes is not expected to increase the pathogenicity above that of the parental wild type. Most alterations are expected to attenuate the micro-organism in respect to the wild type to allow for suitable vaccine development.

Genetically inserted material will be bacterial surface antigens that have been identified as potential targets of the protective immune response. Increased expression of these antigens will permit an enhanced immune response to be made against them, while not increasing the risk associated with each organism.

Addition of standard reporter genes is not expected to alter the pathogenicity of the bacteria and have a history of safe use.
Addition of standard antibiotic resistance genes is not expected to be of concern as these antibiotics are not used to treat infections.

In vivo work may include the use of needles. Risks will be minimised by initial training using non-infectious material, non-resheathing of sharps, immediate disposal into a sharps bin and where possible anaesthesia or restraining to minimise movement during inoculations.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-1300°C for at least 10 minutes or 134-1380°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - Chemical method using Chemgene to a final concentration of 2% incubate 30 mins and discard to drains. For larger scale CL2 work autoclave in the Jenner CL3 facility autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-1300°C for at least 10 minutes or 134-1380°C for at least 3 minutes), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-1300°C for at least 10 minutes or 134-1380°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration.

Animal bedding - EITHER autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-1300°C for at least 10 minutes or 134-1380°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill OR dispose via clinical waste stream for incineration.

Animal carcasses - dispose as infectious clinical waste stream for incineration.

Degree of kill:

- Autoclaving, effectively 100% kill (annual validation)
- Incineration, effectively 100% kill (licensed incinerator)
- Chemical, effectively 100% kill (following manufacturers guidelines)

**Project Ref** 553/18.4

- **Date Ackn'd**: 29/03/2018
- **CU2 Project Title**: Understanding DNA Repair Mechanisms
- **Class**: Class 2
- **Culture Vol**: ≤ 1 Litre
- **Non-GMM Consent Granted**: Not Applicable
- **Project notified under transitional arrangements**: N

**Project Additional Information**

- **Purposes of the contained use**: Use of replication defective lentiviral particles to study the DNA damage response pathways.
- **Recipient or parental organism**: E. coli K12 derivatives (class 1)
Mammalian cell lines
Replication defective lentiviral particles

**Host/vector system**

E. coli K12 derivatives (class 1)
Mammalian cell lines
Replication defective lentiviral particles

**Origin & function**

Genes to be studied are mammalian in origin and predicted to be involved in the DNA damage response pathway. Examples of such genes include PARP gene family, genes involved in DNA repair (such as Ku70, BRCA1, XRCC1) and other DNA damage response genes (such as ATM, ATR, Chk1). Genes may be over-expressed, knocked down or contain specific mutations.

Other genes are standard antibiotic resistance genes and standard reporter genes.

CRISPR/Cas9 system and guide RNA will be used for genome editing to target genes creating specific mutations.

WPRE is frequently used to enhance viral titres.

**Evaluation of foreseeable effects**

The lentiviral particles generated will be able to infect a cell but unable to replicate. As the genes being looked at are involved in the DNA damage response pathway there is the potential that some of the modifications could affect tumour suppressor genes or other systems which could lead to proliferation. Risks will be controlled by the use of MSCs and not using sharps.

CRISPR/Cas9 system will be used to create specific mutations to genes. As above, some of the genes to be targeted may be tumour suppressor genes or mutations lead to proliferation. There is some evidence that use of lipid based transfection methods with CRISPR/Cas9 can lead to modification of epidermal cells. As such it is a requirement that gloves are worn.

WPRE may have potential oncogenic properties.

Standard antibiotic resistance genes and reporter genes have a history of safe use and are not expected to alter the overall risks.

Date Project Ceased

02/03/2022
This project aims to study the role of genes in regions associated with risk of developing type 1 and type 2 diabetes using replication defective retro and lentivirus.

Standard mammalian cell lines from human and rodents including podocytes, myocytes, neuronal and induced pluripotent stem cells.

Pancreatic islets from human donors and other human primary cells.

Pancreatic islets from other species.

Standard commercially available replication defective retro and lentiviral systems.

Virus producer cells, such as HEK293 cells.

Mammalian genes and their regulatory elements associated with the signalling pathways and biological processes linked to diabetes. Examples of genes include cytokines (such as IL-2 and IL-21), splice factors (such as RBM17) and kinases (such as PFKFB3). shRNA and sgRNA targeted to these genes.

Standard reporter genes such as LacZ, luciferace and fluorescent genes.

Standard antibiotic resistance genes.

CRISPRiCas9 genes for targeted gene editing.

WPRE may be present in the lentiviral systems.

Retro/lentiviral vectors are replication defective and therefore pose minimal risk to the environment however they could pose a risk of insertional mutagenesis. This is managed by minimising use of sharps. WPRE is present in many lentiviral systems and could potentially be an oncogene.

The genes under investigation are associated with the risk of developing diabetes. Overexpression, knocking out, selective mutations or alterations to regulatory elements are not expected to be hazardous if accidental exposure were to occur.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250C for at least 15 minutes or 126-1300C for at least 10 minutes or 134-1380C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250C for at least 15 minutes or 126-1300C for at least 10 minutes or 134-1380C for at least 3 minutes), or inactivate by chemical means (following manufacturers guidelines), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250C for at least 15 minutes or 126-1300C for at least 10 minutes or 134-1380C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (eg needles, syringes, scalpels) - No sharps to be used for virus work

Correlative electron microscopy studies of HIV pseudoviruses and host factors

This project aims to define the effects of host factors on the function of capsid and viral infectivity in the context of native host cells using non-infectious virus-like particles and non-replicating pseudoviruses.

Recipient or parental organism

- E. coli K-12 or B derivatives
- Mammalian cells

Host/vector system

- Retroviral packaging plasmids, such as p8.91 and p8.2
- Envelope plasmids, such as pMDG
- Plasmid carrying the transgene, such as pHRSINcSGW (CSGW)
- Standard packaging cell lines, such as HEK293 cells

Origin & function

Plasmids are based on standardly available backbones but contain various combinations of HIV genes to create 2nd generation replication defective lentiviral particles.

- p8.2 encodes HIV-1 Gag-pol, tat, rev, vpr, vpu, vif, and nef genes and is based on the HIV-1 provirus with a 1.3Kb
deletion of the env gene and deletions of the L TRs, whereas pS.91 contains only gag-pol, tat and rev genes from HIV-1 and has a more greater section of the genome deleted. The transgene is solely a standard reporter gene to allow for visualisation of the virus like particles once inside the target cells. WPRE may also be present in some of the plasmids.

Standard antibiotic resistance genes.

Evaluation of foreseeable effects

To generate replication defective virus like particles, either pS.2 or pS.91 will be transfected along with the plasmids supplying the envelope gene and the transgene into a standard producer cell line, such as HEK293 cells. Work will initially be with pS.91 and then the effect of the accessory proteins and their interactions with the host factors will be studied using pS.2. Neither pS.2 nor pS.91 contain the env gene, which is responsible for engaging the CD4 receptor in the surface of the target cell, therefore they cannot generate infectious particles once inside the target cell. The risk of recombination between the plasmids is low as there are no significant regions of homology between them (except pS.2 and pS.91 which aren't transfected together). Therefore the likelihood of generating replication competent HIV is very low. Accidental exposure could lead to insertional mutagenesis however the likelihood of this occurring is also low as no sharps are used in the process.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-1300°C for at least 10 minutes or 134-1380°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-1300°C for at least 10 minutes or 134-1380°C for at least 3 minutes), or inactivate by chemical means (following manufacturers guidelines), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-1300°C for at least 10 minutes or 134-1380°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Degree of kill:

Autoclaving, effectively 100% kill (annual validation)

Incineration, effectively 100% kill (licensed incinerator)

Chemical, effectively 100% kill (following manufacturers guidelines)
Appropriate containment and control measures have been assigned in accordance with the latest guidance issued by ACGM.

Significant Change ID
**Project Additional Information**

**Purposes of the contained use**

Use of replication defective lentiviral systems to modulate expression of candidate genes to study the role played in tumorigenesis. Also the use of CRISPR to create point mutations, additions and deletions, in candidate genes.

**Recipient or parental organism**

Mammalian cell lines and primary cells - especially disabled hosts which should be recognised as foreign by the human immune system. Due to the potential presence of adventitious agents certain cell lines will be handled at containment level 2.

**Host/vector system**

Standard replication defective lentiviral vectors where the number of HIV genes have been reduced to gag, pol, rev, tat and vpr. The envelope protein is VSV-G which allows amphotrophic infection. The gene are split onto different plasm ids so this risk of replication competent virus being produced is minimal. Virus producer cells, such as HEK 293 cells (and derivatives of)

**Origin & function**

- mammalian cDNA for genes involved in cellular pathways such as fumerate hydratase, succinate dehydrogenase and G-protein coupled receptors, BMP2, GREM1, p16, p21, SOX9
- shRNA to knock down expression of genes involved in cellular pathways
- Standard reporter genes, such as GFP
- Standard antibiotic resistance genes, such as amp, kan and Neo.
- Cre recombinase
- WPRE
- methylation or histone modification factors, such as DNMT3A
- Other genes identified during the course of the project may also be expressed / knocked down.
- CRISPRi/Cas 9 gene editing technologies (including guide RNA) will be used to make deletion, insertion or point mutations.

**Evaluation of foreseeable effects**

E. coli K12 or B derivatives are disabled hosts which cannot colonise the human gut and have a history of safe use. Genes are not expected to be expressed in these systems due to the lack of bacterial promoter. Mammalian cell cultures are especially disabled hosts which should be recognised as foreign by the human immune system. Due to the presence of adventitious agents certain cell lines will be handled at Containment Level 2. As lentivirus integrates into the host DNA and lacks essential genes for replication, mammalian cells, which have been infected pose minimal risk.

293 cells (and various derivatives) are used to produce viral particles which are capable of one round of infection. These cells will be handled at Containment Level 2 with the use of sharps minimised. Lentiviral particles are infectious but replication defective however they are capable of integrating into the host genome where they may cause insertional mutagenesis. Control measures are in place to minimise the likelihood of exposure however needles are required for inoculations.
Innoculations using transduced cells pose minimal risk to the worker as the lentivirus will be integrated into the host genome and replication defective. The cells should be recognised as foreign by the human immune system.

Innoculations using lentivirus capable of one round of infection poses the greatest risk due to the use of needles. Workers are trained in these procedures including the policy on not re-sheathing needles and disposing of intact needle-syringe assembly into sharps bins immediately after use.

shRNA constructs will be used to deplete the target endogenous mRNA and therefore restrict gene function. The constructs carrying a target cDNA will be used to express or overexpress a specific gene and thus to study its function.

The inserts primarily have a role in regulating cellular pathways and are not considered to be inherently toxic, to have harmful physiological or pharmacological properties or to affect the pathogenicity of the host. Although loss of activity or overexpression of some of the genes is seen in certain tumors it is likely that other mutations are required for the progression of the disease. However as some of the genes could be potential oncogenes (or tumor suppressor genes) a precautionary approach with these genes in combination with lentivirus will be taken and handled at containment level 2.

CRISPR Cas 9 technologies are used in conjunction with lentivirus or standard plasmid systems to make deletion, insertion or point mutations to specific genes. Nickase Cas9 and dead Cas9 will be utilised where necessary. Some concerns have been raised with regards to CRISPR technology in conjunction with lipofectamine and as such a precautionary approach will be taken with gloves being worn to prevent exposure to the skin.

Methylation or histone modification factors can be used to activate or suppress the transcription of endogenous genes. Accidental exposure to a single gene is considered to be low risk.

WPRE is commonly present in lentiviral vector systems and may be a potential oncogene. As such a precautionary approach will be taken.

Some concerns have been raised internally with regards the use of CRISPR systems in conjunction with lipid based delivery systems. As such the use of gloves is required and the work assigned to class 2.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

## Project Additional Information

### Purposes of the contained use

Use of replication defective retro / lentiviral vectors to study how ligand binding to receptors triggers intracellular signalling and how signals are integrated by different receptors to shape cellular activation.

### Recipient or parental organism

Mammalian cell lines and primary cells - especially disabled hosts

### Host/vector system

- Standard replication defective retro / lentiviral systems (2nd and 3rd generation)
- Viral producer cell lines, such as HEK293 cells (and derivatives of)

### Origin & function

- Surface receptors, such as T-cell and B-cell receptors, collagen and OSCAR
- Signalling adaptor molecules, such as GADS, LAT and DAP
- Phoshatases, such as CD45, SHP and PTPN
- Kinases, such as ZAP, LCK and CSK
- shRNA to knock down the expression of endogenous surface receptors and molecules in their signalling pathway.
- Standard protein tools, such as Biotin, Streptactin and Spy Catcher
- Standard reporter genes, such as GFP, Luciferase, and Flag
- Standard antibiotic resistance genes, such as amp, kan, and neo.
- Woodchuck hepatitis posttranslational regulatory element (WPRE) to enhance transgene expression.

### Evaluation of foreseeable effects

The inserts express a protein or modify the expression of an endogenous protein and these are not known to be oncogenes. Individually the genes are not expected to have any adverse effects.

The viruses are replication defective and easily inactive in the environment.

The protein tags, reporter genes and antibiotic resistance genes are standardly used and have a history of safe use.

WPRE may be present in some of the constructs and as this may be a potential oncogene a precautionary approach is being taken.

Sharps are not required for this work and therefore this potential route for exposure is minimised.

Once the virus has integrated into the host genome the cells pose no greater risk than the untransformed version.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-1300°C for at least 10 minutes or 134-1380°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-1300°C for at least 10 minutes or 134-1380°C for at least 3 minutes), or inactivate by chemical means (following manufacturers guidelines), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-1300°C for at least 10 minutes or 134-1380°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Degree of kill:
- Autoclaving, effectively 100% kill (annual validation)
- Incineration, effectively 100% kill (licensed incinerator)
- Chemical, effectively 100% kill (following manufacturers guidelines)

### Project Additional Information

**Purposes of the contained use**

We wish to investigate several key questions about the evolution of social traits (cell-cell interactions) using hazard group 2 human pathogens, including Salmonella Typhimurium and Pseudomonas aeruginosa and go on to use our understanding of social evolution theory and ecological theory to understand bacterial behaviour in infections. Specifically, we will investigate the extent to which social behaviour of bacteria affects their ability to infect hosts, cause disease and compete with other bacteria. We will focus on the use of molecular weapons as competitive traits and ask how human gut bacteria can resist invasion by a pathogenic competitor. We will measure the extent to which the natural microbiome can give us insights into how social behaviour can mediate colonisation resistance (prevention of a pathogen taking hold) within a host.

**Recipient or parental organism**

Hazard group 2 non-aerosol born enteric and environmental bacterial pathogens such as:
- Salmonella typhimurium
- Pseudomonas aeruginosa

**Host/vector system**

- Standard K-12F-, coliand B derivatives
- Standard non-mobilisable and mobilisation defective plasmids
Origin & function

Standard reporter genes such as GFP and other fluorophores
Standard antibiotic resistance genes
Colicin, pyocins, T655 effectors and prophage knock-outs and knock-ins. These are toxins or other competition mechanisms that the bacteria use to target and kill other bacteria (akin to antibiotics). They are not known to have harmful effects on humans.
Transposon (Tn) library mutants and evolved bacteria have mutations of random genes

Evaluation of foreseeable effects

Standard reporter genes have a history of safe use and are not expected to alter the characteristics of the GMO with respect to the wild type.
Standard antibiotic resistace genes are those commonly used in biotechnology. None of the antibiotics are used in a clinical setting to treat infections involving these pathogens.
Gene deletions of Colicin, pyocin, T655 effectors and prophage. Bacteria with knockouts of these regulatory genes are less able to fight against other bacteria or more vulnerable to the attack of their own kind due to the lack of the immunity genes. Therefore they are either likely to have or have been demonstrated to have reduced fitness and virulence relative to wild type strains. Tissue tropism and host range are unlikely to be affected.
Tn libraries. Bacteria with a randomly inserted transposon likely carry a disruption in a specific gene, resulting in a multitude of possible effects.
Consequently, harmful properties associated with the GMMs are at the most comparable to those of the wild type organism.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 13, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), or inactivate by chemical means (following manufacturers guidelines), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration. Use of sharps will be avoided where possible but scalpels are required for in vivo work.

Animal bedding - EITHER autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), dispose via the industrial (black bag) waste stream for landfill.
Animal carcasses - dispose via clinical waste stream for incineration.
Degree of kill:
Autoclaving, effectively 100% kill (annual validation)
Incineration, effectively 100% kill (licensed incinerator)
Chemical, effectively 100% kill (following manufacturers guidelines)

Project Ref 553/19.10

Date Ackn’d 04/09/2019
CU2 Project Title In-vitro, In-vivo and Ex-vivo studies using Hepatitis B virus
Class 3
Culture Vol Class 2 < 1 Litre
Non-GMM Yes
Consent Granted

Project notified under transitional arrangements N
Withdrawn N
Tick if notifying a connected programme of work N
The overall aim of the work is to study Hepatitis B Virus through in-vitro cell culture methods, in-vivo animal models and ex-vivo human HBV samples.

Recipient or parental organism

Hepatitis B virus - Hazard Group 3

Host/vector system

Cell lines capable of generating Hepatitis B and supporting HBV infection, such as HepG2.2.15 and HepG2.A64 and na"ive HepG2, Huh 7, and HepaRG.
HBV- replicon plasm ids
Replication deficient Adeno associated virus to transfer HBV genome into cells
Replication deficient Adenovirus to transfer HBV gennome into cells

Origin & function

HepG2 was transfected with a plasmid that contains four 5' to 3' tandem copies of the HBV genome and resistance to G418 to create cell line HepG2.2.15. The DNA is found to be chromosomally integrated and also episomally as relaxed circular, covalently closed DNA. Viral DNA is also found in growth media.
HepG2 was transfected with a plasmid (pTriexHBV1.1) which contains 1.1 copies of the HBV DNA to create cell line HepG2.A64.
Other plasmids containing copies (multiple or overlength) of HBV DNA of various specific genotypes will be utilized. CRIPSR-Cas9 will be used to create mutations of HBV genes.
Standard reporter genes such as GFP and Luciferase.

Evaluation of foreseeable effects

The HBV particles isolated from human blood, serum, culture supernatants of HepG2.2.15, HepG2.64 and cells transfected or infected with HBV replicon plasm ids or Adeno-HBV/AAV-HBV are infectious in nature. HBV is transmitted through percutaneous or permucosal exposure to infectious bodily fluids (or infectious cell media).
Addition of standard reporter genes is not expected to increase the hazard of HBV over that with the wild type version poses. Neither are standard antibiotic resistance genes.
Mutation of individual genes is expected to have a negative consequence for the fitness of the virus however they will still handled as class 3.

AAV and replication defective adenovirus transfer of HBV genome. These viruses are replication defective and nonintegrating and therefore pose minimal risk to the environment.

In vivo studies pose the greatest risk due to the use of needles. This will be minimised by the work being carried out by suitably trained individuals. The animals will be restrained in a smooth tunnel which allows efficient access to the tail vein. All needles will be disposed of immediately and not resheathed.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

As Hepatitis B is a blood borne pathogen which is not infectious via the aerosol route it is highly unlikely that the laboratories would be fumigated in the event of a spill.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

| Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250C for at least 15 minutes or 126-1300C for at least 10m inutes or 1 34-1380C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill. |  |

**Project Additional Information**

**Purposes of the contained use**

The aim of the project is the study of the infection process of herpesvirus infections.

**Recipient or parental organism**
Mammalian cells such as African green monkey kidney cells and baby hamster kidney cells
Human cell lines such as foreskin fibroblasts and retinal pigment epithelial cells

**Host/vector system**

BACS containing complete viral genome of Human Herpesvirus transfected into mammalian cells to generate replication competent infectious viral particles. Modification of the BACS will be done in E. coli using standard molecular biology techniques. This part of the work does not involve infectious viruses and following the guidance in section 2 of SACGM Compendium of guidance has been assigned to class 1.

**Origin & function**

Standard reporter genes such as GFP, YFP, mCherry, CFP and other small molecule tags, such as His, IHF, streptavidin, HA, snap, halo, clip.
Genes involved in the process of viral entry, such as gB, gH/gL, gM, gN and gO may be modified or knocked out to assess their involvement in the infection process.

**Evaluation of foreseeable effects**

Herpesviruses (HSV 1 and 2 and Human herpesvirus 5) are hazard group 2 micro-organisms and the addition of standard reporter genes and small molecular tags are not expected to alter the characteristics of the parental virus.
Tagging or knocking out entry associated gene are expected to result in equal or reduced infectivity compared to wild type virus.
HSV-1 can cause cold sores and related skin lesions in healthy individuals. HSV-2 is generally sexually transmitted. Human herpesvirus 5 is also known as human cytomegalovirus. The viruses become latent after the primary infection and can cause re-occurring infections. Approximately two thirds of the population have latent HSV-1 infections and approximately 70% of the population have had human CMV. Transmission is via contact either direct or indirect (eg kissing and sharing toothbrushes) for HSV-1, sexual contact for HSV-2, aerosols may also pose a risk from these viruses in the laboratory setting, and via contact and aerosols for Human herpesvirus 5.

For production of virions, mammalian cells will be transfected with BACS containing viral genome. The extracellular virus is then purified from the cell culture supernatant by ultracentrifugation and the purified virus used for infection, structural and biochemical studies, including cryo electron microscopy and mass spectrometry.
Work will be carried out in a class II micro-biological safety cabinet. Centrifuge rotors will be loaded and unloaded in a class II cabinet and ultracentrifugation will be done with aerosol-tight buckets. Plunge freezing is also done in an MSC. Gloves must be worn and care must be taken to ensure gloves are not contaminated.
Acyclovir, Gancyclovir or Foscarnet may be prescribed in the event of accidental exposure.

**N/A**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

WASTE MANAGEMENT MEASURES
All waste will be disposed of in accordance with local WTCHG Waste Disinfection policy, and using practice
consistent with the University of Oxford BioRisk Management policy.
Consumables (mainly plasticware e.g. pipettes, flasks, tubes) - will be rinsed/soaked in 1% Virkon solution in a
dispojar contained within the MSC. At the end of the session, plastic disposables will be transferred to an autoclave
bag, which will then be sealed and autoclaved using a make safe cycle as specified in BS 2646, Part 3, 1993 (134C
for 5 minutes / WHG discard autoclaves), with discharge of any excess liquids to drains, and disposal of solids via the
industrial (black bag) waste stream for landfill.
Liquids (e.g. samples, culture supernatants, tissue culture media) will be collected within the MSC, disinfected with
1% Virkon solution, prior to being autoclaved out of the lab. There are no drains available for liquid disposal in the
facility (OPIC yellow suite). Should the work move to a different containment level 2 laboratory 1% virkon overnight
will be sufficient without additional autoclaving.
Sharps - No sharps will be used.
Degree of kill:
Autoclaving, effectively 100% kill (annual validation);
Incineration, effectively 100% kill (licensed incinerator);
Chemical disinfection with 1% Virkon, effectively 99.998% kill.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form  

Tick if you are claiming exemption from disclosure for section of the risk assessment

Please enter comments on the GM safety committee on the risk assessment
Harvesting of gradient bands using gradient fractionator - Does this do away with the use of needles to pierce the tube to collect the band? They don't mention the use of needles in the risk assessment so I presume so. Use of sharp needles would be one of the biggest risk when working with this virus so if they are using them this would need to be addressed.

The use of the gradient fractionator avoids the need for using needles, and thus eliminates the risk associated with sharp needles.

Virus purification/dialysis - I presume this is done to concentrate the virus? Are there any risks to this step? The virus is more concentrated but it is also in smaller volumes. The use of PPE (gown, gloves and glasses) and biosafety cabinet (TriMat 2) minimise the splash risk/generation of aerosols which constitutes the main potential route of transmission, thus virus handling is the same both before and after concentration.

Total volume of cell culture supernatant may be up to 800ml - this seems a rather large volume, is it made up of multiple smaller ones?

This is made up of multiples of less than 50mL aliquots, which combined make a total volume of up to 800mL.

It might be worth considering whether there are any differences in the pathogenicity / attenuation of the various laboratory strains available - is it possible to do the work using a relatively highly attenuated strain, or not, or are the strains which are already proposed highly attenuated?

Where possible attenuated versions of these viral strains are used, however, to answer questions regarding viral entry and replication attenuated viruses are not appropriate.

My 'index of concern' about HSV is a bit higher than for some other things which are handled at CL2 (eg 3rd gen lentiviruses). Although common it is a genuine pathogen & I wouldn't want to splash it in my face - as well as encephalitis, it can cause nasty corneal ulcers, and any infection which is acquired will establish lifelong latency.

It might be worth ensuring that users are aware that aciclovir might be felt to be worthwhile / beneficial for some exposures & so it is certainly worth contacting occupational health in the event of an exposure (more so than for some other organisms for which occupational health can't offer much!).

Is there any need to avoid sharps when handling purified HSV? It's not mentioned but presumably it's desirable, as with most other Class 2 assessments?

Discuss and accurately define waste parameters.

They could better specify the disinfecting agent(s) that will be used to treat the ultracentrifuge buckets. Virkon is corrosive, so it would damage the seals etc. EtOH would dry out any virions, thus inactivating them, but it would need to be applied thoroughly and left to dry properly.

**Project Ref** 553/19.12
### Purposes of the contained use

Use of attenuated Maraba virus to deliver HIV antigens to promote an immune response to HIV either individually or in combination with other vaccines.

### Recipient or parental organism

Maraba virus - Hazard Group 2

### Host/vector system

Virus stocks will be imported ready made

### Origin & function

The Maraba virus has been modified to have mutations in the L 123W and the Q242R genes. The transgenes to be delivered are synthetic genes coding for chimeric proteins derived from parts of HIV-1 and filovirus genes such as tHIVconscX and FILOcepX. These chimeric proteins are based on conserved regions to give an increased depth of T-cell responses. These artificial proteins have no known enzymatic or biological activity or significant homology to human proteins. They are not expected to increase virulence or decrease the level of attenuation or change the host range of the virus. Standard reporter genes such as GFP or luciferease may also be present in the virus.

### Evaluation of foreseeable effects

Maraba virus is a single stranded RNA virus of the vesiculovirus genus of the Rhabdoviridae family which was isolated from the Brazilian sand fly. It has been genetically modified by mutations L 123W in the gene for the Matrix protein and Q242R in the gene for the glycoprotein. The mutations profoundly affects the ability of the virus to...
replicate in normal cells however it demonstrated a faster replication, a larger burst size, and an increased killing potency in tumor cells, in comparison to the wild-type. Infection of immune cells is abortive. Human phase 1 trials are underway and no adverse effects have been reported other than 'flu like' symptoms with high intravenous doses. Two work place exposures from needlestick injuries lead to milder symptoms. Humans are not a natural host for the virus but tissue tropism has been influenced to improve replication in cancer cells.

The transgenes to be delivered are for artificial proteins and have no known enzymatic or biological activity or significant homology to human proteins. They are not expected to increase virulence or decrease the level of attenuation or change the host range of the virus. Transgene product will be expressed in the cytoplasm of the infected cells before the normal cell shuts down the virus replication.

Standard reporter genes have a history of safe use.

The greatest risk will be from the in-vivo work due to the presence of sharps. These risks will be mitigated by ensuring that workers are suitably trained in procedures before using this virus. The animals will be restrained during inoculations into the tail vein. Sharps will be disposed of immediately and not resheathed. There is published data that reported that no live virus was detected in secretions / excretion and therefore this is an unlikely route of transmission to other animals or workers however standard procedures will be followed and animals and bedding will be treated as infectious.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250C for at least 15 minutes or 126-1300C for at least 10 minutes or 134-1380C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250C for at least 15 minutes or 126-1300C for at least 10 minutes or 134-1380C for at least 3 minutes), or inactivate by chemical means (following manufacturers guidelines), discharge to drains.

Sharps (eg needles, syringes, scalpels) - autoclave then dispose via clinical waste stream for incineration.

Animal bedding - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250C for at least 15 minutes or 126-1300C for at least 10 minutes or 134-1380C for at least 3 minutes), or inactivate by chemical means (following manufacturers guidelines), or via clinical waste stream for incineration.

Animal carcasses - autoclave and dispose via clinical waste stream for incineration.

Degree of kill:
- Autoclaving, effectively 100% kill (annual validation)
- Incineration, effectively 100% kill (licensed inCinerator)
- Chemical, effectively 100% kill (following manufacturers guidelines)

### Purposes of the contained use

Plant pathogens are major causes of crop losses around the world. This work aims to understand plant immunity against various types of plant pathogens.

#### Recipient or parental organism

- **a.** Bacterial plant pathogens such as *Pseudomonas syringae*, *Acidovorax avenae* and similar pathogens.
- **b.** Filamentous plant pathogens such as *Phytophthora infestans*, *Phytophthora capsici*, *Cladosporium fulvum* and similar pathogens.
- **c.** Viral plant pathogens such as tobacco mosaic virus, tobacco rattle virus, potato virus X and similar pathogens.

#### Host/vector system

- E. coli K-12 or B derivatives
- A. tumefaciens (disarmed strains)
- Standard plasmids

#### Origin & function

- **a.** The genomes of *P. syringae* and *A. avenae* will be modified (gene deletion, modification or overexpression) to generate knock out strains, strains with altered expression of endogenous genes as well as strains able to express foreign DNA and standard reporter genes. Target bacterial genes will be selected based on their involvement in disease such as pathogen associated molecular patterns (plant defence elicitors) and putative inhibitors of plant enzymes.

- **b.** The genomes of the plant pathogenic fungus *Cladosporium fulvum* and the plant pathogenic oomycetes *Phytophthora infestans* and *P. capsici* will be modified to generate deletion strains, strains with modified endogenous genes as well as strains able to express standard reporter genes. Target genes in each species will be selected based on their involvement in disease such as effector proteins (pathogen derived modulator of the plant immune system) and will be deleted or modified using gene targeting or CRISPR-Cas9 derived techniques.

- **c.** The gene material inserted in the viral vectors used for protein expression include fluorescent markers (e.g. GFP, RFP); fragments of genes from plants (for VIGS) or effectors (mostly hydrolase inhibitors) from pathogens that we hold under the DEFRA licence (for transient expression). For gene silencing, the viral vectors will carry a 200-400 bp fragment of a plant (*N. benthamiana* or *S. lycopersicum*) gene of interest. This fragment will not encode a full-length protein and it is usually not translated. The fragment triggers the degradation of the targeted plant gene. The overexpression or downregulation of genes in these plants is likely to modify aspects of the physiology of the intervened plants associated to the plant immune system.

### Evaluation of foreseeable effects

A number of the pathogens to be genetically modified are pathogens of crops and require a licence from the relevant regulatory authority to comply with the Plant Health Order. A licence is already in place and the group have extensive experience of working with wild type pathogens.

The modifications to the plant pathogens are not expected to make them more hazardous than the wild type strains. Where they have any observable effect, mutations are likely to reduce plant pathogenesis.

Expression of standard reporter genes has a history of safe use and is not expected to alter the pathogenicity.

Proteins are not expected to be expressed in cloning strains of *E. coli* and *A. tumefaciens* due to promoter specificity.

The pathogens are not known to pose a hazard to humans and the modification are not expected to alter this.

All pathogens will be used for in-vivo inoculations of plants (*N. benthamiana*, *A. thaliana*, tomato and bean). This
poses the greatest risk of loss of containment. Therefore any pathogens transmissible by aerosols will be handled in a Class II micro-biological safety cabinet and will be transported between rooms in sealed containers. Standard laboratory practice should minimise loss of containment for those pathogens requiring direct contact. Plants infected with sporulating plant pathogens will be grown in sealed boxes within growth cabinets. In-vivo inoculations are via syringe inoculation, dip inoculation, spray infection or directly inoculated to plants by rubbing with an abrasive. Infected plants are housed separately to non-infected in either growth chambers or a growth room.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-1300°C for at least 10 minutes or 134-1380°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial waste stream for landfill. Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-1300°C for at least 10 minutes or 134-1380°C for at least 3 minutes), or inactivate by chemical means (following manufacturers guidelines), discharge to drains. 2% virkon for at least 30 mins is effective against the pathogens being used.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-1300°C for at least 10 minutes or 134-1380°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial waste stream for landfill.

Sharps (eg needles, syringes, scalpels) - sharps are not used but syringes are dispose via clinical waste stream for incineration. Sharps bins are autoclaved prior to disposal.

Plant material and soil - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-1300°C for at least 10 minutes or 134-1380°C for at least 3 minutes), discharge via the industrial waste stream for landfill.

Degree of kill:

- Autoclaving, effectively 100% kill (annual validation)

Tick if you are claiming exemption from disclosure for section of the risk assessment N
The GMSC had comments on:-
1) movement between locations.
   we use sealed propagation boxes to move inoculated plants between CL2 rooms on the 2nd and 3rd floor;
2) containment for spray inoculations and volumes.
   we use the Class-II safety cabinet in the inoculation room for spray inoculations;
3) Clarify how inoculations are done.
   we will use the CL2 inoculation room and laboratory for droplet inoculations, infiltrations and dip inoculations when the
   risk of aerosols are negligible;
4) Containment of spores from sporulating pathogens.
   we will only open sealed boxes with sporulating GM pathogens in the Class-II safety cabinet;
5) Did access to the room containing growth cabinets need to be restricted.
   no door lock is needed for room S210 since there is restricted access to the building and a clear sign on the door and
   on the relevant growth cabinets that it is a CL2 lab containing licenced pathogens. Sporulating plant pathogens will
   only be in sealed boxes inside one of these cabinets;
6) Transport of waste to the autoclave.
   waste bags containing plant pathogens will be sealed before taken to the autoclave in the basement.

The aim of this research is to determine the structure and biochemically characterise clinically relevant membrane proteins. In order to generate large quantities, we wish to use lentivirus to stably integrate the gene into mammalian cells.

Recipient or parental organism

Standard mammalian cell lines
Replication defective lentiviral systems such as a 3 plasmid system.

Host/vector system

Standard E. coli K-12 and B deriviatives and non-mobilisable or mobilisation defective plasmids.

Origin & function

Peptide transporters, organic anion transporting polypeptide transporters, nucleotide sugar exchangers, amino acid transporters, such as
SLC15 Peptide transporters
SLC19 Vitamin transporters
SLC35 nucleotide sugar transporters
SLC6, 7, 36, 38 amino acid transporters
SLC22 organic anion transporter
SLC16 monocarboxylate transporters
Inducible promoters e.g. Tet on / off.
WPRE element
di and tri peptides
thiamine, folic acid
nucleotide sugars
amino acids
monoamine neurotransmitter, carnitine, cAMP, urate
lactate, pyruvate
Inducible promoters e.g. Tet on / off.
WPRE element

**Evaluation of foreseeable effects**

Replication defective lentiviral particles can enter mammalian cells and integrate randomly into the host genome however they cannot replicate and spread. The genes required for viral particles are split onto multiple plasmids significantly reducing the likelihood of generating replication competent virus. There is the potential for the random integration to knock out a tumour suppressor gene however the likelihood of this occurring is minimal.

None of the inserted genetic material is expected to pose a risk. in addition the genes are often driven by an inducible promoter and as such wouldn’t be expressed outside of laboratory conditions. The lentiviral vectors contain the WPRE element which may have potential oncogenic activity and therefore a precautionary approach is taken.

**Project Additional Information**

**Purposes of the contained use**
The aim of the project is to characterise the cellular and molecular biology of haematopoietic stem and progenitor cells (HSPCs) and how these become disrupted during the development of myeloid malignancies. Molecular targets identified in our studies will be mechanistically validated using a combination of retroviral or lentiviral overexpression/knockdown or CRISPR/CAS9 mediated genome editing.

**Recipient or parental organism**
- Standard E. coli K-12 and / or B derivatives - class 1
- Mammalian cells, such as TF1, HL60, K562 etc
- Primary haematopoietic cells, murine and human
- Viral producer cells, such as HEK293 derivatives or NIH3T3 derivatives

**Host/vector system**
- Standard replication defective lenti and retroviral particles generated by transfection of producer cells with multiple vectors providing necessary genes, such as Gag, pol, env and gene of interest.

**Origin & function**
The proteins under study, e.g. MPL, NF1, KRAS, G6B are expected to influence aspects of lineage choice, selfrenewal and/or differentiation in the final haematopoietic recipients, reflecting what is known or suspected of their normal biological function.
- Standard reporter genes, such as GFP
- Standard antibiotic resistance genes, such as ampicillin,
- Many lentiviral vectors also contain WPRE which is potentially an oncogene.
- CRISPR / Cas 9 and guide RNA

**Evaluation of foreseeable effects**
Some of the gene products are potentially oncogenic, for example, through modification of self-renewal or proliferation pathways. We are interested in targeting both tumour suppressor and oncogenes known to be associated with the development of haematological malignancies. As such they could have potentially harmful consequences.
- Standard reporter genes have a history of safe use.
- Standard antibiotic resistance genes have a history of safe use.
- Amphotropic retroviruses pose minimal risk to human health as they cannot enter human cells and being replication defective pose minimal risk to the environment.
- CRISPR/CAS9 allow targeted mutation of specific genes. Off target mutations will be minimised by blast searches comparing guide RNA with the genome.
- Mammalian cells which have been transduced by the virus will be used in vivo. As the viruses are replication defective
they pose minimal risk once they have integrated into the cellular DNA and the cells can be handled at the same containment as the unmodified ones.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

We aim to understand basic principles of host recognition and control of virus infections and of mechanisms by which immune responses are regulated including understanding viral strategies for evading immune control. Replication-defective lentivirus or other retroviruses will be used to modulate or edit gene expression.

Recipient or parental organism

- Standard E. coli K-12 for cloning (class 1)
- Mammalian cells, such as HEK293, Jurkat, Hela and Vero
- Primary cells, including human PBMCs and isolated T cells

Host/vector system

- Standard systems for generation of replication defective Lentivirus and retrovirus where genes required for virion production are split onto multiple plasm ids.
**Standard virus produced cells, typically based on HEK293 cells**

**Origin & function**

Mammalian genes or viral genes (fragments, mutants or tag versions) typically encoding viral receptors or proteins with roles in the host immune system, such as MHC molecules, T cell and NK cell receptors and co-stimulatory molecules, cellular ligands for NK receptors and costimulatory molecules, cytokines/chemokines, antiviral proteins. Genes derived from viruses, particularly herpesviruses

- shRNA or RNAi
- CRISPR I Cas 9 gene editing system including guide RNA
- Standard reporter genes, such as GFP
- Standard antibiotic resistance genes, such as geneticin
- WPRE gene

**Evaluation of foreseeable effects**

Replication defective lentivirus and retroviruses have had all non-essential genes removed from the vectors and the remaining genes split onto separate plasmids with minimal homology to reduce the risk of homologous recombination. As they are replication defective they are unable to disseminate within the host or environment. They do however integrate into the host genome and as such there is the potential for insertional mutagenesis. Also many lentiviral systems contain the post-transcriptional regulatory element from the woodchuck hepatitis virus, which may potentially have oncogenic activity.

The genes to be expressed, knocked down or edited are not expected to be hazardous. They are not known to increase the survival of the GMO, nor increase their ability to evade the immune system. None of the genes to be expressed or modified are known oncogenes.

CRISPR/Cas 9 has become a common tool for targeted gene modification. The guide RNA targets the Cas9 nuclease to introduce a break at a specific site in the genome, repair of which introduces mutations/indels into the targeted gene.

Standard reporter genes and antibiotic resistance genes have a history of safe use.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-1300°C for at least 10 minutes or 134-1380°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream.

Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-1300°C for at least 10 minutes or 134-1380°C for at least 3 minutes), or inactivate by chemical means (following manufacturers guidelines), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-1300°C for at least 10 minutes or 134-1380°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream.
Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration. No sharps will be using in conjunction with the replication defective viruses.

Degree of kill:
- Autoclaving, effectively 100% kill (annual validation)
- Incineration, effectively 100% kill (licensed incinerator)
- Chemical, effectively 100% kill (following manufacturers guidelines)

Is an emergency plan required according to regulation 20? [N]

### Project Additional Information

#### Purposes of the contained use

This project aims to use lentivirus to study the role of genes in regions associated with the risk of developing multiple autoimmune diseases. Related genes acting in the same signalling pathways or biological processes may also be investigated.

#### Recipient or parental organism

- Standard mammalian cells, such as HEK293, Jukat and THP-1
- Primary mammalian cells

#### Host/vector system

- Standard replication defective lentiviral systems where the genes, such as gag-pol and env are split on to separate plasmids. All non-essential genes are deleted.
- Viral producer cells, such as HEK293 derivatives

#### Origin & function

- Overexpression, knockdown or mutation of genes associated with the risk of developing multiple different autoimmune diseases or related genes acting in the same signalling pathways, such as Tyrosine kinase 2 (TYK2), Interleukin-12 receptor B1 and B2 (IL 12RB1) and (IL 12RB2), Interleukin-23 receptor (IL23R), Interferon alpha and beta receptor subunit 1 and 2 (IFNAR1 and IFNAR2). TYK2 is a member of the Janus-activated kinase family and plays a key role in the signal transduction pathway of many cytokines, including type 1 interferons, IL-12, and IL-23. IL 12RB1 and B2 are a cytokine receptor chain shared by the IL-12 and IL-23 cytokine receptor. IL23R is a cytokine receptor chain of the IL-23 cytokine receptor. IFNAR1 and 2 are a cytokine receptor chain of the IFN-alpha and IFN-beta receptor.
- CRISPR Cas 9/ guideRNA and TALENS used to create specific mutations to genes
- Standard marker or reporter genes such as LacZ, fluorescent proteins, luciferase etc
- Standard antibiotic resistance genes, such as amp, kan, hygro etc
- WPRE - Woodchuck post regulatory element.

#### Evaluation of foreseeable effects

- Replication defective lentiviral particles are capable of integrating into the host genome and as such have the potential for insertional mutagenesis. This risk is minimised as no sharps are used in conjunction with the virus. Once integrated the particles are incapable of producing more viral particles as the necessary genes are not present. Many lentiviral systems contain the post-transcriptional regulatory element from the woodchuck hepatitis virus (WPRE) which could potentially have oncogenic activity.
The inserts are not expected to have harmful physiological or pharmacological properties. All genes to be investigated have only small individual effects on overall disease risk as the genes are non-HLA genes and are candidates for common (not monogenic) autoimmune diseases. Thus no single gene studied would be capable of causing autoimmune disease upon manipulation. Modification of the genes is not expected to increase their hazard. TALENS and CRIPSR-Cas9 will be used to modify the genes at specific locations. Off target results will be minimised by using highly specific guides and checking specificity bioinformatically. Standard reporter genes and antibiotic resistance genes have a history of safe use.

Appropriate containment and control measures have been assigned in accordance with the latest guidance issued by ACGM.
This project aims to explore the mucosal immune responses to bacterial infection in airways disease and their modulation by macrolides and immune cell ligands.

Recipient or parental organism

Hazard Group 2 bacteria such as Haemophilus influenzae, Moraxella catarrhalis, Streptococcus pneumoniae, Pseudomonas aeruginosa and Staphylococcus aureus.

Standard laboratory strains of E. coli K-12.
**Host/vector system**

Mobilisation defective plasm ids such as PLS88 and PeJ18

**Origin & function**

Antibiotic resistance genes, such as those resistant to azithromycin.
In addition the plasm ids will contain standard antibiotic resistance genes, such as Kanamycin for cloning purposes and selection of resistant clones.

**Evaluation of foreseeable effects**

Respiratory pathogens used in this work will be hazard group 2 pathogens. These pathogens are opportunistic and generally only cause disease in compromised hosts.
The introduction of a single antibiotic resistance gene will confer resistance to that antibiotic. However, the bacteria will still be treatable with other classes of antibiotics.
Procedures that generate aerosols will be carried out within a class II micro-biological safety cabinet. Where FACS is carried out the samples will be fixed prior to analysis. If sorting is required it will be done in a system with aerosol management in place.
Mice will be intranasally infected with small volumes of bacteria. These infections will be carried out within a class II micro-biological safety cabinet. After a designated period of time samples will be homogenised and CFU counts obtained. All work will be done in a class II MSC.
As the antibiotic resistance gene is on a mobilisation defective plasmid, it's introduction into a standard laboratory strain of E. coli ·K-12 is not expected to overcome the attenuations of the strain and the work can be carried out at Class 1.

## Project Additional Information

### Purposes of the contained use

This project aims to study the HIV budding process in the context of native host cells, using cellular cryo-electron tomography (cryoET) and correlative live-cell and cryoET imaging in super-resolution.

### Recipient or parental organism

Mammalian cell lines such as U2OS, COS? and U3?3-MAGI

Human Immunodeficiency Virus

### Host/vector system

- Non-mobilisable plasmids encoding full molecular sequence of HIV.
- E. coli K-12 or B derivatives

### Origin & function

Standard marker genes such as GFP and other fluorescent tags.

Various mutants of HIV typically those of genes in the late domain which are involved in subverting the cellular machinery that regulates cargo sorting, membrane remodelling and fission processes, the Endosomal Sorting Complex Required for Transport (ESCRT) machinery. For example PTAP late domain, YPxL late domain and YP late domain.

### Evaluation of foreseeable effects

E. coli K-12 and B derivatives are disabled hosts which are used for cloning purposes. Protein expression does not occur due to the lack of bacterial promoters. Protein expression only occurs in eukaryotic cells. Accidental exposure poses minimal risk as the bacteria are non-colonizable, the amount of plasmid DNA present is low and the transfection efficiency of naked DNA is insignificant. Good Microbiological Practice will minimise the risk of exposure.

Work assigned to class 1

Transfection of mammalian cells with the plasmid will lead to the production of HIV.

The late-domain mutants are being compared with wild type to assess the effect on localisation in the cell, gag lattice morphology, presence of lattice gaps, evidence of maturation and other structural features. It is not expected that these mutants will present any greater hazard than the wild type.

Addition of standard reporter genes is not expected to alter the hazard from that of the wild type.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) - inactivate by chemical means then autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - inactivated by chemical means then autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge to drains.

Research into the molecular cell biology of various kinetoplastid parasites, primarily the generation and function of cell organisation to address questions about the function of cell shape and structure on motility.

Kinetoplastids such as
Hazard group 3 - Leishmania donovani, Leishmania braziliensis, Trypanosoma brucei rhodesiense
Hazard group 2 - Leishmania mexicana, Leishmania major, Trypanosoma brucei brucei, Trypanosoma brucei gambiense
Hazard group 1 - Leishmania Tarentolae, Crithidia (fasciculata, oncopelti, deanei) and Herpetomonas (megaseliae and roitman)
Trypanosoma brucei are specified animal pathogens and will also comply with those regulations.

E. coli K-12 and standard plasmids or
Homologous recombination of linear DNA

The main class of genes which will be subjected to targeted mutations or expressed exogenously are proteins involved in the core biochemistry or molecular biology of the cells. This will primarily involve: Cytoskeletal and flagellar
genes, such as microtubule associated proteins, microtubule motor proteins and regulatory secondary messenger binding proteins, membrane (particularly flagellar) proteins; housekeeping genes involved in the generation of the cytoskeleton and flagellum, such as intraflagellar transport proteins, cargo adapter proteins and enzymes regulating their function or sensing the environment; genes involved in the targeting of proteins to particular cellular compartments or structures, such as RAB/RAN GTPases potentially regulating organelle targeting, structural components like transition zone proteins and transmembrane protein transporters; and genes involved in the regulation of the expression of these proteins, such as mRNA binding and degrading proteins, nuclear compartment proteins and transcription regulatory factors.

Also RNA to interfere with expression of exogenous genes
Standard antibiotic resistance genes
Standard reporter genes
CRISPRI Cas 9 (or similar) technology

**Evaluation of foreseeable effects**

Genetic modifications will involve genes expected to be involved in the fundamental cell biology or biochemistry of the cell and are expected to either reduce cell viability and attenuate virulence or to be neutral for use as a molecular cell biology tool. It is extremely unlikely that these genetic modifications will increase virulence as the core biochemistry of the cell has been heavily selected through evolution for cell viability therefore any change is likely to be detrimental. It is not plausible that these changes will affect host range, widen tissue tropism or reduce sensitivity of the parasite to host immune defences. It is also considered that no new risks could be created through the transfer of any cryptic gene to a potentially pathogenic species background.

The mutants generated will be phenotypically and genetically stable with negligible potential for unintended transfer of genetic material. Mutants are likely to be of reduced fitness to wild-type organisms (as outlined in the project overview) with no possibility of increasing the vector or host range, enhance or widen issue tropism or decreasing susceptibility to destruction by the immune system.

Drug selectable markers used are unrelated to the primary therapeutic agents for the parasites.

Standard reporter genes are not expected to increase the pathogenicity and have a history of safe use.

CRISPRiCas 9 technology will be used for directed modification of the endogenous loci. Expression of the Cas 9 protein is not expected to increase the pathogenicity of the parasites.

In vivo work poses a risk due to the use of needles. A standard operating procedure detailing use of sharps will be produced for the work and individuals will be well trained on procedures using less hazardous micro-organisms in the first instance. Parasites are not transmissible via saliva or excreta but a bite could generate an open wound which provides a site for potential exposure. Experimental infection of the insect vector (sandflies or tsetse flies) involves feeding a blood meal (or analog) mixed with parasites. Insects are maintained in sealed and/or netted containers within a dedicated insectarium with a standard operating procedure detailing monitoring of insects and dealing with escapees.

Live cell microscopy will require the use of glass slides and coverslips and specialised glass bottomed fluidic chambers. A standard operating procedure for the handling of this will be produced.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Laboratory sealable for fumigation - As these parasites are not normally infectious by the airborne route and are rapidly killed outside of a host or controlled culture conditions by dessication, osmotic shock, and detergents,
fumigation would not be required. Use of micro-biological safety cabinet - parasites are not transmitted via aerosols (although in reality most work will be done in an MSC for sterility reasons)

Specific measures to control aerosol dissemination - parasites are not transmitted via aerosols and are rapidly killed outside of the host or controlled culture conditions by dessication, osmotic shock and detergents.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-1300°C for at least 10 minutes or 134-1380°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-1300°C for at least 10 minutes or 134-1380°C for at least 3 minutes), or inactivate by chemical means (following manufacturers guidelines), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-1300°C for at least 10 minutes or 134-1380°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (eg needles, syringes, scalpels) - Where possible sharps will be avoided however some use is essential and they will be disposed via clinical waste stream for incineration.

Animal bedding - EITHER autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-1300°C for at least 10 minutes or 134-1380°C for at least 3 minutes), dispose via the industrial (black bag) waste stream for landfill OR dispose via clinical waste stream for incineration.

Animal carcasses - dispose via clinical waste stream for incineration.

Solid insect food and dead insects - EITHER autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-1300°C for at least 10 minutes or 134-1380°C for at least 3 minutes), dispose via the industrial (black bag) waste stream for landfill OR dispose via clinical waste stream for incineration.

Degree of kill:

Autoclaving, effectively 100% kill (annual validation)

Incineration, effectively 100% kill (licensed incinerator)

Chemical, effectively 100% kill (following manufacturers guidelines)

Is an emergency plan required according to regulation 20? N

Page 9286 of 15326
Project Additional Information

**Purposes of the contained use**

The purpose of this research is to use lentiviruses to deliver genetic elements to specific brain regions or mammalian cell lines to test the genes’ role in sleep homeostasis. In doing so, this project will provide evidence for or against the hypothesis that these genes are crucial to the regulation of mammalian sleep in the regions that have been targeted.

**Recipient or parental organism**

| E. coli K-12 or B derivatives |
| Mammalian cells |
Host/vector system

Plasmids are standard non-mobilisable or mobilisation defective. The viral genes, generally gag, pol and env, derived from lentiviruses such as HIV, MoMLV and EIAV, are divided onto different plasmids, with the gene of interest also being on a separate plasmid. Producer cell lines, such as HEK293 cells or derivatives of.

Origin & function

shRNAs or microRNAs targeting ion channels and related subunits
Genes involved in function of neurons or processes within such as Kcnab1-3
Reporter genes (e.g. GFP, luc etc)
Standard antibiotic resistance (e.g. chloramphenicol, ampicillin, etc)

Health and Safety

Normal mammalian (e.g. TRPV1, P2X2) or algal (e.g. channelrhodopsin-2) ion channels or selective alterations of those channels
Genome editing tools (e.g. TALENs, Cas9-CRISPR)
Mitochondrial electron transport chain elements (e.g. SOG1, AOX)
Producers of oxidative agents (e.g. miniSOG)
Redox sensors (e.g. MitoTimer)
Oxidative stress-reducing agents (e.g. Glutathione peroxidase)
Woodchuck hepatitis virus post transcriptional regulatory element

Evaluation of foreseeable effects

Genes are not expected to be expressed in E. coli - therefore cloning in E. coli is class 1

Contained Use Notification

The lentiviral particles are able to transduce a wide variety of cells however due to their replication defective nature they are only capable of a single round of infection. Replication defective lentiviruses have key genes (gag, pol, rev and env) separated onto separate plasmids with minimal homology. Separating the DNA required for virion production onto 3 plasmids with minimal homology means there is minimal risk of homologous recombination. A third plasmid contains the gene of interest along with cis-acting signals required for reverse transcription and integration. As the gag, pol, rev and env plasmids do not contain packaging sequences none of the genes are present in the packaged viral genome.

The packaged sequence may contain the post-transcriptional regulatory element from the woodchuck hepatitis virus (WPRE) which may have oncogenic potential.

The main risk with lentivirus would be the random integration into the host genome resulting in a disruption of a gene function. However control measures reduce the likelihood of that occurring. As the virus particles are replication defective dissemination into the environment is unlikely.

The inserts to be delivered to the target neurons and cell lines are not expected to be toxic or oncogenic. The inserts are all deemed not to increase the pathogenicity or alter the tropism of the virus.

The greatest risk comes from the use of sharps for the in vivo work. Injections are done using stereotaxic equipment and fine glass 'needles' which minimises contact.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250C for at least 15 minutes or 126-1300C for at least 10 minutes or 134-1380C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250C for at least 15 minutes or 126-1300C for at least 10 minutes or 134-1380C for at least 3 minutes), or inactivate by chemical means (following manufacturers guidelines), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250C for at least 15 minutes or 126-1300C for at least 10 minutes or 134-1380C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (eg needles, syringes, scalpels) - autoclave then dispose via clinical waste stream for incineration.

Animal bedding - autoclave using a make safe cycle as specified in BS 2646, Part 3,1993 (either 121-1250C for at least 15 minutes or 126-1300C for at least 10 minutes or 134-1380C for at least 3 minutes), dispose via the industrial (black bag) waste stream for landfill.

Animal carcasses - dispose via clinical waste stream for incineration.

Degree of kill:
 Autoclaving, effectively 100% kill (annual validation)
 Incineration, effectively 100% kill (licensed incinerator)
 Chemical, effectively 100% kill (following manufacturers guidelines)

### Project Ref 553/20.2

**Date Ackn’ed**: 15/01/2020

**CU2 Project Title**: Molecular genetics of interorganelle communication

**Class**: Class 2

**CultureVolClass2**: < 1 Litre

**CultureVolumeClass3-4**: Non-GMM

**Consent Granted**: Yes

**Withdrawn**: No

**Tick if notifying a connected programme of work**: N

**Historical Significant Changes**

**Historical Date of Additional Info**

**Significant Change ID**

**Date of Significant Change**

### Project Additional Information

**Purposes of the contained use**

Use of replication defective lentivirus to study interorganelle communication

**Recipient or parental organism**

E. coli K-12 and B derivatives

Mammalian cell lines

**Host/vector system**

Plasmids are standard non-mobilisable or mobilisation defective.

Health and Safety

Executive

Activity Notification

Standard replication defective lentiviral vectors where the gag, pol, env and the gene of interest are split across 3
plasm ids
Producer cell lines, such as HEK293 and their derivatives.

Origin & function
Proteins involved in organelle tethering, lipid transport or organelle fission, such as cytoskeleton associated proteins (Miro, Cenp-f), Fission machinery (MFF, DRP1, MID49, MID51), lipid modifying proteins (cyclopropane fatty acid synthase, PE methyl transferase, PS decarboxylase)
Standard selection markers (auxotrophies, resistance to chemicals), detectable markers (fluorescent, luminescent proteins, epitope tags), lipid modifying and membrane targeting proteins from non-pathogenic organisms (E. coli, Acetobacter aceti), or enzymes necessary for genomic modifications (Cre recombinase, flp recombinase, Ac transposase, Cas9 nuclease)
Some of the genes are from pathogens however at no point will the pathogen be handled. Genes will be obtained in plasmids. e.g. TEV protease from tomato etch virus, HA from H. influenzae, Cas9 nuclease from S. pyogenes

Evaluation of foreseeable effects
Genes are not expected to be expressed in E. coli - therefore cloning in E. coli is class 1.

Executive
Activity Notification
The lentiviral particles are able to transduce a wide variety of cells however due to their replication defective nature they are only capable of a single round of 'infection'. Replication defective lentiviruses have key genes (gag, pol and env) separated onto different plasm ids with minimal homology. Separating the DNA required for virion production onto 3 plasm ids with minimal homology means there is minimal risk of homologous recombination. The plasmid with the gene of interest has the cis-acting signals required for reverse transcription and integration. As the gag, pol and env plasm ids do not contain packaging sequences none of the genes are present in the packaged viral genome. The packaged sequence may contain the post-transcriptional regulatory element from the woodchuck hepatitis virus (WPRE) which may have oncogenic potential.
The main risk with lentivirus would be the random integration into the host genome resulting in a disruption of a genes function. However control measures reduce the likelihood of that occurring. As the virus particles are replication defective desemmination into the environment is unlikely.
The inserts to be delivered are not expected to increase the hazard of the lentiviral particles.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250C for at least 15 minutes or 126-1300C for at least 10 minutes or 134-1380C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.
Liquids (eg samples, culture supernatants, tissue culture media) -autoclave using a make safe cycle as specified in
BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-1300°C for at least 10 minutes or 134-1380°C for at least 3 minutes), or inactivate by chemical means (following manufacturers guidelines), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-1250°C for at least 15 minutes or 126-1300°C for at least 10 minutes or 134-1380°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (e.g., needles, syringes, scalpels) - dispose via clinical waste stream for incineration. However not used in conjunction with lentivirus particles.

Degree of kill:
- Autoclaving, effectively 100% kill (annual validation)
- Incineration, effectively 100% kill (licensed incinerator)
- Chemical, effectively 100% kill (following manufacturers guidelines)

</tbody>
</table>
**Project Additional Information**

**Purposes of the contained use**

Use of a modified MVA to produce vaccines against many pathogens

**Recipient or parental organism**

Modified Vaccinia Ankara is a replication deficient viral vector (due to abortive infection) that was derived from the vaccine used to eradicate smallpox. It is employed widely in the development of vaccines and has a history of safe use.

**Host/vector system**

- E. coli and BAC-MVA for modifying the genome
- Vero (African green monkey) cells for production of the virus
- other mammalian cell line and primary cells

**Origin & function**

- Deletion of a single gene in left terminal region
- Standard marker genes such as GFP etc.
- Genes encoding proteins expressed either for the purpose of generating an immune response (as an antigen) or to enhance the immune response to the vector (as an adjuvant) may be inserted.
- Some inserted genes may express pathogen glycoproteins. These could potentially be incorporated into the MVA membrane and change the cell tropism of MVA VerOX. Genetic material will be synthetically synthesised and not obtained from micro-organisms.
- Vaccines against many diseases are being investigated but examples include Nucleoprotein (NP) and Matrixprotein (M1) from influenza, antigens from Mycobacterium tuberculosis, HIV and malaria.

**Evaluation of foreseeable effects**

- MVA-BAC - the genome of MVA and its derivatives in DNA form is non-infectious and cannot generate virus without the aid of a helper virus (generally attenuated fowlpox, FP9)
MVA is a naturally attenuated virus which is severely host restricted and can't replicate in human cells. A single deletion was created in the left terminal region leading to a strain which showed limited replication in Vero cells. This strain was then passaged more than 40 times in Vero cells which resulted in a strain that could replicate to significantly greater levels than the original making it practical for vaccine manufacturing. This passaging lead to other natural deletions within the MVA genome. When tested in human cell lines (HEK293 and Huh7.5) the mutant strain showed the ability to replicate and show cytopathic effects. Therefore the work is being reassigned to class 2 while further work is done to assess replication in other human cells (both cell lines and primary cells). As a vaccine strain this will be used to express standard marker genes such as GFP etc and the expression of these proteins should not increase the risk. Also genes encoding proteins expressed either for the purpose of generating an immune response (an antigen) or to enhance the immune response (an adjuvant). Inserts will not be oncogenic, allergenic or toxic. Some inserted genes may express pathogen glycoproteins. These could potentially be incorporated into the MVA membrane and change the cell tropism of MVA VerOX. These proteins will be modified to ensure either secretion of the glycoprotein or mutations in the receptor binding domain of the glycoproteins to block cell tropism. Genetic material will be synthetically synthesised and not obtained from micro-organisms. The inserts are expected to generate an immune response to provide protection against the pathogen. Vaccines will be used for in-vivo work. Inoculations will take place in a class II micro-biological safety cabinet. Accidental needlestick injuries are a potential route of exposure however all staff are well trained and competent in the procedures using hazard group 1 / class 1 viruses. Animal bites could also be a potential route of infection and all staff are aware of first aid procedures and symptoms of infection.

N/A

Containing and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Project Ref 553/20.4

Date Ackn'd: 05/03/2020

CU2 Project Title: The role of the host AHR in sensing bacterial infection

Class: Class 2

Consent Granted: Not Applicable

Project notified under transitional arrangements [N]

Tick if notifying a connected programme of work [N]
**Project Additional Information**

**Purposes of the contained use**
To study the communication system between bacterial pathogens and their hosts.

**Recipient or parental organism**
Hazard groups 2 bacteria such as Pseudomonas aeruginosa

**Host/vector system**
The majority of the modified P. aeruginosa have been generated elsewhere although some may be created in house in the future.
E. coli K-12 or B derivatives, such as DHSalpha and Top10 and standard plasmids such as those based on pUC backbone. Cell lines and organoid model systems Zebrafish larvae.

**Origin & function**
Modification of the genes involved in quorum sensing such as phz, lasR, rhlR
Standard reporter genes such as fluorescent (GFP) and luminescence (Lux) genes

**Evaluation of foreseeable effects**
Quorum sensing (OS) plays a major role in biofilm formation and virulence. Modification to the OS associated pathway genes are expected to decrease biofilm forming potential and reduce potential pathogenicity of the resulting strains.
Addition of standard reporter genes is not expected to alter the ability to form biofilms or the virulence.
Standard work with cell lines or organoids exposed to bacteria will be done in a class 2 MSC.
Injections into zebrafish embryos will involve 5nl and will be done using a micromanipulator so there is no direct handling of the needle once it has been loaded with minimal likelihood of aerosols being generated.

02/03/2022
Investigating malnutrition-associated intestinal inflammation and impact on cryptosporidium infection

Study using genetically modified Cryptosporidium in-vitro and in-vivo to assess effects of modulating intestinal immune regulatory function, modulating diet and host-microbiota cross-talk.

Recipient or parental organism
Cryptosporidium tyzzeri

Host/vector system
The genetic modification involves CRISPR-Cas driven homologous recombination.

Origin & function
Standard reporter genes such as luciferase and mCherry
Standard antibiotic resistance genes such as Neomycin
Expression of model antigen / peptide e.g. ovalbumin epitope SIINFEKL integrated into a parasite protein that is ordinarily exported into infected epithelial cells e.g. MEDLE2 in orer to explore the generation of antigen specific immune responses.

Evaluation of foreseeable effects
Cryptosporidium tyzzeri is a apicomplexan protozoal parasite that was isolated from a wild mouse. It is generally considered to be a mouse pathogen however infections
have been detected in humans and as such shows zoonotic potential. Route of infection is oral - faecal

In immuocompetent hosts infection is generally self limiting. Immuno compromised individuals are at risk of prolonged infection and complications.

The addition of standard reporter genes and standard antibiotic resistance genes is not expected to alter the pathogenicity of the parasite nor alter its host range.

The addition of model antigen / peptide is not expected to alter the pathogenicity of the parasite nor alter its host range.

Suspensions of oocysts will be used for infection studies via oral gavage using blunt needles.

</tr>
</tbody>
</table>

### Evaluation of foreseeable effects

<table>
<thead>
<tr>
<th>Effects</th>
</tr>
</thead>
<tbody>
<tr>
<td>E. coli work - class 1 Genes are driven by mammalian promotors and therefore are not expected to be expressed in E. coli</td>
</tr>
<tr>
<td>Lentiviral vectors provide a means of transducing otherwise hard to transfect cell types (e.g. monocyte cell lines), and they also enable stable expression of genes within cells. These systems split essential genes (Gag, Pol, Rev and Env) along with the transgene of interest onto mutiple plasmids. Within the cells the vector sequence is generated and is packaged into infectious lentiviral particles that are released into the supernatant. These can then be harvested and used to infect cell lines of interest. However as these vector particles do not encode all the genes necessary for viral replication, the cells infected will not produce viral particles, and there will be no further viral spread. Lentivirus has the potential to cause insertional mutagenesis and as such the use of sharps will be minimised. Once the mammalian cells have been transduced and viral media removed they are safe to be handled as class 1 due to the replication defective nature of the virus.</td>
</tr>
<tr>
<td>Standard reporter genes and antibiotic resistance genes have a history of safe use and are not expected to increase the hazard posed. Some of the genes whose expression is being modulated could potentially be oncogenes or affect proliferation as disruptions to the genes either overexpression, decreased expression or mutations are often linked to various cancers. However it is likely that other factors also contribute to formation of cancers. To minimise potential exposure sharps will not be used in conjunction with the viral particles and an MSC will be used. CRISPR/Cas 9 is now a frequently used tool to create specific mutations in genes. As with the lentivirus, modulation of the expression of genes of interest could alter the proliferation of transduced cells. As such the use of an MSC and no sharps policy will be implemented.</td>
</tr>
</tbody>
</table>

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) –autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), or inactivate by chemical means (following manufacturers guidelines), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (eg needles, syringes, scalpels) - Not used

Degree of kill:
- Autoclaving, effectively 100% kill (annual validation)
- Incineration, effectively 100% kill (licensed incinerator)
- Chemical, effectively 100% kill (following manufacturers guidelines)

Project Ref 553/21.1

Date Ackn'd CU2 Project Title Class CultureVolClass2 CultureVolumeClass3-4

02/03/2022
Antigen processing and presentation of viral epitopes to T cells

T cells are activated following recognition of viral epitopes on HLA molecules on the cell surface of, mostly, antigen presenting cells. Our aim is to identify and investigate the viral epitopes presented to T cells and determine how these epitopes are generated through antigen processing. By using replication impaired lentiviral vectors, target genes will be delivered to cell lines for high-level and long-term expression. We will then investigate the T cell response to these viral proteins as well as manipulating components of the antigen processing pathway to determine how each viral protein is processed within the cell.

Recipient or parental organism

- mammalian cells
- HEK293 cells (and derivatives)
- Primary human cells

Host/vector system

- E. coli K-12 or B derivatives
- Standard non-mobilisable or mobilisation defective plasmids.
- Standard replication defective lentivirus systems

Origin & function

Our initial focus for these studies will be SARS-CoV-2 but this work is likely to expand to other viral infections in the future but any risks will be similar.

1. Generate B cell lines with stable expression of SARS-CoV-2 proteins:
   a. Individual expression of Spike, Nucleoprotein, Membrane protein, ORF3a, ORF7a, ORF7b, ORF8
   b. Tandem expression of Spike + Nucleoprotein, Nucleoprotein + ORF3a, Nucleoprotein & ORF7a, Nucleoprotein + ORF7b, Nucleoprotein + ORF8
2. Generate B cell lines with natural mutations within SARS-CoV-2 proteins:
   a. Mutations within ORF3a and Nucleoprotein
3. Generate B cell lines with stable expression of the human receptor ACE2 for live infection assays of these cells to confirm data seen in cell lines with individual SARS-CoV-2 proteins.

Standard reporter genes such as GFP (and derivatives), luciferase and epitope tags
Standard Antibiotic resistance genes such as Amp, Kan, Gen

WPRE - Woodchuck hepatitis virus post-transcriptional regulatory element

### Evaluation of foreseeable effects

Standard replication defective lenti (or retro) viral particles will be used. The genetic material is split onto a number of separate plasmids with a number of genes from the original virus omitted. These insert their genetic material into the host genome and as such could potentially cause insertional mutagenesis.

Individual expression of viral proteins holds little risk as no viral particles could be generated in these cells.

It has been shown that spike alone can induce a neutralising antibody response in murine studies. However, it has also been shown that expression of spike protein alone is sufficient to induce syncytia formation of ACE2 expressing cells. This was only true for some cell lines and was shown to be inhibited by the presence of IFITM1 protein at the cell surface which is naturally expressed by B Cell Lines. Additionally, B cell lines do not naturally express ACE2 which should prevent syncytia formation. ORF3a alone has been shown to induce apoptosis of cell lines when expressed individually.

Tandem expression of two proteins should still prevent the propagation of viral particles due to a lack of genes necessary for propagation.

Addition of ACE2 to B cells will increase their infection by SARS-CoV-2 but this tool is essential for these experiments and labs across the world are using ACE2-transduced cell lines for these experiments. A number of human cell types already express the ACE2 receptor. Potential exposure to the virus containing this insert is minimised by the use of a Class II MSC and not using sharps.

Standard reporter genes are not expected to be hazardous and have a history of safe use.
Standard antibiotic resistance genes are not expected to be hazardous and have a history of safe use.

Some concern has been raised with regards to the potential oncogenic activity of the post-transcriptional regulatory element from the woodchuck hepatitis virus (WPRE), which is frequently included to increase transgene expression in lentiviral systems.

Sharps will not be used in preparations containing virus particles or transfected packaging cells. Thus, reducing the chances of such exposure

FACS analysis may be utilised however once the replication defective lentivirus has integrated into the hose genome it poses minimal risk. Cells will be washed to remove any unbound viral particles.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15
minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) –autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), or inactivate by chemical means (following manufacturers guidelines), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration. Sharps are not used with the viral particles.

Degree of kill:
Autoclaving, effectively 100% kill (annual validation)
Incineration, effectively 100% kill (licensed incinerator)
Chemical, effectively 99.99% kill (following manufacturers guidelines)

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N

Project Ref 553/21.10
The project will assess the live/dead populations of bacteria in the enterobacteriaceae family when exposed to various concentrations of either single or combinations of antibiotics.

**Recipient or parental organism**

Enterobacteriaceae such as *E. coli* and *Klebsiella pneumoniae*

**Host/vector system**

Non-mobilizable vectors, such as
- pBAD26
- pUC18/19
- pHSG398
- pHSG299
- pAw8-mCherry

**Origin & function**

Standard reporter genes, such as mCherry, GFP and RFP.

- mcr-1 - ‘mobilised colistin resistance’ gene – confers resistance to the antibiotic colistin only on vectors pHSG398 and pHSG299.
- mgrB - mediates susceptibility to colistin - only on vectors pHSG398 and pHSG299.

**Evaluation of foreseeable effects**

*E. coli* is a common inhabitant of the human gastrointestinal tract. Pathogenic strains can cause mild disease in most humans; it is the most common cause of UTIs, and is...
also known to cause enteritis, sepsis and neonatal meningitis.

K. pneumoniae is a normal commensal living in the human mouth and gut, and is ubiquitously found in nature, including soil, water and animals. It is an opportunistic pathogen and is associated with hospital-acquired infections (pneumonia, UTI, meningitis, sepsis and infections around indwelling medical devices), mainly in immunocompromised individuals.

The colistin resistance gene on pHSG398/pHSG299 plasmids does not increase the virulence of the strains. Additionally, there is a wide variety of alternative antimicrobial agents that can be used to successfully treat infections cause by E. coli, as colistin is used as a last-resort antibiotic. Handled strains are not multi-drug resistant and hence are susceptible to a range of other antibiotics.

Please enter comments on the GM safety committee on the risk assessment

Appropriate containment and control measures have been assigned in accordance with the latest guidance issued by ACGM.
We aim to understand how cells of the body produce and detoxify endogenous toxins, such as reactive aldehydes, and what processes are required to prevent, or repair DNA lesions induced by those toxic metabolites in the context of tissue homeostasis, cancer and aging. To this end, we plan to combine different cellular systems and genome editing tools to (1) search for genes that mediate abovementioned processes, (2) to validate candidate factors and (3) to understand the molecular mechanisms that govern cellular and systemic responses to genotoxic stress.

Several converging lines of evidence implicate elevated levels of endogenous aldehydes might alter in the immune responses to viral and pathogen infections in humans. We can model this by infecting aldehyde-accumulating and control mice with various pathogens expressing fluorescent or bioluminescent reporters or epitope tags which facilitate monitoring of viral infection and immune responses.

Genes of interest will likely include known enzymes that carry out detoxification of toxic metabolites (e.g. Adh5 or Aldh2 that detoxify aldehydes), genes involved in metabolic processes that directly lead to production of toxic by-products (such as histone demethylation which generates formaldehyde), DNA repair factors (such as members of the Fanconi Anaemia pathway, nucleotide-excision repair pathway and other major repair mechanisms) as well as gene identified by screens (1) or relevant scientific literature searches.

Woodchuck hepatitis virus post-transcription regulatory element (WPRE)

<table>
<thead>
<tr>
<th>Evaluation of foreseeable effects</th>
</tr>
</thead>
<tbody>
<tr>
<td>The proteins to be expressed, modulated or knocked down will generally not pose any hazard, but some of the mammalian proteins could be oncogenic and some may be tumour suppressors (5% of human genes). Modulating expression of the genes may lead to an alteration of the proliferation/differentiation balance or induction of apoptosis of the transduced cells and/or their progeny. Other possible effects include altered drug response, increased/decreased tolerance to genotoxic stress, changes in cellular metabolism and homeostasis. The possibility of inadvertently generating novel biological activities cannot be excluded.</td>
</tr>
</tbody>
</table>

WPRE is a common component of replication defective viral systems but concerns have been raised about the oncogenic potential.

Lentiviral and amphotropic retroviral particles integrate into the host genome which could potential lead to insertional mutagenesis. Sharps will not be used except where necessary for in vivo work.
AAV and adenoviral particles generally remain episomal and the expression of the genes of interest is transient.

Expression of standard marker proteins is not expected to alter the pathogenicity of the viruses / bacteria.

In some cases, lenti-/retro-/AAV- or adenoviral preps will also be directly delivered to mice by injection.

In addition, mice will be exposed to certain pathogens as below. These pathogens will be modified to contain standard reporter genes (e.g. GFP derivatives and luciferase) or epitope tags. This is not expected to alter the pathogenicity.

While adenoviridae in general are classified as hazard group 2 by ACDP, there is no report of MAV-1 causing human infection. The genome is quite similar to that of human adenoviruses but MAV-1 does not encode virus-associated RNAs (which are expressed by human adenovirus to suppress innate immune recognition). MAV-1 has a tropism for endothelial cells and cells of the monocyte/macrophage lineage, and it also infects astrocytes. MAV-1 infects tissues throughout the mouse, and the highest levels of virus are found in the brain, spinal cord, and spleen after intraperitoneal infection. Mice infected with MAV-1 develop adaptive immune responses, both cell mediated and humoral.

Human rotavirus is classified as hazard group 2. However, rotaviruses are usually species-specific, and only SA11 and derivatives will be used, a simian strain that is well-adapted to tissue culture and propagated in MA104 cells. No cases of human infection by SA11 have been reported, and it is unlikely to cause human disease.

Influenza A is classified as a hazard group 2 pathogen. However, Influenza A (mouse-adapted PR8 strain) is an H1N1 virus based on a human isolate from Puerto Rico in 1934. The virus used is highly attenuated, non-virulent and non-infectious in immunocompetent humans but is mouse-adapted and highly infectious in mice. This is a commonly used and well-studied model of influenza infection.

Salmonella typhimurium is classified as a hazard group 2 pathogen. It is a gram-negative bacterium causing disease in a broad range of hosts. In human the disease is frequently limited to the gastrointestinal tract. Enterocolitis from S. Typhimurium manifests within 72 hours and features acute inflammation of the intestinal mucosa and Peyer’s patches with a polymorphonuclear leukocyte infiltration, causing secretory diarrhoea. In the absence of invasive disease, infection does not proceed beyond the mesenteric lymph nodes and there is no bacteraemia. Antibiotics are not indicated in uncomplicated S. Typhimurium infection, management is conservative only.

Citrobacter rodentium is a gram-negative enteric pathogen causing gastrointestinal disease in mice but there are no reports of pathogenicity to humans. Hazard Group 1 but will be handled in a manner to limit spread to other mice.

Mice will be inoculated with pathogens in a class II MSC. The inoculation will take place using oral gavage, intranasal delivery, or by injection subcutaneously, intravenously, or intraperitoneally. Subcutaneous and intraperitoneal injections should be performed using short needles and sufficient distance between injection site and restraining hand that injection through the animal into the operator is physically impossible. For intravenous injections, mice should be restrained in a mechanical restrainer so that injection can be performed with a single hand. Syringes with needles attached are to be disposed of into sharps bins immediately after use without resheathing. In case of large-volume injections (95 ml per kg body weight), mice will be anaesthetised during the injection to minimize the stress to the animals and enabling easy administration of the virus/DNA by a trained operator.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

N/A
Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) – autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), or inactivate by chemical means (following manufacturers guidelines), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (eg needles, syringes, scalpels) - autoclave then dispose via clinical waste stream for incineration.

Animal bedding – EITHER autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), dispose via the industrial (black bag) waste stream for landfill OR dispose via clinical waste stream for incineration.

Animal carcasses - dispose via clinical waste stream for incineration. Those which may contain replication competent pathogens will be autoclave prior to disposal via the clinical waste stream.

Degree of kill:
Autoclaving, effectively 100% kill (annual validation)
Incineration, effectively 100% kill (licensed incinerator)
Chemical, effectively 100% kill (following manufacturers guidelines)

Please enter comments on the GM safety committee on the risk assessment

The committee had a number of comments on the initial draft of the risk assessment which were dealt with in subsequent drafts.
1. FACS sorting is not mentioned in the work section. Please can this be addressed, including whether or not the FACS sorter needs to be within an MSC and a justification as to why not if that is the case.
2. Are any of the pathogens listed GMOs?
3. Have you discussed with BMS whether these pathogens can be used in the facility?
4. Injection of mice with virus: You will need to provide a lot more information on the inoculations as this is one of the biggest risks. So, how are the mice restrained, what type of inoculations, how needles are disposed of, no resheathing of needles etc.

Appropriate containment and control measures have been assigned in accordance with the latest guidance issued by ACGM.

### Project Additional Information

**Purposes of the contained use**

- Replication defective lentiviral vectors will be used to facilitate research in understanding the mechanisms underlying neurodegeneration in a range of diseases

**Recipient or parental organism**

- Mammalian cell lines, such as primary cells, induced pluripotent stem cells and tissue samples

**Host/vector system**

02/03/2022
E. coli K12 derivatives - class 1
Second and third generation lentiviral vectors will be used where the gene of interest, the gag-pol genes and envelope genes are on separate plasmids
Virus producer cell lines, such as HEK293 and derivatives

### Origin & function

- Reporter genes (e.g. GFP, YFP, RFP, mCherry)
- Standard antibiotic resistance (e.g. Neomycin, Hygromycin, Puromycin and ampicillin).
- shRNAs, sgRNAs.
- Genome editing tools (e.g. TALENs, Cas9-CRISPR).
- Tet repressor/activator systems.
- Neurotrophic / neuroprotective factors (e.g. BDNF, CNTF, GDNF and NGF).
- Inflammatory mediators (e.g. TREM2)
- Protein homeostasis pathways (e.g. NEDD4, USP30)
- Neurodegenerative susceptibility genes (e.g. SNCA, DJ1, OPA1).
- Optogenetics/calcium sensors (e.g. ChR2, ChR1, GCaMP)
- pH sensitive vesicular endo/exocytosis fluorescent reporters (e.g. Synapto-pHluorin, SypH)
- Protein trafficking (e.g. RAB7, autophagy genes)
- Designer receptors exclusively activated by designer drugs (DREADDs) for specific neuronal silencing (e.g. GluC1, hM4D)

### Evaluation of foreseeable effects

Replication defective Lentiviral particles can enter numerous host cells depending on the envelope protein. They integrate into the host genome and as such have the potential to cause insertional mutagenesis if there was accidental exposure to them. The use of sharps is minimised when handling lentiviral particle however their use in necessary for in-vivo work.

Animals with be anaesthetised and lentiviral constructs expressing the gene of interest will be stereotaxically injected into the substantia nigra using a microinfusion pump. To prevent needlestick injuries during these experiments, needles will be disposed immediately after the procedure in appropriate sharps-bin.

The protein products of the genes to be studied are not expected to be toxic or cancer inducing in any way. However, the HIV receptors are also receptors for chemokines and as such the genes could modulate immune function, especially chemotaxis, in target cells. This could provide a growth/ invasion advantage to cells. Initially, the shRNAs, TALENs or Cas9-CRISPR systems to be used are not targeting known tumour suppressors. However, there is potential for off-target effects with, which could potentially have tumorigenic effects. This will be minimised by careful design with as little sequence homology as possible to off-target genes, including BLAST searches against genome databases.

Gene transfer is possible, significantly from the transfected producer cell lines, as the resulting Lentiviral/Retroviral vector will be able to infect a wide range of cells, including human cells, as the VSV-G or Rabies-G envelope enable amphotropic infection. However dissemination in the environment is limited due to the viruses being replication defective.

Some of the vectors may contain the woodchuck hepatitis virus regulatory element (WPRE) and there is some limited evidence of its oncogenic potential. Some of the genes of interest may modulate immune function.

Once the virus has integrated into the genome of the host cell it poses minimal risk and the cells can be handled at containment level 1 after a given period of time. Viral concentration is achieved by centrifugation and ultracentrifugation in air-tight containers and rotors which are loaded and unloaded within an MSC.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

**Project Ref** 553/21.4
The aim of the project is to analyse the genes and regulatory regions involved in extreme immune responses. Generation of replication defective lentivirus for modulation of genes implicated in or linked to the immune response. Plasmids and lentiviral particles containing sgRNAs (for CRISPR/CAS9 gene-editing) will be generated with the aim of disrupting and/or editing genes and regulatory regions in order to assess their impact on extreme immune responses.

Recipient or parental organism

Mammalian cell lines, such as HPA1 and K562
Primary human cells, such as monocytes and macrophages

Host/vector system

E. coli K12 derivatives
Second and third generation lentiviral vectors will be used where the gene of interest, the gag-pol genes and envelope genes are on separate plasmids
Virus producer cell lines, such as HEK293 and derivatives

Origin & function

Initial genes of interest will include TLR4, Myd88 and Zfp36 (genes involved in immune response) but other genes involved in the immune response will be looked at.

TLR4 is a member of the Toll-like receptor (TLR) family which plays a fundamental role in pathogen recognition and activation of innate immunity. TLRs are highly conserved from Drosophila to humans and share structural and functional similarities. They recognize pathogen-associated molecular patterns that are expressed on infectious agents, and mediate the production of cytokines necessary for the development of effective immunity. This
The receptor has been implicated in signal transduction events induced by lipopolysaccharide (LPS) found in most gram-negative bacteria.

Myd88 is a gene that encodes a cytosolic adapter protein that plays a central role in the innate and adaptive immune response. This protein functions as an essential signal transducer in the interleukin-1 and Toll-like receptor signalling pathways. These pathways regulate the activation of numerous proinflammatory genes.

Zfp36 plays a role in anti-inflammatory responses; suppresses tumour necrosis factor (TNF)-alpha production by stimulating ARE (AU-rich element)-mediated TNF-alpha mRNA decay and several other inflammatory ARE-containing mRNAs in interferon (IFN)- and/or lipopolysaccharide (LPS)-induced macrophages. It plays also a role in the regulation of dendritic cell maturation at the post-transcriptional level, and hence operates as part of a negative feedback loop to limit the inflammatory response.

Other genes will be included, for example gene hits from iPS-macrophage CRISPR screen (work previously carried out at the TDI).

Other targets involving putative regulatory regions relevant to the induced innate immune response based on previous and ongoing work in the lab will also be designed.

The sgRNAs used will be chosen mainly from the published TKOv3 CRISPR library (Hart et al., 2017), which has been designed to minimize off-target effects, or from custom design for specific target regions.

Standard reporter genes, such as GFP

CRISPR/Cas9

Standard antibiotic resistance genes, such as puromycin

Evaluation of foreseeable effects

Replication defective Lentiviral particles can enter numerous host cells depending on the envelope protein. They integrate into the host genome and as such have the potential to cause insertional mutagenesis if there was accidental exposure to them. The use of sharps is minimised when handling lentiviral particles.

The shRNAs Cas9-CRISPR systems to be used are not targeting known tumour suppressors. However, there is potential for off-target effects with, which could potentially have tumorigenic effects. This will be minimised by careful design with as little sequence homology as possible to off-target genes, including BLAST searches against genome databases.

Some of the vectors may contain the woodchuck hepatitis virus regulatory element (WPRE) and there is some limited evidence of its oncogenic potential.

Some of the genes of interest may modulate immune function.

Standard reporter genes and antibiotic resistance genes have a history of safe use.

Once the virus has integrated into the genome of the host cell it poses minimal risk and the cells can be handled at containment level 1 after a given period of time.

Most of the genetic inserts are not likely to cause significant effect on an individual. It is theoretically possible that upon accidental exposure, the lentivirus could infect the cells of an individual, integrate into the genome and
disrupt the genes that it is designed to target (for example TLR4, Myd88 and Zfp36), thus causing impaired immune
response in the infected cells of the exposed individual. However, as described previously, these viruses are self-inactivating, they are not capable of activating gene
transcription from the inactivated viral LTR and they are
replication incompetent. Thus, in this extremely unlikely event, the gene modification would only occur in the
infected cells and would not spread to other cells.

The worst-case scenarios could be 1) expression of oncogenic genes and/or 2) the chance integration of the virus into a tumour suppressor, thus disrupting that gene's
function, or 3) reprogramming of cells of the exposed individual and subsequent teratoma formation. However, in all cases, the virus particle would be incapable of infecting
more than one cell and would not be self-replicating. In terms of immune response to infection, the body would employ several methods to target and eliminate any cells
infected with the lentivirus (first with the innate immune response via IFN gamma secretion and then with adaptive immune response via development of transgene-specific
T cell-mediated and antibody-mediated responses).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware e.g. pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15
minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag)
waste stream for landfill.

Liquids (e.g. samples, culture supernatants, tissue culture media) – autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15
minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), or inactivate by chemical means (following manufacturers guidelines), discharge to
drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or
134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Degree of kill:
Autoclaving, effectively 100% kill (annual validation)
Incineration, effectively 100% kill (licensed incinerator)
Chemical, effectively 100% kill (following manufacturers guidelines)

### Project Additional Information

**Purposes of the contained use**

Study of viral and cellular modifications during infection. Ubiquitylation is one of the most commonly utilized cellular post-translational modifications (PTM), routinely targeted by pathogens to deregulate and hijack host intracellular pathways. Viruses utilize ubiquitylation to target central signalling pathways such as NFκB and MAPK that are crucial for their replication, propagation and immune evasion.

Other viruses reorganize the host secretory pathway to undergo cell-to-cell transmission via secretory autophagosomes or exosomes, while evading immune detection.

**Recipient or parental organism**
Influenza Virus - 8-Plasmid-based influenza-virus production from HEK293T cells to rescue recombinant virus.

Zika Virus such as MR766 or PRVABC59

Replication defective Lentivirus

Host/vector system

Mammalian cells such as HEK293T, A549, Calu-3 or HeLa cells (wild type or modified versions of)

Viral producer cells such as MDCK, HEK293, Vero (and variants of)

Primary cells such as CD14+ monocytes or iPS cells

Origin & function

Influenza virus

Recombinant H1N1 with loss-of function mutants:

A/WSN/33 (H1N1) deltaNS1 (non structural protein 1)

A/PR8 (H1N1) deltaNS1

The other inserted genetic sequences into recombinant influenza (into the non-structural protein NS1 or matrix protein M2 lacking the LC3 interaction domain) are loss-of-function mutations and makes the viruses less competent in replication, assembly and budding.

Zika Virus

venus-tag version of of Zika strains such as MR766

Replication defective lentivirus

Use of shRNA to silence expression of specific genes of the autophagy and lipid droplet pathways in mammalian cells.

Expression of cDNA of wild type or modified genes in deficient backgroud.

Use of CRIPSR/Cas9 systems to modify genes of interest

Genes of interest are autophagy pathway (e.g. Ulk1, Atg16L, LC3, Beclin-1), lysosomal degradation (Snap25, Syntaxin-17, Vamp8) or ER quality control processes (Hrd1, Ube2g2, Aup1).

Generation of subviral particles

Expression of recombinant flavivirus prME and that of coronavirus N, E, M and S from pCS-lentiviral vectors are expected to form subviral particles (non-replicative) that are constitutively secreted from cells and express a fluorescent tag for visualisation. These are structural proteins of these viruses and will not carry any genetic material within them. Structural proteins that carry mutations which result in a loss of their ability to form subviral particles will also be used in parallel.

Evaluation of foreseeable effects

Influenza is a Hazard group 2 respiratory pathogen. All strains to be used are either lab adapted versions or currently circulating strains. No variant of high risk will be used.

The modifications to the viruses are loss of function mutations and makes the viruses less competent in replication, assembly and budding than the wild type version. All vial work will be done in Class II MSC, and centrifugation will be done in sealed rotors.

Zika virus is a hazard group 2 pathogen and is primarily transmitted to humans through the bite of an infected Aedes species mosquito. Evidence suggests that transmission may also occur from mother to child in utero, through sexual contact, or through blood transfusion. All aerosol generating procedures will be done in a class II MSC and centrifugation will be done in sealed rotors. No sharps will be used in the processes. The addition of standard reporter genes is not expected to increase the risk from the genetically modified versions over the wild type.

Replication defective lentivirus can stably integrate into the host cell genome however no further viral particles can be produced. The modification are to either over-express, knock down or mutate expression of genes involved in autophagy pathway, lysosomal degradation or ER quality control processes. Modification of these genes is not expected to pose a risk however lentiviral integration can potentially cause insertional mutagenesis. As such no sharps will be used.
Replication defective lentiviruses will also be used to produce subviral particles. The normal function of these subviral particles is to reorganise host secretory pathways – ER, ERGIC and Golgi membranes, as well as autophagic compartments to generate unique secretory vesicles for transport. However they contain no genetic material and are not capable of replication. Expression of the subviral particles is not expected to pose a risk.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

02/03/2022
**Project Additional Information**

**Purposes of the contained use**

The focus of the research conducted by our group is to better understand protein glycosylation, and the roles that glycans play in health and disease. To help achieve these research aims, we will use the lentivirus expression system.

**Recipient or parental organism**

Mammalian cells such as CHO (and derivatives of)

**Host/vector system**

Standard replication defective lentiviral systems (2nd or 3rd generation)

Lentiviral producer cells such as HEK293 cells (and derivatives of)
Standard reporter genes such as GFP, Emerald, Luc, Cherry etc.
Standard antibiotic resistance genes such as puro etc.

Woodchuck Hepatitis Virus Posttranscriptional Regulatory Element (WPRE)

Genes of glycoproteins such as ion channels (e.g. acetylcholine receptor subunits), transporters (e.g. amino acid transporters like SLC1A2) receptors (e.g. MUSK, LRP4), and excreted proteins (e.g. antibodies and AGRN).
Genes of proteins known to interact with glycoproteins such as RAPSN, DOK7, DMD.
Genes of proteins involved in protein glycosylation and dolichol synthesis pathways, such as DPAGT1, ALG13, ALG14, ALG1, ALG2, ALG11, PMM2, GMPPB, OGT and SRD5A3.

In addition, modified versions of the GOI will also be used.

**Evaluation of foreseeable effects**

Standard replication defective lentiviral HIV based systems use only essential genes - tat, rev, gag, pol. They lack the accessory genes such as vif, vpr, vpu and nef, which are essential for viral replication. The likelihood of generating replication competent lentivirus is therefore minimal.

Lentiviral particles integrate into the host genome as such have the potential to cause insertional mutagenesis. Use of sharps is limited when handling lentiviral particles.

Lentiviral systems often contain WPRE which may have oncogenic properties. Exposure is limited due to control measures such as use of MSCs to control aerosols and no sharps.

Standard reporter genes have a history of safe use and are not expected to increase the hazard of the lentiviral particles.

The genes of interest are not expected to increase the hazard. In many cases gene expression is controlled by Tet and therefore only occurs in the presence of doxycycline.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Please enter comments on the GM safety committee on the risk assessment
Appropriate containment and control measures have been assigned in accordance with the latest guidance issued by ACGM.

Comments from the WIMM GM Safety Committee
Reviewer 1.
1. Will the work be done solely in the WIMM? This is important because if it will be done in other Departments the GMRA will have to be approved by their committees as well.
2. Where will the EM grid screening be done?
3. Cell line post transduction are class 1 as they are especially disabled hosts. They may need handling at CL2 under CoSHH but that is separate legislation.
Reviewer 2
1. In the UK it is A&E not ER. – Done
2. Can you put in the link to the IRIS accident reporting? – Done
Reviewer 3
1. You have a list of plasmids for the Lentiviral work. What we also need is a list of the genes you will be expressing or manipulating, and some brief details about them.
Other reviewers: Typos only and addition of wording.

Purposes of the contained use

The aim of this project is to characterize the function of known and candidate tumour modifying genes by CRISPR-mediated knock-out (CRISPR-KO), knock-in (CRISPR-KI), interference (CRISPRi), and/or activation (CRISPRa).

Recipient or parental organism

E. coli K-12 - class 1

Mammalian cell lines such as human cell lines and human primary cells

Viral producer cell lines such as HEK293 cells (and derivatives of)

Host/vector system

Standard replication defective lentiviral systems

Origin & function

Standard reporter genes such as GFP etc

Protein degradation moieties such as an auxin-induced degron and/or small epitopes

Standard antibiotic resistance genes such as puromycin
CRISPR Cas 9 or other derivatives

guide RNAs to target Cas9 modification of:-
Cancer promoting genes and tumour supressor genes for knock-in, knock-out, interference and / or activation.

Evaluation of foreseeable effects

Replication defective lentivirus particles are derived from HIV however only essential genes are still present such as gag, pol, rev and env (generally from VSV-G). The plasmids containing these genes do not contain LTRs or packaging signals and therefore none of the structural genes are present in the packaged viral genome. The packaging plasmid containing the Cas9 associated RNAs contains a packaging signal and the LTRs. This is self inactivating as it carries a deletion in the 3'LTR. Upon integration into the host genome the 3' LTR is copied to the 5' LTR rendering it transcriptionally inactive. As these can integrate into the human genome there is potential for insertional mutagenesis.

CRISPR-Cas9 is derived from S. pyogenes and can be programmed to introduce DNA double-strand breaks at specific loci specified by a sgRNA. When targetted to coding regions of genes Cas9 can create a frame shift insertion / deletion mutation that results in a loss of function (knock-out).

When a template DNA, containing tag-encoding DNA and homology sequences encompassing the Cas9-targetting site, are separately provided with Cas9 and sgRNA, the tag can be incorporated at the site of Cas9-induced DNA damage through homology-directed repair mechanisms (knock-in).

An engineered catalytically dead Cas9 (dCas9) mutant, typically containing two silencing mutations (D10A + H841A) of the nuclease domains, can also be used to effectively modify gene expression, known as CRISPR interference (CRISPRi) or CRISPR activation (CRISPRa). Functional CRISPRi machinery requires co-expression of sgRNA and a dCas9 mutant gene. The sgRNA allows for highly specific binding to a desired position in the genome, and coupled with dCas9, the complex provides sterical hindrance or activation of RNA polymerase at the site, leading to efficient transcriptional modification.

An efficient transcriptional repression can be accomplished by fusing dCas9 to an effector domain, i.e. Krüppel associated box (KRAB). The dCas9-KRAB complex recruits co-repressors, such as KRAB-box-associated protein-1 (KAP-1), at a sgRNA-defined site, and in this way, suppresses transcription (CRISPRi). Conversely, when the dCas9-targeting platform is used to recruit strong transcriptional activators, by fusing dCas9 to a tripartite transactivation complex (VPR), which is composed of VP64 (i.e. four copies of the transactivation domain (VP16) of the Herpes simplex virus), P65, and Rta proteins, at a sgRNA-defined site, gene expression can be induced (CRISPRa). Both CRISPRi and CRISPRa have successfully been used for genome-wide studies.

Expression of known cancer causing (oncogenes) and supressing genes (tumour suppressor genes) can promote and inhibit cell growth, respectively. The manipulation of cancer modifying genes may affect cell growth in culture. Whilst there is potential risk that these genes may promote cancer, there is no evidence that these genes acting alone have any cancer initiating activity, and their activity in cancer is in the context of modulating the phenotype of existing activated oncogenic mutations.

A worst-case scenario would be the chance integration of virus into tumour suppressor gene, thus disrupting its function. Even so, this single event is unlikely to cause any tumour formation and so the overall risk is still low.

Fluorescent proteins are common investigative tools and no hazards are associated with their use.

Blasticidin and puromycin genes are widely used for antibiotic selection and no hazards have been identified with its expression in mammalian cells.

WPRE has been linked to liver tumours in mice and therefore could have oncogenic potential.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Project Ref 553/22.2

Date Ackn’d: 19/01/2022

CU2 Project Title: Profiling the pharmacokinetics of lentivirus gene therapy vectors in normoperfused organs

Class: Class 2
CultureVol: 1-50 Litres
Consent Granted

Historical Significant Changes

Withdrawn: N

Tick if notifying a connected programme of work: N

Project notified under transitional arrangements: N

Project Additional Information

Purposes of the contained use

Use of replication defective lentiviral vectors to assess its pharmacokinetic profile in a closed loop system.
Recipient or parental organism

Mammalian cells and organs.

Host/vector system

Standard replication defective lentiviral vectors

Origin & function

Replication defective lentivirus system is based on HIV-1 however only 3 genes from HIV are required to generate high titre virus. These are gag/pol and rev. The genes are codon optimised to minimise regions of homology. The mutated form of WPRE is used preventing the expression of the pro-proliferative X-protein. VSV-G env is expressed to coat the vector particle and allows entry into human cells.

Standard reporter genes such as GFP

Evaluation of foreseeable effects

The viral vectors are replication defective but can enter human cells and integrate into the host genome potentially causing insertional mutagenesis.

GFP is a standard marker protein which allows for visualisation of cells containing the virus.

The virus will be dosed into a closed system containing an organ and approx 1.6L of blood. Regular samples can be taken without the need for needles.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (eg samples, culture supernatants, tissue culture media) –autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125oC for at least 15 minutes or 126-130oC for at least 10 minutes or 134-138oC for at least 3 minutes), or inactivate by chemical means (following manufacturers guidelines), discharge to drains or if blood sent for incineration as clinical waste.

Sharps (eg needles, syringes, scalpels) - dispose via clinical waste stream for incineration. Use of sharps in minimised

Organs - sent for incineration as clinical waste.

Degree of kill:
Autoclaving, effectively 100% kill (annual validation)
Incineration, effectively 100% kill (licensed incinerator)
Chemical, effectively 100% kill (following manufacturers guidelines)
Appropriate containment and control measures have been assigned in accordance with the latest guidance issued by ACGM.

### Project Additional Information

#### Purposes of the contained use

The aim is to study the detailed function of the type III secretion system of Shigella flexneri serotype 5a in relation to this organism's ability to invade eukaryotic cells in culture (as simplified model system for how it causes disease). Type III secretion systems (secretons) are widely distributed, essential virulence determinants of Gram-negative bacteria. They are encoded by approximately 25 genes, which share homology with those encoding flagellar basal bodies. Type III secretion systems serve to translocate, upon contact with eukaryotic host cells, proteins from the bacterial cytoplasm into the host cell cytoplasm. The protein effectors of virulence are thought to be moved directly from the bacterial cytoplasm through the secreton (embedded in both bacterial membranes) to insert within Shigella flexneri serotype such as 5a and 2a, wild-type and mutants.

#### Recipient or parental organism

Shigella flexneri serotype such as 5a and 2a, wild-type and mutants.

#### Host/vector system

Non-mobilisable plasmid vectors.

#### Origin & function

DNA from pWR100 (S. flexneri 5a large virulence plasmid) carrying genes or fragments of genes from the ipa, mxi/or spa operons.

Normal/expected biological action of inserted DNA/RNA or transcribed/translated gene product: formulation of a part of the type III secretion machinery (each gene product alone cannot lead to biologically active structure in terms of secretion). Localisation in either the bacterial cytoplasm, inner or outer membrane of bacterial surface. Alternatively generation of a complete or a fragment of the known translocated effector proteins (IpaA-D and IgD) in the bacterial cytoplasm.

#### Evaluation of foreseeable effects

The modifications to the Shigella flexneri are likely either not to affect the organism's fitness/virulence or to actually decrease it. Since the mutations made or planned expression of genes resulting in the loss of a normal function, in no instance would the work to be undertaken be expected to increase fitness or virulence. Antibiotic markers will be used that are not the primary therapeutic agents. The reporter genes will be either neutral or lead to a reduction in bacterial fitness. Gene transfer in this species does not necessitate the use of vectors that will increase the subsequent movement of altered genes. In each instance the donor and recipient species are the same except during gene construction and manipulations in disabled E.coli. Therefore, no new or additional potential risks will be created through the movement of any virulence gene to a new potentially pathogenic species background. For these reasons none of these manipulations will affect the host range, enhance or broaden tissue tropism, or decrease susceptibility to host defence mechanisms.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Consumables (mainly plasticware e.g. pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Liquids (e.g. samples, culture supernatants, tissue culture media) - optionally pre-treat using 2% Virkon then always autoclave using a make safe cycle as specified in BS...
2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge to drains.

Agar plates - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (either 121-125°C for at least 15 minutes or 126-130°C for at least 10 minutes or 134-138°C for at least 3 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Sharps (e.g. needles, syringes, scalpels) - dispose via clinical waste stream for incineration.

Degree of kill:

autoclaving, effectively 100% kill (animal validation)
incineration, effectively 100% (licensed incinerator).

Appropriate containment and control measures have been assigned in accordance with the latest guidance issued by ACGM.

Lentiviral-mediated expression of proteins involved in membrane trafficking and cytokinesis in mammalian cells.

Project Ref 554/08.1

Date Ackn'd 27/07/2011

Date Project 02/03/2022

CU2 Project Title Lentiviral-mediated expression of proteins involved in membrane trafficking and cytokinesis in mammalian cells.

Class 2 Consent Granted

Culture Vol Class 2 < 1 L

Non-GMM
The aims of this work is the quantitative transduction of gene products in mammalian cell lines (human telomerase immortalized retinal pigment epithelium — hTERT-RPE1, mouse NIH3T3 fibroblasts, and dog kidney polarized epithelial cells — MUCK) with the purpose of studying the effects of protein expression resulting from these gene products on membrane trafficking and cytokinesis in these cells. Protein expression will be achieved via lentivirus transduction of gene products encoding the proteins of interest (some of which may be oncogenes).

Recipient or parental organism

Mammalian cell lines (eg human telomerase immortalized retinal pigment epithelium — hTERT-RPE1, mouse NIH3T3 fibroblasts, and dog kidney polarized epithelial cells — MDCK). They are auxotrophic and require growth conditions that would not be satisfied outside the laboratory cell culture facility and thus have extremely limited survival in the environment.

Host/vector system

We will use the ViraPower T-Rex Lentiviral Expression System (Invitrogen). This system facilitates highly efficient delivery of a target gene or RNA to dividing and non-dividing mammalian cells using a replication-incompetent lentivirus. Based on the lentikat system developed by Cell Genesys (Dull et al. J. Virol. 1998 72:8463-8471), the ViraPower Lentiviral Technology possesses features which enhance its biosafety while allowing high levels of expression in a wider range of cell types than traditional retroviral systems. See attached assessment for details.

Origin & function

The inserted DNA sequences code for proteins involved in the regulation of membrane trafficking and cytokinesis. The genes to be investigated fall into two categories: (i) membrane traffic, the 63 Rab GTPases and the family of 40 GTPase-activating protein regulators; (ii) cytokinesis, the Aurora BINCENP/Borealin/Survivin, Cit, and Plk1 mitotic kinases, protein phosphatases Cdc4, PP1 and PP2A, the microtubule binding protein PRC1, anillin and septin scaffolding molecules, RhoA, the centralspindlin Rho regulator complex, microtubule severing enzymes of the katanin family, and the kinesins KIF2OA, K1F23, KIF4A, and KIF14. While some of these DNA sequences may code either for oncogenes, or modulators of cell growth, none of the DNA sequences code for toxins.

Evaluation of foreseeable effects

Insertion of the gene into the target cell lines will be accomplished using lentiviral-mediated transduction. With this procedure accidental exposure as a result of needle sticks will be minimal because sharps will not be used. However, in the case of accidental exposure it is unlikely that the inserted gene would result in the formation of a neoplasm. Although some of the genes used may code for oncogenes, carcinogenesis is a multifaceted process that requires change both within the cell and to the cell microenvironment. Therefore, it is unlikely that the inserted gene would satisfy these requirements. Moreover, immune surveillance will likely remove any cells which begin...
To express high levels of the gene product. In end effect, the chance for harmful biological effect to manifest itself as a result of accidental exposure is minimal and likely equivalent to other transfection techniques.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be treated with a final concentration of 0.1% Virkon S overnight prior to disposal down the sink. Solid waste will be autoclaved and then sent for incineration. The autoclave dedicated to waste disposal is routinely serviced and runs will be logged. Liquid spills will be treated with 1% Virkon S prior to clean up and disposal as solid waste. Surfaces will be wiped with 10% ethanol in liquid form. Virus inactivation by 0.09% Virkon S solutions has been demonstrated to result in a 6-log decrease in titres of purified and unpurified virus within 5 minutes. The use of 0.1% Virkon S with overnight incubation is therefore an effective means to inactivate viruses.

Is an emergency plan required according to regulation 20? N

### Project Additional Information

#### Purposes of the contained use

In order to aid our previous studies of the interaction of the hepatitis C (HCV) E2 glycoprotein with different PBMC subsets and the possible immunomodulatory consequences of this interaction, we would like to carry out studies with the HCV pp, which express heterodimers of E1 and E2 on their surface. The proposed work would include in vitro analysis of interaction of HCV pp with cell lines and PBMC subsets and investigation of whether HCV pp are able to modulate the activation/functions of different immune system cell types (derived from human peripheral blood), using a variety of in vitro immunological assays.

#### Recipient or parental organism

Murine leukemia virus (MLV), which is a murine retrovirus classified as a category 1 pathogen.

#### Host/vector system

The vector packaged into the pseudotyped MLV particles encodes the marker protein green fluorescent protein (GFP). This is not thought to have any harmful properties. The particles will be pseudotyped with the HCV E1 and E2 proteins. These are not thought to be toxic or oncogenic, but there is some evidence to suggest that the E2 protein may be able to modulate the activation/functions of human lymphocyte subsets. However, it is very unlikely that accidental exposure to a small quantity of HCV pp (which are not able to replicate) would have any harmful immunomodulatory effects.

#### Origin & function

The HCV pp will be provided by our collaborators, the Institute Pasteur in Lille, France; they will not be produced here.

The method by which the HCV pp are generated is described in Bartosch et al, HJournal of Experimental Medicine, 197:633-642 (2003).

In vitro experimental use at containment level 2.

#### Evaluation of foreseeable effects

Pseudotyping of the MLV-based particles with the HCV E1 and E2 proteins results in the particles having a tropism different to that of ecotropic MLV. HCV pp have been shown to bind to and enter human cells expressing what are thought to be HCV receptors (CD81 and other proteins) [Bartosch et al, Journal of Experimental Medicine, 197:633-642, 2003].

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

CU2 Project Title INVESTIGATION OF BACTERIAL PATHOGENESIS

Class 2

Consent Granted Not Applicable

Project notified under transitional arrangements

Withdrawn N

Tick if notifying a connected programme of work N

Historical Significant Changes Project transferred from GM8 28/09/2011

**Project Additional Information**

The aim of this project is to 1) construct strains of these bacteria lacking specific genes, 2) establish whether gene inactivation has affected their ability to cause disease.
and 3) further characterise the proteins encoded by these virulence genes.

Recipient or parental organism

*Escherichia coli*, *Shigella* spp., *Neisseria meningitidis*, *Neisseria gonorrhoeae* and *Haemophilus influenzae* are ACDP Hazard Group 2, as they are human pathogens. The organisms will have the equivalent or less potential to cause human disease as the wild-type bacterium. The insertions will interrupt gene function and are likely to attenuate the host.

Host/vector system

- *Neisseria meningitidis*, *Neisseria gonorrhoeae*, *Haemophilus influenzae* (Hosts)/pMID216 and derivatives (vector)
- *Shigella* and *E. coli* (Host)/pCR2.1, pUC and pET derivatives, pACYC184, pSTM115, pYH204, pMID216 (vectors)

Origin & function

Source of genetic material (inserts): transposons and antibiotic resistance markers.

Source of genetic material (vectors): pCR 2.1 topo, pACYC184, pUC and pET derivatives: commercially available

- pMID216 from collaborator
- pYH204, pSTM115: generated in own laboratory

Evaluation of foreseeable effects

All the GMMs are ACDP Hazard Group 2 except the disabled *E. coli* strain.

The modification of the host bacteria is in the form of insertions into the chromosome that inactivate gene function. The insertions carry antibiotic resistance markers that encode for resistance against antibiotics not used for treatment of infections caused by these micro-organisms. These modifications should not pose any increased risk to human health. The environmental survivability of the GMM will be similar to the parental wild-type strains.

For disabled *E. coli*, the modifications is in the form of a self replicating plasmid which may contain cloned genes from the pathogenic bacteria. The plasmids confer resistance to ampicillin, kanamycin, and erythromycin. There is a wide variety of alternative agents that can be used to treat successfully infections cause by *E. coli*. The environmental survivability of the GMM will be similar to the parental strain.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

**Chemical disinfection of GMM waste except *N. meningitidis***:
1% virkon as per manufacturers instructions, at least 1 hour exposure. Plates and plasticare sterilised by autoclaving.
Discard cycle 134 degrees C for 30 min. 100% kill. Machine and cycle validated after each cycle by thermograph; autoclaves thermocouple tested regularly (6 monthly) qualified engineer.

**Autoclaving of waste contaminated by *Neisseria meningitidis***: Discard cycle 134 degrees C for 30 min. 100% kill. Machine and cycle validated after each cycle by thermograph; autoclaves tested regularly qualified engineer.
It was considered that work with disabled E. coli strains could be conducted in Containment Level 1 facilities. However, this work will be done in a Containment Level 2 laboratory along with the work on Neisseria gonorrhoeae, Haemophilus influenzae, Shigella flexneri, and E. coli K1. The importance of prompt reporting any incidents and episodes of diarrhoeal disease among researchers working with Shigella spp. was highlighted.

People working with N. meningitidis must complete a health questionnaire; any persons with suspected immunodeficiency must be seen by the Occupational Health doctor before working with the bacterium. It was recommended that work with N. meningitidis is carried out in a dedicated (Containment Level 3) room. Only individuals who have undergone a locally approved training programme would be allowed to work with live N. meningitidis. All person must be aware of the signs and symptoms of meningococcal infection, and should seek early medical advice should they become unwell, informing medical staff of their potential exposure to N. meningitidis at the work place. All accidents/spillages to be reported promptly to the Occupational Health Department and Department Safety Officer. A list of individuals allowed to work with the meningococcus, details of the clinical presentation of N. meningitidis infection, and guidelines for safe working is to be kept at the entrance to the designated facility at all times.

Project Additional Information

Purposes of the contained use

Human immunodeficiency virus type 1 (HIV-1) is a lentivirus that causes a persistent infection in humans associated with the development of an acquired immunodeficiency syndrome (AIDS) which, if untreated, is ultimately fatal. We are studying innate and T cell responses in individuals who have repeatedly been exposed to HIV but have no developed fully-seropositive infection (and unexposed control individuals), and in patients recently infected with HIV who naturally contained viral replication with differing efficiency. Our objective is to identify viral and immune correlates of good control of virus replication, to inform HIV vaccine design. As part of these studies, we propose to compare the relative susceptibility of PDMCs from different individuals to in vitro infection with different HIV isolates, and then go on to dissect mechanisms contributing to differences in in vitro viral replication (focusing particularly on the role of host innate effector mechanisms in inhibiting viral replication).

Some experiments will be carried out with uncloned HIV stocks (including primary virus isolates derived from different infected individuals); but we would also like to work with viral stocks prepared from proviral DNA clones, both for consistency, and to enable identification of viral genetic determinants of differences in in vitro replication capacity.

Recipient or parental organism

Plasmids containing infectious molecular clones of HIV will be grown up in disabled host bacteria such as the E.coli K12 derivatise DH5α; and then transfected into a eukaryotic cell line such as 293T (a human kidney cell line).

The bacteria to be used are non-pathogenic and unlikely to survive outside culture media or disseminate themselves in the environment. There should be no expression of HIV gene products with these bacteria; but should the plasmid DNA somehow gain entry into dividing eukaryotic cells, there would be potential for HIV production from these cells (HIV RNA production being driven from the LTRs).

293T cells are a highly transfecatable derivatise of the 293 cell line (an adherent cell line of epithelial morphology derived from human kidney, which contains some adenovirus 5 DNA sequences) into which the temperature sensitive gene for SV40T antigen was inserted. Due to the presence of adenoviral and SV-40 T sequences, which confer the potential to form tumours, this cell line should be handled at containment level 2.

Transfection of these cells with molecular clones of HIV will result in production of HIV.

HIV is a lentivirus that is known to infect humans (via routes including the blood and via mucosal surfaces), and establishes a lifelong persistent infection ultimately associated with the development of AIDS. HIV -1 is classified as an ACDP category 3 pathogen. Many of the infectious molecular HIV clones to be used will be composed of sequences derived from different HIV isolates - ie will result in the generation of genetically modified (chimeric) virus.

Host/vector system

We initially plan to work with plasmid pNL4.3, which contains an infectious molecular clone derived from the NY5 and LAV HIV isolates (Adachi et al, J Virol 59 284-291).
1986) and generates a CXCR4-utilising virus; and a matched clone (pNL4.3BaL ecto) in which the gp160 ectodomain has been replaced with that of HIV BaL (a CCR5-utilising virus isolate). Details of these HIV molecular clones (both of which are contained in the plasmid pUC18) are provided in the two accompanying pdf files. In future, infectious clones of other HIV isolates and chimeras containing other gp160s or gp 160 fragments may also be used. Some clones may also include marker proteins such as GFP. All the viruses generated from these clones will be of similar or lower pathogenicity to those detailed above. These clones will be obtained from repositories or external collaborators; we do not propose to generate or modify infectious molecular clones of HIV ourselves.

Origin & function

As detailed above, we plan to work with infectious molecular clones derived from CXCR4 and CCR5-utilising HIV isolates. These will include chimeric clones, in which the env gene (or fragments thereof) may be derived from different HIV isolates. Some clones may also contain the marker protein GFP. Infectious HIV will be derived from these clones. Viruses expressing different envelope glycoproteins (the virion surface protein that mediates attachment and entry into host cells) will be generated from different chimeric clones.

Evaluation of foreseeable effects

1. Growth of plasmids containing infectious molecular clones of HIV in E.coli. Bacteria
The plasmids we will work with will contain full-length molecular clones of HIV. Plasmid stocks will be prepared by growth in disabled host bacteria such as the E.coli K12 derivative DH5α.
The pathogenicity of the host bacteria in which the plasmids are to be grown is very unlikely to be affected by the presence of the plasmids. There should not be any expression of HIV genes within the bacteria.
The HIV molecular clones will be contained within the pUC18 plasmid, which is a non-mobilisable vector. Plasmid sequences are thus unlikely to be transferred to other bacteria.
E.coli bacteria containing HIV molecular clones are very unlikely to cause harm to human health. They should not express any HIV gene products, and the presence of the plasmid DNA is not expected to affect their pathogenicity.
It is very unlikely that E.coli bacteria transfected with HIV molecular clones would survive in the environment; and since the plasmid DNA is non-mobilisable, it would also be very unlikely that this would be transferred to other bacteria. These GMOs thus pose an extremely low risk to the environment.

It is unlikely that plasmid DNA contained within the bacteria would be transferred into human cells and initiate HIV production. Nonetheless, this could potentially occur, and is a risk that should be considered. Given the (extremely low) risk that plasmid DNA encoding full-length molecular clones of HIV could conceivably enter replication-competent human cells and initiate production of infectious HIV, it is proposed that plasmid DNA and bacteria containing it should be handled under containment level 2 conditions, to minimise the risk of an infectious exposure incident occurring.
Plasmids containing HIV molecular clones and bacteria containing these plasmids will thus be worked with in category 2 containment laboratories. Gloves and eye protection will be worn at all times when handling these reagents (to minimise the risk of contact with skin or mucosal surfaces). The use of glass and of sharps (eg needles) will be avoided where possible, to minimise the risk of sharps injuries that may result in exposure to plasmid DNA. Equipment and work-surfaces will be decontaminated after use using a suitable a chlorine-containing disinfectant, and all waste will also be treated with disinfectant and/or autoclaved.

2. Transfection of eukaryotic cells with full-length molecular clones of HIV to generate infectious virus
Plasmids containing full-length molecular clones of HIV will be transfected into eukaryotic cells (eg 293T cells), which will then produce infectious HIV particles. Upon transfection of the plasmids into 293T cells, the pathogenicity of the cells themselves is unlikely to change. There is also very little risk of plasmid sequences being transferred from transfected 293T cells to other cell lines.
293T cells transfected with HIV molecular clones would also be very unlikely to survive in the environment.
However 293T cells transfected with HIV molecular clones will produce infectious HIV, which could initiate human HIV infection. These cells and the viruses derived from them thus present a high risk to human health - equal to that of naturally-occurring HIV isolates.
Transfection of plasmids into eukaryotic cells and all subsequent work with transfected cells with thus be performed under in category 3 containment laboratories, following the category 3 laboratory code of practice.
3. Use of HIV viruses derived from infectious molecular clones
HIV is a lentivirus that is known to infect humans (via routes including blood and via mucosal surfaces), and establishes a lifelong persistent infection ultimately associated with the development of AIDS. HIV-1 is classified as an ACIP category 3 pathogen.

Some of the HIV clones we propose to work with are chimeric clones containing partial/entire env genes from one HIV isolate in the backbone of another. As gp160 is the virion envelope glycoprotein, its sequence does affect virus interaction with host cell receptors and hence viral tropism and pathogenicity. However it is not expected that any of the chimeric viruses we will generate will exhibit a level of pathogenicity greater than that of the group of primary HIV isolates from which their component sequences were derived.

HIV sequence could potentially be transferred from the chimeric viruses that we generate from molecular clones to other HIV viruses, if replication competent cells were to become co-infected with the chimeric virus and another HIV isolate. However this should not result in the generation of recombinant viruses any more pathogenic than those that could be generated naturally by recombination between the parental virus from which the chimeric virus was derived and the HIV isolate concerned.

The HIV virions we generate would pose a similar risk to the environment as that posed by natural HIV isolates. HIV virions are extremely labile- but if laboratory staff were to become infected, they could potentially transmit virus to other people. To minimise this risk, in the event of any potential HIV exposure incident, the staff involved would be tested for HIV infection, and also receive antiretroviral therapy to try and prevent full-blown infection from occurring.

HIV viruses derived from infectious molecular clones will only be used for in vitro experimental work. All work involving these viruses will be performed in category 3 containment laboratories, following the category 3 laboratory code of practice.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

#### Historical Significant Changes
Transferred from GM97 10/08/2011

---

### Purposes of the contained use

Hepatitis C Virus (HCV) is a Hepacivirus belonging to the family of the Flaviviridae that causes a persistent infection in about 80% of infected individuals. The primary site of infection is the liver, where chronic infection can lead to liver cirrhosis and hepatocellular carcinoma (HCC). The virus has also been found in peripheral blood mononuclear cells (PBMCs) and the central nervous system (CNS).

We are studying the modulation of immune functions and infection of different PBMC subsets by the virus, to understand how HCV establishes and maintains a persistent infection.

As HCV isolates cannot be grown in cell culture, these experiments will be carried out with the HCVcc generated from different molecular clones (as detailed below).

---

### Recipient or parental organism

The E coli K12 derivative will be DH5α will be transduced with the plasmids containing the HCV molecular clones and cultured. The isolated plasmid DNA from these...
bacteria such as the E. coli K12 derivative DH5α will be used to produce plasmids containing infectious molecular clones of HCV; these will then be transfected into a hepatocyte cell line such as Huh-7.5. The bacteria to be used are non-pathogenic and unlikely to survive outside culture media or disseminate themselves in the environment. The Huh-7 cell line and its derivatives (Huh-7-Lunet) are derived from a hepatocellular carcinoma (HCC). The Huh-7.5 cell line (used for production of HCVcc) is derived from the Huh-7 cell line but contains an inactivating mutation in the RIG-1 gene. RIG-1 is the intracellular sensor for dsRNA and its inactivation makes the Huh-7.5 cell line highly permissive to HCVcc replication. When uninfected, this cell line should be handled at containment level 1. Many of the infectious molecular HCV clones to be used will be composed of sequences derived from different HCV isolates - i.e. will result in the generation of genetically modified (chimeric) virus.

HCV is a Hepacivirus that is known to infect humans, via routes including the blood and via mucosal surfaces. It establishes a lifelong persistent infection in about 80% of infected individuals that is ultimately associated with diseases such as liver cirrhosis and HCC. HCV is classified as an ACDP hazard group 3 pathogen.

Until recently, HCV could not be grown in cell culture, so the use of HCV replicons, HCV proteins or HCV pseudoparticles (HCVpp) was necessary. The discovery of a clone called JFH-1, isolated from a Japanese patient with fulminant hepatitis, revolutionised the field, because it was the first clone that could replicate and produce infectious virus in cell culture and led to the production of what is called HCVcc (cell-culture derived HCV). Currently, there are only a few HCV clones that can replicate and produce infectious virus. These include H77 (genotype 1a), Con1 and HCV-CG1b (genotype 1b), JFH-1 (genotype 2a) and a few structural chimeras of JFH-1 (H77-JFH-1, Con1-JFH-1, 452-JFH-1 and J6-JFH-1). We initially plan to work with the HCVcc chimera J6-JFH-1, which generates higher infectious titres compared to the JFH-1 clone, but also plan to use the original JFH-1 clone, the chimeras listed above and other structural chimeras (JFH-1 viruses containing glycoproteins from other viruses) in the future. Details of these HCVcc constructs are provided in the attached table.

We do not propose to generate or modify infectious molecular clones of HCV ourselves. However, we will grow up bacteria (E. coli derivatives) that harbour plasmids containing HCVcc molecular clones supplied to us by other investigators (Ralf Bartenschlage, Arvind Patel). There should be no expression of HCV gene products within these bacteria; but should the plasmid DNA somehow gain entry into dividing eukaryotic cells, there would be potential for HCV production from these cells. Viral stocks will be generated by transfecting plasmids containing proviral DNA clones into Huh-7.5 cells or other hepatocyte cell lines, collecting the supernatant, and finally concentrating the virus. These viral stocks will then be used in in vitro assays.

### Origin & function

As detailed above, we plan to work with different infectious HCV molecular clones. These will include chimeric clones, in which the structural proteins and the non-structural proteins may be derived from different HCV clones. Infectious HCV will be derived from all these clones.

### Evaluation of foreseeable effects

1. Growth of plasmids containing infectious molecular clones of HCV in E. coli. Bacteria

Disabled host bacteria such as the E. coli K12 derivative DH5α will be used to isolate plasmids containing infectious molecular clones of HCV; these will then be transfected into a hepatocyte cell line such as Huh-7.5 for productuon of HCVcc.

The bacteria to be used are non-pathogenic and unlikely to survive outside culture media or disseminate themselves in the environment. E. coli bacteria containing HCV molecular clones are very unlikely to cause harm to human health. There should be no expression of HCV genes within the bacteria. The pathogenicity of the host bacteria in which the plasmids are to be grown up is very unlikely to be affected by the presence of plasmids.

It is very unlikely that E. coli bacteria transfected with HCV molecular clones would survive in the environment; and since the plasmid DNA is non-mobilisable, it would also be very unlikely that this would be transferred to other bacteria. These GMOs thus pose an extremely low risk to the environment.

It is unlikely that plasmid DNA contained within the bacteria would be transferred into human cells and initiate HCV production. Nonetheless, this could potentially occur, and is a risk that should be considered.

Given the (extremely low) risk that plasmid DNA encoding full-length molecular clones of HCV would conceivably enter replication-competent human cells and initiate production of infectious HCV, it is proposed that plasmid DNA and bacteria containing it should be handled under containment level 2 conditions and in a microbiology safety cabinet, to minimise the risk of infectious exposure incident occurring.
Plasmids containing HCV molecular clones and bacteria containing these plasmids will thus be worked with in category 2 containment laboratories. Gloves and eye protection will be worn at all times when handling these reagents (to minimise the risk of contact with skin or mucosal surfaces). The use of glass and of sharps (e.g. needles) will be avoided where possible, to minimise the risk of sharps injuries that may result in exposure to plasmid DNA. Equipment and work-surfaces will be decontaminated after use using 70% Ethanol and all waste will also be treated with 5% Virkon over night and/or autoclaved (see attached reference for minimal contact times in order to inactivate HCV and general disinfection procedures used in our containment level 3 laboratory).

2. Transfection of liver cell with full-length molecular clones of HCV to generate infectious virus
Plasmids containing full-length molecular clones of HCV will be transfected into liver cell lines (Huh-7.5 cells), which will then produce infectious HCV particles. Upon transfection of the plasmids into Huh-7.5 cells, the pathogenicity of the cells themselves is unlikely to change. There is also very little risk of plasmid sequences being transferred from transfected Huh-7.5 cells to other cell lines. Huh-7.5 cells transfected with HCV molecular clones would also be very unlikely to survive in the environment. However Huh-7.5 cells transfected with HCV molecular clones will produce infectious HCV, which could initiate human HCV infection. These cells and the viruses derived from them thus present a high risk to human health - equal to that of naturally-occurring HCV isolates.
Transfection of plasmids into liver cell lines and all subsequent work with transfected cells will thus be performed under in containment level 3 laboratories, following the category 3 laboratory code of practice.

3. Use of HCV viruses derived from infectious molecular clones
Many of the infectious molecular HCV clones to be used will be composed of sequences derived from different HCV isolates - i.e. will result in the generation of genetically modified (chimeric) virus. HCV is a Hepacivirus that is known to infect humans, via routes including the blood and via mucosal surfaces. It establishes a lifelong persistent infection in about 80% of infected individuals that is ultimately associated with diseases such as liver cirrhosis and HCC. HCV is classified as an ACDP hazard group 3 pathogen. Some of the HCV clones we propose to work with are chimeric clones containing structural genes from one HCV isolate in the backbone of another. As E1 and E2 are the virion envelope glycoproteins, their sequences affect virus interaction with host cell receptors and hence viral tropism and pathogenicity. However it is not expected that any of the chimeric viruses we will generate will exhibit a level of pathogenicity greater than that of the group of primary HCV isolates from which their component sequences were derived.
The viruses derived from them would pose a similar risk to the environment as that posed by natural HCV isolates. Being enveloped viruses, HCV virions are extremely labile - but if the laboratory staff were to become infected, they could potentially transmit virus to other people. To minimise this risk, in the event of any potential HCV exposure incident, the staff involved would be tested for HCV infection, and also receive antiviral therapy to try and prevent full-blown infection from occurring. HCV viruses derived from infectious molecular clones will only be used for in vitro experimental work. All work involving these viruses will be performed in containment level 3 laboratories, following the category 3 laboratory code of practice.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste from bacterial cultures will be treated with 5% Virkon for over night prior to discarding. Solid waste will be disinfected by autoclaving or incinerated. Equipment and work-surfaces will be decontaminated after use using a suitable chlorine-containing disinfectant.

Liquid waste from the category 3 containment labs will be treated with a suitable disinfectant (e.g. 5% Virkon over night) prior to discarding. Solid waste will be disinfected by autoclaving. Equipment and work-surfaces will be decontaminated after use using a suitable disinfectant (e.g. 70% ethanol)

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N
The Institute for Animal Health's Genetic Modification Safety Committee has reviewed and approved this work and associated risk assessment.

Project Ref 118/04.1

Date Ackn’d 15/01/2007

CU2 Project Title
IDENTIFICATION AND CHARACTERISATION OF BIOFILM-REGULATED FACTORS PRESENT IN MEMBERS OF THE ORAL MICROBIAL FLORA

Class 2
Non-GMM Consent Granted Not Applicable

Project notified under transitional arrangements N

Historical Significant Changes
TRANSFERRED FROM GM 118 - 15/1/07
Cells grown in biofilms behave and respond differently to cells grown in liquid media suspensions. Understanding how these changes affect the phenotype of a biofilm-grown cell is critical to our ability to control and manipulate bacterial biofilms, which play a major role in beneficial applications like water purification and detrimental scenarios like infections from implanted devices and bio-fouling of air-conditioning systems and water distribution networks. Members of the oral bacterial flora have been extensively studied and cultured in mono- and mixed- species culture, and thus lend themselves to more sophisticated studies involving the up-regulation and down-regulation of factors that direct their adaptation to the biofilm lifestyle. In the main, the biofilm-adaptive factors identified in different bacterial strains have been associated with stress responses as well as activation of mobile genetic elements, but the regulatory factors are still not well understood, nor have all the biofilm adaptive factors been identified. The goals of the work covered by this application are to examine in detail these biofilm adaptive responses in members of a well characterised mixed oral bacterial consortium both in single and mixed culture conditions.

1. Porphyromonas gingivalis, 2. Prevotella nigrescens, 3. Fusobacterium nucleatum, 4. Neisseria subflava, 5. Streptococcus mutans, 6. Streptococcus oralis, 7. Streptococcus sanguis, 8. Veillonella dispar, 9. Actinomyces naeslundii, 10. Lactobacillus rhamnosus. 1, 2, 3, 8 are Gram negative anaerobes, 4 is a Gram negative aerobe, 5,6,7,9 and 10 are Gram positive facultative anaerobes. All species are members of the normal human oral flora and all have been on occasion reported as opportunistic pathogens. The strains used will initially be 1. W50, 2. T588, 3. ATCC10953, 4. A1078, 5. R9 and UA159, 6. EF186, 7. 209, 8. ATCC17745, 9. WVU627 and 10. AC413.

Recipient organism: K12 laboratory strains of Escherichia coli will be used for all cloning work. K12 strains are considered to be non-colonising.

E. coli strains MC1061 or DH5 - a will be used to propagate shuttle and suicide vectors. E.coli strain S17 will be used to mobilise the mobilisable (but not conjugative) shuttle vectors. Various shuttle vectors proposed for use are pVA838, pDL278 and pFX3 which are nonmobilisable Streptococcal/E.coli shuttle vectors; pT-COW a mobilisable but cnonconjugative E.coli/Prevotella-Porphyromonas shuttle vector; and pBR322 a non mobilisable E.coli plasmid. His-tag vectors like the pQE derivatives from Clontech for specific use in E.coli.

Various biofilm adaptive factors from these oral strains will be cloned and identified. Not overt attempt to express these elements will be made until they have been suitably characterised by sequencing. Identified factors that have been determined not to be toxins may be cloned into vectors for the express purposes of recombinant protein purification or expression for future studies on their role in biofilm adaptation.

In all cases the aim of this work is to identify factors present in ACDP cat2 organisms that are activated under biofilm growth. No overt attempts will be made to express any of these factors in E.coli until they have been identified. Although increased toxin production has been associated with other biofilm-forming organisms like Pseudomonas aeruginosa, the purpose of these studies will not be to study toxin expression, so if toxins are identified as being biofilm adaptive factors in these oral organisms they will not be targets for future study. Instead, this proposed work involves identifying other genetic elements that are strictly involved in the cells ability to adapt to the biofilm environment (i.e. global regulatory factors, mobile genetic elements, stress response facorsnonovel membrane proteins, and other elements not directly capable of conferring virulence factors to the ACDP category 1 E.coli K12 species beyond that of the original ACDP category 2 oral organism. Therefore handling recombinant E.coli at containment level 2 conditions obviates any foreseeable effects. In the case where vectors are introduced into the oral bacteria this will be done either to mark them with an antibiotic resistance marker found on vectors suitable to those organisms or to reintroduce regulatory sequences for reporter gene analysis. In either case, the virulence of the oral bacteria will not be enhanced so work done under containment level 2 conditions, again, obviates any foreseeable effects.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation requested.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All biological waste will be handled according to the School's strictest guidelines. All waste, with the exception of glass pipettes will be bagged or boxed in metal tin cans and be subjected to autoclaving according to the British Laboratory Standards for biological waste. These autoclaves are regularly serviced and tested by the School. This will result in a 100% kill with all non-glass waste ultimately subjected to incineration and glass waste being washed (post autoclaving) with recirculation into the general glassware pool. Glass pipettes will be neutralised in fresh bleach-based disinfectant before being washed and autoclaved as is the standard practice within the School.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form  

Tick to confirm that you have attached a risk assessment to this form  

Tick if you are claiming exemption from disclosure for section of the risk assessment

Please enter comments on the GM safety committee on the risk assessment

At the meeting of the safety committee on 10th July 2003 it was agreed that the project was class 2.

Date Project Ceased  02/03/2022
The objective is to develop our understanding of key regulatory and signalling systems such as those influencing nitrogen metabolism and the regulatory response to ambient pH in A. fumigatus. This will utilise approaches that will have successful employed with A. nidulans. In response to comparative genomic analysis as well as proteomic and transcriptomic data, molecular genetic analysis will be undertaken to investigate the function of key regulons and the putative regulatory and signalling components. An initial step will be to construct strains disrupted for specific genes identified by the upstream analysis. This will be achieved by homologous integration of deletion constructs bearing selectable markers such as Neurospora crassa pyr-4 (encoding pyrophosphorylase orotidine MP decarboxylase). Additionally we will construct epitope tagged versions of key genes to identify interacting proteins. This work involves standard cloning procedures in laboratory strains of E. coli, followed by transformation into A. fumigatus. Assessment of the effect of mutations will be through plate tests, northern and proteomic analyses of wild-type and mutant strains. The identity of transformed A. fumigatus strains will be confirmed by PCR, sequencing and Southern, as appropriate.

A. fumigatus is harmless to normal healthy people, but it is listed in ACDP hazard group 2. It can cause postoperative infections, aspergilloma (particularly in patients with cystic fibrosis, post-TB, asthmatics), sinusitis in normal people and eye infections. Immunosuppressed individuals are the most at risk of developing pneumonia, disseminatin to other organs and serious illness. Conidia (spores can cause an allergic response in sensitive individuals. It is usually transmitted by inhalation of airborne condia which are widely distributed in nature. Conidia can be readily isolated from most environments including air, human homes, offices, work-places and soil. A. fumigatus is sensitive to amphotericin B, itracomazole and voriconazole. It is also susceptible to 1% sodium hypochlorite and 70% ethanol.

Standard cloning procedures will be carried out in laboratory strains of E. coli to produce deletion constructs and epitope tagged versions of regulatory genes. Standard pUC based vectors will be used for this work. These constructs or PCR amplified and gene disruption in A. fumigatus utilises cosmids (e.g. from pWe15 cosmid libraries) bearing the sequence of the gene of interest will be prepared for transformation into A. fumigatus in E. coli strains (e.g. KS272) expressing the phage Reda and Redb recombination functions. This will involve replacement of a region of the gene of interest with the sequence of a marker gene to facilitate selecion of recombinants in both E. coli and A. fumigatus. Purified cosm id DNS will be transformed into A. fumigatus.

The genetic material will originate from A. fumigatus and will have a role in regulation or signalling in nitrogen metabolism or in response to pH.

Virulence is multifactorial, and so far discrete virulence determinants in A. fumigatus have not been identified. However, nitrogen and pH regulatory mechanisms have been implicated in the pathogenicity of other pathogenic fungi. Strains deleted are AfareA which have been tested for pathogenicity have reduced pathogenicity compared with...
the parental strain. One study has reported that a revertant from AfareA deletion, where an uncharacterised mutation led to increased expression of specific nitrogen regulated genes, had increased pathogenicity. We do not intend to create revertants in this project, and we anticipate that this project will therefore produce strains with reduced pathogenicity. The regulatory genes and signalling genes produce regulatory proteins or enzymes, which are unlikely to have a harmful biological activity alone. Experiments using isolated DNA, RNA or protein should therefore involve little risk. Cloning within laboratory strains of E.coli will not involve expression, and should also be low risk. Vectors will be capable of expression in Afumigatus and Anidulans, but not in E.coli.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

none

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Conidia: Measures to control the spread of conidia by handling plate cultures in a Class 2 cabinet. The caninet to be sprayed with 70% ethanol before and after use, and between strains. Plates to be taped closed and exterior decontaminated (70% ethanol) for transport between cabinet and incubator in case of dropping a plate. Use scatter plates before/after work to test that conidia are contained by these measures. Mycelium: Mycelium to be ground to a powder in cabinet. Waste mycelium will be autoclaved to ensure that it is inactivated if not previously killed by extraction procedures. Any contamination incidents decontaminated with 1% sodium hypochlorite for 30 min. Spent growth medium: Spent medium, and washes from liquid cultures to be incubated with bleach prior to discard down drain. Inform Occupational Health so they can record work with this allergenic sensitiser (if deemed appropriate).

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

At the meeting of the safety committee on 10th July 2002 it was commented that the work should take place in a pathogen handling room. The containment should be checked with a non-pathogenic or non-GM strain before worked commenced.

STUDIES ON THE ROLE AND REGULATION OF SECRETED PROTEINS OF STAPHYLOCOCCUS AUREUS AND ENTEROCOCCUS FAECALIS

Purpose of the contained use

Contained use is required to prevent dissemination of genetically altered commensal bacteria that have the capacity to cause disease.

Recipient or parental organism

The parental strains of the two organisms that will be used are for Staphylococcus aureus strains SH1000 (8325/4) and Newman and for Enterococcus faecalis strains OG1RF and JH2-2. These are opportunistic pathogenic bacteria. These are not attenuated strains but are the commonly used strains for genetic manipulation. Staphylococcus aureus SH1000 (8325/4), Newman in conjunction with the following plasmids: pAZ106, pLTV1, pMUTIN4, pCL84, (all integrative) pCU1, pSB2035 (both replicative).

Enterococcus faecalis OG1RF, JH2-2 with/without the following plasmids: pAZ106, pLTV1, pMUTIN4, (all integrative), pSB2035, pCU1, pTCVlac, pAT28 (replicative).

Escherichia coli BL21 (DE3) in conjunction with pETderivative vectors (T7 promoter)

Host/vector system

S. aureus and E. faecalis genes will be amplified and cloned into the vectors listed in section 7 using E. coli. The plasmids produced and containing the correct inserts will be purified and used to transform E. faecalis and S. aureus. The plasmids used are for two separate types: 1) replicative and maintained extrachromosomally for functions such as gene reporters and gene complementation; 2) integrative for generating insertional replacement mutations and maintained due to recombination with chromosome.

Overexpression of proteins will only be done in E.coli BL21 (DE3) using the pET system. No overexpression of proteins will be done with either S. aureus or E. faecalis as host.

Origin & function
The S. aureus and E. faecalis strains that will be used for the proposed study are laboratory isolates that have been obtained from laboratories that are currently researching the area of host/pathogen biology. Originally, these were isolated from humans.

The intended functions are to study the role and regulation of surface and secreted proteins of these two commensal bacteria to investigate their potential roles during opportunistic infection. This will mainly be done by in vitro analysis of gene and protein expression and this will be done in coordination with a diversity of characterised mutant strains of these organisms to determine the hierarchy of gene expression for virulence and secreted protein production. Murine abscess models of infection will be used for study of staphylococcal mutants that are predicted by virtue of in vitro observations to have a role in virulence. These models of infection will be studied outwith the University of Liverpool in collaboration with others. E. faecalis mutants will be tested in invertebrate models of infection at Liverpool using the worm Caenorhabditis elegans, a well established model of infection.

Evaluation of foreseeable effects

S. aureus is a category 2 microorganism and the mutations that will be made are likely to reduce virulence of the organism compared to the parent strain. This drop in virulence may even reduce the S. aureus strain to category 1, however, due to the ability of S. aureus to colonise humans all of the work will be done in category 2 condition.

E. faecalis is a category 2 microorganism and the mutations that will be made are likely to reduce virulence of the organism compared to the parent strain. This drop in virulence may even reduce the E. faecalis strain to category 1, however, due to the ability of E. faecalis to colonise the digestive tract of human the work will be done in category 2 conditions.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste will be placed in labelled, capped glass bottles and autoclaved, which results in total kill. Any spillages will be cleaned up with 2% w/v stericol and waste will be autoclaved, again resulting in a total kill. Lab coats will be worn at all times and after work is completed hands will be vigorously washed prior to exiting the category 2 laboratory.

Project Additional Information

We are conducting studies on the impact of Human Immunodeficiency Virus (HIV) and its treatment among people who are co-infected with the hepatitis B virus (HBV). For this purpose we are collecting blood samples from two cohorts of patients in Ghana and Malawi. In these regions antiretroviral therapy has recently become available to treat HIV infection. The first-line combination includes three drugs active against HIV, typically stavudine, lamivudine (LMV) and nevirapine. Of these drugs, LMV also has activity against HBV. Thus patients who are HIV/HBV co-infected receive three drugs for HIV but only one for HBV. There are two problems associated with the use of LMV as the sole agent against HBV:

1) Control of HBV replication is usually suboptimal, leading to the development of HBV drug resistant variants carrying mutations in the polymerase (pol) gene targeted by LMV. Ongoing HBV replication leads to progressive liver damage and a risk of liver cancer. Thus, as survival increases in these communities due to control of HIV, a potential is emerging for significant HBV-related liver disease to become apparent.

2) As the HBV surface (S) and pol genes are expressed in alternative reading frames from the same region of the viral genome (Figure 1), selective pressure exerted by LMV on pol can cause mutations in both pol and S. Mutations in the HBV surface antigen (HBsAg) can affect key antigenic determinants, creating the potential for immune and vaccine escape. In addition mutations in HBsAg can lead to loss of recognition in diagnostic assays.

We have preliminary data that show high rates of emerging HBV LMV resistance in the two African cohorts and have also identified virus variants that carry highly mutated HBsAg, including some diagnostic escape mutants. We now wish to extend these studies by constructing a system for HBV that will allow us to characterize the viral phenotype, including drug resistance, viral fitness, and HBsAg expression and immune recognition in vitro. We have extensive experience with similar systems applied to the study of HIV phenotypes, where we use both replicative and non-replicate recombinant vectors containing virus gene segments of interest inserted as "cassettes". The vector may also be modified by site directed mutagenesis (SDM) to study mutations of interest. We plan to follow a similar approach with HBV.

It has long been established that certain circular DNA viruses replicate through a rolling circle mechanism. By mimicking this mechanism, a construct that contains a full length viral genome plus a partial repeat ("full-length plus") can direct the production of virus particles upon transfection into cell lines in vitro. HBV clones have been traditionally produced in this way. We will amplify the whole HBV genome from one or a few interesting samples and clone it into standard cloning vectors (pUC or pCR based vectors). Full-length plus HBV clones will be generated by adding a partial repeat to the cloned full genome. Individual gene segments will be sub-cloned into generic expression vectors (pCMV or pSV40 expression vectors). In some cases, gene segments derived from certain patient viruses will be exchanged with those of the reference clone to study their effect on phenotype in the context of a common backbone. In addition, mutations of interest will be introduced by SDM. We will then transfect the viral...
construct in vitro into cell lines with the purpose of studying replication capacity, drug susceptibility and immune recognition of the various viruses.

To facilitate the interpretation of the proposed experiments, we summarise below the main characteristics of the HBV replication cycle (Figure 2). One key feature is that the virus replicates through an RNA intermediate form by reverse transcription, and in this respect it is similar to HIV.

UNABLE TO INCLUDE DIAGRAM (Figure 1)
Figure 1. Schematic representation of the structure of the HBV genome with the four opening reading frames (ORFs) P, S, C, and X. The ORFs encode seven different proteins through use of varying in-frame start codons. ORF P encodes for the polymerase protein; ORF S encodes the three surface proteins; ORF C encodes both the e and core protein; ORF X encodes the X protein. The genome also contains genetic elements which regulate levels of transcription, determine the site of polyadenylation, and mark a specific transcript for encapsidation into the nucleocapsid. The four ORFs transcription are controlled by four promoter elements (preS1, preS2, core and X).

HBV regions contain a partially double stranded 3.2 kb genome termed the relaxed circle DNA (rcDNA). The negative sense strand is complete while the positive sense strand is only partial. Upon infection of cells, the genome is transported into the nucleus where it is converted into a fully double stranded, covalently closed circular DNA (cccDNA). This persists as an epiphasis in the nucleus, a sort of minichromosome that serves as a template for the replication of viral RNAs by the cellular RNA polymerase II. Several transcripts are produced, which are classed as genomic and sub-genomic RNAs. Subgenomic transcripts serve as mRNA for the X and surface proteins. The larger genomic transcripts are longer than one genome in length and serve to produce e, core and polymerase proteins. A particular genomic transcript, lacking the ATG start codon for the e protein, is designated as pregenomic RNA (pgRNA). The pgRNA, in addition to serving as mRNA for the core antigen and the viral polymerase, is selectively packaged into immature viral capsids in the cytoplasm, and reverse transcribed by the viral polymerase to produce the rcDNA genome for progeny virions.

UNABLE TO INCLUDE DIAGRAM (Figure 2)
Figure 2. Schematic representation of the HBV life cycle. The virus particle attaches to the hepatocyte through cellular receptor (1). After translocation to the cytoplasm (2), the nucleocapsid releases the viral genome to the nucleus (3) where it is converted into a covalently-closed circular DNA (cccDNA) to serve as template for viral RNA transcription (4). The viral mRNAs are translated into viral proteins in the cytoplasm (5), and the pgRNA (6) is encapsidated together with the viral polymerase into a capsid made of core protein (7). Upon maturation of the virus particle, DNA is synthesized by the viral polymerase using pgRNA as template (8-9). The newly synthesized nucleocapsid can either initiate a new round of cccDNA synthesis in the nucleus (10), or acquire the viral envelope in the ER/Golgi apparatus with release of mature virions by exocytosis (11).

This mode of virus production does not result in cell death.

Recipient or parental organism

E.coli strains K12 (for example DH5 alpha, HB101, TOP10 and Mach1)
Cell lines - Epithelial cell lines such a HepG2, HepaRG cells, HepG2.2.15, HeLa; T-cell lines such as Jurkat; Embryonic cell lines such as HEK293.

Host/vector system

Cloning vectors: pUC and pCR vectors.
Mammalian expression vectors: pCMV and pSV vectors.

The cloning vectors used for this study will be pUC or pCR vectors. They contain a T7 promoter/priming site as well as f1 and co/E1 origin of replication. They also contain genes that confer resistance to the antibiotics Kanamycin and Ampicillin. They are not known to cause harm to humans. If cloning vectors escaped into environment, their antibiotic resistance gene may potentially be taken up by bacteria making them less susceptible to the antibiotics.

The expression vectors used will be pCMV and pSV vectors. They contain promoters/replication origin sites from cytomegalovirus and SV40 respectively, which are needed to maintain plasmids in mammalian cells and transcribe the inserted genes. They also contain genes that confer resistance to Kanamycin and Ampicillin to allow selection in E. coli and to Gentamicin or Puromycin for selection in mammalian cells. They are potentially able to replicate in mammalian cells and cause the cells to become resistant to the specific antibiotics. They may potentially cause drug resistance if they are taken up by and maintained in bacteria.
Two full-length and full-length plus constructs will be produced for each sample in cloning vectors (pUC or pCR) (Figure 3).

The first two products, pF1 and pF2, corresponding to the full-length 3.2kb HBV DNA genome, are produced with two sets of PCR primers targeting different sites of the HBV genome. The third construct, pHB-1, contains full-length HBV DNA plus a partially repeated sequence ("full-length plus"). Only this full-length plus plasmid is capable in vitro of producing all the viral proteins and RNAs required for assembly of HBV virions.

Individual viral genes (i.e. surface antigen, e antigen, core antigen, x protein, polymerase) will be subcloned into expression vectors. The proteins will be expressed in cell lines.

Some of the products will be modified by SDM.

HBV production does not cause major pathogenic effects on the cells. If samples are not handled appropriately, virus proteins may potentially cause immune reactions.

All plasmid production and purification will occur in the containment level 2 molecular laboratory. All bacterial cultures will be grown in plastic flasks and laboratory health and safety procedures will be followed. Plasmids will be stored in clearly labelled boxes at -20°C.

Hepatitis B Virus

The cloned full-length plus HBV genome will be capable of expressing the proteins and the nucleic acid required for the assembly of HBV particles. The individual gene clones will be able to produce individual proteins, such as HBsAg, e antigen, core antigen, polymerase, x protein. Samples may harbour mutations in certain regions of the genome, either occurring in vivo in the clinical sample under study or introduced SDM. Some of the mutations are expected to modify the susceptibility of HBV to antiviral drugs or immune responses, while others are expected to modify the levels of HBsAg expression and recognition. Some mutations are expected to affect virus fitness i.e. the virus ability to replicate and infect. The mutations that will be studied are those found to occur naturally in infected individuals. In SDM experiments involving the pol gene, it is anticipated that mutations will also indirectly be introduced to the S gene due to overlapping structure of the ORFs.

The likelihood of adverse events after accidental exposure is estimated to be low.

Accidental transfer may occur through percutaneous exposure (e.g., sharp injuries) or membrane exposure (e.g., splash to the eyes) of infectious material. HBV virus particles are quite stable and remain viable for 7 or more days on environmental surfaces at room temperature. The full-length plus HBV sequences and HBV particles are potentially harmful to humans. The outcomes may include acute infection resulting in hepatitis; in a subset of individuals a chronic carrier state may be established. Over several years, a subset of chronically infected individuals will develop complications such as liver cirrhosis and hepatocellular carcinoma.

A number of factors attenuate the risk of adverse outcomes.

Production of infectious HBV by the in vitro system described in this proposal has proved difficult. To date only non-productive infections have been achieved. However, transfection of full-length plus genomes has been shown to produce virions capable of infecting transgenic mice. Thus the possibility of human infection should be taken into account. Clinical samples from HBV infected patients represent a further and more significant potential source of infection.

In the healthcare setting we are very familiar with the management of occupational exposure to HBV and clear protocols are in place. These include minimising the risk of accidental exposure through good laboratory practice (e.g., no sharps, use of personal protective equipment, prompt disinfection of spillages), pre-exposure HBV vaccination, and post-exposure HBV prophylaxis. All people performing the laboratory work have been vaccinated against HBV as per national regulations. Should an exposure occur the laboratory worker has received instructions on how to manage exposed sites by careful washing and first aid kits are available in the laboratory for this purpose. The laboratory worker will then contact the responsible virology consultant immediately (or deputy) for deciding upon post-exposure prophylaxis. This may include
further HBV vaccine dose, HBV Immunoglobulin or antiviral therapy as deemed appropriate by the consultant, who will take into account the circumstances of the exposure, the source of the exposure, and the vaccination history of the recipient to guide the decision. Should infection occur despite these pre- and post-exposure interventions, acute hepatitis may result which may require clinical management but very rarely will result in a risk of mortality. Pre-exposure vaccination and post-exposure prophylaxis, even in the unlikely scenario that they are not sufficient to prevent infection, will attenuate the risk of severe acute hepatitis. In immune competent adults, acute hepatitis B rarely (<1-5%) results in a chronic HBV infection, and the risk is further reduced by the use of pre-exposure vaccination and post-exposure prophylaxis.

Thus, the overall risk of exposure to infectious material is considered to be low and the clinical risk associated to an exposure is considered to be minimal.

As a further potential hazard, individual proteins may cause immune reactions and trigger antibody production.

The full-length plus sequences and virus particles are unlikely to cause harm to species in the environment as HBV has a narrow host range which is limited to humans and chimpanzees; in these species it may cause acute and chronic hepatitis. Humans are the main natural host for HBV. As noted above, HBV virus particles are quite stable in the environment and remains viable for 7 or more days on environmental surfaces at room temperature. The individual proteins have the capacity to cause immune reactions if accidentally transferred to species in the environment.

These risks will be addressed by HBV vaccination of laboratory workers as per national guidelines, good laboratory practice (e.g., no sharps; use of personal protective equipment including laboratory coats, eye protection and gloved, and prompt disinfection of spillages with either 5% Trigene or 70% ethanol and proper disposal of waste). These procedures are covered in the laboratory Health & Safety manual and Standard Operating Procedure (SOP). HBV particles produced in vitro as part of this study will be maintained in the containment level 3 laboratory. It should be noted that the HBV constructs have no or limited ability to establish productive infections (see above).

**Evaluation of foreseeable effects**

The HBV sequences to be used in this study will be derived from plasma and serum of HBV infected patients. The donor organism is pathogenic if not handled appropriately and may cause infection as described above.

The risk of infection and related adverse clinical events is considered to be low.

The HBV sequences that we aim to amplify and express are the cause of HBV infection and mediate disease pathogenesis.

The full-length plus HBV clone is capable of producing virions when expressed in HepG2 cells; therefore the most hazardous step is transfection of the construct into the cell line and transduction with HBV viral supernatants.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste in the Department of Virology is disposed of by autoclaving (Standard autoclave cycle is 135 degrees C, 3150 mBar, 10 minutes). Liquid waste is collected in glass waste bottles and autoclaved. Solid waste is placed in double autoclave bags, autoclaved and then disposed of through approved routes. Details of these procedures can be obtained in the department Safety Manual. Spillages should be absorbed onto paper towels which will be autoclaved and the surface should be decontaminated and cleaned with 70% ethanol.

Waste from the CL3 laboratory (GF478) is additionally treated with the following measures. Virus, infected cells, pipette tips, flasks and all other plastics used will be inactivated in 10% TriGene overnight in disposable jars. Liquid waste, in 105 trigene, is solidified with vernagel prior to removal from the CL3 laboratory. Sealed containers...
and disinfected bags are placed inside metal tins which will be closed and disinfected prior to transport to the autoclave. The autoclaving conditions are checked with 12 thermocouples. The expected degree of kill is 100%

1. Liquid waste including viruses, infected cells, pipette tips, flasks and all other plastics used will be inactivated by Trigene 5% followed by autoclaving.

Bacterial culture liquid waste and contaminated plastics will be autoclaved. Bacterial cultures will be grown in disposable plastic flasks that will be autoclaved after use.

2. The degree of kill for these procedures is 100%

3. The autoclaving conditions follow those applied to the NHS diagnostic guidelines according to the requirements of Clinical Pathologic Accreditation. Standard autoclave cycle is 135 degrees C, 3150 mBar, 10 minutes. The autoclaving conditions are checked with 12 thermocouples.

4. Sealed and disinfected bags placed inside metal tins which will be closed and disinfected prior to transport to the autoclave.

Project Additional Information

Purposes of the contained use

Generate improved Avian Pneumovirus (APV) vaccines by introducing rational changes using infectious clone technology.

Current commercial vaccines have been created randomly by serial passage of field virus isolates in cell culture. The mutations generated appear to be reversible. These vaccines have been shown to lead to disease in commercial poultry, almost certainly as a result of their reversion back to the parent type virus.

The aim of this project is to introduce attenuating mutations using reverse genetics/infectious clone technology. It is anticipated that stable vaccines, incapable of reversion will be generated. This will be by either:

- incorporation of several attenuating motifs (identified from studying existing vaccines and their progenitors)
- deletion of genes demonstrated to attenuate another similar pneumovirus (Respiratory syncytial virus).

Candidate vaccines will be tested in turkeys in the Leahurst Poultry Isolation Unit.

Recipient or parental organism

Avian pneumovirus is in common circulation in commercial poultry, game birds and probably other unidentified avian species. In experimental conditions, APV has been shown to infect only a minority or avian species. Infection of a range of birds (turkeys, chickene, ducks, geese, pheasants, guineafowl and pigeons) resulted in virus only being isolated from the first two (Gough 1988). Experimental infection of the most susceptible avian species known (turkeys) causes mild, non-fatal respiratory disease. Infection in chickens is frequently asymptomatic and game birds infected with APV do not show disease. Wild seagulls have also been found to be seropositive for the virus but disease has not been observed. It is thought likely that other wild birds may be infected but no significant studies have been carried out.

Because of its low pathogenicity, APV is considered to be a category 1 organism (though not yet formally classified). Field strains are treated at this level of containment in UK laboratories (IAH Compton, CVL Weybridge, Intervet Cambs. Vet. Path Liverpool University) and similar laboratories abroad.

With APV infection in commercial turkeys farms, the virus can predispose to secondary pathogens and there can be serious economic losses. With commercial chickens farms disease is rarely seen but reduced weight gain and egg laying statistics suggest that a sub clinical infection probably occurs.

APV is a labile enveloped virus which has a short life in the environment outside of an avian host. Turkeys placed in a room vacated of infected birds did not become infected. It can be demonstrated to transmit to other birds in close contact in experimental conditions. Bird to bird contact has been shown to be the most successful method of virus transfer between birds but aerosol transmission by infected respiratory droplets probably also plays a part. The initial 1980's APV outbreak which spread...
rapidly from East Anglia to Wales, against the prevailing wind suggests that direct contact with personnel and vehicles to be the main mode of transmission. This is supported by the fact that a key hatchery in southern Scotland which has avoided such contact still remains free of the disease, 15 years later.

### Host/vector system

The virus itself is being attenuated hence no host is involved.

### Origin & function

**Origin:** APV field virus.

**Function of modified organism:** Vaccination of turkeys and chickens against disease caused by APV.

### Evaluation of foreseeable effects

The initial work will produce a virus of identical sequence to the field strain and it will therefore have exactly the characteristics of that strain and hence present identical risks.

The modified viruses (the candidate vaccines) would either show reduced pathogenicity or remain unaltered. This has proved the case with similar reverse genetics work with other members of the Paramyxoviridae (e.g. RSV, NDV, Rinderpest). Any viable viruses resulting have all shown reduced or unaltered pathogenicity. Tropism stayed the same or become more restricted.

The risks to the environment would be expected to be the same or less than those encountered when making and testing conventional live attenuated APV vaccines and less than when using field strains (as used routinely in all vaccine challenge models). The changes introduced will either remove virulence factors or introduce attenuating mutations (as identified by sequencing existing conventional live vaccines and their progenitors). In contrast the conventional live vaccines in general use and produced by random mutations, would be likely to introduce larger unknown changes. However such changes have never been observed.

APV causes an acute respiratory infection and has never been shown to or suspected of causing persistent infections. In experimental conditions turkeys remain infected for a short period (approximately 1 week) and it appears likely to be of advantage to the virus to produce maximal disease and virus shedding within that period. Rapid generation of high viral titres and maximum virulence are likely to be the infection characteristics most likely to give the virus a selection advantage. Hence it is likely that current field strains are close to the maximum potential virulence of the organism. Certainly viruses randomly mutated during conventional vaccine development have never been found to increase virulence - rather they have become less virulent or virulence has remained unchanged.

It is likely that vaccines are even less fit to survive in the environment than wild type strains. Conventional vaccine studies employing molecular biological diagnostics have indicated that live vaccines do not persist in the environment. During long term studies on UK turkeys farms, vaccine was only detected after it has been applied to the actual groups of birds, whereas field strains were found to cycle routinely. It is assumed that this reflects the vaccine's reduced fitness compared to better adapted field strains, in general circulation in the environment.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

AVP is labile envelope virus which is not stable in the environment outside of a host. Mild agents such as 70% ethanol readily inactive the virus.

LABORATORY
All manipulations and culture work will be contained within laboratory 1.10. Generated viruses may be moved in sealed containers to en suite freezer facilities for storage.

Manipulations will be performed in purpose installed class 2 cabinet. Areas within the cabinet will be wiped down routinely with Virkon after use.

All infected materials will be transferred to autoclave bags which will be contained within lock top polyethylene bins. The combination will prevent spillage or penetration in the event collision. The combination will be moved to the en-suite autoclave where bags will be transferred and treated.

**ISOLATION UNIT**

Birds will be vaccinated with the GMO then 3 weeks later challenged with field virus to test vaccine efficacy.

The unit contains 8 poultry rooms. Entry to the unit is via a locked door into a robing area where full overalls, head covering and gloves are put on. Boots are dipped in FAM disinfectant. After robing a central corridor is entered and from here there is access to each poultry room via its own anti room. Exhaust air is from each poultry room is HEPA filtered. Footbaths containing FAM disinfectant for boot dipping are in the corridor and inside the entrance of each anti room. Overalls, head coverings and gloves are discarded into FAM disinfectant after use, while still within the outer secure area.

Rooms and anti rooms will be disinfected by Virkon spay before and after each experiment.

Poultry and litter will be bagged and incinerated after each experiment. Both are almost certainly NOT infectious by the experiment finish but, in any event, persisting virus would be wild type field virus (not the GMO).

Drains within poultry areas are sealed for the duration of the experiment and until disinfection has occurred.

**Project Additional Information**

**Purposes of the contained use**
To investigate putative virulence homologues of FHV with a view to improve the safety and efficacy of vaccines

**Recipient or parental organism**
FHV is a respiratory pathogen of cats not known to infect non-felids. FHV in which putative virulence homologues have been deleted is expected to show an attenuated phenotype.

**Host/vector system**
FHV/gfp

**Origin & function**
The gfp expression cassette to be inserted has been obtained by PCR from the commercially available vector pEGFP-N1 (Clontech UK Ltd). GFP is a marker protein that fluoresces green and is being used to allow the identification and selection of recombinant FHVs.

**Evaluation of foreseeable effects**
Recipient micro-organism FHV is not listed in ACDP hazard groups 2, 3, or 4. Any recombination (unlikely) would only result in reversion to wild type phenotype. There are no known hazards associated with the inserted gene product and its expression (personal communication, Clontech, attached). GFP has been widely used as a marker in many infectious systems and no harmful effect has ever been demonstrated following insertion of this gene. Deletions of putative virulence homologues or other alpha-herpesviruses have resulted in attenuation of the virus and as FHV is not infective for humans it is highly unlikely that the GMM would be infective for humans. No aspect of the proposed work require specific control measures to safeguard human health. FHV only survives up to 24 hours in the environment and is highly...
susceptable to standard disinfectants. FHV with specific deletions in putative virulence homologues would be expected to be attenuated relative to wild type virus.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

none applied for

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All laboratory waste is placed in autoclave bags and transported to the autoclave in lidded buckets. Waste is autoclaved at a temperature of 121C for 20 minutes. The autoclave is routinely monitored and maintained according to the guidelines laid down by the insurers. After autoclaving, the waste bags are secured in yellow clinical waste sacks and placed in the refrigerated container designated for such waste awaiting collection by the University contractor, for ultimate incineration.

CU2 Project Title SEMLIKI FOREST VIRUS MEDIATED IL12 IMMUNOGENE THERAPY FOR

Class 2

CultureVolClass2 1-50 Litres

ClassVolumeClass3-4
The aim of the project is to evaluate in malignant human glioma cell lines cytotoxicity, dose response effect, and IL12 secretion of a recombinant Semliki Forest Virus vector (SFV) expressing transgene human IL12.

The recipient micro-organism are immortalised human malignant brain tumour cells (cell lines U87MG, LNZ308, T98).

The vector is based on SFV, an insect alphavirus naturally infecting and replicating in subtropical mosquito species only. The human IL-12 gene has been inserted downstream from non-structural genes of SFV, whose structural genes encoding essential capsid and membrane proteins have been deleted and are provided by a helper vector. Recombinant SFV vectors are produced by recombination in the packaging cell line HEK293.

The inserted cDNA encodes human IL-12, an immunostimulatory cytokine identified as an activator of the cytolytic function of NK cells, antigen-specified cytotoxic T cells, and a potent inducer of IFNy production.

Natural SFV infection only occurs when infected mosquitoes take a blood meal from viraemic vertebrate hosts. There is virtually no risk of natural spread of SFV from one human to another or from an animal to a human in the absence of the competent mosquito vector. There are no known mosquito species susceptible to SFV in the UK and therefore the risk of virus transmission to wildlife is considered negligible. Humans infected with SFV by mosquitoes may develop mild symptoms with uncomplicated and complete recovery. The present SFV virus is not mobilisable because it is replication incompetent. Replication disabled SFV mutants have been produced by deleting structural virus genes, which are provided in trans by a helper vector for recombination in a suitable cell line. This ensures that the recombinant SFV undergoes only one cycle of infection without further replication. In theory, replication competent virus (RCV) may be produced by recombination in the packaging cell line, but the real chance of such recombination is virtually nil because of the multiple deletions in the virus genome. In addition, the SFV vector does not encode resistance to any drug or antibiotic. The human IL-12 gene cannot be incorporated into the virus envelope, and thus the possibility of alteration of tissue tropism or host range of SFV is considered negligible. Furthermore, liposomal encapsulation further reduces natural SFV tropism. All virus preparations will be produced at the facilities of Regulon, Inc., in Palo Alto, CA, USA. Sterile recombinant SFV in suspension is delivered ready to use.
The inserted human IL12 gene does not encode a pathogenic protein as proven by prior in vitro and in vivo data. No harmful biological activity of hIL12 is known.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste which may contain viable SFV vectors, such as used medium, SFV infected cells, and plastic disposable objects (flasks, pipettes, etc.) will be collected and autoclaved. The autoclaved waste will be then subjected to the normal waste management cycle in the laboratory. The autoclave is managed by a contractor company (Priorclave Tactrol). Autoclave testing and quality assurance are performed and recorded yearly. The autoclave is located in the laboratory tract immediately across the GM rooms and run by lab staff.

CU2 Project Title STUDIES OF PKC DYNAMICS (INVOLVING EXPRESSION OF PKC CONSTRUCTS)

Class 2

CultureVolClass2 < 1 Litre

CultureVolumeClass3-4

02/03/2022
Project Additional Information

Purposes of the contained use
PKC has been shown to be a key signalling molecule in pathophysiology of the pancreas. The aim of this study is to examine Ca (2+) dependent/independent translocation of GFP tagged PKC isoforms in living mouse pancreatic acinar cells. A variety of PKC isoforms will be expressed in pancreatic acinar cells using replication deficient adenoviruses.

Recipient or parental organism
During production of replication deficient adenoviruses following Host organisms will be used: E.coli derivatives: XL1 BLUE, DH10B and a cells line QB1-HEK-293 (supplied by Obliogen, Nottingham, UK). All hosts are well characterised, non-pathogenic and are included by Obliogen (Nottingham, UK) in a standard kit for production of replication deficient adenoviruses. Finally replication deficient adenoviruses will be used to transfect freshly isolated pancreatic acinar cells maintained in primary culture. These cells are short lived, and therefore will not be able to survive outside tissue culture conditions and do not present any danger to environment.

Host/vector system
Vestors to be used in this project pEGFP (Clontech, Oxford, UK), pCDNA 3 (Invitrogen, Paisley, UK), pCR259 and pCR276 (Qbiogene, Nottingham, UK) pGEM, pSHUTTLE (Promega, Southampton, UK)
Recombinant PKC - GFP constructs will by produced and incorporated into virus transfer vectors. The production of replication deficient adenoviruses will require standard E. coli derivatives (XL1 Blue, DH10B) and HEK-293 cell lines.
All viral vectors contain necessary components for Tn7 transposition events. Viral vectors: pCR259, a 4488bp adenoviral transfer vector containing coding sequences for Ampicillin resistance, Tn7 transposition CMV promoter, origin of replication and a multiple cloning site. Transpose-Ad 294 vector is a 38275 bp vector containing the adenoviral genome (minus regions E1-3 needed for replication) and coding sequences for Tn7 transposition.

Origin & function
E. coli derivatives (XL1 Blue (Stratagene California, USA), DH10B (Qbiogene, Nottingham, UK) and QB1-HEK-293 cell lines will be purchased from Obliogen (Nottingham, UK) other vectors (see above) will be purchased from Clontech (Oxford UK), Invitrogen (Paisley, UK) and Promega (Southampton, UK). PKC encoding vectors, PKC-GFP encoding vectors and/or virus transfer vectors of these constructs and/or E1-E3 deficient recombinant viral plasmids will be received from collaborating laboratories. There are a few laboratories that developed PKC-GFP constructs (eg laboratory of Professor Saito in Tohoku University in Japan, Laboratory of Professor R. Rizzulto in University of Ferrara in Italy, Laboratory of Professor T Mayer in Stanford University, USA). We will receive constructs from one or more of these highly reputable laboratories. The overall aim of the project is to elucidate the role of PKC activation in pathophysiology of acute pancreatitis. A variety of PKC isoforms from different sources will be...
expressed in pancreatic acinar cells using replication deficient adenoviruses.

The cells will be stimulated by substances that could potentially be responsible for triggering acute pancreatitis (bile acids, ethanol and high doses of calcium releasing secretagogues). The activation/translocation of PKC isoforms will be monitored using fluorescence microscopy.

**Evaluation of foreseeable effects**

The PKC constructs encode functional regulatory proteins. This necessitates containment level 2. The constructs are linked to non-hazardous reporter proteins (eg GFP). Viruses containing constructs of interest could potentially be able to infect human cells. However these viruses would not be able to replicate in human cells. The recombinant adenoviruses made with Transpose-Ad expression system kits are replication deficient viruses that have deletions in the E1 and E3 regions; they will not replicate in cells other than complementing cells (QB1-HEK-293).

The E.coli derivatives to be used are disabled, non-pathogenic in man and considered ACDP group 1. The DNA inserted plasmid is eukaryotic in origin, contains a promoter which does not encode for a protein and hence is not hazardous, the marker proteins (eg green fluorescent protein) have no known hazardous effects. Eukaryotic genes delivered are unlikely to give a selective advantage to the E. coli host and it is unlikely that they would be processed in bacteria correctly as they contain eukaryotic signals eg for mRNA processing.

Established mammalian cell lines require defined media and conditions for growth, and therefore are unable to survive outside these conditions.

Isolated pancreatic acinar cells are short living cells, and unable to survive more than 24 hours after isolation.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Both liquid and solid GM waste produced during the stages of virus production including and following transfection of QB1-HEK293 cells will be autoclaved to achieve 100% kill prior to disposal. Autoclaving will be done at the end of each working day when contained work has been carried out. The autoclave is managed by laboratory staff and maintained by Priorclave engineers. The autoclave is services and calibrated every half year by Priorclave engineers. The autoclave is located in the laboratory suite (room 1.05a in Henry Wellcome Gastro Laboratories). Both liquid and solid waste will then be sent for incineration.

Solid waste produced at earlier stages of the virus production (including bacterial culture plates, disposable plastic pipettes, pipette tips and microfuge tubes) will be disposed of into autoclave bags in dedicated bins for regular autoclaving. Autoclaved waste will be later incinerated. Disposable culture vessels and other contaminated glass and plastic-ware will be soaked in disinfectant overnight, then sent for incineration. Waste media produced before stages of virus production (before transfection of QB1-HEK 293 cells) will be chemically disinfected (1% Vircon overnight) prior to disposal in dedicated sinks. Re-useable glass and plasticware will be disinfected overnight or autoclaved. Benches will be disinfected routinely before and after procedures and at the end of each day.

Y

02/03/2022
On its meeting held on 27 January 2003 the Genetic Manipulation Committee of Departments of Physiology and Human Anatomy and Cell Biology of The University of Liverpool considered application for contained use of PKC constructs and replication deficient adenoviruses containing PKC constructs. The Committee considered that containment level 2 is appropriate for stages of laboratory work involving transfection of HEK 293 cells, maintenance of these cells in culture, isolation of viruses and transfection of pancreatic acinar cells. These procedures will be conducted in Henry Wellcome Gastro Laboratories facilities shared by Department of Medicine and Department of Physiology, located on the premises of Department of Medicine. Other stages of experimentation will require containment level 1. The Genetic Manipulation Committee considered and approved Risk Assessment and waste disposal procedures for this project.

### Project Additional Information

#### Purposes of the contained use

The level of containment use is required for the handling of B. cepacia. In this proposal, the GM B. cepacia strains represent no greater risk to human health or the environment than do the parent strains.

#### Recipient or parental organism

The recipient organism is a ubiquitous environmental bacterium. It is also an opportunistic pathogen, particularly important with patients with cystic fibrosis. The GMOs produced in this project will not represent any greater threat than the parental organism.

#### Host/vector system

The vectors to be used are pKNOCK vectors, pDM4 and pCVD442, all plasmids incapable of replication in B. cepacia. If the experiments are successful, sequences introduced into these plasmids will be incorporated into the B. cepacia genome by homologous recombination. The plasmid pBBR1Tp will be used to re-introduce functional genes in order to complement mutations.

#### Origin & function

The intended functions of the introduced genetic material is to replace functional genes with genes disrupted or "knocked out" by the insertion of antibiotic resistance markers. By knocking-out genes required for functional type III secretion it will be possible to further elucidate the role of such a secretion system in the pathogenicity of B. cepacia. The antibiotic genes chosen do not confer resistance to antibiotics normally used for the treatment of B. cepacia infections. In the B. cepacia strains to be used, there are levels of intrinsic resistance to these antibiotics that would render them useless for therapeutic purposes. The experiments will use selection for high-level resistance.

#### Evaluation of foreseeable effects

The GMOs will probably not be as capable of causing disease as the parental organisms, since our purpose is to knock-out possible virulent genes. However, this has yet to be demonstrated experimentally. The GMOs do not represent a greater hazard than the parental organisms and will be treated in the same way, at containment level 2. B. cepacia is already widespread in the environment and would therefore not represent an environmental threat. Careful handling in the laboratory should ensure that there is no risk of infection to laboratory workers.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

#### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

#### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All cultures of GM B. cepacia, and all consumables used in the handling of the GMOs will be subjected to autoclaving and incineration following the normal procedures for disposal of clinical waste. The effective degree of kill is 100%. The efficiency of the autoclaving is monitored annually by the multi-point thermocouple checks during an annual service and inspection. External validation of the pressure vessel certificate also occurs annually. In addition, a chart recorder produces a record of each run to confirm effective killing.

GM VIRUSES EXPRESSING HERPESVIRUS GENE PRODUCTS

Class 2

Culture Vol Class 2 < 1 litre

Non-GMM Consent Granted not applicable

Project notified under transitional arrangements N

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

Project Additional Information
Purposes of the contained use

The aim of this experimentation is to transfer the genes encoding herpesvirus gene products to cells in tissue culture, including professional antigen presenting cells, to investigate the immune response to such antigens and their potential immune evasion properties. Transduced target cells will be used in cytotoxicity assays with epitope-specific cytotoxic T lymphocytes (CTL). It is planned to utilise two different GM viral vector systems to express the same panel of foreign genes. This will enable specific target cells to be infected with the optimal vector system and allow the research to be carried out in a comprehensive manner. The two vector/host systems are (1) Replication-defective genetically modified adenovirus (Ad5) vectors and (2) vaccinia viruses, based on the western reserve (WR) strain. These will be used to achieve specific and efficient gene transfer of the inserted herpesvirus coding sequences.

Recipient or parental organism

Adenoviruses

The vectors will be constructed based on adenovirus serotype 5 (Ad5) which is an ACDP Hazard Group 2 pathogen. Ad5 infects humans, in healthy adults it does not normally cause overt disease, and most adults will have been exposed to one of the common subgroup C viruses (includes Ad5) by adolescence. Ad5 primarily infects the respiratory tract, although it is shed via the gut and can probably replicate therein. Live enteric vaccines (for serotypes 2, 4, 5 and 7) have been used successfully in adults. The vectors used in this work are replication-defective by virtue of E1-deletion, and so are regarded as safer than the wild-type virus. The genetically modified adenoviral vectors are designed to result in efficient expression of the herpesvirus genes in transduced cells, in the absence of expression of adenovirus gene products. Adenoviruses are relatively stable at room temperature and are naturally infectious to the respiratory tract as aerosols.

Vaccinia viruses

The vectors will be constructed based on vaccinia virus western reserve (WR) strain, which is an ACDP Hazard Group 2 pathogen. Vaccinia virus is a large DNA virus, with a coding capacity of over 175kb and contains approximately 150-200 genes, many of which are essential for productive virus infection. Routes of natural infection with wild type vaccinia virus include vaccination (application of freeze dried virus preparation to abraded skin area) and contact with skin lesions produced by vaccination. In the laboratory, vaccinia may be transmitted to workers by ingestion, injury with contaminated sharps, and droplet or aerosol exposure of mucus membranes or broken skin. Vaccinia infection results in local pustular lesions at site of infection. It may cause severe disease in individuals with active skin disorders such as eczeme or psoriasis, or in immunocomprised individuals. Acute conjunctivitis may occur after inoculation into the eye but permanent eye damage is rare. Eczema vaccinatum may occur in people suffering from eczema. Infection may spread rapidly producing deep seated pustular lesions in affected skin. Disseminated vaccinia necrosum can occur in immunosuppressed or immunodeficient individuals.

Host/vector system

Adenovirus vectors

The vectors to be used in this work will be replication-defective, genetically modified human adenovirus type 5 (E1-deleted) viruses. They are regarded as safer than the wild-type virus. If accidental inoculation were to occur, the viral DNA would be introduced into a number of cells giving transient, high level expression of the transgene over a period of a few days to weeks (possibly months). However, the GM virus will be replication-defective and following an accidental inoculation, further spread would not occur. The recombinant virus will not be capable of autonomous spread in the event of accidental operator infection. In the unlikely event that an operator were to receive an 'infectious dose' of virus via the respiratory tract, it would only lead to replication of the GM virus if they had a concurrent infection with wild type virus, and the same cells took up both the wild type and GM viruses. The risk of double infection with recombinant and wild type virus is considered to be very low.

Vaccinia vectors

Vaccinia virus is a large DNA virus, with a coding capacity of over 175kb and contains approximately 150-200 genes, many of which are essential for productive virus infection. However, a number of genes are dispensable for growth, in vitro, and are suitable insertion sites for foreign genes. Vaccinia virus WR will be the host strain used either a the wild type strain for insertion of foreign genes into the thymidine kinase (TK) locus or a strain deleted for the VP37 gene (designated vRB12). Insertion of
foreign genes in to the TK locus results in the generation of viruses with a TK-minus phenotype, which have been shown to be attenuated compared to wild type virus in mice. However, this should not be taken to imply a lower virulence in man. The VP37 gene encodes an envelope protein which is essential for the envelopment and egress of extracellular virus particles, thus deletion of this gene prevents production of extracellular virus and blocks plaque formation in standard viral plaque assays. Using the vRB12 virus (VP37-deleted) as the host vector foreign genes are inserted into the VP37 locus in conjunction with a wild type VP37 gene, thus rescuing the VP37 deletion and restoring a wild type (WR) phenotype.

Origin & function

Epstein-Barr virus

Epstein-Barr virus (EBV) is a B-lymphotropic y-herpesvirus that is carried as a life-long infection by the vast majority of individuals in all communities. Despite the asymptomatic nature of EBV infection, the virus has potent cell growth transforming potential for its principal target cells, the B lymphocyte, and experimental infection of B cells in vitro leads to the establishment of permanently growing B lymphoblastoid cell lines (LCLs) which carry EBV as a latent infection. In healthy EBV-positive individuals the persistent viral infection is controlled by immune mechanisms, in particular cytotoxic T cell surveillance. All of the eight EBV proteins expressed in a latently infected B cell (EBNAs 1, 2, 3A, 3B, 3C, -LP and LMPs 1 and 2) elicit CTL responses, as do all of the lytic antigens studied to date (eg BMLF1, BMRF1, BRLF1, BZLF1). EBV induced transformation requires the co-operative action of at least five of the latent antigens (EBNAs 1, 2, 3A, 3C and LMP 1).

Latent antigens:

EBNA 1: exhibits sequence specific DNA binding activity, binds to the origin of plasmid replication on the viral genome and is essential for the cell cycle-depenent replication of the viral episome in the transformed cell: EBNA 1 may act as a transcriptional activator in addition to its genetic maintenance function.

EBNA 2: essential for transformation, a transcriptional transactivator with no demonstrable sequence-specific DNA binding activity. EBNA2 has the capacity to transactivate both viral and cellular gene expression.

EBNA3A: essential for transformation, a presumed transcriptional transactivator with no demonstrable sequence-specific DNA binding activity.

EBNA3B: no known function, no known activity in in vitro assays, and is dispensible for B cell transformation.

EBNA3C: essential for transformation, a presumed transcriptional transactivator with no demonstrable sequence-specific DNA binding activity.

EBNA-LP: required for optimal transformation. EBNA-LP deleted viruses still have transforming capacity for resting human B cells but their efficiency of transformation is drastically reduced. It enhances the transcriptional transactivator function of EBNA2.

LMP1: the major transforming protein of the virus with multiple phenotypic effects in human cells. LMP1 has transformin function in the conventional Rat 1 assay system, and in certain 3T3 cell assays. However, expression of LMP1 in human cells (eg the SCC 12F epithelial cell assay) induces phenotypic changes but does not convert the cells to malignancy.

LMP2: dispensable for B cell transformation, with no known function in conventional rodent cell transformation assays. This protein is thought to interfere with virus reactivation from latency to lytic cycle in B cells by blocking signalling events at the latently infected cell membrane.

Lytic antigens: EBV lytic cycle genes are expressed at the onset of EBV lytic cycle and expression follows a temporal and sequential order. Lytic gene products are required for full activation of the lytic cycle and are required for lytic gene expression, DNA replication, morphogenesis and egress of virus particles. The following are examples of the lytic genes to be expressed.

BMLF1: a post-transcriptional activator of gene expression.
BZLF1: transactivator of lytic gene expression, DNA binding protein.

BRLF1: a post-transcriptional activator of gene expression.

gp350: expressed during the lytic cycle, it is of the most abundant glycoprotein present on the viral envelope. Mediates viral infection of B cells through binding to the viral receptor CD21.

gp85: expressed during the lytic cycle, has significant homology to the HSV-1 glycoprotein gH. It is a relatively minor component of the envelope which is important in fusion of virus and cell membranes.

Lymphocryptoviruses (LCV)

Lymphocryptoviruses are γ-herpesviruses closely related to EBV, which naturally infect Old World Primates. In vivo LCV infection in non-human primates resembles EBV infection in humans. Sequence analysis of the genomes of both H. Rhesus (Macaques) and H Papio (baboons) has identified close homologues of virtually every EBV gene, both latent and lytic antigens.

EBNA1 homologues: EBNA1 proteins are very well conserved in both H. Rhesus and H Papio. Episomal maintenance and transcriptional transactivation functions are conserved, as are the presence of internal repeat domains.

Human herpesvirus 8 (or KSHV)

Human herpesvirus 8 (or KSHV), is a γ-herpesvirus initially identified in Kaposi's sarcoma tumor cells. The target cells of HHV8 have not been clearly identified, although B-lymphocytes and endothelial cells can be infected with low efficiency in vitro.

LNA-1: HHV8 latency associated nuclear antigen 1 (LNA-1) is involved in maintaining the HHV8 episome in infected cells, where it is thought to tether the viral genome to chromatin during mitosis.

Murine herpesvirus 68

Murine herpesvirus 68 (MHV-68), is a γ-herpesvirus which is a natural pathogen of small rodents. Primary infection occurs in lung epithelial cells, after which a latent infection is established in B lymphocytes.

ORF73: No function has yet been identified for the ORF73 gene product.

Herpesvirus saimiri

Herpesvirus saimiri (HSV) is a γ-herpesviruses which can establish specific replicative and persistent infections in primate hosts. In the natural host, squirrel monkeys, HVS infection causes an asymptomatic infection.

ORF73: No function yet identified for the ORF73 gene product. Shown to encode a 64kDa nuclear protein.

Herpes simplex virus
Herpes simplex virus (HSV), a member of the herpesvirus family, is a common human pathogen which first infects mucosa, before spreading via sensory neurons into ganglia where a life-long latent infection is established. During periods of latency, HSV is relatively resistant to host immune responses. This can be attributed to the fact that during latency HSV infects neuronal cells which lack MHC class I molecules and to limited viral gene expression. Upon viral reactivation/lytic cycle HSV infects epithelial cells and may come under immune surveillance.

ICP46: encoded by an immediate early gene, ICP47 is a small protein which binds to the cytosolic face of the transporter associated with antigen processing (TAP), thereby preventing translocation of antigenic peptides from the cytosol into the ER.

**Evaluation of foreseeable effects**

**Adenovirus**

Ad5 infects humans and is classified as an ACDP group 2 pathogen. In healthy adults it does not normally cause overt disease, and most adults will have been exposed to one of the common subgroup C viruses (includes Ad5) by adolescence. The vectors used in this work are replication-defective by virtue of E1-deletion, and so are regarded as safer than the wild-type virus. The adenovirus vectors are able to enter human cells, which may lead to the expression of the reporter genes. Integration of the viral DNA into the chromosomes of the host cell is not a part of the normal life cycle of the virus, and would be a very rare event. The viral DNA is likely to be lost from the infected cells over a period of days to a few weeks; this may be faster in replicating cells, or in vivo where immune responses against the foreign gene products or against viral proteins expressed at a low level may eliminate the infected cells. The recombinant virus will not be capable of autonomous spread in the event of accidental operator infection. Any exposure to recombinant virus would be likely to elicit an immune response to the incoming virus, and as the major capsid protein (hexon) is the major neutralising antigen, this would be primarily a type 5 response. Many individuals have pre-existing immunity to Ad5 and a secondary immune response to the recombinant virus would be expected.

It is not thought that the recombinant viruses would pose a serious risk to plants or animals. There is no evidence that human adenoviruses cross species barriers and so a replication defective virus could not be maintained in non-human hosts. It is not anticipated that insertion of foreign genes into the adenoviral vector would broaden the range of host species, nor increase the stability of the viruses in the environment.

**Vaccinia virus**

The GM modified viruses are replication competent and the host virus is classified as an ACDP Hazard Group 2 pathogen. There is no reason to suspect that the inserted genes will increase the potential hazards, nor will have any attenuation effect. However, it must be considered that vaccinia virus may cause severe disease to humans who have skin disorders or to immunocompromised individuals.

Vaccinia virus has a broad host range which includes animal species such as cattle, cats, rodents, pigs and rabbits, therefore presents the possibility of infection of these animals if accidentally released. However, there is no evidence that vaccinia can become established in the wild and there appears to be no natural animal reservoir of the virus.

It is not thought that the recombinant viruses would pose a serious risk to plants.

It is not anticipated that insertion of foreign genes into the vaccinia virus would broaden the range of host species, nor alter it pathogenic properties.

**Inserted genes:**

EBV induced transformation requires the co-operative action of at least five latent antigens (EBNAs 1, 2, 3A, 3C and LMP1). However, when expressed individually only two have transforming potential.

The EBV LMP1 gene when expressed alone may pose an oncogenic risk to human cells. However, even in the most sensitive assay of human epithelial cell transformation...
available in vitro (where for instance activated ras molecules induce efficient malignancy), LMP1 alters the cellular phenotype but does not confer a malignant phenotype on the cells. The EBV EBNA1 gene has been shown in one report to induce lymphomas in transgenic mice when expression was directed to the B cell compartment. This has not been confirmed in further independent studies. Importantly, vaccinia virus infection of cells ultimately leads to cell death and lysis of infected cells. Therefore, transformation of the infected cell is unlikely to occur. Furthermore, Ad5-based vectors are unable to infect B lymphocytes to any significant level in vitro and thus potential infection of B lymphocytes in vivo as a consequence of accidental exposure of the operator to the GM virus would appear very low. It is also worth noting that in healthy EBV-positive individuals the persistent viral infection is controlled by immune mechanisms, in particular cytotoxic T cell surveillance. All of the above EBV latent proteins can elicit CD8+ CTL responses. With the notable exception of EBNA1, all of the latent antigens are efficiently processed by the MHC Class I antigen processing pathway. We therefore consider it likely that cells expressing individual EBV latent proteins from a recombinant viral vector would be immunogenic to the T cell system in vivo. The specific issue of T cell recognition of EBNA 1 is one of the questions which the present experimental protocol is designed to address. Immunity to vaccinia virus per se (both humoral and cell mediated) will also play a role in the immune control of any accidental infection of laboratory workers. Thus cell infected with a vaccinia expressing EBNA1 will be subject to immune control by anti-vaccinia immunity.

LCV EBNA1-homologues are reported to be close homologues to EBV EBNA1 and thus for the reasons stated above are unlikely to alter the existing traits of the GM viruses.

HHV8 LNA-1 has been reported to interact with p53 and pRB, thus may have a potential role in transformation, although this is not yet been shown. In the case of these GM viruses for the same reasons as stated for the EBV potential transforming proteins, it is not expected LNA-1 will alter the pathogenic traits of either Ad5 or vaccinia.

It is not known if the ORF73 proteins from MHV-68 or HVS have any transforming potential. It is not expected that expression of these gene products will lead to additional hazards.

The question of whether the ORF73 homologues can be targets for CD8+ CTL is one of the aspects being investigated.

HSV ICP47 is expressed as an immediate early gene product, which can bind to the cytosolic portion of human TAPs thus preventing transport of antigenic peptides. This block in the normal MHC class I antigen processing pathway will lead to reduced surface expression of MHC class I molecules at the cell surface. This will ultimately prevent recognition of infected cells by CTL. However, it should be noted that HSV-specific CD8+ CTL can be generated from PBMC of HSV infected individuals and that, target cells infected with ICP47 +ve recombinant HSV vectors expressing a foreign antigen can be recognised by antigen specific CD8+ CTL in cytotoxicity assays. However, as the level of expression of ICP47 from the GM viruses may be somewhat higher than from the HSV, it may be expected that a CTL response to the GM virus may be reduced as a result of the ICP47 protein. Nevertheless, the recombinant virus should still be controlled by the host's humoral immune response, including antibody-dependent cellular cytotoxicity (ADCC). Furthermore, an MHC class I negative cell is likely to be targeted by natural killer (NK) cells, which are known to control HSV infection in vivo. It has also been shown that production of IFN and the consequent up regulation of TAP genes can overcome the ICP47 mediated block. This may be relevant in vivo.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

For both types of GM viruses 1% Virkon has been tested and shown to be effective. Additionally 1% SDS have been tested on adenovirus and 70% ethanol on vaccinia virus and shown to be effective. Solid virus containing waste is bagged and placed in a designated metal container which is removed to the autoclave. Liquid virus waste is discarded to bottles which are placed in a designated metal container for autoclaving. Any sharps and pipettes are steeped in disinfectant (1% Virkon) for a minimum of 20 minutes before disposal in an approved sharps box. The disinfectant is discarded down the sink. Any glassware used in the virus room is steeped overnight in 1% Virkon.
The genetic modification safety committee met on 17th May 2001 and discussed this proposal. There was some discussion whether it was appropriate to notify two vector systems using the same form but the committee decided that this was a valid approach. The committee considered that the work proposed was no greater than class 2 activity.

### Project Additional Information

#### Purposes of the contained use

To generate recombinant Epstein-Barr virus genomes (R-EBV) which contain variants of the Epstein-Barr Nuclear Antigen (EBNA) 1 gene. The R-EBVs will be based on the B95.8 prototypic laboratory strain of EBV. EBV transformed human B lymphocytes (lymphoblastoid cell lines, LCLs) will be generated using both R-EBVs and the B95.8 prototype strain. The EBNA1 protein from the prototypic laboratory strain (B95.8) contains an internal repeat of approx. 250 amino acids, comprising of exclusively glycine and alanine residues (the GAR domain). EBNA1 variants containing different sized GAR domains have been generated in plasmid constructs. The aim of this proposal is to transfer these EBNA1 constructs into the EBV genome for analysis of immune recognition of R-EBV transformed human B lymphocytes (LCLs) by EBNA1-specific CD8+ cytotoxic T lymphocytes (CTL). These R-EBVs will also express a reporter gene (E-GFP) and the selectable marker neomycin. Wild type B95.8 strain EBV transformed human B cells (LCLs) will also be generated as controls for the above experiments.

#### Host/vector system

The R-EBVs will be based on the B95.8 prototypic laboratory strain of EBV.
The neomycin resistance is gene from the Tn5 transposon and confers resistance to the drug G418, allowing positive selection of cells containing the EBV episome. Green fluorescent protein (GFP) is a naturally fluorescent protein from the jellyfish Aequorea victoria which fluoresces bright green upon exposure to UV light. GFPs are becoming widely used as reporter genes.

**Evaluation of foreseeable effects**

EBV is widespread in human populations with up to 90% of adults carrying the virus as a persistent infection. EBV is naturally transmitted by the oral route via salivary contact. There is no evidence of aerosol spread. In the laboratory there is the risk of direct infection of blood lymphocytes in the event of accidental inoculation of virus-producing cells or of virus containing culture supernatant into the bloodstream of the operator via a cut or wound. However, the potential for growth of EBV-positive cells in vivo following accidental self-inoculation is extremely unlikely, further such an occurrence has never been reported in the literature.

Innoculation of cells from in vitro maintained EBV-positive human cells lines into the operator would almost certainly elicit a vigorous cytotoxic T cell response against allogeneic HLA class I antigens expressed on the cell surface. In the case of B cell lines, an additional response would also be generated against HLA class II antigens since such lines express class II as well as class I antigens. Such allogeneic responses are quantitatively much stronger (i.e. involve a greater frequency of responder cells within the circulating T cell pool) than responses against conventional foreign antigens such as virus-encoded proteins. Hence the allogeneic cell population would almost certainly be destroyed in vivo.

There is no difference expected in terms of pathogenic potential between wild type EBV and R-EBV. The presence of reporter genes or of drug resistance genes in the EBV genome is very unlikely to influence the fate of viral infection.

Project Additional Information

Purposes of the contained use
The contained use is required for handling P. aeruginosa regardless of whether the bacterium is genetically-modified or not.

Recipient or parental organism
The GMO and the wild-type parent are opportunistic pathogens that do not represent a significant risk to healthy individuals so long as they are handled properly, under containment level 2. There would be a greater risk associated with anybody who has cystic fibrosis. The GMOs do not represent any greater risk than the parental organisms.

Host/vector system
Vectors to be tried include the pKNOCK system, and various plasmids that carry the sacB counter-selectable marker. All of these plasmids are incapable of replication in...
P. aeruginosa. Plasmid pBBR1Tp would be used to complement mutations by re-introducing cloned genes into P. aeruginosa. A plasposon-based system for the introduction of transposon-based DNA to create random mutants in P. aeruginosa may also be used. The integration is stably maintained because the transposon lacks the necessary transposase after integration has occurred and cannot therefore transpose again. In each case antibiotic resistance markers for chloramphenicol, kanamycin, tetracycline or trimethoprim will be introduced into P. aeruginosa.

Origin & function

The intended function of the introduced genetic material is to replace functional genes with genes disrupted or “knocked out” by the insertion of antibiotic resistance markers. By knocking out functional genes we will be able to study the role of such genes in virulence-related functions such as adherence or cytotoxicity. The DNA will be introduced from disabled E. coli strains using the vector systems described. Cloned P. aeruginosa DNA will come either from a cosmid library or be synthesised using PCR amplification.

Evaluation of foreseeable effects

The GMOs will represent no greater hazard than the parent organism. Indeed, if we have knocked-out genes that are important in virulence, they may actually be less hazardous. The P. aeruginosa parent will acquire antibiotic resistances against antibiotics that are not of therapeutic use. P. aeruginosa occurs naturally in environments such as soil and water, but the clinically-adapted strains that we are using are likely to be less able to compete in such environments than those occurring there naturally. There are no foreseeable effects that suggest any GMO requires any greater care in handling than the parent organism, which requires containment level 2.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All cultures of GM P. aeruginosa, and all consumables used in the handling of the GMOs, will be subjected to autoclaving and incineration following the normal procedures for disposal of clinical waste. The effective degree of kill is 100%. The efficacy of the autoclave is monitored annually by multi-point thermocouple checks during an annual service and inspection. External validation of the pressure vessel leading to the issue of a pressure validation certificate also occurs annually. In addition, a chart recorder produces a record of each run to confirm effective killing.

Please enter comments on the GM safety committee on the risk assessment

The Departmental Genetic Modification Safety Committee met on 27 September 2002 and considered that the work proposed represented no greater hazard than working with the wild-type organism. It was noted that the proposal was very similar to a previously notified activity using Burkholderia cepacia.

Project Containment
### Project Additional Information

**Purposes of the contained use**

Biomedical Research. The contained use is required for handling parental viruses regardless of whether they are genetically-modified or not.

**Recipient or parental organism**

Murine herpesvirus type 4 (MHV-4); Herpes simplex virus type 1 (HSV-1); Varicella-Zoster Virus (VZV); vaccinia virus; disabled murine retrovirus.

**Host/vector system**

Recombinant herpesviruses (MHV4, HSV1, VZV) and replication defective derivatives.

Vaccinia virus WR strain.

Disabled murine retroviruses based upon either murine stem cell retrovirus or Maloney murine leukaemia virus.
For recombinant herpesviruses, the recombinants will be based upon laboratory strains of the viruses contained in bacterial artificial chromosome clones. The intended function of the introduced genetic material is to replace functional genes with genes disrupted or "knocked out" either by point mutation or by the insertion of marker genes such as the jelly fish green fluorescent protein. This enables the study of the functions of the disrupted genes.

For recombinant vaccinia and defective retroviruses the viruses are based on laboratory strains and the inserts will be genes derived from the above herpesviruses. The aim is to study the functions of the proteins by expression in mammalian cell culture systems.

**Evaluation of foreseeable effects**

For the recombinant herpesviruses and vaccinia virus, the GMOs will represent no greater hazard than the parent organism. Indeed, if we have knocked-out genes that are important in virulence, they may actually be less hazardous. There are no foreseeable effects that suggest any GMO requires any greater care in handling than the parent organisms, which require containment level 2.

For recombinant disabled retroviruses, some of the inserts derived from herpesviruses will be transforming to cells in culture and are therefore potential oncogenes. The recombinants are replication defective and are therefore unable to multiply and spread after initial infection. In addition the likelihood of infection is low, being however, these vectors will be infectious to human cells and the direct introduction of viruses containing potential oncogenes represents a potential hazard greater than the parental organism. Retroviruses containing such inserts therefore require containment level 2.

Please enter comments on the GM safety committee on the risk assessment

The Departmental Genetic Modification Safety Committee met on 27 September 2002 and considered that, for herpesvirus and retrovirus recombinants the work proposed represented no greater hazard than working with the wild-type organism and that for retrovirus recombinants the proposed level of containment was reasonable.
Project Additional Information

Purposes of the contained use

The contained use is required for handling wild-type E. coli regardless of whether the bacterium is genetically-modified or not.

Recipient or parental organism

The work is part of an investigation into the interactions between the colonic epithelial cell and mucosa-associated Escherichia coli isolated from Crohn's disease and colon cancer (Martin et al 2004). The work is a collaboration between the Medical Microbiology Department at Duncan Building and the Gastroenterology Group, School of Clinical Sciences, Henry Wellcome Laboratories [GM485]. The mucosa-associated E. coli isolates lack conventional virulence genes but have adhesive/invasive properties. The GMOs do not represent any greater risk than the parental organisms. Indeed the purpose of the GM work is to make mutations in genes associated with adhesive/invasive properties or cytotoxicity. The role of the mucosal E. coli in disease, if any, remains unclear, but they will be treated as recommended for non-VTEC E. coli (ACDP hazard groups 2).
Host/vector system

We will use the E. coli strain SM10 (pir) as a source of the mini-Tn5phoA donor plasmid pUTKml. We also propose to keep the option of using a similar plasposon based random mutagenesis system. In addition, we propose to make a number of specific mutations in genes with possible roles in adhesion/invasion, or cytotoxicity. For this we will use the method described by Datsenko et al (2000) as used by Barnich et al (2004) in which a targeted sequence containing the gene of interest is replaced with a selectable antibiotic resistance gene (kanamycin) generated by PCR using primers with 50-nucleotide extensions that are homologous to regions adjacent to the gene of interest. The inactivated DNA will be introduced by electroporation into target E.coli strains (colonic epithelial cell and mucosa-associated Escherichia coli isolates) transformed previously with plasmid pKOBEG (or a similar vector), encoding red proteins from bacteriophage lambda. An alternative strategy will involve using pKNOCK vectors carrying resistance genes for chloramphenicol, tetracycline and kanamycin (Alexeyev 1999). The mutants will be complemented to demonstrate that any phenotypic variation is due to the specific gene inactivation. This will involve reintroducing intact cloned genes into the mutants using standard plasmid cloning vectors. The antibiotic resistance markers will be restricted to chloramphenicol, tetracycline, kanamycin or ampicillin.

Origin & function

Mutants will be screened for loss of the ability to cause haemagglutination of human group O red blood cells. In addition, we propose to make a number of specific mutations in genes with possible roles in adhesion/invasion, or cytotoxicity. The effect of these inactivations will then be assessed using as endpoints red cell haemagglutination, adherence to, and invasion of, intestinal epithelial cells, intracellular localisation and multiplication within epithelial cells, expression of flagellae and pili. In addition, we will study the action of mutant E. coli strains on surrogate markers for inflammation and development of colonic malignancy including COX2 activation (overexpressed in malignancy), NFkB activation and IKK degradation (tumour promotion), disruption of apoptosis (malignant cell survival), VEGF expression (angiogenic potential) and proinflammatory cytokine expression.

These will be introduced into the chromosome. The intended function is to cause mutation of activities that may have a role to play in virulence.

Evaluations of foreseeable effects

Random mutagenesis can lead to inadvertent up-regulation of genes. As stated previously, these strains appear to lack the conventional virulence genes carried by EPECs and other pathogenic groups. However, there is a small risk that an unknown virulence-related gene may be up-regulated. Such mutants will not be retained following the screen for reduced haemagglutination and/or adherence/invasion/cytotoxicity. Any alteration of pathogenic traits in the specific knock-08tmmutations is likely to be making the strain less pathogenic since the aim is to "knock-out" genes that might contribute to pathogenicity. There are no foreseeable effects that suggest GMOs would require any greater care in handling than the parent organism, which requires containment level 2.

The organism may be hazardous but lacks known virulence genes. Antibiotic resistance genes may be introduced into the organism and it is theoretically possible that they might be passed on to other bacteria. Antibiotics unsuitable for therapeutic use will be used.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Duncan Building:
All cultures of GM E. coli, and all consumables used in the handling of the GMOs, will be subjected to autoclaving and incineration following the normal procedures for disposal of clinical waste. The effective degree of kill is 100%. The efficacy of the autoclave is monitored annually by multi-point thermocouple checks during an annual service and inspection. In addition, a chart recorder produces a record of each run to confirm effective killing.

Henry Wellcome Laboratories:
Solid waste (tips, tubes etc.) are placed in a pot with a sealable lid and taken for autoclaving and incineration. Disposable cell-culture plastic vessels will be soaked in...
disinfectant (1% Virkon) overnight, autoclaved and then sent for incineration. Waste media will be chemically disinfected (1% Virkon) overnight prior to disposal in disinfectant. Benches will be disinfected routinely before and after experimental procedures and at the end of each working day. Autoclaving (to achieve 100% kill) will be performed within the working laboratory (NUF1.05A) at the end of each working day when contained work has been carried out. The autoclave is managed by laboratory staff and maintained by Priorclave engineers (calibrated and serviced on a 6 month basis).

**Project Additional Information**

**Purposes of the contained use**

We are interested in the processes involved in tissue regeneration and repair, and the mechanisms by which we can manipulate the healing process to enhance repair. This work involved characterising and manipulating various aspects of cell biochemistry in order to understand the mechanisms of these processes. We will use commercially available lentiviral and retroviral systems to mediate stable over-expression and knock down of key genes that are implicated in the processes that occur subsequent to tissue injury, as well as those involved in the repair process.

**Recipient or parental organism**

Packaging cells will be used to produce both lentiviral and retroviral particles. These particles will then be used to transduce our cell line of interest (The immortalised human juvenile costal chondrocytes (T/C-28a2) and primary cultures of a variety of mesenchymal cells, in particular chondrocytes). These pseudotyped viruses are both replication defective and the probability of reversion to wild-type is negligible. For more information please refer to the attached risk assessment form.

**Host/vector system**

Retroviral system: The plasmids used for retroviral gene delivery and expression are derived from the Moloney murine leukemia virus (MMLV). To generate infectious virus particles the retroviral transfer vector will be transfected into commercially available packaging cell lines containing chromosomally integrated expression cassettes for viral proteins Gag, Pol, and Env, which would result in the formation of pseudotyped virus particles.

Lentiviral system: pKLO.1-puro vector transfer plasmids will be co-transfected into packaging cells along with the pCMV-VSV-G envelope vector, and a packaging vector (MISSION Lentiviral Packaging Mix, Sigma), the identity of which is proprietary. For more information of host cells please refer to the attached risk assessment form.

**Origin & function**

Small interfering RNAs (siRNAs) expressed from short hairpin RNAs (shRNAs) are used to mediate gene specific RNA interference (RNAi) in mammalian cells. shRNAs are encoded by short sequences (~20-60 bp) specific to genes of interest and are supplied in commercially available lentiviral or retroviral transfer vectors. Gene over-expression will be mediated by full length gene sequences amplified by PCR and cloned into the multiple cloning sites of commercially available viral transfer vectors. Lentiviral system: The lentiviral packaging plasmid retains the Gag, Pol, and Rev protein encoding sequences from HIV-1. The VSV-G sequence in the envelope vector derived from the vesicular stomatitis virus. The pKLO.1-puro plasmid only retains the HIV-1 viral sequences necessary for reverse transcription, RNA packaging, RNA transport (RRE), and cDNA integration into the hosts chromosome.

Retroviral system: A third generation retroviral system will be utilised in this study. The plasmid vectors used for retroviral gene delivery and expression are derived from MMLV. Vectors contain the bacterial origin of replication and ampicillin-resistance gene, an extended MMLV packaging signal, and a multiple cloning site (MCS) located between the MMLV 5’ and 3’ long terminal repeat sequences (LTRs).

In both systems, once packaging cell line has been transfected with the necessary vectors, pseudotyped viral particles are produced. The supernatant is then used to infect target cells. Upon infection, the viral RNA molecule is reverse transcribed by reverse transcriptase (which is present in the virion particle), and the gene of interest, flanked by the LTRs, is integrated into the host DNA. Because the vector itself does not express viral proteins, once a target cell is infected, the LTR expression cassette is incapable of another round of virus production.

02/03/2022
Three systems utilise pseudotyped viruses, which increases the possibility of transduction of human cells at high titre. Utilisation of SIN vectors attenuates the potential risk of insertional mutagenesis that would otherwise exist for these vectors. The specific safety features of third generation retroviral systems significantly reduces the likelihood of replication competent viral (RCV) generation, by increasing the number of recombination events that are required to reconstitute a competent viral genome. For additional information please refer to attached risk assessment form.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste will be aspirated into Virkon and disposed of in an appropriate manner. Used plastic and glassware will be treated with Virkon and autoclaved promptly.

Project Ref 554/08.1

Date Ackn'd CU2 Project Title Class CultureVolClass2 CultureVolumeClass3-4

02/03/2022
Lentiviral-mediated expression of proteins involved in membrane trafficking and cytokinesis in mammalian cells.

The aim of this work is the quantitative transduction of gene products in mammalian cell lines (human telomerase immortalized retinal pigmented epithelium — hTERT-RPE1, mouse NIH3T3 fibroblasts, and dog kidney polarized epithelial cells - MUCK) with the purpose of studying the effects of protein expression resulting from these gene products on membrane trafficking and cytokinesis in these cells. Protein expression will be achieved via lentivirus transduction of gene products encoding the proteins of interest (some of which may be oncogenes).

Recipient or parental organism

Mammalian cell lines (eg human telomerase immortalized retinal pigmented epithelium — hTERT-RPE1, mouse NIH3T3 fibroblasts, and dog kidney polarized epithelial cells - MDCK). They are auxotrophic and require growth conditions that would not be satsisfied outside the laboratory cell culture facility and thus have extremely limited survival in the environment.

Host/vector system

We will use the ViraPower T-Rex Lentiviral Expression System (InVitrogen). This system facilitates highly efficient delivery of a target gene or RNA to dividing and non-dividing mammalian cells using a replication-incompetent lentivirus. Based on the lentikat system developed by Cell Genesys (Dull et al. J. Virol. 1998 72:8463-8471), the ViraPower Lentiviral Technology possesses features which enhance its biosafety while allowing high levels of expression in a wider range of cell types than traditional retroviral systems. See attached assessment for details.

Origin & function

The inserted DNA sequences code for proteins involved in the regulation of membrane trafficking and cytokinesis. The genes to be investigated fall into two categories: (i) membrane traffic, the 63 Rab GTPases and the family of 40 GTPase-activating protein regulators; (ii) cytokinesis, the Aurora B, INCENP/Borealin/Survivin, Cit, and Piki mitotic kinases, protein phosphatases Cdc4, PP1 and PP2A, the microtubule binding protein PRCI, anillin and septin scaffolding molecules, RhoA, the centralspindlin Rho regulator complex, microtubule severing enzymes of the katanin family, and the kinesins KIF2OA, K1F23, KIF4A, and KIF14. While some of these DNA sequences may code either for oncogenes, or modulators of cell growth, none of the DNA sequences code for toxins.
Insertion of the gene into the target ceN lines will be accomplished using lentiviral-mediated transduction. With this procedure accidental exposure as a result of needle sticks will be minimal because sharps will not be used. However, in the case of accidental exposure it is unlikely that the inserted gene would result in the formation of a neoplasm. Although some of the genes used may code for oncogenes, carcinogenesis is a multifaceted process that requires change both within the cell and to the cell microenvironment. Therefore, it is unlikely that the inserted gene would satisfy these requirements. Moreover, immune surveillance will likely remove any cells which begin to express high levels of the gene product. In end effect, the chance for harmful biological effect to manifest itself as a result of accidental exposure is minimal and likely equivalent to other transfection techniques.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

n/a

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Liquid waste will be treated with a final concentration of 0.1% Virkon S overnight prior to disposal down the sink. Solid waste will be autoclaved and then sent for incineration. The autoclave dedicated to waste disposal is routinely serviced and runs will be logged. Liquid spills will be treated with 1% Virkon S prior to clean up and disposal as solid waste. Surfaces will be wiped with 10% ethanol in liquid form. Virus inactivation by 0.09% Virkon S solutions has been demonstrated to result in a 6-log decrease in titres of purified and unpurified virus within 5 minutes. The use of 0.1% Virkon S with overnight incubation is therefore an effective means to inactivate viruses.

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

This work will investigate the pathological effects and functions of Angiotensin type 1 and type 2 receptors, Ang 4 and Mas receptors in promoting fibrosis in response to stimulation by AngiotensinII. The project involves the use of short hairpin RNAs (shRNAs) to prevent the mRNA expression of RAS target genes. In primary human renal proximal tubular cells (hPTC; Cambrex) and immortalised hPTC line (HK-2 cells; ATTC). The cells will be transfected with the respective shRNAs using lentivirus plasmid vector pLKO. 1-Puro alone or packed as lentiviral transduction particles.

**Recipient or parental organism**

DH5 and HB101 bacteria, HK-2 cells and primary hPTC are recognised as non-colonising and disabled and are equivalent to ACDP hazard group 1. The likelihood of the GMMs actively causing harm is negligible. The non-pathogenic and the inserted gene products are not expected to increase the fitness of the organism. The potential to cause harm to animals and plants is negligible. The GMMs are unlikely to survive in the environment due to the requirement for auxotrophs for survival which are unlikely to be satisfied in the environment.

**Host/vector system**

The pLKO.1 vector is a lentiviral (HIV)-based plasmid which integrates into the host genome. The vector is regarded as a Risk Group Level 2 (RGL-2) 1 material and safe to use due to its modified features (deletion of a number of accessory genes implicated in the virulence of HIV, minimal genome of the viral particles, non-replicating and self-inactivation features) making it incapable of producing virus once infected into the host cell. Potentially, the lentiviral particles are capable of infecting human cells.

**Origin & function**

For the purpose of this project, specific shRNAs are designed to bind in a complementary way mRNA of target members of the human Renin-Angiotensin System (RAS). This will lead to the degradation of the target mRNAs and will abolish the protein expression of these genes.
The shRNA sequences are cloned into pLKO.1 vector to facilitate the transfection of the cells and stable expression of the shRNAs. The vector is a lentiviral (HIV) based plasmid which integrates into the host genome. As stated above, the vector safe to use due to its modified features (deletion of a number of accessory genes implicated in the virulence of HIV, minimal genome of the viral particles, non-replicating and self-inactivation features), making it incapable of producing virus once infected into the host cell.

Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

The procedure outlined for level 2 containment will be sufficient and so no unusual procedures should be necessary. It is standard school of clinical science practice that all tissue culture work is carried out at biological safety level 2. No sharps will be used during transformation/ transfection procedures, nor in the subsequent culturing of the cells.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The waste material containing viable GMMs including spent culture fluid and other media will be chemically inactivated (Virkon) as per manufacturer's specifications. The hard waste will be packed accordingly and autoclaved.

02/03/2022
Knockout mutation of putative virulence genes in Escherichia coli associated with urinary infections, and a study of the effects on ureteric contractility

The work is part of an investigation to study the interaction of bacteria with the surface channels and receptors of human and rat ureters. The work is a collaboration between Prof Susan Wray and Dr Theodor Burdyga (School of Biomedical Sciences, Division of Physiology) and Dr Craig Winstanley (School of Infection and Host Defence, Division of Medical Microbiology). This will be achieved by making mutations in urinary pathogenic E.coli (UPEC)-specific genes and studying the effects of such mutations on ureteric contractility. The genetic manipulation of E.coli strains will take place within the School of Infection & Host Defence, with the contractility assays taking place in Physiology. The recipient bacteria are the most widely studied UPEC strains J96, 536 and CFT073, each of which were isolated from a patient with pyelonephritis. The GMM's do not represent any greater risk than the parental organisms and therefore will be treated as ACDP hazard group 2.

We will make the knockout mutants by using the method described by Datsenko & Wanner (2000) (PNAS USA 97:6640) as used by Barnich et al (2004) (Infect Immun 72:2484) in which a targeted sequence containing the gene of interest is replaced with a selectable antibiotic resistance gene (kanamycin or possibly tetracycline) generated by PCR using primers with 50-nucleotide extensions that are homologous to regions adjacent to the gene of interest. The inactivated DNA will be introduced by electroporation into target E.coli strains transformed previously with plasmid pKOBEG encoding red proteins from bacteriophage lambda. The genes to be targeted for mutation include genes encoding CNF1 and LPS production. The effect of gene inactivation will then be assessed using incubation with rat or human ureter tissue and isolated cells followed by contractility measurements and confocal imaging. Mutants will be complemented by cloning gene back using the plasmid vector pHSG575 (carries chloramphenicol resistance).

In addition, we propose to introduce a green fluorescent protein expressing plasmid vector (pBRD940; Wigley et al. 2001 (Infect Immun 69:7873): carrying ampicillin resistance) into a UPEC strain (J96,536 and CFT073) in order to monitor the location of bacteria following incubation with ureter samples.
The GMMs will be uropathogenic E.coli with additional kanamycin resistance. These will be knockout mutants, and may be less pathogenic than wild-type UPEC, but they should be considered as potentially pathogenic (in the same way as the wild-type strains). Other GMM's will be UPECs containing low copy number plasmids (pHSG575) for complementation, or GFP-containing plasmids (pBRD940). The added genetic material will be either antibiotic resistance genes or a green fluorescent protein expressing plasmid. The antibiotic resistance genes chosen are not themselves harmful. GFP is not harmful and will be introduced in order to monitor the location of bacteria following incubation with ureter samples.

Evaluation of foreseeable effects

The recipient bacteria are the most widely studied UPEC strains J96, 536 and CFT073, each of which was isolated from a patient with pyelonephritis. The antibiotic resistance genes are not themselves harmful and GFP is not known to be harmful. Tetracycline, chloramphenicol and kanamycin are not antibiotics generally used in the treatment of E.coli infections.

The risk for human health is the same as with wild-type UPEC. Any alteration of pathogenic traits in the specific knock-out mutations is likely to be making the strain less pathogenic since the aim is to "knock-out" genes that might contribute to pathogenicity. The most likely infection route is gastrointestinal however, they lack the necessary virulence genes to cause enteropathogenic infections, but they could conceivably become part of the normal flora. There are no foreseeable events that suggest GMMs would require any greater care in handling than the parent organism which are very well characterised UPEC that require containment level 2 handling. The infectivity and host-range of the GMM can be assumed to be comparable to that of wild-type UPECs.

Origin & function

The GMMs will be uropathogenic E.coli with additional kanamycin resistance. These will be knockout mutants, and may be less pathogenic than wild-type UPEC, but they should be considered as potentially pathogenic (in the same way as the wild-type strains). For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Duncan Building:
All cultures of GM E.coli and all consumables used in the handling of the GMMs will be subjected to autoclaving and incineration following the normal procedures for disposal of clinical waste. The effective degree of kill is 100%. The efficacy of the autoclaves is monitored quarterly by multi-point thermocouple checks. Autoclaves are subjected to an annual service and inspection. External validation of the pressure vessel leading to the tissue of a pressure validation certificate also occurs annually. In addition, a chart recorder produces a record of each run to confirm effective killing.

Physiology laboratories:
Small solid waste (tips, tubes etc) will be collected in an autoclave biohazard bin and taken for autoclaving and incineration. Disposable cell-culture consumables will be soaked in 1% Virkon disinfectant overnight and autoclaved prior to incineration. Waste media will be chemically inactivated in 1% Virkon overnight prior to disposal. Cell culture hoods and benches will be disinfected routinely before and after experimental procedures and at the end of each working day. Autoclaving will be monitored using TST (Time, steam, temperature) test strips in each run (Albert Browne Ltd, TST class 6 emulating indicator 121 degrees C for 20 mminutes). The autoclave is validated by annual thermocouple mapping and maintained by Priorclave engineers annually.

Project Additional Information
**Purposes of the contained use**

The generation of induced pluripotent stem (iPS) cells from adult somatic cells may potentially provide a patient-specific source of pluripotent stem cells creating significant clinical potential. The use of iPS cells for therapeutic purposes is at present hampered due to the use of potentially harmful retroviral vectors involved in their production.

The aim of this study is to investigate non-viral methods of producing iPS cells, namely nucleofection. The cells of interest will be keratinocytes isolated from normal adult humans and the study will involve cotransfecting these cells with plasmid DNA using a nucleofector device, manufactured by Amaxa, in order to stimulate iPS cell production.

**Recipient or parental organism**

Human epidermal keratinocytes isolated from normal human adult donors, which have been tested for mycoplasma, Hepatitis B, Hepatitis C and HIV-1 viruses and do not pose any risk to human health and safety.

**Host/vector system**

Plasmid DNA, which will be constructed commercially and arrive ready for transfection. Each vector will contain the open reading frame of the desired genetic material within a PCMV6 vector. This vector contains a CMV promoter for mammalian expression of the inserted genetic material, the human growth hormone polyA signal is located downstream of the insert and the SV40 ori for replication in mammalian cells. It also contains the ColE1 ori, which is the bacterial origin of replication and the f1 ori, which is the filamentous phage origin or replication allowing the recovery of single stranded plasmids. Each vector also contains an antibiotic resistance gene for isolation of successfully transfected cells and fluorescent tag.

**Origin & function**

The following genes are involved in regulating the undifferentiated state of embryonic stem cells. Through transferring these genes to somatic cells the cells intrinsic regulatory network can be overcome allowing the cells to revert back to a pluripotent, undifferentiated state.

- **Oct4**, transcript variant 1. Accession number: NM_002701.4
  This transcription factor is essential to maintain the self renewal of undifferentiated embryonic stem cells and is associated with a pluripotent phenotype.

- **Sox2**. Accession number: NM_003106.2.
  This is another transcription factor that works in conjunction with Oct4 in maintaining the self renewal of undifferentiated embryonic stem cells and is also associated with a pluripotent phenotype.

- **Kruppel-like factor 4 (Klf4)**. Accession number: NM_004235.3
  This transcription factor normally functions in differentiating epithelial cells but can act as both an oncogene by repressing p53 and also as a tumour suppressor.

**Evaluation of foreseeable effects**

The nucleofector device will be used to deliver each of the three genes to the nucleus of human epidermal keratinocytes. Cells that are successfully co-transfected with each of these genes will undergo reprogrmming and revert to an undifferentiated phenotype. Even in combination with the nucleofector solution and optimised nucleofection program, which aid entry of these genes to the nucleus it is predicted that the likelihood that these cells will receive all three reprogramming genes will be around 1% using optimised conditions, therefore when considering the risks associated with humans being exposed to each of these three genes the likelihood that they would receive all three is extremely unlikely and coupled with the stringent containment measures that will be put in place we feel the risks to human health and safety are minimal.

Along with the direct effects of reprogramming and maintaining an undifferentiated state these genes may interact with a large number of other genes affecting a wide range of cellular functions, previous studies have used the same combination of genes and have not shown any unusual effects therefore it is unlikely they pose any additional risks should humans be exposed to these genes. It should also be noted that whilst absorption of plasmid DNA through intact skin is unlikely it is possible [Kang.

The majority of the inserted genetic material will pose no risk to human health and safety however one of the proposed genes, Klf4 is capable of producing oncogenic proteins and must be given due consideration. This investigation utilises an optimised electroporation method, which transfers the genetic material to the cell nucleus however the efficiency of this gene transfer is likely to be low. When considering the risks to human health and safety and the likelihood of this gene transfer is likely to be low. When considering the risks to human health and safety and the likelihood of this genetic material being transferred to human cells through direct contact we have found this to be extremely unlikely due to the poor mobilisation of the proposed vector. As we are aware of the potential effects of gene transfer containment measures will be put in place to minimise any risk to human health and safety.

There are also significant barriers that will prevent the transfer of inserted genetic material to the environment. In order for transfer to occur there has to be a release of functional DNA, persistence of the DNA then uptake by competent organisms. The lack of homology between eukaryotic and prokaryotic DNA makes transfer of genetic material to bacteria highly unlikely. Most bacteria in the environment are not normally in a competent state and those that are have low transformation efficiencies. The possibility that there would be an adverse environmental impact is even more remote since assuming that this highly unlikely transformation even did occur there would have to be expression of the protein and the expression would have to confer a selective advantage otherwise the genetic material would be lost due to random mutation or deletion. In combination with the stringent containment measures that will be followed I do not foresee any potential hazards.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste, such as plastic disposables, will be placed in leak proof container containing 1% Virkon solution for 24 hours then autoclaved on cycle 1, which reaches 134 degrees celcius and lasts for 2 hours. Once autoclaved all waste will be disposed of in a yellow clinical waste incinerator bag and incinerated.

All fluid waste, such as cell culture medium, will be emptied into Virkon 1% solution and also autoclaved on cycle 1. Once work has been carried out using the designated class II safety cabinet this cabinet will be dismantled and disinfected with Virkon 1% solution then washed down twice with 70% ethanol and subjected to formaldehyde bomb fumigation to remove any waste.

Virkon manufacturer's data states it is a bactericidal and fungicidal disinfectant suitable for killing bacteria, spores and viruses from hard surfaces such as an experimental equipment and safety cabinets.

The autoclave manufacturer states that all autoclaved material will be sterilised and free from bacteria and viruses giving 100% kill.

The formaldehyde bomb manufacturer states all microorganisms will be killed post fumigation.

**Purposes of the contained use**

We will clone fragments of human genomic DNA encompassing specific exons of our genes of interest or a protein tag, along with a selection marker, into the pAAV vector. The plasmid will then be transfected into HEK293T cell line along with the pHelper packaging and pAAV-RC envelope vectors. The transfected cells will release...
replication-incompetent AAV particles into the supernatant and this virus will be used to infect human cell lines in order to generate recombinant cell lines. In these cell lines, the endogenous exons of our genes of interest will be replaced by the ones encoded in the designed pAAV vector resulting in either

- exon loss to knock-out gene function
- introduction of a SNP/small deletion/small insertion into the endogenous gene or
- a tagged version of the endogenous gene using a reporter gene e.g. luciferase.

**Recipient or parental organism**

AAV vector plasmid will be propagated in bacterial strains of E. coli, such as:
- XL-1 blue (Invitrogen)
- DH5alpha (Invitrogen)
- SCS110 (Stratagene)
- JM109, JM110 (Promega)

Viral vectors will be propagated in mammalian cell lines from the following list; all cell lines are from ATCC/CRUK mammalian cell collections unless otherwise stated.

- Only fully authenticated, long-established cell-lines posing minimal risk will be used.
- HeLa Human cervical adenocarcinoma cells
- AAV-293 cells Human embryonic kidney cells optimised for producing AAV vector
- HEK293T Human embryonic kidney cells
- K562 Human chronic myeloid leukemia cells
- HepG2 Human Hepatocellular Carcinoma cells
- DU145 Human Prostate carcinoma cells
- LNCap Human Prostate carcinoma cells
- HT29 Human Colonic Epithelial cells
- PANC1 Human Pancreatic carcinoma cells
- SUIT-2 Human Pancreatic carcinoma cells (Mark Boyd laboratory, Liverpool)
- MCF-7 Human Breast Carcinoma
- MCF-10 Human Breast Carcinoma
- H1975 human lung adenocarcinoma cells
- H1680 human lung adenocarcinoma cells
- A549 human lung adenocarcinoma cells
- SW48 human colonic epithelial cells
- MCF10a human breast cancer cells
- NIH 3T3 NIH Mouse embryonic fibroblasts
- MIA Paca-2 Pancreatic carcinoma cells
- BxPC-3 Ovarian carcinoma cells
- AsPC-1 Pancreatic carcinoma cells
- Capan-1 Pancreatic carcinoma cells
- Capan-2 Pancreatic carcinoma cells
- FAMPAC Pancreatic carcinoma cells
- SW837 Rectal cell line
- SW480 Colonic cell line
- HPDE6-E6E7 pancreatic ductal cells

The following isogenic cell lines expressing an oncogene or with loss of tumour suppressor may be subject to further modifications:

- X-Man (Horizon Discovery; http://www.horizondiscovery.com/) isogenic MCF 10a human breast cancer cells and SW48 human colonic epithelial cancer cells expressing wither a single mutant PI3Kalpa (1047R), PI3Kalpa (E545K), EGFR (deleted E746-A570) or K-Ras (G12V), a double mutant of PI3Kalpa (H1047R) & EGFR
(delE746-A750) or finally MCF10a cells null for PTEN.

SW837 Rectal cell line
SW480 Colonic cell line
HPDE6-E6E7 pancreatic ductal cells

The following isogenic cell lines expressing an oncogene or with loss of a tumour suppressor may be subject to further modifications:
X-Man (Horizon Discovery; http://www.horizondiscovery.com/) isogenic MCF10a human breast cancer cells and SW48 human colonic epithelial cancer cells expressing
either a single mutant P13Kalpha (H1047R), P13Kalpha (E545K), EGFR (deleted E746-A750) or K-Ras (G12V), a double mutant of P13Kalpha (H1047R) & EGFR (del
E746-A750) or finally MCF10a cells null for PTEN.

Host/vector system

pAAV-MCS, pHelper and pAAV-RC vectors from the Stratagene Helper-Free AAV system will be used to make AAV-2 viral particles.

A synthetic plasmid equivalent to pAAV-MCS but containing the homology arms of the target genomic DNA surrounding a Neomycin resistance selection cassette will be
made for transfection into the AAV-293 cells

Origin & function

PCR-generated protein-coding regions from mammalian genomic DNA for intracellular proteins involved in endocytosis, signalling, oncogenesis, tumour suppression, and
the Kennedy pathway. These include kinases and phosphatases that respectively add or remove phosphate groups from other proteins or lipids. GTPases that are
GDP/GTP binding molecular switches acting as adaptors for the recruitment of other signalling proteins. Ubiquitin modifying enzymes that add or remove ubiquitin - a major
post-translational modification in all signalling networks. Enzymes involved in lipid biosynthesis and lipid modifications . Cytoskeletal proteins important for regulating cell
organisation, cell division and membrane trafficking. Transcription factors involved gene expression and other DNA binding proteins. None of the DNA sequences code for
toxins.

Evaluation of foreseeable effects

Viral vector and host bacteria:
Wild type AAVs are not categorised by the Advisory Committee on Dangerous Pathogens (ACDP). AAVs are defective by nature (i.e. need a helper virus to replicate). They
are not associated with human illnesses, although a possible link between AAV and spontaneous abortion has been made. The hazards to human health can be expected
to be low. The AAV system we are using (Stratagene Helper-Free AAV system) is a 'gutless' system which does NOT require wild-type adenovirus to supply helper
functions.
The AAV system that will be used is AAV serotype 2 virus, over 80% of the human population is serotype positive illness. Transmission may be via direct needle stick,
aerosol, faecal-oral route or direct conjunctival injection.
The main hazard associated with AAV vectors arises from the inserted genetic material.
The pAAV-MCS plasmid containing the two homology arms each targetting approx 2kb of genomic DNA and transfected into AAV-293 cells together with helper plasmids
(pHelper and pAAV-RC) to enable replication and packaging of AAV-2 viral particles.
Bacterial strains, such as DH5alpha E. coli will be used for DNA propagation.

Mammalian cells that will be modified:
We will be modifying endogenous genes cloned from mammals encoding signalling, transcription, tumour suppressors, oncoproteins and trafficking proteins. Some of our
proteins of interest are known proto-oncogenes (theGTPase Ras and the protein and lipid kinases Raf, EGFR, Met, PI3K, Akt) or tumour suppressors (p53, APC, Rb,
PTEN). NB. The majority of proteins that we study have no known oncogenic potential however they are subject to the same precautions in our laboratory as the known
proto-oncogenes.
The genetic material inserted into the AAV vector will be of 3 types:
1. For exon loss to knock-out functions. Genetic material: Genetic DNA surrounding the region to be targetted and a selection cassette to knock-out gene function.

2. Introduction of a SNP/small deletion/small insertion into the endogenous gene. Genetic material: Genomic DNA encompassing the region to introduce the SNP/small deletion/small insertion of interest and a selection cassette.

3. For a tagged version of the endogenous gene using a reporter gene eg. Luciferase, GFP, HaloTag. Genetic material DNA encompassing the region to be targetted, a reporter gene and a selection cassette.

In every case we will not be inserting the complete gene from the endogenous locus. This technology targets the endogenous gene locus and therefore we only need to target the region of interest.

It is possible that the AAV will be able to exist episomally within the cell, this is a short lived phenomenon typically lost within the first 2 passages of cell culture. Drug selection for positive clones is only initiated after the first passages to prevent selection for false positives derived from episomally expressed Neomycin resistance. No cDNA will be used and the AAV2 viruses will be incapable of expressing any part of the genomic DNA that they carry. The human pGK promoter is 3’ to the LH arm targeting the endogenous gene. The promoter is only there to enable expression of the drug resistance cassette eg. For Neomycin resistance and will not drive expression of any part of the target gene.

**Direct effects:**

Insertion of a gene into the target cells will be accomplished via AAV-mediated transduction. With this procedure accidental exposure as a result of needle sticks will be minimal because sharps will not be used. However in the case of accidental exposure it is unlikely that the inserted gene will result in the formation of a neoplasm for two reasons:

1. We are using fragments of DNA to target parts of exons within endogenous genes via targeted homologous recombination. This is an inefficient process with >0.01% successful targeting per virion therefore the vast majority of infections result in insertions outside the target area generating non-functional/non-coding DNA Integration.

2. Although some genes that we will target may code for oncogenes or tumour suppressor genes (TSGs) carcinogenesis is a multifaceted process that requires changes both within the cell and to the cell microenvironment. Therefore it is unlikely that the inserted genes would satisfy these requirements. The chance for harmful biological effect to manifest itself as a result of accidental exposure is minimal and likely equivalent to other transfection techniques.

**Effects of gene transfer:**

For each of the 3 types of inserted genetic material the hazards are as follows:

1. Exon-loss to knock out functions.

This will have very few hazards with it as we typically removing gene function. If the gene targetted is a TSG (eg. PTEN or p53) there may be an effect on the cell characteristics depending on the particular gene.

Worst case scenario: if an end-user were to infect themselves it is possible that the targeting construct could remove the function of the endogenous gene in the infected cells. However it would only target one allele of the gene rendering the cell heterozygous. For TSGs the tumourigenic effect is only seen when both alleles are removed. Since cancer is a multistep process, the removal of gene function is very unlikely to lead to complete cancer. At worst it would make the few targetted cells one step along the path to tumourigenesis.

2. Introduction of a SNP/small deletion/small insertion.

This is the procedure that has the most risk. For example we may want to introduce a mutaton known to be oncogenic (eg. Changing codon 12 from Glycine to Valine in Ras). Transformation of cells has been shown to be a multi-step process requiring mutation in more than one gene therefore introduction of a single mutation provides a low risk of transforming any cell line. There is a potential for it to be oncogenic when recombined in the genes endogenous locus. However expression levels of this altered version of the gene will be generally lower as it is expressed under the control of its endogenous promoter, this is in comparison to the effects on cells of the same mutation under the control of a high level exogenous (eg. Viral) promoter which has been typically shown to be transforming in cell lines.

Worst case scenario: If an end user were to infect themselves with this type of recombinant AAV vector it is possible that the targeting construct could change the function of the endogenous gene in the infected cells. It would only target on a allele of the gene rendering the infected cell heterozygous but has been shown to be associated with progression along the tumourigenic process. Since cancer is a multistep process this gain of gene function is very unlikely to lead to complete cancer. At very worst it would make the few targetted cells one step along the path to tumourigenesis. The degree of infection is likely to be small in the end user because the targeting process is very inefficient so even if cells are infected with recombinant AAV virus very few of these would have the DNA corrected inserted into the target gene. In summary, the highest
level of risk comes from this class of gene manipulations however even if an end-user were to be infected there would be a very low risk of the infected cells being correctly
targetted. If the cells are correctly targetted these cells are unlikely to be cancerous - at worst they will be one step along the path to cancer.

This will have very low hazards associated with it as we are not changing the endogenous expression or characteristics of the targetted gene. Reporter genes such as GFP
or luciferase have no hazards associated with them.
Worst case scenario: if an end-user were to infect themselves with this type of recombinant AAV vector it is possible that the targetting construct could make a fusion
protein with the reporter gene. However since the reporter gene has no hazards associated with it the only result would be that the infected cells would express the reporter
gene.
There is no evidence that when the inserted genetic material recombines with the host cell lines genomic DNA that any sequences of the AAV viral genome are
incorporated. In the recombinant AAV viral particles the only AAV genomic sequences present are the LTRs (for specifying integration sites) and there is no evidence that
these are incorporated into the host genome during homologous recombination.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste (Plastic dishes, pipettes and tubes used for cell, bacterial and viral culture and handling)
Disposal procedure: Waste double bagged and autoclaved on standard cycle. Pipettes decontaminated via soaking in holder with 2% Trigene Advance or 5% Rely+On
Virkon advance before disposal in Cin-bin for incineration.

Waste will be transported to the autoclave double bagged in autoclave bags and placed in a lidded container.

Autoclaves: Boxer 200/200L, LTE Scientific series 280 and F03 LTE osprey. Validation: Annual service and callibration carried out by engineer. Boxer 200 gives printout
our individual runs to confirm temperature and time.

Liquid waste (Waste media from viral, bacterial and cell cultures)
Disposal procedure: Trigene Advance at a final concentration of >2% or Rely+On Virkon (final concentration 5%). Overnight prior to disposal in dedicated sinks.

Good occupational hygiene practice will be used throughout.

Is an emergency plan required according to regulation 20? Y

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
The genetic modification safety committee agreed that the project is assessed as containment level 2.

A summary of comments was tabled and the following items discussed.

- E. coli cloning was not adequately represented/included in the risk assessment. This was corrected.
- The start date was incorrect and should be changed
- Section 2.1 - Discussion was held about whether the cell lines which would be modified by AAV in this project were previously purposefully infected with viruses, for the purposes of transforming them. Following discussion, it was agreed that the cancer cell lines in this study were transformed in nature.

The committee pointed out that although the AAV are not categorised by the Advisory Committee on Dangerous Pathogens (ACDP), it does not naturally follow that they are Containment Level 1.

- Section 4.6.1 - The committee advised that 'recent publications have looked for a possible link between AAV and spontaneous abortion'. This is a tenuous risk but needs to be included on the risk assessment as a duty of care to staff.

### Project Ref 554/12.2

**Date Ackn’d** 31/01/2012

**CU2 Project Title**

- Molecular microbiology and physiology of the human commensals and opportunistic pathogenic bacteria Staphylococcus aureus, Staphylococcus epidermidis, Enterococcus faecalis and Enterococcus faecium

**Class**

- Class 2

**CultureVolClass2** ≤ 1 Litre

**Non-GMM Consent Granted**

- Consent Granted

**Project notified under transitional arrangements**

- **N**

**Tick if notifying a connected programme of work**

- **N**
The research aims are to determine the virulence and environmental survival determinants that enable these bacteria to cause disease and survive in the environment and therefore to provide theories regarding their transmission and ability to cause pathology during infection. The use of recombinant strains will allow the individual genetic contributions of determinants.

Recipient or parental organism

(see attached documentation)
Staphylococcus aureus strains: SH1000 (and isogenic variants 8325-4, RN4220); Newman; UAMS-1.
Staphylococcus epidermidis strains: RP62a, 1457, Tu3298
Enterococcus faecalis: OG1RF; JH2-2; V583, CG110
Enterococcus faecalis: TX0104
Escherichia coli: (K12 strains: DH5alpha,Top10,), BL21(lambda DE3)

Host/vector system

(see attached documentation)
For S. aureus and epidermidis strains:
pAZ106, pMUTIN4, pSK5632, pCU1, pMK4, pLTV1, pSB2035

Plasmids for proposed work:
1. General cloning plasmids (pBluescriptSK, pUC18, pSL1190, pAZ106) colE1 based plasmids for cloning S. epidermidis genes without attempting to express encoded products.
3. pSB2035 RNAIII-gfp-luxABCDE, this is a pMK4 based plasmid that allows promoter fusions that expresses the gfp and lux operons for assays of gene expression in S. epidermidis (with cloning in E. coli strains listed) Cm [PMID: 11598083]
4. pLTV1 21kb colE1, pE194ts replicons, shuttle plasmid that contains spoVG-lacZ translational fusion for generating lacZ fusions during rounds of mutagenesis using the transposon Tn917 mutations in S. aureus. Amp, Cm, Tet, Erm [PMID: 2163385]
5. pBT2, pE194ts replicon containing the Mariner transposon, with similar properties to Tn917, except it has a more random integration pattern. Amp, Tet, Erm [PMID:21173311]

For E. faecalis and faecium work:
1. General cloning plasmids (pBluescriptSK, pUC18, pSL1190, pAZ106) colE1 based plasmids for cloning S. epidermidis genes without attempting to express encoded products.
products.

2. pTCVlac  12kb pAMB1, pACYC184 replicons, shuttle plasmid that contains spoVG-lacZ translational fusion for generating lacZ reporters in E. faecalis (FEMS Micro Lett 156:193 [1997]) Ern Kan

4. pTCVlac(gfp)(lux) this is a plasmid that will be generated to allow translational fusions to gfp gene or lux operons for assays of gene expression in E. faecalis (with cloning in E. coli strains listed)  Erm Kan

5. pAT18 pAMB1, colE1 replicons, universal shuttle vector with multiple cloning site from pUC18 (Nucleic Acids Res 18:4296 [1990])Amp, Spc

6. pCU1 pE194, colE1 replicons, universal shuttle vector with multiple cloning site from pUC19 (Nucl eic Acids Res 18:4296 [1990]), Amp,Cm

7. pLTV1  21kb colE1, pE194ts replicons, shuttle plasmid that contains spoVG-lacZ translational fusion for generating lacZ fusions during rounds of mutagenesis using the transposon Tn917 mutations in E. faecalis. Amp, Cm, Tet, Ern (PMID: 2854092, PMID: 8763945)

8. pAZ106 8.3kb colE1 replicon based vector that contains spoVG-lacZ translational fusion for generating reporter fusions in E. faecalis.  Amp, Ern (PMID: 9846745)

9. pET family plasmids (pET24d+, pET21a) and pTB361/375 colE1 replicon based vector for T7 promoter driven overexpression of proteins.

Origin & function

The genetic material will be derived from Staphylococcus or Enterococcus strains, either those listed above or from clinical isolates. The selection of DNA will NOT include known toxins and correspondingly there will be no attempt to increase expression of toxins by their cloning with promoters for overexpression. These toxins are very well characterised and not the subject of investigation.

The derived strains are for use with models of survival, growth and bacterium-bacterium interaction.

Evaluation of foreseeable effects

The four bacteria that will be genetically manipulated are commensals that cause opportunist disease. The manipulations that will be undertaken are aimed at generating mutants that have reduced fitness and should thus be attenuated for infection or of equal virulence to their isogenic parent. Studies are NOT aimed at increasing virulence. Infections with GMM will be prevented using the standard microbiological containment procedures used with expertise in the laboratory. The GMM will remain sensitive to clinical antibiotics prescribed for disease and will not be endowed with increased pathogenicity.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Containment level 2 only

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

(information also on risk assessment forms attached)
Waste will be collected in bags (solid waste e.g. tips, wipes, agar plates) and transported, double bagged in sealed metal cannisters from Room 302 to the autoclaves, which are located in the wash up facility in room 101 of the Life Sciences Building. There are two cycles in use; Sterilisation cycle 121 degrees C for 15 minutes; Discard cycle 131 degrees C for 15 minutes. These machines are serviced, validated by thermocouple testing by contractor and calibrated every 6 months. In event of an autoclave breakdown waste will be stored at 4°C until autoclave repaired.

Spills will be wiped with solid waste treated as above. The area contaminated will then be sterilised using chemical treatment with Virkon or Trigene using the described procedures for these chemicals; Information on efficacy can be found at http://www2.dupont.com/RelyOn/en_US/assets/downloads/europe/Virkon_efficacy_data.pdf Trigene; Basic information of efficacy is available at the website below and a full list of organisms against which it can be used is available from the manufacturer or the Safety Office in the Life Sciences Building room G31.

Please enter comments on the GM safety committee on the risk assessment
Studies on the growth, physiology and virulence of Staphylococcus epidermidis: major commensal of human skin and opportunist pathogen.

14/12/10 Considered by the Biological Safety Committee. It was requested that a number of minor alterations be made to sections 2.1, 4.1, 4.3, 4.4, 4.4.1, 4.4.2 and 4.6.1.

15/6/11 Reconsidered by the Biological Safety Committee. Alterations made satisfactorily. Approved at Class 2.

Studies on the growth, physiology and virulence of Enterococcus faecium: gut commensal of humans and opportunist pathogen.

14/12/10 Considered by the Biological Safety Committee. It was requested that a number of minor alterations be made to sections 2.1, 4.1, 4.3, 4.4, 4.4.1, 4.4.2 and 4.6.1.

15/6/11 Reconsidered by the Biological Safety Committee. Alterations made satisfactorily. Approved at Class 2.

Studies on the growth, physiology and virulence of E. faecalis: gut commensal of humans and opportunist pathogen.

Periodic up-date of Class 2 risk assessment 2003-08. The following minor changes have been made from the original proposal:

The title has been changed from 'Studies on the role and regulation of Enterococcus faecalis surface protein'.

Additionally use commonly used laboratory strain Enterococcus faecalis V583.

Additionally use cloning plasmid pAZ106 (A promoterless lacZ erm insertion vector).

Additionally use pCJK72 Bursa aurealis mariner transposon delivery plasmid, Cm, Erm. There is published work describing the use of this plasmid.

Updated risk assessment considered by the Institute Biological Safety Officer and the University Biological Safety Advisor, July 2011 and circulated to the Biological Safety Committee August 2011. It was agreed that the proposal is Class 2.
Studies on the growth, physiology and virulence of Staphylococcus aureus

Periodic up-date of risk assessment 2003-07. The following minor changes have been made from the original proposal:

The title has been changed from: Studies on the role and regulation of Staphylococcus aureus surface proteins.

There has been up-dating of S. aureus strains by including Newman (a Staphylococcus aureus strain that maintains the agr phenotype and UAMS-1 (a rsbU-positive clinical isolate).

Additionally use cloning vector pSK5632, a low copy S. aureus shuttle vector, pBT2 and pE194ts containing the Mariner transposon.

Updated risk assessment considered by the Institute Biological Safety Officer and the University Biological Safety Advisor, July 2011 and circulated to the Biological Safety Committee August 2011. It was agreed that this proposal is Class 2.

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID
**Project Additional Information**

**Purposes of the contained use**

The research aims to determine virulence and environmental survival determinants of Salmonella Typhimurium. Analysis of Salmonella Typhimurium transcriptomes (using the next generation sequencing-based RNA-Seq approach) from different infection-relevant environmental conditions will identify candidate genes involved in virulence and environmental survival. The use of recombinant strains will allow the individual genetic contributions of these different determinants to be elucidated. We hope that the identification of genes responsible for virulence and environmental survival will lead to novel prophylactic or therapeutic approaches to combat Salmonella infection.

**Recipient or parental organism**

Salmonella enterica serovar Typhimurium, strains: ST4/74 (and derivative SL1344), LT2, D23580
Escherichia coli K12, strains: DH5alpha, Top10

**Host/vector system**

Plasmids:
- pKD46, pKD20 - which encode the Lambda Red system for making chromosomal mutations (Datsenko and Wanner, PNAS 2000).
- pCP20 - encodes Flp recombinase gene for removal of cassettes inserted by Lambda Red, and flanked by Flp sites (Cherepanov et al., Gene 1995)
- pDIGc and pDIGi - these plasmids each carry a fluorescence marker. These will be used to perform a newly developed technique called Fluorescence Dilution that measures intracellular survival and replication of bacteria (Helaine et al., PNAS 2009)
- Plasmids expressing GFP and RFP to be used for competition experiments (Segura et al., J. Microb. Meth. 2003)
- Standard cloning vectors: pBAD (Invitrogen), pUC (Vieira et al., Gene 1982)
Generalised transduction with bacteriophage P22.

**Origin & function**

The genetic material will be derived from the Salmonella enterica serovar Typhimurium strains, listed above. The genes that will be analysed are potentially involved in environmental survival and virulence. The derived strains are for use with models of bacterial infection: in vitro growth on solid and in liquid media mimicking infection-relevant conditions, as well as infection models involving cultured cell lines (RAW264.7 macrophages, and HeLa and Caco-2 epithelial cells).

**Evaluation of foreseeable effects**

One of the Salmonella Typhimurium strains we will manipulate genetically is non-virulent (LT2), and the other three cause disease (ST4/74, SL1344, and D23580). The manipulations that will be undertaken are aimed at generating mutants that have single, or sets of inactivated genes. None of the resulting GMO will be more virulent than the D23580 strain. Studies are NOT aimed at increasing virulence.
Any effect of infections with GMM will be prevented using the standard microbiological containment procedures that are carefully applied in the laboratory. The GMM will remain sensitive to clinically-relevant antibiotics.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Containment level 2 only.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

| Waste will be collected in bags (solid waste e.g. tips, wipes, agar plates) and transported, double bagged in sealed metal canisters from Room 302 to the autoclaves, which are located in the wash-up facility in Room 101 of the Life Sciences Building. The area contaminated will then be sterilised using chemical treatment with Virkon or Trigene using the described procedures for these chemicals; Information on efficacy of Virkon can be found at http://www2.dupont.com/RelyOn/en_US/assets/downloads/europe/Virkon_efficacy_data.pdf Trigene; Basic information of efficacy is available at the website below and a full list of organisms against which it can be used is available from the manufacturer or the Safety Office in the Life Sciences Building room G31. http://www.medi-mark.co.uk/images/uploads/TriGene_2p_lab.pdf |

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
This risk assessment was considered by a meeting of the Biological Safety Committee on 26th June 2012. The following changes were requested before final approval could be given.

1. In the summary, please include something about the genetic modification risks.
The genetic modifications planned for this project do not aim to, and are highly unlikely to make a more virulent strain than ST313. 

2.1 Please provide more detail of the strains. Is STM SL1344 correct?
The full names have now been provided.

3.1 b. It is not clear from the text the reason for the plasmids being listed under Inserted genetic material.
We have now specified how the plasmids will be used, and why.

3.2 a. Human health is again considered here. This section is about the environment. Should consider any possible effects on animal health.
STM LT2 is not virulent, and does therefore not impose a risk on the environment. SL1344 and ST4/74 are known to cause disease in humans (self-limited gastroenteritis), as well as in calf, pig and chicken. Salmonella Typhimurium ST313 only causes serious disease in the at-risk patient group (see 4.6.1).

The level 2 containment and control measures should prevent the GM organisms from reaching the environment and causing harm to humans or animals outside the laboratory.

4.1 It was not felt that delayed opening would reduce the risk of aerosols. At least a validated time delay should be stated. State what the standard protective measures are.
Centrifugation and vortexing will be carried out in sealed tubes. Potential risk will be minimised by delaying opening for a minimum of 30 seconds, opening and transferring in a safety cabinet and the wearing of appropriate personal protective clothing.

4.4 Give effective contact time for Trigene. Can give the Trigene web-site, but should also give the appropriate details on the form. The safety office is 3.19 not G31.
For every-day use, a 1:100 dilution of Trigene advance will be used, and contact time for disinfection will be at least one minute. In the case of destruction of liquid waste, or in case of a larger spill (e.g. bacteria culture, max volume 50 ml) a 1:50 solution of Trigene will be used, and the contact time for disinfection will be at least 10 minutes before rinsing or soaking up with blue wipes.

4.4.1. Five autoclaves are available so no need to store. OK
4.4.2 Give details specific for Salmonella and correct location of safety office 3.19 OK

4.6.1. The effect on immuno-compromised individuals should be considered in the risks to human health section. With the level 2 containment and good laboratory practice, the risk of Salmonella infection should be negligible. However, any immuno-compromised individual working on this project in the lab must have permission from relevant consultant, as there is a potential risk that these individuals, if infected, can aquire the more severe form of disease associated with ST313.
Corrections were made and the risk assessment was approved on 28th June 2012.

### Project Additional Information

#### Purposes of the contained use

Mutation of Salmonella and Campylobacter isolates by transduction using bacteriophages or by insertion mutagenesis using plasmids enables us to study the roles of certain genes during infection.

#### Recipient or parental organism

Salmonella enterica. To include serovars: Typhimurium, Pullorum, Derby, Virchow, Gallinarum, Enteritidis

Campylobacter jejuni

#### Host/vector system

- **pUT mini-Tn5 plasmids** (R6K-based suicide delivery plasmids)
- **EZ-Tn5 transposome <KAN-2>** (R6K deleted)
- **P22 temperate bacteriophage** (infects Salmonella Typhimurium). A P22 mutant, P22 HT105/1 int-201 will be used as it has a high transducing frequency.

#### Origin & function

Transposons (Mini-Tn5 transposons) encoding antibiotic resistance genes (kanamycin, ampicillin, nalidixic acid, tetracycline) and/or green fluorescent protein (Mini-Tn5TcGFP transposons). EZ-Tn5 transposons containing kanamycin selectable marker (<KAN-2>). The function of the transposons is to induce insertional
mutagenesis in the host organism. The function of the antibiotic resistance genes and green fluorescent protein is as selection markers. The Tn5 system is a naturally occurring transposition system found in gram-negative bacteria. EZ-Tn5 is a hyperactive Tn5 transposition system.

Bacteriophages P22 containing Salmonella Typhimurium chromosomal DNA fragments (transducing particles) and antibiotic resistance genes. P22 is related to bacteriophage λ and is used for generalized transduction of host organisms whereby genes of interest can be inserted into the host genome.

Evaluation of foreseeable effects

The GMOs will not pose any greater risk than wild-type Salmonella spp or Campylobacter jejuni. The purpose of transduction of the isolates and/or the insertional mutagenesis is to disrupt the function of certain genes. This disruption will either attenuate the organism's survival and/or virulence or the organism will continue to display wild-type phenotype.

An indirect effect of the mutagenesis is the acquirement of antibiotic resistance. However, the antibiotic resistance genes used as markers are not routinely used in the treatment of enteric infections. Theoretically it would be possible for antibiotic resistance genes to be transferred from mutant isolates to other bacteria, however this would be unlikely to occur in a laboratory situation. For gene transfer to occur, a series of very low frequency events would have to take place.

There is a very small risk that unknown virulence-related genes may be up-regulated with introduction of GFP. However, this has not been observed for GFP-expressing strains already constructed including Salmonella Pullorum 449/87 pBRD940.

There may be a theoretical risk to animals (which is low because clinical disease is not usually seen in infected animals). There is no known potential for harm to plants. These isolates are unlikely to survive well in the environment, although this has not been specifically tested. The likelihood of the GMM actively causing additional harm is very low and may be less fit than the unmodified organism.

Transposase activity of the insert is not maintained in the target cells so gene transfer/recombination would occur only at the normal, random rate. Plasmids used are designed to have a restricted host range and will not be conjugative (i.e. plasmids will not carry genes necessary for the ability to transfer themselves to other bacteria). As such these sequences cannot readily be transferred to other organisms.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste including contaminated agar plates, cell culture plastic ware, pipette tips, microplates and tubes will be autoclaved at 126 degrees Celcius for 15 minutes and then incinerated. Pipette tips and innoculating loops will also be soaked in 1% Virkon before incineration. Liquid waste including cell growth media and bacterial cultures will be autoclaved at 12 degrees Celcius for 15 minutes and then incinerated. Small volumes of liquid waste will be disinfected in 1% Virkon and then washed down the sink with copius amounts of water. Contaminated surfaces will be disinfected with 1% Trigene.

The autoclave is monitored using a thermocouple and there is a regular testing schedule. It is serviced biannually.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
Risk assessment was presented to GMSC meeting on 12 December 2012 after external expert review. Several minor comments were raised that required revision primarily the addition of extra detail such as room numbers. The revised version was circulated January 2013 and approved at the GMSC meeting 5th February 2013

**Project Additional Information**

**Purposes of the contained use**

The tumour necrosis factor (TNF) cytokine superfamily plays a crucial role in immune regulation by modulating lymphocyte proliferation and apoptosis. CD40 ligand (CD40-L) and TRAIL both belong to this family. Expression of CD40-L and TRAIL have been reported to induce cell death and apoptosis in carcinomas. The aim of the study is to assess whether membrane bound mutant of CD40-L and a
CD40-TRAIL chimera (composed of CD40-L N-terminal domain and the TRAIL C-terminus domain) which resist cleavage from the membrane would be more potent in cell death induction in CD40 or TRAIL-positive E1-negative established carcinomas, also the mechanism by which these ligands induce cell death.

The effect on growth, survival and cell signalling of these established mammalian cell lines will be monitored following expression of CD40-L, CD40-L-TRAIL chimera and mutant sequences (which resist cleavage from membrane) by replication deficient recombinant adenovirus (RAD) or replication competent recombinant adenovirus infection. The virus (dl922-947) has a mutation within the CR2 domain of the E1A region, this virus would only be tested with carcinoma cell lines with a defect in the Rb pathway. Taking into account the widespread expression of CD40 and TRAIL receptors in carcinomas and the growth inhibitory effects of CD40-L and TRAIL in CD40-and TRAIL-positive tumour cell lines respectively, these studies may provide novel therapeutic approaches for the treatment of carcinoma.

Recipient or parental organism

For work related to replication deficient adenovirus expressing CD40L, only E1-negative established CD40-positive tumour cell lines would be used (Pancreatic cell lines including Panc1, Suit2, Bladder carcinoma cell line EJ, Liver cell line HepG2, other CD40-positive or negative (as a negative control) may be used as well, as long as these cell lines are E1-negative to avoid any possible recombination with the replication deficient adenoviral vector. As a safety measure all carcinoma cell lines (either CD40 positive or negative) intended to be tested with the Adenoviral vectors would be tested firstly by PCR for any possible contamination with E1a and E1b DNA.

Host/vector system

For work related to replication efficient adenovirus (dl922-947, within the CR2 domain of the E1A region) expressing CD40L only carcinoma cell lines that either CD40-positive or negative and are E1-negative, in addition have established defect in Rb pathway would be tested. This virus in no way would replicate in normal cells or carcinoma cell lines that have a normal pRb pathway and are E1-negative due to the mutation within the CR2 domain of the viral E1A.

For work related to replication deficient adenovirus expressing TRAIL, only E1-negative carcinoma cell lines that either TRAIL receptor-positive or negative (as a negative control) would be tested to avoid any possible recombination. These viruses have already been constructed and so no bacterial cell work is required.

Although we already have enough stock from these viruses, but possible bulking up of these viruses may be needed, for bulking up replication deficient adenovirus expressing either CD40L or TRAIL, HEK 293 cells would be used, although this cell line is E1-positive, and there is a possibility of contamination of the produced stocks from this cell line with the wild-type adeno vector due to possible recombination, the contaminating wild-type
adenoviruses would be incapable of expressing the transgene as the transgene sequence would be lost during the recombination process, also the resultant wild-type viral DNA sequence would be missing the E3 region required for suppression of host immunity. To minimize the probability of recombination, propagation of these viruses in HEK 293 cells would be carried out for a minimal period (around 3 days), also produced stocks would be routinely checked by PCR technique (we will check the presence of deleted E1 sequence in the viral DNA) for any possible contamination with wild-type adenovirus, any contaminated viral stocks with wild-type adenovirus would be destroyed.

For bulking up replication efficient adenovirus expressing CD40L, the alveolar basal epithelial A549 cell line would be used, this cell line has a well-established defect in pRb pathway which would result in replication of our replication efficient adenovirus. However, it is E1 negative, therefore, there is no possibility of recombination occurring, for additional safety viral stocks produced would be checked for any contamination with the wild-type adenovirus by PCR using specific primers to test the presence of CR2-deleted sequence (d922-947), positive and negative controls would be tested within the PCR test.

Origin & function

1. CD40L, wild-type and non-cleavable mutant,
2. Wild type CD40L and non-cleavable CD40L mutant (lacking cleavage site, 324-348bp) are expressed under the CMV promoter as membrane bound structures, where only wild-type CD40L would be subject to cleavage from membrane into soluble ligand by the action of MMPs enzymes
3. TRAIL wild-type, expressed under CMV promoter as membrane bound, also subject to cleavage into soluble ligand by the action of MMPs enzymes
4. CD40L-TRAIL fusion, composed of the intercellular domain of CD40L (1-324bp) fused to extracellular domain of TRAIL (340-846bp), expressed under the CMV promoter as a membrane bound molecules not subject to cleavage from membrane as it lacks both CD40L and TRAIL cleavage sites

Evaluation of foreseeable effects

Theoretically expression of transgene is possible in airway epithelium if exposed to vector within aerosols. However, the membrane expression resultant from these vectors is such that this would be very localised. Furthermore, target receptor expression is low/absent in normal compared with malignant epithelium such that these agents are likely to have a differentially greater effect on cancer cells compared with normal cells such that the risk of adverse effects is likely to be minimal.

CD40 ligation has the potential to stimulate inflammation in exposed airway. However, again, the membrane expression of ligands is such that this would be very localised. Ligation of TRAIL receptors would not induce inflammatory effects.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

I would not like to request derogation from full containment measures

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

For solid waste: 1% Virkon used for most surface decontamination. Due to corrosion potential of Virkon, 0.5% SDS is used if decontamination of centrifuge buckets is required. We have validated both of these against adenovirus. We have also validated Klercide 5 against adenovirus.

All liquid waste is treated by autoclaving at 130°C for 60 mins, before disposal to drains. 1% Virkon used for most surface decontamination.

Disposable solid waste which is or may be contaminated with GMMs is also inactivated by autoclaving at 130°C for 30 mins, before removal as "clinical waste". Autoclaving achieves effectively 100% kill of all GMMs.

There is also possible risk of accidental spillage in the process of centrifugations, however if this is the case we would immediately decontaminate all the affected areas with enough 1% Virkon solution.

Is an emergency plan required according to regulation 20? N

#### Significant Change ID

#### Date of Significant Change

#### Project Additional Information

**Purposes of the contained use**

Knockdown of gene expression and expression of decoy RNA molecules in primary human cell types

**Recipient or parental organism**

The pLKO.1 pLenti6/V5-DEST lentiviral vectors. Mammalian cell lines and primary cells including 293FT packaging cell line.

**Host/vector system**

The pLKO.1 & pLenti6/V5-DEST

**Origin & function**

shRNA targeting RNA binding proteins (KSRP, HuR and TTP), green fluorescent protein, non-coding cDNA sequences designed to be expressed as “RNA decoys” (with the aim of promoting upregulation of SOX9 mRNA)

**Evaluation of foreseeable effects**

Lentiviral particles have the capacity to infect mammalian cells, including those of the laboratory worker. Upon infection the lentivirus will incorporate its genetic material into the host cell's genome. This has the potential to result in insertional mutagenesis. This is minimized in each of the lentiviral systems employed through self-inactivating systems where the virus is deleted in 3'LTR.

Lentiviral particles produced and /or used in this study will be replication defective and the probability of reversion to wild-type is negligible. Viral particles have the capacity to infect human cells and will insert genetic material into the cells’ genomes, which carries the risk of insertional mutagenesis. The specific safety features of the vectors...
carried by these viral particles allow these microorganisms as to be handled safely at containment level 2 in accordance with ACDP class 2 guidelines. The major risk in this work is through sharps injuries and aerosol generation. Sharps will not be used in the experiments under any circumstances, whilst exposure to aerosols will be minimilised by working in a class II laminar flow hood and not centrifuging open tubes.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Please enter comments on the GM safety committee on the risk assessment

The need for greater description of the genes targeted by the GM strategy was discussed and has been amended now on the form. Disposal of waste material was discussed. The use of dedicated bins for rooms G23 and G26 will be instigated. These bins will have sealable lids for transportation of the waste to the autoclave. This system will be rolled out across other containment level II projects within the Leahurst main building. There was some debate about whether this work requires level II containment given that the lentiviral systems used are of the latest generation and are replication incompetent, which gives the potential to handle them under level I containment. As a result of these discussions it has been decided that because (i) genes targeted have been linked to tumor formation in some studies and (ii) much of the work will be conducted on primary human cells (requiring level II containment anyway) that level II containment would be the most appropriate.

Animal Units Large Scale Activities Human Clinical Applications
**Project Additional Information**

**Purposes of the contained use**

The research aims to understand the molecular mechanisms by which viruses cause disease in their natural environment, hence providing information on how effective anti-viral therapies may be designed and validated.

**Recipient or parental organism**

Mouse cells will be used and will include: mouse embryonic fibroblasts from different mouse strains: wild type 129/Sv; IFNalpha/beta reector KO; RNaseL KO; PKR KP; and established cell lines NIH3T; BHK21. Canine cell line, MDCK, will be used in vitro for virus plaque assays to measure virus infectivity and fitness.

**Host/vector system**

**Origin & function**

For MHV-68 and SFV vioruses where deletion mutants may be used, these constructs have been shown to have similar growth properties to their parental (wild type) viruses and in some cases grow even less well in comparison to their parental viruses. Therefore, there is no increased hazard associated with these constructs.
References to back up above statement include:
No genetic manipulation will be carried out on the mouse-adapted flu virus.

Evaluation of foreseeable effects

Studies are not aimed at increasing virulence. No virus infection in mice will be carried out at the Biosciences Building. Only mouse cells and canine cell line, MDCK will be infected with these viruses for in vitro work.

Mouse cell cultures: Cell lines BHK 21 (ATCC No. CCL-10), C127 (ATCC No. CRL-1804), L929 (ATCC No. CCL-1) and NIH3T3 (ATCC No. CRL-1658) will be used. We will also use a number of mouse embryo fibroblast (MEF) cell cultures to assess the growth characteristics of MHV-68 and SFV-derived viruses. These primary cells are obtained from healthy mice and will be provided from our collaborators (Edinburgh and Institute of Animal Health). These include 129/SvEv and IFNa/bRKO129/SvEv C57BL/6x129/SvEv C57BL/6x129/SvEv PKRKO.

MDCK is a canine epithelial cell line (ATCC No. CCl34).

Viruses: MHV-68 BAC pHA3 (Adler et al., 2000) is the parental BAC construct which was used to generate MHV-68 Viruses: MHV-68 mutants. Our interest is in the non-structural genes of MHV-68 which may play a role in RNA degradation. Currently, only one gene, ORF37, has been linked to RNA degradation. The virus constructs MHV-68ORF37 Stop and its corresponding revertant MHV-68ORF37Rev will be used in our in vitro studies. The growth of MHV-68ORF37 is highly attenuated in immunocompetent cells and the growth of MHV-68ORF37Rev is similar to the parental virus. SP6-SFV4 is the parental infectious clone used to generate SFV mutants (Liljestrom and Garoff, 1991). The constructs are SFV4(3H)-RLuc (Attarzadeh-Yazdi et al., 2009), SFV4-SteGFP (Tanberg et al., 2007), SFV4-RDR (Fazakerley et al., 2002).

Fazakerley et al. 2002: A single amino acid change in the nuclear localization sequence of the nsP2 protein affects the neurovirulence of Semliki Forest virus. J. Virol. 76:392-6

Widely used mouse-adapted laboratory flu A strains A/WSN/33 (H1N1) and A/PR/8/34 (H1N1) will be used for in vitro assays.

Fazakerley et al. 2002: A single amino acid change in the nuclear localization sequence of the nsP2 protein affects the neurovirulence of Semliki Forest virus. J. Virol. 76:392-6

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Evaluation of foreseeable effects

No glass or sharps will be used. Working surfaces e.g. insides of containment cabinets shall be cleaned first with 1% Virkon solution followed by 70% ethanol both before and after operations. In the event of a significant spillage (when working with high titre stocks), the class 2 cabinet will be fumigated with formaldehyde and also prior to maintenance work.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Understanding the molecular basis of mRNA degradation in viral infections.

Historical Significant Changes Withdrawn N

Tick if notifying a connected programme of work N

Historical Date of Additional Info
Project Additional Information

Purposes of the contained use

Types of activities: Bacterial and cell culture, Electroporation of plasmids into bacteria, use of In vivo mouse models

The aim of this project is to create mutations in genes encoding for such virulence factors and determine the effect of the mutations on various phenotypic properties including host tissue adhesion and invasion properties, growth characteristics in artificial sputum medium and other biofilm models, and virulence properties in vitro as well as in vivo using previously established mouse models (carriage, invasive pneumonia, sepsis, meningitis). The proposed research involves the introduction of antibiotic resistance cassettes (i.e., ampicillin, chloramphenicol, erythromycin, penicillin, spectinomycin) into target genes in the pneumococcal chromosome or complete deletion of target genes. Such

7. Characteristics of the GMO(s) including the evaluation of foreseeable effects - Public Register experiments have been previously carried out for this organism in the AK research group (University of Leicester), and the systems used for the creation of "knock-out" mutants have therefore already been optimized and validated.

Gene-deficient mutants (e.g., NanA−) will be made by insertion-duplication mutagenesis. For example, part of the nanA gene (HindIII nucleotide [nt] 2449 to SphI nt 3090 fragment) will be cloned into pVA891, and the construct transformed into the laboratory strain D39. A single crossover mutation occurs which incorporates the entire plasmid, thereby disrupting the NanA gene and rendering the recombinant erythromycin resistant (Manco et al. (2006) Infect Immun. 74(7): 4014–4020). Analysis of NanA− by Southern blotting will confirm that there is an insertion mutation in the nanA gene. Other S. pneumoniae mutants (e.g., pneumolysin, NanB) will be constructed using insertion-duplication, point, or deletion mutations, as described previously (Berry et al. (1999) Infect Immun. 67(2): 981–985). D39 and other strains in which ply has been disrupted by insertion-duplication mutagenesis or in which the wildtype ply has been replaced by a mutated gene encoding pneumolysin with two or three amino acid substitutions - Asp385→Asn, Cys428→Gly and Trp433→Phe - will be tested for their complement activation and cytolitic activities. All transformations will be carried out into Escherichia coli DH5α.

Complementation of mutants will be carried out by using pBBR1Tp or similar plasmid vectors to introduce cloned genes back into pneumococcal mutants. In addition, we propose to keep the option of
using a plasposon based random mutagenesis system with the same antibiotic resistance markers plus a tetracycline resistance cassette.

Molecular marking of relevant S. pneumoniae strains:
S. pneumoniae strains including the laboratory strain D39 will be labelled with an erythromycin resistance cassette and fluorescence markers including green fluorescent protein or GFP, using a previously described procedure (Kadioglu et al. 2001 FEMS Microbiol Lett., 194 (1): 105-110). The plasmid pGFP1 has gfp in the shuttle vector pVA838. The gene, for the mut 3 variant of GFP, is excised as a BamH1–Sph1 fragment from pKEN2, and ligated into pVA838, previously cut with BamH1 and Sph1, to generate pST1. Expression of gfp is from an uncharacterised pneumococcal promoter, isolated from a library of pneumococcal DNA in pST1. Chromosomal DNA is isolated from pneumococcal clinical isolate CCUG10175 (University of Göteborg Culture Collection). DNA is digested with Sau3A and fragments between 0.2 and 2 kb ligated into dephosphorylated BamH1-digested pST1. To accumulate stocks of recombinant plasmids, the library is first electroporated into Escherichia coli DH5a. Plasmid DNA will be isolated from all transformants and then the pooled DNA used to transform wild-type pneumococcus, using competence-stimulating peptide. Pneumococcal transformants will be selected on Brain–Heart Infusion agar containing erythromycin (1 mg/ml). Pneumococcal transformants will be examined for fluorescence under UV microscopy. Labelled strains will be used in vitro as well as in vivo (risk assessments specific to experimentations in mice have been reviewed and approved by the Biomedical Services Unit committee of the University of Liverpool) and will be visualised using epifluorescence and confocal microscopy.

Recipient or parental organism

Streptococcus pneumoniae. Its serotypes of importance to human infection such as serotypes 1, 2, 3, 4, 6B, 19F etc.

Host/vector system

plasmid pMSH14, reporter plasmid pGFP1, plasmid pVA838, pVA891, pALC2073, pKEN2, pST1

Origin & function

S. pneumoniae mutant strains with penicillin resistance. Penicillin and its derivatives are the most commonly used antibiotics in humans for the treatment of pneumococcal infections. However, the mutants we create will be gene mutants of major virulence factors, hence the resulting mutants will be attenuated in virulence and will not present a hazard.

Evaluation of foreseeable effects

The antibiotic resistance genes chosen are not themselves harmful. In addition, selection during our experiments will require antibiotic levels in excess of 50 μg/ml in order to overcome the inherent resistance of the strains. These are levels in excess of any that would be of therapeutic use.
Inserting fluorescent markers does not affect fitness or confer any additional virulence. For knockout mutations the vectors are designed to be incapable of replication in Streptococcus pneumoniae (suicide vectors). The insertionally inactivated or mutated genes are introduced into the chromosome via homologous recombination. The vector is lost because of inability to replicate. Any alteration of pathogenic traits will make the host strain substantially less pathogenic (in most cases avirulent) since the aim is to "knock-out" genes that contribute to pathogenicity and bacterial virulence.

<tr>
<td>For solid waste e.g. Tips, tubes, pipettes and agar plates: Agar plates containing cultures are discarded to a designated metal container for autoclaving. Solid waste (tips, tubes etc.) are placed in a sealed &quot;sweetie jar&quot; and taken for autoclaving and incineration. Pipettes are steeped in disinfectant (1% Virkon) for a minimum of 20 minutes before disposal. The disinfectant is discarded down the sink. Any spillage is disinfected using 1% Virkon. For liquid waste: Liquid cultures are autoclaved. Any spillage is disinfected using 1% Virkon. Autoclaves in Ronald Ross Building are operated by trained laboratory staff. A record is produced for each decontamination run to confirm, by means of a temperature probe placed within the load, attainment of suitable temperatures for 100% kill of viable organisms. Validation of autoclave cycles is maintained by 6-monthly servicing and yearly thermocouple testing carried out by BMM Weston engineers.</td>

The original proposal was circulated a week in advance of the GMSC meeting of 12th December 2012. Following the meeting a number of amendments were requested. These were mostly typing errors, but some more detail on vectors and inserted DNA was required. These amendments have now been completed.

**Project Ref 554/14.2**

- **Date Ackn’d**: 24/03/2014
- **CU2 Project Title**: Identification and characterisation of virulence factors of Salmonella enterica and Campylobacter jejuni isolates during experimental infection of chickens
- **Class**: Class 2
- **Culture Vol**: ≤ 1 Litre
- **Consent Granted**: Non-GMM

**Project notified under transitional arrangements**: N

**Historical Significant Changes**

**Historical Date of Additional Info**

**Significant Change ID**

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

Mutation of Salmonella and Campylobacter isolates by transduction using bacteriophages or by insertion mutagenesis using plasmids enables us to study the roles of certain genes during infection.
Bacteria expressing GFP allow imaging of infection sites by confocal microscopy to better understand the infection process.

Recipient or parental organism

Salmonella enterica, including serovars Typhimurium, Pullorum, Derby, Virchow, Gallinarum, Enteritidis, Hadar and Infantis
Campylobacter jejuni and coli

Host/vector system

pUT mini-Tn5 plasmids (R6K-based suicide delivery plasmids)
EZ-Tn5 transposome <KAN-2> (R6K deleted)
P22 temperate bacteriophage (injects Salmonella Typhimurium). A P22 mutant, P22 HT105/1 int-201 will be used as it has a high transducing frequency.

Origin & function

Transposons (Mini-Tn5 transposons) encoding antibiotic resistance genes (kanamycin, ampicillin, nalidixic acid, tetracycline) and/or green fluorescent protein (Mini-Tn5TcGFP transposons). EZ-Tn5 transposons containing kanamycin selectable marker (<KAN-2>). The function of the transposons is to induce insertional mutagenesis in the host organism. The function of the antibiotic resistance genes and green fluorescent protein is as selection markers. The Tn5 system is a naturally occurring transposition system found in gram-negative bacteria. EZ-Tn5 is a hyperactive Tn5 transposition system.

Bacteriophages P22 containing Salmonella Typhimurium chromosomal DNA fragments (transducing particles) and antibiotic resistance genes. P22 is related to bacteriophage λ and is used for generalized transduction of host organisms whereby genes of interest can be inserted into the host genome.

Evaluation of foreseeable effects

The GMOs will not pose any greater risk than wild-type Salmonella spp or Campylobacter jejuni. The purpose of transduction of the isolates and/or the insertional mutagenesis is to disrupt the function of certain genes. This disruption will either attenuate the organism's survival and/or virulence or the organism will continue to display wild-type phenotype.

An indirect effect of the mutagenesis is the acquirement of antibiotic resistance. However, the antibiotic resistance genes used as markers are not routinely used in the treatment of enteric infections. Theoretically it would be possible for antibiotic resistance genes to be transferred from mutant isolates to other bacteria, however this would be unlikely to occur in a laboratory situation. For gene transfer to occur, a series of very low frequency events would have to take place.

There is a very small risk that unknown virulence-related genes may be up-regulated with introduction of GFP. However, this has not been observed for GFP-expressing strains already constructed including Salmonella Pullorum 449/87 pBRD940.

There may be a theoretical risk to animals (which is low because clinical disease is not usually seen in infected animals). There is no known potential for harm to plants. These isolates are unlikely to survive well in the environment, although this has not been specifically tested. The likelihood of the GMM actively causing additional harm is very low and may be less fit than the unmodified organism.

Tranposase activity of the insert is not maintained in the target cells so gene transfer/recombination would occur only at the normal, random rate. Plasmids used are designed to have a restricted host range and will not be conjugative (i.e. plasmids will not carry genes necessary for the ability to transfer themselves to other bacteria). As such these sequences cannot readily be transferred to other organisms.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

**Laboratory Waste**
Solid waste including contaminated agar plates, cell culture plastic ware, pipette tips, microplates and tubes will be autoclaved at 126 degrees Celsius for 15 minutes and then incinerated. Pipette tips and inoculating loops will also be soaked in 1% Virkon before incineration.

Liquid waste including cell growth media and bacterial cultures will be autoclaved at 12 degrees Celcius for 15minutes and then incinerated. Small volumes of liquid waste will be disinfected in 1% Virkon and then washed down the sink with copius amounts of water.

Contaminated surfaces will be disinfected with 1% Trigene or Distel.

The autoclave is monitored using a thermocouple and there is a regular testing schedule. It is serviced biannually.

**Animal Unit Waste**
Solid waste including animal bedding, uneaten feed, animal bodies (all are eviscerated as part of necropsy), used protective clothing, paper, wipes and swabs will be autoclaved at 126 degrees Celsius for 20 minutes and then incinerated.

Liquid waste including cell growth media and bacterial cultures will be autoclaved at 12 degrees Celsius for 15 minutes and then incinerated. Small volumes of liquid waste will be disinfected in 1% Virkon and then washed down the sink with copius amounts of water.

Contaminated surfaces will be disinfected with 2% Trigene or Distel following Standard Operating Procedures of the unit.

The autoclave is newly installed and is monitored using a thermocouple and there is a regular testing schedule. It will be serviced biannually.

GMSC on 11/2/2014 recomended minor changes to the risk assessment. The amended assessment was approved by Chair’s action after circulation to Chair, Biological Safety Officer and University Biological Safety advisor on 13/2/2014

Project Containment
### Project Ref 554/14.3

**Date Ackn'd** 09/04/2014  
**CU2 Project Title** Modulation of adhesion signalling in cell culture by expressing or suppressing adhesion signalling-associated proteins via lentiviral infection  
**Class** Class 2  
**Culture Vol** < 1 Litre  
**Consent Granted** Non-GMM  
**Project notified under transitional arrangements** N

#### Project Additional Information

**Purposes of the contained use**

Proteins identified as components or regulators of adhesion-signalling complexes (adhesome) will be transiently or stably over-expressed in mammalian and human primary and established cell lines using a lentiviral transduction system. For some of the signalling molecules, mutated constructs will be lentivirally-transduced to modulate functional activity eg dominant-negative or constitutively active constructs. Lentivirus-mediated delivery of shRNA will be used to suppress expression of adhesome components in the same cell lines. Also, lentivirus-mediated delivery of Tetracycline (Tet)-inducible shRNA will be used to suppress expression of adhesome components in the same cell lines.

The categories of molecules to be expressed or suppressed (including some key examples) are:

- **Transmembrane adhesion receptors** e.g. Integrins, syndecans, CD98, Cadherins, Nephrin
- **Receptor tyrosine kinases** e.g. EGFR, PDGFRa, HER2, FGFR
- **Cytoskeletal and focal adhesion proteins** e.g. filamin A, talin, kindlin, vinculin, EB1, ACF7, APC, Afadin, WASP family, LifeAct
- **GTPases and GTPase regulators** e.g. Rac1, RhoA, Cdc42, Arf6, p190RhoGAP, IQGAP, Ras suppressor 1, p115RhoGEF, RacGAP1
- **Phosphorylation regulators** e.g. PKC, Src, RACK1, ILK, FAK, MAPKs, PTPN13, PPP2a/1a
- **Matrix proteinase regulators** e.g. MT1-MMP, MMP9, MMP2, UPAR, TIMP-1
Intracellular trafficking regulators e.g. AP2, flotillin, clathrin, caveolin, dynamin

Intramolecular and intermolecular FRET biosensors e.g. Raichu-Rac, Lyn-Src biosensor, Arf6-CyPET/YPET-GGA3

Following lentiviral expression or shRNA transduction, the function of these molecules will be assessed by proteomic analysis of adhesion-signalling complexes, co-immunoprecipitation, assessment of signalling molecule activity/phosphorylation and analysis of cell migration and adhesion. Fluorescently labelled proteins will be expressed for imaging applications.

In section 7, consideration is given separately to 2 stages of the lentiviral transduction process:

Work Package A) Co-transfection of lentiviral packaging vectors and lentiviral expression plasmids into packaging cells and subsequent harvesting of gene of interest-encoding or shRNA encoding lentiviruses

Work Package B) Infection of recipient cells with lentiviruses encoding gene of interest or shRNA oligonucleotide sequences targeting gene of interest

Recipient or parental organism

Work Package A)
293T and 293FT Human renal epithelial cell line. Stably transfected with SV40 large T-antigen.
293T and 293FT are well-characterised human cell lines that are unable to colonise the worker and contains no known adventitious agents. However it is stably transfected with the SV40 large T-antigen to allow episomal amplification of vectors that contain the SV40 origin. Therefore it is classified as specially-disabled (SACGM guidance notes, part 2, section 2.5, table 2.5.1)

Work Package B)
Immortal established cell lines:
Mouse embryonic fibroblasts (MEF) – Immortalised with Large T-antigen
T-antigen Immortalised Fibroblasts (TIF) – Human fibroblasts immortalised with Large T-antigen
CA1, H357, C1, VB6, VB6Δ11aa - established human oral squamous cell carcinoma cell lines
BT20, MCF7, MDA-MB-231, MDA-MB-468, BT-474, SKBR3 - established human breast carcinoma cell lines
MCF10a - established human breast epithelial cell line
H441, DMS 114, DMS 53, DMS 153, NCI-H1299, CaLu - established human lung carcinoma and adenoacarcinoma cell lines
Capan-1, PaCa-2, PaCa-3, BxPC-3, PANC-1, - established human pancreatic carcinoma and adenocarcinoma cell lines
AsPC-1 - established human pancreatic adenocarcinoma cell lines derived from metastatic site (ascites)
A375 – established human malignant melanoma cell line -
B16-F10 – established mouse melanoma cell line
HT1080 – human fibrosarcoma cell line
A2780 - established human ovarian carcinoma cell lines
K562 – established human erythroleukaemia cell line
MRC-5, MRC-9 - human lung fibroblast cells (+/- hTert immortalisation)
PS-1 – pancreatic stellate cells (+/- hTert immortalisation)
hTERT-HPNE – established pancreatic ductal cells (hTert immortalised)

Primary cell lines:
Primary human umbilical artery endothelial cells (HUAEC)
Primary human umbilical vein endothelial cells (HUVEC)
Primary mouse mammary epithelial and pancreatic ductal adenocarcinoma cells
Human foreskin fibroblasts (HFF) – Primary normal dermal fibroblasts from foreskin
Mesenchymal stem cells (MSC) – derived from human bone marrow
Human embryonic stem cells (huESC) – derived from human blastocyst
Mouse embryonic stem cells (muESC) – derived from mouse blastocyst

Adventitious agents are not present in established immortalised cell lines. Mouse primary cell lines will not contain human adventitious agents. Primary human cells have been screened for basic microbiological adventitious agents but should be treated as potentially infectious and contaminated biological specimens and handled at Biosafety Level-2.

Host/vector system

Work Package Ai) Lentiviral protein or shRNA Expression System:
Lentiviral Packaging Vectors (pMD2.G, psPAX2)
Lentiviral expression Vectors (pWPXld, pWPi, PLVTHM) encoding:
Human or Mouse adhesion signalling-associated proteins or shRNAs (detailed in Section 6):  
- Transmembrane adhesion receptors  
- Receptor tyrosine kinases  
- Cytoskeletal and focal adhesion proteins  
- GTPases and GTPase regulators  
- Phosphorylation regulators  
- Matrix proteinase regulators  
- Intracellular trafficking regulators  
- Intramolecular and intermolecular FRET biosensors

Work Package Aii) Tet-inducible Lentiviral shRNA System
Lentiviral Packaging Vectors (pLP1, pLP2, pLP/VSVG), pENTR/H1/TO Entry construct
pLenti4/BLOCK-iT Vector encoding:
shRNA oligonucleotides to suppress expression of Human or Mouse adhesion signalling-associated proteins:  
- Transmembrane adhesion receptors  
- Receptor tyrosine kinases  
- Cytoskeletal and focal adhesion proteins  
- GTPases and GTPase regulators  
- Phosphorylation regulators  
- Matrix proteinase regulators  
- Intracellular trafficking regulators  
- Intramolecular and intermolecular FRET biosensors

Work Package B) Lentiviruses produced as a result of transfection of the lentiviral expression and packaging vectors described in Section 7Ai and 7Aii will be used to infect the immortal established cell lines and primary cell lines described above.

Origin & function

Work Package Ai) Lentiviral protein or shRNA Expression System
Lentiviral Packaging Vectors (pMD2.G, psPAX2):
Origins:
- HIV1 (gag, pol, rev and tat)
- Vesicular Stomatitis Virus (VSVg envelope protein)

Biological activities/functions:
- gag – structural capsid protein from HIV1 required for generating the viral core.
- pol – reverse transcriptase from HIV1 required for reverse transcription of the RNA genome prior to pro-viral integration.
- rev – accessory protein from HIV1 required for the nuclear export of the full length viral genome to promote packaging.
- tat – accessory protein from HIV1 required for extension of transcription from the HIV1 LTR promoter.
- VSVg – amphotropic viral envelope protein permitting viral infection into most vertebrate cell types.

Lentiviral expression Vectors (pWPXLD, pWPI, PLVTHM):

Human or Mouse adhesion signalling-associated proteins or shRNAs:
- Transmembrane adhesion receptors
- Receptor tyrosine kinases
- Cytoskeletal and focal adhesion proteins
- GTPases and GTPase regulators
- Phosphorylation regulators
- Matrix proteinase regulators
- Intracellular trafficking regulators
- Intramolecular and intermolecular FRET biosensors

Biological activities:
Adhesion signalling pathways can affect many cellular properties including cell fate, proliferation, differentiation, apoptosis and migration, and can be associated with tumourigenesis and immune response. The exact effects will, however, be cell type specific.

Work Package Aii) Tet-inducible Lentiviral shRNA System

Lentiviral Packaging Vectors (pLP1, pLP2, pLP/VSVG)

Origins:
- HIV1 (gag, pol, rev and tat)
- Vesicular Stomatitis Virus (VSVg envelope protein)

Biological activities/functions:
- gag – structural capsid protein from HIV1 required for generating the viral core.
- pol – reverse transcriptase from HIV1 required for reverse transcription of the RNA genome prior to pro-viral integration.
- rev – accessory protein from HIV1 required for the nuclear export of the full length viral genome to promote packaging.
- tat – accessory protein from HIV1 required for extension of transcription from the HIV1 LTR promoter.
- VSVg – amphotropic viral envelope protein permitting viral infection into most vertebrate cell types.

### Biological activities:
Adhesion signalling pathways can affect many cellular properties including cell fate, proliferation, differentiation, apoptosis and migration, and can be associated with tumourigenesis and immune response. The exact effects will, however, be cell type specific.

#### Work Package B)

Lentiviral transduction will be used to express or suppress the following classes of Human or Mouse adhesion signalling-associated proteins:

|• Transmembrane adhesion receptors |
|• Receptor tyrosine kinases         |
|• Cytoskeletal and focal adhesion proteins |
|• GTPases and GTPase regulators    |
|• Phosphorylation regulators       |
|• Matrix proteinase regulators     |
|• Intracellular trafficking regulators |
|• Intramolecular and intermolecular FRET biosensors |

Adhesion signalling pathways can affect many cellular properties including cell fate, proliferation, differentiation, apoptosis and migration, and can be associated with tumourigenesis. The exact effects will, however, be cell type specific. Use of lentiviral vectors for the expression of these proteins or shRNA oligonucleotides will ensure their long-term expression in infected cell lines.

As the generated lentiviruses are replication-incompetent, upon exposure to human tissue, infection would be restricted to the site of exposure (see below). Experimental procedures will be conducted without the use of sharps preventing the possibility of needlestick injuries. Furthermore, the generated lentiviruses will not survive outside of its specific culture medium.

### Evaluation of foreseeable effects

#### Work Package A) Mechanisms of gene product expression control:

**Lentiviral Expression System:**

| Lentiviral Packaging Vectors (pMD2.G, psPAX2), gag, pol and rev – CAG promoter which is a strong constitutively active eukaryotic promoter comprising the CMV enhancer, and chicken beta-actin promoter and intron. |
| VSVg – CMV promoter which is a strong constitutively active eukaryotic promoter |
| Lentiviral Expression Vector (pWPXLd, pWPI, PLVTHM) |
Human or Mouse adhesion signalling-associated proteins or shRNAs (classes listed above):

- Eukaryotic promoter comprising elongation factor 1 alpha (EF1A) promoter.

Tet-inducible Lentiviral shRNA System:

Lentiviral Packaging Vectors (pLP1, pLP2, pLP/VSVG),
gag and pol – eukaryotic promoter comprising the CMV promoter and human beta-globin intron
rev – RSV enhancer/promoter

VSVg – CMV promoter which is a strong constitutively active eukaryotic promoter and human beta-globin intron

pLenti4/BLOCK-iT Vector:

shRNA oligonucleotides targeting Human or Mouse adhesion signalling-associated proteins (classes listed above) – Rous Sarcoma Virus (RSV) enhancer/promoter for Tat-independent production of viral mRNA in eukaryotic cells. Modified human H1 promoter containing 2 prokaryotic tet operator 2 (TetO2) sequences induces shRNA expression only in presence of tetracycline.

Potential for recombination and reversion to wild type:

The pWPXLd, pWPI, PLVTHM and pLenti4/BLOCK-iT-DEST vector systems are engineered to prevent generation of replication competent viruses.

The pWPXLd, pWPI, PLVTHM and pLenti4/BLOCK-iT-DEST vectors contain the LTRs and packaging sequences from HIV1 but they lack the gag, pol, env, rev and tat genes. Therefore these vectors cannot be packaged successfully in the absence of an external source of these proteins.

In addition, the 3' LTR contains a mutation within the promoter sequence. During reverse transcription and genomic integration of the provirus, this sequence will be copied to the 5' LTR. As a consequence, transcription of the complete viral genome from the 5' LTR of the provirus will not be possible preventing the generation of new viral particles even in the presence of viral proteins.

Mutation of the 3' LTR promoter also ensures that transcription of downstream genomic sequences following proviral integration cannot occur.

The different proposed inserts will not alter the stability of the recombinant viruses compared to the parental virus. It is very unlikely that the minimum of four independent recombination events required to produce a replication competent virus will occur. In addition, the vif, vpr, vpu and nef HIV1 virulence genes have been deleted. Therefore the likelihood of reversion to wild type virus is negligible.

The pWPXLd, pWPI, PLVTHM and pLenti4/BLOCK-iT-DEST vectors also contain an RRE element to enhance the nuclear export of the genomic transcript (but only in the presence of rev expression), and hence viral packaging, and a WPRE sequence to improve transcript stability. The WPRE, however, does not encode protein X as the codon encoding the initiating methionine has been mutated.

The VSV-G from Vesicular Stomatitis Virus is used in place of the HIV-1 envelope

The pWPXLd system is a 2nd generation lentiviral system and the pLenti4/BLOCK-iT lentiviral shRNA system is a 3rd generation (gag/pol, rev/tat and VSVg are separated on different vectors).
For the pLenti4/BLOCK-iT Lentiviral shRNA System, expression of the gag and pol genes from pLP1 has been rendered Rev-dependent by virtue of the HIV-1 RRE in the gag/pol mRNA transcript. Addition of the RRE prevents gag and pol expression in the absence of Rev

WP A Lentiviral Systems References:

Work Package A Direct Effects:

Transfection of all of the vectors in either the Lentiviral Expression Systems, or Tet-inducible Lentiviral shRNA System, into the eukaryotic host cells will initiate production of replication-incompetent and self-inactivating lentiviruses encoding adhesion signalling-associated proteins or shRNA oligonucleotides to suppress expression of adhesion signalling-associated proteins. Pseudotyped viruses will be produced carrying the VSVg coat protein. As a consequence the recombinant viruses will be able to infect most vertebrate cell lines and tissues, including humans.

The host cells will produce lentiviruses that will either express or suppress the following classes of Human or Mouse adhesion signalling-associated proteins:

- Transmembrane adhesion receptors
- Receptor tyrosine kinases
- Cytoskeletal and focal adhesion proteins
- GTPases and GTPase regulators
- Phosphorylation regulators
- Matrix metalloproteinase regulators
- Intracellular trafficking regulators
- Intramolecular and intermolecular FRET biosensors

Exposure of humans to these viruses would cause the localised expression or suppression of components of adhesion-mediated signalling pathways. Adhesion signalling pathways can affect many cellular properties including cell fate, proliferation, differentiation, apoptosis and migration, and can be associated with tumorigenesis, angiogenesis, inflammation and immunological responses. Adhesion signalling mechanisms are also targeted by pathogens, to promote cellular uptake, so it is conceivable that the viruses could modulate the susceptibility of cells to infection. Thus, it is possible that exposure to the generated viruses may regulate these processes in humans. However, as described in 3.1b and “Assessment Form 4”, the viral delivery systems have been engineered to ensure that generated viruses are replication-competent and self-inactivating.
However the likelihood of harmful effects to humans caused by exposure to the transfected mammalian cells (293T/293FT) is minimised as the gene products will be expressed in a well characterised cell line that has been screened for adventitious agents, is unable to colonise the worker, will not survive outside of its specific culture medium, and will be immune rejected if accidental exposure occurs. Moreover, as detailed in “Assessment Form 4”, the lentiviral vector systems are engineered to prevent generation of replication competent viruses. Moreover, the VSVg coat protein will activate complement unlike the HIV1 coat protein. As a consequence, a stronger immunological reaction will be provoked following infection with the recombinant pseudotyped viruses improving viral clearance.

WP A Direct Effects References:

Work Package A Indirect Effects:

The VSVg coat protein will activate complement unlike the HIV1 coat protein. As a consequence, a stronger immunological reaction will be provoked following infection with recombinant pseudotyped viruses improving viral clearance.

Individually, expression of the HIV1 gag and pol proteins is cytotoxic, whilst expression of VSVg can cause cell fusion.

Work Package A Effect of Gene Transfer:

The vectors are mobilisable, but only once as they are self-inactivating. The encoded cDNAs are incapable of integrating into the eukaryotic genome of the host cells.

As discussed above, using these vector systems, it is very unlikely that the minimum of four independent recombination events required to produce a replication competent virus will occur. In addition, the vif, vpr, vpu and nef HIV1 virulence genes have been deleted. Therefore the likelihood of reversion to wild type virus is negligible.

If accidental release was to occur, host cells or viruses encoding the genetic material will not survive outside of their specific culture medium. 293T and 293FT cells are an...
established human cell line that are multiple auxotrophs, and are very sensitive to both dehydration and UV exposure. They will not survive beyond a few minutes outside of their normal growth medium.

Work Package A Summary of Risks:

Viruses encoding Adhesion Signalling-associated molecules may have the potential to regulate processes associated with tumourigenesis and immune function. However, the selected viral delivery systems are engineered to eliminate viral replication in infected cells. The primary risks are associated with exposure to the viruses rather than the virally-transduced cell lines

Laboratory use and decontamination procedures are in place to prevent exposure of workers and co-workers to both viruses and infected cells during handling

Work Package B) Mechanisms of gene expression control

The pWPXLd, pWPI, PLVTHM and pLenti4/BLOCK-iT-DEST vector systems are engineered to prevent generation of replication competent viruses.

The pWPXLd, pWPI, PLVTHM and pLenti4/BLOCK-iT-DEST vectors contain the LTRs and packaging sequences from HIV-1 but they lack the gag, pol, env, rev and tat genes. Therefore these vectors cannot be packaged successfully in the absence of an external source of these proteins.

In addition, the 3’ LTR contains a mutation within the promoter sequence. During reverse transcription and genomic integration of the provirus, this sequence will be copied to the 5’ LTR. As a consequence, transcription of the complete viral genome from the 5’ LTR of the provirus will not be possible preventing the generation of new viral particles even in the presence of viral proteins.

Mutation of the 3’ LTR promoter also ensures that transcription of downstream genomic sequences following proviral integration cannot occur.

The different proposed inserts will not alter the stability of the recombinant viruses compared to the parental virus. It is very unlikely that the minimum of four independent recombination events required to produce a replication competent virus will occur. In addition, the vif, vpr, vpu and nef HIV-1 virulence genes have been deleted. Therefore the likelihood of reversion to wild type virus is negligible.

The pWPXLd, pWPI, PLVTHM and pLenti4/BLOCK-iT-DEST vectors also contain an RRE element to enhance the nuclear export of the genomic transcript (but only in the presence of rev expression), and hence viral packaging, and a WPRE sequence to improve transcript stability. The WPRE, however, does not encode protein X as the codon encoding the initiating methionine has been mutated.

The VSV-G from Vesicular Stomatitis Virus is used in place of the HIV-1 envelope

The pWPXLd system is a 2nd generation lentiviral system and the pLenti4/BLOCK-iT lentiviral shRNA system is a 3rd generation (gag/pol, rev/tat and VSVg are separated on different vectors).

For the pLenti4/BLOCK-iT Lentiviral shRNA System, expression of the gag and pol genes from pLP1 has been rendered Rev-dependent by virtue of the HIV-1 RRE in the gag/pol mRNA transcript. Addition of the RRE prevents gag and pol expression in the absence of Rev

WP B Lentiviral Systems References:
Pseudotyped viruses will be produced carrying the VSVg coat protein. As a consequence the recombinant viruses will be able to infect most vertebrate cell lines and tissues, including humans. Exposure to the viruses would cause the localised expression or suppression of components of adhesion-mediated signalling pathways. The viruses would modulate adhesion signalling pathways which can affect many cellular properties including cell fate, proliferation, differentiation, apoptosis and migration, and can be associated with tumourigenesis, angiogenesis, inflammation and immunological responses. Adhesion signalling mechanisms are also targeted by pathogens, to promote cellular uptake, so it is conceivable that the viruses could modulate the susceptibility of cells to infection. The exact effects will, however, be cell type specific.

The viral vector has the potential to deliver genetic material into humans, as the VSVg env protein permits infection of most vertebrate cells, including humans. However, as discussed in 3.1.b, the lentiviral vector systems are engineered to prevent generation of replication competent viruses. Moreover, the VSVg coat protein will activate complement unlike the HIV1 coat protein. As a consequence, a stronger immunological reaction will be provoked following infection with the recombinant pseudotyped viruses improving viral clearance.

WP B Direct Effects References:

Work package B Indirect Effects:

Some of the encoded "adhesion signalling-associated" genetic material may alter the tumourigenicity or invasion of infected cancer cell lines. However, these cells are likely be immune rejected upon accidental exposure.

The VSVg coat protein will activate complement unlike the HIV1 coat protein. As a consequence, a stronger immunological reaction will be provoked following infection with recombinant pseudotyped viruses improving viral clearance.

Individually, expression of the HIV1 gag and pol proteins is cytotoxic, whilst expression of VSVg can cause cell fusion.

Work package B Effect of Gene Transfer:

The vectors are mobilisable, but only once as they are self-inactivating. The encoded cDNAs are incapable of integrating into the eukaryotic genome of the host cells.

As discussed above, using these vector systems, it is very unlikely that the minimum of four independent recombination events required to produce a replication competent virus will occur. If accidental release was to occur, host cells or viruses encoding the genetic material will not survive outside of its specific culture medium.

Work Package B Summary of Risks:

Viruses encoding Adhesion Signalling-associated molecules may have the potential to regulate processes associated with tumourgenesis and immune function. However, the selected viral delivery systems are engineered to eliminate viral replication in infected cells. The primary risks are associated with exposure to the viruses rather than the virally-transduced cell lines. Laboratory use and decontamination procedures are in place to prevent exposure of workers and co-workers to both viruses and infected cells during handling.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid Waste: Pipettes, culture flasks, centrifuge tubes, filters, syringes
Solid waste will be autoclaved (124°C for 15mins). All autoclaved waste will be subsequently incinerated.
Degree of kill: 100%

Liquid Waste:
Virus-containing medium from transfected 293T/293FT and medium from lentivirally-transduced recipient cells (which will not be generating virus)
Liquid waste will be autoclaved (124°C for 15mins) followed by disposal down a sink with copious amounts of water.
Degree of kill: 100%
Primary Autoclave: 200L Boxer Autoclave.
Room 3.17 Nuffield Building

Alternative Autoclave: Astell Scientific AA091.
Room 1.19 Nuffield Building

Autoclave testing/monitoring procedures:
200L Boxer autoclave: Automated report printout system
200L Boxer/Astell Scientific AA091: Annual Thermocouple test and calibration by service engineer

Committee asked that it was ensured that any areas where virus was stored was secure. It was agreed that the building security systems offered suitable security.

Details of how liquid waste will be transported to autoclave to be added

Add that "any cuts to the skin will be covered"

Recommendation to liase with technical staff so that waste transported to the autoclave is processed immediately, any storage of waste should be in the laboratory until the autoclave is available.

Committee agreed with Class 2 designation. Lesley Andrews (UoL Biological Safety Advisor) will undertake notification to HSE once relevant forms are completed.

Examining the role of ROR2 in the cartilage differentiation pathway of mesenchymal stem cells

Project Additional Information

Purposes of the contained use

Mesenchymal stem cells (MSCs) from bone marrow can be used to generate cartilage cells for the use in treatment of cartilage diseases such as osteoarthritis. This research aims to examine the mechanisms by which stem cells produce cartilage and to determine whether the amount and quality of cartilage produced can be maximised.

Recipient or parental organism

The recipient cells will be primary human bone marrow-derived mesenchymal stem cells (MSCs). Bone marrow is obtained from human patients and MSCs are isolated and grown for up to 8 passages in vitro.

Host/vector system

The initial aim will be to transfect plasmids into human MSCs using nucleofection (electroporation). If this method proves inefficient, Integration-Deficient Lentiviral particles will be used to deliver DNA and/or mRNA into cells. These are third-generation disabled, self-inactivating and replication incompetent lentiviruses (Dull, T. et al. A third generation lentivirus vector with a conditional packaging system. J. Virol. 72, 8463-8471 1998).

Origin & function

The inserted genetic material will be:

a) The gene for receptor tyrosine kinase-like orphan receptor 2 (ROR2). ROR2 is a transmembrane receptor protein
for Wnt5a which plays a key role in cartilage and growth plate development. The aim is to examine the role of ROR2 in the differentiation of stem cells into cartilage.
b) Reporter genes such as luciferase or fluorescent proteins will be inserted for promoter-reporter screening studies. Both ROR2 and the reporter genes will be generated artificially for incorporation into plasmids.

Evaluation of foreseeable effects

The genetically modified human MSCs will only be used for in vitro mechanistic studies on cells grown in the laboratory.

The most hazardous GMO which could potentially be constructed during this work would be a recombinant lentivirus containing the ROR2 gene.

ROR2 is known to be overexpressed in a number of solid tumours. However it is a receptor protein within the complex Wnt signalling pathway and has not been shown to be oncogenic alone. As the ligand for ROR2, namely Wnt5a, has been shown to be oncogenic in some settings, there is the potential that ROR2 itself could be oncogenic despite the lack of specific information on this point. However, where ROR2 will be over-expressed it will be under the control of an inducible promoter.

As described above, the lentivirus particles are third-generation disabled, self-inactivating and replication incompetent lentiviruses and although the viruses could infect human cells if internalised, they would not spread.

Reporter genes such as luciferase or fluorescent proteins have no known effects which are harmful to human health.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Any solid waste (tissue culture flasks, serological pipettes, plastic tubes etc) will be autoclaved (131°C for 15 mins) prior to incineration. Any liquid waste will be inactivated by incubating with 1% Virkon for 24 hours before being autoclaved and discarded.

No sharps will be used during any of the procedures. Working surfaces e.g. insides of Class II Biological Safety Cabinets will be cleaned with 1% Virkon solution before and after operations. In the event of a significant spillage, the cabinet will be fumigated with formaldehyde and also prior to any maintenance work.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
This risk assessment was considered at the meeting of the IIB/School of Life Sciences Biological Safety Committee on 12th December 2014. The Committee raised the following points.

1. The committee noted the potential hazard of the inserted DNA and considered it appropriate that the risk assessment be Class 2 as proposed.
2. Under 3.1, in the list of features of the third generation packaging system, in b), please include a statement that the system is self inactivating. Deletion of the 3’ untranslated region reduces the potential for transactivating cellular genes due to insertion.
3. Under 4.1, please indicate how/whether the procedures will reduce aerosols.

The above points should be addressed on this version of the risk assessment and the changes made highlighted on the form.

The required changes to the risk assessment have been made and the risk assessment is approved, 16th December 2014.

### Purposes of the contained use

Biomedical Research. The contained use is required for handling parental viruses regardless of whether they are genetically-modified or not.

### Recipient or parental organism

Influenza A virus

### Host/vector system

Recombinant influenza A virus

### Origin & function

Influenza A recombinants will be based upon laboratory strains of the viruses or low pathogenicity human strains contained in plasmid vectors. The intended function of the genetic material is disrupt/"knock out" or alter function by mutation or add fluorescent marker genes. This enables the study of the functions of the disrupted genes.

### Evaluation of foreseeable effects

The experiments proposed involve gene deletion, mutation or replacement of specific genes with the corresponding gene from another strain. For reassortants between the human-derived or laboratory adapted viruses, this is not predicted to create viruses with novel tropism or pathogenicity as they either already share similar characteristics (the recent human isolates) or are highly attenuated in humans (PR8, WSN). Whilst we cannot exclude the possibility that changing the internal genes might increase the pathogenicity of the virus, the fact that the tropism remains the same, there is widespread immunity to the human strains proposed and the use of attenuated strains limits the risk.

All influenza virus strains used are classified by ACDP as Hazard Group 2. Since none of the currently proposed modifications is expected to make the virus more hazardous than the wild-type parent, the work will be assigned to ACGM class 2.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All cultures of GM viruses, and all consumables used in the handling of the GMOs, will be subjected to autoclaving and incineration following the normal procedures for disposal of clinical waste. The effective degree of kill is 100%. The efficacy of the autoclave is monitored annually by multi-point thermocouple checks during an annual service and inspection. External validation of the pressure vessel leading to the issue of a pressure validation certificate also occurs annually. In addition, a chart recorder produces a record of each run to confirm effective killing.

Is an emergency plan required according to regulation 20?  N  

If yes, tick to confirm that it is attached to this form  N  

Tick to confirm that you have attached a risk assessment to this form  Y  

02/03/2022
The Departmental Genetic Modification Safety Committee met on 18th November 2014 and considered that the work proposed presented no greater hazard than working with the wild-type organism and that the proposed level of containment was reasonable.

### Project Additional Information
Purposes of the contained use

Treponema species, specifically Treponema medium-like, Treponema phagedenis-like and Treponema pedis digital dermatitis (DD) associated spirochetes, are thought to be the aetiological agents of DD. Digital dermatitis (DD) is an endemic, global disease which results in severe lameness in agricultural ruminants such as cows, sheep and goats. As such, the disease causes significant welfare and economic concerns. No effective vaccine is available and treatment options are limited and generally ineffective.

Physical characteristics of DD treponemes are poorly characterized. Due to their anaerobic and fastidious nature, growth of DD treponemes is difficult in the laboratory setting. However, our laboratory has been able to successfully isolate and grow DD treponemes for a number of years now and have recently obtained genome sequences for several isolates. The ability to generate targeted gene knockouts these DD treponemes will enable our laboratory to identify possible transmission and virulence factors, such as cell surface antigens and define novel functions. This will ultimately aid in the development of potential treatments, vaccines and diagnostics for DD.

Recipient or parental organism

The recipient organisms are proposed to be: Treponema medium-like DD spirochete T19, Treponema phagedenis-like DD spirochete T320A and Treponema pedis T3552B. There are currently no attenuated strains available and all are considered ACDP hazard group 2 ("Treponema spp."). These organisms are anaerobic and fastidious in nature. They are not a known zoonosis agent. They are related distantly at a genus level to the human syphilis pathogens (Treponema pallidum subspecies pallidum) although demonstrate most similarity to treponemes associated with human periodontal disease (Treponema medium, Treponema denticola), a polymicrobial disease of humans considered to involve both environmental factors as well as said infectious agents. Therefore there could be considered a relatively limited potential risk to humans. Not known to produce toxins or agents which can cause harm to humans.

Host/vector system

We plan to perform this work by transformation of a knockout cassette (for details of genetic material involved, see next section) directly into the recipient DD treponemes. The knockout cassette functions via replacement of the target gene of interest with an antibiotic resistance marker, through the process of recombination. The cassette will be transformed into the cells on a linearized pGEM®-T vector (distributed by Promega. Catalog number: A1360). The vector will be linearized, non-mobilisable and has no protein expression capability (except for the erythromycin resistance determinant). Upon successful recombination, the vector will be will be genomically located, further reducing risk of horizontal transfer. The knockout cassette will be generated, maintained and propagated in Escherichia coli, for which a separate GM Class 1 risk assessment has been performed.

Origin & function

Putative virulence factors targeted for deletion will be identified by bioinformatics analysis of DD treponeme genomes. Genes will be deleted by allelic replacement of the target gene with an erythromycin resistance deletion cassette constructed in E. coli. Successful replacement will therefore provide the recipient organisms with resistance to erythromycin.

The artificially generated deletion cassette will consist of flanking upstream and downstream regions of the gene targeted for deletion, which will be amplified using genomic DD Treponema DNA as PCR template. The flanking upstream and downstream regions will be approximately 500 bp in size. These fragments will consist of either non-protein coding regions or fragments of protein coding regions. In the cases where protein coding regions will be included, care will be taken to ensure resulting fragments will not have the capacity to encode for a functional protein. A target T19 gene will not be considered if are adjacent to an entire small protein coding region (<500 bp) which would inadvertently be contained within a resulting up or downstream amplicon.

Generated up and downstream regions will be artificially fused by SOEing PCR (Synthesis by Overlap Extension PCR) to an Erythromycin resistance cassette (EryC).
including promoter and gene encoding erythromycin resistance determinant (eryC). The eryC resistance cassette will be amplified from plasmid pLN164 (a commercial Staphylococcus expression vector: distributed by Sigma Aldrich, Catalog number T6701-2UG) by PCR. The pLN164 plasmid is for PCR template only and will not be transformed into any organism.

The three generated PCR amplicons will be synthesized into a single fragment by SOEing PCR. The resulting artificial fragment will be cloned into a pGEM®-T vector (distributed by Promega. Catalog number: A1360) and resulting recombinant plasmids transformed, maintained and propagated in the laboratory strain E. coli TOP10 (distributed by Invitrogen. Catalog number: C4040-10). For transformation, the plasmid harbouring the resistance cassette will be harvested from E. coli and linerized using a suitable restriction enzyme prior to transformation into the recipient host.

**Evaluation of foreseeable effects**

The function of the inserted material is to replace a gene encoding a potential virulence factor with an erythromycin resistance gene, thereby deleting the gene encoding the potential virulence factor from the recipient microorganism. The inserted material will only code for erythromycin resistance and will not code for any other proteins. Successful recipients will display erythromycin resistance through constituent expression of EryC, a ribosomal methylase. EryC methylates erythromycin ribosomal binding sites, rendering the cells immune to erythromycin action. No direct (e.g. toxin, oncogenic, etc), known harmful effects to humans or wildlife are known regarding EryC. Insertion of the deletion cassette is intended to delete putative virulence factors. As such it may alter pathogenicity and immunogenicity. It is predicted that as potential virulence factors are deleted, virulence and viability would be reduced. Deletion of potential virulence factors in Treponema denticola have demonstrated reduced pathogenicity however, increased biofilm formation was observed in when a hypothetical protein, TDE2508, was deleted in T. denticola ATCC 35405. As such there is a potential for an indirect increase in factors involved in virulence.

In the event of a breach in bio containment resulting in a highly unlikely human infection, the effect of the presence of eryC would presumably prevent the use of Erythromycin as a treatment option. However, other effective antibiotics, such as penicillin, are available for treatment. As the inserted material encodes for erythromycin resistance an indirect environmental hazard is the potential for wild type DD treponemes harboring erythromycin resistance. Erythromycin is not used to treat cases of DD, so development of erythromycin resistance amongst environmental treponemes in the wild, although possible, is unlikely. Erythromycin is used to treat other, mainly Gram positive bovine infections, such as mastitis.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

n/a

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Solid waste will be placed in loosely sealed autoclave bags and autoclaved at 121°C, 15psi, 15min. Autoclaved waste will then be incinerated externally. Liquid waste will either be managed with Chemical inactivation with 2% Virkon for 24 hours or, Non – virkon treated liquid waste will be placed in loosely sealed pyrex duran bottles and autoclaved at 121°C, 15psi, 15min.

In house autoclaves are validated annually by a United Kingdom Accreditation Service (UKAS) calibration test. Degree of kill is 100%. Process is monitored by use of autoclave tape*

Virkon is a powerful bacteriocidal disinfectant that has been shown to provide 100% kill against many microorganisms when used at 1% concentration for 1 hour. We have validated virkon effectiveness against all three groups of DD treponemes when used at 2% for 24h and routinely use this method with wild type treponemes, including the strains proposed for genetic modification.

**Project Ref** 554/16.1

- Date Ackn'd: 06/04/2016
- CU2 Project Title: Interactions between Toxoplasma gondii and the host immune system
- Class: Class 2
- CultureVolClass2: Non-GMM
- CultureVolumeClass3-4: Consent Granted

**Project Additional Information**

- Purposes of the contained use:
  The aim of this project is to study interactions between Toxoplasma gondii and the host immune system, both in vitro and in mouse models. We aim to understand how the
parasites manipulates cells of the host immune system to enhance its spread. To identify cells and tissues containing parasites we will utilise parasites engineered to express fluorescent proteins, and to secrete cre recombinase into target cells. To study T cell responses to the parasite, we will use parasites engineered to express fluorescent proteins and the model antigen, ovalbumin (OVA). To investigate the role of parasite factors in manipulation of host cell behaviour, we will use gene knockout parasites.

Recipient or parental organism

Toxoplasma gondii is a parasitic protozoan of the phylum apicomplexa. It is an ACDP HG2 pathogen. T. gondii establishes chronic infection, and is highly prevalent in human populations, livestock, and the environment. 30% of all people are thought to have been infected with T. gondii at some point in their lives. Infection in immune competent people is usually asymptomatic, but may present as a mild flu-like illness or, in a minority of cases, ocular disease. However, encephalitis can occur following reactivation of the parasite in immune-compromised individuals, and infection during pregnancy can result in damage to the developing fetus. Natural infection most commonly occurs through the oral route. The parasite stages used are susceptible to most disinfectants and there is a very low risk of released material remaining infectious in the environment. Prophylactic treatment is available following accidental exposure.

Host/vector system

These parasites have already been generated at other institutions. They are described in:

Coombes et al, PNAS, 2013, Epub PMID: 23650399

Td-tomato, OVA and Cre-expressing lines:
T. gondii of the Prugniaud strain and lacking the endogenous gene for hypoxanthine guanine phosphoribosyl transferase (HPT) were used. To generate parasites expressing tandem dimeric tomato red fluorescent protein, parasites were electroporated with the pCTR2t vector which expresses td-tomato under the constitutive alpha-tubulin promoter, and the selectable marker chloramphenicol acetyl transferase (CAT). Stable lines expressing tdTomato were generated by chloramphenicol selection, and cloned by limiting dilution.

The parental Prugniaud-tdTomato parasites were electroporated with the pBT/P30OVA vector, which expresses secreted P30-OVA from the alpha-tubulin promoter and the selectable marker Ble. Stable lines expressing OVA were generated by phleomycin selection, and cloned by limiting dilution.

tdtomato and OVA expressing parasites were then engineered to secrete Cre recombinase into host cells. Parasites were electroporated with the toxofilin-Cre vector, which expresses the selectable marker HPT, and the epitope tagged rhoptry protein, toxofilin, fused to Cre. Stable lines expressing Cre were generated by mycophenolic acid selection, and cloned by limiting dilution.

Similar lines containing proteins fluorescing at different wavelengths may also be used (for example, Green fluorescent protein (GFP) in place of Td-tomato). Different background strains of T. gondii expressing these same proteins, and generated using the same methods, may also be employed (for example RH instead of Prugniaud). Risks are identical to as described for the Prugniaud Td-tomato lines.

GAD (glutamate decarboxylase) deficient line:
A cassette encoding CAT or a phleomycin resistance cassette and a gentamycin resistance marker was amplified by PCR, adding 50 bp matching the immediate 5’ and 3’ flanks of the TGME49_080700 (GAD) locus. These cassettes were introduced into EL250 bacteria carrying cosmid TOXP947 and recombination was induced by heat shock. Clones carrying recombinant cosmids were isolated by kanamycin/gentamycin double selection and replacement was verified by restriction analysis. The modified cosmids were transfected into a ∆Ku80 Prugniaud background (deficient in non-homologous end joining) and chloramphenicol or phleomycin resistant parasites were established and cloned. Parental ∆Ku80 Prugniaud parasites will also be used in this study.
**Origin & function**

Td tomato is a fluorescent protein. It will be used to identify parasites in infected cells and tissues.

Ovalbumin is used as a model T cell antigen and is the most abundant protein in egg white.

Cre recombinase, derived from the bacteriophage P1, is an enzyme that catalyzes site specific DNA recombination. It is used to determine when host cells have been actively invaded by the parasite.

CAT, HPT and Ble are selectable marker genes. CAT is a bacterial enzyme responsible for chloramphenicol resistance. HPT (T. gondii) is a non-essential nucleotide salvage pathway enzyme. Reintroduction of this gene into HPT mutants confers resistance to culture in mycophenolic acid. Ble, derived from the bacterial transposon, Tn5, confers resistance to phleomycin.

**Evaluation of foreseeable effects**

There is no evidence to suggest that expression of Tdtomato, OVA, or Cre-recombinase changes the pathogenicity, immunogenicity, host range, tissue tropism or means of transmission of the parasite.

TdTomato and ovalbumin can be considered inert markers, and there is no evidence to suggest any harmful effects. Cre recombinase is only functional in other hosts if exogenous LoxP sites have been introduced. There is an extremely low chance of an endogenous LoxP site occurring in a mammalian genome. Phleomycin and Chloramphenicol are not effective treatments for Toxoplasmosis in humans, so the presence of the selectable marker genes should not pose an additional risk. GAD deficient parasites exhibit a modest reduction in virulence in mice compared to the parental strain based on survival, time to death, or weight loss.

We will be working with the tachyzoite and bradyzoite/tissue cyst forms of the parasite. These are susceptible to most disinfectants and are unlikely to survive or persist if accidentally released. Laboratory exposures are most often associated with the use of sharps. Splashing of concentrated parasite preparations onto mucous membranes may also result in infection. Prophylactic chemotherapy is available following known exposures.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

We will be working with the tachyzoite and bradyzoite/tissue cyst forms of the parasite. Infectivity is lost following exposure to most disinfectants and to heat.

Solid waste will be autoclaved (discard cycle - 126 degrees for 30 minutes), followed by incineration by an external contractor. Transport to autoclave is in autoclave bags contained within plastic, lidded bins.

Liquid waste will be autoclaved (discard cycle - 126 degrees for 30 mins). Transport to autoclave is in bottles sealed with a screw cap and placed within plastic bins.

The autoclave undergoes annual service and thermocouple validation by a priorclave engineer. Prints of runs are available. In the event of autoclave failure, chemical disinfection may be used. The ability of 2% virkon to inactivate parasites has been validated in-house.
Assessment circulated in May 2013
Committee met on 21st May 2013
28th June comments sent by UBSA who also sits on IB GMSC but had not been able to attend the meeting

1.2 Information on the strains used was requested to be added - completed
4.1 'Class 2 Microbiological Safety Cabinet' - altered to ClassII
Transport between buildings to be following triple packaging principles –clarified
4.2 RA/SOP requested for intraperitoneal infection of mice and Vibratome sectioning –provided
4.4 Discard cycle must be defined - completed
4.4.1 Complete means of transport to autoclave - completed
Alternative arrangements in the event of autoclave failure will be by chemical inactivation not autoclave in Ronald Ross building.
4.4.2 In house testing of 2% Virkon for inactivation completed by Senior Technician
4.5.2 More detail required for spillage information - completed
4.6.1 All workers will be notified of risks to immunocompromised/pregnant individuals - notices are posted on laboratory door when work is taking place with T.gondii

Please enter comments on the GM safety committee on the risk assessment

</tr>
</tbody>
</table>
Enterovirus 71 (EV71) is an emerging cause of mass outbreaks of hand-foot-and-mouth disease, with neurological complications, in Asia which threatens the UK. Using virus isolates, reverse genetics and clinical material collected already from our studies in Asia (Solomon et al, Lancet, 2010), plus tissue culture models, and in house ‘Omics approaches (Isabel García-Dorival et al, JProteome, 2014) RNA-Seq will be used to identify and quantify the host cell transcriptome response to infection, conduct a bioinformatics comparison for severe versus mild disease, and validate the findings using molecular/cell biology approaches. The ultimate aim is to determine avenues for treatment of this potentially devastating infection.

To achieve this aim, recombinant EV71 virus will be produced from the transfection of plasmids containing the genome of EV71 into mammalian cell culture, resulting in the expression of virus that is antigenically homologous to that of the native virus originally isolated. The plasmid contains a RNA Pol I promoter at the beginning of the EV71 genome which, when transfected into the human RD cell line, will facilitate transcription of mRNA which will translated and form infectious virus.

Using site directed mutagenesis, the region of the genome that produces the immunogenic capsid protein of the virus will be mutated and a substituted with a triple codon sequence of another EV71 that has been associated with a differing severity of disease. The plasmid can then be used to express the recombinant virus and assessment of virulence change can be measured via cell culture methods and changes in host transcriptome can be measured by transcriptomic and proteomic methods.

Recipient or parental organism
Recipients of the specialized expression plasmids are common laboratory authenticated commercial mammalian cell lines Human Rhabdomyosarcoma (RD) cells, Vero and A549 Cells purchased from ECCAC.

Host/vector system
ThermoFisher Scientific generic bacterial plasmid with Kanamycin resistance, RNA Pol I promoter, HDV Ribozyme Cleavage site and murine terminator sequence to be transfected into Human Rhabdomyosarcoma (RD) cells, Vero cells or A549 cells for virus production.

Origin & function
Three synthetically generated EV71 genomes originally isolated from patients in Malaysia with varying degrees of severity. The strains to be inserted are similar to Human Enterovirus 71 isolate S19841-SAR-03. They are B5 genotypes.
The inserted genome will result in the expression of fully formed infectious virus, identical to the native virus originally isolated.

The inserted material will produce infectious EV71 when transfected into cell culture, this is potentially hazardous to humans. It is known to cause Hand, Foot and Mouth Disease (HFMD) and in severe cases neurological and cardiac complications, it is transmitted via faecal-oral route.

Site directed mutagenesis on the antigenic viral epitope may have a positive or negative effect on the pathogenicity of the virus depending on the sequence used to mutate the gene. However often the results of mutations results in an attenuating affect.

Given the linear, non-segmented genome of enteroviruses, the likelihood, in the event of a containment breach, of it being able to result in any gene transfer or recombination is low. Recombination could only occur if the plasmid was in cell culture alongside another EV71 strain. No wild type or other recombinant variants will ever be in the same vicinity as another. Therefore gene transfer cannot occur. In the event that gene transfer did occur, the resultant GMOs will be no more harmful than the original recipient.

**Evaluation of foreseeable effects**

There is a potential risk to human health in the event that there is a containment breach however as long as the general laboratory safety procedures and control measures stated in risk assessment are followed there is no greater risk to human health than that of any other hazard group 2 pathogen.

While the most severe EV71 genome isolate inserted may have caused neurological or cardiac complications, it cannot be solely assumed that this was as a result of the virus; complications with the hosts’ response may have been a factor in the development of a more severe illness.

Resultant GMOs of culture origins are unlikely to survive in the environment, as their optimal growth conditions are not commonly found outside of the laboratory. EV71 is does not code for an animal or insect toxin or another product that could silence a gene encoding any crucial metabolic enzyme in susceptible hosts.

Enterovirus 71 genome does not encode any material for drug or antibiotic resistance, including those currently used for medical treatment, including animals.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Used cell culture flasks directly to autoclaved at a minimum of 121°C (load temperature) for 15 minutes before being destroyed as clinical waste.

Stripettes to be soaked overnight in 2% Virkon* then incinerated.

Solid waste will be autoclaved at a minimum of 121°C (load temperature for 15 minutes and may then be disposed of via the normal industrial waste skip).

Any cell culture media will be collected in reinforced glass bottles (as per standard practice in IC2) and then autoclaved at a minimum of 121°C (load temperature) for 15 minutes.

Process testing will be thermocouple testing schedule

*See manufacture’s data: https://www.chemours.com/RelyOn/en_US/assets/downloads/europe/Virkon_Lit_No_C-1.pdf
Poliovirus belongs to the same genus and species as EV71, however is a different serotype. It has been demonstrated by the manufacturer that virkon decontaminates poliovirus, therefore it can be inferred that virkon should also disinfect EV71

Is an emergency plan required according to regulation 20? N

Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

CU2 Form on HSE website to be completed and signed. The final document to be sent to Lesley Andrews. Lesley will send to the HSE with details of payment, (the correct method to be discussed and arranged with Steph Sanford, IGH Finance Team). Lesley will advise on the start date of the project.

Start date on the risk assessment form will need amending.

Infectious dose is not known.

Section 2.1 – Cells lines – phrase is ‘authenticated commercial cells lines’ and to include where purchased from.

3.1a Further ID of cells needed, also mention virus here.

3.1b – Elaborate on how pathogenicity of viruses increases or decreases – route of infection needs to be included

4.1 – now Class II cabinet. Virus pipetting mentioned – all tissue work to be carried out in cabinet

4.3 – Scale of the project is good – add number of replicates – plan for standard experiment of 6 or 9 flasks

4.4 – Remove plant treatment of solid waste, tick autoclave box for solid waste. Glassware – to be reinforced – no breakable glass to be used

4. In the event of autoclave break-down – correct transportation SOP has already been completed. Transport left blank, means of validation to be supplied by Debby Sales. Correct link to Virkon to be used. Carry out some validation experiments on Virkon, send validation data. Carry out in-activation experiments and record outcomes.

### Project Additional Information

**Purposes of the contained use**

The spirochetes include the aetiological agents of ruminant digital dermatitis (DD), human syphilis and leptospirosis. Digital dermatitis and leptospirosis are endemic, global diseases which results in severe disease in agricultural ruminants such as cows, sheep and goats. As such, these diseases causes significant welfare and economic concerns. Physical characteristics of pathogenic spirochetes are poorly characterized largely due to their fastidious nature. The aim of this study is to validate and use a novel expression vector which will enable expression of bacterial and specifically spirochetal outer membrane proteins in *Escherichia coli* to define novel functions. This will ultimately should aid in the development of potential treatments, vaccines and diagnostics.

Initial validation of plasmid will include construction of recombinant plasmids containing both spirochetal (*Treponema spp.* and *Leptospira spp.*) and non spirochetal bacterial (*Neisseria meningitidis*, *Pseudomonas aeruginosa*, *Wolbachia*) genes encoding outer membrane proteins (OMPs) whilst subsequent use of plasmid to study bacterial function will be limited to spirochete genes only.

Transformation of the recombinant plasmids into the commercially available protein expression host *E. coli* BL21 AI or BL21 DE3.

Heterologous expression of these bacterial outer membrane proteins in the outer membrane of transformed *E. coli*.

Demonstrate functionality of OMPs heterologously expressed in *E. coli*.

Demonstrate proteins can be purified from *E. coli* outer membranes.
Escherichia coli TOP10 and BL21-Al or BL21 DE3. Escherichia coli with the exception of non-pathogenic strains are HG2 biological agents (http://www.hse.gov.uk/pubns/misc208.pdf). E. coli TOP10 is a lab strain disabled to such an extent that it is unable to cause harm to human health and therefore is considered as HG1 (http://www.hse.gov.uk/biosafety/gmo/notifications/publicregister.pdf). Specifically E. coli TOP10 is a laboratory strain which contains recA and endA mutations that prevent undesirable recombination events and carryover nuclease in miniprep DNA, respectively. E. coli BL21-Al or BL21 DE3 is/are lab strain routinely used as an expression host. BL21 have been shown to be non pathogenic (Chart et al., Journal of Applied Microbiology (2000) 89: 1048-1058) and therefore can be classified as HGI. For BL21-Al and BL21 DE3 the expression of the recombinant proteins is dependent of a supply of the inducing agent, Arabinose and/or IPTG respectively. The use of an inducible expression system, as opposed to a constitutive expression system, is a deliberate choice to add an extra layer of control over protein expression. In the event of a containment breach, protein expression will be diminished. Maintenance of the recombinant plasmid (within either host) on which the protein is encoded is dependent on the presence of ampicillin. Removal of ampicillin will quickly result in the loss of the recombinant plasmid due to its metabolic burden on the host. Comparison between these lab adapted strains and pathogenic strains have typically identified around 20 virulence genes difference between commensal and pathogenic E. coli (Lu S, et al., Emerg Microbes Infect. 2016 Dec 7,5(12):e122. Bekal et al., J Clin Microbiol. 2003 May;41(5):2113-25. Chapman TA, et al., Appl Environ Microbiol. 2006 Jul;72(7):4782-95,) and have a long established history of safe use. Given here we are only inserting a single gene under tight regulation the rule of producing a pathogen should be considered negligible. Indeed it is widely considered that a single gene is insufficient to convert commensal E. coli pathogenic E. coli, and that instead a combination of genes encoding toxins, colonization factors and other functions are required to make a commensal E. coli pathogenic (Kaper JB et al., Nat Rev Microbiol. 2004 Feb;2(2):123-40).

**Host/vector system**

- Pent-D-TOPO, a gateway entry vector
- pDESpMOMP, a modified Invitrogen pDEST17 expression vector.
- All pDEST and pENT vectors are non-mobile
- pENT vectors do not have expression functionality

**Origin & function**

- porA from Neisseria meningitidis
- wsp from Wolbachia pipientis
- ompL 1, from Leptospira interrogans
- TP0326 from Treponema pallidum
- + 12 Further predicted adhesins from Treponema spp. and Leptospira spp.

The genes of interest are Leptospira/Treponema-specific genes that encode surface-exposed proteins. We already have data that these genes encode cell surface proteins with functions of binding to the host extra-cellular matrix or wound healing proteins.

**Evaluation of foreseeable effects**

The generated E. coli strains are predicted, upon induction, to be heterologously expressing a recombinant protein in their outer membrane. (Details of the proposed proteins are below). All of the described proteins below are considered putative virulence factors through the mechanism of adhesion with the exception of PorA which is a porin.
However, the addition of the above proteins to E. coli BL21 AI or BL21 DE3 is unlikely to cause the strain to become virulent in human or animals. This is thought for several reasons:

Several mechanisms are required for E. coli to become pathogenic. E. coli BL21 does not carry the well-recognized pathogenic mechanisms required to cause the majority of enteric infections and are unlikely to survive in host tissues and cause disease (for example, BL21 primary outer membrane protease, OmpT, is disabled). Addition of a single virulence factor, in the absence of other virulence factors, is unlikely to cause the strain to regain its ancestral pathogenic potential.

The expression of the recombinant proteins is dependent of a supply of the inducing agent, Arabinose or IPTG.

The use of an inducible expression system, as opposed to a constitutive expression system, is a deliberate choice to add an extra layer of control over protein expression. In the event of a containment breach, protein expression will be diminished.

Maintenance of the recombinant plasmid on which the protein is encoded is dependent on the presence of ampicillin. Removal of ampicillin will quickly result in the loss of the recombinant plasmid due to its metabolic burden on the host.

Additionally observation of good laboratory practices should minimize any risk. In the event of a breach in containment, absence of the plasmid maintenance and protein expression dependent features described above (Arabinose and IPTG and Ampicillin) will render the strain unable to express the recombinant proteins.

Further detail on proteins encoded by cloned genes:

- **PorA**: N. meningitidis PorA is a major outer membrane porin [1]. It is a major component of the meningitis B recombinant vaccine. Additionally, it is speculated to have some pathogenic potential. PorA was assumed to have function in antimicrobial resistance; however, this was recently disproven [2].

- **TP0326**: The Treponema pallidum TP0326 protein is a BamA ortholog [3]. These proteins are conserved in all Gram-negative bacteria, both pathogenic and non-pathogenic. Its function is involved in the maintenance of the outer membrane. As such, it is not considered a virulence factor. Previous heterologous expression of TP0326 in E. coli did not cause any observable phenotype.

- **WSP**: Wsp is a major outer membrane protein of the arthropod endosymbiont Wolbachia pipientis [4]. Wsp function is not well understood, but is thought that it may play some role in adhesion to endosymbiont host [5]. Therefore it could be argued that this protein has the ability to provide E. coli with increased adhesin to cellular structures. While this is a possibility, it is unlikely that this will cause the strain to become virulent in humans or animals.

- **OmpL 1**: Leptospira interrogans porin L 1 is an outer membrane protein with the ability to adhere to specific ECM components [6].

- **12 Further predicted adhesins from Treponema spp. (n=6) and Leptospira spp. (n=6)**. The genes of interest are Leptospira/Treponema-specific genes that encode surface-exposed beta barrel proteins. We have produced data that demonstrate these genes as encoding cell surface proteins with functions of binding to the host extra-cellular matrix or wound healing proteins. In each case only one gene will be added for expression and functional study. The addition of single adhesins to E. coli in the absence of other virulence factors, is unlikely to cause the strain to regain its ancestral pathogenic potential.

Given the bacterial strains are lab attenuated the addition of a single gene with adhesive or porin ability is unlikely to enable the production of a pathogen. However it could be considered that there is some limited risk given the outer membrane proteins (OMPs) from Treponema spp. or Leptospira interrogans could enhance virulence of the E. coli host strains, enabling invasiveness and colonization of the human gastrointestinal tract (if accidental exposure/infection of a person were to occur). Furthermore there may also be potential for extra-intestinal infection and the virulence determinants required to enable extra intestinal infection are less clear. Taken together these
Concerns we consider this contained use activity is considered to be class 2.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

GM solid waste material including contaminated agar plates, cell culture plastic ware, pipette tips, microplates and tubes etc are to be autoclaved (waste transferred either weekly or when bin full for autoclaving) with autoclave at 126 degrees C for 30 minutes. Primary machine is a Priorclave which runs this program and back up machine is a Rodwell autoclave. Autoclaved waste will then be incinerated externally. Liquid GM waste including cell growth media will be placed in loosely sealed pyrex duran bottles and autoclaved at 126°C, 30 min. Liquid waste will then be washed down the sink with copious amounts of water. Contaminated surfaces will be disinfected with 1 % Distel. In house autoclaves are validated annually by a United Kingdom Accreditation Service (UKAS) calibration test. Degree of kill is 100%. Process is monitored by use of autoclave tape* Distel has been validated for deactivation of E. coli at 1 % concentration (https://www.starlabgroup.com/GBen/ sidelcumentldownload/186645_123)

Circulated 5/9/18. The Leahurst Departmental Genetic Modification Safety Committee met on 12th September 2018 and it was suggested that the work proposed did present a greater hazard than working with the wild-type organism and that the proposed level of containment potentially needed to be amended to category 2. Amendments on containment and waste disposal streams were suggested. After additional review the project was deemed Class 2. Agreed approval on chair’s action subject to amendments. Approval 21/9/18 subject to HSE notification.

Project Additional Information
Purposes of the contained use

(Scientific purpose, aim and Justification)

Our research group focuses on the scientific understanding of the pathogenesis and genomics of human pathogens from ACDP category 2, with a particular emphasis on identifying and characterising virulence factors, immune resistance determinants and potential vaccine and drug targets from bacterial pathogens. Our work involves genetic manipulation of lab-adapted and commensal strains that colonise or infect humans and the cloning e.g., knockout or insertion, expression and characterisation of virulence determinants from these strains into class 1 disabled laboratory strains of bacteria such as Escherichia coli or food-grade Lactobacillus Lactis for heterologous expression.

The following is an overview of the GM research activities that form our connected programme of work:

Activity 1. Creation of knock-out and insertion mutations in genes encoding for virulence factors in Streptococcus pneumoniae, S. agalactiae, and S. pyogenes - and determine the effect of these mutations on various phenotypic properties including adhesion and invasion properties, growth characteristics in vitro, e.g., cell lines and biofilm models, and virulence properties in vivo using previously established mouse models e.g., carriage, invasive pneumonia, sepsis, septic arthritis.

We will clone DNA fragments from the Streptococcal species (listed above) into non-mobilisable vectors in laboratory strains respective of each bacterial species. It is often necessary to clone genes or DNA fragments of interest from class 2 pathogens into class 1 disabled laboratory strains of bacteria such as E. coli to enable subsequent analysis such as DNA sequencing or to enable further constructs to be engineered. The results obtained in Activity 1 will inform part of the work carried out in Activity 2.

Activity 2. Expression of vaccine candidate genes (identified in Activity 1 or elsewhere) in a disabled bacterial host for the purpose of assessing their immunogenicity and protective efficacy in murine models. We will exclude from this assessment deliberate cloning of intact soluble toxin genes, hence toxin will only be expressed in their non-lytic variant form i.e., toxoid.

Within the last 20 years the concept of bacterial vector-based (BVB) vaccines has gained renewed interest due to increased immunological understanding and availability of molecular techniques making possible the construction of safer bacterial vector-based vaccine formulations. BVB vaccines include genetically modified and attenuated strains of human commensal bacteria whereby high levels of expression can be achieved hence facilitating evaluation of the immunogenicity and protective efficacy of vaccine gene candidates. The following class 1 microorganisms will be used as vaccine antigen-BVB formulations:

1. food-grade Lactococcus lactis strains
2. derivatives of the Escherichia coli K-12 strain which have been demonstrated to be avirulent, and have a long history of safe use in humans
3. auxotrophic aroA-deleted virulence attenuated Salmonella typhimurium

These 3 BVB systems were selected on the basis of recent WHO literature reporting their safe use in humans for oral (i.e., nasopharynx or gut by oral gavage) and parenteral (e.g., intramuscular, intravenous, intraperitoneal) delivery routes. (WHO meeting report 2003, Informal consultation on characterisation and quality aspect of vaccines based on live vectors, Lin, et al. (2015). Live-Attenuated Bacterial Vectors: Tools for Vaccine and Therapeutic Agent Delivery. Vaccines, 3(4), 940–972).

Work carried out in activity 2 strictly pertains to the in vitro and in vivo handling of the BVBs described within this document, but does not pertain to any of the mutagenesis or cloning experimental procedures that have been/will be used to generate the BVBs. The vaccine-antigen BVB formulations will strictly be outsourced from commercial sources e.g., Thermo Fisher Gene Art.

Recipient or parental organism

Activity 1:
- Streptococcus pneumoniae
- Streptococcus agalactiae
- Streptococcus pyogenes

Activity 2:
- Food-grade Lactobacillus Lactis
- Escherichia Coli K12 and derivatives
- AroA-deficient attenuated Salmonella Tiphymurium*

Host/vector system

Activity 1:
Any of the following expression vectors (i.e., plasmids) may be used for transformation into the 3 streptococcal species of interest:
1. Suicide vectors for Site directed mutagenesis (pucMUT, pACH74 and pAS1TAG)
2. Transposon mutagenesis (pR412, pJR233 and pJDM-STM)
4. GFP expressing integrative plasmids (pBaSysBioll, pBSU101, pGFP, YFP, pCFP, pLS1GFP, pMV158GFP, pLS70GFPcat, pMV158GFP)
5. pLS758, pMSP3535, pCEM, pCTet, Janus are used for tagging or replacement of genes with resistance genes against tetracycline, erythromycin and Kanamycin.
6. pET is an expression vector for protein overproduction.
7. pHY304 is a temperature-sensitive plasmid for insertional mutagenesis.
8. pSIV is an inducible shuttle vector system.

Activity 2:
Any of the following plasmid vectors may be used:
Lactobacillus Lactis: pTRKH3-slpGFP, pTRKH3-ermGFP, pT1NX, pPA32, pVE5547
Escherichia Coli K12: pBR322, OPPF-UK pOPIN vectors, PCDNA3.1
Salmonella Tiphymurium: pBR322, pSC101, pmQ117 and derivatives.

In this coordinated programme of work, the vectors that will be used are well-characterised vectors that (i) are either non-mobilisable or mobilisation-defective in bacteria; and (ii) contain only selective markers that are already in routine use in standard cloning vectors; and (iii) contain no recognisable harmful sequences e.g., Schedule 5 of the ACS ACT 2001 or substances prohibited by the Chemical Weapons Convention.

Origin & function

All genetic materials will be derived synthetically or via production of genetic material in E. coli using standard molecular biology approaches.

Activity 1:
The genes studied in this work will derive from streptococcal species: S. pneumoniae, S. agalactiae, S. pyogenes. The genes may be involved in nutrient uptake, metabolism, signaling, host immune responses, in vitro growth and cell wall biosynthesis and assembly. The aim of this work is to establish the functions of genes involved in these essential processes through gene deletion and observing/characterizing the phenotypes of these mutant strains in murine models, in comparison to their wild-type counterparts.

Activity 2:
The vaccine candidate genes studied in this work may derive from any of the family of proteins listed below, which will be expressed in one or more of the bacterial hosts listed in section 2 of this document:
Bacteria: Various cell-wall associated proteins (e.g., choline-binding proteins), surface-exposed proteins involved in complement activation as well as various neuraminidases, IgA proteases, adhesins and metalloproteases, and pore-forming toxins e.g., pneumolysin, streptolysin, β-hemolysin/cytolysin. Other virulence factors are those that promote immune evasion and resistance to host defences.
Viruses: hemagglutinin, genes of the polymerase complex, neuraminidases, non-structural glycoproteins, envelop proteins.
Parasites: proteases, surface antigen e.g., gp46/M2 or parasitesurface antigen 2 (PSA-2), kinases, ribosomal proteins, flagellar antigens.

The risk assessment for Activity 2 does not pertain to any of the mutagenesis or cloning experimental procedures that will be used to generate the genetically modified bacterial hosts – as these will be outsourced commercially or via the University of Liverpool Technology Directorate - but only to the handling and evaluation of their immunological properties in vitro and in vivo. In other words, the risk assessment for Activity 2 does NOT pertain to the handling or genetic modification of any ADCP 2 pathogens. In all cases, the intent is to assess the immunogenicity and protective efficacy of food-grade or disabled microorganisms class 1 genetically modified to express a non-functional subunit protein, i.e., a truncated protein variant containing immunodominant epitopes only and no biological function.

Evaluation of foreseeable effects

RISKS TO HUMANS:
• Exposure of humans to the bacterial species listed in section 5, by inhalation or contact with contaminated aerosols could occur in the event of a breach of containment such as the spillage of viable culture. Sepsis, respiratory or skin inflammatory reactions could result. However, this is highly unlikely as the strains used in this project are either lab-adapted or disabled strains, hence represents a very low risk to human health. Streptococcus agalactiae will infect cattle but is only of risk to severely immunocompromised human individuals.
• All of the vectors are in common usage for bacterial research. None of the vectors are likely to transfer genetic material to any other environmental microorganisms. The
genes which will be transferred or deleted in this investigation belong to specific targeted functional classes the expression or loss of expression of which is highly unlikely to influence the pathogenesis of the hosts. Expression of antibiotic resistance cassettes for selection use resistance to antibiotics (e.g. ampicillin, kanamycin, gentamicin or streptomycin), which will confer resistance to antibiotics well below the therapeutically used levels.

- The selection strategy will specifically exclude the use of genes such as toxins or known allergens.
- For the reasons outlined above the risk to humans from exposure to the GMMs is highly unlikely to be greater than exposure to the original parental strains. None of the deletion/insertion mutants, or other manipulated strains are likely to be any more or any less pathogenic than the parental strains. The GMMs are expected to exhibit the same level of pathogenicity as the parental strains and will therefore be handled under the same level of containment (class 2) and with the same stringent handling and disposal procedures as the unaltered parental strains as described in the available associated local risk assessment, SOPs and COPs.

**ENVIRONMENTAL RISKS:**

- The foreseeable effects include the introduction of antibiotic resistance genes which could represent a hazard if released into the environment and transferred to other organisms. All GMOs and GM material will be decontaminated and sterilized before disposal and operational protocols described herein, hence make release unlikely. Therefore transfer of genetic material to other environmental microorganisms remains extremely unlikely.
- Other than those hazards intrinsic to the vectors named above, there is no risk to the environment. All necessary safety precautions will be taken so that there is sufficient containment with no environmental release i.e., bagging, autoclaving and/or incineration of all disposed biological materials.
- The environmental survivability of our GMO is envisaged to be the same as their wild type, with the advantage that without appropriate selection pressure reversion to the wild type is likely, hence there is no increased risk to the environment posed by the GMM compared to the wild type.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

For preparation of plasmid DNA/protein, bacteria will be collected by centrifugation and lysed. Liquid waste material will be rendered non-viable by decontamination overnight with Virkon (1%) and autoclaving prior to sink disposal. Any contaminated solid waste (e.g. contaminated disposable plasticware, agar plates, DNA) will be either bagged or placed in lidded Disposafe jars, and autoclaved (121 degrees C for 30 minutes) prior to disposal.

Virkon is routinely used as per the manufacturers recommendations:

- Solid surfaces are disinfected with 1% Virkon solution.
- Plastic ware that can be effectively disinfected is treated with 1% Virkon for a minimum of 1 hour prior. Any contaminated glassware is treated with 1% Virkon solution for a minimum of 1 hour prior to cleaning.
- Liquid waste (culture and medium) is disinfected by the addition of Virkon to give a 1% final working concentration. 2% or 3% solutions of virkon are used for buffered solutions. A minimal contact time of 1 hour is allowed prior to disposal to sewers (as per manufacturer’s recommendation).
- Accidental spillages of liquid waste will be inactivated with 2% Virkon

The category II laboratory will be regularly monitored by members of staff and laboratory manager to ensure good housekeeping and hygiene is regularly maintained with particular emphasis on treatment and disposal of infectious biological waste.

Monitoring:

- Disinfection: The disinfectant of choice (Virkon) is used in strict accordance with the manufacturer’s (Antec’s) guidelines.
- Autoclaving: To ensure 100% efficacy, testing of the autoclave is carried out annually, by the manufacturer, to demonstrate, using a 12 point test with independent thermocouples, that the correct temperature and pressure have been reached for the required time. On subsequent runs verification that the correct conditions were reached is obtained through use of a temperature probe in the centre of the load. Testing is arranged and test reports are kept by the Health and Safety Co-ordinator.
- Inspections: Safety inspections are carried out annually to ensure Local Rules are adhered to and that risk assessments and training records are in order. Inspection reports are kept by the Health and Safety Co-ordinator.
- Microbiological Safety Cabinets: Tested on a six monthly basis with annual KI test. Certificates of conformity are displayed on each cabinet and copies kept by the Health

Please enter comments on the GM safety committee on the risk assessment
In relation to Activity 1 risk assessment:
Assessment circulated 06/06/19, meeting held 27/06/19, revised RA received 16/07/19 and approved 17/07/19.

Panel comments on original submission:
Panel agreed with proposed class II designation but felt that elements of the RA required clarification. More detail needed on at-risk groups (e.g. pregnant women for GBS).
Could get potential virulent strains
Home office license number missing
Pregnant women should not work with Strep B
Section 1.1: Project title - need to change title to include 'Knockout and Insertion'
Section 1.1: Location of work – need to add BSU to this section
Section 1.2: HSE notification number missing
Section 2.1: ‘routine basis’ – needs to be more specific.
Section 3.1b, Inserted genetic material: needs to be re written
Section 3.1b, Direct effects: Info needed
Section 4.2: May use sharps at BSU?
Section 4.3: More detail required. How often? Scale? How much?
Section 4.4: Plastic container, not a metal container. Swap Sweetie jar to Disposafe jar. Overnight soaking in 1% Virkon, not 20 minutes. For liquid waste, place Duran bottle and/or plastic tubes in to appropriate plastic container for autoclaving.
Section 4.4.1: Include room numbers for autoclave rooms on 1st floor and 2nd floor. Replace ‘BMM Weston engineers’ with ‘Autoclave engineers’

UPDATED 17/07/19: Revised RA received and reviewed. All suggested changes have been made and a class II designation confirmed.

UPDATE 24/07/19 – from University of Liverpool Biological Safety Officer:
The UBSA was provided with the signed off risk assessment on 18 July 2019. She had not been invited to the GMSC meeting and provided feedback on the RA on 19 July 2019.
A general comment is lack of justification of statements- you must justify every statement and give details as prompted by the notes- read the notes please.
1.1 location of work requires more details, room numbers and space refs if possible for all areas. In vivo work presumably in BSU not TC rooms as stated. Start date needs amending.
1.2 1.2 page 3 there is a reference to HSE notification xxxxx?
It's good to future proof by including the Tn option.
The animal work does not appear to be described? This is very important- to describe the work procedures, hazards to human health and the environment and the control measures- HSE scrutinise this very carefully.
2.1 state hazard groups of recipients, state properties of the vectors, are they mobilisable, transmissible? State origins of the inserts- where is this genetic material from?
2.2 is there a possibility that with virulence genes knocked out the organism may become less pathogenic? This would be worth mentioning although of course it's unlikely to lose its pathogenicity altogether as multiple factors are involved.
3.1b- what they need to address is whether the antibiotics used for selection are used therapeutically? Consider if someone became infected could they be treated effectively with another antibiotic?
Effect of gene transfer contains some good reasoning but must consider IF the antibiotic resistance genes were transferred to other bacteria what could be outcome?

3.1.1 consult the notes on what is required- this doesn’t answer the question. – consequence of exposure- likelihood of exposure, any uncertainties must be recorded.

3.2 must focus on environmental risk- not repeat what has been said for human health 3.2a I think there are other Streps that can infect animals but these three can’t? 3.2.b – concentrate on environment and give justification in the Summary

4.1 tissue homogenisation suddenly appears with no indication of how we got there! This work flow needs to be included in the RA. I would put it into section 1.2

4.2 the information provided seems to be focused on sharps bins and disposal but information is required about use of sharps and control measures- HSE have asked for more information on this in the past and will scrutinise it in detail. This is one of their “things”

4.3 not sure what Committee is referred to here but there is no BSU GMSC.

4.4 no contact times stated for Virkon, is 1% correct- most people say 2% or 1% final concentration. Animals?

4.4.1 trolley used to move waste?

4.4.2- do you really have in house test data- if you state it HSE may ask to see this.

In relation to Activity 2 risk assessment:

Assessment circulated 06/06/19, meeting held 27/06/19, revised RA received 16/07/19 and approved 17/07/19

The original RA contained the work proposed here together with some proposed work on viral vaccine vectors. Panel advised splitting into two separate RAs with a viral vector one designated class I and a bacterial vector one designated class II.

Additional suggestions made by the panel were:

- Need to be more specific about storage
- RA is very broad. It needs to be project specific – i.e. which viruses using?
- Aims need to be more specific.
- Could split in to 2 – viruses Class I and bacteria Class II

Section 3: More references are required.

Section 3.1b, Inserted genetic material: needs to be re written

Section 4.2: Sharps will be used. What would you do if there was a needle stick injury?

Section 4.3: How much bacteria will be used? How frequent?

Section 4.4: Autoclaves bags are not used in the main lab for autoclaving biological waste. Small plastics are put in a Disposafe jar and then transferred to an autoclave bin. Bacterial plates and large plastics (flasks, plates etc), are placed directly in to an autoclave bin. Stripettes soaked in 1% Virkon overnight.

Liquid waste – need to re-write this section. Glassware is not decontaminated with 5% Virkon prior to autoclaving. Virkon should not be autoclaved.

Replace ‘BMM Weston engineers’ with ‘Autoclave engineers’

Section 4.6: Ticked yes for OH. Please confirm.

UPDATE 17/07/19 – Revised RA reviewed and designated class II. All panel comments have been addressed.

UPDATE 24/07/19 – from, University of Liverpool Biological Safety Officer:

The UBSA was provided with the signed off risk assessment on 18 July 2019. She had not been invited to the GMSC meeting and provided feedback on the RA on 19 July 2019.

1.1- Don’t use acronyms, include details of rooms including space refs, start date amendment
1.2 - There is some confusion in the middle of second paragraph around the word order
Safe use/intended use- do you mean all recipients (not vectors?)
Again very little information on mouse work- this is essential to describe the work procedures, hazards to human health and the environment and the control measures-
HSE scrutinise this very carefully.
2.1- hazard groups of recipients? This may be 1? Properties of vectors- mobilisable, transmissible, do they express?
2.3 and 2.4 both answered no- would this not be 2.3 yes, and 2.4 not sure? As it stands it would be class 1, but class 2 selected (correctly but not justified)
31. focuses on the antibiotic resistance genes and fluorescence markers but the virulence genes are not mentioned, not considered. The work is class 2 largely because of
the virulence genes being cloned? I don’t understand how class 2 provisional is reached from the assessment provided. Summary of risks to human health states “None”
but class 2 is chosen?
3.2 does not adequately consider and justify risk to the environment, you must do this and justify statements
4.1 sudden mention of animal tissue homogenisation with no lead up to this- we don’t know what this is or how it has been generated.
4.3 scale- I think they mean bacterial cultures (not vectors)- serum? What serum- how are the hazards if any from this controlled?
This section does include some information on animal work which is helpful. However a more detailed consideration of the risk to human health and the environment is
required.
4.4 solid waste – animal carcasses? Isn’t incineration used for final disposal? Sealed containers would explode in the autoclave, is 1% Virkon correct? No contact time
stated, how long is autoclave cycle at 130?

**Project Additional Information**

**Purposes of the contained use**

We want to propagate class 2 GM respiratory viruses in the laboratory for use in infection studies. This includes rhinovirus (RV) and respiratory syncytial virus (RSV).

**Propagation of RV in cell lines**
RVC was recently identified (2006) by PCR based methods. Few studies have used RVC in infection studies as it could not be propagated in the laboratory like RVA and RVB (propagation in HeLa cells). This is due to the fact RVC uses a different receptor for host cell entry (CDHR3) than RVA and RVB, which is not expressed on HeLa cells or other tissue culture cell lines. Reverse genetics methods have now been utilised to propagate RVC in the laboratory by transfecting standard cell lines (HeLa/ WI-38/ MRC5) with viral RNA. Rhinovirus has a positive-sense SS-RNA genome, the naked RNA is infectious, therefore, it can initiate a complete viral reproduction cycle that produces infectious progeny viruses when it is transfected into a permissive cell. Using this method RVC cannot propagate between cells but can replicate within the transfected cells to produce viable virus that can be isolated and purified for further infection studies.

We will use plasmids already constructed by collaborators and construct our own plasmids that contain a whole genome cDNA copy of RVC, RVA and RVB genomes. The majority of the strains propagated are wild type (WT), however, some of these plasmids will also contain a eGFP gene (fluorescent virus) which will allow us to visualize viral infection during infection studies. RNA generated from these plasmids when transfected into permissive cell lines will allow us to propagate these viruses and purify them for use in infection studies in primary human airway epithelial cells (can be naturally infected by all RV strains).

**Propagation of RV in HeLa-E8 cell line**
RVC uses a different receptor (human Cadherin Related Family Member 3 (CDHR3)) for host cell entry, than RVA and RVB, which is not expressed on HeLa cells or other cells lines normally used to propagate RV strains in the laboratory. Current methods used to propagate RVC in the laboratory for infection studies are by transfecting standard cell lines (HeLa/ WI-38/ MRC5) with infectious viral RNA. However, this virus cannot propagate between cells. As the virus cannot spread to other adjacent cells the amount of virus produced is limited, limiting the scope and number of experiment that can be performed.

CDHR3 has multiple alleles, one of these has been associated with severe asthma exacerbations (GG>AA). This AA allele has been shown to cause increased RVC binding and replication as it results in increased CDHR3 expression on the cell surface. So in order to get round the fact RVC doesn’t naturally infect HeLa cell line, which are used for RVA and RVB propagation, these cells have been engineered to express the CDHR3 asthma allele (AA). This allows RVC to naturally infect cells and spread to adjacent cells during infection. Negating the need for the long winded reverse genetics cloning approaches that are currently required to work on RVC strains. We will use this cell line, which has been engineered and will be provided by collaborators, to propagate RVC viral strains via natural infection (clinical isolates) or through transfection of a whole genome copy of viral RNA into the GM cell line.

**Propagation of fluorescent tagged RSV strains**
Fluorescent tagged RSV will be propagated in Hep2 cell line, with infection occurring naturally. Infection in these cells will allow viral propagation and subsequent purification for future infection studies in primary human airway epithelial cells (can be natural infected by all RSV strains). The RSV fluorescent tagged virus will be purchased commercially from ViraTree (https://www.viratree.com), RSV-GFP5/ RSV-DsRed5/ RSV-FarRed5, which all grow similarly to the parent virus.
GM virus will be propagated in:

- Commercially available cell lines (HeLa/ WI-38/ MRC5/ Hep2)
- GM modified cell line (HeLa-E8)
- Primary human airway epithelial cells (nasal/ bronchial brushings)

Cells infected with virus

HeLa - HeLa cells are the oldest and most commonly used cell line and are derived from human cervical cancer. These are widely used in the virology research field and are used for propagation of rhinovirus in the laboratory.

WI-38 - is an immortalised human cell line composed of fibroblasts derived from lung tissue of a 3-month-gestation aborted female fetus. These are widely used in the virology research field and are used for propagation of rhinovirus in the laboratory.

MRC5 - is an immortalised human cell line composed of fibroblasts derived from lung tissue of a 14 week old aborted caucasian male fetus. These are widely used in the virology research field and are used for propagation of rhinovirus in the laboratory.

Hep2 - This line was originally thought to be derived from an epidermoid carcinoma of the larynx, but was subsequently found to have been established via HeLa cell contamination. These are widely used in the virology research field and are used for propagation of RSV in the laboratory.

Primary human airway epithelial cells - obtained from nasal or bronchial brushings. Cells are widely used in the respiratory research field as they are the main target of a number of respiratory viruses, including RV and RSV. RVC can infect these cells naturally.

HeLa-E8 - GM modified version of HeLa cell line, which expresses the CDHR3 RVC receptor.

Production of the HeLa-E8 cell line is described in Bochkov et al, 2015 (1) and in patent US20190055521A1. Briefly, to make this HeLa-E8 cell line, the mutation in domain 5 (C529Y) of CDHR3, which is a naturally occurring mutation (AA allele) seen in around 3% of the population, was engineered into a lentiviral vector containing wild-type CDHR3 sequence (GG allele) under the control of a CMV promoter to express the gene of interest. Causing high level expression of CDHR3 on the HeLa cell surface, and the resultant transduced cells were susceptible to RVC infection. In nature people with the AA allele express CDHR3 protein at higher levels on the cell surface compared to the GG allele. This allele is associated with childhood asthma with severe exacerbations, and has been shown to result in increased binding, infection and viral replication during RVC infection.

Adventitious agents are not present in established immortalised cell lines. Primary human cells should be treated as potentially infectious and contaminated biological specimens and handled at Biosafety Level 2.

Host/vector system

Construction of GM viruses using reverse genetics

Reverse genetics methods are required to propagate RVC in the laboratory by transfecting standard cell lines with viral RNA. Rhinovirus has a positive-sense SS-RNA genome, the naked RNA is infectious, therefore, it can initiate a complete viral reproduction cycle that produces infectious progeny viruses when it is transfected into a permissive cell. The virus can then be purified and use in infection studies in primary airway epithelial cells.
The RNA for transfection is amplified from plasmids in which a full length cDNA copy of the viral genome has been cloned (7.2kb). RNA is generated from these plasmids using the Promega RibomAX Large Scale RNA Production Systems, generating a RNA copy of the viral genome via T7 RNA polymerase. Construction of the plasmids used for RNA generation is described in our class 1 bacteria GM risk assessment. This procedure is also described in detail in Rhinoviruses Methods and Protocols, chapter 12 and Bochkov et al 2011 and 2015 1,2.

Some of these plasmids have been provided to us by our collaborators Professor Gern (University of Wisconsin), who developed the methodology for RVC viral replication (2). We will also generate plasmid containing a cDNA copy of the RV genome from clinical isolates. Some of these will also contain a GFP tag. Therefore, viruses generated using this methodology will be wild type viruses (cDNA cloned from clinical isolates) or GFP tagged viruses. If GFP tagged the eGFP gene sequence will be inserted in-frame between proteins VP1 and 2A protease (as described in Bochkov et al, 2015 (1). This gene is inserted between the two 2A protease recognition sites (LISSA/GPS) to release the GFP from viral polyprotein upon translation. Virus generated from this plasmid will fluoresce during infection and this will allow us to visualise viral infection in tissue culture and primary cells.

Rhinovirus GM virus

For fluorescence microscopy studies we will also use a fluorescent tagged RSV, which are commercially available and have been constructed as described on the ViraTree website (https://www.viratree.com), RSV-GFP5/ RSV-DsRed5/ RSV-FarRed5. These GM viruses generated in wild-type parent RSV strain A2 are modified to express the fluorescence proteins from a gene cassette placed between the P and M genes.

HeLa-E8

HeLa-E8 cells have already been constructed and will not be modified further. Production of the HeLa-E8 cell line is described in Bochkov et al, 2015 (1) and in patent US20190055521A1.

CDHR3

pLX304 expressing wild-type CDHR3 was purchased from TransOmic. The pLX304 vector provides a high level expression of CDHR3, and the resultant transduced cells were susceptible to RVC infection. The vector is publicly available. The mutation in domain 5 (C529Y) of CDHR3 was engineered into this vector containing wild-type CDHR3 sequence. This genetic change causes increased expression of CDHR3 on the HeLa cell surface, making them susceptible to RVC infection. Both alleles of this gene are naturally present in the human population.

The exact role of CDHR3 in the host is not 100% clear but the protein once produced is found within the cell or cell surface associated. It is a member of the Cadherin Related Family Member proteins, cadherins are important for the formation of adherence junctions so it is hypothesised to be involved in cell to cell adhesion.

GM viruses

For production of viable virus A RNA copy of the viral genome is generated from plasmids provided to us by collaborators or constructed by ourselves (described in detail In our GM bacterial class 1 RA). RNA is generated from cDNA using the Promega RibomAX Large Scale RNA Production Systems, generating a RNA copy of the viral genome via T7 RNA polymerase. Viruses generated in this manner are wild type but still classed as GM, except the strains where a eGFP gene has been incorporated into the genome creating a fluorescent virus, these are not wild type. cDNA that is cloned into the plasmids is generated from patient sample (such as nasopharyngeal aspirates) that have been infected with RV naturally. The eGFP gene which encodes a green fluorescent protein will be amplified from the pC15-GFP, which was constructed as described in Bochkov et al 2015 (2). Enhanced green fluorescent protein was originally isolated from Aequorea Victoria, and produces bright green fluorescence when exposed to blue light (395nm). This gene and is widely used in the research field as a reporter gene.

RSV strains, for fluorescence microscopy studies, are commercially available and have been constructed as described on the ViraTree website (https://www.viratree.com), RSV-GFP5/ RSV-DsRed5/ RSV-FarRed5. Infectious viral virions will be provided to us to propagate in the laboratory. In these strains the fluorescent genes are cloned on an expression cassette between viral genes P and M. This is inserted into parent RSV strain A2. Genes cloned into these strains to make them fluorescent include eGFP (RSV-GFP5) as noted above. RSV-DsRed5 contains a variant of Discosoma sp. red fluorescent protein which has faster maturation and lower non-specific aggregation. It fluoresces red/orange when excited with light at 488/ 532nm. RSV-FarRed5 expresses super bright far-red fluorescent protein mKate2, an improved version of a monomeric far-red fluorescent protein from sea anemone Entacmaea quadricolor (excitation/emission maxima at 588 and 633 nm). All proteins are widely used in the research field.

Overview

Viral GM

Reverse genetics methods are required to propagate RVC in the laboratory by transfecting standard cell lines with viral RNA. Viral RNA used for cell transfection is amplified from plasmids in which a full length cDNA copy of the viral genome has been cloned (7.2kb). These have been provided to us by our collaborators Professor Gern (University of Wisconsin), who developed the methodology for RVC viral replication. Plasmids provided to us contain a full length cDNA copy of the viral RNA genome from RVA (pA16-R16.939), RVB (pB52-Rz_V.2), RVC (pC15-Rz) and RVC GFP tagged (pC15-GFP). The cDNA genome has been cloned downstream of a T7 promoter. RNA is generated from these plasmids using the Promega RiboMAX Large Scale RNA Production Systems, generating a RNA copy of the viral genome via T7 RNA polymerase. We will use the same methodology to create plasmids that contain a cDNA copy of the viral RNA genome of clinical RVC strains. Some will also be GFP tagged using the same methodology as that used to generate pC15-GFP.

RSV strains

For fluorescence microscopy studies using RSV, we will use fluorescent tagged RSV strains, which are commercially available and have been constructed as described on the ViraTree website (https://www.viratree.com), RSV-GFP5/ RSV-DsRed5/ RSV-FarRed5. These GM viruses generated in wild-type parent RSV strain A2 are modified to express the fluorescence proteins from a gene cassette placed between the P and M genes. Using these strains we can visualise viral infection of cells.

HeLa-E8 cell line GM

HeLa-E8 cells have been produced using a lentiviral vector systems as described above. They have been provided to us by collaborators. HeLa-E8 cells express the CDHR3 viral receptor for RVC on their cell surface, and are used for RVC propagation in the laboratory as RVC can naturally infect these cells. These cells will be used to propagate RV through natural infection and also by transfection of a whole RNA viral genome into cells. This Includes WT RV clinical isolates and GFP tagged RV clinical isolates.

Direct effects

HeLa-E8

The cell line HeLa-E8 is not infectious. For the construction of this cell line lentiviral vectors were used, these are self inactivating and replication incompetent so would not still be present. The transfer plamid (pLX304) selected for in the HeLa-E8 clone contains no genetic material that could result in lentiviral replication and progeny production. Further, once we receive the cell line the cells will not contain any plasmid DNA.

If the cells were released into the environment they would not survive as they require media enrichment to survive. The CDHR3 gene transfected into the cells is naturally occurring, this transfected Y529 allele that is present in the human population causes increased cell surface expression of CDHR3 on the HeLa cells resulting in increased viral binding and replication. This phenomenon is also the same in the cells of people who carry this allele (Y529). The single amino acid change in the protein does not change the total cellular expression of the CDHR3 protein but increases the levels present at the cell surface. The exact role of CDHR3 in the host is not 100% clear but the protein once produced is found within the cell or cell surface associated, it would not be release into the tissue culture media or be toxic to humans if we encountered it. These cells are unable to colonise workers and contains no adventitious agents.

Environmentally these cells are human derived and would be unable to colonise plants or animals, and contains no adventitious agents. The CDHR3 protein is human derived and it would not have any effects on plants or animals if released. There are animal homologues of this protein but as RVC is solely a human pathogen, genetic changes in this protein would mean it is different enough to not function the same as the human CDHR3. Therefore, it would not be toxic to animals or plants in the unlikely event it was released.

Propagation of GM virus

Transfection of a complete viral RNA genome into tissue culture cells results in production of live infective virions, which can be isolated and purified for infection studies. All viral strains used in this study originally came from clinical isolates and are therefore pathogenic. Except the fluorescent tagged viruses, all tagged strains have been shown to grow similarly to the wild type strain and addition of these genes gives no advantage to the virus. Propagation of all viruses noted in the RA pose potential hazard to health, they are class 2 respiratory pathogens. Both viruses in healthy individuals cause mild cold/ flu like symptoms. Disease can be more severe in children, the elderly, and people with underlying health conditions.

These viruses are solely human pathogens and they can spread when an infected person coughs or sneezes. You can get infected if you get droplets from a cough or...
sneeze in your eyes, nose, or mouth, or if you touch a surface that has the virus on it, like a doorknob, and then touch your face before washing your hands. These viruses can survive for several hours on hard surfaces, for shorter periods on fabrics. 40% of rhinoviruses are still infectious on hands after an hour.

These viruses are solely human pathogens. There are animal infection models for both of these pathogens (RV/ RSV) but these require large doses of virus for infection and often don’t recapitulate the symptoms of human disease. Therefore, these viruses don’t pose a direct infectious threat to any plant or animal present in the external environment, bar humans. The viral infected cells (cell lines/ primary cells) cannot survive outside of cell culture as they require media supplement to survive so pose no threat to the environment.

Indirect effects
HeLa-E8 cells

The CDHR3 receptor is expressed on human cells and is the receptor for RVC. The CDHR3 allele cloned into the HeLa cells is naturally occurring. In these cells the CDHR3 protein is expressed to higher levels on the cell surface. Its role in the host is not fully clear but it hypothesised to be involved in cell to cell adhesion. Overexpression of this protein doesn’t affect the cells in any way that would make them hazardous to work with.

These HeLa-E8 cells are used for propagation of RVC, which uses this CDHR3 receptor in nature to infect host cells. Genetic mutation have been noted in the viral strains after multiple passaged in HeLa-E8 cells, but these changes made the virus more infectious for these cells and less infectious in primary human cells and was therefore less virulent in humans.

There are animal homologues of CDHR3, but as RVC is solely a human pathogen, genetic differences in this protein mean it is different enough to not function the same as the human CDHR3. Therefore, any genetic changes that occur in the infecting virus would not make them more virulent for animals or plants. To prevent the chance of genetic changes occurring in viral progeny a maximum passage number of 5 will be used when creating viral stocks.

Propagation of GM virus

Infection of the cell lines/ primary cells should not be effected by the virus. These viruses have no DNA intermediates so there is no potential for viral genetic material to integrate into the cells genetic material. All cells lines and primary cells are widely used in the virology field. These cells are unable to colonise workers and contains no adventitious agents. Therefore, the cells do not pose a hazard to human health. If the cells were released into the environment they would not survive as they require media enrichment to survive.

There is the potential for genetic changes to occur in the viral pathogens. This occurs naturally in these viruses which are generally very genetically variable, especially rhinovirus. Infection of these cell lines with virus could lead to the virus adapting to growth in these cell and uncontrolled genetic changes occurring in the virus. Genetic changes have been noted after multiple passaged of the virus in cell lines. However, this often results in better growth of the virus in the cell line used for propagation rather than increased infectivity and growth in primary cells. So, would reduce its infectivity in primary human cells. Infection of primary human cells will only be for infection studies (virus not passaged) reducing the chance of viral mutations occurring that would make them better at growth in human cells. Further the primary AEC donor will never be that of the person growing the cells, preventing the potential for the viruses to develop a tropism for growth in that donors cells, and become more virulent.

The infected cells pose no hazard to the environment. If the cells were released into the environment they would not survive as they require media enrichment to survive. Genetic changes that could occur after multiple passages would not make them more infective for animals or plants as all cell lines are all human derived and viruses solely human pathogens. To reduce the chance of any genetic mutations occurring in the viruses a maximum passage number of 5 will be used to make viral stocks using all cell lines.

Gene transfer
HeLa-E8 cells

CDHR3 is stably integrated into the HeLa-E8 genome and cannot be transferred between this cell line and others. The lentiviral vectors used for gene delivery are self inactivating and replication incompetent, therefore no lentiviral particles would remain in the cells once received from collaborators.

RV has no DNA intermediates during its replication cycle. Therefore, viral genetic material would not be incorporated into the genetic material of these cells. If the cells were released into the environment they would not survive as they require media supplement to survive. The viruses themselves if released into the environment could survive for a short period outside the host.

Propagation of GM virus

These viruses can survive for several hours on hard surfaces, for shorter periods on fabrics. 40% of rhinoviruses are still infectious on hands after an hour. Both viruses have no DNA intermediates during their replication cycle. Therefore, we would not expect viral genetic material to be incorporated into the genetic material of the cells in which the viruses are propagated/ infected. If the cells were released into the environment they would not survive as they require media supplement to survive. The viruses themselves if released into the environment could survive for a short period outside the host, we would not expect the viruses if coming into contact with other
similar viruses to exchange genetic material. There is a small chance if the virus was to infect the same cells of the same type of virus that genetic material could be exchanged. Horizontal gene transfer in this manner does not commonly occur in these types of virus. Further, the majority of the viruses used are wild type and are circulating in the human population, the exception being the fluorescent tagged viruses. The addition of the fluorescent tags to these viruses has not changed the virulence of these strains as shown by similar growth characteristics of the parent strain and would not be more hazardous to humans. These viruses do have the potential if infecting a human to be transferred person to person as this is the natural route of infection of these viruses.

Summary
HeLa-E8 cell line
The constructed cell line poses no threat to human health and the environment, it is not infectious and would be unable to survive if not supplemented with tissue culture media. The cell line contains a gene that is already present in nature. This cell line is solely used for propagation of RV strains and therefore all work will be performed in a class II microbiological safety cabinet (MSCs), therefore risk of release of the cell line or propagating virus is extremely low. Expression of the CDHR3 gene in this cell line does not increase the virulence of viral strains we are infecting them with. No sharps will be involved in the process outlined. Transfer of material outside of the class II microbiological safety cabinets (MSCs) will be in sealed containers.

Propagation of GM virus
The main hazard is release of the GM respiratory viruses and potential for infection of lab members, as these viruses can survive for a short period on inanimate objects outside of the host. The majority of viruses used are not GM and the ones that are tagged with fluorescent markers are not more pathogenic than the WT strain. If infection did occur we would expect this to result in mild cold symptoms as seen in the majority of the human population, as all lab members are healthy adults. If the GM virus infects the same cell of someone already infected with that virus there is potential for viruses to exchange genetic material. However, the majority of the viruses used are wild type and already circulate in nature, bar the fluorescent tagged viruses. The addition of the fluorescent tags to these viruses has not changed the virulence of these viruses.

There is a small chance if the virus was to infect the same cells of the same type of virus that genetic material could be exchanged. Horizontal gene transfer in this manner does not commonly occur in these types of virus. Further, the majority of the viruses used are wild type and are circulating in the human population, the exception being the fluorescent tagged viruses. The addition of the fluorescent tags to these viruses has not changed the virulence of these strains as shown by similar growth characteristics of the parent strain and would not be more hazardous to humans. These viruses do have the potential if infecting a human to be transferred person to person as this is the natural route of infection of these viruses.

Summary
HeLa-E8 cell line
The constructed cell line poses no threat to human health and the environment, it is not infectious and would be unable to survive if not supplemented with tissue culture media. The cell line contains a gene that is already present in nature.
This cell line is solely used for propagation of RV strains and therefore all work will be performed in a class II microbiological safety cabinet (MSCs), therefore risk of release of the cell line or propagating virus is extremely low. Expression of the CDHR3 gene in this cell line does not increase the virulence of viral strains we are infecting them with. No sharps will be involved in the process outlined. Transfer of material outside of the class II microbiological safety cabinets (MSCs) will be in sealed containers. Transfer of material between laboratories will also be done in accordance with the Carriage of Dangerous Goods Regulations if live virus is being transferred. Members working with class 2 agents will be appropriately trained. We have an appropriate disinfection procedure in the event of a spillage/accidental release.

Propagation of GM virus

The main hazard is release of the GM respiratory viruses and potential for infection of lab members, as these viruses can survive for a short period on inanimate objects outside of the host. The majority of viruses used are not GM and the ones that are tagged with fluorescent markers are not more pathogenic than the WT strain. If infection did occur we would expect this to result in mild cold symptoms as seen in the majority of the human population, as all lab members are healthy adults. If the GM virus infects the same cell of someone already infected with that virus there is potential for viruses to exchange genetic material. However, the majority of the viruses used are wild type and already circulate in nature, bar the fluorescent tagged viruses. This gene does not alter viral virulence. There is the possibility of viral strains acquiring genetic changes which could alter their virulence, however this is no more likely than the chance of this occurring in nature. The most likely outcome is the pathogens change to adapt to become less virulent due to their passage in cell lines. Passage of virus will not be performed in primary human cells, these will only be used for infection studies. A limited passage number of 5 will be used when propagating viruses in cell lines. The likelihood of infection is extremely low as all work will be performed in a class 2 microbiology cabinet. No sharps will be involved in the process outlined. Transfer of material outside of the class 2 biosafety cabinet will be in sealed containers. Transfer of material between laboratories will also be done in accordance with the Carriage of Dangerous Goods Regulations if live virus is being transferred. Members working with class 2 agents will be appropriately trained. We have an appropriate disinfection procedure in the event of a spillage/accidental release. If plates/tubes need to be opened at sites other than IITP, this will be performed in a class II microbiological safety cabinet (MSCs).

The viral GM strains pose a negligible hazard to the environment. These viruses are solely human pathogens and are not infectious in animals or plants

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid Waste: Pipettes, culture flasks, centrifuge tubes, filters, syringes, infected cultures on transwells
Solid waste will be autoclaved (126°C for 45mins free steam cycle). All autoclaved waste will be subsequently incinerated.
Degree of kill: 100%

Liquid Waste:
Virus containing medium from viral propagation and viral infection studies and medium from growth of HeLa-E8 cells will be disposed of as below.
Liquid waste will be autoclaved (126°C for 45mins free steam cycle) followed by disposal down a sink with copious amounts of water.
Degree of kill: 100%

Viral infected cultures can also be chemically inactivated using 2% Virkon, mixed 1:1 with liquid waste (final concentration 1%). Waste can be disposed of down the sink after 1h with copious amounts of water. Autoclave disposal will be used preferentially over chemical disinfection.
Degree of kill: 100%

Primary Autoclave: Astell Scientific Autoclave Model AMA250BT65.
Room laboratory 1st floor, Institute in the Park, Alder Hey
Alternative Autoclave: Astell Scientific Autoclave Model AMA340POJ.
Room 0624 Centre for Women's Health Research

Autoclave testing/monitoring procedures:
Both Astell Scientific Models: Annual Thermocouple test and calibration by service engineer.
Committee suggested splitting RA into multiple RA, so class 1 is included in one RA and all class 2 work on a separate RA.

Committee asked to include an extra site so that we have a back up autoclave in the event of a failure of the one in the IITP.

Recommendation to avoid transferring waste/GM cultures between laboratories where possible trial alternative viral purification methods to ultracentrifugation.

Stipulated before undertaking experiments evidence must be provided to show no viral aerosols are created when adding neutrophils to live infective culture during microscopy (see GM RA 2).

Committee agreed with Class 1 designation for RA 1 and Class 2 designation for RA 2 and 3. Lesley Andrews (UoL Biological Safety Advisor) will undertake notification to HSE once relevant forms are completed.

Project Ref 554/20.2

- Date Ackn’d: 17/06/2020
- CU2 Project Title: Understanding patterns and drivers of evolution in microbial communities using labelled strains and targeted knockouts
- Class: Class 2
- CultureVolClass2: 1-50 Litres
- Non-GMM: Consent Granted
- Date Project Ceased: 02/03/2022

Project notified under transitional arrangements: N
Bacterial evolution plays an important role in ecosystem functioning, and has a significant effect on human health and disease, food security, and industrial output. Interactions between species play a key role in determining the trajectory and tempo of evolution. Species interactions can involve competitive and facilitative interactions between organisms, and can also involve horizontal gene transfer. Characterising the interactions between bacteria is a necessary step in understanding the patterns and drivers of microbial evolution. To achieve this, genetic tools are routinely used to track different members of the community, and to generate targeted gene knockouts to assess the causal contribution of different alleles to fitness. Genetic markers are usually resistance genes or encode fluorescent proteins. Generating knockouts also routinely involves the use of selectable resistance markers.

Recipient or parental organism

- The mini-Tn7 system, used extensively in Pseudomonas species (Bao et al. 1991 [Gene 109 (1): 167–68], Choi et al. 2005 [Nature Methods 2 (6): 443–48], Koch et al. 2001 [J. Microbiol. Methods 45 (3): 187–95], Lambertsen et al. 2004 [Env Microbiol. 6 (7): 726–32]) inserts DNA into a single, known, non-coding attTn7 site in the genome. For Pseudomonas aeruginosa, selectable markers and reporters, with or without the lacIq repressor, will be introduced into the delivery vector pUC18T-mini-Tn7 which is unable to reproduce in Pseudomonas. The construct will then be inserted into the recipient Pseudomonas by transformation alongside a helper suicide plasmid pTNS2 which carries the Tn7 transposase genes in trans. Selection for the mini-Tn7 cargo (i.e. lacIq alongside selectable markers) results in the outgrowth of clones which have acquired the mini-Tn7 cassette into the attTn7 site. Candidates will be screened by PCR, targeted sequencing, and phenotypic assays to ensure they are of the expected genotype.
- A homologous recombination method which replaces an allele at a single known genomic site (Court et al. 2002 [Ann. Rev. Gen. 36:361-388]). The replacement allele and ~2 kb of flanking region is cloned into the multiple cloning site of the suicide vector pTS-1, which cannot replicate in Pseudomonas. Selection for the genes carried by pTS-1 results in the outgrowth of merodiploid (single crossover) integrants. Selection against pTS-1 integration using sucrose (pTS-1 encodes SacB which renders carriers sensitive to sucrose) results on double crossovers whereby in some cases the resident allele has been replaced.
- Introduction of the plasmid pRL27 which harbours an active kanamycin resistance Tn5 derivative (Larsen et al. 2002 [Arch. Microbiol. 178.3: 193-201]). Introduction of pRL27 is likely to result in the insertion of the Tn5 derivative into a resident replicon, potentially causing gene disruption.
- Plasmid curing will be achieved by one of two routes. (i) Introduction of the sacB gene into the plasmid by pTS-1-mediated homologous recombination as described above. Selection on sucrose favours strains which have lost the plasmid. (ii) Introduction of the CRISPR-encoding vector pCAS9 derivative pNAW136 (Jiang et al. 2013 [Nat. Biotech. 31 (3): 233-239]). This plasmid encodes the Cas9 nuclease and a locus into which CRISPR spacers can be introduced by PCR. Plasmids can be cured by
introducing anti-plasmid spacers, which cause Cas9 to degrade the plasmid DNA. pNAW136 is unstable due to a low copy number origin of replication (RK2) and thus is quickly lost in the absence of selection.

Candidates will be screened by PCR, targeted sequencing, and phenotypic assays to ensure they are of the expected genotype. Generated strains will be used in growth experiments, including long-term culture, fitness assays, and gene expression assays.

### Origin & function

</tbody>
</table>

Insertion cassettes will express fluorescent proteins under the control of the lac derivative promoter PA1/03/04 or Pτac which are constitutively expressed in Pseudomonas. Where a non-lac-repressible promoter is required the rmB1 promoter or the pLpp promoters will alternatively be used.

Selectable markers are expressed from either their own native promoter, or the Pc promoter.

### Evaluation of foreseeable effects

1. The GMOs will be modified to carry selectable markers and reporter genes, including antibiotic resistance genes and fluorescent protein-encoding genes outlined above. These modifications will modulate specific resistance to particular antimicrobials and other chemicals (outlined above) and cause the modified strains to exhibit particular fluorescence or luminescence properties. The biggest hazard comes from the introduction of antibiotic resistance genes, as accidental release could accelerate the spread of antimicrobial resistance and raise infection risk, particularly for those who are immunocompromised e.g. with cystic fibrosis.

2. The GMOs will be modified to delete endogenous genes, in particular to generate strains that fail to produce metabolites and secretions that mediate cell-cell interactions, and/or virulence factors such as pyocyanin and lasR protease. Many of these and similar knockout mutants generated previously have reduced growth and virulence properties relative to wild-type, so their release would be unlikely to pose any additional hazard.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**Not applicable.**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Not applicable.**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

1. Solid waste, including: agar plates and spent solid culture media; glass media bottles; microtitre plates; liquid handling tips.

Waste is inactivated by autoclaving before disposal. Plastic waste will be placed in sealed boxes and transported to the linked Life Sciences building for autoclaving at...
126°C for 20 minutes.

Contaminated single use pipette tips are placed into dedicated yellow “Bio-Bins” for incineration. These are labelled and sealed before they leave the laboratory. Contaminated plates and single use tubes are disposed of via yellow incineration bags, labelled and sealed with a cable tie. These are transported to the appropriate clinical waste bins outside Life Sciences Building Stores in a clearly marked UN-compliant CL2 transport container.

2. Spent culture media.

Autoclaving is the preferred route for inactivation of GMMs. Cultures will be autoclaved in the Life Sciences building at 126°C for 20 minutes. These autoclaves have a computerised log of all runs, which can be downloaded. The autoclaves are serviced twice a year and validated/calibrated once yearly by Select Engineering Services, 13 Hurst Close, Over Hulton, Bolton BL5 1DT. Inactivated cultures will be poured down the laboratory sink and flushed copiously with water.

Where autoclaving is not possible, Virkon disinfectant will be added to final concentration of 1% w/v and left for at least 8 hours before being poured down the laboratory sink and flushing copiously with water. Virkon is an effective agent for >5-log reduction of Pseudomonas aeruginosa according to the manufacturer's guidelines, which have been supported by in-house tests.

Sample for analytical flow cytometry will be inactivated by fixation with formaldehyde/glutaraldehyde. Each batch of fixative will be validated by spreading samples of fixed cells on solid media and inspecting for growth.

Please enter comments on the GM safety committee on the risk assessment
The IIB/SoLS BSSC met on 30th January and reviewed this GMM CL2 risk assessment. The committee requested the following modifications.

1. This RA is a Class 2 and must be notified to HSE.
2. The university safety officer advised Dr Hall there is a process before this work can be carried out:
   • Jamie to complete an HSE form (JB to email the form to Jamie).
   • Fee approx. £1,000.00
   • Jamie to provide contact details of person who administers the finance.
   • Only when Jamie receives an acknowledgement receipt, and payment (preferably by BACS) has been cleared can the work be carried out.
3. Section 2.1 Hazard Group 2 needs to be stated.
4. Section 2.1 Clinical plasmids needs more detail.
5. Section 2.2. Queried does this increase organism’s virulence? Advised that detail in this section should state “does not make more virulent”.
6. Section 3 Need to state which antibiotics are effective treatments.
7. Section 3.1.1 Need to state no anticipated additional risk as mentioned in previous section.
8. Section 4.3 Scale of activity needs to state frequency, volume, and quantity.
9. Section 4.4 “Solid Waste” should state Bio bins are dedicated for contaminated single use pipette tips.
10. Section 4.4.1 - Need to state Autoclave cycle.
11. Section 4.4.2 - The Virkon link appears to be broken.
12. Section 4.6.1 – Warning signs to be also put on main doors.

Project Ref 554/21.1
The aim of this project is to test the protective properties of select recombinant parasite proteins when used to vaccinate against African trypanosomes (Trypanosoma vivax) in mouse models. We will vaccinate mice with multiple recombinant antigens and challenge vaccinated and control mice via subcutaneous injection of trypanosomes. We will compare patent infections in vaccinated and control mice after needle challenge to quantify the protective effect of vaccination by measuring parasitaemia with a bioluminescent assay that detects parasites anywhere within the host animal. A positive result will be complete protection against infection in vaccinated mice, that is, no pathology and no observable parasites in bioluminescent screens. The outcome of the project will be such assessment of metacyclic-stage proteins discovered by our labs in previous work. Positive demonstration of protection will lead to clinical trials of the vaccine candidate in livestock.

Trypanosoma vivax strain Y486 is a unicellular eukaryotic flagellate. It is a potent pathogen of livestock, capable of inducing life-threatening, acute infections and thereafter cyclical, chronic infections that may cause death in animals that do not self-cure. The organism requires inoculation by blood-feeding flies (Glossina spp.) to effect transmission in the natural system. The organism is incapable of infecting humans and its natural insect vector is not found outside of Africa. T. vivax is a SAPO2 organism and therefore requires containment level 2 (License SAPO/554/2016/1a).

Trypanosoma vivax strain Y486 is genetically modified to introduce specific reporter genes that will facilitate parasite imaging in the mouse. These reporter genes, which naturally provide either fluorescence or bioluminescence to many organisms, include the green fluorescent protein mNeonGreen, the red fluorescent protein mCherry, and the bioluminescence-generating firefly luciferase. Reporter genes are accompanied by selection marker genes used for the selection of trypanosomes which have acquired the reporter genes (selection drugs not used in the mouse). These genes, which naturally confer on to bacteria resistance to specific antibiotics, include hyg, neo, pac and bsr. All transgenic inserts will contain the bla gene which is used for the selection of bacteria during the molecular cloning phase of the transgene creation (not used when in mice).
The mNeonGreen gene is an engineered version (21 coding substitutions) of the Branchiostoma lanceolatum green fluorescent protein LanYFP.
The mCherry gene derives from the DsRed fluorescent protein found in Discosoma spp.
The luciferase gene is found in the Renilla spp. firefly.
The hyg gene (kinase from Streptomyces hygroscopicus), confers resistance to hygromycin B through phosphorylation.
The neo gene (aminoglycoside phosphotransferase from Streptomyces fradiae), confers resistance to neomycin.
The pac gene (puromycin N-acetyltransferase from Streptomyces alboniger), confers resistance to puromycin.
The bsr gene (deaminase from Aspergillus terreus), confers resistance to blasticidin resistance gene.
The bla gene (beta-lactamase from Escherichia coli), confers resistance to ampicillin.

Evaluation of foreseeable effects

Both reporter and drug selection genes (described above) can be considered inert markers, and there is no evidence to suggest any harmful effects. Fluorescent proteins and luciferases have been extensively used in molecular and cellular biology to make whole cells fluoresce, including pathogenic parasites such as trypanosomes, and are known to have no effects in cell physiology and virulence.
Drug selection markers (hyg, neo, pac, bsr, bla) have also been broadly used in multiple organisms to positively select for genetically modified individuals. Drug selection is only carried out in vitro so the selection drugs will not be administered to infected mice. The presence of these resistance markers in trypanosomes does not pose and additional risk since these drugs are not treated for trypanosomiasis in the host.
We will be inoculating mice with infected blood, either from frozen stabilate or existing infections. Bloodstream forms of the parasite are susceptible to most disinfectants and are unlikely to survive or persist more than a few minutes if accidentally spilt. The greatest risk to livestock is the accidental release of an infected mouse, which is subsequently bitten by a blood-feeding fly that also feeds on livestock. There is no risk to human health. Prophylactic chemotherapy is available for animals following known exposures.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Infecctivity of trypanosome cells is lost following exposure to most disinfectants and to heat.
Solid waste will be autoclaved (discard cycle - 126 degrees for 30 minutes), followed by incineration by an external contractor. Transport to autoclave is in autoclave bags contained within plastic, lidded bins.
Liquid waste will be autoclaved (discard cycle - 126 degrees for 30 mins). Transport to autoclave is in bottles sealed with a screw cap and placed within plastic bins.
The autoclave undergoes annual service and thermocouple validation by a priorclave engineer. Prints of runs are available. In the event of autoclave failure, chemical disinfection may be used. The ability of 2% virkon to inactivate parasites has been validated in-house.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
Assessment circulated in 4th March 2020
Committee met on 28th October 2020
The committee was content to approve the proposed work dependent upon satisfactory clarification of the following points:
• Section 1.1 room numbers/space refs and specific contained use activities must be explicitly stated - Completed
• Section 3.1 state these are SAPO 2 organisms- as this is why it’s class 2 - Stated, with licence number
• 3.1b can the GMM RA for bacterial cloning be cross referenced - RA provided and cross-referenced
• 3.2a I would add that these parasites are not found in UK livestock - Statement added.
• 3.2.1 what if an infected mouse escaped? - Careful consideration of the risk and impact added.
• 4.1 flow cytometry- is this the first mention? Where is this done? Need a proper Sop/diagram for the packaging and transport - Need for flow cytometry removed.
• What about the containment and control measures in the BSU and CPI? Remember need to comply with containment measures in Table 1c (GMMs used in animal facility) of regs in addition to Table 1 for lab containment measures. - Details of animal containment measures added.
• 4.4, Is some waste --cadavers?-- to be taken to BSU? - Waste disposal routes clarified and justified in the GMM; SOP for transport added.
• 4.4.1 virkon treatment- but not for cadavers- what if BSU autoclave broke down? - Contingency for broken autoclave stated.

Project notified under transitional arrangements N
Our research group focuses on the understanding of the pathogenesis of human pathogens from ADCP category 2 with an emphasis on anti-microbial resistance mechanisms. This work will focus on genetically manipulating a "wild-type" A. baumannii strain (ATCC17978) to introduce/knockout resistance genes, with the aim of creating model pathogens with distinctly defined resistance genotypes/phenotypes.

What follows is an overview of the GM activities pertaining to this programme of work, the technologies are similar and include a hybrid CRISPR/Cas9 and recombinase approach.

Activity 1: Generation of mutations and insertion of genes that encode for resistance factors in A. baumannii and determination of the effect of these mutations on resistance to anti-microbials.

The genes inserted and/or mutated will encode for common class of anti-microbial resistance genes including:

- **β-lactamases:**
  - Class 1: TEM, SHV, CTX-M-15, VEB-3, ACD-30
  - Class 2: IMP-1, VIM-1, NDM-1
  - Class 3: Oxa-23, Oxa-40, Oxa-51, Oxa-58, Oxa-66, Oxa-72

- **Aminoglycosides:**
  - ArmA, AAC(3)-IIa, ANT(2")-Ia, ANT(3")-Ia, APH(3")-Ia, APH(3")-Vla

- **Ade Family:** AdeR D20N, AdeR A91V, AdeR P116L, AdeR E219A, AdeR G30D, AdeR R152K, AdeR T153M

- **Tetracycline resistance:**
  - TetA, TetB, TetM

- **Fluoroquinolone resistance:**
  - gyrA: S83L, D87N, E84K
  - ParC: G78C, S80R/L/W

Activity 2: Using CRISPR-Cas9 "base-editing" to knock-out resistance genes in A. baumannii. This activity will utilise a Cas9-fused "base editor" to introduce premature stop codons into certain A. baumannii genes effectively knocking out protein expression. Guide RNAs targeting early glutamate residues (CAG and CAA) in the genes below will result in gene disruption.

- **LpxCAD operon:** LpxA, LpxC, LpxD
- **PmrAB:** PmrA, PmrB,
- **Ade family:** AdeA, AdeB, AdeG, AdeH, AdeJ, AdeK, AdeL, AdeN, AdeS
- **Omp family:** OmpA, OmpD, Omp25, Omp33
- **Porins:** CarO

Work carried out in activities 1 and 2 pertains to the handling and mutagenesis of A. baumannii. Synthesis of the tools to enable this is contained in a separate Class I activity that has been passed by the Departmental GM committee at Liverpool.
2. Acinetobacter baumannii (ATTC17978)

**Host/vector system**

**Activity 1:**
The following plasmids will be used for modification of A. baumannii:
1. **pCasAb-apr_121998**
   - Ampicillin resistance cassette, S. pyogenes Cas9, A. baumannii RecAb recombinase system.
   - Contains the broad-host range plasmid RSF1010 replication of origin (allows replication in E. coli and A. baumannii).
2. **pSGAb-km_121999**
   - Contains WH1266 and ColE1/pUC replication origin (replication in A. baumannii and E. coli respectively). SacB counter-selection marker, Kanamycin resistance cassette and an S. pyogenes guide RNA cassette.
3. **pSGAb-spe_122000**
   - Contains WH1266 and ColE1/pUC replication origin (replication in A. and E. coli respectively). SacB counter-selection marker, Spectinomycin resistance cassette and an S. pyogenes guide RNA cassette.
   - In addition a DNA template containing the gene to be inserted flanked by regions of homology to the A. baumannii genome to facilitate homology-dependent repair.
4. **pAB1 expression plasmid based on the pSGAb-km plasmid backbone**
   - generated from pSGAb-km following KpnI and XbaI digestion and polylinker insertion.
   - Contains WH1266 and ColE1/pUC replication origin (replication in A. baumannii and E. coli respectively). Kanamycin resistance cassette and polylinker.
5. **pAB2 expression plasmid based on the pSGAb-spe plasmid backbone**
   - generated from pSGAb-spe following KpnI and XbaI digestion and polylinker insertion.
   - Contains WH1266 and ColE1/pUC replication origin (replication in A. baumannii and E. coli respectively). Spectinomycin resistance cassette and polylinker.

**Activity 2:**
1. **pBECAB-apr_122001**
   - Contains WH1266 and ColE1/pUC replication origins (replication in A. baumannii and E. coli respectively). Ampicillin resistance cassette for selection in E. coli, S. pyrogenes nCas9 (D10A) fused to Apobec-1 (cytosine deaminase), SacB counter-selection marker and a S. pyogenes guide RNA cassette.
   - The vectors are low copy and contain common selective markers. The Cas9 protein and base-editor are under a control of a lac operon which is only active following derepression with IPTG (pAB2 expression plasmid based on the pSGAb-spe plasmid backbone generated from pSGAb-spe following KpnI and XbaI digestion and polylinker insertion contains WH1266 and ColE1/pUC replication origin (replication in A. baumannii and E. coli respectively). Spectinomycin resistance cassette and polylinker.) an alolactose mimic which activates transcription from the lac operon, so no editing will occur in the absence of IPTG. The plasmids also contain a sacB counterselection marker for “curing” the plasmids following editing. The sacB gene encodes a levansucrae which when transformed bacteria are cultured in the presence of sucrose produces the cytotoxic metabolite levan effectively selecting for clones that have lost the editing plasmids.

**Origin & function**

All inserted genetic materials will be derived synthetically then cloned using standard molecular biology approaches.

**Activity 1:**
- **β-lactamases:**
  - Resistance to beta-lactam antibiotics is primarily through expression of β-lactamases which hydrolyse β-lactam rings resulting in inactivation of β-lactam antibiotics. There are several beta-lactamases associated with resistant A. baumannii strains.
  - **Class 1:** TEM, SHV, CTX-M-15, VEB-3, ACD-30
  - **Class 2:** IMP-1, VIM-1, NDM-1
  - **Class 3:** Oxa-23, Oxa-40, Oxa-51, Oxa-58, Oxa-66, Oxa-72
  - Strains expressing these proteins will retain sensitivity to aminoglycosides, tetracyclines, fluoroquinolones, and colistins.
  - Amino glycoside resistance:
    - ArmA, AAC(3)-Ila, ANT(2’)-Ia, ANT(3’)-Ia, APH(3’’)-Ia, APH(3’’)-Vla
  - Ade Family:
Strains expressing mutations in these proteins will retain sensitivity to beta-lactams, tetracyclines, fluoroquinolones and colistins.

Tetracycline resistance:
TetA, TetB, TetM
Strains expressing these proteins will retain sensitivity to β-lactams, aminoglycosides, fluoroquinolones, and colistins.

Fluoroquinolone resistance:
Mutations in the DNA gyrase subunit A (GyrA) and the topoisomerase IV subunit C (ParC) have been identified in clinical isolates and are associated with resistance to fluoroquinolones.
GyrA: S83L, D87N, E84K
ParC: G78C, S80R/L/W
Strains containing these mutations will retain sensitivity to β-lactams, aminoglycosides, tetracyclines and colistins.

Activity 2:
Guide RNA targeting early glutamines (CGA, CAA) in the following genes will be targeted to introduce premature STOP codons (conversion to TGA, TAA).
LpxCAD operon: LpxA, LpxC, LpxD
PmrAB: PmrA, PmrB,
Omp family: OmpA, OmpD, Omp25, Omp33
Porins: CarO

Evaluation of foreseeable effects

The vectors are low copy and contain common selective markers. The Cas9 protein and base-editor are under a control of a lac operon which is only active following derepression with IPTG (Isopropyl beta-D-1-thiogalactopyranoside) an alolactose mimic which activates transcription from the lac operon, so no editing will occur in the absence of IPTG. The plasmids also contain a sacB counterselection marker for "curing" the plasmids following editing. The sacB gene encodes a levansucrase which when transformed bacteria are cultured in the presence of sucrose produces the cytotoxic metabolite levan effectively selecting for clones that have lost the editing plasmids.

Risk to Humans:
Yes, but as an opportunistic pathogen, infection is nosocomial and then, only causing symptoms in immunocompromised individuals, after surgery, or those with complex comorbidities. There is a possibility of hazard to employees. Immunocompromised individuals are at a greater risk of infection and therefore should not be handling this organism. Employees should be trained in handling HG 2 pathogens and established disinfection protocols before work starts.

Risk of community spread is unlikely. It will be handled in a laboratory that deals with other HG 2 organisms and has comprehensive disinfection and waste management protocols in place. Staff are trained in handling such pathogens and new employees receive extensive training before any work starts. Laboratory access is also restricted to trained individuals.

There are many clinical options for treatment. Patients would be monitored and only treated if symptoms develop. The treatment strategy is then empiric and guided by the anti-biogram. So there is no one strategy, but many options which would depend on the anti-biogram.

Exposure to humans of A. baumani and the modified strains could occur in the event of breach of containment through aerosols or spillage. Risk of aerosol transmission will be minimised by the use of a Class 2 biological safety cabinet. There is no risk of A. baumannii infection from aerosols in a healthy, non-immunocompromised individual. Anti-biograms will be performed on the modified strains and clinical options will be available, if required.

None of the genes we intend to modify are recognised virulence genes so modified strains will not pose a greater risk of infection than the wild-type strain (ATCC17978).

Risk to the Environment:
The genes are genomically encoded and not within any mobilizable genomic element so the risk of horizontal transfer is low.
The Class 2 laboratory in which this work will be carried out, personnel regularly work with hazard group 2 micro-organisms and their AMR variants procedures are in place for containment which are covered by a specific Group 2 organisms General Risk Assessment.

Protocols include:
Restricting laboratory access to authorized individuals
Risk assessment-specified disinfection procedures.
Safe storage for organisms and cell lines.
Laboratory procedures which give rise to infectious aerosols are conducted in a microbiological safety cabinet. Bench surfaces are decontaminated at the end of the day and following a spillage. Protocols have been in place for many years regarding waste management and disinfection protocols to mitigate against environmental transmission. Risk of community spread is unlikely. It will be handled in a laboratory that deals with HG 2 organisms and has comprehensive disinfection and waste management protocols in place. Staff are trained in handling such pathogens and new employees receive extensive training before any work starts. Laboratory access is also restricted to trained individuals.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

E. coli:
For preparation of plasmid DNA and basic cloning/manipulation, bacteria will be collected by centrifugation and lysed according to the plasmid purification kit instructions. Liquid waste will be disinfected using Virkon (1%) prior to sink disposal.

NEB Stable E. coli (recA1): From NEB MSDS: Biological Safety Level One (BSL-1) containment, using standard microbiological practices, is suitable for work involving well-characterized microbiological organisms not known to consistently cause disease in immunocompetent adult humans, and present minimal potential hazard to laboratory personnel and the environment. Centers for Disease Control and Prevention (CDC) Guidelines (Biosafety in Microbiological and Biomedical Laboratories, 5th Edition).

A. baumannii:
Virkon is a broad spectrum disinfectant, which when used at a concentration of 1% has been shown to cause a 5-log reduction in A. baumannii counts. It has also been demonstrated to have activity against MDR A. baumannii and has been used to control outbreaks in healthcare settings. Doidge M, Allworth AM, Woods M, Marshall P, Terry M, O'Brien K, Goh HM, George N, Nimmo GR, Schembri MA, Lipman J, Paterson DL. Control of an outbreak of carbapenem-resistant Acinetobacter baumannii in Australia after introduction of environmental cleaning with a commercial oxidizing disinfectant. Infect Control Hosp Epidemiol. 2010 Apr;31(4):418-20. doi: 10.1086/651312. PMID: 20175684.

Monitoring:
The laboratory in which this work will be carried out already handles several hazard group 2 MDR organisms and has already specific containment and disinfection procedures in place. Agar plates with bacterial cultures will be autoclaved (121°C for at least 60 min) prior to disposal and incineration. Tubes contaminated with bacterial medium will be autoclaved (121°C for at least 60min) prior to disposal and incineration. For larger spills contaminated tissue paper will be transferred to a biohazard bag and autoclaved. Smaller spills will be wiped with 1% Virkon solution followed by 70% Ethanol and contaminated wipes disposed as solid waste in biohazard bags (autoclaving cannot be used when using Virkon). Autoclaving will be the preferred method of decontamination of solid waste but in the event disinfection is required vessels will be completely immersed in 1% Virkon overnight (according to the Manufacturer's instructions).

Inspections:
Safety inspectors are carried out annually to ensure Local Rules are adhered to and that risk assessments and training records are up to date. Reports are kept by the Health and Safety Coordinator.

Biological Safety Cabinets:
Cabinets are tested every 6 months with and annual KI test. Certificates of conformity are displayed on each cabinet and copies kept by the Health and Safety Coordinator.
A. baumannii is currently unclassified and therefore not listed on the HSE’s approved list of biological agents (ACDP), although it is listed on the PHE website as a Class 2 pathogen. A justification was therefore written for the Biological Safety Officer who agreed to locally classify it as Class 2.

Regarding comments of the local GM safety committee:

Activity 1: Recombinase-Aided CRISPR-Cas9 Insertion of Resistance Genes into Acinetobacter baumannii

Researchers applying for local classification as Hazard group 2 because unclassified in ACDP.

Risk assessment received 03/09/2021
Circulated to Committee 11/09/2021
Discussed at committee meeting 16/09/2021 with researcher

“Recombinase-Aided CRISPR-Cas9 Insertion of Resistance Genes into Acinetobacter baumannii” was discussed. The committee requested the following amendments:

- Please address comments from above consistent with all 3 GMRAs
- In Section 4.6.1, remove section on “severe burns”

Pending amendments the proposal was formally approved as Class 2 and will be submitted for HSE approval by UBSA
- In Section 1.1, revise start and end dates
- In Section 2.2, indicate the most hazardous GMM to be constructed
- In Section 4.3, provide more detail regarding the scale of activity
- In Section 4.4, replace bacterial with bacteriocidal
- In Section 4.4.1, remove reference to liquid waste transportation
- In Section 4.4.1, correct references to ITM

Activity 2: Inactivation/Mutation of antimicrobial resistance genes using Base-Editing in Acinetobacter baumannii

“Inactivation/Mutation of antimicrobial resistance genes using Base-Editing in Acinetobacter baumannii” was discussed. A baumanii is currently unclassified in ACDP and the research group is seeking approval from HSE to classify the bacteria locally as hazard group 2. The committee requested the following amendments:

- Please address comments from above consistent with all 3 GMRAs
- Add a table of abbreviations
- Indicate / acknowledge that the plasmids are transmissible
- In Section 4.4, rewrite section on inactivation including amend/correct “hood surface”, remove mention of liquid waste in solid waste section (Section 4.4.1), remove wording of “out of my control” (Section 4.4.1)
- In Section 4.4.2, provide information and not just a link
- Move information from Section 4.5.3 to Section 4.6
- In Section 4.6, provide details

Pending amendments the proposal was formally approved as Class 2 and will be submitted for HSE approval by UBSA

02/03/2022
Our project aims to understand how the immune systems of calves respond to Cryptosporidium parvum infections. C. parvum is a parasite that infects the gastrointestinal tract of many animals. In cattle, infection is most pronounced in very young calves of less than six weeks old, where it often results in diarrhoea. C. parvum negatively impacts both the animals' welfare and productivity by compromising gut function during infection and longer-term.

We are interested in using B-cells isolated from C. parvum-infected calves to produce anti-Cryptosporidial monoclonal antibodies. It has been demonstrated that the co-expression of human B-cell lymphoma 6 (BCL-6) and human B-cell lymphoma extra-large (BCL-XL) causes the immortalisation of B-cells. The immortalisation of B-cells using this method allows for the continuous production of monoclonal antibodies. The continuous supply will in turn allow us to assess the neutralising effects the antibodies could have on C. parvum. We hypothesise that supplementing milk replacer with antibodies against C. parvum will enable farmers to protect their calves from this parasitic infection, particularly where natural passive transfer has failed.

We will transfect pMIEG3-BCL6 and pMIG-BCL-XL plasmids into HEK293T cells (a Human Embryo Kidney epithelial-derived cell line), along with human immunodeficiency virus (HIV) or murine leukaemia virus (MLV) gag/pol, and VSVG packaging vectors to produce pseudoviruses that are capable of delivering the human BCL-6 and human BCL-XL genes. We also propose to use reporter genes (luciferase and/or GFP) as controls for the production of the pseudovirus. We will use both MLV derived vectors as well as the 2nd Generation HIV packaging / reporter vectors in order to maximise the prospect of successfully immortalising primary bovine B-cells.
Recipient of the plasmids is a common laboratory authenticated commercial mammalian cell line Human Embryo Kidney (HEK)293T cells, purchased from ECCAC. Primary B cells from calves with Cryptosporidium parvum infection

Pseudotypes containing either BCL-6 or BCL-XL will be produced from HEK293T cells after they have been transfected with a packaging vector (murine leukaemia virus, MLV; MLV-CMVpr-gag-pol [aka pHCMV5349] OR a 2nd Generation HIV self-inactivating plasmid pCMV D R8.91 OR psPax2) AND pMD2.G VSVG

Origin & function

The pseudotypes will deliver BCL-6 and BCL-XL to isolated bovine B cells to immortalise them. Onward transmission of the oncogenes is not possible as it is delivered by a single round infectious pseudovirus. The pseudovirus is a potential hazard to humans, as it could deliver the oncogenes through direct contact with skin.

Evaluation of foreseeable effects

There is a potential risk to human health in the event that there is a containment breach however as long as the general laboratory safety procedures and control measures stated in the risk assessment are followed there is no greater risk to human health than that of any other hazard group 2 pathogen. BCL-6 and BCL-XL are considered oncogenes as they lead to cell immortalization when expressed together. The viral pseudotype produced after transfection of HEK 293T cells can potentially be transmitted to workers through direct contact with skin and also with the mucosa e.g., through a percutaneous injury or a splash in the eye. This direct contact between the workers cells and the pseudovirus will lead to cell immortalisation (cell will become cancerous) through the forced expression of oncogenes. Therefore, long gloves will be worn as an extra precaution to ensure there is no uncovered skin while experiments are carried. All experiments will also be performed inside an ACDP Category/Class II Microbiological safety cabinet which will again help to mitigate the risk of contact between the pseudovirus and worker. However, given that the pseudovirus is replication-defective, it cannot propagate in humans and therefore will not cause further damage.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

For both bacterial and tissue culture work, the solid waste produced will be autoclaved at a minimum temperature of 126°C (load temp) for 50 minutes before being destroyed as clinical waste. Bacterial liquid waste will be treated with an equal volume of 2% Virkon* and left overnight before disposal down the drain with copious water. Cell culture liquid waste from tissue culture experiments will be collected in reinforced glass bottles (as per standard practice in IC2) and then autoclaved at a minimum temperature of 126°C (load temp) for 50 minutes before being destroyed as clinical waste. In the event that the autoclave in IC2 breaks, solid and liquid waste from pseudovirus experiments and also solid waste from bacterial work will be decontaminated using 2% Virkon and left overnight. The waste is then rinsed and disposed of in yellow clinical waste bags to be incinerated. Autoclaves in IC2 Building are operated by trained laboratory staff. A chart record is produced for each decontamination run to confirm, by means of a temperature probe placed within the load, attainment of suitable temperatures for 100% kill of viable organisms. Validation of autoclave cycles is maintained by 6-monthly servicing and yearly thermocouple testing carried out by an external engineer. *2% Virkon is a well characterized disinfectant known to completely inactivate many viruses including HIV-1 virus and poxviruses, which are much "hardier" than the pseudotypes being produced.

**Project Additional Information**

02/03/2022
**Purposes of the contained use**

This research is to be notified as a connected programme of work utilising transfection of cDNAs into human cell-lines in order to induce expression of said gene products under the control of known promoters provided by plasmid vectors. It contributes to the research goal of understanding the contribution of genes to hormone signalling pathways, especially in relation to breast cancer.

**Recipient or parental organism**

Recipients are established human cell lines (eg breast cancer cell lines) and an immortalised normal breast epithelial cell line hTERT-HME1. Epithelial tumour cells can cause tumours when injected subcutaneously in immuno-compromised mice. However, the potential for harm is much less in immuno-competent humans, where the primary potential for harm comes from possible adventitious pathogens (viruses). Cell lines are expected to have limited survivability in the environment and modifications are not expected to increase their pathogenicity.

**Host/vector system**

The plasmid vectors are mobilisation deficient, devoid of significant known toxic or pathogenic potential and would be classified as class 1 were it not for their use in mammalian cell-lines. The design of the RheoSwitch Mammalian Inducible Expression System is such that the insert DNA is only expressed in the presence of RSL1 ligand, which is a synthetic non-steroidal compound and therefore extremely unlikely to be found in the environment. Any other vectors will be limited to similarly well characterised plasmids.

**Origin & function**

The primary inserts will be full length cDNAs encoding estrogen receptors Eralpha and Erbeta, derived from human normal or tumour tissues or cell line material. In addition cDNAs resulting from alternative splicing of the ER mRNA (for both Eralpha and Erbeta) will also be used. The cDNAs resulting from alternative splicing of the ER mRNA (for both Eralpha and Erbeta) will also be used. The cDNAs to be used are unlikely to include a toxic or pathogenic determinant although due to the unknown nature of the estrogen receptor variants, the deletion variants may have a deleterious effects on the recipient cell line.

Alternative gene products (eg X-box binding protein 1) will be limited to those unlikely to increase the toxic or pathogenic potential for harm, even when constitutively expressed or modified by addition of reporter proteins. Most inserts will be transcription factors, or genes known to modulate transcription (eg co-activators of co-repressors).

Some inserts may have been previously mutated by site-directed mutagenesis to pinpoint specific residues/amino acids involved in protein function. It is envisaged that insert modification (eg fluorescent labelling or tagging) is more likely be detrimental to gene function than enhance any latent pathogenicity or toxicity.

Initial expression of the insert DNA will be induced only by addition of RSL1 synthetic ligand (requiring additional transfection with plasmid pNEBR-R1), subsequently a strong constitutive promotor may be used (eg CMV). Plasmid vectors additionally contain selective markers (eg G418 resistance).

**Evaluation of foreseeable effects**

Recipients are established human cell lines eg breast cancer cell lines: KPL-1, MCF7, ZR75, MDA-MB-231 and an immortalised normal breast epithelial cell line hTERT-HME1. These cell lines are biological agents for which containment level 2 is appropriate, owing largely to the fact that they are long-term cultures of human origin and are not fully characterised. The primary potential for harm comes from possible adventitious pathogens (viruses). Cell lines are expected to have limited survivability in the environment.

The primary inserts will be full length cDNAs encoding estrogen receptors (ER), cDNAs resulting from alternative splicing of the ER mRNA or alternative gene products, largely constituting related transcription factors. The cDNAs to be used are unlikely to include a toxic or pathogenic determinant although due to the unknown nature of the estrogen receptor variants, the deletion variants may have a deleterious effects on the growth properties of the recipient cell lines. Most insert DNA is naturally occurring in these cell lines, the experiments will merely control the level of expression of individual variants.

The plasmid vectors when used are mobilisation deficient, devoid of significant known toxic or pathogenic potential and would be classified as class 1 were it not for their
use in mammalian cell-lines. All sequences cloned will be of mammalian origin and unlikely to contain promoters active in non-mammalian organisms. Expression in mammalian cells is controlled by previously validated promoter elements (very strictly inducible in the case of the Rheoswitch system) and is unlikely to be observed outside of a controlled laboratory environment. Potential for transfer to and gene expression in other organisms is negligible and therefore negligible hazard to human health. Vectors are unlikely to alter pathogenic traits of the host.

There is little potential for alteration of pathogenic traits and no obvious significant increase on the hazards of the non-transfected cell lines.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

- This work involves standard laboratory protocols, and there are no unusual procedures that require additional containment measures. Standards of work and containment are specified in the CCRT Code of Practice, with reference to the governing regulations and guidelines. All personnel should be familiar with the relevant safety documentation and have received training specifically for the use of GMM.
- Both unmodified and GM modified cells will be grown in small scale closed containers in a category 2 containment area. A class II safety cabinet will be used for all manipulations and both sharps glass containers will be avoided. As specified in the governing code of practice for biological agents.
- Solid waste will be bagged, sterilised by autoclaving and later incinerated as clinical waste. Liquid waste in disposable culture flasks will be sterilised by autoclaving and incinerated as clinical waste. Other liquid waste will be sterilised by autoclaving and disposed of via the drains. The autoclave is situated within the laboratory suite and is managed by Wirral NHS Trust engineers. A programme of testing and quality assurance is carried out on a quarterly and annual basis and records kept.
- It is appropriate for all manipulations to be undertaken within the specified GM area in a laboratory where access is restricted to authorised personnel only. Regular safety checks are performed by safety officers and matters arising reported to safety committees; safety records will be kept.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

**Please enter comments on the GM safety committee on the risk assessment**

The CCRT GM safety committee is satisfied that the risk assessment is suitable for the purpose stated, providing suitable records are kept and any significant variation notified.

The assessment has been reviewed by the University Biological Safety Adviser who made a number of suggestions regarding the scope of the work, in particular that the work should be notified as connected programme, given the number of different phases that are proposed. These suggestions were incorporated in the final assessment.

**Project Containment**
Project Additional Information

**Purposes of the contained use**

To study the role of the p53 pathway in cancer. Genes such as MDM2 have been implicated as critical molecules in this pathway and to study this we need to be able to efficiently deliver these genes (also non-oncogenic genes such as p53, MTBP, E-MTBP and Lac-Z will be expressed from similar viruses) to a range of cell types - particularly had to transfect cells such as mouse embryo fibroblasts (MEFs) and a range of pancreatic cancer derived cell lines.

**Recipient or parental organism**

E. coli XL-Blue are a K12 derivative strain and are not expected to survive outside of the laboratory. There is no evidence that these bacteria are pathogenic. 293T, MEFs and other cell lines would not be able to survive outside of the laboratory environment. Retroviral vectors have generally been designated as ACGM category 1 except where the gene to be inserted is pathogenic or where the envelope is human tropic. We propose to create replication defective retroviruses with either rodent or human tropic envelopes. Retroviral vectors with these modifications are ACGM2.
Host/vector system

The three-plasmid system would require at least 2 recombination events to produce a single fragment of DNA that could encode replication competent retrovirus (RCR). Since there is little or no homology between the three plasmids a single recombination event is unlikely.

Origin & function

MDM2 (for example) is known to be an oncogenic protein. Retroviruses are also inherently potentially oncogenic because they are obligate mutagens: when the provirus is integrated into the host genome, it may at random be integrated into a site that causes inactivation of a tumour suppression gene. MTBP, E-MTBP and p53 induce cell cycle arrest (Boyd et al., JBC 2000). We will be inserting wild-type p53. As yet the roles of MTBP and E-MTBP, a deletion mutant of MTBP, are not completely known, although it has been demonstrated that MTBP causes G1 arrest and E-MTBP inhibits tumour cell growth more effectively in the cell lines tested than either MTBP or p53. Retroviruses are obligate mutagens: when the provirus is integrated into the host genome this might occur at random into, for example, a tumour suppression gene.

Evaluation of foreseeable effects

Bacterial transformation - the transformed strain will be no more virulent or pathogenic than the original.

The three plasmid system used should ensure that the virus is not mobilisable.

We expect moderately high levels of expression of the transduced genes driven by the MDMV LTR.

These replication defective viruses could infect human cells.

Retroviral production - a VSV-G envelope will be used to improve infectivity of the virus but only to produce replication defective viruses containing a non-oncogenic insert. We will test supernatants for evidence of RCR by infecting permissive cells with viral supernatant and then passing cells. Supernatant from these cells will be screened at weekly intervals by re-inoculating these at \( \geq 1/10 \) dilution onto permissive cells. MDM2 can readily be detected by western blot. By inoculating double null (MDM2/p53 null) MEFs we can readily detect even very low levels of MDM2.

MTBP and E-MTBP can readily be detected by western blot. By inoculating p53 null cells (H1299) p53 can also be detected by western blot. Lac-Z can be screened by in-situ Beta Gal assay.

Retroviral production - we will use either an ecotropic or a VSV-G envelope. These do not by themselves increase the pathogenic traits of the retrovirus although the VSV-G envelope which will be used to improve infectivity of the virus (it is monomeric and therefore higher tires of more stable virus can be produced c.f. eco/ampho-tropic retroviral envelopes) does alter the virus host range to include humans and other mammals.

The retroviral vector will also contain the neomycin gene, which will result in resistance to G418. This would not be used as a treatment for laboratory-acquired infection.

The major alteration affecting likely harm will be the inclusion of a known oncogene (eg MDM2) into the retrovirus. This will create the risk of transfer of an oncogene into mammalian in particular human cells.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

After bacterial transformation, flasks will be decontaminated by the addition of fresh 10% bleach.

During retroviral production, once the producer cells have been transfected with the 3 plasmid components they will be considered potentially infectious. BSL2 precautions will be required. Experiments will take place in a laminar flow hood with the operator wearing a disposable surgical gown (near opening) with snug fitting surgical latex gloves worn over the elasticated wrists of the gown. Care will be taken so as not to produce aerosolisation of viral containing supernatants. Items of equipment exposed to virus will be soaked in 1% Virkon or 1% sodium hypochlorite or 10% bleach for 15 mins before removal from the laminar flow hood and then disposed of in the usual manner: ie all solid waste will be incinerated and all inactivated liquid waste will be disposed of down the sink. Once cells are no longer required for producing virus, they will be destroyed by adding fresh 10% bleach and leaving for 24 hours before disposal as liquid or solid waste whichever is most appropriate. All solid waste will be transferred to yellow clinical waste bins and sent to the RLBHU for incineration.
The GMSC considered the risk assessment and decided that the use of potentially oncogenic inserts means that this project is Class 2. The GMSC were content that the workers involved were aware of the risks and were technically capable of working at Class 2 level. The laboratories to be used are adequate for this work. As an additional observation it was noted that Class 1 work would take place alongside this Class 2 project. The GMSC requested that all work to be carried out in the laboratories alongside this class 2 activity should be carried out to CL2 standards.

## Project Additional Information

### Purposes of the contained use

To study the effect of mutations encoding antiretroviral resistance upon replicative function and drug susceptibility

### Recipient or parental organism

#### Introduction

Wild type HIV-1 (wt HIV-1): Wild type HIV-1 describes infectious HIV-1 viruses that do not exhibit resistance to therapeutic drugs and lack the according resistance mutations. These are produced by eukaryotic cells transfected with plasmids such as pHXB2D, pNL4-3 and pMJ4. All plasmids contain single retroviral genomes (proviruses) derived from patient isolates or laboratory strains and produce infectious viruses when transfected into permissive cells.

HIV-1 vectors: HIV-1 vectors are plasmid clones of HIV-1 proviruses derived from lab strains which are NOT replication-competent. Those vectors used within this project have deletions within their genes to prevent production of infectious virus. Such deletions will be contained within either the gag (protease), pol (RT) or env genetic regions. Such vectors also carry a resistance gene e.g. ampicillin, in order to enable the selection of vector containing prokaryotic cells. The risk from these vectors is minimal in prokaryotic cells e.g. E. coli, as the HIV-1 genes are unable to be expressed. As a result work involving these vectors may be carried out under ACGM class 1 conditions as the clone itself is non-infectious. Once transfected into an appropriate cell line in the presence of full length genes (for which the vector is defective) infectious virions are able to be produced. Vectors used within this investigation will be defective due to deletions in the gag, pol and env genetic regions.

Drug resistant HIV-1: Genes of interest encoding mutations will be amplified from clinical material derived from patients exhibiting resistance to drugs after therapy, or generated by site specific mutagenesis upon wt genetic material. These mutations within the gene of interest will encode for an HIV-1 with a phenotype of resistance to a particular, or a combination of, antiretroviral drugs.

Recombinant viruses: Recombinant viruses will be constructed by homologous recombinations between the HIV vectors (with deletions in the appropriate genes) and genetic material derived from either laboratory strains (simulating wild type virus) or 'normal' genes in the context of the same viral background. The presence of both components is required within the appropriate cells before recombination can take place.

#### Risk of infection

Levels of infectious recombinant virus produced (under containment conditions) during this investigation are anticipated to fall within the ranges measured in the blood of persons infected with HIV-1, although many viruses with drug resistance mutations replicate at reduced rates compares to wt virus. The risk of HIV-1 infection following exposure to infected blood through sharp injury is estimated to be around 0.3% , whereas that associated with a splash exposure with blood is in the region of 0.09%. This in absence of Post - Exposure Prophylaxis (PEP).

#### Management of Infection

If exposure does occur, it is managed through the administration of PEP constituting a four week course of antiretroviral drugs . Although the success rate of this course is high, it is not 100%. Some recombinant and wild-type viruses contain mutations which render them of increased susceptibility to particular antiretroviral drugs. Some resistance mutations may affect more than one drug; however there are sufficient drug combinations currently available against drug resistant HIV-1.

#### Other risks
The potential integration of a complete retroviral vector into the host genome may also have the potential to affect host cellular function i.e. insertional mutagenesis, leading to the possibility of tumour formation, subsequent to exposure to wt lentiviral vectors and HIV-1 lab strains. Integration of complete lentiviral vectors into host cell genomes has been recently described however the overall likelihood of such events is thought to be low (J. Virol. 2008 Oct 22). Additionally, it may be speculated that the transduction of eukaryotic cells with expression vectors, or infection of such cells with recombinant HIV-1 or retroviral vectors may also result in the immortalisation of the cell line with altered properties. Such cells may retain the ability to establish tumour formation within exposed laboratory workers following a significant exposure although the likelihood of such an event is considered extremely remote. Even in such a rare occurrence, the chances of such cells becoming established and productively proliferating within the worker would be further limited by immune defence mechanisms such as MHC mismatching. Furthermore, mutations within the env region may result in the altered tropism of viruses. Such events as these however would be unlikely to influence the susceptibility of the virus for particular drug therapies in the event of exposure.

Environmentally, these viruses pose a minimal risk. HIV-1 is an enveloped particle and is consequently labile. There is no reason to suspect that mutations will result in structural changes to progeny virions, thus it is unlikely that any changes to viral genes will affect its interactions within the physical environment. Infectivity of wt HIV-1 is completely destroyed by desiccation or disinfection and waste disposal protocols implemented within the containment level 3 (CL3) laboratory, the chance of residual virus remaining infectious is unlikely.

Virus producing cell lines

The cell lines, MT4 and C8166 that will be used to propagate the virus in vitro are persistently infected with HTLV-I (although C8166 cells carry, but do not express the HTLV-I genome). C8166 is derived from umbilical cord blood cells (Virology. 1983; 129:51) whereas MT4 is a human T cell lymphoma cell line (Acta Microbiol Hung. 1992; 39(3-4):271-9). Both have been immortalised by HTLV-I virus. Cell lines were chosen as they exhibit characteristic morphologies when infected by HIV-1. There is a risk of exposure to HTLV-I when working with MT4 cells, although the virus is known to be highly cell-associated and the chance of infection is low. Additionally, the risk of HTLV-I virus particles recombining with lentiviral vectors is minimal, as is the likelihood of recombination with recombinant HIV.

In summary: the main consequence of exposure to vectors engineered to express viral genes is the potential transfer of GMM to the laboratory worker. Laboratory associated exposure to the recombinant virus would carry similar implications as exposure to the 'non-resistant' wild type HIV-1 (grown from clones in cells) and drug resistant HIV-1 (derived from patient material). In spite of any such mutations effective drugs remain available to treat infection with recombinant viruses. Additionally, such risks working with such GM organisms are further reduced by good working practice and adherence to SOPs under CL3 conditions. The availability of PEP further reduces the risk of infection after a significant exposure. Therefore the overall likelihood of infection is very low. Should infection occur despite PEP then consequently the health risks are those associated with wt HIV-1 infection.

Characteristics of the GMO

Recombinant viruses will fall into three groups:

i) Those in which inserted regions, cloned directly from patient samples, contain mutations which encode for resistance to particular (or a combination of) antiretroviral drugs.
ii) Those in which inserted regions are cloned directly from wild type HIV-1 laboratory strains such as pHXB2.
iii) Those in which inserted regions contain mutations generated in vitro which represent intermediate 'halfway' stages between drug resistance and wild type

Forseeable effects

1) Health
There is no reason to expect that viruses generated by this work will be more pathogenic than 'non-resistant' wt HIV-1 virus. There is also the possibility that exposed laboratory workers may acquire a mixed infection (of both resistant and non-resistant HIV-1) although this risk is reduced as the viruses will be cultured under CL3
containment conditions however any such exposure to mixed viral populations is considered to pose no greater danger than infection by either virus individually. Although resistance mutations may affect more than one drug there are considered to be sufficient numbers of drugs, with different mechanisms of action, currently available for application against drug-resistant virus.

2) Environment
The presence and persistence of recombinant viruses within the environment is extremely limited and therefore adherence to disinfection and waste disposal protocols implemented within the CL3 laboratory further reduces the chances of viruses' surviving within the environment.

Cell lines
Cells proposed for use within this project will fall into 2 classes:

i) Prokaryotic cells required for the propagation of HIV-1 vectors. These include E. coli DH5α, TOP10 and equivalent cells.

ii) Eukaryotic cells required for construction and propagation of recombinant HIV-1. These include 293T, MT4, C8166 and equivalent cells.

Origin & function
Origin of viral genomic genetic material
Several HIV-1 vectors are intended for use within this investigation. Genetic regions of these vectors will be replaced with regions of interest in order to study the effects regarding susceptibility to certain antiretroviral drugs and on viral replication.

The pHIVΔRTStEII vector contains the complete provirus of the HIV-1 laboratory strain HXB2D with a 1.4kb deletion within the RT region. The clone is non-infectious but when transfected into an appropriate cell line with full length RT coding sequence provided in trans infectious virus is produced by homologous recombination. All procedures within the protocol prior to transfection are carried out in E. coli and present no infection risk. This vector is unable to initiate virus production when introduced into a target cell in the absence of a full length RT coding sequence and therefore is unlikely to regain wild type phenotype in the absence of RT. This minimises the level of risk to the laboratory worker to the vector during laboratory manipulations. Sharps are not used and good laboratory practice means the risk to workers is negligible.

This plasmid and its equivalents [containing deletions/mutations within the gag (protease), pol (Integrase) and env] will be used to determine the impact of mutations within these regions upon resistance

All molecular clones used within this investigation will be obtained from the National Institute of Health AIDS Research and Reference Reagent program (www.aidsreagent.org)

Origins of the genetic material to be inserted into replication-deficient vectors
Inserts encoding for drug resistance: Genes of interest encoding mutations will be amplified from clinical material derived from patients exhibiting resistance to drugs after therapy. These mutated genes of interest will encode for an HIV-1 with a phenotype of resistance to a particular, or a combination of, antiretroviral drugs.

Inserts coding for 'non-resistant' wild type HIV-1: Genes of interest (gag, pol and env) will be cloned from the HIV-1 laboratory strains pHXB2D, pNL4-3 and pMJ4. All three plasmids contain proviruses derived from patient isolated and laboratory strains which produce infectious virus when transfected into appropriate cells. Such inserts will encode for an HIV-1 virus without a resistance phenotype.

Inserts containing intermediate mutations for HIV-1 drug resistance: Genes of interest will be cloned from the HIV-1 laboratory strains and isolates. Sequences will then be altered using in-vitro mutagenesis to induce partial sequence identity to drug resistance motifs, simulating intermediate stages in the development of drug resistance to particular (or a combination of) antiretroviral drugs.
Cloning vectors: These are commercial vectors used for the purpose of cloning and amplifying regions of interest and include pCR2.1TOPO derivatives, pUC vectors, pBLUESCRIPT vectors, pcDNA3.1, pCMV/Zeo and pEGFP-1.

Evaluation of foreseeable effects

These are detailed in the above sections.

To summarise: The main risk is accidental exposure of laboratory workers to infectious recombinant and wild-type HIV-1.

The handling of bacterial cultures and plasmids for cloning is carried out under ACGM class I conditions and therefore poses little risk, if any. At this stage of the work the risk of exposure of workers to infectious virus is minimal.

The HIV-1 vectors are derived from well characterised laboratory strains of HIV-1, Theses are not able to form infectious particles unless in the presence of a full length RT region in trans (either wild type or mutated). Such an event would ONLY occur within the contained environment of the CL3 suite. An additional foreseeable risk is the oncogenic potential of the vector to the host genome upon potential exposure. The probability of such an event is extremely low and in this respect these vectors pose a minimal risk.

The defective HIV-1 vectors can ONLY form replication-competent viruses when both the HIV-1 vector and genetic region of interest are present within the cell. Recombination in the absence of either is extremely unlikely, as is the chance of spontaneous recombination with retrovirus genomes within, or associated with the aforementioned cell lines. The presence of replication competent recombinant HIV-1 poses the main risk to laboratory workers, although the risk is no more significant than that posed by handling wild type HIV-1 virus. The main risk of exposure in the laboratory is via cuts and abrasions with contaminated sharp instruments, or splash exposures as HIV-1 is not readily transmitted by aerosol. Through adherence to CL3 working guidelines and good laboratory practice, this risk is significantly reduced. The use of PEP after accidental exposure makes the risk of an established infection very low. Should infection occur, the recombinant viruses are unlikely to be any more pathogenic than those circulating in infected patients. No genes of the source strain of HIV-1, from which the lentiviral vector has been derived, have been shown to be oncogenic or teratogenic.

The potential risk of exposure to HTLV-I during this work has been discussed previously, however as work with this cell line is confined to the CL3 suite; the risk of exposure to this virus is minimal.

Environmentally, providing correct guidelines upon disinfection and waste are followed there are no foreseeable risks posed by either the wild type or recombinant viruses due to their nature as enveloped viruses.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Laboratory workers are responsible for the following procedures:

Class 1 GMM products include HIV-1 genetic regions of interest derived from clinical samples or laboratory strains which have been cloned into plasmid vectors and the production of replication defective viral vectors.

Method of Class I GMM waste disposal
All GMM waste both solid (e.g. flasks, tubes and plates) and liquid (e.g. culture medium) is double bagged into clear autoclave bags and placed into metal autoclave tins for autoclaving. Autoclaving conditions follow the NHS diagnostic guidelines and adhere strictly to the requirements of the Clinical Pathology Accreditation. Standard autoclave cycle conditions are 135°C at 3150 mBar for 10 minutes. Temperature and pressure parameters of each autoclave cycle are recorded and reviewed. Additionally, Browns tubes and autoclave tape are used to assess each run.

Spillages are dealt with using KLORSEPT granules. Disinfected spillages are then absorbed onto paper towels which are then autoclaved.

Methods of Class 3 GMM waste disposal

Class 3 waste products will include cell culture medium containing antiretroviral drugs, cells and wt/recombinant HIV-1 virus.

All CL3 GMM liquid waste is emptied from plastic culture flasks into a sweetie jar within the MSC containing 2x6g sachets if Vernagel gelling agent. All CL3 GMM solid waste (e.g. flasks, tubes, tips and plates) are then immersed in a container of 10% Trigene Advance located within the microbiology safety cabinet and allowed to disinfect for at least 16 hours. Lids are sealed upon 2L lidded containers and liquid contents are allowed to gel before being double baged, and loosely swan-necked prior to disinfection and being placed within a sealable plastic autoclave bucket.

After disinfection of solid waste has been allowed to take place the container is removed from the hood. Disinfected solid waste is poured into a sieve placed over a sink whilst disinfected liquid waste is poured down the sink and washed down the mains drainage with copious amounts of water. All disposable solid waste from the sieve is placed into double autoclave bags which are disinfected and swan-necked loosely. Laboratory plasticware including jugs are double bagged and loosely sealed by swan-necking prior to further disinfection. Bagged and sealed plastic ware (i.e. beakers and jugs) are then placed in a sealable metal tin for autoclaving. The remaining disinfected solid waste is placed (using the sieve) into double autoclave bags. These are loosely sealed prior to disinfection and placed into sealed yellow autoclave bins. After each work session all surfaces are disinfected with 5% Trigene Advance in order to eliminate any residual virus. At the end of each work day, autoclave bins and sealed metal tins are surface disinfected with 5% Trigene Advance before they are placed in a lockable trolley by a trained member of the CL3 team, and transported directly to the local autoclave (within the department) for immediate incineration under standard autoclaving cycles. No GMOs will remain viable after treatment.

After autoclaving, sealed plastic autoclave bins will be labelled and sent offsite for incineration. Metal transport tins and any plastic ware from the CL3 are returned directly to the CL3 suite in order to prevent them entering general laboratory circulation.

Is an emergency plan required according to regulation 20? N

### Project Additional Information

#### Purposes of the contained use

The sponsor will use the material as a positive control antigen in an in vitro immunological study. Typically as ELISA spot test and antigen-specific intracellular cytokine assay for measurement of antigen-specific T lymphocytes.

#### Recipient or parental organism

The parental organism is the Vaccinia WR strain (American Type Culture Collection [ATCC] # VR-1354). It is thymidine kinase negative. The virus has been used as a vaccine strain in humans.

#### Host/vector system

Three constructs of the vaccinia will harbour the nucleic acids encoding the following:
- Hepatitis B core antigen
- Hepatitis B surface antigen
- Influenza matrix protein M1.

#### Origin & function

The material will be used to provide viral antigens for in vitro immunological studies. The source of the material is as follows:
- Hepatitis B core antigen: Virology Department of GlaxoSmithKline Biologicals
- Hepatitis B surface antigen: Virology Department of GlaxoSmithKline Biologicals (originally from ATCC VR# 2046)
- Influenza matrix protein M1: Virology Department of GlaxoSmithKline Biologicals

#### Evaluation of foreseeable effects

The GMMs consist of the WR strain of vaccinia with one of each of the viral genes listed above inserted into the thymidine kinase locus of the parental vaccinia. There are no foreseeable increased adverse properties of the GMMs compared to the parental vaccine backbone.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

#### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None.
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste consisting of disposable pipettes will be submerged overnight (16h minimum) in 2% Virkon, removed and double bagged into autoclave bags. The bags will be autoclaved at 131 C for 30 minutes, bagged and finally removed from the facility and incinerated as clinical waste. Disposable plastic disposable culture vessels will be treated as above. Liquid waste will be mixed with an equal volume of 2% Virkon in a sealed vessel, left overnight and treated as above. The inactivation is 100%. The waste autoclave is validated and maintained. The sterilising run is completed before bagging for incineration.

Date of Significant Change

Project Additional Information

Purposes of the contained use

The purpose of the work is to manufacture a master virus seed stock of an attenuated VEEV human vaccine candidate, followed by the manufacture of a Phase 1 clinical lot of the attenuated VEEV vaccine candidate strain V3526. The attenuated virus will be cultured in MRC5 cells, following electroporation of the RNA, and purified using sucrose gradient centrifugation. All procedures will be conducted under full GMP compliance.

Recipient or parental organism

The parental organism is VEEV. The candidate strain is an attenuated VEEV human vaccine candidate.

Host/vector system

Escherichia voli vector pBR322.

Origin & function

The alteration of the macromolecular structure in V3526 through site-directed mutagenesis reduces infectivity associated with wild-type virulent VEE virus, while at the same time retaining its immunogenic potential. As these intrinsic differences between the origin and molecular structure of wild-type VEE virus and the V3526 vaccine candidate are such a critical element of the hazard assessment, the construction and selection of V3526 are described below:

Wild-type clone V3000 is a full-length RNA genome clone of VEE 1A/B (Trinidad donkey strain, VEE TrD) in the Escherichia coli vector pBR322 (Davis, et al., 1991; Davis et al., 1989b). It was constructed from four complementary DNA (cDNA) fragments in a series of cloning steps, including the placement of a T7 promoter at the 5’-end of the VEE genomic clone, for in-vitro run-off transcription of viral genomic replicas (Figure 1) (Davis, et al., 1991; Davies et al., 1989a; Johnston, R.E. and J.F. Smith 1988). The resulting viral RNA can be transfected into cell cultures (eg chicken embryo fibroblasts) to generate virus progeny (Davis, et al., 1991; Davis, et al., 1989a).

Site-directed mutagenesis of V3000 resulted in a set of 15 full-length viral cDNA clones with single mutations. These 15 full-length clones were constructed based on mutations originally identified by either comparative sequence analysis of attenuated VEE virus strains or by targeted mutagenesis of replication-critical domains of the VEE genome (Davis, et al., 1984; Grieder, et al., 1995). The most attractive single mutations were then combined in various permutations resulting in vaccine candidates with multiple mutations (Davis, et al., 1995). Fourteen of these multiple-mutation candidates were again evaluated in murine models for safety and immunogenicity. Based on these results, V3526 was chosen.

Evaluation of foreseeable effects

There are no foreseeable increased adverse properties of the GMM compared to the parental VEE virus. Please refer to the hazard assessment enclosed with this application.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
The GMM derogation has been downgraded to category level 2. Please refer to the hazard assessment enclosed with this application for justification.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste consisting of disposable pipettes will be submerged overnight (16 hours minimum) in 2% Virkon, removed and double bagged into autoclave bags. Project Ref 557/03.2

Date Ackn'd 02/03/2022
## Project Additional Information

### Purposes of the contained use

The GMO under consideration is a replication competent Herpes Simplex virus Type 1 containing a gene encoding for GM-CSF, a cytokine involved in the stimulation of T cells. The tests to be undertaken are routine safety testing for the presence of viral contaminants.

### Recipient or parental organism

The parental organism is HSV type 1.

### Host/vector system

ICP34.5 deleted HSV1 can replicate in dividing cells but cannot replicate in non-dividing cells.

### Origin & function

JSV1 deleted for the ICP34.5 gene will only replicate in dividing cells including cancerous cells. The insertion of the gene encoding for GM-CSF which produces a cytokine encoding for T-cells enables the vector to be utilised in forms of cancer therapy.

### Evaluation of foreseeable effects

There are no foreseeable increased adverse properties of the GMM compared to the parental Herpes Simplex virus. Please refer to the hazard assessment enclosed with this application.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Project Ref 557/04.1

Date Ackn'd 07/05/2004

Date Project Ceased

CU2 Project Title

To test a recombinant Vaccinia (rVV) containing tumour antigens for cancer therapy by in vitro methods.

Class 2

CultureVolClass2 Not Applicable

Consent Granted

Non-GMM Not Applicable
The recombinant Vaccinia virus will be used in tests undertaken as part of routine safety testing for the presence of viral contaminants or to investigate integration and expression of the vector construct in the germ line, target tissue or non-target tissue as part of a biodistribution study. Nucleic acid will be extracted from viral seed, viral vaccine or tissues harvested from animals inoculated with the recombinant vector, and detection of the viral vector assessed in each sample by Polymerase Chain Reaction.
Extracted viral nucleic acid will also be used as a positive control during the study.

**Evaluation of foreseeable effects**

As the insertion of the tumour antigen genes into the vaccinia viral vector does not alter the tropism of the virus or its interactions with host defences it is considered to be no more pathogenic than the parental virus, which is categorised by ACDP as a hazard group 2 biological agent (ACDP Categorization of biological agents according to hazard and categories of containment, 4th edition, 1995 [second supplement]).

Please refer to the GMO Risk Assessment enclosed with this application.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

The ACGM and ACDP level of containment would be category 2. All manipulations using infected tissue or live virus will be performed in a class 2 safety cabinet within a level 2 containment facility. Handling of extracted DNA will be performed within a level 2 laboratory.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Solid waste consisting of disposable pipettes will be submerged overnight (16 hours minimum) in 2% Virkon, removed and double bagged into autoclave bags. The bags will be autoclaved at 121 deg C for 15 mins, bagged and finally removed from the facility and utilising a “non-burn” heat treatment/disinfection process will be rendered non-hazardous.

Liquid waste will be mixed with an equal volume of 2% Virkon in a sealed vessel, left overnight and treated as above.

The waste autoclave is validated and maintained. The sterilising run is completed before bagging for incineration.

The combination of autoclaving and non-burn heat treatment/disinfection will result in an inactivation of 100%.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

The committee required that the work be notified to the HSE.
The work is to be undertaken in a designated room by designated personnel.
Fumigation of the biocontainment hood will be performed.
All waste disposal and laboratory cleaning will be performed by the designated operator.

**Project Containment**
The sample will be clarified to remove cellular debris, ultracentrifuged to pellet any viral particles present and resuspended in disruption buffer containing detergents, followed by Reverse Transcriptase Polymerase Chain Reaction.
considered one of the safest and effective live attenuated vaccines ever developed. According to current biosafety guidelines, the ChimeriVax - JE vaccine virus is officially BSL2.

**Origin & function**

The infectious clone (cDNA copy) of 17D virus, which was subsequently used to create ChimeriVax - JE, was constructed starting from a sample of the virus obtained from ATCC at passage 2347-8. Since ATCC is not currently distributing passage 234 sample, a Safety Data Sheet for this virus is not available. However, this virus is virtually identical to all other 17D vaccines manufactured worldwide, because its passage history differs from the commercial vaccines only at a few terminal passages. All 17D vaccines, including the ATCC passage 234 sample, have originated from one sample, Colombia 88 vaccine at passage 228. All current commercial 17D vaccines are produced at passage levels between 233 and 239 to ensure phenotypic and genetic similarity. The 187D virus is a BSL - 2 agent.

The Chimerivax will be used in tests undertaken as part of routine safety testing for the presence of viral contaminants, especially reverse transcriptase activity. The sample will be clarified to remove cellular debris, ultracentrifuged to pellet any viral particles present and resuspended in disruption buffer containing detergent, followed by an RT-PCR. The sample consists of ChimeriVax TM-JE Bulk Harvest cultured in Vero cells.

During the procedure the virus will be inactivated by disruptin buffer containing the following detergents, Igepal and DTT. Handling of the sample will be performed in a Class II hood. The process in which the recombinant virus will be used does not increase the risk associated with the virus.

**Evaluation of foreseeable effects**

Insertion of the envelope protein genes into the viral vector does not alter the tropism of the virus or its interactions with host defences. In selecting the most successful YF 17D chimeras containing the prM-E genes, two strains were examined, Nakayama, a virulent JE strain and the attenuated JE Vaccine strain SA14-14-2. Both chimeras replicated efficiently in several simian, human, mouse and mosquito cell cultures. It was concluded that the SA-14-14-2 envelope protein provided an additional degree of attenuation, therefore this was selected as the candidate chimeric JE vaccine.

For wild type yellow fever virus, antural hosts are Aedes mosquitoes. However, as a result of attenuation, the 17D vaccine strain lost its ability to replicate in mosquitoes, and replicates to extremely low levels in humans and non-human primates, which precludes infection of mosquitoes feeding on vaccinees and thus uncontrolled spread in nature. The ChimeriVax - JE vaccine had been demonstrated to possess the same restricted replication characteristics.

If introduced to humans it is possible that Chimerivax - JE would replicate to low levels, but cannot replicate in mosquitoes. However, due to the nature of the work to be performed and the containment procedures in place within the laboratory, the overall risk to the environment is considered negligible.

Chimerivax -JE can replicate in humans and non-human promates to extremely low levels. As the virus cannot replicate in mosquitoes there is no vector for transmission. The risk to human health and safety is negligible.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

In conclusion the recombinant Chimerivax-JE virus is considered as a Hazard Group 2 biological agent, this conclusion arises due to the fact that JEV and YF vaccine strains belong to Hazard Group 2 (ACDP Categorization of biological agents according to hazard and categories of containment, 4th edition, 1995).

The ACGM level of containment would be class 2 and ACDP level of containment is level 2. All manipulations will be performed in a level 2 containment facility.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Solid waste consisting of disposable pipettes will be submerged overnight (16 hours minimum) in 2% Virkon, removed and double bagged into autoclave bags. The bags will be autoclaved at a minimum of 121 deg C for 15 minutes, bagged and finally removed from the facility and utilising a "Non-Burn" heat treatment/disinfection process will be rendered non-hazardous.
Liquid waste will be mixed with an equal volume of 2% Virkon in a sealed vessel, left overnight and treated as above.

The waste autoclave is validated and maintained. The sterilising run is completed before bagging for incineration.

The combination of autoclaving and non-burn heat treatment/disinfection will result in an inactivation of 100%.

Purposes of the contained use

The sponsor's material will be tested using a number of different assays for the detection of adventitious agents. This will include in vitro and in vivo tests for growth of infectious agents in various cell lines or animal systems, as well as reverse-transcriptase assays and possibly nucleic acid testing.

Recipient or parental organism

The replicon vaccine vector system was developed from an attenuated strain of Venezuelan equine encephalitis virus (VEE). The replicon RNA consists of the cis-acting 5' and 3' ends of the VEE genome, the complete non-structural protein gene region, and the subgenomic 26S promoter. The genes encoding the VEE structural proteins were replaced with the gene encoding gD2.

Host/vector system

The replicon construct is a single cycle vector. It contains the 5' region of the virus genome encoding the non-structural protein genes, which express replicase and transcriptase functions, the cis-acting sequences required for replication and packaging of the genome, and the promoter sequence for transcription of the subgenomic mRNA, upstream of the inserted gD2 gene. It is therefore capable of RNA replication and transcription, and high level expression of the inserted gene, within the cell cytoplasm. It lacks the sequences for the structural protein genes, and therefore cannot induce particle assembly and spread.

Origin & function

Sequences encoding the HSV-2 gD gene were inserted. High level expression of HSV-2 gD would be expected in infected cells.

Herpes simplex virus is a hazard group 2 human pathogen. Glycoprotein D is an envelope glycoprotein, involved in receptor-recognition and entry into cells. The protein is not known to be toxic, and a number of subunit HSV-2 vaccines incorporating gD-2 have been shown to be safe in humans.

Evaluation of foreseeable effects

The replicon RNA is packaged into VRPs for use of a bipartite helper system. Two separate RNA constructs, encoding the capsid and envelope genes respectively, are co-transfected into Vero cells with the replicon RNA, to provide the structural proteins in trans. The helper RNA constructs retain the cis-acting elements required for genome replication, and the promoter for transcription of subgenomic RNA, but lack the packaging signals.

Although VRPs will not produce infectious virus and spread, there is a small but finite risk that replication competent virus could be produced either by co-packaging of...
Replication competent virus was detected following co-transfection of a VEE replicon and a number of different monopartite (single) helper plasmids. Partial sequence analysis of three independent isolates suggested that these arose from non-homologous recombination, at different sites within the heterologous gene insert. The use of a bipartite helper system was introduced to significantly reduce the risk of replication competent virus, by increasing the number of recombination events required to generate an infectious virus.

At least two independent recombination events would be required to generate a recombinant, replication competent virus. The Sponsor estimates the frequency of such events to be in the order of 1 in 10e12. In addition, as these are likely to be non-homologous recombination events, the frequency of generating a replication competent virus may be considerably lower, as most such events might be expected to result in deletion/truncation of functional sequence elements, and generate non-viable recombinants.

No replication competent virus was detected in VRP stocks generated using the bipartite helper system, either in plaque assays, following blind passage on BHK cells, or following intracranial inoculation of suckling mice. A number of studies have subsequently been published using this system for different VEE replicon vaccine constructs, reporting no detection of replication competent virus. It was also noted that over 1000 rodents, a very sensitive host for VEE, and 64 macaques have been given primary doses as high as 10e8 of VRP, with no detectable clinical signs.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The vector is based on an attenuated vaccine-candidate strain, V3014. The replicon construct is a single-cycle vector, which will not produce infectious virus progeny, and will not spread to uninfected cells. Replication of the virus RNA takes place in the cytoplasm, and there is no DNA intermediate, minimising the risk of integration into the host cell genome. The inserted gD sequence would not be expected to increase the risk of the construct. The vector can therefore be considered to be of significantly lower risk than the parent strain, and classed as a class 2 GM activity.

The ACGM level of containment would be class 2 and the ACDP level of containment is level 2. All manipulations will be performed in a minimum of level 2 containment.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

VEE is an enveloped virus, of low-medium resistance to physico-chemical inactivation. It is sensitive to solvents and detergents, and to disinfectants including 1% sodium hypochlorite, 70% glutaraldehyde, and formaldehyde.2.3.

All liquid waste will either be autoclaved, or discarded into Virkon at a final concentration of at least 1%, and allowed to soak overnight prior to discard. Solid waste will either be soaked overnight in * 1% Virkon, and then autoclaved, or autoclaved directly at a minimum of 120 degrees C, 15 lbs pressure for 15 minutes. Autoclaved waste is then uplifted by a contractor and subsequently processed through a heat treatment process, prior to landfill.

In-house studies have shown that 1% Virkon is effective for the inactivation of a broad range of viruses. The performance of the autoclave is validated on an annual basis.

Solid (non-carcass) animal waste will be collected, placed in an incinerator bag in a locked bin, and then sent for incineration off-site. All liquid waste will be discarded into Virkon (final concentration 1%), for a minimum of 16 hours prior to discard. Carcasses will be placed in an incinerator bag in a locked bin, and incinerated on-site.
The committee required that the work be notified to the HSE. The work is to be undertaken in designated rooms by designated personnel. Fumigation of the biocontainment hood will be performed. All waste disposal and laboratory cleaning will be performed by the designated operator.

### Date of Significant Change

#### Project Additional Information

#### Purposes of the contained use

To perform routine biological safety testing on materials intended for human use. Materials will be tested using a number of different assays for the detection of adventitious agents. This may include tests for growth of infectious agents, as well as reverse-transcriptase assays and nucleic acid testing.

#### Recipient or parental organism

The parental virus for this vector is Human adenovirus type 5 (a group C adenovirus). Human adenoviruses are widespread, and are associated with a number of clinical syndromes, including acute febrile respiratory illness, epidemic keratoconjunctivitis and gastroenteritis.

Human adenoviruses are classed as hazard group 2 agents, by ACDP.

#### Host/vector system

The vector is a conditional replication competent adenovirus. The main features include (i) replacement of the Ad5 E1 promoter with a modified human telomerase reverse transcriptase (mTERT) promoter, to allow preferential expression of E1A in tumour cells, (ii) insertion of a stop codon at the start of the E1B 19K open reading frame, and (iii) insertion of the gene for human relaxin within a non-essential region of the virus genome.

#### Origin & function

The vector system is based on human Ad5. The construct is a conditional replication competent virus, designed to replicate efficiently within tumour cells, but not in most normal cell types. There is no known toxicity associated with the inserted gene, and expression of the gene would not be expected to alter the tropism of the virus. Based on its host range restriction, the vector would be expected to be no more hazardous, or possibly less so, than its parent virus.

Vector stocks provided for testing are grown on HEK 293 cells, a complementing cell line containing the E1 region of Human Ad5. There is therefore a risk that high titre stocks could contain replication competent adenovirus, containing a wild-type E1 region, and the inserted relaxin gene. Such recombinants would not be expected to be significantly more pathogenic than the parent virus.

#### Evaluation of foreseeable effects

The vector is based on human Ad5, and is host-range restricted, growing efficiently only in cells expressing active telomerase. The inclusion of relaxin is not expected to increase the risk of the construct. The construct is not considered to be of higher risk than its wild-type parent. Wil-type Ad5 is a class 2 human pathogen.

Due to the containment procedures in place within laboratory areas, the procedures governing working practices, and the fact that human adenovirus would not be considered pathogenic for animals following natural infection, the overall risk to the environment is considered low.

Therefore, the adenovirus vector described above is classed as ACGM class 2 and ACDP class 2.

All work with infectious materials will be performed within containment level 2 laboratories, with all manipulations performed in a biosafety cabinet. Use of sharps, and
procedures which may generate aerosols, will be avoided wherever possible. Operators handling infectious materials will wear appropriate protective clothing (gown/lab coat or equivalent, gloves, eye protection).

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be inactivated by either autoclaving (with or without prior chemical inactivation), or by incubation overnight in the presence of Virkon at a final concentration of at least 1%, prior to discard.

Solid waste will be collected in suitable clinical waste packaging, appropriately sealed, then placed and stored in designated containers within a secure area until collected for off-site incineration.

In the event of a spill, the area will be cleaned using 2% Virkon, and 70% isopropanol, and mopped up with disposable wipes, which are then discarded as for solid waste. Larger spills may be disinfected using solid Virkon, and hoods may be fumigated with formaldehyde vapour if necessary.

In-house studies show that 1% Virkon, and formaldehyde fumigation, are effective for the inactivation of a broad range of viruses, including Ad5. The performance of the autoclave is validated on an annual basis. All disinfectants have a defined expiry date and a documented procedure is in place for preparation of the reagents.

Is an emergency plan required according to regulation 20?  N

### Project Additional Information

**Purposes of the contained use**

To manufacture a pre-master virus seed stock, master virus seed stock and clinical batches of reassortment H5N1 vaccine material under good manufacturing practice.

**Recipient or parental organism**

Human influenza virus strain A/PR/8/34 (PR8) (H1N1).

**Host/vector system**

The reassortments will be produced by reverse genetics using either an 8 plasmid or 12 plasmid strategy.

**Origin & function**

The reassortments are intended for use in the production of inactivated human influenza pandemic vaccines.

The parental virus is the human influenza virus strain A/PR/8/34 and is a member of the influenza A genera of the orthomyxoviridae family. PR8 has over 100 passages in each of mice, ferrets and embryonated eggs. The result of such a passage history is almost complete inability to replicate in man and complete attenuation in man.

The inserted genes are the haemagglutination (HA) and neuraminidase (NA) gene segments of a highly pathogenic H5N1 avian influenza virus. The HA gene is modified to reduce pathogenicity; the multiple basic amino acids at the HA connecting peptide (cleavage site), which are associated with high pathogenicity, will be greatly reduced to a single basic amino acid. Further detailed information is provided in the attached risk assessment and the WHO publication "WHO (2005) annex 5. WHO biosafety risk assessment and guidelines for the production and quality control of human influenza pandemic vaccines".
The reassortment virus is derived using reverse genetics and contains 6 internal gene segments of PR8 and the NA and modified HA segment of highly pathogenic H5N1 avian influenza virus isolates. It is envisaged that such reassortments derived in this way would be attenuated for humans and would be of low pathogenicity for chickens and animals compared to the H5 wild type. An indirect hazard may exist through secondary reassortment with a human or animal influenza virus. Several events would need to occur for this to happen and the probability that a PR8 reassortment strain will replicate and combine with another influenza virus(es) in human cells is considered to be minimal. The reassortment virus has avian receptor specificity and the contribution of the PR8 genes to replication and virulence in birds is unknown. However, experimental evidence has shown that not only is the virus attenuated for humans but also for chickens, whereby removal of the multi-basic amino acids from the H5 x PR8 reassortments is likely to have a major part to play in reducing the risk for chickens. Although pigs are not susceptible to infection with PR8, a reassortment containing a single gene (HA) from an H1N1 isolate infected pigs. It is therefore possible that pigs could be susceptible to a H5N1 reassortment and that these species would also be susceptible to secondary reassortments between H5N1 reassortment and a pig virus. Furthermore, there is evidence in the USA that triple reassortments between avian, pig and human influenza viruses can circulate in pigs. Further detailed information is provided in the attached risk assessment and the WHO publication "WHO (2005) annex 5. WHO biosafety risk assessment and guidelines for the production and quality control of human influenza pandemic vaccines".

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Contaminated waste from the cleanrooms is sealed in autoclave bags which are then sprayed liberally with 2% Virkon and 70% IPA. The sealed bag is placed inside a second autoclave bag which is sprayed with 2% Virkon and 70% IPA and sealed. Disposable pipettes, which have been in contact with viral material, are disposed of (in biosafety hood) into a roller bottle or other container, which is at least a third full of 2% Virkon. When this container is full the lid is replaced, and the whole container sprayed with 2% Virkon and 70% IPA prior to placing in the autoclave bag.

Autoclave waste is held in the cleanroom, where possible, until all processing is complete for that day. After processing all waste is transported to the waste autoclave room.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Please enter comments on the GM safety committee on the risk assessment
The risk assessment attached has been revised to take account of the comments provided by the GMSC, and the content therefore reflects the consensus view of the committee.

The question was raised of how long a quarantine period should be applied for laboratory workers coming in contact with porcine species; it was agreed that a period of 48 hours should be recommended and this was duly noted in the risk assessment.

The matter of avoidance of any work performed with other influenza viruses while work on the H5N1 reassortment virus is being performed was discussed. It was agreed that on the whole the standard working procedures and policies governing work practices at BioReliance would preclude work being performed on influenza at the same time and within close proximity to the H5N1 work. In addition, pipettes should be decontaminated prior to being removed from the biological safety cabinet by soaking in 2% Virkon overnight.

Project Additional Information

Purposes of the contained use
To manufacture adenovirus vector material, including pre-master virus seed stock, master virus seed stock and clinical batches, in compliance with Good Manufacturing Practice.

Recipient or parental organism
Human and Simian adenoviruses

Host/vector system
Adenovirus vectors provided for manufacturing are typically replication incompetent, deleted in the E1 region of the genome. A region essential for adenovirus replication. The E1-deleted vectors can therefore only be propagated in specifically designed complementing cell lines expressing the adenovirus E1 region (e.g. 293/PER.C6 cells). These vectors would not replicate and spread within an infected host, and therefore can be considered non-pathogenic in humans and animals. (continued on page 10 *)

Origin & function
Manufacturing
Adenovirus vectors provided to BioReliance for manufacturing are designed for use as vaccines, or for use in gene therapy, or the treatment of the cancer. Examples of genes expressed by these vectors are shown in table 2, Appendix I of GMO # 190. The genes are stably inserted within the virus genome, most commonly under promoters designed for high level expression in the infected cells. They include vaccine antigens from structural or surface proteins of the target pathogen, hormones or cytokines.

Evaluation of foreseeable effects
Vaccine antigens are typically structural or surface proteins derived from the target pathogen, and not themselves biologically active, and are therefore generally unlikely to be directly toxic or harmful. There may, however, be exceptions. For example, the Ebola virus glycoprotein, which is involved in receptor binding and virus entry, is also thought to contribute to haemorrhage during infection, and can induce a cytopathic effect in transfected cells in vitro. Tumour-specific antigens may be expressed by vectors designed for use in the treatment of cancer, and again these are typically not biologically active, and are unlikely to be directly toxic or harmful.

As adenoviruses are non-enveloped viruses, with a tightly regulated capsid structure, it is considered unlikely that the expressed antigens could become incorporated into the virus capsid, and alter the host range or tropism of the vector particle.

Therapeutic products expressed by the gene therapy vectors may be biologically active, e.g. hormones or cytokines. Although typically intended to replace normal human proteins deficient in the relevant individuals, some of these products may potentially be harmful to a host if expressed at high levels or within certain tissues, or be of higher risk for certain individuals (e.g. pregnant women, immuno-compromised host) Growth factors or cytokines, for example, may be teratogenic in an unborn foetus, or potentially provide a growth advantage to a developing tumour.

In the majority of cases, it is considered unlikely that expression of therapeutic gene product or vaccine antigen would increase the host range or pathogenicity of the adenovirus vector. However, vectors used as vaccines or for cancer therapy may also express immuno-modulatory genes, designed to enhance the immune response to tumour cells or target antigens. In the absence of direct data, it may be difficult to predict the effect such genes might have on the normal immune response to the virus, and hence the effect on the pathogenicity or risk of the recombinant adenovirus. (continued on page 10 ##).

Please enter comments on the GM safety committee on the risk assessment

A comment was made that clarification of the following terms used within the manufacturing environment at BioReliance should be made within the risk assessment:

1. Clarification on the zones referenced with respect to clean rooms and biosafety cabinet (section 6.2)
2. Clarification on the name of disinfectant referenced (LpH, section 7.0)

Both of these comments were addressed within the drafting of the GMO risk assessment.

Date Project Ceased

Biological safety testing of lymphocytes isolated from HIV patients and transduced with retrovirus vector

Class 3

Consent Granted Yes

Project notified under transitional arrangements N
### Project Additional Information

**Purposes of the contained use**

To perform biological safety testing of transduced lymphocytes intended for use in anti-retroviral therapy. Tests may include biochemical, immune-based or molecular assays, such as ELISA or PCR assays, as well as inoculation of the materials in vitro. The assays are intended for detection of potential containments (e.g. sterility, mycoplasma, in vitro and PCR assays for viral containments including replication competent retrovirus).

**Recipient or parental organism**

Human lymphocytes isolated from patients positive for Human Immunodeficiency virus.

**Host/vector system**

The human lymphocytes are transduced with a retrovirus vector whose expression inhibits infection with Human Immunodeficiency virus type 1 (HIV-1). The vector, M87o, codes for a protein that consist of the following modules: a signal peptide (SP) to direct translocation in the cell, the antiviral C peptide (C46), a hinge and a membrane spanning domain (MSD). M87o was obtained by insertion of this cassette into the optimized retroviral vector, MP71, derived from Myeloproliferative sarcoma virus (MPSV). The vector expresses a membrane-anchored peptide derived from the HIV-1 gp41 transmembrane glycoprotein which blocks membrane fusion and hence entry of the HIV virus. Transcription of the inserted genes is regulated by the LTR promoter of MPSV. The SP comprises the sequence dLNGFR, the low affinity nerve growth factor receptor, to direct translocation into the endoplasmic reticulum. The antiviral C peptide (C46) interacts with the trimeric coiled coil of HIV-1 gp41 which is consequently locked in a fusion incompetent state and entry of HIV-1 into the target cell is inhibited. The hinge sequence is derived from the human IgG2 to reduce potential immunogenicity and the MSD from human CD34 T cells which enables more stable anchoring in the membrane in the target cell. At the 3' UTR, there are regulatory elements, WPRE (from woodchuck hepatitis virus, without X protein) and RRE (Rev-responsive element).

**Origin & function**

The GMO under review is cultured human lymphocytes isolated from HIV patients which utilise membrane-bound T20 expressed, via a retroviral vector (M87o), on the surface of HIV target cells to act as an effective inhibitor of HIV replication. The planned procedure includes that patients may receive a transplant of autologous CD34+ cells transduced with M87o or allogenic m87o-modified CD34+ cells as part of an anti-retroviral therapy. Highly active antiretroviral therapy (HAART) can effectively suppress human immunodeficiency virus (HIV) replication and thereby slow progression of immunodeficiency but cannot eradicate the virus and must be administered to the patient continuously to prevent viral rebound. Extended treatment with antiretroviral drugs is invariably accompanied with problems such as toxicity and viral resistance, hence, complementary antiviral therapies, such as gene therapy could improve efficacy of treatment.

**Evaluation of foreseeable effects**

Primary human cells are extremely unlikely to survive in the environment, or following accidental inoculation of an operator. Retroviral vectors are unlikely to survive in vivo as they are susceptible to complement-mediated killing. Further, independently of transduction, the patient's lymphocytes would be recognised as allogeneic (non-self).
cells, and destroyed by an immune competent operator's immune system.

The vector is stably integrated into the host cell genome. There are no human retroviral sequences or infectious human retroviruses able to mobilise an MLV retroviral sequence, such as this vector. Therefore, the risk of mobilization/transfer is low. The expressed proteins are not known to be toxic or harmful, and the level of protein expression is unlikely to increase the risk of the materials.

The vector is replication defective. It does not encode capsid or envelope proteins, or the proteins required for replication, mobilization or integration of the retrovirus genome. The vector is integrated in the host cell, and therefore should represent a low risk of transfer. The vector contains promoters and enhancers for expression of the transgene and is not expected to be toxic or harmful as it is present in a multitude of clinically used retroviral vectors.

Testing for replication competent retroviruses (RCR) is to be performed and although no RCR formation has been described to date, there is the possibility of RCR presence.

Since the GMO has been derived from HIV+ patient cells, the presence of wild-type HIV in the test item cannot be excluded and constitutes a significant risk in handling. The transduced lymphocytes must be considered a GM class 3 activity due to the risk of infection with the ACDP category 3 virus, HIV-. Furthermore, operators should be aware that in the event of accidental exposure, a serological response to HIV may occur due to the possible expression of gp41 HIV derived gene insert (independent of any extraneous HIV being present in the test material).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

In accordance with Bio Reliance standard operating procedures (SOPs), all waste will be inactivated by autoclaving (with or without prior chemical inactivation), prior to collection by an external contractor. The waste will then be subject to further heat treatment.

All solid waste will be collected in suitable clinical waste packaging i.e. double seamless, tear-resistant autoclave bags, appropriately sealed, placed and stored in designated containers within a secure area until autoclaved and then collected for off-site inactivation.

All plasticware and solid waste will be rinsed and/or immersed in 2% Virkon prior to being placed in autoclave bags in the Class II hood which will be closed with autoclave tape and placed in the large double autoclave bags for autoclaving and subsequent removal as above.

Disposal of potentially infectious material such as the test article or supernatant from infected cell cultures should be discarded according to the relevant SOP and discarded into 10% Virkon or equivalent by an operator wearing appropriate PPE. Following overnight decontamination in the Class II hood under UV illumination, the sealed container should be autoclaved at a minimum of 121°C for 20 minutes.

In-house studies have shown 1% Virkon to be effective in the inactivation of a broad range of viruses, including HIV, a retrovirus model (CP39222).

The performance of the autoclaves is validated in accordance with a pre-determined schedule.
1. Sections 4.0 and 5.0; include justification for stating primary human cells are unlikely to survive in the environment.

2. Add as per SOP # KPSP2010, lab must be evacuated immediately for all spills occurring outside the biological safety cabinet.

**Historical Significant Changes**

**Historical Date of Additional Info**

**Significant Change ID**
**Project Additional Information**

**Purposes of the contained use**

To produce a stock of recombinant live attenuated Measles virus expressing Chikungunya genes. The manufacture will be performed in a containment level 2 cleanroom within our GMP manufacturing facility.

**Recipient or parental organism**

The recipient organism is the Schwartz strain of the Measles virus.

The measles virion is an enveloped, non-segmented spherical particle of diameter 120-150nm, classified as a species of the genus Morbillivirus, in the family Paramyxoviridae containing a helical nucleocapsid of negative stranded RNA which encodes nine known proteins in the order 3' -N-PVCR-M-F-H-L-5'. Proteins P, V, C and R are in overlapping reading frames. Viral proteins have been purified from these products as the haemagglutinin (H), matrix (M), nuclecapsid (N), fusion (F) and phosphoproteins (P).

Measles virus can be grouped into a large number of genotypes based on the sequences of the NP or the H gene, enabling epidemiological study and this is the basis for global vaccination programmes. Measles Virus haemagglutinates primate erythrocytes only and lacks neuraminidase.

The Measles Virus can be adapted for growth in a number of cell lines or in eggs.

Replication of virus is cytoplasmic and syncytial formation of multinuclear giant cells occurs followed by gradual cell death. Progeny virions exit the cell by budding at the plasma membrane.

The Edmonston strain of MV was isolated in 1954 by cultivation on primary human kidney and primary human amnion cells. It was subsequently adapted to propagation in chicken embryos and to chicken embryo fibroblast cells, to produce the attenuated Edmonston A and B seeds, The Edmonston B vaccine was licensed in 1963 as the first Measles vaccine and was widely used until 1975. This vaccine strain was efficacious, but extremely reactogenic producing fever and rash. Further passages of Edmonston A and B on chicken embryo fibroblast cells produced the more attenuated Schwarts and Moraten strains, whose sequences have been shown to be identical. The Schwartz reversion of vaccine strains to those causing pathogenicity has not been demonstrated. Recombination between paramyxoviruses is rare and does not occur naturally. Measles virus replication occurs solely in the cytoplasm which excludes risk of integration of genetic material. The Measles vaccine virus infects only human or primate cells expressing the CD46 receptor. Following inoculation of humans, its replication is transitory and viraemia is very low, therefore the risk of transmission is negligible.

Wild-type Measles Virus is an ACPD hazard group 2 pathogen.

**Host/vector system**

The GMO described is a recombinant MV vector containing a Chikungunya virus (CHIKV) construct composed of envelope protein. There are many instances in the literature which cite the use of CHIKV E1, and E2 envelope proteins as CHIKV-specific serodiagnostic for Chikungunya fever.

The MV vector was derived from one of the safest and most widely used Measles vaccines, the live, attenuated Schwartz strain vaccine virus, by cloning cDNA from viral particles purified from an industrial production batch using procedures designed to optimise cloning fidelity. The vector sequence, present in the construct, is the same as that if the Schwartz vaccinal strain. Investigators demonstrated that the growth kinetics and production yield of the molecular clone and the original virus were identical.

The plasmid was transfected into the helper cell line 293-3-46 to enable rescue of the recombinant virus and co-cultivated with primate Vero cells. Recombinant virus rapidly adapted to growth in Vero cells. Construction of the original cloned Schwartz strain included sequencing of the rescued virus following co-culture in CEF cells.
co-culture in Vero cells was accompanied by mutation in 2 out of 15,894 nucleotides which were widespread throughout all clones representing the viral population. Thus, it was suggested that adaptation of the host cell of Schwartz virus might affect the properties of the virus. However, safety appears to be retained, as since 2003, the date of the original cloning of the Schwartz strain, the recombinant virus has been developed for use as a vaccine for West Nile Virus.

Origin & function

The GMO under consideration is a replication competent live attenuated recombinant Measles Virus that contains the Chikungunya envelope protein. The recombinant virus was derived from the widely used Schwartz strain Measles vaccine. The Sponsor has indicated that the recombinant virus is intended to be used as a vaccine against Chikungunya fever. From information provided by the Sponsor, the GMO is unlikely to cause disease. The client has stated that infection by the virus in humans is via CD4 receptor, but entry into host cell is also reported to be mediated by CD46 for the Edmondson strain of the virus.

Chikungunya virus (CHIKV) is an insect-borne Togavirus, of the genus Alphavirus. Chikungunya (CHIK) fever, the disease caused by CHIKV, was first recognised in epidemic form in East Africa during 1952-1953. The virus is indigenous to tropical Africa and Asia, where it is transmitted to humans by the bite of infected mosquitoes, usually of the genus Aedes aegypti salivary glands is asymptomatic and lifelong, CHIK fever is transmitted by Aedes aegypti to humans, but it should be noted that there is no human to human transmission. The main symptoms of Chikungunya infection are sudden onset of chills, fever, headache, rash and debilitating arthralgia causes fever and severe joint pain. Other symptoms include muscle pain, headache, nausea, fatigue and rash. The word Chikungunya is thought to derive from description in local dialect of the contorted posture of patients addlicted with the severe joint pain associated with this disease. The disease shares some clinical signs with Dengue, and can be misdiagnosed in areas where Dengue is common.

There have been recent breakouts of Chikungunya in Africa, Asia and the Indian subcontinent. In recent decades mosquito vectors of Chikungunya have spread to Europe and the Americas. In 2007, disease transmission was reported for the first time in Europe. Since the beginning of 2006, there has also been an explosive emergence of the disease in nations in the Indian Ocean area. By March 7, 2006, 157,000 people had been infected in the French island La Reunion, and the disease had spread to the islands of Seychelles, Mauritius, and Mayotte. Subsequently, the disease has appeared in India, China and European countries.

Evaluation of foreseeable effects

Expression of the Chikungunya product of the inserted gene results in an antigen designed to produce antibody to Chikungunya fever. In the absence of any information being provided by the Sponsor, toxicity is assumed and as a result, the material should be handled in line with standard COSHH level 2 safety procedures. Efficacy and safety results have similarly not been disclosed by the Sponsor.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste from the manufacturing pilot labs and cleanrooms must be disposed of in accordance with current SOP's. The current procedures for inactivating viral waste in manufacturing pilot labs and cleanrooms are as outlined below:

Liquid waste is treated with LpH solution (at a concentration of 16ml LpH per 2L of liquid waste) and left for at least 30 minutes contact time. Pipettes are disinfected by repeated aspirating (3 times) with LpH solution (at a concentration of 16ml LpH per 2L of water for irrigation) prior to placing back into the pipette wrapper which is subsequently sprayed with Klercide B and 70% IPA prior. Flasks and other vessels are wiped down with wipes sprayed with LpH solution, Klercide B and 70% IPA prior to removal from the biosafety cabinet. Gilson pipette tips are discarded into an appropriate vessel which is closed and cleaned prior to removal from the biosafety cabinet. All viral waste is placed into separate autoclave bags which are sanitised with LpH (at a concentration of 16ml LpH per 2L of water for irrigation) prior to exiting the cleanroom/pilot lab. All waste should be double bagged in autoclave bags prior to removal from the pilot lab/cleanroom. The double bagged waste is placed in yellow UN...
approved outer disposal bags and placed in yellow bins for transfer to the secure containers for waste uplift for off site inactivation.

In the event of a spillage the procedures are summarised below:

1. For a small scale spill within the biosafety cabinet (<500ml) and low concentration of material (diluted virus stock or bulk harvest materials) the spillage is contained with cleanroom wipes. The affected area is treated with LpH solution (at a concentration of 16ml LpH per 2L of water for irrigation) and left for at least 30 minutes contact time before wiping dry and spraying with 70% IPA and wiping dry again.

2. For a larger volume spill (>500ml) or high concentration of virus (final product or concentrated virus) within the biosafety cabinet work will stop and the spillage will be contained by wiping up with cleanroom wipes. The affected area is treated with LpH solution (at a concentration of 16ml LpH per 2L of water for irrigation) and left for at least 30 minutes contact time before wiping dry and spraying with 70% IPA and wiping dry again. A senior member of staff is contacted for further advice and the biosafety cabinet formaldehyde fumigated at the end of the processing day.

3. For any size of spill out with the biosafety cabinet but within the cleanroom operators should leave the cleanroom immediately to contain aerosols and notify senior manufacturing staff. After clearance from senior manufacturing staff and after at least 30 minutes the spillage will be contained with cleanroom wipes treated with LpH solution left for a 30 minutes contact period. The area once treated with LpH solution is wiped dry and sprayed with 70% IPA and wiped dry again. All actions taken will be recorded in an incident/accident report.

The risk assessment attached has been revised to take account of the comments provided by the GMSC, and the content therefore reflects the consensus view of the committee.

Note that the committee endorses the view that a cautionary approach to classification be adopted. The attached risk assessment reflects the planned manufacturing activities at BioReliance, taking account of manufacturing processes and scale.

Purposes of the contained use

Biosafety testing of recombinant lentiviral vector (pCCL-INVO-SP) virus-containing supernatant and associated materials. Testing will compromise sterility testing, mycoplasma detection assays, in vitro cell culture assays, molecular-based nucleic acid detection assays, biochemical and immunological based detection assays. All assays are designed to detect adventitious agents.

The GMO under consideration is a recombinant lentiviral vector, derived from HIV-1, expressing a therapeutic gene SPINK5 product which performs a critical role in the maintenance of a healthy skin barrier. The gene, SPINK5, is under the control of a 500kb element cloned from the human involucrin promoter which restricts transgene expression to the site of the skin pathology. The recombinant lentivirus has been pseudotyped with an alternative coat protein, the vesicular stomatitis virus glycoprotein (VSV) G protein, to increase the tissue-tropism range of the vector. The vector is intended for ex vivo clinical use in humans. The vector will be used to transduce keratinocyte stem cells (KSC) from patients with the skin disease Netherton syndrome (NS). The gene-modified stem cells will be propagated and used as autografts in NS patients in a Phase I clinical trial.

Recipient or parental organism

The parental virus is Human immunodeficiency virus type 1 (HIV-1), a species in the genus Lentivirus (family Retroviridae), which is the primary aetiologic agent of Aquired Immunodeficiency Syndrome (AIDS), a disease that results in the gradual destruction of the helper-T cell population in infected individuals, leading to immunosuppression.

Lentiviruses are large single-stranded, positive sense, enveloped RNA viruses which contain an RNA-dependent DNA polymerase. Following entry into the host cell, viral RNA is reverse-transcribed into a covalently linked circle of double-stranded DNA (provirus) which is integrated into the cellular DNA by action of the virus-encoded integrase and other cellular co-factors. The integrated proviral DNA thereafter remains latent or is transcribed by cellular transcriptional activators and is replicated in tandem with the host cell DNA. All lentiviruses contain several genes in addition to the three major genes encoding the main retrovirus structural proteins Gag and Env and the main enzymic protein Pol.
Several factors make retroviral vectors attractive for gene therapy including their relatively large cloning capacity and their ability to stably integrate into the host cell genome, which is a likely requisite for long-term expression. Further, they do not transfer viral genes and avoid transduced cells that are destroyed by virus-specific cytotoxic T cells. In addition to these characteristics that are common to all retroviral vectors, lentiviral vectors can transduce non-dividing cells, a crucial asset for genetically modifying the main target tissues of gene therapy such as the brain, soft-tissue organs and the haematopoietic system, and enable efficient in vivo delivery, integration and stable expression of transgenes. However, biosafety of HIV-based vectors requires most careful evaluation, taking into account the significant pathogenicity of the parent virus.

HIV-1, a category 3 pathogen can infect man and some non-human primates.

The HIV-1 genome is complex and attenuation of the recombinant virus described here has been achieved by removal, modification or replacement of viral genes encoding factors necessary for virulence and replication competence.

**Host/vector system**

The lentiviral vector is derived from HIV-1. Wild type HIV-1 has been assigned to ACDP hazard group 3 however the recombinant HIV-1 vector has been modified extensively as detailed below, such that it can be derogated and re-classified as suitable for handling under ACGM level 2 conditions in BioReliance.

The HIV-1 based lentiviral vector gene-delivery system comprises two elements, the packaging system, which includes structural proteins and enzymes for the generation of infectious particles, and the transfer vector, itself, intended to deliver the inserted therapeutic gene to the host cell. The GMO comprising this submission is a “third generation” HIV-1-derived vector containing only three of the nine HIV-1 parental genes, gag, pol and rev, rendering it clinically acceptable. The extensive deletions have also eliminated the possibility of generation of wild-type virus through recombination.

This 3rd generation, replication-defective, self-inactivating (SIN) vector has undergone further modification by introduction of a deletion in the U3 region of the 3’ long terminal repeat (LTR) of the DNA used to produce the vector RNA. During reverse transcription, this deletion transferred to the 5’ LTR of the proviral DNA, the implication being that sufficient viral sequence can be eliminated to abolish transcriptional activity of the LTR thus, abolishing the ability to produce full length vector RNA in transduced cells which minimizes the risk of emergence of replication competent retroviruses (RCR). The SIN lentiviral particle enables production of infective particles only in the first round of infection. The risk associated with the expressed product(s) of the SIN-LTR element is expected to be low. Self inactivation minimizes the risk that RCR will be produced. Further, it reduces the likelihood that cellular coding sequences located adjacent to the vector integration site will be aberrantly expressed, either due to the promoter activity of the 3’ LTR or through an enhancer effect. Finally, the SIN design prevents potential transcriptional interference between the LTR and the internal promoter driving the transgene.

**Origin & function**

The inserted genes comprise a codon-optimised human SPINK5/LEKTI gene which functions as a serine protease inhibitor and the regulatory elements (involucrin promoter and the mutated WPRE intended to increase transgene expression).

The expressed product of the therapeutic gene, SPINK5 is not expected to be toxic or harmful. The gene product is a protein named LEKTI, a serine protease inhibitor expressed in the uppermost compartments of the skin epidermis, which plays a critical role in the regulation of proteases involved in production of cellular components necessary to the maintenance of a healthy skin barrier. The natural gene is expressed in healthy individuals. The SPINK5 gene is under control of a 572bp enhancer derived from the human involucrin promoter which mediates compartment specific gene expression restricted to the supra-basal layers of the epidermis and is resistant to methylation mediated silencing effects. The natural gene is also expressed in healthy individuals and there is confirmatory evidence of in vitro expression of the gene being restricted to the outer layers of the skin. In addition there is evidence of efficacy and safety of this vector use in a mouse model.

The lentiviral vector was produced following transient transfection of human 293T cells by four plasmids using the calcium phosphate precipitation technique. One plasmid encoded the therapeutic transgene. The 3 accessory plasmids encoded separately, the structural proteins and enzymes required for replication, the surface glycoprotein (env coat protein of vesicular stomatitis virus [VSV-G]) and the regulatory elements required for packaging the recombinant. The final product is illustrated in Figure 2 and...
shows the lentivirus 5' and 3' SIN long terminal repeat (LTR) flanking the rev responsive element (RRE), central polypurine tract (cPPT), the transgene expression cassette including the internal promoter INVO, the therapeutic gene SPINK5 and the post-transcriptional regulatory element (WPREmt). Please see attached Risk Assessment for vector maps.

**Evaluation of foreseeable effects**

The GMO under consideration is a lentiviral vector derived from HIV-1. Wild type HIV-1 has been assigned to ACDP hazard group 3 however the recombinant HIV-1 vector has been modified extensively. The GMO is a replication defective, self-inactivating virus vector incapable of stable integration in target cells.

There is only a theoretical risk of generation of RCR following recombination events between the transfer and packaging plasmids during production. The material has not yet been tested for the presence of RCR; however, testing is planned.

Expression of the vector gene product (LEKTI protein) is unlikely to represent a significant risk to the operator as the natural gene product is expressed in healthy individuals. Expression of the therapeutic gene will be limited to the outer layers of the skin. This specificity of site of the target cells and the likelihood of complement inactivation of the VSV-G attachment protein will likely mitigate adverse effects of a possible needle stick injury.

The risk of accidental inoculation by sharp or needlestick injury is low if safety procedures for ACDP class 2 organisms are followed, however, there remains a low risk of seroconversion to the vector product or the vector itself as a universal consequence of introduction of foreign protein into an immunocompetent host.

Based on the above considerations it is judged by BioReliance that the GMO as a replication defective, self-inactivating virus vector, can be derogated from the ACGM classification of the wild type virus and re-classified as suitable for handling under ACGM level 2 conditions.

The intended purpose of the recombinant virus is to transduce stem cells which will be expanded in vitro and used as autograft material in specified patients. It has been judged that risks associated with handling of the recombinant virus and virus-infected cells etc will be appropriately contained using COSHH level 2 safety procedures.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Lentivirus vectors (including HIV vectors) are enveloped viruses, which are generally sensitive to disinfectants including 1% sodium hyperchlorite, 2% glutaraldehyde and formaldehyde. Inhouse studies suggest that 2% Virkon and formaldehyde fumigation are effective for the inactivation of HIV viruses, under the conditions used at BioReliance UK.

All waste must be disposed of in accordance with current Standard Operating Procedure. Current requirements are as follows:

- Liquid waste will be inactivated by either autoclaving (with or without prior chemical inactivation), or by incubation overnight in the presence of Virkon at a final concentration of at least 1% (v/v), prior to discard.
- Solid waste will be collected in suitable clinical waste packaging, appropriately sealed, placed and stored in designated containers within a secure area until collected for off-site incineration. In addition, in Pentlands, animal carcasses will be placed in an incinerator bag in a locked bin and incinerated on-site.
- In the event of a spill, the area will be cleaned using 2% (w/v) Virkon, and 70% (v/v) isopropanol, and mopped up with disposable wipes, which are placed in an autoclave bag, for incineration. Larger spills may be disinfected using solid Virkon, and hoods may be fumigated with formaldehyde vapour if necessary.

In house studies have shown that 1% Virkon is effective for the inactivation for the inactivation of a broad range of viruses, including HIV (Validation Report # 39222).

**MONITORING**
BioReliance works to the quality standards of Good Laboratory Practice (GLP) and Good Manufacturing Practice (GMP). These quality standards require that the performance of all equipment is validated before use, and that equipment is re-validated to a pre-determined schedule. The monitoring and validation is overseen by the Equipment Support Department. In addition, all equipment is required to be maintained and checked for function on a regular basis. The equipment includes all air handling, biosafety cabinets, autoclaves etc.

All disinfectants have a defined expiry date and a documented procedure is in place for preparation of the reagents.

All work with the genetically modified organism will be documented, and will be performed in accordance with standard protocols and/or standard operating procedures.

ENVIRONMENTAL PROTECTION

Humans and some non-human primates are the only natural hosts for HIV-1. All biosafety testing will be performed on this recombinant lentivirus vector, in BioReliance, using class 2 biological safety cabinets in ACGM class 2 containment laboratories.

All work with the recombinant lentivirus vector will be performed at a minimum of containment level 2 with all waste decontaminated appropriately. In order to protect the samples during testing, work will generally be performed at containment level 2, and manipulation of the samples will be performed within a class 2 biosafety cabinet, or negative pressure isolator.

Due to the low risk of spread of the vector, the containment procedures in place within the laboratory areas, and the procedures covering working practices, the overall risk to the environment is considered negligible.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The risk assessment (GMO#228) attached has been submitted to HSE as the organism assessed therein does not conform absolutely to the conditions set for classification of activities already notified under BioReliance Risk Assessment for Connected Programme of Work (CPW#02). Specifically, the GMO was assessed as a 3rd generation, self inactivating lentiviral vector based on HIV-1 and as such considered highly attenuated and replication deficient. RCR testing is requested but has not been performed as yet. The material was assigned to ACGM and COSHH class 2.

The risk assessment attached has been revised to take account of the comments provided by the GMSC, and the content therefore reflects the consensus view of the committee.

Project Additional Information

Purposes of the contained use
To produce a stock of recombinant live attenuated Measles virus expressing Dengue genes. The manufacture will be performed in a containment level 2 cleanroom within our GMP manufacturing facility

Recipient or parental organism
The recipient organism is the schwartz strain of the Measles virus.

Measles Virus (MV) is an enveloped, spherical particle of diameter 120-150nm, containing a helical nucleocapsid of negative stranded RNA which encodes eight known proteins in the order 3'-N-PCV-M-F-H-L-5'. Proteins P,C and V are in overlapping reading frames. Viral proteins have been purified from these products as the haemagglutinin (H), matrix (M), nucleocapsid (N), fusion (F) and phosphoproteins (P). Measles virus can be grouped into a large number of genotypes based on the sequences of the NP or the H gene enabling epidemiological study and is the basis for global vaccination programmes. Virus haemagglutinates primate erythrocytes only and lacks neuraminidase. Virus can be adapted for growth in a number of cell lines or in eggs. Entry into the host cell is via a cell surface receptor (CD46 for Edmonston strain), replication is cytoplasmic and syncytial formation of multinuclear giant cells occurs followed by gradual cell death. Progeny virions exit by budding at the plasma membrane.

The Edmonston strain of MV was isolated in 1954 by cultivation on primary human kidney and primary human amnion cells. It was subsequently adapted to chicken...
embryos and to chicken embryo fibroblast cells to produce the attenuated Edmonston A and B seeds. The Edmonston B vaccine was licensed in 1963 as the first Measles vaccine and was widely used until 1975. The vaccine strain was efficacious but reactogenic, producing fever and rash. Further passages of Edmonston A and B on chicken embryo fibroblast cells produced the more attenuated Schwarz and Moraten viruses, whose sequences have been shown to be identical. The Schwarz vaccine has a history of safe and effective use. Measles virus is very stable (only phenotype exists) and reversion of vaccine strains to those causing pathogenicity has not been demonstrated. Recombination between paramyxoviruses is rare and does not occur naturally. Measles vaccine virus infects only human or primate cells expressing the CD46 receptor. Following inoculation of humans, its replication is transitory and viraemia is very low, therefore the risk of transmission is negligible.

Wild-type Measles virus is an ACDP hazard group 2 pathogen.

Host/vector system

The GMO described here is a recombinant MV vector containing a Dengue virus (DV) construct composed of four envelope domain III (EdIII), each taken from one of the four DV serotypes, fused with the ectodomain of the DV membrane protein (ectoM). Dengue virus is pathogenic flavivirus (mosquito-borne), endemic in vast tropical and sub-tropical areas, which infects 50-100 million humans annually with 25,000 deaths. Infection with one serotype of DV does not confer protection to infection from the other three. In fact DV, in the presence of non-neutralising antibody, can produce disease of increased severity. An effective vaccine against DV must induce antibody against all four serotypes.

The MV vector was derived from one of the safest and most widely used Measles vaccines, the live, attenuated Schwarz strain vaccine virus, by cloning cDNA from viral particles purified from an industrial production batch using procedures designed to optimize cloning fidelity. The vector sequence, present in the construct, is the same as that if the Schwarz vaccinial strain. Investigators demonstrated that the growth kinetics and production yield of the molecular clone and the original virus were identical.

An additional transcription unit (ATU) was inserted into the plasmid (pTM-MVSchw) to enable expression of the transgene product(s). Sequences coding for the tetravalent DV antigen, incorporating the EdIII of DV serotypes 1-4 in combination with the pro-apoptotic ectoM sequence was cloned into the plasmid. The tetravalent DV antigen is designed to induce neutralising and non-facilitating antibodies against all four DV serotypes.

The C-terminal immunoglobulin-like EdIII, a 100 amino-acid sequence stabilized by a disulphide bridge, is involved in receptor binding and contains critical epitopes that elicit both type-specific antibodies (i.e., that cross-neutralise DV but not other Flaviviruses), and serotype-specific antibodies (i.e., that neutralise one DV serotype but not another), thus is the antigen of choice to develop a tetravalent DV vaccine.

The plasmid was transfected into the helper cell line 293-3-46 to enable rescue of the recombinant virus and co-cultivated with primate Vero cells. Recombinant virus rapidly adapted to growth in Vero cells. Construction of the original cloned Schwarz strain included sequencing of the rescued virus following co-culture in CEF and in Verocells. It was found that while the MV sequence remained unchanged following co-culture in CEF cells, co-culture in Vero cell was accompanied by mutation in 2 out of 15,894 nucleotides which were widespread throughout all clones representing the viral population. Thus, it was posited that adaptation of the host cell of Schwarz virus might affect the properties of the virus. However, safety appears to be retained as since 2003, the date of the original cloning of the Schwarz strain, the recombinant virus has been used safely as a vaccine for West Nile Virus.

Origin & function

The GMO under consideration is a replication competent, live attenuated recombinant Measles Virus that contains genetic elements from Dengue Virus (DV). The recombinant virus was derived from the widely used "Schwarz strain" Measles vaccine. The Sponsor has indicated that the recombinant virus is intended to be used as a vaccine against all 4 strains of DV. From information provided by the Sponsor the GMO is unlikely to cause disease. The client has stated that infection by the virus in humans is via the CD4 receptor, but entry into the host cell is also reported to be mediated by CD46 for the Edmonston strain of the virus.

Dengue is a mosquito-borne infection which is found in tropical and sub-tropical climates that causes a severe flu-like illness (dengue fever) and can cause a potentially lethal complication called dengue haemorrhagic fever. Aedes aegypti or Aedes albopictus mosquitoes which feed during the day transmit Dengue to humans. In some Asian countries dengue haemorrhagic fever is a leading cause of serious illness and death among children.
**Evaluation of foreseeable effects**

Expression of the Dengue product of the inserted gene results in an antigen to produce antibodies to Dengue types 1-4. In the absence of any information being provided by the Sponsor, toxicity is assumed and as a result, the material should be handled in line with standard COSHH level 2 safety procedures. Efficacy and safety results have similarly not been disclosed by the Sponsor.

For in vivo work the assays would be performed in suckling mice, adult mice and embryonated chicken eggs.

- 20 suckling mice will be inoculated via the intraperitoneal and intracerebral routes and observed for evidence of viral contaminants for 14 days.
- 10 adult mice will be inoculated via the intraperitoneal and intracerebral routes and observed for evidence of viral contaminants for 21 days.
- Eggs will be inoculated via the allantoic or yolk sac route and incubated for 7 days at the end of which the embryos will be examined for abnormalities/mortality and the allantoic and yolk sac fluids analysed for the presence of haemagglutinating viruses using a haemagglutination assay.

Control measures which would be used for in vivo activities are:

- All work will be performed within containment level 2 laboratories
- Animals will be accommodated in microfiltration cages
- Inoculation of eggs and animals will be performed in class II biological safety cabinets
- Post mortem examination and egg fluid harvests and analysis will be performed in class II biological safety cabinets
- Rodent barriers will be in place at all external exit doors
- Needles will not be re-sheathed after use but will be placed in sharps bin immediately after use.

For in vivo work the assays would be performed

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All waste from the manufacturing pilot labs and cleanrooms must be disposed of in accordance with current SOP's. The current procedures for inactivating viral waste in manufacturing pilot labs and cleanrooms are as outlined below:

Liquid waste is treated with LpH solution (at a concentration of 16ml LpH per 2L of liquid waste) and left for at least 30 minutes contact time. Pipettes are disinfected by repeated aspirating (3 times) with LpH solution (at a concentration of 16ml LpH per 2L of water for irrigation) prior to placing back into the pipette wrapper which is subsequently sprayed with Klercide B and 70% IPA. Flasks and other vessels are wiped down with wipes sprayed with LpH solution, Klercide B and 70% IPA prior to removal from the biosafety cabinet. Gilson pipette tips are discarded into an appropriate vessel which is closed and cleaned prior to removal from the biosafety cabinet. All viral waste is placed into separate autoclave bags which are sanitised with LpH (at a concentration of 16ml LpH per 2L if water for irrigation) prior to exiting the cleanroom/pilot lab. All waste should be double bagged in autoclave bags prior to removal from the pilot lab/cleanroom. The double bagged waste is placed in yellow UN approved outer disposal bags and placed in yellow bins for transfer to the secure containers for waste uplift for off site incineration.

In the event of a spillage the procedures are summarized below:
1. For a small scale spill within the biosafety cabinet (<500ml) and low concentration of material (diluted virus stock or bulk harvest material) the spillage is contained with cleanroom wipes. The affected area is treated with LpH solution (at a concentration of 16ml LpH per 2L of water for irrigation) and left for at least 30 minutes contact time before wiping dry and spraying with 70% IPA and wiping dry again.

2. For a larger volume spill (>500ml) or high concentration of virus (final product or concentrated virus) within the biosafety cabinet work will stop and the spillage will be contained by wiping up with cleanroom wipes. The affected area is treated with LpH solution (at a concentration of 16ml LpH per 2L of water for irrigation) and left for at least 30 minutes contact time before wiping dry and spraying 70% IPA and wiping dry again. A senior member of staff is contacted for further advice and the biosafety cabinet formaldehyde fumigated at the end of the processing day.

3. For any size of spill out with the biosafety cabinet but within the cleanroom operators should leave the cleanroom immediately to contain aerosols and notify senior manufacturing staff. After clearance from senior manufacturing staff and after at least 30 minutes the spillage will be contained with clean room wipes treated with LpH solution left for a 30 minutes contact period. The area once treated with LpH solution is wiped dry and sprayed with 70% IPA and wiped dry again. All actions taken will be recorded in an incident/accident report.

For in vivo work waste bedding and carcasses will be incinerated on site.

To perform a range of Biosafety tests on the material(s) [replication competent, attenuated recombinant Dengue Virus] as requested by the Sponsor (Bioreliance client)

Purposes of the contained use

Biosafety testing of replication competent, attenuated recombinant Dengue Virus (virus-containing supernatant and associated materials). Information from the Sponsor indicates that testing comprises only molecular-based nucleic acid detection assays designed to detect adventitious agents. The risk assessment will therefore be restricted to handling of the GMO under conditions which will not amplify infectious virus.

The GMO under consideration is a replication competent, attenuated recombinant Dengue Virus. The recombinant virus was derived from Dengue virus serotype 4 into which the M and E sequences of Dengue virus serotype 2 have been inserted. The Sponsor has indicated that the recombinant viruses intended to be used as a vaccine against Dengue Virus in humans and is unlikely to cause disease having been shown to be attenuated in healthy dengue- naive adults.

Recipient or parental organism

Dengue virus (DENV) is a pathogenic flavivirus (mosquito-borne), endemic in vast tropical and sub-tropical areas, which infects 50-100 million humans annually with 500,000 cases of severe disease and up to 21,000 deaths. Natural hosts for dengue infection are humans and mosquitoes but the virus can infect several monkey species. DENVs are most commonly transmitted to humans by infected Aedes aegypti mosquitoes and infection is maintained in a human to mosquito to human cycle. The drastic increase in the incidence of DENV infection (approximately 30 fold) over the last 50 years is primarily due to the geographical spread of Ae. Aegypti to new countries and from urban to rural settings Dengue represents a major public health problem throughout the tropical areas of the world and there is an urgent need to develop a protective vaccine.

The causative dengue viruses are members of the genus Flavivirus within the family Flaviviridae. There are four serotypes termed DENV1 to DENV4 and at least three genotypes within each serotype. All flaviviruses are lipid-enveloped, positive-sense, single stranded RNA viruses approximately 55nm in diameter. The genome of approximately 11000 nucleotides is capped at the 5’ terminus but has no 3’ terminal poly A tract. It encodes a single open reading frame, flanked by untranslated regions at each end, which is translated into a polyprotein that is further cleaved into at least ten proteins. The main structural proteins are the capsid which forms a nucleocapsid complex with virion RNA, a non-glycosylated membrane (M) protein derived from a precursor (prM) and an envelope (E) protein which are both embedded in the lipid envelope and displayed on the virion surface. The E protein plays a role in receptor binding and membrane fusion and is known to constitute a major immunogen during flavivirus infection. E protein contains most of the sites that react with neutralising antibodies and with many protective epitopes. There are seven non-structural proteins,
including an RNA-dependent RNA polymerase, a helicase and a protease, which act as enzymes enabling various stages of the virus replication cycle. The viral proteins required for inducing protective immunity are the prM, E and/or NS1 genes and have been used in the development of a number of genetically engineered dengue vaccines.

Following infection the virus is thought to replicate in local dendritic cells, infect macrophages and lymphocytes then enter the bloodstream from where it spreads to the peripheral organs and central nervous system. Most DENV infections are non or mildly symptomatic. The incubation period is generally 4 to 7 days and most symptomatic infections display some or all of the symptoms including sudden onset fever, headache, muscle and joint pain anorexia, abdominal pain and nausea. Rash is common in dengue as are reactions in numbers of white blood cells and platelets circulating in the bloodstream. However, dengue illness can be life threatening when there is evidence of clinically significant bleeding or of severe organ involvement or of severe plasma leakage leading to shock or respiratory compromise. Without proper treatment, the case-fatality rate of the severe form of dengue can reach 20% and most of the hospitalized patients are children.

Infection with one serotype of DENV does not confer protection to infection from the other three. In fact DENV, in the presence of non-neutralising antibody, can produce disease of increased severity. It is likely that an effective vaccine against DENV must induce antibody protective against all four serotypes. There are currently no commercially available DENV vaccines but several candidate vaccines exist at pre-clinical and clinical trial stages.

Wild-type Dengue virus is an ACDP hazard group 3 pathogen.

Host/vector system

The GMO described here is a recombinant serotype 4 dengue virus where the M and E sequences have been replaced with the M and E sequences of Dengue virus serotype 2.1. The recombinant virus is replication competent but has been shown to be attenuated in healthy dengue-naïve adults.

The GMO is a live virus, rDEN2/DEN4Δ30 (ME) and was developed using a chimerization approach. The coding sequences of the prM (membrane precursor) and the E structural proteins of a recombinant DEN4 virus were replaced by those of a prototypic DEN2 strain (New Guinea C) and further attenuated by the introduction of a 30-nucleotide deletion (Δ30) into the untranslated region of the genome. 1.10. This deletion had been previously identified as attenuating in the candidate vaccine rDEN4Δ30, developed at the NIH institute of health, which was found to be safe and immunogenic in healthy adult volunteers.

In preclinical studies, rDEN2/DEN4Δ30(ME) was found to be attenuated in two dengue animal models (SCID-HuH7 mice and rhesus macaques)12. In addition, the virus was found to be poorly infectious for mosquitos by both oral and intrathoracic routes 12. Evaluation of the vaccines in humans was therefore conducted in a double-blind placebo controlled phase I clinical trial and was found to be safe and highly immunogenic. 10 The recombinant virus was found to be highly infectious with 100% of vaccines having developed viraemia and/or seroconverted following administration of a dose of 3log10 pfu virus. The study authors noted four points that indicated safety of the candidate vaccine:

● No symptoms of dengue illness was noted in the vaccinees.

● The level of viraemia noted was very low. Only 11% vaccines inoculated with 3log10 pfu virus showed viraemia with a mean peak titre of 6log 10pfu/ml which is very low compared to the 5 to 9log 101U/ml viraemia levels noted in patients infected with wild type virus. This indicates significant restriction of replication of the vaccine virus in humans.

● Each of the individual isolates in the study cohort that were evaluated (18) retained the delusion mutation and nucleotide changes in the vicinity of the deletion were not observed. Thus the attenuating mutation was highly stable after a period of replication of over two weeks in the vaccines.

● The above properties were displayed by all the dengue species (rDEN4Δ30, rDEN1Δ30and rDEN2/DEN4Δ30(ME) used as vaccines in other clinical trials giving confidence that the attenuating deletion is stable and effective in a range of viruses.

Thus the GMO under consideration shows evidence of safe use in humans at the vaccine dose. However, there remains concern regarding handling of large amounts of virus. The virus is infectious and can replicate to high titre in Vero cells (>7log10 pfu/ml)10 which must be considered when handling the virus in vitro cell culture-based
assays. In addition, there is a potential concern that immunocompromised individuals could experience higher levels of viraemia associated with the vaccine dose.

The recombinant virus has been sequenced and only DENV sequences are present. Similarly, the small vaccine trial showed genetic stability for the virus over the short term of viraemia in the vaccines. The engineered mutation of a 30 nucleotide deletion makes reversion to the wild type phenotype by mutation highly unlikely, however, there is a risk of mutation following subculture in vitro which is pertinent in this GMO risk assessment. Nucleotide and amino acid changes were noted following extended (10 passages) subculture in MRC-5 and Vero cell lines. These changes correlated with a small increase in virus titre and higher pathogenicity (neurovirulence/DENV-induced haemorrhage) in newborn mouse models using inocula containing virus doses higher than those used for human vaccination.

There remains a theoretical risk that recombination might occur with wild-type or other virulent dengue viruses and produce a less attenuated virus. Such a risk is almost negligible in a non-endemic area like the United Kingdom and the risk applies to people that have been previously infected.

**Origin & function**

Expression of the DENV products of the inserted genes results in an antigen designed to produce antibody to DENV serotype 2. There is no additional risk associated with expression of the serotype 2 M and E proteins compared to those of other dengue serotypes. DENV2 proteins have been used as components of live attenuated dengue vaccines which have shown safe use in Phase I clinical trials and are currently under investigation in larger clinical studies in Brazil. In addition, recombinant yellow fever virus-based vaccine expressing tetravalent dengue antigens has shown both safety and efficacy in humans and has progressed to Phase III clinical trials in Australia. The recombinant virus under review is a chimera of DENV 4 and DENV 2 sequences which has produced a replication competent virus. Safety of this recombinant virus rests on evaluation of the extent of attenuation of the virus. As described above, the recombinant virus has shown favorable levels of safety, viraemia and immunogenicity in human clinical trials.

**Evaluation of foreseeable effects**

The recombinant virus is replication competent but has shown evidence of attenuation in mice, rhesus monkeys and mosquitos. In addition, the vaccine virus has been used safely in a Phase I clinical trial in humans and has progressed to further clinical development. The virus is intended for use as a vaccine in humans.

The risk of reversion to a more virulent virus by mutation or recombination is very low. The vaccine virus is a positive sense, single stranded RNA virus for which class of viruses there is little or no evidence of recombination. Deliberate laboratory manipulation of various flavivirus species designed to select and amplify the products of rare recombination events has obtained recombinant viruses only from Japanese encephalitis virus which, moreover, exhibited impaired growth properties. Thus the risk of reversion to wild-type characteristics through either recombination or mutation which would necessarily be required to counteract the effects of a deletion of 30 nucleotides in the genome in this virus is considered to be very low.

Since handling of the GMO will be restricted to laboratory manipulations which will not amplify infectious virus, the risk is judged negligible.

Based on the above considerations, the recombinant virus is judged to be ACGM level 2.

As per BioReliance CPW#2 section 4, the GMO is considered a replication competent virus based on an attenuated strain of a hazard group 3 pathogen. There is a negligible risk of reversion to the wild type phenotype and ACGM level 2 is judged appropriate.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**
Virus is susceptible to several common disinfectants including 1% sodium hypochlorite, 70% ethanol, 2% glutaraldehyde and detergents. Reminders should be given to laboratory personnel that gloved hands should be disinfected prior to withdrawal from the category II safety cabinet.

All waste must be disposed of in accordance with current Standard Operating Procedure. Current requirements are as follows:

Liquid waste will be inactivated by either autoclaving (with or without prior chemical inactivation), or by incubation overnight in the presence of Virkon at a final concentration of at least 1% (w/v), prior to discard.

Solid waste will be collected in suitable clinical waste packaging, appropriately sealed, placed and stored in designated containers within a secure area until collected for off-site incineration. In addition, in Pentlands, animal carcasses will be placed in an incinerator bag in a locked bin, and incinerated on-site.

In the event of a spill, the area will be cleaned using 2% (w/v) Virkon, and 70% (v/v) isopropanol, and mopped up with disposable wipes, which are placed in an autoclave bag, for incineration. Larger spills may be disinfected using solid Virkon, and hoods may be fumigated with formaldehyde vapour if necessary.

In house studies have shown that 1% Virkon is effective for the inactivation of a broad range of viruses.

**MONITORING**

BioReliance works to the quality standards of Good Laboratory Practice (GLP) and Good Manufacturing Practice (GMP). These quality standards require that the performance of all equipment is validated before use, and that equipment is re-validated to a pre-determined schedule. The monitoring and validation is overseen by the Equipment Support Department. In addition, all equipment is required to be maintained and checked for function on a regular basis. The equipment includes all air handling, biosafety cabinets, autoclaves etc.

All disinfectants have a defined expiry date and a documented procedure is in place for preparation of the reagents.

All work with the genetically modified organism will be documented, and will be performed in accordance with standard protocols and/or standard operating procedures.

**ENVIRONMENTAL PROTECTION**

It is expected that conditions appropriate for the parental dengue virus would apply to the recombinant virus. Dengue virus is a lipid-enveloped virus, sensitive to physio-chemical inactivation. It is relatively labile to heat and can be inactivated by exposure to ultra violet and visible light and steam sterilization.

Dengue virus is susceptible to several common disinfectants including 1% sodium hypochlorite, 70% ethanol, 2% glutaraldehyde and detergents.

Humans, some non-human primates and some laboratory strains of mice would be expected to be susceptible to infection with the recombinant virus, however it is significantly attenuated for pathogenicity. The transmissibility of the recombinant virus has been characterized by the Sponsor as very low due to the absence of the mosquito vectors in the United Kingdom.

Humans and mosquitoes are the only natural hosts of dengue virus and infection is not transmitted from human to human.

All work with the recombinant virus will be performed at a minimum of containment level 2 with the additional requirement that no operators who are immunocompromised in any way should handle the recombinant virus. This would include operators who are pregnant or are at risk of pregnancy.

Since the risk assessment will be restricted to handling of the GMO under conditions which will not amplify infectious virus and with consideration of the containment procedures in place within the laboratory areas including the procedures governing working practices, the overall risk to the environment is considered negligible.

Wild-type dengue virus is an ACDP hazard group 3 human pathogen with the potential for serious disease. There is a correlation with the presence of non-neutralising
antibody to dengue virus in an infected person and the likelihood of developing severe disease. The likelihood of developing severe disease is linked to the age and immune status of the infected person.

The recombinant dengue virus under review is replication competent but is attenuated and has shown safe usage in mice, rhesus monkey and mosquito models. There is evidence of safe use of the virus as a vaccine in humans in a small phase I clinical trial. The recombinant virus should therefore present no significant risk to human health and, if handled appropriately with regard to the risk of spread, to the environment.

However, infection with the live recombinant virus could represent a risk to pregnant women and a significant risk to immunocompromised individuals. The risk is unknown as neither of these patient demographics is well-represented in clinical trials involving safety of therapeutics. The risk assessment should be read and understood by all operators and any operator who might be at increased risk for virus infection should not handle the recombinant virus.

The risk, albeit low, to immunocompetent persons nevertheless requires strict adherence to laboratory health and safety rules for containment in order to limit the chance of laboratory acquired infection and subsequent spread to more susceptible individuals.

Due to the presumed attenuated nature of the virus, the containment procedures in place within the laboratory areas, and the procedures governing working practices, the overall risk to human health and safety is considered low.

Due to the potential for severe disease additional advice has been requested from the HSE which will be included in the final version of the risk assessment.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

Please enter comments on the GM safety committee on the risk assessment

The risk assessment (GMO#235_Draft) attached has been submitted to HSE as the organism assessed therein does not conform absolutely to the conditions set for classification of activities already notified under BioReliance Risk Assessment for Connected Programme of Work (CPW#02). Specifically, the GMO was assessed as a replication competent virus based on an attenuated strain of hazard group 3 pathogen. There is a negligible/very low risk of reversion to the wild type phenotype and ACGM level 2 is judged appropriate, however, given the serious pathogenic potential of the parent virus, additional discussion with the HSE is required before a final decision is reached on the classification. The material was assigned to ACGM and COSHH class 2.

The risk assessment attached has been revised to take account of the comments provided by the GMSC, and the content therefore reflects the consensus view of the committee, however the GMO risk assessment will not be finalised until a response from the HSE has been received.

## Project Additional Information

### Purposes of the contained use

Biosafety testing of recombinant lentivirus virus-containing supernatant and associated materials. Testing will comprise sterility testing in the first instance as this is the only test requested by the Sponsor but the GMO risk assessment has included the possibility that other in vitro Bio Safety tests might be performed including, in vitro cell culture assays, molecular-based nucleic acid detection assays, biochemical and immunological based detection assays. All assays are designed to detect adventitious agents.

The GMO under consideration is a recombinant lentivirus derived from a HIV-1 plasmid and has been engineered to be replication competent but attenuated by deletion of the nef element. The virus is intended for therapeutic use in patients infected with wild type HIV-1.

### Recipient or parental organism

The parental virus is Human Immunodeficiency virus type (HIV-1), a species in the genus Lentivirus (family Tetroviridae), which is the primary aetiologic agent of Acquired Immunodeficiency Syndrome (AIDS), a disease that results in the gradual destruction of the helper-T cell population in infected individuals, leading to immunosuppression.

Biosafety of HIV-like viruses/vectors requires most careful evaluation, taking into account the significant pathogenicity of the parent virus.

HIV-1, a category 3 pathogenic can infect man and some non-human primates.
The HIV-1 genome is complex and attenuation of the recombinant virus described here has been achieved by the modification of the nef viral gene encoding factors necessary for virulence. Note that the virus remains replication competent.

**Host/vector system**

The GMO is produced following transfection of Jurkat cells by the HIV-1 plasmid (pELI-71-91). The cells are stably transfected.

**Origin & function**

The virus is intended as a therapeutic in HIV-infected patients. The rationale behind the use of the GMO is that continuous exposure of symptomatic HIV infected patients to an HIV-1 immunogen (nef-deleted but retaining the elements tat, pol, gag, env and vpr will result in a decrease in HIV viral load due to one or more immunological mechanisms including chemokine-mediated restoration of specific cytotoxic T lymphocytes against HIV antigen-expressing cells and activation of B lymphocytes.

**Evaluation of foreseeable effects**

The GMO under consideration is an attenuated replication competent lentivirus derived from HIV-1. Wild type HIV-1 has been assigned to ACDP hazard group 3. Like the wild-type virus, the GMO has been assigned to ACDP hazard group 3 and must be handled at a minimum of BioSafety Level 3. Although the recombinant virus has been modified by deletion of the nef gene which confers significant attenuation of the virus the virus remains replication competent and is therefore classified as suitable for handling only under ACGM level 3 conditions in BioReliance.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Lentiviruses (including HIV vectors) are enveloped viruses, which are generally sensitive to disinfectants including 1% sodium hypochlorite, 2% glutaraldehyde and formaldehyde. In house studies suggest that 2% Virkon and formaldehyde fumigation are effective for the inactivation of HIV viruses, under the conditions used at BioReliance UK. All waste must be disposed of in accordance with current Standard Operating Procedures. Current requirements are as follows:

- Liquid waste will be inactivated by autoclaving in the Category 3 facility, following incubation overnight in the presence of Virkon at a final concentration of at least 1% (w/v).
- Solid waste will be collected in suitable clinical waste packaging, autoclaved in the Category 3 facility, appropriately sealed, placed and stored in designated containers within a secure area until collected for off-site incineration.

In the event of a spill, the area will be cleaned using 2% (w/v) Virkon, and 70% (v/v) isopropanol, and mopped up with disposable wipes, which are placed in an autoclave bag, for incineration. Larger spills may be disinfected using solid Virkon, and hoods may be fumigated with formaldehyde vapour if necessary. In house studies have shown that 1% Virkon is effective for the inactivation of a broad range of viruses, including HIV (Validation Report #39222).

The GMO under consideration is a replication competent infectious Category 3 virus and as such must be handled only under ACGM level 3 conditions. BioReliance standard operating procedures apply: KPSP 3006, KPSP 1901, KPSP2003.

**MONITORING**

BioReliance works to the quality standards of Good Laboratory Practice (GLP) and Good Manufacturing Practice (GMP). These quality standards require that the
performance of all equipment is validated before use, and that equipment is re-validated on a pre-determined schedule. The monitoring and validation is overseen by the Equipment Support Department. In addition, all equipment is required to be maintained and checked for function on a regular basis. The equipment includes all air handling, biosafety cabinets, autoclaves etc.

All disinfectants have a defined expiry date and a documented procedure is in place for preparation of the reagents.

All work with the genetically modified organism will be documented, and will be performed in accordance with standard protocols and/or standard operating procedures.

ENVIRONMENTAL PROTECTION

Humans and some non-human primates are the only natural hosts for HIV-1. All work with the recombinant lentivirus vector will be performed at a minimum containment level 3 with all waste decontaminated appropriately by autoclaving prior to discard and eventual incineration.

Due to the low risk of spread of the virus, the containment procedures in place within the Category 3 laboratory and the procedures governing working practices, the overall risk to the environment is considered low.

Production of GMP seed stocks of replication competent Respiratory syncytial viruses (RSV) on behalf of client

Purposes of the contained use

To produce seed stocks of replication competent genetically modified RSV based upon a clinical isolate previously adapted to tissue culture.

Recipient or parental organism

The recipient organism is chimeric A2 strain of RSV.

Human respiratory syncytial virus (RSV) is an enveloped. Non segmented negative strand RNA virus classified as a member of the Pneumovirinae, a subfamily of the Paramyxoviridae. RSV is ubiquitous, existing as a single serotype but as two antigenic subgroups which co-circulate globally. Infection is spread by respiratory secretions and almost all children are infected by age four years. Outbreaks occur annually in winter or early spring. The immune response to RSV does not protect against reinfection long term (protective immunity is induced but recedes with time) and the infectious rate is about 40% for all exposed people. Antibody to RSV generally decreases illness severity, although cases of inflammatory disease have been observed in vulnerable hosts with low level antibody. Disease may be asymptomatic, mild or severe, including bronchiolitis and pneumonia. RSV represents a particular risk to immune-compromised individuals including the elderly.

The RSV virion consists of a lipid-enveloped, RNAse resistant helical nucleocapsid containing the viral polymerase. Entry into the host cell is by cell-surface fusion; viral replication is cytoplasmic and progeny virions exit by budding at the plasma membrane. The genome is a single strand of negative sense RNA which is transcribed in a sequential stop-restart mode, producing subgenomic mRNAs in which eleven genes and their encoded proteins have been identified. The virus grows in a variety of human and animal cells, notably Hep-2 and A549 cell lines and less efficiently in some bovine cells, however serial propagation of virus infected cultures can result in reduced yields of virus.

All members of the Paramyxoviridae have six essential genes in common, encoding the following:- the RNA -binding N protein of the nucleocapsid; the nucleocapsid phosphoprotein P; the major polymerase subunit L; the nonglycosylated matrix protein M; an attachment glycoprotein G, H or HN; the fusion glycoprotein F. Individual virus...
species have one to five additional genes. Manipulation of these genes has produced alteration in the encoded proteins which, under selection pressure has produced phenotypes useful for vaccine development.

For some years vaccine research has centred on live cold-passaged (cp), temperature-sensitive (ts) RSV vaccines (denoted cpts vaccines) which are thought to be most useful in young infants. The availability of cDNA technology has allowed further refinement of existing live attenuated cpts candidate vaccines to produce engineered vaccines that are satisfactorily attenuated, immunogenic, and phenotypically stable.

Wild-type RSV is an ACDP hazard group 2 pathogen.

Host/vector system

The recombinant viruses described here have been produced by synthetic generation of wild type viral nucleic acid sequence.

No new insets are present and the viruses were recovered from Vero cells.

The GMO's are replication competent but are host range restricted, replicating in Vero cells and Hep-2 (human epithelial) cells. The GMO's have not been attenuated in any way therefore as infectious viruses there is a risk of RSV infection to any non-immune host. Infection with RSV is not expected to be clinically significant in healthy, immunocompetent adults but there is a risk to immunocompromised individuals. Risk is likely to be minimal when handled appropriately under Category 2 containment.

Origin & function

The risk assessment considers risk from the perspective of the virus as synthetically-produced wild type virus which for RSV is ACDP Class 2.

The genetic manipulations have not altered the risk for the synthetic RSV, which is assumed to not be significantly changed from that of the wild type virus. There is no additional risk associated with the insert since no new genes have been inserted into the recombinant viruses. All wild type RSV strains are ACDP class 2 pathogens.

Evaluation of foreseeable effects

Wild type RSV - all strains are ACDP class 2 pathogens.

The recombinant RSV's are replication competent and will be propagated in vitro in a designated cell lines. The Sponsor states that the viruses are host range restricted and can grow only in Vero and HEP2 cell lines but there is a significant amount of literature reporting growth of wild type RSV in other cell lines e.g. primary human respiratory epithelia and the A549 cell line. It should be noted therefore that in vitro propagation of these viruses can result in high titres of virus for which there is a significant risk of aerosolisation. All handlers will be made aware of this risk and the requirement for strict adherence to aseptic technique and good laboratory safety practices appropriate to ACDP class 2. For this purpose a "read and understand" log is part of BioReliance's risk assessment and should be signed by all personnel prior to handling the GMOs.

The vaccine viruses are negative sense RNA viruses for which class of viruses, recombination has not been observed, thus the risks considered for these GMO's are those of the wild type virus.

Based on the considerations, the recombinant respiratory syncytial viruses are judged to be ACGM level 2.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Disposal of all waste from the manufacturing cleanrooms must be in accordance with current SOPs. Procedures currently in place for inactivating viral waste in manufacturing pilot labs and cleanrooms are as outlined below:

Liquid waste is treated with LpH solution (at a concentration of 16ml LpH per 2 litres(L) of liquid waste) and left for at least 30 minutes contact time. Pipettes are disinfected by repeated aspiration (3 times) with LpH solution (at a concentration of 16m; LpH per 2L of ‘water for irrigation’) before being replaced in the pipette wrapper which is then sprayed with Klercide B and 70% IPA. Flasks and other vessels are wiped down with the wipes sprayed with LpH solution, Klercide B and 70% IPA prior to their removal from the biosafety cabinet. Gilson pipette tips are discarded into an appropriate decontamination vessel which is closed and cleaned prior to its removal from the biosafety cabinet. All viral waste is placed into separate autoclave bags which are sanitised with LpH (at a concentration of 16ml LpH per 2L of 'Water for irrigation') prior to exiting the cleanroom/pilot lab. All waste should be double bagged in autoclave bags prior to removal from the pilot lab/cleanroom. The double bagged waste is then placed in yellow UN approved outer disposal bags and palced in the yellow bins for transfer to the secure containers intended for waste uplift for offsite inactivation.

In the even of a spillage the procedures are summarized below:

1. For a small scale spill within the biosafety cabinet (<500ml) and low concentration of material (Diluted virus stock or bulk harvest material), the spillage is contained with cleanroom wipes. The affected area is treated with LpH solution (at a concentration of 16 ml LpH per 2L of 'Water for irrigation') and left for at least 20 minutes contact time before wiping dry and re-spraying with 70% IPA followed by a second wipe clean.

2. For a larger volume spill (>500ml) or high concentration of virus (final product or concentrated virus) within the biosafety cabinet, work will stop and the spillage contained by wiping up with cleanroom wipes. The affected area is treated with LpH solution (at a concentration of 16ml LpH per 2L of 'Water for irrigation') and left for at least 30 minutes contact time before wiping dry and re-spraying with 70% IPA followed by a second wipe clean. A senior member of staff should be contacted for further advice and the biosafety cabinet fumigated with formaldehyde at the end of the processing day. There would be no strict requirement for the cabinet to be "out of commission" and not used between spillage/clean and fumigation, however, since use of the cleanroom is limited to one product at a time, there would be no risk of contamination to other test samples.

3. For any size of spill out with the biosafety cabinet but contained within the cleanroom, operators should leave the cleanroom immediately to mitigate risk from aerosols and notify senior manufacturing staff. Following a waiting period of at least 30 minutes and when permission for re-entry has been given by senior manufacturing staff, the spillage will be contained with cleanroom wipes treated with LpH solution with a minimum 30 minutes contact period. The area once treated with LpH solution is wiped dry and re-sprayed with 70% IPA followed by a second wipe clean. All actions taken will be recorded in an incident/accident report.

The risk assessment attached has been revised to take into account of the comments provided by the GMSC, and the content therefore reflects the consensus of the committee.

Note that the committee endorses the view that a cautionary approach to classification be adopted. The attached risk assesment (BioReliance GMO#261) reflects the planned manufacturing activities at BioReliance, taking into account of manufacturing processes and scale.

### Project Additional Information

**Purposes of the contained use**

The proposed use is two-fold: firstly establish ing virus batch titre of the recombinant lentivirus and secondly the subsequent use of the GMO recombinant lentivirus as a positive control in BioSafety testing designed to supply system suitability information during testing of the Sponsor's test articles to be submitted for future testing. Testing will therefore compromise a basic virus titration assay (as described above) and routine assays for the detection of replication competent lentiviruses (RCL). The titration assay is deSigned to quantify the level of viral infectivity in the current GMO and the RCL assay is designed to detect replication competent lentivirus in the Sponsor's future test article in assays which will include a positive control culture inoculated with a dilution of the GMO. All handling, inoculation, culture maintenance and passage will be performed in the Category 3 laboratory (for initial titration and subsequent use in routine testing).

**Recipient or parental organism**
The parental virus is Human immunodeficiency virus type 1 (HIV-1), a species in the genus Lenlivirus (family Retroviridae), which is the primary aetologic agent of Acquired Immunodeficiency Syndrome (AIDS), a disease that results in the gradual destruction of the helper-T cell population in infected individuals, leading to immunosuppression. Assessment of the biosafety of HIV-like viruses/vectors requires most careful evaluation, taking into account the significant pathogenicity of the parent virus.

HIV-1, a category 3 pathogen can infect man and some non-human primates. It is infectious to a range of cell lines in vitro.

The HIV-1 genome is complex and attenuation of the recombinant virus described here has been achieved by the deletion of the nef, vpr, vif and vpu viral genes encoding factors necessary for virulence. Note that the virus remains replication competent necessitating strict adherence to handling procedures appropriate to Category 3 pathogens. All handling, inoculation, culture maintenance and passage will be performed in the Category 3 laboratory (for initial titration and subsequent use in routine testing).

Handling of this GMO in BioReliance should present no hazards additional to those routinely encountered in the Category 3 laboratory where other Category 3 pathogens including HIV are handled.

Host/vector system

The GMO is produced following transfection of an unspecified producer cell line by the HIV-1 plasmid (HXB2-del-acccUCS?). The cells are stably transfected.

The virus containing supernatant is inoculated and amplified in C8166 lymphoblastoid cells.

Origin & function

The Sponsor's future test articles are (a range of) replication incompetent lentiviral vectors based on H1V-1 . This material, although Class 2 pathogens, would be handled under Class 3 containment conditions due to the requirement for the use of a Class 3 pathogen as a positive control in the routine assay.

The GMO under review is intended as a positive control for use in in vitro assay systems, specifically related to detection of RCl as described in Sections 5 and 6 above. The rationale behind the use of the GMO is to provide a system suitability control ie a positive control virus that is also a genetically modified virus based on HIV-1 in order to better mimic the test article and achieve the optimum sensitivity and accuracy of the test system.

Evaluation of foreseeable effects

The GMO under consideration is an attenuated replication competent lentivirus derived from HIV-1. Wild type HIV-1 has been assigned to ACDP hazard group 3. Like the wild-type virus, the GMO has been assigned to ACDP hazard group 3 and must be handled at a minimum of BioSafety level 3. Although the recombinant virus has been modified by deletion of the nef, vif, vpr and vpu gene which confers significant attenuation of the virus the virus remains replication competent; therefore, the modified virus is classified as suitable for handling only under ACGM level 3 conditions in BioReliance.

All handling, inoculation, culture maintenance and passage will be performed in the Category 3 laboratory (for initial titration and subsequent use in routine testing).

Handling of this GMO in BioReliance should present no hazards additional to those routinely encountered in the Category 3 laboratory where other Category 3 pathogens including HIV are handled.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not Applicable
lentiviruses (including HIV vectors) are enveloped viruses, which are generally sensitive to disinfectants including 1% sodium hypochlorite, 2% glutaraldehyde and formaldehyde. In house studies suggest that 2% Virkon and formaldehyde fumigation are effective for the inactivation of HIV viruses, under the conditions used at BioReliance UK.

All waste must be disposed of in accordance with current Standard Operating Procedures. Current requirements are as follows:
- Liquid waste will be inactivated by autoclaving in the Category 3 facility, following incubation overnight in the presence of Virkon at a final concentration of at least 1% (w/v).
- Solid waste will be collected in suitable clinical waste packaging, autoclaved in the Category 3 facility, appropriately sealed, placed and stored in designated containers within a secure area until collected for off-site incineration.
- In the event of a spill, the area will be cleaned using 2% (w/v) Virkon, and 70% (v/v) isopropanol, and mopped up with disposable wipes, which are placed in an autoclave bag, for incineration. Larger spills may be disinfected using solid Virkon, and hoods may be fumigated with formaldehyde vapour if necessary.
- In house studies have shown that 1% Virkon is effective for the inactivation of a broad range of viruses, including HIV (Validation Report # 39222).

The GMO under consideration is a replication competent infectious Category 3 virus and as such must be handled only under ACGM level 3 conditions. BioReliance standard operating procedures apply: KPSP 3006, KPSP 1901, KPSP2003.

**MONITORING**
BioReliance works to the quality standards of Good Laboratory Practice (GLP) and Good Manufacturing Practice (GMP). These quality standards require that the performance of all equipment is validated before use, and that equipment is re-validated to a pre-determined schedule. The monitoring and validation is overseen by the Equipment Support Department. In addition, all equipment is required to be maintained and checked for function on a regular basis.

The equipment includes all air handling, biosafety cabinets, autoclaves etc.

All disinfectants have a defined expiry date and a documented procedure is in place for preparation of the reagents.

All work with the genetically modified organism will be documented, and will be performed in accordance with standard protocols and/or standard operating procedures.

**ENVIRONMENTAL PROTECTION**
Humans and some non-human primates are the only natural hosts for HIV-1. All biosafety testing will be performed on this recombinant lentivirus, in BioReliance in at least ACGM class 3 containment laboratories.

All work with the recombinant lentivirus vector will be performed at a minimum of containment level 3 with all waste decontaminated appropriately by autoclaving prior to discard and eventual incineration. Due to the low risk of spread of the virus, the containment procedures in place within the Category 3 laboratory and the procedures governing working practices, the overall risk to the environment is considered low.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y
The risk assessment (GMO#262) attached has been submitted to HSE as the organism assessed therein does not conform absolutely to the conditions set for classification of activities already notified under BioReliance Risk Assessment for Connected Programme of Work (CPW # 02).
Specifically, the GMO was assessed as a Class 3 virus.

Date of Significant Change

Project Additional Information
Purposes of the contained use

To perform one or more BioSafety tests to exclude the presence of adventitious agents in the Sponsor's GMO material. All handling, inoculation, culture maintenance, passage and storage of test materials will be performed under ACDP BioSafety Level 2 conditions. Additional endpoint testing (e.g. by Molecular methods such as QPCR, QPERT etc), if such is required, will be performed under ACDP BioSafety Level 2 conditions.

Recipient or parental organism

The host cell line is a human bone marrow Mesenchymal Stem Cell (MSC) line from a healthy donor, produced by single clonal selection of cells transduced by a replication incompetent lentiviral vector containing one or more therapeutic genes. MSCs are multipotent stromal cells capable of producing a variety of specialised differentiated cell types including oestoblasts, adipocytes, chondrocytes and myocytes. They contribute to the maintenance and regeneration of diverse tissues after injury and during chronic inflammation. The damaged tissue releases signals which result in the mobilization of MSCs and their subsequent recruitment to the site of injury. Tumours are seen by the body as something akin to a chronic wound, and as a result, MSCs are actively recruited to the tumour environment, resulting in a potential to exploit MSCs as targeted vectors in anti-tumour therapy.

Mammalian cells are not themselves considered pathogenic to animals or humans, and are viewed as especially disabled hosts, as they are considered incapable of survival outwith their highly specific tissue culture environment, and would be rapidly cleared by the host immune response in the event of accidental exposure of an operator (Ref.: ACGM Compendium of Guidance 2016). Many cell cultures have a long history of safe use, and are considered unlikely to cause harm to humans, animals or plants and are viewed as presenting minimal risk to operators and the environment (in the absence of adventitious agents).

MSCs are considered safe (Ref.: Zhao Q. et al, J Cellular Immunotherapy (2016) 2:3-20)- they do not form teratoma and can be used for tissue regeneration and repair. On 19 June 2018, 850 clinical trials were identified as extant in "ClinicalTrials.gov". If this safe description applies in a clinical setting with parenteral inoculation of MSCs in patients, in vitro use i.e. handling of limited volumes of MSCs in a laboratory setting with no expected direct contact with operators should be considered safe.

However, as all cell lines have the potential to harbour or amplify adventitious agents, and since testing for presence of such agents will be performed in the test facility, all procedures involving the culture of the cell line will be performed under containment level 2 (for COSHH purposes).

Host/vector system

The GM cell line has been transduced by a replication incompetent second generation lentiviral vector based on HIV. The parental virus of this type of lentiviral vector is Human immunodeficiency virus type 1 (HIV-1), a species in the genus Lentivirus (family Retroviridae) and the primary aetiologic agent of Acquired Immunodeficiency Syndrome (AIDS), a disease that results in the gradual destruction of the helper-T cell population in infected individuals leading to immunosuppression. Lentiviruses are large single-stranded, positive sense, enveloped RNA viruses which contain an RNA-dependent DNA polymerase. Following entry into the host cell, viral RNA is reverse-transcribed into a covalently linked circle of double-stranded DNA (provirus) which is integrated into the cellular DNA by action of the virus-encoded integrase and other cellular co-factors. The integrated proviral DNA thereafter remains latent or is transcribed by cellular transcriptional activators and is replicated in tandem with the host cell DNA. All lentiviruses contain several genes in addition to the three major genes encoding the main retrovirus structural proteins Gag and Env and the main enzymatic protein Pol.

Several factors make retroviral vectors attractive tools for gene therapy including their relatively large cloning capacity
and their ability to stably integrate into the host cell genome, which is a likely requisite for long-term expression. Further, they do not transfer viral genes and avoid transduced cells that are destroyed by virus-specific cytotoxic T cells. In addition to these characteristics that are common to all retroviral vectors, lentiviral vectors can transduce non-dividing cells, a crucial asset for genetically modifying the main target tissues of gene therapy such as the brain, soft-tissue organs and the haematopoetic system, and enable efficient in vivo delivery, integration and stable expression of transgenes. However, biosafety of HIV-based vectors requires most careful evaluation, taking into account the significant pathogenicity of the parent virus.

The HIV-1 genome is complex, comprising the standard retroviral elements that are each synthesized as three polyproteins that produce either, the inner virion structure-Gag (cleaved into matrix, capsid and nucleocapsid proteins), the viral polymerase enzyme-Pol (producing reverse transcriptase and endonuclease/integrase enzymes) or the glycoprotein of the virion envelope-Env. The HIV 1 genome also encodes proteins with regulatory and auxiliary functions. These comprise two essential regulatory elements: Tat, which activates transcription and Rev, which modulates viral RNA transport. In contrast, the elements, Nef, Vpr, Vif and Vpu are non-essential for replication in certain tissues and are termed accessory proteins. These small proteins are multifunctional and in general, Vif and Nef function as infectivity enhancers by suppression of cellular enzymes and down regulation of host cell surface receptors. Vpr is associated with intracellular virus transport and cell cycle arrest and Vpu augments the release of progeny virus.

The recombinant lentiviral vector described here has been modified extensively as detailed below, such that it can be derogated and re-classified as suitable for handling under ACGM level 2 containment conditions in BioReliance. Production of the lentiviral vector encoding the therapeutic transgene has been accomplished by transient cotransfection of the human epithelial cell, HEK 293 with a combination of three plasmids (transfer, packaging and envelope vectors). The Sponsor has stated that the transfer vector contains the viral L TRs, psi (41) packaging signal sequence and therapeutic gene. The packaging vector encodes the gag, pol, Rev and Tat genes. The envelope vector encodes Env (VSV-G) gene. On transfection of the producer cell line (HEK 293), this split packaging system enables production of lentiviral particles that contain only the genetic elements contained in the transfer vector. Four virulence genes, negative factor (nef), virion infectivity factor (vif), viral protein U (vpu) and viral protein R (vpr) have been deleted from the viral packaging construct. Additionally, the wild type envelope protein has also been deleted from the construct.

The GMO under evaluation is a 2nd generation replication-defective, self-inactivating (SIN) vector and has undergone further modification by introduction of a deletion in the U3 region of the 3’ long terminal repeat (L TR) of the DNA used to produce the vector RNA. During reverse transcription, this deletion is transferred to the 5’ L TR of the proviral DNA, the implication being that sufficient viral sequence can be eliminated to abolish transcriptional activity of the L TR (i.e. no transcription of the full length virus is possible after it has been incorporated into the host cell) thereby abolishing the ability to produce full length vector RNA in transduced cells which minimizes the risk of emergence of replication competent retroviruses.

The Sponsor has stated that the lentiviral vector used to transduce the MSC cells is non-mobilisable and nonreplicative, as it lacks the required genes for assembly of the virus. Since only the transfer vector contains L TRs and a psi sequence, only it can integrate into the host cell chromosome and such a minimal genome cannot produce replication competent virus.

Origin & function

The Sponsor's test article described here and related test articles (same cell line transduced using the same lentiviral vector platform but expressing different therapeutic genes) are cell lines transduced with second generation, self-inactivating lentiviral vectors expressing human proteins intended for therapeutic use in humans. These materials would be handled in the test facility during the performance of a range of biosafety testing at a
Evaluation of foreseeable effects

The Sponsor has indicated the use of Addgene vector pWPT1 to produce the transfer plasmid containing the L TR with SIN element and encoding the cytidine deaminase gene and Woodchuck Hepatitis virus Post-translational Regulatory Element; two separate accessory plasmids encoding CMV, Gag, Pol, RRE, Rev and Tat (Packaging Vector) which will produce the surface glycoprotein, the structural proteins, nucleic-acid polymerases/integrase, reverse transcriptase and regulatory elements required for packaging a recombinant lentiviral particle and VSV-G, PolyA and CMV promoter (Envelope Vector) which will produce the envelope protein and enable infectivity of the final packaged vector. The system is based on 3 non-overlapping expression constructs in order to increase the segregation of cis and trans acting functions and has been engineered such that minimal homology exists between packaging and transfer vectors, thereby reducing the likelihood of homologous recombination and the generation of replication competent lentiviruses (RCLs). In addition, the packaging construct is deleted of four additional HIV accessory proteins; vpu, vpr, nef, vif. The Rev responsive element (RRE) maintained in the gag/pol plasmid makes the gag/pol gene expression rev dependent. The transfer vector encodes the transgene and sequences necessary for expression, encapsidation, reverse transcription and integration of the viral genome. In order to minimize the risk of RCL generation, the 3’ L TR of the transfer vector has been deleted in the U3 region by the Sponsor. The introduction of this 254 bp deletion is designed to abolish the production of full-length vector RNA in transduced cells by exploiting the reverse transcriptase mechanism which generates both U3 regions from the 3’ of the viral genome, thus transferring the deletion to the 5’ L TR of the proviral DNA. The lentiviral particle is therefore conceived with a self-inactivating mechanism that enables the production of infective particle only in the first run of infection. A Woodchuck Hepatitis Virus Post-transcriptional Regulatory Element (WPRE) sequence is also included in the transfer vector, which has the effect of increasing transgene expression by transcript stabilisation. Routinely mutated WPRE sequences are designed lacking a transcription fragment of the potentially oncogenic woodchuck hepatitis virus-X protein, however, the Sponsor has not indicated that is the case in this submission. The likelihood of reversion to wild type virus by recombination events is effectively zero in a virus with such extensive deletions. Further, due to deletions in the U3 region of the 5’ and 3’ L TRs, the vector is self-inactivating, and therefore represents minimal risk of generation of RCR.

The recombinant lentivirus vector will integrate into target cells, thus there is a theoretical risk of insertional mutagenesis, however the nature of self-inactivation, where both L TRs are inactivated upon integration into the target cell genome, makes it unlikely that cellular coding sequences located adjacent to the vector integration site would be aberrantly expressed due to genetic elements within the vector. In addition, the self-inactivated vector will replicate only once following initial infection. This very limited replication will occur only in the transduced cells that come into contact with the vector with no spread to adjacent cells further limiting the likelihood of significant effects on cellular genes. Thus, in the very unlikely event of transfer of the viral vector to a handler or other mammalian hosts, the extent of spread would be limited to the cells initially transduced.

The recombinant lentivirus has been pseudotyped with an alternative coat protein, the vesicular stomatitis virus glycoprotein (VSV) G protein, with consequent alteration to the tissue-tropism range of the vector to include human, mouse and bovine cell types. Biosafety testing will involve handling of the vector in a variety of cell types however, there is published evidence that lentiviruses pseudotyped with VSV-G are rapidly inactivated by human complement which would reduce the potential of infection from a needle stick injury.

As described above, the risk associated with the GMO is expected to be low due to the presence of the SIN-L TR element. Self inactivation minimizes the likelihood that RCR will be produced. Further, it reduces the likelihood that cellular coding sequences located adjacent to the vector integration site will be aberrantly expressed, either due to the promoter activity of the 3’L TR or through an enhancer effect. Finally, the SIN design prevents potential transcriptional interference between the L TR and the internal promoter driving the transgene.
The Sponsor has stated that the entire genome of the lentiviral vector has been sequenced and a conclusion reached that no components enabling replication competent lentivirus were present. Testing for Replication competent lentivirus has been performed on the GMO cell seed stock has been performed by the Sponsor but the RCL test status of this GMO material is not known. The material has been submitted to the test facility and the sister test facility (BioReliance US) for RCL testing.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not Applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

The GMO is a replication defective, self-inactivating virus vector incapable of stable integration in target cells. There is a theoretical risk of generation of RCR following recombination events between the transfer and packaging plasmids during production. The material has not yet been tested for the presence of RCL, however, testing is planned. Expression of the vector gene product (cytidine deaminase) is unlikely to represent a significant risk to the operator. Further, it is unlikely that an isolated contamination incident would enable expression of sufficient quantities of the protein to cause a clinical effect. The likelihood of complement inactivation of the VSV-G attachment protein would also likely mitigate adverse effects of a possible needle stick injury. The risk of accidental inoculation by sharp or needlestick injury is low if safety procedures for ACDP class 2 organisms are followed; however, there remains a low risk of seroconversion to the vector product or the vector itself as a universal consequence of introduction of foreign protein into an immunocompetent host. It is expected that exposure to the test article would not be harmful in an immunocompetent individual, however the effects of the antibody or an unborn foetus are not known. Therefore COSHH assessment recommends that this material be handled under COSHH level 2 containment and that pregnant women avoid contact with large volumes of the test article. Based on the above considerations, it is judged that the GMO as a replication defective, self-inactivating virus vector, can be derogated from the ACGM classification of the wild type virus and re-classified as suitable for handling under ACGM level 2 conditions.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The main risks associated with the processes to be used are where infectious agents are handled at high titre or under conditions, which may result in amplification of the virus (i.e. cell culture assays). While the wild-type virus is restricted to infection of CD4+ cells, this recombinant virus vector has been pseudotyped with VSV-G env so that infection of a broad range of mammalian cell types is possible in a laboratory setting. However, that the recombinant virus is replication incompetent mitigates this risk significantly. The major risk of operator exposure is via direct inoculation (e.g. needlestick injury), ingestion, or droplet or aerosol exposure of mucous membranes or broken skin. Operators should be aware that eye infections can have serious consequences, and so the use of safety glasses is particularly important. Care should be taken at all times to ensure that all operators wear appropriate protective clothing that is correctly fitted and fastened appropriately. All biosafety testing of this recombinant lentivirus vector should be performed in at least ACGM class 2 containment laboratories. All work with the recombinant lentivirus vector will be performed at a minimum of containment level 2. In order to protect both the samples during testing, and the operator, all handling of this GMO will be performed at containment level 2 within a class 2 biosafety cabinet or negative pressure isolator. Lentivirus vectors are enveloped viruses, which are generally sensitive to disinfectants including 1 % sodium
hyperchlorite, 2% glutaraldehyde and formaldehyde. In house studies suggest that 2% Virkon and formaldehyde fumigation are effective for the inactivation of HIV viruses, under the conditions used at BioReliance UK. All waste must be disposed of in accordance with current Standard Operating Procedure. Current requirements are as follows:

Liquid waste will be inactivated by either autoclaving (with or without prior chemical inactivation), or by incubation overnight in the presence of Virkon at a final concentration of at least 1% (w/v), prior to discard.

Solid waste will be collected in suitable clinical waste packaging, appropriately sealed, placed and stored in designated containers within a secure area until collected for off-site incineration. In addition, in Pentlands, animal carcasses will be placed in an incinerator bag in a locked bin, and incinerated on-site.

In the event of a spill, the area will be cleaned using 2% (w/v) Virkon, and 70% (v/v) isopropanol, and mopped up with disposable wipes, which are placed in an autoclave bag, for incineration. Larger spills may be disinfected using solid Virkon, and hoods may be fumigated with formaldehyde vapour if necessary.

In house studies have shown that 1% Virkon is effective for the inactivation of a broad range of viruses, including HIV (Validation Report # 39222).

BioReliance works to the quality standards of Good Laboratory Practice (GLP) and Good Manufacturing Practice (GMP). These quality standards require that the performance of all equipment is validated before use, and that equipment is re-validated to a pre-determined schedule. The monitoring and validation is overseen by the Equipment Support Department. In addition, all equipment is required to be maintained and checked for function on a regular basis. The equipment includes all air handling, biosafety cabinets, autoclaves etc.

All disinfectants have a defined expiry date and a documented procedure is in place for preparation of the reagents. All work with the genetically modified organism will be documented, and will be performed in accordance with standard protocols and/or standard operating procedures.

Humans and some non-human primates are the only natural hosts for HIV-1. All biosafety testing will be performed on this recombinant lentivirus vector, in BioReliance, using class 2 biological safety cabinets in ACGM class 2 containment laboratories.

All work with the recombinant lentivirus vector will be performed at a minimum of containment level 2 with all waste decontaminated appropriately. In order to protect the samples during testing, work will generally be performed at containment level 2, and manipulation of the samples will be performed within a class 2 biosafety cabinet, or negative pressure isolator.

Due to the low risk of spread of the vector, the containment procedures in place within the laboratory areas, and the procedures governing working practices, the overall risk to the environment is considered negligible.

**Purposes of the contained use**
To perform one or more Biosafety tests to exclude the presence of adventitious agents in the Sponsor's GMO material.
All handling, inoculation, culture maintenance, passage and storage of test materials will be performed under ACDP Biosafety Level 2 conditions.

**Recipient or parental organism**
Herpesviruses are relatively large enveloped double-stranded DNA viruses in the family of Herpesviridae in order of...
Herpesvirales. They have large genomes and virions are generally in the size of 180-225 nm in diameter.
Equid herpesvirus-1 is of a genus of Varicelloviruses that causes wide-spread infection in horses. Primary infection
by EHV-1 is characterized by upper respiratory tract disease of varying severity that is related to the age and
immunological status of the infected animal.
The RacH strain was derived from EHV-1 and was attenuated by repeated passage in cell culture. Wild-type EHV-1
and the RacH strain are considered to not pose any health risks to humans, however, the RacH EHV-1 can replicate
in vitro in various cell type including MDBK and Vero cells.

Host/vector system
The RacH EHV-1 genome was originally cloned as a bacmid that included a CMV-driven GFP gene as a marker. An
expression cassette encoding the gene of interest (Rabies G protein) was then cloned into the RacH EHV-1 backbone
using a two-step recombination process. The donor DNA was inserted into an existing ORF1/2 deletion present in the
RacH genome. This deletion has been shown to not negatively impact RacH replication in vitro or change its
immunogenicity.
A codon-optimized gene encoding the Rabies G (glycoprotein) from Rhabdovirus strain SADB19 is inserted in the
RacH backbone. The insert is under the control of the CMV5 mammalian promotor with a polyadenylation signal
inserted in the ORF1/2 region described above. SADB19 is the standard vaccine strain used for vaccinating animals
globally and has a safe history of use.
The safety of RacH-based products in equines has been demonstrated for several modified live vaccines. For
example, the Rhinopneumonitis Modified Live Virus vaccine, Rhinomune® is an example of a licensed vaccine
derived from RacH. In addition to horses, RacH based vectors have been tested in other species including cattle,
pigs, dogs, cats and mice without any serious side effects.

Origin & function
The recombinant virus is intended as a veterinary vaccine. The recombinant virus has been submitted for Biosafety
testing in the Merck BioReliance Services facility.
In vitro assays for detection of adventitious agents will be performed.

Evaluation of foreseeable effects
The genetic modification itself poses no additional risk to the health of the operator, the wider community or the
environment.
The recombinant vector is a replication-competent EHV-1, expressing a single Rabies virus G protein. Although the
vector is replication-competent it is not expected to be pathogenic to humans or animals. The construct is known to
replicate in a variety of vertebrate cells, including some commonly used for in vitro biosafety assays (e.g. Vero,
MDBK). The G protein expressed from the inserted gene is not known to have any associated toxicity, although the
protein may elicit an antigenic response if in contact with an individual’s immune system.
The risk of accidental inoculation by sharp or needlestick injury is low if safety procedures are followed; it is expected
that exposure to the test article would not be harmful in an immune competent individual, however the effects on an
unborn foetus are not known.
The recombinant virus should present no significant risk to human health, or to the environment; however after
assessment it is recommended that this material be handled under a minimum of containment level 21ACGM Class 2
containment and that pregnant women avoid contact with large volumes of the test article.
The recombinant virus is a live, attenuated vaccine strain which has not undergone inactivation but has been
attenuated, although the attenuation factor has not been determined. A* work using the recombinant virus, including
disposal of waste materials, will be performed at a minimum of containment level 2.

02/03/2022

Project Ref 557/21.3

Date Ackn’d CU2 Project Title Class CultureVolClass2 CultureVolumeClass3-4

02/03/2022
A Simian Retrovirus Type 3 (SRV-3) viral seed stock synthetically produced by the transfection of 293T cells

As a retrovirus, the SRV-3 is an enveloped single stranded RNA virus. It has an icosahedral capsid, and its genome contains four genes: gag, pro, pol and env. It transcribes its RNA genome into double-stranded DNA by using a Mg2+ dependent reverse transcriptase enzyme.

SRV-3, formerly known as Mason-Pfizer Monkey Virus (M-PMV) is a beta retrovirus, i.e., simian type D retrovirus and is enzootic in many populations of Asian monkeys of the genus Macaca and is associated with immunodeficiency diseases in these animals. In infected macaques, SRV-3 may be present in blood, saliva, urine, and other body fluids.

SRV-3 is not classified as a Specified Animal Pathogen nor cited on The Advisory Committee on Dangerous Pathogens (ACDP) "Approved List". The United States Centers for Disease Control and Prevention (CDC) and National Institutes for Health (NIH) classify SRV as a Hazard Group 2 pathogen.

The recombinant SRV-3 virus stock will be used to generate a further virus bank at Merck BioReliance® Services (UK) which will serve as a positive control for specific (non-routine) replication-competent retrovirus (RCR) testing.

The virus is synthetically produced by the transfection of 293T cells. The virus has a wild-type-like genome and is not attenuated or deliberately modified. The virus therefore poses no greater risk than the wild-type virus. The 293T cells are transiently transfected using a single plasmid expressing the full-length SRV-3 genome. The plasmid, a standard cloning vector (pIC119H) is of pUC origin. Additional to the SRV-3 genome it encodes standard selective markers beta-lactamase (ampicillin resistance). A full sequence and annotation is included in the risk assessment.

The recombinant virus will be used as a positive control specific (non-routine) replication-competent retrovirus (RCR)
Testing conducted at Merck BioReliance Services.

**Evaluation of foreseeable effects**

The virus will be cultured to high titres for the preparation of the virus bank in cell culture, and then used in multipassage culture assays with the potential to grow to high titres in those assays.

Although the recombinant virus is not known to be zoonotic and is considered of low risk to the operators themselves where manipulation of the virus occurs, this should be conducted at Containment Level 2 [CU] and any open container work only be performed in a Class 2 Biological Safety Cabinet with operators wearing gloves, sleeve covers and a disposable gown.

Primary routes of infection with the virus is via injection, due to the natural route of transmission of the virus therefore, the use of sharps is strictly prohibited. Accidental splashing and exposure to mucosal membranes is a secondary risk factor therefore, all open container work will be performed within a Class 2 Biological Safety Cabinet and centrifugation of preparations with infectious potential must be performed using sealed centrifuge rotors or sample cups which are loaded and unloaded in the Class 2 Biological Safety Cabinet.

Due to the containment procedures in place within the laboratory areas, the intrinsic design of the C12 laboratory, decontamination of waste, the procedures governing working practices, the overall risk to escape to the environment is considered low.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not Applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Liquid waste as per Section 12 will be subject to chemical inactivation prior to disposal. Therefore a derogation to Part 2, Table la 8 "Autoclave required in the building" of the Regulations is requested.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Liquid waste is treated with Virkon prior to disposal to drain. Virkon is used at a minimum final concentration of 2% for the purpose of decontaminating liquid waste. Liquid waste is left to decontaminate for at least 16 hours. Merck BioReliance Services have conducted in house studies to determine the viricidal effect of Virkon, with data demonstrating that enveloped viruses are inactivated at a concentration of 2% Virkon following a 16hr incubation with a minimum reduction of at least 5.9 logs. The studies were conducted using 10% FBS to mimic a protein load. The studies on these enveloped viruses demonstrate that rSRV-3 being used would be inactivated in the same manner based on the biological and physical properties of the wild type virus.

Solid waste will be collected in suitable clinical waste packaging, appropriately sealed, placed and stored in designated containers within a secure area until collected for off-site incineration.

Purposes of the contained use

Small scale production of Herpes Simplex type-1 virus for further biologic al testing with the aim of optimising production methods.

Recipient or parental organism

Herpes Simplex type-1 virus (strain JS-1 ECACC Accession Number 01010209)
**Host/vector system**

Herpes Simplex type-1 virus deleted for neurovirulence factor ICP34.5 and culture in BHK cells in vitro. GM-CSF, a cytokine involved in the stimulation of T-cells, is under control of the human cytomegalvirus immediate early promotor (HCMV IE).

**Origin & function**

**Evaluation of foreseeable effects**

The design of the facility and the category 2 handling and waste inactivation procedures utilised mean that release of vector outside of contained use is highly unlikely. If such release was to occur then it is unlikely that the vector will be harmful to humans, animals or plants. The vector is modified so that replication only occurs in rapidly dividing cells and not non-dividing cells. Considerable literature shows that HSV 1 deleted for ICP34.5 is non-pathogenic in animals and humans. Approximately 80% of the human population are seropositive for HSV-1. Infection is by contact and transmission by the aerosol route is not though to occur. The therapeutic gene delivered, human GM-CSF is present in normal, healthy humans. The virus is fragile, and is rapidly inactivated by desiccation, lipid solvents and mild detergents. The fact that contact is required for transmission attests to the instability of the virus outside the host.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All waste materials (eg. liquid waste, flasks and pipettes) are inactivated by autoclaving (126 degrees C for 45 minutes) before disposal to effectively give 100% kill of the GMM. The autoclaving procedure is performed according to formal written standard operating procedures (KPBT0161 and KPBT0162) and has been validated. The inactivation of waste by autoclaving is monitored/validated by the following means:

* chemical indicators (eg autoclave tape) are used on all autoclave runs and the temperature and pressure for each run is recorded and verified against requirements.

* Once a week correct autoclave operation is verified by the use of chemical indicators.

* Once every two months correct autoclave operation is verified by the use of biological indicators.

**Is an emergency plan required according to regulation 20?** N

**If yes, tick to confirm that it is attached to this form** N

**Tick to confirm that you have attached a risk assessment to this form** Y

Please enter comments on the GM safety committee on the risk assessment

Standard level 2 containment procedures should be employed for this work.

**Project Containment**

02/03/2022
The sample will be cleared to remove cellular debris, ultracentrifuged to pellet any viral particles present and resuspended in disruption buffer containing detergents, followed by Reverse Transcriptase Polymerase Chain Reaction.
The yellow fever live attenuated vaccine virus strain 17D replicates to low levels in vaccinees, and cannot infect mosquitoes, which precludes its spread in nature. It is considered one of the safest and effective live attenuated vaccines ever developed. According to current biosafety guidelines, the ChimeriVax - JE vaccine is officially BSL2.

**Origin & function**

The infectious clone (cDNA copy) of 17D virus, which was subsequently used to create ChimeriVax - JE, was constructed starting from a sample of the virus from ATCC at passage 2347-8. Since ATCC is not currently distributing passage 234 sample, a Safety Data Sheet for this virus is not available. However, this virus is virtually identical to all other 17D vaccines manufactured worldwide, because its passage history differs from the commercial vaccines only at a few terminal passages. All 17D vaccines, including the ATCC passage 234 sample, have originated from one sample, Colombia 88 vaccine at passage 228. All current commercial 17D vaccines are produced at passage levels between 233 and 239 to ensure phenotypic and genetic similarity. The 17D virus is a BSL-2 agent.

The ChimeriVax will be used in tests undertaken as part of routine safety testing for the presence of viral contaminants, especially reverse transcriptase activity. The sample will be clarified to remove cellular debris, ultracentrifuged to pellet any viral particles present and resuspended in disruption buffer containing detergent, followed by an RT-PCR. The sample consists of ChimeriVax TM-JE Bulk Harvest cultured in Vero cells. During the procedure the virus will be inactivated by disruption buffer containing the following detergents, Igepal and DTT. Handling of the sample will be performed in a Class II hood. The process in which the recombinant virus will be used does not increase the risk associated with the virus.

**Evaluation of foreseeable effects**

In sertion of the envelope protein genes into the viral vector does not alter the tropism of the virus or its interactions with host defences. In selecting the most successful YF 17D chimeras containing the prM-E genes, two strains were examined, Nakayama, a virulent JE strain and the attenuated JE vaccine strain, SA14-14-2. Both chimeras replicated efficiently in several simian, human, mouse and mosquito cell cultures. It was concluded that the SA-14-14-2 envelope protein provided an additional degree of attenuation, therefore this was selected as the candidate chimeric JE vaccine.

For wild type yellow fever virus, natural hosts are Aedes mosquitoes. However, as a result of attenuation, the 17D vaccine strain lost its ability to replicate in mosquitoes, and replicates to extremely low levels in humans and non-human primates, which precludes infection of mosquitoes feeding on vaccinees and thus uncontrolled spread in nature. The ChimeriVax - JE vaccine has been demonstrated to possess the same restricted replication characteristics.

If introduced to humans it is possible that Chimerivax-JE would replicate to low levels, but cannot replicate in mosquitoes. However, due to the nature of the work to be preformed and the contamination procedures in place within the laboratory, the overall risk to the environment is considered negligible.

Chimerivax -JE can replicate in humans and non-human primates to extremely low levels. As the virus cannot replicate in mosquitoes there is no vector for transmission. The risks to human health and safety is negligible.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

In conclusion the recombinant Chimerivax-JE virus is considered as a Hazard Group 2 biological agent, this conclusion arises due to the fact that JEV and YF vaccine strains belong to Hazard Group 2 (ACDP Categorization of biological agents according to hazard and categories of containment, 4th edition, 1995).

The ACGM level of containment would be class 2 and the ACDP level of containment is level 2. All manipulations will be performed in a level 2 containment facility.

For only GMOs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

02/03/2022
In the search for new and effective pharmaceuticals with minimal side effects, GSK intends to express known and novel membrane receptors in mammalian cells in order to obtain functional data and to determine the specificity of closely related receptors. Regulatory proteins such as accessory G proteins which modulate the function of the receptor, and may be essential for activity, will also be expressed and evaluated. To avoid the generation of large numbers of stable recombinant cell lines, we intend to use a recombinant baculovirus system which will allow transient expression in mammalian cell lines. Baculoviruses are a well studied system for the production of recombinant proteins in insect cells. They are unable to replicate in mammalian cells, and the usual insect-specific promotors are ineffective in mammalian cells. By replacing the standard polyhedrin gene promoter sequence with that of an efficient mammalian promoter (such as the CMV IE promoter/enhancer) baculoviruses are able to express recombinant products in mammalian cells, though they remain incapable of replication in these cells. (Condreay et al 1998). Baculovirus particles containing the product gene under CMV promoter control will be generated in insect cell cultures using standard procedures, and used to transfect mammalian cell lines. The transient gene expression, generally at low levels compared to stable cell lines, can be increased ten-fold or more by addition of a histone deacetylase inhibitor such as sodium butyrate which inhibits the normal silencing of transfected DNA.

Ref: Condreay et al (1998) PNAS 96 127
**Baculovirus CL1**
These organisms fall into ACDP hazard group 1

**Host/vector system**
For generation of recombinant baculovirus, shuttle vectors containing the product gene under CMV promoter control are transfected into insect cells (e.g. Sf-9) using standard procedures such as the Bac to Bac expression system (Life Technologies).

(Recombinant cell lines expressing receptors and G-proteins: CL 1)

**Origin & function**

**Evaluation of foreseeable effects**
The baculovirus is able to transfect mammalian cells, but is unable to replicate in them. Efficient expression of the gene products under control of the CMV promoter is achieved only by addition of an inhibitor of cellular histone deacetylase. It is possible that inappropriate expression of a transmembrane receptor or regulatory protein could have detrimental effects. However, the only likely routes of infection would be mouth, nose or eyes, and the amounts which might enter by such routes (via aerosols or splashes) would be small (microlitres). In addition, baculoviruses are rapidly inactivated (>99% in 30 minutes) by the complement system of normal human serum (Hofmann and Strauss '98). The work will use standard laboratory and bioreactor methods and does not involve processes which would generate significant quantities of aerosols. Needles (sharps) will not be used. Laboratory operations involving production of baculoviruses and transfection of cell lines will be carried out in a microbiologic safety cabinet, which will be sufficient to reduce the likelihood of infection to effectively zero. Bioreactor operations will be carried out under CL2 conditions as defined in table 2 of the GMO Regulations 2000. Typically, the baculovirus will be used to transfect mammalian cells either in multi-well plates (eg 96-well) for assay, or in bioreactors for preparation of batches of cells. Batches of cells will be collected (centrifugation) and washed under CL2 conditions. The transient recombinant cell lines expressing receptors generated by this system, including low levels of residual virus, are unlikely to pose a risk to health, and may be handled under conditions of CL1 (e.g for analysis). Similar stable cell lines have previously been categorised as CL1.

**Project Ref** 315/01.7

- **Date Ackn’d**: 11/10/2002
- **CU2 Project Title**: UTILISATION OF STREPTOMYCES SPECIES SUCH AS STREPTOMYCES LIVIDANS AS AN EXPRESSION SYSTEM FOR THE PRODUCTION OF CYTOKINES
- **Class**: Class 2
- **CultureVolClass2**: < 1 litre
- **Consent Granted**: Non-GMM
- **Consent Granted**: not applicable
- **Project notified under transitional arrangements**: N

**Withdrawn**: N

**Tick if notifying a connected programme of work**: N

**Historical Significant Changes**

**Historical Date of Additional Info**

**Significant Change ID**

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

The aim is evaluate and utilise Streptomyces lividans for production of heterologous proteins of biopharmaceutical relevance. Initially murine TNFa. will be overexpressed and secreted by Streptomyces lividans to evaluate the conditions required for high level protein production. If successful the work may be extended to use of other Streptomyces species and expression of other cytokines, including novel cytokines. Laboratory work with Streptomyces will be carried out at up to 0.5L volumes. If required, larger volumes of crude product (up to 15L) will be produced from bioreactor cultures.
**Recipient or parental organism**

Streptomyces species such as Streptomyces lividans. These organisms fall into the lowest ACDP hazard group 1.

**Host/vector system**

Non-pathogenic Streptomyces species transfected with non-conjugative plasmids (unable to transfer to other species).

**Origin & function**

GSK proprietary libraries.

**Evaluation of foreseeable effects**

Human and non-human cytokines may have biological activity if delivered to a site of action (eg if ingested or inhaled). The use of Class 2 biological safety cabinets and gloves will reduce the likelihood of harm from laboratory work to effectively zero. For larger scale work, the operation of bioreactors is designed to minimise release through exhaust gases or during sampling of cultures, and the work will be effectively contained at CL2 according to Schedule 8 of the GMO (Contained Use) Regulations 2000.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste cultures, supernatants, and cell debris of up to 0.5 litre will be inactivated by autoclaving in validated autoclaves (>120 deg C for >15 min); larger volumes will be heat-treated in fermenters (>120 deg C for >15 min); plastic and other solid waste will be autoclaved as described and/or incinerated.

**Is an emergency plan required according to regulation 20?** N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

The Committee approved the risk assessment at CL2.

**Project Additional Information**

**Purposes of the contained use**

In the search for new and effective pharmaceuticals with minimal side effects, GSK intends to express known and novel kinases in mammalian cells in order to obtain functional data and to determine the specificity of closely related kinases. Kinases are a large class of enzymes found in all cell types which activate their target proteins by phosphorylation. Frequently, the target molecule itself will be a kinase, which when activated can progress the signal by phosphorylation of the next enzyme in the signal cascade. The kinases may be modified to modulate their activity and to evaluate the mechanism of action, for example by analysing the effect of single amino acid substitutions. To avoid the generation of large numbers of stable recombinant cell lines, we intend to use a recombinant baculovirus system which will allow transient expression in mammalian cell lines.

Baculoviruses are a well studied system for the production of recombinant proteins in insect cells. They are unable to replicate in mammalian cells, and the usual insect-specific promoters are ineffective in mammalian cells. By replacing the standard polyhedrin gene promoter sequence with that of an efficient mammalian promoter (such as the CMV IE promoter/enhancer) baculoviruses are able to express recombinant products in mammalian cells, though they remain incapable of replication in these cells. (Condreay et al 1998). Baculovirus particles containing the product gene under CMV promoter control will be generated in insect cell cultures using standard procedures, and used to transfect mammalian cell lines. The transient gene expression, generally at low levels compared to stable cell lines, can be increased ten-fold or more by addition of a histone deacetylase inhibitor such as sodium butyrate which inhibits the normal silencing of transfected DNA.
Baculovirus CL1
These organisms fall into ACDP hazard group 1.

Host/vector system
For generation of recombinant baculovirus, shuttle vectors containing the product gene under CMV promoter control are transfected into insect cells (eg Sf-9) using standard procedures such as the Bac to Bac expression system (Life Technologies).

(Recombinant cell lines expressing kinases: CL1)

Origin & function
Libraries of human DNA from academic collaborators.

Evaluation of foreseeable effects
The baculovirus is able to transfect mammalian cells, but is unable to replicate in them. Efficient expression of the gene products under control of the CMV promoter is achieved only by addition of an inhibitor of cellular histone deacetylase. It is possible that inappropriate expression of a kinase could have detrimental effects. However, the only likely routes of infection would be mouth, nose or eyes, and the amounts which might enter by such routes (via aerosols or splashes) would be small (microlitres). In addition, baculoviruses are rapidly inactivated (>99% in 30 minutes) by the complement system of normal human serum (Hofmann and Strauss ‘98)*. The work will use standard laboratory and bioreactor methods and does not involve processes which would generate significant quantities of aerosols. Needles (sharps) will not be used. Laboratory operations involving production of baculoviruses and transfection of cell lines will be carried out in a microbiological safety cabinet, which will be sufficient to reduce the likelihood of infection to effectively zero. Bioreactor operations will be carried out under CL2 conditions as defined in table 2 of the GMO Regulations 2000. Typically, the baculovirus will be used to transfect mammalian cells either in multi-well plates (eg. 96-well) for assay, or in bioreactors for preparation of batches of cells. Batches of cells will be collected (centrifugation) and washed under CL2 conditions. The transient recombinant cell lines expressing kinases generated by this system, including low levels of residual virus, are unlikely to pose a risk to health, and may be handled under conditions of CL1 (eg. for analysis). Similar stable cell lines have previously been categorised as CL1.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

### Project Additional Information

**Purposes of the contained use**

In the search for new and effective pharmaceuticals with minimal side effects, GSK intends to express known and novel nuclear receptors in mammalian cells in order to obtain functional data and to determine the specificity of closely related receptors. Nuclear receptors are ligand regulated transcription factors which mediate their physiological effects by modulating the expression of target genes. The nuclear receptors may be modified to modulate their activity and to evaluate the mechanism of
action, for example by analysis the effect of single amino acid substitutions. To avoid the generation of large numbers of stable recombinant cell lines, we intend to use a recombinant baculovirus system which will allow transient expression in mammalian cell lines.

Baculoviruses are a well studied system for the production of recombinant proteins in insect cells. They are unable to replicate in mammalian cells, and the usual insect-specific promoters are ineffective in mammalian cells. By replacing the standard polyhedrin gene promoter sequence with that of an efficient mammalian promoter (such as the CMV IE promoter/enhancer) baculoviruses are able to express recombinant products in mammalian cells, though they remain incapable of replication in these cells. (Condreay et al 1998). Baculovirus particles containing the product gene under CMV promoter control will be generated in insect cell cultures using standard procedures, and used to transfect mammalian cell lines. The transient gene expression, generally at low levels compared to stable cell lines, can be increased ten-fold or more by addition of a histone deacetylase inhibitor such as sodium butyrate which inhibits the normal silencing of transfected DNA.

Recipient or parental organism

Baculovirus CL1.
These organisms fall into ACDP hazard group 1.

Host/vector system

For generation of recombinant baculovirus, shuttle vectors containing the product gene under CMV promoter control are transfected into insect cells (eg Sf-9) using standard procedures such as the Bac to Bac expression system (Life Technologies).

(Recombinant cell lines expressing nuclear receptors: CL1).

Origin & function

Libraries of human DNA commercially available or from academic collaborators.

Evaluation of foreseeable effects

The baculovirus is able to transfect mammalian cells, but is unable to replicate in them. Efficient expression of the gene products under control of the CMV promoter is achieved only by addition of an inhibitor of cellular histone deacetylase. It is possible that inappropriate expression of a nuclear receptor could have detrimental effects. However, the only likely routes of infection would be mouth, nose or eyes, and the amounts which might enter by such routes (via aerosols or splashes) would be small (microlitres). In addition, baculoviruses are rapidly inactivated (>99% in 30 minutes) by the complement system of normal human serum (Hofmann and Strauss ‘98)*. The work will use standard laboratory and bioreactor methods and does not involve processes which would generate significant quantities of aerosols. Needles (sharps) will not be used. Laboratory operations involving production of baculoviruses and transfection of cell lines will be carried out in a microbiological safety cabinet, which will be sufficient to reduce the likelihood of infection to effectively zero. Bioreactor operations will be carried out under CL2 conditions as defined in table 2 of the GMO Regulations 2000. Typically, the baculovirus will be used to transfect mammalian cells either in multi-well plates (eg 96-well) for assay, or in bioreactors for preparation of batches of cells. Batches of cells will be collected (centrifugation) and washed under CL2 conditions.

The transient recombinant cell lines expressing nuclear receptors generated by this system, including low levels of residual virus, are unlikely to pose a risk to health, and may be handled under conditions of CL1 (eg for analysis).

</tr>
<tr>
<td><strong>Evaluation of foreseeable effects</strong></td>
<td>The exact function of the human epithelial cell membrane glycoprotein is unknown but it is not considered to present a serious hazard. The only theoretical hazard that can be postulated would be induction of auto-immunity to the protein expressing cells should infection with vaccinia occur. This is considered unlikely as many hundreds of cancer patients have been intentionally immunised against this protein without serious adverse effects. Insertion of this into the vaccinia TK gene should not increase the virulence of the virus and is believed to reduce virulence in mice. The chances of environmental consequences are considered to be effectively zero. Experience gained from widespread use of vaccinia over many years during the smallpox eradication campaign indicates it is unlikely to survive or infect wild mammals.</td>

**Recipient or parental organism**

- Adeno-associated virus type 2

**Host/vector system**

- Replication defective Adeno-associated virus (AAV) vectors encoding human lipoprotein associated phospholipase A2 (Lp-PLA2) and a control inactive Lp-PLA2

**Origin & function**

- Human lipoprotein associated phospholipase A2

**Evaluation of foreseeable effects**

Increased Lp-PLA2 in the blood may be associated with an increased risk for the development of atherosclerosis, and therefore might be detrimental to health if delivered to the target tissue.

The work with AAV does not involve procedures, which would create a significant risk, such as generation of aerosols, and we calculate that if the total virus stock were delivered to a single adult, it would be sufficient only to increase active Lp-PLA2 levels by approximately 1% of normal levels. Therefore initial laboratory work would be highly unlikely to be deleterious to humans, and would be categorised as Class 1.

However, future work may involve increased amounts of virus (up to 10 x 10^10 particles) and will involve the use of sharps, which could deliver the virus to the site of action (blood). Therefore work with AAV will be carried out in microbiological safety cabinets and access to the laboratories will be restricted as a precaution. This indicates containment level 2.

## Project Additional Information

**Purposes of the contained use**
- Pharmaceutical Research & Development

**Recipient or parental organism**
- Baculovirus
Host/vector system

Sf9 Insect cells / pBacMaM-1 (based on pFastBac-1 shuttle vector (Invitrogen) whose baculovirus polyhedrin promoter has been removed and replaced with that of the CMV IE promoter/enhancer).

Origin & function

Ion channel sub-units, ion channel modulator proteins from human, rat and mouse which control entry/exit of ions across the cell membrane.

Evaluation of foreseeable effects

The expression of ion channels in Baculovirus is highly unlikely to increase the pathogenicity of the host or its ability to survive outside the culture medium. The pFastBacMam series of vectors and the derivative pBacMam-1 are non-pathogenic and non-replicative in mammalian cells. In the unlikely event of virus entering the body, transient expression of gene products is possible. It is therefore considered that generation of viral stock in Sf9 insect cells should be carried out under ACGM CL2 conditions.

The initial transduction of cultured mammalian cells with pBacMam-1 will be carried out at ACGM CL2 until all residual viral particles not taken up by the cells have been washed away. The effectiveness of this washing step in removing residual viral particles has been proven experimentally.

The other steps in the experiment, namely growing stocks of the vector in E. coli and culture of the modified mammalian cells is considered to entail minimal risk and will be conducted at ACGM CL1.

The expression of ion channels in Baculovirus is not expected to alter its host range or survivability in the environment. The host Sf9 insect cells are disabled and unlikely to persist in the environment. The budable form of the Baculovirus vectors being used is disabled and cannot infect hosts outside the laboratory - the normal insect host is only infected by the occluded form of the virus.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**Class** Class 2  
**Culture Vol Class** 1-50 litres  
**Class Culture Volume**  
**Non-GMM** not applicable  
**Consent Granted**  
**Project notified under transitional arrangements** N

### Project Additional Information

**Purposes of the contained use**  
Pharmaceutical research and development

**Recipient or parental organism**  
Standard human cell lines including HEK293T, Jurkat, K562, Hel, Cos, RAMOS, RPM 18226, Saos2, IMR-32, U20S, A549, H292, T84, Hela, SKN-SH-Sy5y, SKN-SH-MC, N132, NG108, Ntera2, U373MG, HepG2 which are all considered to be well characterised and having a long history of safe use.

**Host/vector system**
Modified human (FLYA13) "split genome" packaging cell line and/or Orbigen Phoenix Ampho Human HEK293 packaging cell line, and/or Clontech Ampho-pack HEK293 packaging cell line, using a murine amphotrophic virus (pWZLneo) vector based upon the Murine) MuLV) group of retroviruses, having the ecotropic receptor inserted downstream of the LTR promoter in order to generate replication incompetent viral particles.

**Origin & function**

Mouse cationic amino acid transporter protein (Mouse Ecotropic Receptor).

**Evaluation of foreseeable effects**

The aim of the work is to produce a set of standard human cell lines expressing the Mouse Ecotropic Receptor at the cell surface and thereby enable various other human proteins to be introduced into those lines via a modified virus which would be unable to infect human cells lacking the mouse ecotropic receptor.

The nature of the expressed insert, the mouse ecotropic receptor, is considered to pose no risk to humans.

The use of split human cell line packaging systems for the pWZLneo vector that bear the Gag, Env and Pol genes on separate plasmid systems within the line will minimise the risk of recombination occurring when producing the modified viral particles to give replication competent virus.

Human packaging cell lines also reduce the risk, compared to murine packaging cell lines, of the cell line bearing endogenous retroviral sequences that can recombine to produce competent virus.

The murine amphotrophic virus is capable of infecting human cells and the properties conveyed by the ecotropic receptor might permit any cells carrying this receptor to be infected by viruses that would otherwise not be capable of infecting a human cell. For this reason the GMSC consider use of a Class II microbiologic al safety cabinet is essential for work involving infecting the human cell lines with pWZLNeo carrying the mouse ecotropic receptor. The cells that result can safely be handled at containment level 1.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

### Project Additional Information

- **Purposes of the contained use**: Pharmaceutical research and development.
- **Recipient or parental organism**: Immortalised mammalian cell line such as T47D and CV1.
Host/vector system

Immortalised mammalian cell line such as T47D and CV1/pBacMam-1 (based on pFastBac-1 shuttle vector (Invitrogen) whose baculovirus polyhedrin promoter has been removed and replaced with that of the CMV 1E promoter/enhancer).

Origin & function

cDNA encoding nuclear receptors and co-regulators from human, rat and mouse. Nuclear receptors are ligand regulated transcription factors which mediate their physiological effects through modulation of the expression levels of target genes. Nuclear co-regulators modulate the effects of nuclear receptors by promoting or suppressing their transcriptional activity.

Evaluation of foreseeable effects

The expression of nuclear receptors and co-regulators is highly unlikely to increase the pathogenicity of the host or its ability to survive outside of the culture medium. The pFastBacMam series of vectors and the derivative pBacMam-1 are non-pathogenic and non-replicative in mammalian cells. In the unlikely event of virus entering the body, transient expression of gene products is possible. It is therefore considered that generation of viral stock in Sf9 insect cells should be carried out under ACGM CL2 conditions.

The initial transduction of the cultured mammalian cells with pBacMam-1 will be carried out at ACGM CL2 until all residual viral particles not taken up by the cells have been washed away. The effectiveness of this washing step in removing residual viral particles has been proven experimentally.

The expression of nuclear receptors and co-regulators is not expected to alter host range or survivability in the environment. Project Additional Information

Purposes of the contained use
Pharmaceutical Research and Development

Recipient or parental organism
Immortalised mammalian cell line such as HEK293 and CHO cells.

Host/vector system
The vector system contains only the non-structural SFV genes and a conditionally lethal mutation in the spike gene of the helper construct which means that virus is non-infectious until activated by protease.

Origin & function
All GPCRs and accessory protein (e.g., RAMPS, G-proteins, peptide and protein (GPCR fusions)). GPCRs are cell associated proteins with seven transmembrane domains linking the outer and inner cell surfaces. They are responsible for passing signals (usually in the form of an extracellular ligand) to the intracellular signalling apparatus via various accessory proteins such as G-proteins.

**Evaluation of foreseeable effects**

The expression of GPCRs is highly unlikely to increase the pathogenicity of the host or its ability to survive outside of the culture medium. The gene products are all membrane associated. Function requires the presence of a specific ligand and the presence of intact intracellular signalling apparatus. The gene may only function in particular cell types and requires expression in appropriate cell types. The expression of GPCRs is not expected to alter host range or survivability in the environment.

Semliki forest virus can be classified as a mild human pathogen. It uses a blood-borne transmission pathway and is normally spread by mosquitoes among rodents and birds in central Africa. In humans, mild flu symptoms lasting 7 days may occur. The vector system used in the lab is not capable of replication as only the RNA containing the non-structural genes and insert gene is packaged into the viral particle. Additional safety measures include a conditionally lethal mutation in the spike gene of the helper construct which means that virus is non-infectious until activated by protease.

## Project Additional Information

### Purposes of the contained use

Pharmaceutical Research and Development.

### Recipient or parental organism

Immortalised mammalian cell lines such as HEK293 and CHO cells.

### Host/vector system

Immortalised mammalian cell lines such as HEK293 and CHO cells pBacMam-1 (based on pFastBac-1 shuttle vector (invitrogen) whose baculovirus polyhedrin promoter has been removed and replaced with that of the CMV IE promoter/enhancer).

### Origin & function

All GPCRs and accessory protein (e.g., RAMPS, G-proteins, peptide and protein GPCR fusions). GPCRs are cell-associated proteins with seven transmembrane domains linking the outer and inner cell surfaces. They are responsible for passing signals (usually in the form of an extracellular ligand) to the intracellular signalling apparatus via various accessory proteins such as G-proteins.

### Evaluation of foreseeable effects

The expression of GPCRs is highly unlikely to increase the pathogenicity of the host or its ability to survive outside of the culture medium. The gene products are all...
membrane associated. Function requires the presence of a specific ligand and the presence of intact intracellular signalling apparatus. The Gene may only function in particular cell types and requires expression in appropriate cell types. The pFastBacMam series of vectors and the derivative pBacMam-1 are non-pathogenic and non-replicative in mammalian cells. In the unlikely event of virus entering the body, transient expression of gene products is possible. It is therefore considered that generation of viral stock in Sf9 insect cells should be carried out under ACGM CL2 conditions.

The initial transduction of the cultured mammalian cells with pBacMam-1 will be carried out at ACGM CL2 until all residual viral particles not taken up by the cells have been washed away. The effectiveness of this washing step in removing residual viral particles has been proven experimentally.

The expression of GPCRs is not expected to alter host range or survivability in the environment. The host Sf9 insect cells are disabled and unlikely to persist in the environment. The budable form of the Baculovirus vectors being used is disabled and cannot infect hosts outside the laboratory - the normal insect host is only infected by the occluded form of the virus.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All virus containing liquids will be treated with suitable disinfectant eg Virkon or Hycolin in accordance with the manufacturer's recommendations and left overnight. All other potentially contaminated materials will be autoclaved either at 134 degrees C for at least 3 minutes or 121 degrees C for at least 15 minutes.

All work will use our standard waste treatment methods.
MANIPULATION OF FULL LENGTH CDNA CLONES OF HUMAN PAPILLOMA VIRUS.

<table>
<thead>
<tr>
<th>Purposes of the contained use</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pharmaceutical research and development.</td>
</tr>
</tbody>
</table>

**Recipient or parental organism**

auxotrophic strains of E. coli, HB101 and DH5alpha.

**Host/vector system**

Non-mobilisable plasmids, Puc19, pBR322 & pBluescript SK containing full length clones of HPV-6, HPV-11, HPV-16 & HPV-18

**Origin & function**

Full length clones of Human papilloma virus will be cloned into E.coli, maintained and amplified. The resultant plasmids will purified for use in the development of DNA vaccines.

**Evaluation of foreseeable effects**

The amplification of the HPV plasmid is very unlikely to increase the pathogenicity of the E coli host or increase its ability to survive outside of the culture medium. In the unlikely event of the E. coli being ingested there is an effectively zero risk of infection from the HPV clones as the virus is not a mucosal pathogen of the gut.

The HPV clones will be re-ligated and digested as part of the preparation for some experiments. These manipulations will generate HPV, which may be infectious if
accidentally inoculated into human skin unprotected by gloves.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

CU2 Project Title USE OF VACCINIA VIRUS RECOMBINANT EXPRESSING OVALBUMIN IN ANIMAL

Class Class 2

CultureVolClass2 < 1 litre

CultureVolumeClass3-4
Project Additional Information

Purposes of the contained use

Pharmaceutical research and development.

Recipient or parental organism

WR strain of vaccinia virus, a tissue culture adapted virus from a vaccine strain used as part of the smallpox eradication programme and is designated ACDP hazard group 2.

Host/vector system

Recombinant vaccinia viruses encoding ovalbumin.

Origin & function

Inserts coding for Ovalbumin will be expressed in vaccinia, recombinants will then be used as a challenge virus in vaccine efficacy studies in mice. It should be noted that recombinant vaccinia virus in this model is being used as a challenge virus rather than a vector for the delivery of heterologous antigen.

Evaluation of foreseeable effects

The WR strain of vaccinia virus does not occur naturally in humans and there is no animal reservoir. The rate of severe adverse reactions post vaccination is 1 in 50,000. It may cause particularly severe disease in people with active skin disorders or the immune compromised, therefore staff will be counselled for their suitability to work with vaccinia virus. Infection with vaccinia is generally self-limiting and therefore, any side-effects of foreign gene expression is likely to be transient.

The work will involve inoculation of mice with infectious vaccinia virus and the subsequent handling of infected tissues from the animals. There is a risk of accidental infection when carrying out these procedures. The use of a TK-vaccinia recombinant limits the spread of the virus within an infected animal and reduces the likelihood of virus being secreted therefore reducing the risk of transmission to the laboratory worker. Administration by the i.p and i.v. routes means that no infectious skin lesions are formed which also reduces possible accidental transmission.
All work involving infectious vaccinia virus will be carried out in a separate designated animal facility. Infected animals are to be housed in cages within negative pressure isolators. All procedural work will be carried out using a class 1 microbiological safety cabinet. The room used for housing mice is maintained under negative pressure relative to the immediate surroundings. All waste (food, bedding carcasses) will be removed from the isolator in triple heat sealed portex tubing. All waste will be autoclaved (134 degrees C for a minimum of 30 minutes).

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All liquids contaminated with GMMs will be treated with suitable disinfectant eg Virkon or Hycolin in accordance with the manufacturer's recommendations and left overnight. Project Ref 558/03.3

Date Ackn'd CU2 Project Title

02/03/2022
GENERATION AND USE OF VACCINIA VIRUS RECOMBINANTS EXPRESSING HCV ANTIGENS AND OVALBUMIN.

Project Additional Information

Purposes of the contained use
Pharmaceutical research and development.

Recipient or parental organism
WR strain of vaccinia virus, a tissue culture adapted virus from a vaccine strain used as part of the smallpox eradication programme and is designated ACDP hazard group 2.

Host/vector system
Recombinant vaccinia viruses will be generated by homologous recombination between sequences within the vaccinia expression vector pSC11 and the vaccinia virus genome.

Origin & function
Inserts coding for Ovalbumin and HCV antigens will be expressed in vaccinia, recombinants will then be used in immunological assay.

Evaluation of foreseeable effects
The WR strain of vaccinia virus does not occur naturally in humans and there is no animal reservoir. The rate of severe adverse reactions post vaccination is 1 in 50,000. It may cause particularly severe disease in people with active skin disorders or the immune compromised, therefore staff will be counselled for their suitability to work with vaccinia virus. Infection with vaccinia is generally self limiting and, therefore, any side-effects of foreign gene expression is likely to be transient. The thymidine kinase (TK) gene is used as the insertion site creating a TK-recombinant virus which is believed to reduce the virulence of the virus in mice, but does not necessarily imply lower virulence in man.

Vaccinia recombinants expressing various HCV antigens under the control of a bacteriophage T7 promoter, have been used in-house. No increase in the virulence of these recombinants above the wild type virus has been observed. In addition our proposed recombinants will contain gene inserts with inactivated enzymes.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

Project Ref 558/04.1

Date Ackn’d 09/09/2004
CU2 Project Title Cloning of shRNA expression cassettes into adeno-associated virus (AAV) vectors
Class 2
CultureVolClass2 1-50 Litres
CultureVolumeClass3-4
and their use to suppress the expression of specific genes in cultured mammalian cells by RNA interference

Pharmaceutical research and development.

Auxotrophic strain of E. coli, DH5alpha and HEK293 cells.

Recombinant plasmids encoding shRNAs will be amplified in the E. coli host. These will be transfected into HEK293 cells together with the plasmid encoding the AAV replication and virion proteins (rep, cap) and the adenoviral 'helper' proteins (VA, E2a, E4). Recombinant AAV vectors will be harvested.

Chemically synthesized, double-stranded oligonucleotides, of sequence corresponding to siRNAs are to be ligated downstream of either the H1 or U6 pol III promoter in AAV vector shuttle plasmid. These will then be packaged into infectious AAV vectors and inoculated into cell cultures (primary cell types from human and rodent origin including neurons, microglia, monocytes, and macrophages as well as continuous cell lines such as Ramos and Jurkat) in an attempt to suppress the expression of genes of interest.

The amplification of the AAV plasmid is very unlikely to increase the pathogenicity of the E. coli host or increase its ability to survive outside of the culture medium. In the unlikely event of the E. coli being ingested there is an effectively zero risk of infection from the HPV clones as the virus is not a mucosal pathogen of the gut.

The viral vectors are replication-defective and as such can transduce cells but are unable to replicate or be transmitted to other cells or hosts. The viral vectors will be inoculated into primary human and rodent cells and continuous cell lines such as Jurkat and Ramos and the effects upon target gene expression evaluated. The parental viral vectors have been well characterised and the expression of the shRNA cassette is not predicted to be harmful, but since the shRNA expression constructs they encode are designed to target novel target genes, downstream effects of gene suppression may not easily be predicted.

Not applicable.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquids contaminated with GMM will be treated with suitable disinfectant eg Virkon or Hycolin in accordance with the manufacturer's recommendations and left overnight. All other potentially contaminated materials will be autoclaved either at 134 degrees C for at least 3 minutes or 121 degrees C for at least 15 minutes.

| Pharmaceutical research and development |

02/03/2022
Recipient or parental organism
Auxotrophic stains of E.coli, TOP10 & GT116, continuous & primary mammalian cell lines eg HEK 293A, Ramos & Jurkat

Host/vector system
Recombinant plasmids encoding shRNAs will be amplified in the E.coli host. These will then be packaged into infectious replication-defective adenoviral vectors using a commercially available kit (the BLOCK-iT Adenoviral Expression System, Invirogen Inc.)

Origin & function
Chemically synthesized, double-stranded oligonucleotides, of sequences corresponding to siRNAs, will be incorporated into infectious, replication-defective adenoviral vectors using the BLOCK-iT Adenoviral Expression System (invitrogen Inc.). Prepared virus will be inoculated into cell cultures (primary cell types from human and rodent origin including neurons, microglia, monocytes, and macrophages as well as continuous cell lines such as Ramos and Jurkat), in an attempt to suppress the expression of genes of interest.

Evaluation of foreseeable effects
The amplification of the plasmid is very unlikely to increase the pathogenicity of the E.coli hosts or increase their ability to survive outside of the culture medium. In the unlikely of the E.coli being ingested there is an effectively zero risk of infection from the clones as the virus is not a mucosal pathogen of the gut.

Since the entire E1 region of the viral genome has been deleted the resulting adenoviral vectors are replication-defective, unable to establish a productive infection and thus amplify itself in infected cells. Viral replication can only occur in cells that express the E1a and E1b proteins such as the 293A cell line used to generate the vector. Adenovirus does not integrate into the host genome upon transduction. The adenoviral vectors, however, are unable to infect a wide range of different cell types and express the shRNA in those infected cells.

The precise effects of expression of the shRNA cassette when delivered to a target cell, are difficult to predict as their purpose is the partial suppression of novel genes. Although in the worse case suppression may lead to cell death or an increase in cell proliferation, this would not be expected to have any adverse affect on an exposed individual unless the exposuree affected a very large number of cells and this is extremely unlikely at the viral titres involved. Additionally, since the virus is replication-competent, the viral genome is present only transiently and will eventually be diluted out as cell division occurs.

Project Additional Information
### Purposes of the contained use

Pharmaceutical Research and Development.

### Recipient or parental organism

Replication defective Adeno Associated virus, Auxotrophic stains of E.coli, TOP10 & GT116, continuous & primary mammalian cell lines eg HEK 293A, Ramos & Jurkat.

### Host/vector system

Open reading frames encoding potential target proteins, will be ligated downstream of the CMV IE mammalian pol II promoter in a AVV vector shuttle plasmid and packaged into infectious replication defective AAV vectors.

### Origin & function

Replication-defective AAV vectors encoding the genes of interest (GPCR, IC, NR and Protease, obtained from commercially available cDNA libraries), will be used to transfect cell cultures (primary cell types of rodent origin such as neurons as well as continuous cell lines such as HEK293A cells) and also be administered to laboratory rodents (by the intravenous, intraspinal or intracranial routes) in order to express the genes of interest and validated them as potential drug targets.

### Evaluation of foreseeable effects

The amplification of the plasmids is very unlikely to increase the pathogenicity of the E.coli hosts or increase their ability to survive outside of the medium. In the unlikely event of the E.coli being ingested there is an effectively zero risk of infection from the clones as the virus is not a mucosal pathogen of the gut.

The viral vectors are replication-defective and as such can infect cells but are unable to replicate or be transmitted to other cells or hosts. Proteins representing potential drug targets will be over-expressed, ie they are naturally expressed in the cells and rodent tissues to which the viral vectors will be administered. Over-expression of target genes is not expected to have any toxic or oncogenic effects.

Some of plasmids involved encode the Woodchuck hepatitis virus post transcriptional regulatory element (WPRE). There are reports describing the development of tumours in a small number of mice inoculated in utero with lentiviral vectors containing the WPRE sequence and of the possibility that sequences within the WPRE may possess oncogenic properties.

**Project Additional Information**

**Purposes of the contained use**

The purpose of the work is to produce long half-life forms of venom peptides which block ion channels. These may have pharmacological utility in regulation of immune activation.

**Recipient or parental organism**

3 expression systems will be used, as described below, under a, b and c:

a) mammalian systems: human epithelial kidney cell line HEK293E, an immortal suspension adapted variant of the parental line transfected with a plasmid encoding the Epstein-Barr virus nuclear antigen.

b) Pichia pastoris expression: using Pichia pastoris KM71H or X33 strains.

c) E. coli expression: using the K12 strain TOP10.

**Host/vector system**

a) The pTT5 vector will be used.

b) The commercially available plasmid pPICZalpha will be used.

c) The pUC based plasmid pDOM5 will be used.

**Origin & function**

The genetic material to be used is fully synthetic in origin. The amino acid sequences on which it was based are derived from a human immunoglobulin variable domain joined to the channel blocking peptide by a synthetic flexible linker region. The channel blocking peptide is derived from a venom toxin peptide. Based on toxicology data from publications, the expressed protein will be a highly active potassium and calcium channel blocker, with a long serum half-life. The effects of prolonging the serum half-life of the toxin are not known. Based on steric effects, it would be likely to decrease the potency of the toxin, but the prolonged half-life would likely result in an enhancement of toxic effects. The biodistribution of the fusion protein would be altered relative to the unfused peptide, but the effect of any breakdown products could be similar to the native peptide. For the purposes of risk assessment, it is assumed that the biological effects would be similar, but more prolonged.

**Evaluation of foreseeable effects**

It is considered unlikely that the GMO will present any environmental risks. There are possible human health effects as detailed below.

**E coli** - The toxic effects by ingestion or expression in the gut are not known. Presumably, as a peptide toxin, a significant portion may be degraded, although due to the highly disulphide crosslinked nature of the peptide, it may be protease resistant. The toxic effects by this route would be potentially immunosuppressive at mucosal surfaces. Systemic exposure to the toxin via gut absorption may result in systemic exposure to the protein. The biological effects of this would be possibly to be toxic, with the possibility of blocking potassium channels in the heart for example. The threshold for this effect is considered higher than could be achieved using the strains used.

**Pichia** - Pichia has been chosen as an expression host, as it is non-colonising, the vectors used have promoters that are non-functional in E. coli, and are integrated and tightly repressed in Pichia culture before induction, thus giving maximal containment of the expression construct. Additionally, conditions for induction of expression in this vector require low glucose levels in the presence of methanol, conditions which are considered highly unlikely to be met in the human gut. The integrated nature of the vector means that transfer to other organisms will be minimised.

**Mammalian expression** - The pTT vector is designed for high level transient expression of cloned genes in the suspension cell line HEK293-E. These cells are a derivative of HEK293-T that have been adapted to suspension growth and to grow in serum-free conditions. The HEK293-E cells are stably transfected with a gene encoding the Epstein-Barr virus nuclear antigen, a protein that promotes nuclear localization of DNA5 that contain its’ binding sequence. The pTT vector contains 1 g tandem repeats of the appropriate sequence, with the aim of maximizing the nuclear localization of the plasmid. Expression of the constructs in these cells may act as an immunosuppressive, and could potentially enhance the ability of the cells to engraft, despite their highly disabled nature although this is considered unlikely.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

none requested

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste will take the form of cell pellets, cuire supernatants, and contaminated consumables. All wastes will be disposed of by autoclaving followed by incineration. The autoclaving is carried out in a autoclave that has been temperature tested, and a load thermocouple is used to ensure target times and temperatures are met. This is backed up by disposal by incineration in a licensed contractor's clinical waste incinerator, which is the route for all of our GM waste. This route will give 100% kill by combination of two validated methods.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The GMSC have reviewed this assessment and consider containment level 2 precautions adequate for this work. Accidental injection of the purified protein or supernants presents the highest hazard and particular attention to avoidance of the use sharps will be employed.

Project Ref 558/08.2

Date Ackn'd CU2 Project Title Class CultureVolClass2 CultureVolumeClass3-4

02/03/2022  Page 9673 of 15326
Production and Propagation of Recombinant and/or Chimeric hepatitis C Virus (HCV).

Date Project Ceased: 27/08/2008

Non-GMM Consent Granted: Yes

Project notified under transitional arrangements: N

Purposes of the contained use:
To produce infectious particles of recombinant and/or chimeric HCV by transfection of viral RNA into cells, followed by the subsequent culture of such viruses by standard virological techniques. (As described in Nature Methods 2, 565 (2005).

Recipient or parental organism:
Hepatocyte cell lines, mostly derivatives of the Huh7 human hepatoma laboratory cell line.

Host/vector system:
Plasmids will be generated containing thU length HCV sequences from different genotypes. Full length RNA will be transcribed from these plasmids and the resulting RNAs will be transfected into hepatocyte cell lines.

Origin & function:
HCV sequences of various genotypes originate from Ralf Bartenschlager (University of Heidelberg), NIH, Rockefeller, clinical isolates and chimeric sequences generated in-house by cloning from the above. Full length viral RNA containing the aforementioned HCV sequences will be generated by in vitro transcription. The RNA will be transfected into hepatocyte cell lines, usually by electroporation but could be by another transfection method (eg lipofection). The cells will produce infectious virus particles which will be harvested, concentrated by centrifugation and used to infect naive cells to further propagate the virus as described in Nature Methods 2, 565 (2005). These viruses will then be used in conventional virus assays to test for efficacy of anti-viral agents and to understand mechanism of action of these agents.

Evaluation of foreseeable effects:
The recombinant chimeric viruses produced will be designed to replicate efficiently in cell culture to produce titres of approximately 1 x 10^6 infectious particles per nil (as measured by fluorescence foci assay). HCV is classified as a ACDP3 pathogen and all the chimeric viruses produced would fall within the same risk category. The work will not affect the host cell tropism range but the viruses may be expected to have increased replication capacity in vitro. However, studies with chimeric HCV have shown that sequences which have adapted to be able to replicate with high efficiency in vitro culture do not show a similar increase in replication capacity in vivo in chimpanzees (Bukh et al 2002, PNAS)
The HCV core (C) protein and non-structural proteins, NS3 and NS5A, are potentially hepatocarcinogenic [reviewed in Hepatology research (2008) 38:1-26]. There are several reports detailing the oncogenic potential of NS3 [eg. World J. Gastroenterol (2003) 9 (3):474-478, 3. Virol. (95) 69, (6), 3893-96]. There is no known hazard for any of the remaining structural or non-structural genes. Any virus accidentally released into the environment is not likely to survive as HCV is restricted to replication in human and chimpanzee cells only.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquids contaminated with GMM will be treated with suitable disinfectant eg Virkon in accordance with the manufacturer's recommendations & left overnight. All other potentially contaminated materials will be autoclaved either at 134°C for at least 3 minutes or 121°C for at least 15 minutes. Autoclaves are monitored on each run and validated annually.

Is an emergency plan required according to regulation 20?

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

As this work will generate thil length viral RNA HCV, the GMSC considers that CL3 containment will be required, and this is therefore a Class 3 activity.

Project Ref 558/08.3
**Assessing the binding and other properties of polyclonal and monoclonal antibodies to Pseudomonas aeruginosa OprM protein.**

The aim of this work is to show binding of polyclonal and monoclonal antibodies to bacteria including Pseudomonas aeruginosa strain PA01 and derivatives. The bacteria would be required to grow in culture in small volumes (up to 250ml). Cells would then be harvested and used in cell-based assays.

**Recipient or parental organism**

Pseudomonas aeruginosa PA01 and derivatives (\(\Delta\)mexAB-oprM, \(\Delta\)mex CD-oprJ, \(\Delta\)mexEFoprN), Genes deleted from part of the RND-type multidrug efflux pump family. Deletion of these genes is likely to make the host strain more susceptible to antibiotics. Various disables commercially purchased E.coli strains. These will be mainly K-12 derivatives (eg DH5a) and CHO-K1/HEK293 cells and derivatives eg DG44.

**Host/vector system**

Expression vectors typically RSV promoter driven. Resistance marker amipicillin, dihydrofolate reductase. All are non-mobilisable plasmids. Also, episomal expression vectors. CMV5 promoter driven. All are non-mobilisable plasmids.

**Origin & function**

Any genetic material used will originate from various disabled commercially purchased E.coli strains (in the case of DNA). These will be mainly K-12 derivatives (eg DH5a). Any protein material will originate from CHO-K1 and HEK293 cells and derivatives eg DG44 or HEK293 cells.

**Evaluation of foreseeable effects**

The aim of this work is to identify polyclonal and monoclonal antibodies to a Pseudomonas aeruginosa membrane protein. The Pseudomonas aeruginosa PA01 and derivatives strains (\(\Delta\)mexAB-oprM, \(\Delta\)mexCD-oprJ, \(\Delta\)mex EFoprN) used have genes deleted that form part of the RND-type multidrug efflux pump family. Deletion of these genes is likely to make the host strain more susceptible to antibodies and is not expected to increase the pathogenicity of the strains.

### Project Additional Information

#### Purposes of the contained use

Open reading frames encoding potential target proteins will be ligated downstream of pol II promoters in a HIV-1 vector transfer plasmid. These will then be packaged into infectious self-inactivating HIV-1 vectors using a commercially available kit ("Block-it Lentiviral RNAi Expression System", Invitrogen Inc.) or similar, replication-defective self-inactivating lentiviral packaging systems and inoculated into cell cultures (primary cell types from human and rodent origin including neurons, microglia, monocytes, and macrophages as well as continuous cell lines such as Ramos and Jurkat), and/or administered to laboratory rodents (by the intravenous, intraspinal or intracranial routes) in order to express the genes of interest and validate them as potential drug targets.

#### Recipient or parental organism

The commercially available kit from Invitrogen is a third generation system based on HIV-1 (see Dull et al., 1998: J. Virol. 72, 8463-71) which allows the construction of a recombinant replication-incompetent, HIV-1-based lentivirus. There are a number of biosafety features which have been introduced to minimise risks. These are as follows:

1. All HIV sequences required for encapsidation and reverse transcription are absent.
2. There is a deletion in the 3' UTR resulting in self-inactivation of virus genome.
3. None of the HIV-1 structural genes contain LTRs and are thus never expressed in the target cell.
4. It contains the minimal number of HIV-1 genes required to generate an efficient vector (only three of the nine are used: gag, pol, and rev).
5. The removal genes are those which are pathogenic therefore no recombinant vector can acquire the pathogenetic features of the parental virus.
6. The tat gene, which is important for replication, has been removed.
7. The packaging genes are contained on 4 separate plasmids and thus the system relies on 4 separate plasmids for the production of transducing particles.
8. These plasmids contain no regions of homology thus preventing any recombination between plasmids.
9. The virus is replication incompetent and as a replication-deficient vector it poses significantly reduced risks. Thus these viruses may infect cells and integrate DNA into the target cell but they are incapable of further replication.

#### Host/vector system

293T cells will be transfected with a lentiviral expression vector (pLenti6, into which the gene of interest will be cloned) and the required packaging plasmids pLP1, pLP2 and pLP3 which supply the structural and replication proteins required for generation of lentiviral vectors.

#### Origin & function

Proteins representing potential drug targets will be over-expressed, i.e. they are naturally expressed in the rodent tissues to which the viral vectors will be administered. Although over-expression of target genes is not expected to have any toxic or oncogenic effects, the precise outcome is difficult to predict. The worse possible scenario for each target gene family is given below:

GPCRs have a role in cell signalling and typically have functions associated with smell sensing, feeding, behaviour, metabolism & homeostasis. Modulating expression of...
GPCRs could therefore be associated with changes in smell sensing, behaviour and the balance of salts, fats and carbohydrates within cells. This could potentially result in decreased cell viability and possibly cell death.

NRs have a role in cell signalling and typically have functions associated with homeostasis, inflammation & regulation of gene expression. Modulating expression of NRs could therefore be associated with changes in the balance of salts, fats and carbohydrates within cells. In addition, modulation of NR expression could lead to the stimulation of, or modulation of, inflammatory responses. This could potentially result in decreased cell viability and possibly cell death.

Ion Channels role is in the movement of ions across cell membranes, they typically have functions associated with neurotransmission and homeostasis. Modulating neurotransmission could thus lead to changes in sensory, motor or cognitive functions. Modulating homeostasis could lead to changes in salt balance which could, in turn, lead to a decreased cell viability and possibly cell death.

Proteases have a role in protein degradation and functional control they are typically associated with tissue remodelling. Modulating the expression of proteases could affect functions such as wound healing or lead to cell death due to the simulation of apoptosis.

Known oncogenes will not be expressed.

**Evaluation of foreseeable effects**

The viral vectors will be inoculated into primary human and rodent cells and continuous cell lines such as HEK293T and Neuro2a and the effects upon target gene expression evaluated. The parental viral vectors have been well characterised and the expression of the cDNA cassette by the transfected cells is not predicted to be harmful.

The viral vector is able to infect a wide range of different cell types, however, since it is replication defective it is unable to establish a productive infection and thus amplify itself in infected cells. Adverse effects following administration of lentivirus vectors have been reported only very rarely and are considered extremely unlikely following accidental exposure to these vectors at the titres to be used.

The viral vector only contains elements required for genome packaging, integration and transgene expression. Furthermore, natural elements that control virus expression have been modified to minimise homology with other retroviral sequences. These features not only prevent viral vector replication but also minimise the potential for the production of replication competent virus by homologous recombination with endogenous retroviral sequences. The viral vector is designed to bestow blasticidin-resistance upon infected cells, however blasticidin is not used for drug therapy in humans and thus would not compromise treatment.

Lentiviral vectors integrate into the host chromosomes and can therefore result in long-term expression. The precise effects of expression of the cDNA cassette when delivered to target cells are difficult to predict as their purpose is the overexpression of novel genes. Although in the worst case, overexpression may lead to cell death or an increase in cell proliferation although this would not be expected as manipulation of genes expected to lead to such a phenotype will not be generated. Any other adverse effects are extremely unlikely at the viral titres to be used.

Designed vectors might, on occasion, contain the Woodchuck Post-transcriptional Regulatory Element (WPRE). Vectors containing the WPRE have been widely used in the past, however one study has reported an association between the use of WPRE and tumour development. Thus the risk of this occurring with the use of our vectors cannot be completely ruled out. In addition, although over-expression of target proteins is not expected to have any toxic or oncogenic effects, the precise outcome is difficult to predict.

All staff generating and testing these vectors will be alerted to the potential oncogenic hazard associated with the use of WPRE-containing vectors. Host E.coli will not be propagated in volumes greater than 400 ml. HIV vectors will be generated in cell cultures of less than 1000ml volumes using CL2 procedures. Syringes will be loaded with viral vectors under CL2 conditions prior to administration to rodents. Volumes injected will be less than 250 ul per injection site. Total dose of viral vector will be between 10e9 and 10e10 transducing units per injection. Animals will be injected by staff trained in the administration of viral vectors to rodents, using standard techniques taking precautions to minimize the chances of inoculating personnel and paying particular attention to the safe disposal of needles. Where possible, animals will be restrained in stereotaxic frames prior to injection. Numbers of animals injected will be no greater than 20 per day. Following injection, the virus is fully contained within the animal. All in vivo work will be done according to specified containment measures.

### Project Additional Information

#### Purposes of the contained use

AAV vectors have great utility in providing the possibility high level sustained expression of recombinant proteins in a variety of tissues in vivo. The recombinant AAV vectors contain no AAV replication proteins, and so are entirely replication deficient, minimising any risk of transmission. The vectors covered in this proposal will be used to express a variety of recombinant gene products known to have low or no inherent toxicity oncogenicity or potential for harm. However, the genes may have the potential to produce a biological effect that may result in a reduction in the viability of the infected cells, so the precise outcome is difficult to predict. Known oncogenes will not be expressed.

#### Recipient or parental organism

E.coli, standard lab strains eg. DH5alpha, JM109, DH10Bac. No expression expected to arise from mammalian promoters in E. coli.

Mammalian cells (CHO K1, HEK 293) are established cell lines.

AAV is not associated with any disease in humans.

#### Host/vector system

AAV vectors have a long history of safe use. The recombinant vectors will be replication defective and are most unlikely to show altered tropism, pathogenicity or immune response. Designed vectors might, on occasion, contain the Woodchuck Post-transcriptional Regulatory Element (WPRE). Vectors containing the WPRE have been widely used in the past, however one study has reported an association between the use of WPRE and tumour development. Thus the risk of this occurring with the use of our vectors cannot be completely ruled out.

#### Origin & function

Many of the target proteins to be expressed using the AAV system are likely to have already been expressed in other mammalian expression systems based on plasmids or Baculoviruses. Genes selected for use will have no or low known toxicity, oncogenicity or potential for harm. Genes will be of human or animal origin, and may be isolated from tissues by PCR or assembled from synthetic oligonucleotides.

#### Evaluation of foreseeable effects

Recombinant AAV's have a long history of safe clinical use. The viral vector is able to infect a wide range of different cell types. However, since it is replication defective it is unable to establish a productive infection and thus amplify itself in infected cells.

The effect of the GMO is therefore most likely to be dependant on the effect of the expressed protein. Genes selected for use will have no or low known toxicity.
oncogenicity or potential for harm. However, the genes may have the potential to produce a biological effect that may result in a reduction in the viability of the infected cells so the precise outcome is difficult to predict. Known oncogenes will not be expressed.

One specific example, considered to be the greatest likely risk is the cytokine, IL-23.

IL-23 is a member of a small family of pro-inflammatory heterodimeric cytokines. The cytokine is naturally produced by activated dendritic cells and phagocytic cells. The receptors for IL-23 are expressed by T cells, natural killer cells and monocytes and DCs. IL-23 is believed to be a critical sign that drives the newly identified T-helper 17 pathway. This can lead to the recruitment of a range of inflammatory cells, in addition to Th17 T cells, and has been shown to be crucial to the pathogenesis of a number of immune-mediated inflammatory diseases (e.g., Psoriasis).

Murine models of chemical carcinogenesis using either IL-23 gene knockout animals or treated with anti-IL-23 neutralising mAbs demonstrate that ablation of the IL-23 gene product allows for a more robust adaptive immune response within the tumour - rendering a protective effect against the chemically induced tumour. An increase in IL-23 expression may be associated with an increased risk of development of cancers.

The work will involve inoculation of mice with recombinant non-replicating AAV and the subsequent handling of tissues from the animals. There is a risk of accidental needlestick injuries when carrying out these procedures. The use of a replication deficient AAV minimises the spread of the virus within an infected animal and minimises the likelihood of virus being secreted therefore reducing the risk of transmission to the laboratory worker.

The work will be carried out as follows:

Procedure for Immunisation with AAV.
Mice will be inoculated inside a class I microbiological safety cabinet for the containment of any aerosols. Virus will be administered by the intradermal, intraperitoneal or intravenous routes using a needle and syringe. Used needles and syringes will be disposed of in the appropriate sharps bin inside the class I cabinet. Any potential contamination of the operator via aerosols should be minimised by the wearing of eye protection, gloves, hat, mask. At the end of the immunisation procedure gloves, hat, mask should be disposed of in the appropriate waste bags.

Animal Containment
Infected animals are to be housed in cages.
All procedural work will be carried out using a class I microbiological safety cabinet.
The room used for housing mice is maintained under negative pressure relative to the immediate surroundings.
All waste (food, bedding carcasses) will be removed from the unit and incinerated.

Procedure for Isolation of Tissues
Tissue isolation will take place in a class I microbiological safety cabinet. The operator should wear the appropriate protective clothing as described above. Mice will be euthanased with an overdose of barbiturate drug (Sagatal). Sharps disposed of in the bin inside of the cabinet. Tissue samples will be removed into either:
(i) a plastic disposable tissue grinder, complete with plastic sheath and screw cap lid to minimise aerosol contamination. Or collected into fixative for histology. These can then be transported to the lab for subsequent processing.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

### Project Additional Information

**Purposes of the contained use**

Use of lentiviral vectors containing wild type fragments of the Woodchuck Hepatitis Virus Posttranscriptional regulatory region.

**Recipient or parental organism**

HIV-1 based lentiviral vectors

**Host/vector system**

Lentiviral vector system

**Origin & function**

The WPRE region is included in lentiviral vectors to increase transgene expression by improving the processing of the 3' end of mRNA transcripts.

**Evaluation of foreseeable effects**

The wild type version of the WPRE element contains an open reading frame that codes for a C-terminal fragment of the Woodchuck hepatitis virus X protein. The C-terminal fragment has been indirectly linked with tumour formation, by a possible cooperation with ras and myc oncogenes (1,2); however, mice treated with LVs containing the wild type WPRE or a mutated version did not develop tumours (14).

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste will be decontaminated using Virkon at 1% in a 12h exposure. Solid waste will be double-bagged and autoclaved before disposal. Sharps will be disposed of in sharp bins that will be autoclaved before disposal.

Please enter comments on the GM safety committee on the risk assessment

Although the vector contains the WPRE sequence it is not capable of expressing the X protein of WHV and so Class 1 categorisation is consistent with the SACGM guidance on lentiviral vectors. March 2016

Change of classification due to using LV-GFP, since this vector has a wild type version of the WPRE element. Also because of the introduction of using Rapid Evaporative Ionization Mass Spectrometry which will create a small amount of aerosol.

Date Ackn'd 28/12/2016

CU2 Project Title Generation of lentivirus coding for an oncogene or cytokine

Class 2

CultureVolClass2 1-50 Litres

Consent Granted

Project notified under transitional arrangements N

02/03/2022
## Project Additional Information

### Purposes of the contained use

Use of Lentiviral vectors with the WPRE region coding for Oncogene or Cytokine.

### Recipient or parental organism

E.Coli, CHO, Primary Cells

### Host/vector system

Lentivirus Vectors.

### Origin & function

The WPRE region is included in the lentiviral vectors to increase transgene expression by improving the process of the 3'end of the mRNA transcripts.

### Evaluation of foreseeable effects

High likelihood of harm arising from GMM given the delivery is of an oncogene known to be involved in carcinogenesis, further exacerbated by the use of a delivery vector that will integrate into genomes and the use of a pseudotype that enables transduction of a wide variety of cell types.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

This is not applicable to this notification.

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Autoclaved waste destined for incineration will be transported off site by a registered and competent waste contractor. The Waste will be appropriately contained and labelled up for transportation to an incinerator.

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste will be decontaminated using Virkon at 1 % in a 12h exposure. Solid waste will be double-bagged and autoclaved before disposal. Sharps will be disposed of in sharp bins that will be autoclaved before disposal.

02/03/2022
Cloning of protein expressing cassettes into human immunodeficiency virus -1 (HIV-1) lentiviral vectors containing the endogenous long terminal repeat (LTR) and their use to express specific genes in cultured mammalian cells and subsequent to transduction with lentiviral vectors.

Recipient or parental organism

E.Coli, CHO, HEK, Jurkat cells, Hepatocytes, Primary Cells

Host/vector system

Lentiviral vectors

Origin & function

Peripheral blood mononuclear cells (PBMCs) will be isolated from peripheral blood (obtained from commercial supplier) and activated with TransAct beads (obtained from a commercial supplier) prior to transduction with LTR and SIN GFP encoding lentiviral vectors, or CAR encoding LTRISIN lentiviral vectors.

The chimeric antigen receptor single chain variable fragment (scFv) sequences will be taken from monoclonal antibodies specific for targets including Human Epidermal Growth Factor 2 (HER2/ErbB2), epidermal growth factor receptor variant III (EGFRvIII) and Carcinoembryonic antigen (CEA) - all of which are antigens commonly expressed.
CAR constructs will be designed to include C028 or 4-1 BB costimulatory domains and different spacer domains (i.e. C08 spacer, C04 spacer or TNFR2 spacer) - to enable determination of whether different CAR constructs components can lead to increased risk of insertional mutagenesis. In addition to this, the phosphoglycerate kinase (pGK) promoter commonly used within third generation (SIN) lentiviral vectors may be exchanged for the stronger Spleen Focus-Forming virus (SFFV) promoter within future experiments. The use of this stronger promoter within SIN third generation lentiviral vectors may increase the cis activation and genotoxicity of the viral vector insertion, without increasing the risk of recombination with wild-type HIV-1 virus. This may provide an improved positive control for genotoxicity, compared to 2nd generation L TR lentiviral vectors, by increasing genotoxicity whilst maintaining the SIN lentiviral vector format.

Evaluation of foreseeable effects

If the second generation L TR containing lentiviral vectors were to come into contact with individuals or cells infected with a wild type HIV-1 infection, there would be an increased risk of recombination with wildtype HIV-1 viruses and the formation of replication competent lentiviral vectors compared to when using third generation SIN lentiviral vectors. However, the risk of recombination of second generation lentiviruses with wildtype HIV-1 viruses remains low due to the low homology that the lentiviral vectors have with endogenous HIV-1 viruses. This risk can be further reduced by ensuring that all blood donors are screened for HIV-1 infection. In addition to this, extra pre-cautions would be taken if a lab user suffers from a HIV-1 infection.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

This is not applicable to this notification.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste, such as media taken from transduced cells, will be inactivated with 1 % virkon solution for 24 hours prior to pouring down the sink with plenty of water. Autoclaved waste destined for incineration will be transported off site by a registered and competent waste contractor. The Waste will be appropriately contained and labelled up for transportation to an incinerator.

The risk assessment attached has been reviewed by the GMSC and it has been agreed that this risk assessment should be notified to the HSE as a class 2 GMO.
Project Title: Conditionally self-inactivating lentiviral vector CRISPR-sgRNA libraries

Class 2

Consent Granted

Project notified under transitional arrangements

Withdrawn

Tick if notifying a connected programme of work

Purposes of the contained use

Conditionally self-inactivating lentiviral vector CRISPR-sgRNA libraries

Recipient or parental organism

E.coli K12 derivatives

Host/vector system
Lentiviral Vectors

Origin & function

Lentiviral Vector - sourced from an external supplier

CRISPR Cas9 from Streptococcus Pyrogenes, function - Cas9 introduces a double strand DNA break in cells, targeted by sgRNA, dCas9-VP64 and MS2-P65-HSF1 activate transcription of promoters adjacent to genome location targeted by sgRNA

Evaluation of foreseeable effects

According to the American Biological Safety Association, "the two major risks of lentiviral vectors are: a) the potential generation of replication competent virus; and b) the potential for oncogenesis through insertional mutagenesis."

a) Due to the usage of 3rd generation packaging systems, the lentiviral particles that are produced are replicationdeficient and the virus cannot propagate itself.
b) Following accidental exposure with lentiviral particles, it cannot be excluded that the lentivirus could integrate randomly into the host's genome, and this could increase the risk for oncogenesis when regulatory genes or regions are targeted.

The CRISPR/Cas9 knockout and gene activation libraries have the potential to knock out or activate transcription of all human genes through either on- or off-target activity. If introduced into an operator's cells, knockout or activation of tumour suppressor genes or proto-oncogenes could lead to oncogenesis. Disruption of genes involved in innate or humoral immunity could lead to dysregulation of the immune system. The risk of these events during this work is expected to be extremely low as expressing Cas9 or Cas9 derivatives and sgRNA from separate lentiviral transfer vectors means that vectors encoding Cas9 protein and sgRNA must both enter the same cell to be functionally active against the DNA target site. If target cells are transduced with a Cas9 lentiviral vector and a separate sgRNA lentiviral vector at different timepoints (e.g. 2 weeks apart) this further reduces the risk that both vectors could enter the same cell and carry out gene editing as two separate operator exposures resulting in transduction of the same cell(s) would need to occur.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not relevant to this application.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be decontaminated by using a 1 % Virkon solution, allowing over night decontamination before disposal.
All plastic ware and gloves are collected in an autoclavable plastic bag and autoclaved on site before incineration.
Surface decontamination will be with 1 % Virkon solution.

Is an emergency plan required according to regulation 20?

Project Ref 558/19.1

Date Ackn'd: 10/01/2019

CU2 Project Title: Infection of cultured human cells with mutant strains of Salmonella enterica serovar Typhimurium lacking the prgJ, fltC and fljB genes

Class: Class 2

Culture Vol: < 1 Litre

Non-GMM Consent Granted

Project notified under transitional arrangements

Historical Significant Changes

Date of Significant Change

Project Additional Information
### Purposes of the contained use

Use of *Salmonella enteritica* serovar *typhimurium* Organisms with knock out genes which are still capable of replicating and potentially causing infection.

### Recipient or parental organism

*Salmonella enteritica* serovar *typhimurium*

### Host/vector system

*Salmonella enteritica* serovar *typhimurium*

### Origin & function

The *LlfIC L’fIjB, L’prgJ* and *L’fIiC L’fIjB L’prgJ* strains described in this document carry mutations that result in a degree of attenuation in mouse models of colitis, characterised mainly by reduced intestinal inflammation.

### Evaluation of foreseeable effects

The wild-type *S. Typhimurium* parent strain of these mutants is a Biosafety level 2 organism that can cause human disease, in particular, gastroenteritis. This is usually characterised by vomiting, abdominal cramps, headache, chills and fever up to 39°C. The document 'Standard Risk Assessment for Work with *Salmonella enterica* serovar *Typhimurium'* should be consulted for details on how to work safely with this strain. Details of these controls can be found below:

**Engineering Controls:**
- Work is conducted in laboratories designed to BSL 2 standards. Class 2 Ducted Microbiological Safety Cabinets are used for work which may generate infectious aerosols.
- Sealed centrifuge buckets or rotors are used to contain aerosols during centrifugation of infectious material.

**Administrative Controls:**
- Access to the laboratory is restricted to authorised persons.
- Work is carried out only by suitably trained persons and is conducted following the principles of good microbiological practice and occupational hygiene as described in the Local R&D Biosafety Manual and regulatory guidance for work at BSL 2. The work area will be thoroughly cleaned following completion of the work, and all surfaces disinfected with 70% ethanol or a 1:1 00 Virkon solution to prevent cross contamination.

**Personal Protective Equipment:**
- Laboratory coats and safety glasses are mandatory. Appropriate gloves (from local glove selection guide) are worn when handling hazardous material.

**Signage:**
- A Hazard Card system will be used during all work with *S. Typhimurium* and will clearly display the nature of the hazards to any nearby individuals.

The *b.fIiC b.fIjB, b.prgJ* and *b.fIiC b.fIjB b.prgJ* strains described in this document carry mutations that result in a degree of attenuation in mouse models of colitis, characterised mainly by reduced intestinal inflammation. Although none of these strains have been tested in humans, extrapolation from the mouse data suggests that although they may be partially attenuated, they are still likely to colonise human hosts and have the potential to cause some degree of disease. It is highly likely that they would elicit less inflammation and pathology than the wild-type parent, SL 1344, but they should still be considered virulent.

---

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be decontaminated by using a 1% Virkon solution, allowing overnight decontamination before disposal.
All plastic ware and gloves are collected in an autoclavable plastic bag and autoclaved on site before incineration.
Surface decontamination will be with 1% Virkon solution.

Please enter comments on the GM safety committee on the risk assessment

The GMSC met to discuss this risk assessment and felt the risk assessment had been well written. It was requested that there was a little more clarity added around the cleaning between experiments. Add in a reference to the SACGM guidance. Please provide a little more clarity on the use of 2nd generation L TR and 3rd generation packing components. It was agreed by the GMSC this was a class 2 GMO risk assessment and therefore requires a notification to the HSE.

Please enter comments on the GM safety committee on the risk assessment

The consensus of the GMSC is that although this GMO risk assessment could be considered to be on the border line it would be beneficial to air on the side of caution especially as it can not be ruled out what the house keeping gene is. Therefore this risk assessment is being notified to the HSE.

Project Additional Information

Purposes of the contained use

The purpose of the contained use is to generate recombinant human TNF-alpha for purification and subsequent use as reagent in in vitro assays.

Recipient or parental organism

E. coli JM105 (thi, rpsL(Str), endA, sbcB15, hsdR4, supE_(lac-proAB), f'[traD36,proAB+, lacI, LacZ_M15]), supplied by Amersham Biotech, Amersham, UK).

E.coli NovaBlue (endA1, hsdR17(rk12-,Mk12+), supE44, thi-1, recA1, gyrA96, relA1, lac[f'proA+B+, lacQZ_M15_Tn10(tet)], supplied by Novagen, Madison, USA).

E.coli XL1 blue (recA1 endA1 gyrA96 thi-1 hsdR17 supE44 relA1 lac [FcpROAB lacIq ZDM15 Tn10 (Tet)] (Stratagene).

The host E coli strains NovaBlue, XL1blue and JM105 are E. coli K12 derivatives and have a long history of safe use. They are non-colonising and multiple disabled. In terms of environmental safety, the host strains are multiply disabled, and are unlikely to survive in the environment, and considered non-pathogenic to humans or animals.

Host/vector system

The plasmids are well characterised, non-mobilisable, derivatives of commercially supplied plasmids with an established history of safe laboratory use.

Origin & function

The cDNA encoding human TNF-alpha will be obtained from the Medical Research Council Laboratory of Molecular Biology, in either the native human form, or the E. coli codeon optimised form. Native TNF is expressed in the human as an inactive membrane-bound 233 amino acid precursor, which becomes active upon cleavage between residues 76-77. We will clone the truncated cDNA, encoding the active portion of the molecule in-frame with the N-terminal epitope tags His6 and HA or FLAG. Induction of expression with IPTG (isopropylthiogalactoside) will result in the production of a soluble TNF-alpha fusion protein, which is likely to be biologically active. This fusion protein will be affinity purified on nickel based resin, and eluted with imidazole to produce epitope-tagged TNF-alpha, which may be further purified.

The intended function is therefore to produce active soluble TNF-alpha.

Evaluation of foreseeable effects

TNF-alpha is a pro-inflammatory cytokine, produced mainly by activated monocytes and macrophages, and appears to be a key mediator in the induction of cytokine cascades associated with inflammatory responses. Recombinant human TNF-alpha has been used in a number of clinical trials as an anti-cancer therapy with intravenous doses of up to 300mg being tolerated (eg F Lejeune et al (1994) Journal of Cellular Biochemistry 56:52-61).
The most likely effect of accidental ingestion or injection of recombinant TNF-alpha would be localised inflammation and pyrexia. It is extremely unlikely that a person could be exposed to TNF-alpha levels exceeding the levels used clinically through the experimental work above. Even if all native gut flora were replaced with E. coli harbouring the plasmid encoding the TNF-alpha fusion protein, in the absence of induction protein expression levels are low, and unlikely to exceed this level. There is also a small risk of anaphylaxis, although this risk is common to many proteins, and the Class 2 precautions that this work will be done under will reduce this risk to effectively zero.

The planned experiments utilise disabled host strains that are unlikely to survive in the environment. In terms of environmental safety, the host strains are multiply disabled, and are unable to survive in the environment, and considered non-pathogenic to humans or animals. The expression of a pro-inflammatory cytokine is unlikely to enhance the pathogenic potential of the final GMO, and may decrease any such potential, by inducing a more potent immune response.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

*not applicable*

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

*No containment derogations are being applied for.*

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All solid waste contaminated by GMMs and bacterial cell pellets to be disposed of by autoclaving at a load temperature of 121 degrees C for 20 minutes. This disposal route is considered to give essentially 100% kill of E. coli. The site autoclave is routinely tested for temperature and pressure attainment, and verification of waste inactivation.

All GMM liquid wastes to be inactivated by addition of Virkon to >0.25% final concentration, allowed to stand for 30 min and then disposed of down sinks, with additional running water to dilute the waste.

Contaminated re-useable glass and plastic ware will be similarly disinfected with 0.25% Virkon prior to washing. Virkon has been shown to give >6 logs of kill of E. coli under these conditions (source: Antec International). This will be verified by streaking of a sample of the inactivated fluid onto Luria agar plates, which should show no growth if inactivation is effective.

These procedures will reduce any risk to humans or the environment to effectively zero.

The application was considered by the GMSC to be at class 2. The host/vector system used is of minimal hazard, but hearing in mind the potential biological activity of the cytokine produced, class 2 working was considered appropriate to contain all potential hazards.

**Project Containment**
**Project Ref:** 798/05.1

**Date Ackn'd:** 22/06/2007

**CU2 Project Title:** Expression of Peptostreptococcus magnus Protein L domains B1-4 in E. coli under shake flask and fermentation conditions.

**Class:** Class 2  
**CultureVolClass:** 100-1000 mL  
**Consent Granted:** Not Applicable

**Recipient or parental organism:** RV308 ( (lac)X74 galPO-308::IS2 rpsL). Source ATCC. An E. coli K12 derivative, non-colonising.

**Host/vector system:** pAL15M. Kanamycin resistant, toluic acid inducible expression of insert protein. Mobilisable, OriV and OriT wild type from RK2 are present. Expression is induced in this system using the specific inducer toluic acid. Expression levels in the absence of inducer are low.

---

**Purposes of the contained use:**

Protein L is a cell wall protein of Peptostreptococcus magnus. It has a multiple domain structure, consisting of an A domain, and five B domains, termed B1-B5 which are homologous IgG binding domains. The remainder of the protein anchors it to the peptostreptococcal cell wall.
Origin & function

Insert DNA originally from Peptostreptococcus magnus. Contains the B1-B4 domains of protein L, giving a high affinity IgG binding protein. This will be produced as soluble functional intracellular protein once the culture has been induced with toluic acid.

Evaluation of foreseeable effects

The full length protein is a bacterial superantigen. Expression of the protein in Peptostreptococcus sp. Correlates with virulence. Expression as a cytoplasmic protein would not be predicted based on the available evidence to make the E. coli pathogenic, as the proteins role in pathogenesis correlates with cell surface expression in the wild-type organism.

The B1-B4 domain shown here will also act as a superantigen, and has been shown to stimulate B cell proliferation in a polyclonal fashion, and to cause depletion of subsets of B-cells via apoptosis. Thus the protein may be expected to have immunological effects.

The protein has also been shown to trigger histamine and other cytokine release from mast cells and basophils via cross linking to surface IgEs. Therefore it has the potential to cause anaphylaxis on inhalation or absorption.

The protein may be a sensitiser, and thus skin contact or inhalation must be avoided.

The use of mobilisation competent vector makes transfer to related species more likely. However, expression from a mobilisation defective vector has been shown to be lower, therefore requiring larger culture volumes and increased risks (Affitech data not shown).

Various Peptostreptococci are already found in the environment, some of which express Protein L as a superantigen. Therefore, with the containment used within the lab, together with the inactivation methods used, makes the risk of any additional environmental hazards effectively zero.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Spills will be disinfected with solid Virkon powder. This has been tested by plating experiments on shake flask cultures and low cell density fermentation to give essentially
100% inactivation of organisms in split media. Fermenters will be sterilised post fermentation at 121 degrees C for 60 minutes. This has been shown to give 100% inactivation of organisms. Liquid waste and spent culture medium will be sterilised by autoclaving at 121 degrees C for 60 minutes. This has been shown to give 100% inactivation of viable organisms. Sterile liquid waste will then be offsite incinerated. Centrifuge bottles and solid wastes will be sterilised by autoclaving as above. This has been shown to give 100% inactivation of viable organism. Solid waste will then be offsite incinerated with the clinical waste stream. Re-usable lab items will be disinfected in >2% Virkon for >30 minutes. This has been demonstrated to give essentially 100% kill of viable organisms. They will then be washed. Additional testing of inactivation will be performed, where necessary, by streaking samples onto 2xTY plus kanamycin plates. All items to be cleaned will be kept wet to avoid the production of dry material containing Protein L with dust hazard potential and cleaned promptly.

The application of the expression of Protein L using the Affitech HCD fermentation protocol was approved at class 2 as DM38, and will be notified to the HSE. Emphasis must be placed on the potential for sensitisation and anaphylaxis for the protein, under COSHH. All work with this system must be covered by SOPs for exposure control and cleanup. These will be drawn up and approved before work can start.

</tbody>
</table>
extending serum half-life in E. coli and P. pastoris.

E. coli will be transformed with an expression construct with the intention of maximising expression levels of the fused protein. It has been shown that periplasmic/soluble expression of this cytokine in E. coli results in active protein. In vivo, the protein is known to affect cell growth and development and in clinical trials has been shown to cause a range of effects, both local and systemic. The Domantis GMSC considered the possibility of deleterious effects due to this GMO warranted classification to CL2.

Likewise P. pastoris will, in all probability, secrete active protein. It is considered that the recipient organism in this instance is less liable to colonise or persist in the environment, and this work is therefore classed at CL1.

E. coli stains based upon the genetic backgrounds K12 (TOP10f', JM83, HB2151), W (Mach I) and B (BL21) will be used for cloning and expression work. Vectors used will be based upon the commercially available vectors pET21 and pET23, and the Domantis vector pDOM5. The pET vectors contain the T7 promoter under IPTG control; pDOM5 contains the lac promoter under IPTG control. None of the vectors are considered mobilizable.

The cDNA for cytokine will be created synthetically under contract. The genetic material for the half-life extending moiety derives from Domantis phage libraries. In these constructs this functionality will be inactivated.

The expression constructs generated will be used to direct the production of a recombinant fusion protein, different strategies will be employed based upon refolded inclusion bodies as well as soluble secreted protein. It has been assessed that the fusion expressed in inclusion bodies results in a less hazardous GMM that can be manipulated under CL1. Soluble material will also be produced in mammalian cell culture. Due to the nature of this expression system, it is also considered to be suitable for manipulation at CL1, although for sample protection it will be handled at CL2.

The cytokine is a potent growth factor, with a pleiotropic range of biological effects. Two distinct receptors exist though the specific roles of these distinct molecules has yet to be fully elucidated. The cytokine has been shown to be mitogenic for certain cancer types including breast cancer, and mutations in one of the receptors are associated...
with a range of adverse effects in affected individuals. The production of a fully functional cytokine from genetically modified E. coli has the potential to, in a worst-case setting, expose workers to the effects of the cytokine, which are reportedly related to various types of pain. The formatting with a half-life extending moiety has the likely effect of extending the residence time in the circulation of anyone that may become exposed to the cytokine. This will be unlikely to occur in these compounds where the function will be inactivated; however the larger molecule may still have some minor half-life extension. Although E. coli strains being used are disabled, it is the recommendation of the GMSC that additional containment in line with CL2 regulations are applied for this work.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

The application was considered by the GMSC to be at class 2. The host/vector system used was considered to be of low hazard, but attention was paid to the potential biological activity of the cytokine produced and the likely extended half-life in the event of serum exposure. Therefore class 2 working was considered appropriate to contain all potential hazards.

Project Additional Information

Purposes of the contained use

Minimise risk to human health that may occur should infection of mycobacterium bovis (BCG) with antigens/cytokines modify the BCG to cause a pathological response.

Recipient or parental organism

Mycobacterium Bovis (BCG)
Mycobacterium Smegmatis
Mycobacterium Vaccai
E. coli (DH 5 degrees C)

Host/vector system

Non-mobilisable shuttle-vectors, including pMOD-8, pMOD-12
Expression regulated by mycobacterial heat shock protein.

Origin & function

- Characterised cytokines and antigens.
- The aim is to a) induce an immune response; b) modify the immune response to mycobacteria by expressing cytokines and antigens.

Evaluation of foreseeable effects

Expressions of cytokines and antigens in mycobacteria is likely to improve the immune response. These mycobacteria may be useful for the treatment of cancer by
- generating systemic specific immune responses
- delivering cytokines locally.

No known risk is presented to the environment; The mycobacteria will not obtain a survival advantage when expressing cytokines/antigens.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Work with BCG expressing antigen genes that are not allergens and murine cytokines that are known not to act on human cells will be carried out at containment 2 (Class 2 activity), as these antigens and mouse cytokines have no known biological effect on human cells and consequently will not cause increased pathogenicity of BCG.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All mycobacteria waste generated in Class 1, 2 or 3 activities is to be autoclaved to ensure 100% kill. (Autoclave efficiency checked weekly).

Is an emergency plan required according to regulation 20? Y

If yes, tick to confirm that it is attached to this form Y

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

02/03/2022
The unit Biological Safety Committee felt it was highly unlikely expression of proposed cytokines and antigens would modify the pathogenicity of BCG, however in the absence of data to support this, work with BCG will be performed at Class 3 if using human cytokines.

Project Ref 559/01.7

Date Ackn’d 20/04/2001

CU2 Project Title RANDOM AND SITE DIRECTED TN5 MEDIATED MUTAGENESIS OF BURKHOLDERIA CEPACIA WITH MARKER RESCUE ANALYSIS, TO IDENTIFY HOW ENVIRONMENTAL FACTORS AFFECT GENE EXPRESSION AND RESISTANCE

Class 2  Non-GMM Consent Granted not applicable

Project notified under transitional arrangements N
**Project Additional Information**

**Purposes of the contained use**
To facilitate an MRC/DERA research programme to identify genes that may be involved in resistance to antimicrobial peptides. Additionally this research will examine how the expression of these genes are affected by culture environment.

**Recipient or parental organism**
*Burkholderia cepacia* is a ubiquitous Class ACDP category 2, environmental organism which can cause lower respiratory tract infection in individuals with cystic fibrosis and systemic sepsis in immunocompromised patients especially those with chronic granulomatous disease. GMOs generated during this project are likely to be no more harmful than the unmodified host.

**Host/vector system**
*Burkholderia cepacia* will be the host for insertion of plasmid mediated transposons (Tn5) for insertional inactivation and marker rescue. Initially pOT182 will be used for this purpose as it has been fully characterised and shown to be effective for transposon mediated mutagenesis in *Burkholderia cepacia*.

**Origin & function**
*Burkholderia cepacia* strains will be provided by Dr. K Kerr of the Microbiology Department of the University of Leeds. Dr Kerr has a great deal of experience of working with this organism. The Tn5 transposon containing plasmid pOT182 is a pBR325 based plasmid containing the Tn5-B21 cassette from pSUP 102(Gm) and was provided by Professor I Lamont. The construction of this vector has been described (Merriman and Lamont, 1993, Gene, 17-23). The Tn5 will be used to mutagenise *burkholderia cepacia* and to identify genes that alter susceptibility to antimicrobial peptides. The genes will be identified by sequencing the DNA adjacent to the site of transposition.

**Evaluation of foreseeable effects**
It is expected that recombinant isolates of *burkholderia cepacia* containing the Tn5 cassette are likely to be no more hazardous than the parental organism. The rationale for this is that no new genes (other than those contained within the transposons) will be inserted into the host. The reason for classification of this as a class 2 project is that *burkholderia cepacia* is listed as an ACDP category 2 pathogen.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**
Solid laboratory waste such as pipette tips and disposable loops will be soaked overnight in discard pots containing 1% Virkon and autoclaved. All glassware that comes into contact with *burkholderia cepacia* will be autoclaved. All liquid and solid cultures will be autoclaved. Autoclaving will be carried out at 121°C for 15 minutes. Disposable autoclave waste will be removed for incineration. It is envisaged that these proposals will ensure a 100% kill of all GMOs.

- **Project notified under transitional arrangements**

---

**Project Additional Information**
Purposes of the contained use

The phenotypes of gene disruptants will indicate whether the gene products have essential roles in A. fumigatus. This, in turn, will allow us to evaluate these proteins as potential targets for antifungal agents. Reporter gene studies will enable us to monitor the expression of individual chitinases and their regulators in the intact organism during key morphogenetic events including spore germination, hyphal side branch formation and sporulation. Tandem affinity purification will enable us to purify proteins of interest along with associated components. The co-purifying proteins/other components will be identified by mass spectrometry. Novel regulatory mechanisms identified by this approach may present new targets for antifungal agents.

Recipient or parental organism

Aspergillus fumigatus strain ATCC 13073

Host/vector system

A. fumigatus/all vectors are derived from plasmids of the pUC series and are considered to be non-mobilisable.

Origin & function

For gene disruption, gene(s) encoding enzymes that confer resistance to antibacterial antibiotics (hygromycin and/or phleomycin) will be used to disrupt genes encoding A. fumigatus chitinases or transcriptional regulators by insertion of the resistance genes into the A. fumigatus genome. For reporter gene studies, an Escherichia coli B-galactosidase gene will be inserted into the A. fumigatus genome so that this gene is expressed under the control of specific A. fumigatus promoters. For TAP-tagging, genes encoding a calmodulin binding protein and protein A will be inserted at the C-terminus of chitinase genes to enable expression of tagged chitinase proteins.

Evaluation of foreseeable effects

Most humans inhale several hundred A. fumigatus conidia per day and inhalation of conidia by immunocompetent individuals rarely has any adverse effect. A. fumigatus may provoke severe allergic reactions such as farmer's lung in individuals exposed repeatedly to large numbers of conidia and may cause aspergilloma, an outgrowth of fungus on the surface of preexisting cavities in the lungs of patients treated successfully for TB. A. fumigatus can cause serious, often fatal, infections in immunocompromised hosts. Gene disruption may reduce the virulence of the host while reporter gene studies and TAP-tagging are unlikely to affect the pathogenesis of A. fumigatus.

It should be emphasised that A. fumigatus will be cultured in a sealed incubator and if breakage of a culture vessel occurred within the incubator this could be dealt with readily, using Hycolin, with negligible risk to the operator. If breakage of a 400 ml culture occurred in the laboratory any spores present would, in the first instance, be contained within small drops of the culture medium which could be dealt with, using Hycolin, immediately ie the situation would not arise where large numbers of spores became desiccated and airborne.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Vessels used for the culture and disruption of genetically-modified A. fumigatus will be de-contaminated by autoclaving (departmental facility). Contaminated surfaces will be disinfected using Hycolin and materials used for disinfection will be autoclaved (departmental facility). Culture stocks will be disposed of by autoclaving (departmental facility). It is anticipated that these procedures will result in 100% kill. Autoclaved material will be removed from the building as clinical waste.
At its meeting of 1/3/01 the GM Safety Committee recommended minor modifications to the risk assessment and notification form. These modifications have now been made to the satisfaction of the Committee. D G Adams 27/3/01.

Significant Change ID
**Purposes of the contained use**

To investigate the functions of gene products in the blood stages of the malaria parasite for the discovery of new targets for treatment. Proliferation of the blood stages are responsible for the mortality although these stages are innocuous outside of the bloodstream.

**Recipient or parental organism**

Strains of *P.falciparum* susceptible to several antimalarial drugs will be used. Most commonly, strain 3D7 which is susceptible to all known antimalarial drugs, particularly chloroquine. Only the blood stages will be transfected. High numbers of these parasites (>10^4) injected I.V. would be required to cause infection.

**Host/vector system**

The plasmid vectors for transfection are 1) the published plasmid which encodes resistance to pyrimethamine and 2) a plasmid containing a bacterial resistance gene for the antifungal agent blasticidin. The standard disabled cloning strains of *E.coli* are used for amplification of the plasmid vector.

**Origin & function**

The genetic material consists of genes encoding metabolic enzymes from *P.falciparum* or related protozoa (*Toxoplasma gondii, Eimeria tenella*). There are no foreseeable risks for transfection of housekeeping genes. The genes may integrate into the *P.falciparum* genome, disrupting the endogenous gene, and decreasing the viability of the organism.

**Evaluation of foreseeable effects**

One of the vectors will induce resistance to the antimalarial drug pyrimethamine but pyrimethamine is not commonly used because of the high amount resistance in the field. All the transfected parasites will remain sensitive to other antimalarial drugs (eg chloroquine). There are no foreseeable effects on the risks for the GMMs with the genes transfected except the possible decrease in parasite viability. The blood stages of the parasites are only dangerous if injected into the bloodstream. Injection is impossible as no sharps are permitted in the cultivation facility. Hence the risk is essentially zero.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

I request a derogation to Class 2 for the following activities: movement of material to autoclave; performing manipulations outside the Class 2 cabinet; and aerosol minimisation. I request derogation of the requirement for autoclaving of solid waste to take place within the Class 3 facility to supervised movement of the solid waste to the autoclave 10 meters down the hall. I request permission to perform manipulations of the transfected *P.falciparum* on the benchtop in the Class 3 facility in accordance with Class 2 regulations (Under schedule 8, GM-Contained Use 2000 Regulations). Lastly, all procedures performed will minimise aerosols in accordance with Class 2 regulations rather than prevent aerosols. These derogations are requested because the assessed risk of infection or transmission is negligible for the blood stages of the parasite and infections are treatable with common antimalarial drugs.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste is treated with 2.5% Precept for at least 12 hours, then rinsed down the drain with copious quantities of water.

Solid waste is autoclaved in isolated runs, then incinerated via the University system. Validation of autoclaving via Brown’s TST Control Integrator strips. Validation for incineration via the University of Leeds tagging system.

---

Project Additional Information

Purposes of the contained use

Research work to investigate regulation of cyl (haemolysin) and other virulence factor gene expression in Enterococcus faecalis

Recipient or parental organism

Enterococcus faecalis laboratory and environmental/clinical strains

Host/vector system

Host:: (E. faecalis NCTC775 and environmental isolates (strain types 1, 2 and 3)). E.faecalis is a class 2 bacterium.NCTC775 has been in laboratory culture for many years; it has lost the cyl haemolysis virulence genes essential for infection. The strain types 2 and 3 are also spontaneously attenuated, since they too have lost these cyl genes. Strain 1 (of strain type 1) possesses cyl, but exhibits high sensitivity to vancomycin and was isolated as a contaminant from the environment, rather than a focus of infection. No connection with an infection has been established for this strain. E.coli strains involved in plasmid construct preparation will be laboratory-adapted auxotrophs that are unlikely to survive in the environment, and are therefore considered to be class 1 and hence containment level 1 is sufficient. Vectors. Plasmids pUC, pBluescript; pVA838; pLTV1, pVT1-OK.

Origin & function

Plasmids pUC, pBluescript will be used for specific knock-outs; report studies use pVA838 with gfp gene inserted; random mutagenesis involves pLTV1, pLTV-OK. These are on-mobilisable plasmid vectors that do not possess mob sites; pUC and pBluescript cannot replicate in E. Faecalis. pLTV1 and pTV1-OK both possess Tn917 for insertionional inactivation; these plasmids possess a temperature-sensitive locus that ensures that the plasmid is lost from Enterococcus strains at 42-45OC. There are no genes that might increase the level of risk. the knock-out plasmids also possess erm and tet resistance markers; these are not of clinical significance. Reporter plasmids are based on pVA838 that possesses a streptococcal origin of replication, gfp reporter gene and erm resistance marker. This too is a low risk plasmid since it is unlikely to encounter a suitable host, and possesses no harm or clinically-significant genes.

Evaluation of foreseeable effects

Reporter constructs: GFP reporters have no known toxic properties and there is no known hazard to the envirnment. These genes will be linked to the promoters of specific E faecalis genes such as the cyl (haemolysin) genes; these are short DNA sequences that do not encode proteins.

Mutant construction: no known harmful effect of the Tn917 transposon.

Modified E faecalis likely to be of similar harm as the unmodified host; insertion of Tn917 is expected to insertionally - inactivate genes on the chromosome of E faecalis; therefore, most likely to make the organism less harmful.

Reporters/KOs: The presence of TN917-possessing, or GFP-expressing E faecalis is likely to be no greater risk to humans etc or the environment than the risk of the unmodified organism. Antibiotic resistance markers on the plasmids are either of no clinical significance (Cm) in relation to E faecalis infection, or resistance is found in wild type strains anyway (Em: 50% of isolated strains) and alternative therapies are available. NCTC775, strain types 2 and 3 lack the essential haemolysin virulence factor, hence less harmful than environmental/WT strains. Strain 2 strains are wild type.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Cultures will be decontaminated by autoclaving (121°C/15 min); expected survival is 0%. Regular screening to ensure proper functioning of autoclaves is routinely carried out. Contaminated lab areas can be disinfected effectively; swabs of bench areas can be taken to assess survival; expected survival is 0%. The laboratories (3-04, 3-09) are located in the Old Medical School; the wider environment is unlikely to become contaminated.

In the unlikely event of escape:

E. faecalis: Survival in the environment and ability to colonise are possible, but there are effective containment and disinfection procedures in place, minimising the chances of contact with suitable hosts.

E. coli: these are laboratory-attenuated auxotrophs and therefore are very unlikely to survive in the environment or to colonise.

No significantly increased risk to lab workers and other health individuals in the community at large.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

The GM Safety Committee recommended changes to the original risk assessment and notification form. These modifications have now been made to the satisfaction of the BSO and GMSC chair.

RANDOM AND SITE DIRECTED TRANSPOSON MEDIATED MUTAGENESIS OF ORAL BACTERIA TO IDENTIFY HOW ENVIRONMENTAL FACTORS AFFECT GENE EXPRESSION AND RESISTANCE TO ANTIMICROBIAL COMPOUNDS.

Purposes of the contained use

To facilitate an ongoing research project involving microbial communities and factors affecting gene expression. One aim of the research is to identify genes that may be involved in resistance to antimicrobial peptides or other stress inducing factors eg temperature, oxidation. Additionally this research will examine how the expression of these genes is affected by culture conditions including growth as a complex biofilm.

Recipient or parental organism

P. gingivalis, P. intermedia, P. nigrescens, S. mutans, S. Oralis, S. sobrinus, S. Gordonii, A. naeslundii, C. rectus, T. denticola, A. actinomycetemcomitans are ACDP category 2 organisms which commonly inhabit the oral cavity but are not considered separately to be pathogenic. GMOs generated during this project will have genes inactivated and are therefore likely to be no more harmful than the unmodified host.

Origin & function

Common laboratory strains of the bacteria listed will be used. Many of these bacteria have been the subject of genome sequencing projects and all are well characterised. It is not the aim of this project to transfer genes between the listed species but to inactivate individual genes in a single species and to determine the effects on survival in the community. The aim is to identify genes that may give a selective advantage to a particular species under a defined set of laboratory culture conditions. All cultures will be destroyed subsequent to each experiment. Genetic material to be transferred will include well characterised transposons such as Tn5 and will be delivered via well characterised laboratory strains of E. coli. The Tn5 transposon containing plasmid pOT182 is a pBR325 based plasmid containing the Tn5-B21 cassette from pSUP 102(Gm) and was provided by Professor I Lamont. The construction of this vector has been described (Merriman and Lamont, 1993, Gene, 17-23). These procedures are in routine use in our laboratories.

Recipient or parental organism

P. gingivalis, P. intermedia, P. nigrescens, S. mutans, S. Oralis, S. sobrinus, S. Gordonii, A. naeslundii, C. rectus, T. denticola, A. actinomycetemcomitans are ACDP category 2 organisms which commonly inhabit the oral cavity but are not considered separately to be pathogenic. GMOs generated during this project will have genes inactivated and are therefore likely to be no more harmful than the unmodified host.

Host/vector system

Commercially available (or other well characterised) transposon containing vectors (eg pOT182, pVA2198) grown in suitable laboratory strains of E. coli (eg S17-1, SM10) will be used to inactivate specific, or randomly targeted genes in the oral bacteria P. gingivalis, P. intermedia, P. nigrescens, S. mutans, S. Oralis, S. sobrinus, S. Gordonii, A. naeslundii, C. rectus, T. denticola, A. actinomycetemcomitans. These procedures are in routine use in our laboratories for other projects.

Origin & function

Common laboratory strains of the bacteria listed will be used. Many of these bacteria have been the subject of genome sequencing projects and all are well characterised. It is not the aim of this project to transfer genes between the listed species but to inactivate individual genes in a single species and to determine the effects on survival in the community. The aim is to identify genes that may give a selective advantage to a particular species under a defined set of laboratory culture conditions. All cultures will be destroyed subsequent to each experiment. Genetic material to be transferred will include well characterised transposons such as Tn5 and will be delivered via well characterised laboratory strains of E. coli. The Tn5 transposon containing plasmid pOT182 is a pBR325 based plasmid containing the Tn5-B21 cassette from pSUP 102(Gm) and was provided by Professor I Lamont. The construction of this vector has been described (Merriman and Lamont, 1993, Gene, 17-23). These procedures are in routine use in our laboratories.
Evaluation of foreseeable effects

It is expected that recombinant isolates of P. gingivalis, P. intermedia, P. nigrescens, S. mutans, S. Oralis, S. sobrinus, S. Gordonii, A. Naislundii, C. rectus, T. denticola, A. actinomycetemcomitans containing the transposons are likely to be no more hazardous than the parental organism. The rationale for this is that no new genes (other than those contained within the transposon) will be inserted into the host. The reason for classification of this as a class 2 project is that each of these organisms is listed as an ACDP category 2 microorganism.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid laboratory waste such as pipette tips and disposable loops will be soaked overnight in discard pots containing 1% Virkon and autoclaved. All classware that comes into contact with the listed bacterial species will be autoclaved. All liquid and solid cultures will be autoclaved. Autoclaving will be carried out at 121 degrees C for 15 minutes. Disposable autoclave waste will be removed for incineration. It is envisaged that these proposals will ensure a 100% kill of all GMOs.

TO CLONE THE CDNA(S) FOR THE CELL SURFACE RECEPTOR FOR HUMAN ADENOVIRUS TYPE 3 (AD3). WE AIM TO ADOPT A MAMMALIAN CDNA EXPRESSION STRATEGY WHEREBY A CDNA LIBRARY IS INTRODUCED.

**Project Additional Information**

**Purposes of the contained use**

Fundamental studies on virus receptors and mechanisms of uptake into human cells.

**Recipient or parental organism**

Human 293 cells (to generate replication-defective retroviruses and adenoviruses) and hamster CHO cells for expression screening. No foreseeable effect.

**Host/vector system**

**Host:** See above.

**Vector:** Murine Leukaemia Virus-based vector for expression

Plasmid containing the MuLV LTR (pFB retroviral vector); pVPack; pVpack VSV-G

Adenovirus vector (AdEasy, Qiogene Inc.)

**Origin & function**

The cDNA Library is derived from HeLa cells, which we have shown to be receptor-positive.

The function of the receptor will convert the cell lines from receptor-negative to receptor-positive.

**Evaluation of foreseeable effects**

As most humans already have long-lasting immunity to adenoviruses and already possess the Ad 3 cellular receptor, we do not anticipate that expression of the adenovirus...
3 cellular receptor will confer increased susceptibility to humans of adenovirus or other virus infections.

For both categories of recombinant viruses, the risk of expression of a viral receptor is unlikely to be hazardous to humans as expression of this receptor is ubiquitous.

Receptor-expression human and hamster cells will not colonize the human host.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

We will be performing the production of replication defective retroviruses and screening of CHO cells under containment level 2. Recombinant adenoviruses will also be produced and used under containment level 2.

Virus-containing cells will be treated with Virkon to kill any remaining virus.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Receptor-expressing and transfected cells will be killed by treatment with Virkon. Liquid waste will also be treated with Virkon. Solid waste will be autoclaved, securely packaged and incinerated. Quantities of cells and medium to be used will not generate major spillages, however, in the event of such an incident, we would treat the spillage with granular hypochlorite.

Is an emergency plan required according to regulation 20? **N**

If yes, tick to confirm that it is attached to this form **N**

Tick to confirm that you have attached a risk assessment to this form **N**

Tick if you are claiming exemption from disclosure for section of the risk assessment **N**

Please enter comments on the GM safety committee on the risk assessment

The project was discussed at the local ACGM committee and it was decided that, although relatively low risk, the committee considered it notifiable at Class 2 due to the remote possibility of producing replication competent adenoviruses (RCA) or retroviruses (RCR). However, we will monitor for the generation of RCA and RCR and keep this project under assessment in the light of such findings.

Animal Units | Large Scale Activities | Human Clinical Applications
CLONING OF CDNA COPY OF THE MOUSE INTERLEUKIN-2 (MUIL2) INTO THE XYLANASE OPERON OF BACTEROIDES OVATUS IN E.COLI DH5A. TRANSFER OF CONSTRUCT TO E.COLI J53/R751 AND THEN VIA CONJUGATION TO B. OVATUS

The modified B. ovatus will be used to assess xylan-inducible expression of MuIL2 in vitro. This organism will then be used in experiments as a novel immunotherapy to try and treat and prevent disease.

B. ovatus is ACDP Hazard Group II. The final modified organism will be tetracycline resistant and will be xylanase negative. Although a gut commensal, the likelihood of a GMM colonizing humans or persisting in the environment is minimal. Expression of MuIL2 by this organism should not pose a hazard.

E. coli vector pGEM is non-mobilisable. Vector pBT-2 is an E. coli-Bacteroides mobilisation-defective shuttle vector requiring E. coli strain J53/R751 for transfer. This is a suicide vector in Bacteroides, requiring integration into the genome for maintenance.

The xylanase operon originates from B. ovatus. The MuIL2 gene is a cDNA copy which will be transcribed in a xylan-inducible manner in the final GMM.
The final GMM will be tetracycline resistant and xylanase negative. Expression of MuIL2 should be regulated and the modified organism must compete with resident microflora to colonise. Release of the number of viable organisms required to colonise other animals or humans is unlikely. Survival in the environment is likely to be limited. MuIL2 is unlikely to be produced in large enough quantities to have a significant effect on humans. The modified organism should pose no greater hazard than the wild type.

**Evaluation of foreseeable effects**

Standard containment level 2.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

- All pipette tips, slides, and small disposable plasticware will be disposed of in discard pots containing 2% (v/v) Tego prior to being autoclaved and discarded.
- All waste cultures, media and large plasticware will be autoclaved prior to discarding.
- All glassware will be autoclaved before being washed and returned for use.
- Sharps will be disposed of in a cin bin which will then be autoclaved and incinerated.
- All culture spills will be mopped up with stericol and tissue which will then be autoclaved prior to discarding.
- No viable GMMs will be left after treatment.

**Is an emergency plan required according to regulation 20?**

**If yes, tick to confirm that it is attached to this form**

**Tick to confirm that you have attached a risk assessment to this form**

**Tick if you are claiming exemption from disclosure for section of the risk assessment**

The GM safety committee requested some minor changes to the risk assessment. These changes have been completed to the satisfaction of the BSO.

We aim to use a replication defective human adenoviral vector to introduce the following genes into primary cultures of human cardiac myocytes, vascular smooth muscle and endothelial cells:

(i) the angiotensin type 1 receptor (AT1)
(ii) matrix metalloprotease 9 (MMP9) in both sense and antisense orientations, and also dominant negative mutants of MMP9 may be expressed.
(iii) peroxisome proliferation activation receptor (PPAR) gamma isoform 1 in both sense and antisense orientations.
(iv) Reporter expression cassettes consisting of the bacterial beta-lactamase gene (obtained from Aurora Biosystems) under the control of either the human AP-1, CRE or NF-AT response elements.
(v) A reporter expression cassette in which expression of either the enhanced yellow (EYFP) or enhanced green fluorescent protein (EGFP) (Available from Clontech) is driven by the upstream regulatory region of human angiotensin receptor type 1 or type 2.

By placing genes (i-iii) under the control of the tetracycline response element, the levels of expression of recombinant proteins can be regulated enabling a better understanding of the role of signal transduction pathways in cardiac pathologies.
All transgenes are integrated into an adenoviral genome (using the AdEasy system from Stratagene) from which the early genes essential for replication, contained in the E1 region of the viral genome, have been deleted, to generate replication defective viruses which can only be propagated in human 293 cells. This is a helper cell line (human embryonic kidney cells) which express the leftmost 11% of the Ad5 genome containing the E1 region in trans thus complementing the deleted genes in the viral vector. In addition E3 gene has also been deleted from this particular recombinant virus, significantly reducing the ability of the virus to evade a host immune response.

Origin & function

pAdEasy-1 vector
The pAdEasy-1 vector (Stratagene) is a modified version of human Adenovirus 5 in which the genes in the E1 region of the viral genome, essential for replication, are deleted to generate a replication defective virus. In addition the E3 gene is deleted which significantly reduces the ability of the virus to evade detection by the host immune system.

Human angiotensin receptor.
The peptide agonist angiotensin II activates this receptor to produce a variety of regulatory actions on the cardiovascular, renal, endocrine and neural systems including vasoconstriction, hypertension and aldosterone release. It is not envisaged that expression of this gene will be oncogenic or have adventitious effects in host cells at the levels of expression used. Expression of the gene will be placed under the control of a tetracycline inducible promoter system that levels of expression of the transgene can be finely regulated by the addition of tetracycline. The full coding sequence of the angiotensin type 1 receptor is available as a cDNA in our laboratory.

Peroxisome Proliferation Activation Receptor (PPAR) Gamma
PPARgamma is a transcription factor which is expressed in all of the major tissues of the vasculature including endothelial cells, vascular smooth muscle cells (VSMCs) and monocytes and macrophages. Drugs which activate PPARgamma have been shown to inhibit the proliferation and migration of VSMCs in cell culture. Current data suggests that the antiproliferative effect of PPARgamma on the cell cycle is due to an increase in the levels of cyclin-dependent kinase inhibitors such as p27. Again, as stated in the case for the angiotensin receptor, it must be borne in mind that in all cases, PPARgamma transcripts whether sense or antisense will be under the strict control of a Tetracycline-inducible promoter. A cDNA encoding full length human PPARgamma isoform 1 was obtained from Laboratory of Molecular Hematopoiesis, Sloan-Kettering Institute, New York.

Matrix Metalloprotease 9
MMP9 (also known as Gelatinase B) is responsible for basement membrane degradation essential for tissue remodelling in a number of key developmental and growth processes. MMP9 is found to be up-regulated in many forms of cancer, as its role in basement membrane degradation facilitates malignant cell invasion and metastasis. Transformation of a cell to a full malignant phenotype however, is dependent on a number of changes in expression in genes controlling signal transduction/gene expression cascades within the cell or genes involved in regulation of the cell cycle. It is highly unlikely therefore that alteration of levels of MMP9 expression alone would confer an oncogenic phenotype upon a mammalian cell and to the best of my knowledge there is no case of this being documented in the research literature. In addition, as has been stated for both the case of the angiotensin receptor and PPARgamma above, all transcripts whether sense, antisense or dominant negative mutant will be under the control of a Tetracycline-inducible promoter. A cDNA encoding full length human MMP9 was obtained from Department of Immunology and Oncology, Universidad Autonoma de Madrid.

AP-1/CRE/NF-AT Reporter Constructs
These constructs consist of the bacterial beta-lactamase gene under the control of either the AP-1, CRE or NF-AT response element. The activity of each response element can be measured by assaying the activity of the product protein of the beta-lactamase gene through a simple optically based assay. It is not envisaged that introduction of the beta-lactamase gene into mammalian cells should pose a significant safety risk as mammalian cells are routinely exposed to commercially available ampicillin resistant plasmids containing the beta-lactamase gene with no adverse effects.

Upstream Regulatory Region of Human Angiotensin Type 1 and Type 2 Receptor
The reporter cassette in this virus will contain either a fragment of DNA encompassing approximately 1300bp immediately upstream of the transcriptional start site of human angiotensin II type 2 receptor (GenBank Acc No. X87722) or a fragment encompassing approximately 2700bp upstream of the initiation ATG of human angiotensin II type 1 receptor (GenBank Acc No U07144 - detailed in 'Molecular cloning and expression of the gene encoding human angiotensin II type 2 receptor' Guo et al. Biochem
Reverse Tetracycline Transcription Activator (rtTA)

The rtTA gene was obtained from the plasmid pTet-On which is commercially available from Clontech. It is necessary to make a recombinant virus which expresses this protein so that expression of genes under the control of the Tetracycline response element can be activated when a co-activator ligand such as Doxorubicin is added.

Evaluation of foreseeable effects

All strains of Ad5 are non-oncogenic. Wild-type Ad5 may cause mild respiratory diseases in children. Because the recombinant virus will lack the E3 gene this may produce a virus that will evoke a stronger inflammatory response in a host, but this should also lead to more rapid clearance of the virus from a host system. Primary infection of adenovirus is thought to generate life-long immunity and it is thought that the majority of the adult population are likely to have antibodies to the wild-type virus.

Although replication has been shown to occur in the lungs of experimentally infected cotton rats administered with high doses of virus, there is no evidence that adenoviruses can naturally colonise non-human hosts and therefore pose no significant harm to animals, plants or ecosystems.

Human angiotensin receptor.

The peptide agonist angiotensin II activates this receptor to produce a variety of regulatory actions on the cardiovascular, renal, endocrine and neural systems including vasoconstriction, hypertension and aldosterone release. It is not envisaged that expression of this gene will be oncogenic or have adventitious effects in host cells at the levels of expression used. Expression of the gene will be placed under the control of a tetracycline inducible promoter system that levels of expression of the transgene can be finely regulated by the addition of tetracycline.

Peroxisome Proliferation Activation Receptor (PPAR) Gamma

PPARgamma is a transcription factor which was initially characterised as an adipose-tissue specific factor that played a role in the differentiation of this tissue and regulated a number of adipose specific genes. Drugs which activate PPARgamma have been shown to inhibit the proliferation and migration of VSMCs in cell culture. Current data suggests that the antiproliferative effect of PPARgamma on the cell cycle is due to an increase in the levels of cyclin-dependent kinase inhibitors such as p27. Again, as stated in the case for the angiotensin receptor, it must be borne in mind that in all cases, PPARgamma transcripts whether sense, antisense or dominant negative mutant will be under the strict control of a Tetracycline-inducible promoter.

Matrix Metalloprotease 9

MMP9 (also known as Gelatinase B) is responsible for basement membrane degradation essential for tissue remodelling in a number of key developmental and growth processes. MMP9 is found to be up-regulated in many forms of cancer, as its role in basement membrane degradation facilitates malignant cell invasion and metastasis. Transformation of a cell to a full malignant phenotype however, is dependent on a number of changes in expression in genes controlling signal transduction/gene expression cascades within the cell or genes involved in regulation of the cell cycle. It is highly unlikely therefore that alteration of levels of MMP9 expression alone would confer an oncogenic phenotype upon a mammalian cell and to the best of my knowledge there is no case of this being documented in the research literature. In addition, as has been stated for both the case of the angiotensin receptor and PPARgamma above, all transcripts whether sense, antisense or dominant negative mutant will be under the control of a Tetracycline-inducible promoter.

AP-1/CRE/NF-AT Reporter Constructs

These constructs consist of the bacterial beta-lactamase gene under the control of either the AP-1, CRE or NF-AT response element. The activity of each response element can be measured by assaying the activity of the protein product of the beta-lactamase gene through a simple optically based assay. It is not envisaged that introduction of the beta-lactamase gene into mammalian cells should pose a significant safety risk as mammalian cells are routinely exposed to commercially available ampicillin resistant plasmids containing the beta-lactamase gene with no adverse effects.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
All work will be performed in tissue culture (Category II) facilities with restricted access. The flow cabinet in which work will be performed is equipped with a UV light source which enables sterilisation of the work area upon completion of work. Liquid waste will be virkon treated. Plasticware will be disinfected prior to autoclaving and then incinerated. All work surfaces will be treated with 70% ethanol and 1% virkon spray prior to and upon completion of work. Kill rate by virkon or autoclave treatments is 100%.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Since replication deficient recombinant adenoviruses are normally considered to be class I GMAG work, the risk assessments concerning this work were initially submitted to our local GMAG committee as a class 1 project. Concern was expressed, however, that because of the biological potency of some of the human genes which we intended to express in our adenoviral vector system, such as the angiotensin II type 1 receptor, that this work might fall into the remot of a class 2 project. Because of these reservations, the local GMAG committee suggested that the project be provisionally rejected until we advice had been sought from the HSE on whether the project was class 1 or class 2. After correspondence with HSE we were informed that the proposed project was class 2 and so the risk assessments and HSE notification were amended accordingly.

Project Ref 559/02.6

Date Ackn'd: 24/10/2002
CU2 Project Title: EXPLOITING HERPESVIRUS SAIMIRI AS A GENE KNOCK-IN OR KNOCK-OUT
Class: 2
CultureVolClass2: < 1 litre
CultureVolumeClass3-4:
SYSTEM IN TUMOUR CELLS, PRIMARILY TUMOURS OF THE EWING'S SARCOMA FAMILY (ESFT)

Minimise risk to human health that may occur should people become infected with virus expressing tumour suppressor genes or oncogenes.

Recipient or parental organism
Herpesvirus saimiri (HVS)

Host/vector system
Non-mobilisable expression vectors
Ribozymes

Characterised cytokines, antigens, tumour suppressor genes, oncogenes will be over expressed or expression will be knocked out to investigate their effect on cell behaviour and phenotype using model systems.

The aim of the research is to decrease the growth and induce cell death in the cells by modulating gene expression.

HSV is to be exploited as a delivery system as 1. it has high rates of infectivity and 2. the promoters used are not heavily methylated (hence maximising gene expression/knock-out).

Expression of knock out of cytokines, antigens, tumour suppressor gene or oncogenes will be maximised to decrease the malignant phenotype; characterised by features including cell proliferation, apoptosis and invasion assays. This may lead to the identification of new targets for the development of novel therapeutic strategies.

No known risk is presented to the environment; the HVS will not obtain a survival advantage allowing growth outside the proposed culture conditions.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Effective kill for liquid and solid waste is 100%.
Solid waste (flasks and pipettes): autoclaved and subsequently incinerated. Autoclave efficiency is tested weekly.
Liquid waste: treated with Virkon at a final concentration of 2% for 30 minutes to ensure 100% kill (according to manufacturers instructions). Dispose to drain. Virkon is prepared fresh each week.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N

Project Ref  559/04.1

Date Ackn’d  16/06/2004

CU2 Project Title  Replication of recombinant picornaviruses

Date Project Ceased

Class  Class 2
Culture Vol  < 1 Litre
Non-GMM  Consent Granted  Not Applicable

Project notified under transitional arrangements N

02/03/2022
Purposes of the contained use

This submission covers the construction and use of recombinant forms of the picornaviruses Human Rhinovirus (HRV), Poliovirus (PV), Equine Rhinitis A virus (ERAV), Coxackie A virus (CAV). Such recombinant viruses are intended to facilitate the determination of viral replication efficiency in cell culture, by the expression of a reporter gene from the recombinant genome.

Recipient or parental organism

The picornavirus family are non-enveloped, single stranded, positive sense RNA viruses which includes a number of important human and animal pathogens. The picornavirus genome is approximately 7 Kb and contains a single large ORF encoding a polypeptide of approximately 2,000 amino acids which is processed by host and viral encoded proteases into mature proteins. The life-cycle of these viruses is well characterised. The proposed picornaviruses (section 6) are classified by the ACDP as class II or below.

Host/vector system

Host: Viral RNA transcribed in vitro in the form of sub-genomic replicons will not encode capsid proteins, will not form virus and can not colonise further cells. RNA in the form of a modified full-length genome will give rise to replication competent virus.

Vector: Modifications will be made to viral cDNA contained in standard non-mobilisable DNA plasmids, grown in laboratory adapted strains of Escherichia coli that are unlikely to survive in the human gut (ACGM/HSE./DOE Note 7, annex 1).

Origin & function

* Well documented ‘reporter’ genes expressing proteins such as Green Fluorescent Protein, B-Galactosidase or Luciferase. Such proteins are non-toxic and are not predicted to alter the nature of the virus.
* Rescue of replication-defective mutations by expression of the p7 protein of hepatitis C virus (HCV): The picornavirus 2B protein is thought to have ion channel activity that is required for replication and mutations in this gene are therefore expected to prevent viral replication. We propose to attempt the partial rescue of such mutations by engineering recombinant picornavirus genomes (as described in Sections A and B) to express HCV p7, a 7kD ion channel protein that has been characterised in the laboratory at Leeds. It plays no part in the transmission or host tropism of HCV and as an isolated gene is not toxic when expressed in mammalian cell culture. It is not thought to contribute to the pathogenesis of HCV, beyond its role as an ion-channel required for HCV replication.

Evaluation of foreseeable effects

Viral RNA transcribed in vitro in the form of sub-genomic replicons will not encode capsid proteins, will not form virus and can not colonise further cells. RNA in the form of a modified full-length genome may give rise to replication competent virus. The pathogenic properties of any modified form of the genome are likely to be reduced relative to wild type virus.

Modified viruses present no more human hazard than wild type virus. The infection resulting from such an exposure is predicted to be significantly reduced relative to wild
type virus, due to the reduced replication efficiency of the modified virus. The effect of expression of a non toxic reporter gene product in infected cells would be negligible relative to the effect of normal wild-type virus replication which destroys the cell. The growth of replication-defective mutants is likely to be very inefficient.

Furthermore, in the context of a natural infection, the genetic instability of the inserted gene combined with normal in vivo selection pressures is predicted to cause rapid reversion to a genotype effectively identical to wild-type.

Infection with ERAV causes a mild respiratory disease in horses.

Picornaviruses present no hazard to any other animals, plants or ecosystems.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste and contaminated glassware is inactivated by overnight treatment with chloros (10% final concentration) or virkon (2% final concentration). Plasticware is autoclaved (130 degrees C, 20 minutes). Such chemical or heat treatment results in 100% kill.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Following its meeting on 18 December 2003, the Microbiology GM Safety Committee requested some minor changes to the wording of the risk assessment to clarify which picornaviruses were to be used for the project. These changes have been completed to the satisfaction of the BSO.

The aim of the research is to identify how the gut protects the body from invasion and disease caused by bacteria that either normally live in the gut or those that gain entry via contaminated food. Specifically, we will determine the role intestinal epithelial cells play in preventing microbes from invading the body by determining what the consequences of interfering with the expression of genes known to be important in protecting other cells of the body from invasion are on the ability of intestinal epithelial cells to prevent infection by different types of bacteria. A type of virus, Lentivirus, will be used to deliver toxic molecules to epithelial cells that will interfere with the expression of genes involved in microbial defence.

Lentivirus based vectors have been chosen for this study since of all available gene delivery vehicles they are most suited to the delivery of genes into primary, non-dividing, cells. The vectors to be used are replication defective, HIV-1 based, recombinant lentiviral vectors that can only be generated using a transient triple transfection system. Since all HIV coding sequences have been deleted no viral genes can be transferred to the target cells. Due to the transient and reversible effects of the Lentivirus delivered genes, the final modified cells are expected to be more harmful than the unmodified cells.

Recipient or parental organism

Lentivirus has been significantly modified for biosafety. Use is made of self-inactivating (SIN) vectors, which prevent promoter activity in the viral 5' LTR in the integrated provirus from in target cells, reducing the probability of insertional activation. To minimise the possibility for homologous recombination, the HIV genome is divided into three parts, cloned into separate expression plasmids and extensively modified. The following modifications have been made to prevent viral replication.

1. Packaging vector lacks both LTRs and has no viral packaging signal (y).
2. The env, tat, rev, vpr, vpu, vif and nef viral enes have been deleted from the packaging vector.
3. Rev is supplied in trans on a different vector.
4. The vector expressing the packaged viral genome has a self-inactivating LTR (TATA box deletion) and expresses no viral gene product.
5. Envelope (VSVG) is expressed on a separate vector.

Relevant references:
Packaging vectors:

Self inactivating LTR:

Origin & function
The inserted synthetic sequences will encode interfering RNA (RNAi) or short hairpin RNA (shRNA) species that will result in reduced or no expression of the target genes (eg NOD2, alkaline phosphatase, B-galactosidase) in intestinal epithelial cells. The effect of the NRAi/shRNA is expected to be transient and non-lethal and will only interfere with the cells ability to produce certain cytokines in response to challenge with infectious and non-infectious stimuli.

Evaluation of foreseeable effects
Since all HIV coding sequences have been deleted from the Lentivirus vectors to be used no viral genes can be transferred to the target cells. Due to the transient and reversible effects of the Lentivirus delivered genes, the final modified cells are expected to be no more harmful than the unmodified cells.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
There is very little risk associated with the "escape" of the Lentivirus vectors which alone or in combination cannot produce replication competent virus. Cultured primary intestinal epithelial cells cannot survive outside the culture medium and have a finite life span (≤2 weeks) in vitro. It is expected that Lentivirus-transduced cells will not survive any longer than non-transduced cells (≤2 weeks).

The likelihood of the escape of treated cells is remote. Virus-transduced cells are kept in tissue culture incubators in a category 2 designated tissue culture room within a research laboratory to which only authorised laboratory personnel have access. Access to this laboratory is via locked doors that have a coded keypad locking system and access to the tissue culture room within is restricted to designated personnel and is locked when not in use. A Class 2 cabinet to BSEN 12469 specification will be used to contain virus-producing cell lines and vector-transduced cells. Sharps will be eliminated from all aspects of the laboratory work.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Routine disinfection will be carried out using 1% Virkon spray.
Liquid waste will be diluted with an equal volume of 2% Virkon and left for a minimum of 16h prior to drain discard.
Solid waste will be disposed of by autoclaving at 121 degrees C followed by incineration.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y
Approved by chairmans action in consultation with local BSO, Faculty Safety Manager and an experienced virologist.
To be ratified by the full committee at the next meeting.

6/7/2004 - School of Biology GMAG Committee Chairman.

Project Ref   559/04.3

Date Ackn’d 12/08/2004

CU2 Project Title Investigation of the cellular effects of oncolytic reovirus

Class 2 CultureVolClass2 < 1 Litre

Consent Granted

Non-GMM

Project notified under transitional arrangements N

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

Project Additional Information

02/03/2022
Purposes of the contained use

To minimise risk of human infection by wild type reovirus.

Recipient or parental organism

Wild type reovirus is replication competent. However, its replication is selective to cells which have an activated Ras signalling pathway. Most adults possess antibodies to reovirus and administration of the virus to healthy volunteers only has mild toxicity, including minor respiratory or enteric symptoms (Rosen et al, American Journal of Hygiene) 77:29-37. (Norman and Lee, The journal of Clinical Investigation) (2000): 105, pg 1035-38.

Host/vector system

Wild type reovirus will be used to infect a range of established murine and human tumour cell lines, these are hazard Group 1. Reovirus may also be used to infect normal and tumour liver tissue, this is considered hazard Group 2 due to the potential risk of infection from endogenous pathogens.

Origin & function

Reovirus will be provided by Oncolytics Biotech Inc, Calgary, Canada (Reolysin). This product is currently being used in clinical trials and we wish to investigate whether oncolytic killing caused by reovirus infection can stimulate the immune system and release tumour associated antigens for T cell priming.

Evaluation of foreseeable effects

Reovirus will infect all human cells however, it is only replication competent in cells with activated ras signalling pathways therefore, the risk to human health is minimised. Ras mutations and over expression of the ras signalling pathway are most frequently associated with a transformed phenotype and the development of malignancy. However, there is a theoretical risk that ras signalling may be activated in growth factor stimulated cells, cells that proliferate (wound healing) or in people with cellular proliferative disorders. Therefore, we cannot exclude the possibility that reovirus (Reolysin) might infect and replicate in apparently normal cells, causing lysis. Furthermore, the release of tumour associated antigens following lysis may modify the host immune system to infected cells. However, this is unlikely to result in inadvertent disease. Reovirus will also be readily transmitted via aerosols. Therefore, to protect people from the potential risk of infection all work associated with the virus will be carried out at Class 2.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All reovirus work will be carried out at containment level 2 (Class 2 activity). Virkon is the disinfectant of choice and when used according to the manufacturer's instructions gives 100% kill. Unit procedures for disinfection under category 2 will be followed (see attached sheet). Briefly, all surfaces will be wiped with 2% Virkon and 70% ethanol. All plastics and infected material will be disinfected with 2% Virkon overnight. Gloves and disinfected waste will be autoclaved and incinerated.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y
This project was reviewed by the GMO safety committee of the CR-UK Clinical Centrem STUH on Thursday 15 July 2004. Although reolysin will only replicate in cells with activated attenuated ras signalling pathways the potential for replicating during wound-healing, cellular proliferative disorders and the aerosol transmission of the reovirus warrant classification at Class 2.

### Project Ref 559/04.4

**Date Ackn'd**: 23/09/2004

**CU2 Project Title**: Evaluation of intracellular inhibitors of the HIV-1 Nef protein.

**Class**: Class 3

**CultureVolClass2**: 250 ml

**Non-GMM Consent Granted**: Yes

**Project notified under transitional arrangements**: N

### Project Additional Information
**Purposes of the contained use**

RNA aptamers targeted to the HIV-1 Nef protein will be generated and subsequently tested for the ability to inhibit HIV-1 replication using established cell culture assays. HIV-1 will be produced by transfection of Cos-7 or 293T cells with a proviral clone and subsequent harvesting of culture supernatants. This virus will be used to infect susceptible cells in the presence or absence of aptamers and virus production analysed.

**Recipient or parental organism**

The GMO will be propagated in E. coli strain DH5α as a proviral plasmid clone (DNA copy of the viral RNA genome). Purified DNA will be transfected into either Cos-7 (monkey kidney) or 293-T (human embryonic kidney) cells. Virus will be harvested from these transfected cells and used to infect either Hela-CD4 (human cervical carcinoma) or T-cell lines (Jurkat, CEM) for subsequent experiments.

**Host/vector system**

Plasmids containing a DNA copy of the complete genome of HIV-1 (termed the provirus) will be obtained from University of Heidelberg. The vector backbone is pUC18 - non-mobilisable.

**Origin & function**

Inserted Sequence.

The original pNL4-3 plasmid was generated by cloning a provirus from a bacteriophage library. The library was generated from EcoRI restricted DNA isolated from peripheral blood mononuclear cells (PBMCs) from North American HIV-1 positive individuals. (Genbank accession number M19921). The Nef coding sequence of pNL4-3 was replaced by that of the HIV-1 SF2 isolate (Genbank accession number K02007). The resulting chimeric virus is indistinguishable from pNL4-3 in terms of replication in tissue culture - both Nef isolates have similar functional characteristics.

**Evaluation of foreseeable effects**

The E. coli strains used are laboratory adapted multiple auxotrophs and are unlikely to survive in the environment (ACGM/HSE.DOE Note 7, annex 1). HIV-1 particles are labile, additionally human cell lines containing HIV-1 would be unable to survive outwith tissue culture medium and so present no risk either to the environment or to human health and safety. HIV-1 is not considered to be infectious by any route other than parenteral. The risk of aerosol or water-borne infection of humans is effectively zero.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Propagation of proviral plasmids in E. coli. The E. coli strain used (DH5α) is a laboratory adapted multiple auxotroph and is unlikely to survive in the human gut (ACGM/HSE.DOE Note 7, annex 1). Growth of plasmids can therefore be carried out at Level 2. Purification of plasmids from E. coli and their subsequent use in transfections of mammalian cells will be carried out at Level 3.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Spent culture medium from growth of E. coli containing proviral plasmids will be inactivated by the addition of Virkon (2% s/v - equivalent to 2000 ppm available chlorine) prior to disposal to the sink.

All work involving introduction of proviral plasmid clones into mammalian cells will be carried out in a Class II cabinet. Waste will be inactivated by addition of Virkon to a final concentration of 1% (w/v - equivalent to 1000 ppm available chlorine) for a minimum period of 2 hours prior to removal from the cabinet and disposal to the sink. Used tissue culture pasticware and other solid waste material will be sterilised by autoclaving (121 degrees C for 20 minutes) using the autoclave located within the Level 3 containment facility.
The proposed waste inactivation measures are appropriate for HIV. As an enveloped virus it will be 100% inactivated by either autoclaving or Virkon treatment.

The GMSC was happy to accept the risk assessment. There was a general feeling that it would be better to grow the E. coli carrying the provirus-containing plasmid in the CL3 room 4.15 in Garstang South, since this would then limit all of the work to the CL3 room. This was only a suggestion rather than a requirement and the committee understood and accepted the rationale for conducting this part of the work under Level 2 conditions.

Please enter comments on the GM safety committee on the risk assessment

## Project Additional Information

### Purposes of the contained use

The genetically modified strains will be used for a comparative analysis of proteins exported by the SecA1 and SecA2 translocases of S. pneumoniae, S. aureus, E. faecalis, B. cereus and C. difficile. It is anticipated that the knowledge gained from the comparative analysis of these processes in two pathogens will ultimately lead to the development of novel antimicrobial agents to control infection.

### Host/vector system

The widely used allele replacement vector pG+Host will be used for mutagenesis and gene inactivation of the secA1 and secA2 genes of S. pneumoniae, S. aureus, E. faecalis, B. cereus and C. difficile. The secA1 and secA2 genes will be deleted and mutated in their natural host and also cloned into E. coli for expression and protein purification.

### Origin & function

The comparative nature of the proposed project dictates that the genetic material will originate from S. pneumoniae, S. aureus, E. faecalis, B. cereus and C. difficile. The secA1 and secA2 genes will be deleted and mutated in their natural host and also cloned into E. coli for expression and protein purification.

### Evaluation of foreseeable effects

The release of numbers of viable organisms required to colonise or infect animals or humans is highly unlikely. The genetically modified organisms are unlikely to pose any greater hazard to health than the respective unmodified wild types. The current containment and working procedures in the laboratory are more than sufficient to contain the organisms and prevent a major escape. If any spillages occur the organisms will be inactivated with a disinfectant such as Stericol, then absorbed with paper towels that will be autoclaved prior to disposal. All cultures, media, contaminated glassware and contaminated plasticware will also be autoclaved prior to disposal or reuse, as per School of Biochemistry and Microbiology standard operating procedures.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Prior to autoclaving all small items of glassware and plasticware will be immersed in 0.5% TEGO in specified discard pots. All waste cultures, media and large plastic items...
will be autoclaved prior to discarding. Contaminated reusable glassware will be autoclaved before being washed. Sharps will be disposed of in cin-bins that will be subsequently autoclaved and incinerated. Spillages of microorganisms will be absorbed with absorbant towels, all organisms killed with Stericol and the towels autoclaved prior to disposal. No genetically modified organisms will be viable after the measures described above have been carried out.

Project Ref  559/05.1

Date Ackn’d  03/02/2005
CU2 Project Title  Use of recombinant herpes simplex helper vectors to express variants of human RYRI gene in HEK293 cells and murine dyspedic myoblasts.

Date Project Ceased
Withdrawn  N

Tick if notifying a connected programme of work  N
Purposes of the contained use

The aim of the research is to understand if and how sequence variations in the human RYRI gene implicated in susceptibility to malignant hyperthermia (MH), affect calcium release in skeletal muscle cells.

Recipient or parental organism

The work will be carried out exclusively using cell lines; no GMOs are involved.

Host/vector system

HSV-based vectors have been chosen since they are the only ones currently available that are capable of delivering the 15.5 kb RYRI cDNA into HEK293 cells, dyspedic myoblasts and differentiated myotubes. The expression system has been significantly modified for bio-safety. The cosmid set C6 a48 a consists of overlapping clones that are able to produce all components essential for HSV-amplicon packaging and assembly, but which lack any packaging signal themselves. No recombination is possible between C6 a48 a and the amplicon and no infectious viral particles can be generated.

Reference:

Origin & function

The inserted sequences will encode the human skeletal muscle protein, RyR1, and variations thereof engineered into the RYRI coding sequence by site-directed mutagenesis. The RyR1 protein is responsible for regulating calcium release from intracellular stores during muscle contraction.

Evaluation of foreseeable effects

No organisms will be produced. The modified muscle cell and HEK293 cells are no more harmful than unmodified cells. Cultured 2-2 cells, HEK293 cells and dyspedic myoblasts are unable to exist without culture medium. The likelihood therefore of any of these cells being able to accidentally infect or colonise laboratory staff or any vermin vectors is virtually non-existent.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

No animals or plants are involved. Amplicon-transfected cells will be maintained in tissue culture incubators in a category 2 designated tissue culture room within a research laboratory to which only authorised laboratory personnel have access. Access to this laboratory is via doors that are locked when not in use. There is very little risk associated with the “escape” of the HSV-packaged amplicons and levels of replication competent virus are virtually non-detectable. Cultured myoblasts, myotubes and HEK293 cells cannot survive without culture medium and have a finite life span (<3 weeks) in vitro. Transfected cells will not survive any longer than non-transfected cells (<3 weeks).

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Routine disinfection will be carried out using 1% Virkon spray.
Liquid waste will be diluted with an equal volume of 2% Virkon and left for a minimum of 16 h prior to drain discard.
Solid waste will be disposed of by autoclaving at 121 degrees C followed by incineration.

Is an emergency plan required according to regulation 20? [N]  
If yes, tick to confirm that it is attached to this form [N]  
Tick to confirm that you have attached a risk assessment to this form [Y]  
Tick if you are claiming exemption from disclosure for section of the risk assessment [N]  

Approved by Chairman's action, in consultation with local BSO and Faculty Safety Manager. To be ratified by the full committee at the next meeting.

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

Project Additional Information

Purposes of the contained use

The modified B. ovatus will be used to assess zylan-inducible expression of the genes described in Section 5. Recombinant organisms will then be used in experiments as novel immunotherapies to try and treat and prevent disease.

Recipient or parental organism

B. ovatus is ACDP Hazard Group 2. The final modified organism will be tetracycline resistant. Although a gut commensal, the likelihood of the GMM colonising humans or persisting in the environment is minimal. Expression of the genes described in Section 5 by this organism should not pose a hazard.

Host/vector system

E coli vector pGEM is non-mobilisable. Vector pBT-2 is an E. coli-Bacteroides mobilisation-defective shuttle vector requiring E. coli strain J53/R751 for transfer. This is a suicide vector in Bacteroides, requiring integration into the genome for maintenance.

E. coli DH5α and J53/R751 are ACDP Hazard Group 1.

B. ovatus is Hazard Group 2.

Origin & function

The zylanase promoter originates from B. ovatus. They cytokine/growth factor and antagonist genes will be cDNA copies that will be transcribed in a zylan-inducible manner in the final GMM.

Evaluation of foreseeable effects

The final GMM will be tetracycline resistant. Expression of genes described in Section 5 should be regulated and the modified organism must compete with resident microflora to colonise. Release of the number of viable organisms required to colonise other animals or humans is unlikely. Survival in the environment is likely to be limited. Expressed gene products are unlikely to be produced in large enough quantities to have a significant effect on humans. The modified organism should pose no greater hazard than the wild type.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All pipette tips, slides and small disposable plasticware will be disposed of in discard pots containing 2% (v/v) Tego prior to being autoclaved and discarded.

All waste cultures, media and larger plasticware will be autoclaved prior to discarding.

All glassware will be autoclaved before being washed and returned for use.

Sharps will be disposed of in a cin bin which will then be autoclaved and incinerated.

All culture spills will be mopped up with Trigene and tissue that will then be autoclaved prior to discarding.
No viable GMMs will be left after treatment.

Is an emergency plan required according to regulation 20? N

Project Ref 559/06.1

Date Ackn'd 19/12/2006

CU2 Project Title Development of plasmid vectors for human skin commensal bacteria, namely propionibacteria and corynebacteria.

Class 2 CultureVolClass2 1-50 Litres

Non-GMM Consent Granted

Project notified under transitional arrangements N

Historical Significant Changes

Historical Date of Additional Info
## Project Additional Information

### Purposes of the contained use

To develop plasmid vectors for the introduction of foreign DNA into propionibacteria and corynebacteria. Such vectors will enable the generation of mutants and use of reporter genes to study gene function/regulation in these organisms, metabolism and their role as commensals and potential pathogens.

### Recipient or parental organism

Propionibacterium acnes, P. granulosum and P. avidum are Group 1 organisms and commensals of human skin. Corynebacterium jeikeium is Group 2 and is a human commensal and pathogen. Corynebacterium glutamicum is Group 2 but is not considered pathogenic. Also used will be E.coli K-12 based cloning hosts (e.g. DH5α) that are especially disabled; E.Coli S17-1, a K-12 derivative capable of mobilising plasmids containing the RP4 oriT region; E.coli BL21 and derivatives, hosts for recombinant protein production that are considered equivalent to K-12 strains.

### Host/vector system

- pBluescript, pGEM, pCR and similar pUC-based, non-mobilisable E.coli cloning vectors. pGEM and pET series plasmids, non-mobilisable and mobilisable defective respectively; used for recombinant protein expression. pK18mob2, a pUC-derivative capable of being mobilised from E.coli S-17 but not self transmissible. None of these plasmids encode toxic or otherwise dangerous products. All derive from standard cloning replicons and have a history of safe use in other laboratories.

### Origin & function

Replicons from endogenous propionibacterial and corynebacterial plasmids that will be tested for function in the hosts listed above. Antibiotic resistance markers to allow for selection of recombinant plasmids including hygB from Streptomyces hygroscopicus that confers resistance to hygromycin B, cmx from C.jeikeium conferring resistance gene of transposon Tn5. A fragment of any gene from propionibacteria or corynebacteria used to mediate homologous recombination and inactivation of that gene by plasmid insertion. A promoter of any gene from propionibacteria or corynebacteria ligated to a reporter gene (see below) to allow promoter to be measured. Commonly used reporter genes such as GFP and colour variants, β-galactosidase, bacterial luciferase. Genes from propionibacterial and corynebacterial plasmids encoding proteins potentially involved in replication and transfer functions will be cloned into E.coli for production of recombinant proteins for in vitro functional studies.

### Evaluation of foreseeable effects

The GMOs will contain genes encoding antibiotic resistance but this is not expected to have a harmful effect upon humans, plants or animals as they will not produce potentially harmful products. It is extremely unlikely that GMOs would be able to survive outside culture in the external environment, infect local vermin vectors, or survive as a commensal of animals and plants. These organisms are human commensals (except C.glutamicum) and if they were to escape from containment they must compete with the resident microflora in order to colonise. However, containment measures will ensure that the likelihood of escape of sufficient numbers of organisms for establishment on a human host is effectively zero. The modified organism should pose no greater hazard than the wild-type.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Liquid waste is treated with an equal volume of 2% Virkon and left overnight before drain disposal with 100 volumes of water. Solid waste (culture or cells) must be autoclaved at 121°C (load temperature) for 20 minutes before being destroyed as clinical waste. All glassware will be autoclaved before being washed and returned for use. Sharps will be disposed of in a cin bin which will then be autoclaved and incinerated. All culture spills will be mopped up with 2% Virkon and tissue which will then be autoclaved prior to discarding. No viable GMMs will be left after treatment.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Ticket to confirm that you have attached a risk assessment to this form Y
Ticket if you are claiming exemption from disclosure for section of the risk assessment N

The committee considered the status of Corynebacterium Jeikeium as a host organism in particular because, although it is generally regarded as a commensal, there are references to it being an opportunistic pathogen of humans and it has occasionally been known to cause serious disease in vulnerable individuals. Hence we concur that the correct classification of this project is 2.

AP Kelly - Committee Chair Nov 2006

Date Project Ceased

02/03/2022
**Project Additional Information**

**Purposes of the contained use**
To investigate in 'in vitro' systems the direct adjuvant properties of replication competent wildtype (wt) and recombinant attenuated oncolytic viruses on innate and adaptive immune effector cells. Also, to investigate the ability of wt and recombinant attenuated oncolytic virus infected cells to prime innate and adaptive anti-tumour immunity. Furthermore, since the use of oncolytic viruses may be limited due to the induction of host anti-viral immunity the efficacy of combined oncolytic virotherapy may be investigated.

**Recipient or parental organism**
Wildtype and genetically modified forms of the oncolytic viruses Adenovirus type 5 (Ad5), Measles virus Edmonston B (MV-Edm), vaccinia virus Western Reserve (WR) and specifically wtAd5, Ad5d1309, Ad5d1922-947, Ad5 CMV GFP (expressing GFP), wtMV-Edm, MV-GFP (expressing GFP), wtWR, ddW, vvGMCSF (JX-963) (expressing GMCSF).

**Host/vector system**
A range of established murine and human cancer cell lines will be infected with each of the oncolytic virus strains. These are biological hazard group 1. In addition, primary normal and transformed cells/tissue from cancer patients and allogeneic immune effector cells isolated from the blood of healthy donors will be infected. These are considered to be biological hazard group 2 due to the potential risk of infection from endogenous pathogens.

**Origin & function**
All Ad5 vectors will be provided by (Baits and the London School of Medicine and Dentistry). All MV- Edm vectors will be supplied by (Mayo Clinic College of Medicine, Rochester, Minnesota, USA) The vaccinia virus vectors WtWR and ddW-GFP will be provided by (Stanford University School of Medicine, California, USA) and the vaccina virus vector w-GMCSF (JX-963) will be provided by (JENNEREX Biotherapeutics, Inc., San Francisco, California, USA). The oncolytic viruses Adenovirus type 5 (Ad5), Measles virus Edmonston B, vaccinia virus have all shown promise as therapeutic oncolytic agents. Recombinant oncolytic virus induced-tumour regression generates long term anti-tumour immunity: however the mechanisms by which this occurs remain largely undefined. The aim of this project is to investigate the ability of oncolytic viruses to activate human innate and adaptive anti-tumour immunity. Furthermore, a direct comparison between the wildtype and attenuated recombinant strains of these oncolytic viruses will determine which strain is most effective with regards to tumour selectivity, cytotoxicity, and activating immune effector cells to prime anti-tumour immunity.

**Evaluation of foreseeable effects**
Wildtype Adenovirus type 5 (wtAds) is capable of replication in both normal and transformed cells. The genetically modified variants Ad5d1309 & Ad5d1922-947 can only replicate in tumour cells and are more immunogenic and less hazardous than wt4d5. Ad5-CMV-GFP is completely incapable of replication thus is of negligible hazard. The
natural host for Ad5 is humans, although it can infect a range of other mammalian cells including rodent, swine and rabbit and transduce both dividing and non-dividing cells. It is transmitted via aerosol. Adenoviruses do not integrate into the host genome and therefore the risk of mutagenesis is extremely low. Ad5 has a long history of use as a therapeutic oncolytic agent both as wildtype virus and as a gene therapy vector and has an excellent safety record. Infection in humans usually causes mild, self-limiting disease (mild respiratory disease, gastroenteritis, conjunctivitis) which is well-characterized. Very rarely in infants and children, pertussis-like syndrome, acute febrile pharyngitis and hepatitis has been seen. Exposure to wtAd5, Ad5d1309, Ad5d1922-947 or Ad5-CMV-GFP is highly unlikely to result in toxicity as immune recognition and activation would control viral pathogenesis. All work with these viruses will be carried out in containment level II facilities to minimise exposure to people and the environment. Please see ADDITIONAL COMMENTS SECTION for information on Measles virus Edmonston 8, Vaccinia virus ;Western Reserve.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Virkon disinfectant is effective against Adenovirus, Measles virus, Vaccinia virus at concentrations of 1%, 0. 4%, 1% and 0.16% respectively. The minimum contact time for 100% efficacy is 10 minutes. Virkon at 2% concentration will be used to decontaminate all virally contaminated waste liquids and plasticware and any surfaces and equipment which have been exposed to virus. Following decontamination solid waste will be autoclaved and then sent for incineration. Decontaminated liquid waste will be disposed of via the sink, rinsing with copious water. See also attached risk assessment, sections 7.4 & 7.5.

Chairman, GMAG Local Safety Committee), (LIMM Safety Officer), and ‘University 850) had reviewed the proposal in detail prior to the meeting of the LIMM. The amended proposal was then submitted to the remaining members of the Committee prior to the meeting.

The main issues for discussion and clarification at the meeting centred on where the projects were to be undertaken, the siting of equipment, and routes of disposal. had inspected the proposed work area prior to the meeting. Upon recommendation, the original siting of an EL.ISA plate washer proposed for the study was to be relocated into a Class 2 biological safety cabinet. For centrifugation of samples, the opening of all tubes would be performed in Class 2 biological safety cabinets. For flow cytometry studies, all cells would be fixed with paraformaldehyde before transferring for analysis. asked for the details of the fixation procedure to be included in the submission to HSE. Discussion then centred on procedures for handling and disposing of waste. The committee came to the conclusion that well implemented safety procedures were in place to prevent potential problems of cross contamination of cultures, and safe disposal of contaminated plasticware and solutions. The Committee therefore approved the procedures. The Committee also stressed that all workers entering the lab must be classified as Class 2 workers and register with University Occupational Health.

Permission was given to send off the application to HSE after final approval by on behalf of the University.

02/03/2022  Page 9803 of 15326
We are in the process of characterising three strains of Staphylococcus aureus recovered from patients in Denmark. These strains have been found to possess an antibiotic resistance gene (fusB) which encodes resistance to fusidic acid, but the strains are not phenotypically fusidic acid resistant. To establish how this resistance determinant has been ‘silenced’ in these strains, we wish to introduce several previously-generated plasmid-based constructs into these strains. The constructs are as follows and the rationale for their use is indicated.

Plasmid pCUI carrying the resistance gene fusB expressing from its native promoter will be used to determine whether the gene is being silenced at its promoter. Plasmid pCU1 carrying the fus8 gene fused to a reporter gene, iacZ, will also be used to determine if the fus8 gene is being silenced at its natural promoter. The fusion of iacZ to fusB enables the production of beta-galactosidase which can be easily monitored.
Plasmid pAJ96 carries fusB under the control of an artificial promoter that can be controlled by the antibiotic tetracycline. The construct will enable us to determine if the resistance is silenced post-translationally rather than at the level of gene expression. These plasmid constructs have been used previously in Class I work with the especially disabled host S. aureus RN4220. This application is simply to enable to use of these reporter constructs in non-disabled (clinical) S. aureus host strains to examine their unique properties regarding antibiotic resistance.

Recipient or parental organism

Recipients:
- S. aurous 15522 is a carriage isolate recovered from a human nasal swab.
- S. aureus 2329 was isolated from a patient that developed an abscess with community onset.
- S. aureus 43941 was isolated from a community acquired otitis infection.
All of the above have an inherent potential to cause human infection, be carried by humans and by animal vectors but the modification will not increase the virulence or pathogenicity of the GMMO. Treatment is available for infection and the GMMO is unlikely to cause environmental damage.
The GMMO’s will be modified by the introduction of plasmid vectors containing a resistance gene (fusE) already present but not expressed in these strains, but places it under the control of a native and a non-native promoter and also introduce fusB fused to the reporter gene lacZ.
None of the genes used contain harmful adventitious sequences or oncogenic properties and are not likely to promote allergen/toxin production. The reporter gene has been used previously in laboratory strains of E. coli and S. aureus RN4220.

Host/vector system

Host:
- S. aureus RN4220: restriction-deficient derivative of 8325-4 (which is itself listed as a disabled laboratory strain in the HSE compendium). It accepts foreign (unmodified) DNA.
- E. coli K-12-based cloning hosts (e.g. JM109, XL1 Blue): these are listed in the 1-ISE compendium as especially disabled and are multiple auxotrophs

Vectors:
- pCU1: standard cloning shuffle vector for E. coli/S. aureus (Augustin at at, European Journal of Biochemistry, 1992; 204; 1149-1154)
None of these plasmids encode toxic or otherwise dangerous products.
All these plasmids derive from standard cloning replicons or transposons, have a history of safe use and/or are already in use in other laboratories for similar purposes to those described here, are not self-mobilisable mobilisable in trans.

Origin & function

The inserted sequence, the gene fusB, is present within the recipient organisms and encoded the fusidic acid resistance protein FusB. The vector systems have been described previously and have a safe history of use, the constructs have also been described previously (O’Neill et at, Antimicrobial Agents and Chemotherapy 2007; 51:1731-1740 and O’Neill and Chopra, Molecular Microbiology, 2006; 59:664-676).
The GMMO’s will be used to examine silencing of expression of fusidic acid resistance1 it will determine whether silencing occurs at the gene or protein level. The recipient strains possess the resistance gene fusB but do not have a fusidic acid resistant phenotype, and the constructs when introduced allow the monitoring of gene and protein expression.

Evaluation of foreseeable effects

The final GMMO is highly unlikely to constitute a hazard to the environment or community in the unlikely event of...
maximum scale escape from containment. It is unlikely that it would be able to survive outside culture in the external environment1 infect local vermin vectors, or survive as either a minor pathogen, or a commensal of plants. It is possible that the GMMO may be able to survive as a commensal or as a minor pathogen in animals and humans. However the GMMOs would not be more virulent than the original host strains and no dangerous staphylococcal genes or resistance determinants would be introduced that are not already present in the staphylococci.

The GMMO would not be predicted to cause significant economic or ecological consequences in the case of a major escape.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Solid waste (culture or cells) will be autoclaved at 121°C (load temperature) for 20 minutes to give 100% kill before being destroyed as clinical waste. Liquid waste will be similarly autoclaved at 121°C (load temperature) for 20 minutes to give 100% kill before being destroyed as clinical waste. For discarding pipette tips, other small pieces of disposable plastic-ware and associated small volumes of liquid culture (<1 ml) 1% TEGO 2000 disinfectant is used. This is autoclaved at least weekly to give 100% kill. Emergency spill procedure: Liquid spill — treat with Virkon granules until deep pink, or add an equivalent volume of 2% Virkon — will be left for at least half an hour before being mopped up with plenty of water. Wearing strong gloves of the “Marigold” or similar type, solid spills will be gathered into an autoclave bag, the area affected will be wiped liberally with 2% Virkon. The treated area will be left for half an hour for the disinfectant to have time to act and the area will then be mopped up with plenty of water. Immediately after it has been collected and the affected area has been treated with Virkon, the solid waste will be taken for autoclaving, as above.

Project Additional Information

Purposes of the contained use

We aim to use replication deficient recombinant human adenovirus (rAd) to introduce the following genes and short-hairpin RNAs (shRNA) into primary cultures of human cardiac fibroblasts, vascular smooth muscle cells and endothelial cells, the intact human saphenous vein organ culture (vein graft stenosis model: Porter et al., J Vasc, Surg, 36, 150-157), and commercially available cell lines such as HCAEC's (human coronary artery endothelial cells, Clonetics) and HT-1080s (human fibrosarcoma cells, ECACC):

i) Matrix Metallproteinases (MMP) in both sense and anti-sense orientations and also dominant negative forms may be expressed.

ii) Tissue inhibitors of Matrix Metallproteinases (TIMPs) in both sense and anti-sense orientations and also dominant negative forms may be expressed.

iii) p38 Mitogen-activated protein kinases (p38 MAP kinases) in both sense and anti-sense orientations and also dominant negative forms may be expressed.

iv) Heme-oxygenases (HOs) in both sense and anti-sense orientations and also dominant negative forms may be expressed.

v) Short-hairpin RNAs (shRNA used in RNA interference) targeted against endogenous genes (i-iv)

vi) Coral green fluorescent protein (cGFP)

By placing genes (i-iv) under the control of the tetracycline response element (TRE), the levels of expression of recombinant proteins can be tightly regulated thereby enabling a better understanding of their specific role extracellular matrix (ECM) remodelling in cardiovascular disease.
shRNA – targeted against endogenous genes (i-v) are under the control of the human H1 promoter, an RNA polymerase III (Pol III) promoter, ideally suited to the expression of RNA stem-loops (ie shRNA) in a variety of human cells. cGFP is a fluorescent marker protein, simultaneously expressed by shRNA containing recombinant adenoviruses, and under the control of a cytomegalovirus (CMV) promoter for tracking transfection.

Recipient or parental organism

The recombinant adenoviruses will be introduced into primary cultures of human cardiac fibroblasts, vascular smooth muscle cells and endothelial cells, and into the intact human saphenous vein organ culture (vein graft stenosis model; Porter et al., J, Vasc.36, 150-157.

Host/vector system

Short-hairpin RNA (shRNA used in RNA interference)

shRNA targeted against endogenous genes of stress-induced pathways associated with extracellular matrix (ECM) physiology and regulations (i.e. MMPs, TIMPs, HOs, p38 MAP kinases etc), and therefore essential to cardiovascular remodelling. Custom-designed oligonucleotides (~75bp in length) will be purchased from Invitrogen and cloned into the pRNAT-H1.1/Adeno Shuttle vector.

pRNAT-H1.1/Adeno Shuttle vector (commercially available from www.genscript.com): For use in shRNA expression studies. This is an adenoviral shRNA shuttle vector. It is compatible with Stratagene AdEasy Adenoviral Vector System. The vector is designed for transfection in mammalian cells. An H1 promoter is used to drive siRNA expression. cGFP marker is under the control of cytomegalovirus (CMV) promoter for tracking transfection efficiency. The vector also contains a Kanamycin resistance gene for transformant selection. LITR and RITR regions are available in this vector as a function for recombinant viral DNA replication. Vector is mobilisation defective; capable of replicating plasmid DNA only in bacterial cells under selecting conditions. This plasmid is already available in our laboratory.

This plasmid contains a modified version of the human adenovirus serotype 5 (Ad5 genome in which the E1 and E3 genes have been deleted. The E1 deletion renders the virus replication deficient and incapable of producing infectious viral particles in target cells (provided there is no complementation by the host cells); the E3 deletion significantly reduces the ability of the virus to evade detection by the host immune system. The removal of these two genes not only render the virus incapable of replicating itself, but they also create space for up to 7.5kb of foreign DNA.

Vector is mobilisation defective; capable of replicating plasmid DNA only in bacterial cells under selecting conditions. This plasmid is already available in our laboratory.

Origin & function

To generate the recombination adenovirus (rAd), using the method of T.C. He and colleagues, involves cloning the gene of interest (ie shRNA into a shuttle vector and transferring the gene into the adenovirus genome by means of homologous recombination in an adenovirus packaging cell line. Employing the efficient homologous recombination machinery in E.coli, a rAdS is produced by a double-recombination event between the co-transformed adenoviral backbone plasmid vector and a shuttle vector carrying the gene of interest. Transfect low-passage HEK293 cells with linearised recombinant adenoviral DNA to generate recombinant adenovirus.

pTRE-Shuttle2 (commercially available from www.clontech.com)

pTRE-Shuttle2 is a cloning vector designed for the use with the Adeno-X Tet-on expression system. pTRE-Shuttle2 is used to clone the gene of interest into a tetracycline (Tet)-responsive expression cassette. The expression cassette consists of a Tet-responsive promoter (Phcmv*-1), a multiple cloning site (MCS), and two SV40 polyadenylation signals. The Phcmv*-1 promoter contains the Tet-responsive element (TRE). The TRE element is located just upstream of the minimal cytomegalovirus promoter (PminCMV). Because it lacks the enhancer that is part of the complete CMV promoter, PhCMV*-1 is silent in the absence of binding of the reverse Tet-controlled transactivator (rtTA). Consequently, genes inserted in the MCS are actively transcribed only when rtTA binds the TRE element. Vector is mobilisation defective; capable of
replicating plasmid DNA only in bacterial cells under selecting conditions. This plasmid will be purchased from Clontech.

**Adeno-X System 1 Viral DNA**

To produce recombinant adenovirus transfer the (Tet)-responsive expression cassette containing the gene of interest (from pTRE-Shuttle2) into the ligation-ready Adeno-X System 1 Viral DNA (linearised plasmid containing the recombination deficient Ad5 gene). Transform an E.coli strain with the ligation mixture and identify recombinant clones. Transfect low passage HEK293 cells with linearised recombinant adenoviral DNA to generate recombinant adenovirus. This linearised plasmid will be purchased from Clontech.

**Adeno-X ™Tet-On virus**

trTA is encoded by the Adeno-X Tet-On Virus supplied by Clontech. To establish the Adeno-X Tet-On expression system, target cells are co-infected with the recombinant virus containing the gene of interest together with the Adeno-X Tet-On Virus. The virus will be purchased from Clontech.

**Matrix Metalloproteinases (MMPs)**

Proteins of the matrix metalloproteinase (MMP) family are involved in the breakdown of extracellular matrix in normal physiological processes, such as embryonic development, reproduction, and tissue remodelling, as well as in disease processes, such as arthritis and cancer and cardiovascular pathologies. Most MMPs are secreted as inactive proproteins which are activated when cleaved by extracellular proteinases. MMP genes will be cloned into the pTRE Shuttle2 cloning vector and subsequently used to establish an Adeno-X Tet-On expression system. cDNAs encoding full length human MMPs (MMP-2, MMP-3, MMP-9 and MMP-14 in the first instance will be generated in our laboratory.

**Tissue Inhibitors of Matrix Metalloproteinases (TIMPs)**

TIMPs are endogenous regulators of MMPs and adamalysin metalloproteinase activity, and therefore play important roles in regulating cellular functions that are dependant on matrix composition such as invasion migration, differentiation and proliferation. In addition, TIMP-2 has been shown to be required for MMP-2 activation, while TIMP-3 overexpression induces apoptosis. TIMP genes will be cloned into the pTRE-Shuttle2 cloning vector and subsequently used to establish an Adeno-X Tet-On expression system. cDNAs encoding full length human TIMPs (ie TIMP-1, TIMP-2 and TIMP-4) will be generated in our laboratory. cDNA encoding full length human TIMP-3 is already available in our laboratory (a kind gift from Dr Sarah J George (Bristol Heart Institute, University of Bristol).

**p38 MAP Kinases**

Mitogen-activated protein kinases (MAP kinases) are proteins that control cell responses to inflammation and growth signals. p38 MAP kinases, a member of this protein family, controls the production of growth factors and inflammatory cytokines, the molecules produced by the immune system that cause inflammation. p38 genes will be cloned into the pTRE-Shuttle2 cloning vector and subsequently used to establish an Adeno-X Tet-On expression system. cDNA encoding full length human p38 MAP kinase (α,β,δand y) are already available in our laboratory.

**Heme-oxygenases (HOs)**

Endogenous heme catabolism by the heme oxygenase (HO) family of enzymes, which exist in constitutive (HO-2 and HO-3) and inducible (HO-1) isoform, liberate CO, biliverdin and Fe in stoichiometric amounts. HO exists as a macromolecular complex in the endoplasmic reticulum together with cytochrome c reductase and biliverdin reductase. CO has been established as an important, protective signalling molecule in both the heart and vasculature. HO genes will be cloned into the pTRE-Shuttle2 cloning vector and subsequently used to establish an Adeno-X Tet-On expression system. cDNAs encoding full length human HO-1, HO-2 and HO-3 will be generated in our laboratory.
Coral Green Fluorescent Protein (cGFP)

cGFP is a fluorescent marker protein used to assess transfection efficiency in host cells. A cDNA encoding cGFP is already available in the laboratory. cDNA encoding full length cGFP is already available in our laboratory as part of the pRNAT-H1.1/Adeno Shuttle vector (www.genscript.com).

Evaluation of foreseeable effects

All adenovirus serotypes from subclass C, which include the well studied Ad2 and Ad5 serotypes, are non-oncogenic. Wild-type Ad5 infections involve either the respiratory or gastrointestinal tracts (infections are generally mild in children), or the eye (all persons). Because the rAd will lack the E3 gene this may produce a virus that will evoke a stronger inflammatory response in the host, but this should also lead to a more rapid clearance of the virus from the host system. Adenovirus infections are very common, most are asymptomatic. Primary infection of adenovirus is thought to generate life-long immunity and it is thought that the majority of the adult population is likely to have antibodies to the wild-type virus (most people have been infected with at least one type at age 15). Further, whilst the risk is minute the fear is that the defective virus may regain some of its ability to replicate - this is known to occur with adenovirus systems but to date they have always reverted to wild type adenovirus of one sort or another, i.e. never shed genetically modified virus. Although replication has been shown to occur in the lungs of experimentally infected cotton rats administered with high doses of virus, there is no evidence the adenoviruses can naturally colonise non-human hosts and therefore pose no significant harm to animals, plants or ecosystems.

Short-hairpin RNA (shRNA used in RNA interference)

Not being oncogenic themselves, shRNA targeted against endogenous genes (ie MMPs, TIMPs, Hos) associated with extracellular matrix (ECM) degradation (which facilitates malignant cell invasion and metastasis), will not have adventitious effects or confer an oncogenic phenotype upon the host cells at the level of expression used. After conducting a thorough literature review, I am confident there are no additional risks above those already referred to.

Matrix Metalloproteinases (MMPs)

Most of all MMPs have a role in cancer, although not being oncogenic themselves, since their role in extracellular matrix (ECM) degradation, facilitates malignant cell invasion and metastasis. Transformation of a cell to a full malignant phenotype however, is dependent on a number of changes in expression in genes controlling signal transduction/gene expression cascades with the cell or genes involved in regulation of the cell cycle. It is not envisaged that expression of these transcripts whether Sense, Antisense or Dominant negative mutant will have adventitious effects or confer an oncogenic phenotype upon the host cells at the level of expression used. After conducting a thorough literature review, I am confident there are no additional risks above those already referred to. Expression of the gene will be placed under the tight control of a tetracycline-inducible promoter system. Transgene expression can only occur in response to tetracycline exposure, the levels of which can be finely regulated in this system.

Tissue Inhibitors of Matrix Metalloproteinases (TIMPs)

TIMPs are endogenous regulators of MMPs and adamalysin metalloproteinase activity, although not being oncogenic themselves; nevertheless most if not all MMPs have a role in cancer, since their role in ECM degradation facilitates malignant cell invasion and metastasis. However, like the MMPs and after conducting a thorough literature review, it is not envisaged that expression of these transcripts whether Sense, Antisense or Dominant negative mutant will be oncogenic or have adventitious effects in host cells at the level of expression used. Furthermore, expression of the gene will be placed under the control of a tetracycline-inducible promoter.

P38 MAP kinases

Activation of p38 MAP kinase results in increased production of molecules that cause inflammation such as interleukin-1 (IL-1), tumor necrosis factor (TNF), and cyclooxygenase-2 (COX-2). P38 MAP kinase also regulates the expression of a number of other proteins, including interleukin-6 (IL-6) and vascular endothelial growth factor (VEGF), a regulator of new blood vessel formation that can affect cancer cell growth. Inhibition of p38 MAP kinase could reduce the expression of these and other proteins important in the development and progression of inflammatory disease and cancer. Again, after conducting a thorough literature review it is not envisaged that expression of these transcripts whether Sense, Antisense or Dominant negative mutant will be oncogenic or have adventitious effects in host cells at the level of expression used. Furthermore, expression of the gene will be placed under the control of a tetracycline-inducible promoter.
Heme-oxygenases (Hos)

Cardiac atrial and ventricular myocytes express HO-1 and HO-2, and HO-1 levels can be increased by various stress factors including myocardial infarction. CO limits the cellular damage of ischemia/reperfusion injury in the heart. Indeed, greater cardiac damage is seen following ischemia/reperfusion injury in HO-1 knockout mice. Conversely, HO-1 over-expression in the heart reduces infarct size and other marker of damage following ischemia/reperfusion injury. CO also improves cardiac blood supply through dilation of coronary vessels, and reduces cardiac contractility. In the vasculature, CO also exerts numerous beneficial effects. Its ability to dilate blood vessels is long established, endothelium independent and not due to development of hypoxia through displacement of $O_2$. CO has clear, protective effects in various vascular diseases, such as systemic and pulmonary hypertension, development of atherosclerosis and neointimal hyperplasia due to profiliation of vascular smooth muscle cells following vascular injury. However, several human tumours, including renal cell and prostate cancer, express high levels of HO-1. HO-1 may promote tumour cell survival, hindering anti-cancer therapy effectiveness. In contrast, HO inhibition has been shown to enhance tumour regression in some animal models. After conducting a thorough literature review, it is not envisaged that expression of these transcripts whether Sense, Antisense or Dominant negative mutant will be oncogenic or have adventitious effects in host cells at the level of expression used. Furthermore, expression of the gene will be placed under the control of a tetracycline-inducible promoter.

Coral Green Flourescent Protein (cGFP)

Again, it is not envisaged that expression of this transcript will be oncogenic or have adventitious effects in host cells at the level of expression used.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

All control measures specified as requirements for a Containment Level 2 project will be adhered too (See accompanying Biological Safety Handbook for further details).

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Effective operating procedures (including waste management) as outlined by the accompanying Biological Safety Handbook, together with Good Microbiological Practice (GMP) and Good Occupational Safety and Hygiene (GOSH) will be strictly adhered to. All work will be carried out in the Class II Microbiological Safety Cabinet Hood (manufactured to BS EN 12469:2000).

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

02/03/2022

Page 9811 of 15326
The Genetic Modification Safety Committee requested the following:
Correction of a number of typos in the risk assessment and accompanying handbook.

Full reference
Reference to workers histo-compatibility (page 6) to be reworded to allow clearer understanding.

All changes have been completed in accordance with the GMSC's wishes. Documents were resubmitted to the committee and approved with no further comment.

The committee has therefore approved the project at Containment Level 2.

### Project Additional Information
Purposes of the contained use

The micro-organism to be contained is a modified version of vaccinia virus called vTF7-3, which expresses the DNA-dependant RNA polymerase of bacteriophage T7. This organism was previously constructed by others (Fuerst, Niles, Studier and Moss. 1986. PNAS 83, p8122), and now is a widely-used laboratory reagent. This organism will not be modified further, and so this application is for the use of this organism, rather than for its modification. In general terms, the intended use of vTF7-3 is to express 17 RNA polymerase within the cytoplasm of mammalian cells. These cells can then be transiently transfected with plasmids containing specific cDNA sequences under the control of 17 RNA polymerase promoters. In the specific experimental system described here, these cDNAs encode BtJNV N and L proteins, as well as the sequence of a BUNV RNA strand. Expression of these components leads to assembly of non-infectious BUNV RNA segments that mimic the gene expression characteristics of authentic BUNV. By removing BUNV genes expressing proteins involved in both cell entry and exit, these segments are unable to spread from the cells in which they were assembled.

Recipient or parental organism

The recipient organism is vaccinia virus, which is a member of the poxviridae family of enveloped DNA viruses. It was used from 1798 as a vaccine against smallpox but is no longer used for inoculation of the general population due to the worldwide eradication of smallpox, although it is still used as a vaccine to inoculate members of armed forces against intentional exposure. However, vaccinia virus is categorized by the Advisory Committee for Dangerous Pathogens as a hazard group 2 biological agent due to its ability to cause disease in healthy adults.

Host/vector system

The modified vaccinia virus vTF7-3 will be used to inject baby hamster kidney cells (BHK) cells.

Origin & function

The foreign genetic material inserted into vaccinia virus to generate the vTF7-3 version originated from bacteriophage T7. The inserted sequence was a single cDNA that comprised the open reading frame encoding 17 RNA polymerase, under the control of the vaccinia virus p7.5 promoter. Details of this construction are contained within the original scientific article (Fuerst, Niles, Studier and Moss. 1986. PNAS 83, p8122). The intention of inserting this sequence was to cause the abundant expression of T7 RNA polymerase within the cytoplasm of vaccinia virus vTF7-3 infected cells.

Evaluation of foreseeable effects

No foreseeable change in the life cycle or growth characteristics of vTF7-3 compared to the parental vaccinia virus. The T7 polymerase expressed from this recombinant vaccinia virus will be inactive within mammalian cells. This is because there are no DNA templates within the cytoplasm of mammalian cells, thus infection of vTF7-3 will result in no change of gene expression characteristics of infected host cells. If the 17 RNA polymerase should enter the nucleus of infected cells, this polymerase should also remain inactive, as mammalian genes do not contain the specific 17 RNA polymerase promoter sequences required for gene expression. Therefore, to the best of my knowledge, modification of vaccinia virus to generate vTF7-3 should result in no change to the hazard group classification of this organism, as such it should remain as class 2.

Hazards to human health.

Routes of exposure for laboratory workers include ingestion, inoculation via needles or sharps, and droplet or aerosol exposure of mucous membranes or broken skin. The clinical disease of the parental vaccinia virus is as follows:

Day 3-4 post-inoculation: Formation of papule.
Day 5-6 post inoculation: Formation of pustule.
Day 8-9 post inoculation: Well-formed pustule.
Day 12+ post inoculation: Formation of a scab
Day 17-21 post inoculation: Scar formation.
Mild systemic illness can accompany the localised reaction, including fever and malaise. VACV may cause particularly severe disease during pregnancy, in people with active skin disorders such as significant clinical eczema or psoriasis, or in immune-compromised individuals.

No foreseeable hazards outside of the laboratory, due to the low amount of vTF7-3 to be used.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None requested.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The faculty standard procedure for biological waste disposal will be followed, which results in 100% kill of viruses. Liquid waste will be treated with an equal volume of 2% Viricon and left overnight before disposal down the drain with 100 volumes of water. Solid waste (culture flasks, dishes or other contaminated plastic ware) v.111 be autoclaved at 121°C (load temperature) for 20 minutes before being destroyed as clinical waste.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Comments from GM committee -

1. It is not entirely clear if the recombinant vaccinia virus is also part of this assessment or whether this has been constructed previously under another assessment - clarification is required.
2. I'm not sure I like the final 0MM being described as 'less harmful' - no more harmful than the wild type would be better.
3. The proposal OK as class 1 although I have a couple of comments. Firstly, although there is some good background detail in the description, it would be good to know what the host and pathogenicity is for the Sunyamwera virus. Secondly, reference is made, at the bottom of page 3, to the use of a laminar flow cabinet, which doesn't protect the worker; so this should be a safety cabinet, presumably class II.
4. Could some evidence (ret?) be provided that work with vaccinia virus vTF7-3 can be regarded as a class I activity?

Following the comments of the committee the project (originally submitted as a Containment Level 1 project) was reclassified as Containment Level 2 project. The committee had no further comments.

**Historical Significant Changes**

**Historical Date of Additional Info**

**Significant Change ID**

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

Immortalisation of human bronchial epithelial cells to produce cell lines for future study. We aim to culture samples of normal or abnormal bronchial tissue in conditions favouring the appearance of outgrowths from the tissue pieces. We will then culture these cells and, using viral gene delivery, express hTERT, ID-1 and/or CDK4R24C genes in order to immortalise the cells and produce stable, cloned cell lines based on the original tissue. We hope to produce cell lines with sufficient genetic and phenotypic similarity to the primary material to be useful models of pre-cancer in the lung.

**Recipient or parental organism**

The primary material for our research will be human bronchial epithelial tissue at a range of histological grades, from normal to cancerous. Abnormal tissue of low histological grade is expected to be available only in extremely low quantities, typically as material obtained from endoscope biopsies. The natural limits of population doubling will be bypassed by expressing specified genes associated with the cell cycle control.

**Host/vector system**

Third generation amphotropic retroviral expression system, such as Phoenix packaging cell line based on the Moloney Murine Leukaemia Virus (MoMLV) will be used.
Replication-defective virions are produced in the Phoenix amphotropic producer cell-line 1.2.3 (derived from 293T human embryonic kidney cell-line). This is a third generation system: the cells contain the viral em, gene driven by a CMV promoter in one construct and poi and gag genes in a separate construct driven by an RSV promoter. They are then transfected with a third construct containing the gene of interest plus retroviral packaging signal to allow them to produce particles capable of infecting human cells. Amphotropic retroviral systems have come into wide-scale use due to the ability of the viruses to infect a wide range of primary cells with high efficiency. Once infected, the virus integrates into the host genome, and the expression of the cloned gene of interest is initiated. The retroviruses used in gene delivery systems are simple enveloped RNA virus vectors that generally consist of three genes: gag (coding for core proteins), pol (coding for the viral RNA reverse transcriptase) and env (responsible for generating the viral envelope). Long terminal repeats (LTR5) are found at the end of the genome; these sequences aid viral genome integration and transcription of the inserted genes. A final stretch of the sequence is present to aid packaging of the virus. Their transforming potential comes from their ability to integrate into a cell’s genome.

Where mitosis-independent infection is required, third generation amphotropic lentiviral systems, such as that described by Dull et al. (1998). These systems are based on I-IV-1 but lack tat, vpr, vif, vpu and nef genes, making production of wild-type virus impossible. HIV envelope gene is replaced with Vesicular stomatitis virus G protein (VSV-G). Replication-defective virions are produced by 293T cells containing three separate, non-overlapping packaging constructs. The first contains VSV-G while the other two contain HIV-1 psi and gag genes and HIV-1 rev gene driven by CMV and RSV promoters respectively. The cells are transfected with a fourth construct, the transgene vector. This contains the gene of interest along with its promoter and a chimaeric 5 LTR containing a constitutive CMV promoter to allow efficient transcription of the gene of interest and its promoter in the absence of Tat. The 3’ LTR has a 133bp deletion to allow self-inactivation of the vector whereby the vector inserts the gene of interest into the target genome without the LTR promoter sequence.

Origin & function

We aim to infect primary cultures of human epithelial cells in order to express hTERT, ID-I and mutant CDK4 genes and cause transformation and immortalisation of the target host cells. The inserts are intended to immortalise human cells by overriding elements of cell-cycle control.

hTERT is a human gene encoding telomerase reverse transcriptase, activity of which is known to allow cells to escape from replicative senescence.

CDK4R24C is a mutant of the human cyclin-dependent kinase 4 gene that is insensitive to p16/INK4a inhibition and can therefore override this arm of cell-cycle regulation.

I-IIV-1 but lack tat, vpr, vif, vpu and nef genes, making production of wild-type virus impossible. HIV envelope gene is replaced with Vesicular stomatitis virus G protein (VSV-G). Replication-defective virions are produced by 293T cells containing three separate, non-overlapping packaging constructs. The first contains VSV-G while the other two contain HIV-1 psi and gag genes and HIV-1 rev gene driven by CMV and RSV promoters respectively. The cells are transfected with a fourth construct, the transgene vector. This contains the gene of interest along with its promoter and a chimaeric 5 LTR containing a constitutive CMV promoter to allow efficient transcription of the gene of interest and its promoter in the absence of Tat. The 3’ LTR has a 133bp deletion to allow self-inactivation of the vector whereby the vector inserts the gene of interest into the target genome without the LTR promoter sequence.

Evaluation of foreseeable effects

All plasmids will be amplified in standard E.coli K12 laboratory strains such as DH5α or DH10. Laboratory strain Escherichia coli K-12 and its derivatives are recognised as non-colonising and disabled! have an extensive history of safe use and the genetic lesions are well understood. They have been categorised as belonging to Hazard Group 1, according to the definitions given by the Scientific Advisory Committee for Genetic Modification (SACGM) in the compendium of guidance. They are not considered harmful to humans.

Both the prokaryotic and eukaryotic cell lines, even when the latter are transformed, are highly disabled and unable to propagate in the environment. The plasmid vectors are non-mobilisable and the retrovirus lentivirus are replication incompetent, so further spread is highly unlikely.

The retroviral system is well-characterised, widely-used and non-replicating. Occasionally a sequence will integrate in an adjacent position to oncogenes, leading to an increase in their transcription driven by enhancer/promoter elements found in the LTR. Alternatively, integration may cause disruption of a tumour suppressing gene (TSG) leading to a loss of their activity.

Their safe application as cloning and expression vehicles was based on the observation that the various functional aspects of the viral sequence could be separated. The gene (cDNA) of interest is inserted into a plasmid vector between the LTR sequences. This vector also includes the psi (w) packaging sequence. This plasmid is then transfected into a viral packaging cell line, characterised by the expression of the gag, poi, rev and env sequences.

In this way, three separate recombination events would be required to produce wild-type virus.

The lentiviral system is also well-characterised, widely-used and non-replicating. As with the retroviral system described, a sequence will occasionally integrate in an adjacent position to oncogenes, leading to an increase in their transcription or, alternatively! integration may cause disruption of a TSG leading to a loss of their activity. The cis and trans functions of the system are separated as far as possible. The sequences that encode the packaging components are on constructs lacking cis-acting sequences and so are unable to package themselves. The gene (cDNA) of interest is inserted into a plasmid vector between the LTR sequences. This vector also includes the psi (w) packaging sequence. This plasmid is then transfected into a viral packaging cell line, characterised by the expression of the gag, poi, rev and env sequences.
We will use a third generation system that has the viral packaging sequences divided among three separate constructs. The q and greatly modified LTR sequences will be within the transfer construct. Wild-type virus cannot be created as key components such as tat and much of the U3 region in the LTRs are absent. The production of replication-competent virus is unlikely due to the requirement of several recombination events.

The infection of a worker with replication-defective retrovirus resulting in expression of one of the genes used for immortalisation is possible. The standard procedure produces up to 10^7 viral particles/ml; as these cannot replicate, only a finite number of cells could be infected. Were these inserts to be expressed in a worker's cells, via direct infection by the retrovirus, they have the potential to cause one of the cell-cycle control mechanisms to be overridden and thus the removal of one barrier to cell proliferation. This is undesirable as anything that could lead to mechanisms of cell-cycle control being circumvented theoretically increases risk of cancer, albeit to a very small degree.

Accidental exposure to cultured human cells that express these inserts poses no significant risk to workers as their human leukocyte antigen (HLA) system would recognise cells from culture as foreign and destroy them. In this way, the cultured cells, whether primary or transformed, have the same level of hazard as any other cell culture. Risk can be reduced to negligible levels by use of a class II hood which is cleaned after each use, prompt decontamination and disposal of waste, use of lids on centrifuge rotors, and by wearing gloves for all manipulations. In addition, having easily identifiable lab-coats (e.g. blue-coloured) and equipment such as centrifuges, pipettors, incubators and class II hoods designated for use in retroviral work will minimise the risk of cross-contamination.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Derogation is not being applied for.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All plasticware that has come into direct contact with viral supernatant or cell material that has been transfected or infected, e.g. pipettes, tubes etc., will be decontaminated either by immersing in 1% virkon or trigene prior to autoclaving or by taking directly for autoclaving in a sealed, watertight container. All other consumables will be autoclaved. Serological pipettes will be rinsed briefly by aspirating from a beaker of 1% virkon or trigene in the hood before being placed in an autoclave bag.

Tips and tubes will be placed in a plastic, sealable disposable jar in the hood that will be sealed when not in use and will be autoclaved once filled. The tips/tubes will not be soaked in virkon or trigene as the disposable jar provides an extra layer within the autoclave bag separating workers from the potentially hazardous material.

Liquid waste will be rendered biologically inactive by adding virkon or trigene to give a final concentration of 1% and leaving overnight before discarding down the sink. It can either be aspirated into a beaker of concentrated virkon or trigene in the hood or into a reservoir of concentrated virkon or trigene using a vacuum aspirator. Should the latter option be employed, the vacuum pump system will be fitted with the appropriate filters to prevent aerosol formation (changed once a month) and the nozzle and hose will be rinsed with 1% virkon or trigene at the end of each day.

In case of spillage, aerosols will be allowed to settle before decontaminating the area with 10% virkon or trigene. Any contaminated clothing will be removed and autoclaved.

In the event of an injury, wounds will be thoroughly washed with soap and warm water before being bandaged. If material has entered the eye, it will be washed thoroughly from the eye-wash stations. Where any personal contact has occurred the local Biological Safety Officer (Paul Beal) will be informed.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
The main issues for discussion and clarification at the meeting were:
(i) where the project would be undertaken;
(ii) routes of waste disposal; and
(iii) whether the project should be expanded to include a Lentiviral delivery system to increase the chance of success for infection of primary cultures.

It was established that the work would be undertaken in the tissue culture facility on level 7 Wellcome Trust Brenner Building (WTBB).

Procedures were already in place to prevent potential problems of cross contamination of cultures, and safe disposal of contaminated plastic-ware and solutions. It was stressed that workers entering the lab must be classified as Class 2 workers and register with University Occupational Health. Safety procedures).

In the original proposal, only a (third generation) retroviral delivery system had been proposed. After discussion, the recommendation from the Committee was that a (third generation) lentiviral delivery system should also be included in the application. It was felt that such a system may increase the chances of a successful infection of differentiated primary epithelial cells. Consequently, the number of primary cells required would be decreased, and potentially reduce the number of experiments needed to achieve a successful outcome.

The Committee therefore approved the application with a recommendation that a lentiviral delivery system should also be included.

### Project Additional Information

#### Purposes of the contained use

To better understand metabolic pathways in the obligate intracellular parasite *T. gondii* to identify and valid targets for drug development. These studies will help us understand how the parasite manipulates its host for supply of nutrients. Fluorescent markers (e.g., RFP) will monitor protein expression and localisation and gene knockouts will be generated to examine the requirements for genes encoding enzymes in intermediary metabolism. There is hope of generating attenuated strains through this research will be a safer alternative for future research.

#### Recipient or parental organism

*Toxoplasma gondii* is a single-celled protozoan that is an obligate intracellular ubiquitous parasite that can infect a range of warm blooded animals. Most infections are minor and self-limiting but it can be serious for a developing foetus whose mother contracts the disease during pregnancy or immunocompromised and rare immunocompetent persons. (see [http://www.phac-aspc.gc.ca/msds-ftss/msds 153e-eng.php](http://www.phac-aspc.gc.ca/msds-ftss/msds 153e-eng.php)) hence classification as a Hazard Group 2 pathogen in the ACDP. In the laboratory only the intracellular stages are maintained.

#### Host/vector system

The vector is based on the standard pUC based non-mobilisable cloning vector pKS+ with *T. gondii* sequences for expression in parasites and chloramphenicol acetyl transferase as a selectable marker. There are no several hundred publications using these vectors for *T. gondii* transfections including ones from UK institutions. It does not contain elements for propagation in *T. gondii* (e.g. origins of replication, retrotransposons) and is not expected to be mobilisable.

#### Origin & function

Initial gene disruptions will target an enzyme in amino acid conversion (GenBank No. ACB99414 and ACB99413). Genes encoding enzymes for other metabolic intermediary products (i.e. pyrimidine biosynthetic enzymes, biotin and coenzyme A biosynthesis) may be targeted in future experiments. There are no known hazards associated with these classes of enzymes. Most experiments will only utilise a gene fragment so that the chromosomal copy of the targeted gene is inactivated. The intended function is to disrupt metabolic genes by homologous recombination so that the effect on parasite growth and development can be monitored. The fluorescent marker GFP and RFP, well-described in the literature with no known toxicities, will be fused to genes encoding metabolic enzymes (those described above) to monitor their localisation. There are no foreseeable dangers of non-homologous (i.e. illegitimate) recombination with these gene fragments or markers. No toxins, dangerous enzymes (e.g. proteases), cell surface proteins, or virulence factor (vir) encoding genes will be involved in these studies.

#### Evaluation of foreseeable effects

Infection is possible by ingestion or inoculation of parasites. This will be prevented by following standards of good laboratory practice (e.g. lab coats, disposable gloves, work in Class 2 cabinet, decontamination procedures, handwashing). *Toxoplasma* is not airborne preventing infection by inhalation and all manipulations are conducted in
Microbiology Safety Cabinets to prevent contamination by aerosols. All toxoplasms work is conducted in a CL2 facility devoted to Toxoplasma. Contamination is controlled by using a suitable laboratory environment and decontamination measures, appropriate equipment, safe systems of work, personal protective equipment and by providing the individual worker with suitable information, instruction, training and supervision. The final GMM is likely to be the same risk of harm as the un-modified host. It is possible that the genetic lesions in metabolic pathways will lower fitness. It is plausible that an increase in growth rate may occur in some GMMS but this will not affect virulence. Although Toxoplasma could survive and colonise in animals and humans in the environment in escape is unlikely as this intracellular parasite is dependant upon laboratory culture conditions (media, 37°C, 5% CO2) to survive for any period outside the laboratory. It is sensitive to temperature, dryness, nutrients, and CO2 concentration. In the unlikely event of escape, it would compete poorly with wildtype strains common in the environment (indeed 20-25% of the UK population is seropositive for Toxoplasma). The containment measures used to protect workers health and safety will be sufficient to protect the environment. Even in the event of complete breach of containment, Toxoplasma is normally self-resolving and can be treated with sulfa-pyr and hence there will be little or no risk to the environment. The applicant serves as manager responsible for the CL facility, although safety inspections are undertaken by the Faculty Safety Manager. The CL2 facility only allows authorised users. All users are trained in safety risks and control measures used to mitigate any risk.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquids containing parasites will be decontaminated with PreSept. PreSept is an efficient method of disinfection against all bacteria, viruses, fungi, algae and protozoa containing sodium dichloroisocyanurate (NaDCC) and effective through the entire biocidal spectrum as well as highly resistant to inactivation by organic soilage. Efficacy is believed to be 100%. Following treatment overnight, liquids are washed down waste with at least 100 volumes of water.

Solid waste (culture or cells) will be autoclaved with minimum cycle parameters of 121°C (load temperature) for 20 minutes. Autoclave function is monitored by indicator strips. No parasite can survive autoclave conditions.

All material coming into contact with viable organisms will be rendered safe by the use of Virkon, used in accordance with the manufacturer's instructions.

Emergency spill procedure:

Liquid spill - treat with Virkon granules until deep pink or add an equivalent volume of 2% Virkon – will be left for at least half an hour before being mopped up with plenty of water.

Wearing strong gloves of the “Marigold” or similar type, solid spills will be gathered into an autoclave bag, the area affected will be wiped liberally with 2% Virkon. The treated area will be left for half an hour for the disinfectant to have time to act and the area will then be mopped up with plenty of water. Immediately after it has been collected and the affected area has been treated with Virkon, the solid waste will be taken for autoclaving, as above.

All spills of genetically modified microorganisms (GMMO) will be reported immediately to the local Biological Safety Officer, or local Safety Supervisor in the absence of the BSO: all spills and their mode of treatment will be recorded. Any personal injury where an infection by a GMMO may be involved will be reported immediately to one of the local BSO's or Safety Supervisors and the immediate advice of Occupational Health will be sought.

**Project Additional Information**

**Purposes of the contained use**

To infect human or murine cells with retro- or lenti-viral gene delivery systems. As the result, cells will permanently harbour genes encoding (1) transcription factors,
epigenetic regulatory molecules, cell cycle regulators or oncogenes, (2) small hairpin RNA, (3) RNA aptamers or (4) genes encoding peptide aptamers without any replicating viruses. These genes are continuously expressed or can be induced by addition of chemicals such as 17β-estradiol, Tamoxifen, or Tetracycline. Transduced cells will be used for DNA and RNA analysis, cultured in vitro or transplanted into immuno-compromised mice.

Recipient or parental organism

MMLV (Moloney murine leukaemia virus) or MSCV (murine stem cell virus) based replication defective, non-mobilisable retroviral vectors e.g. pBabe. These are well-established and widely used retrovirus based expression vectors with a history of safe use.

The third generation of lentiviral vectors, e.g. pHIV7, HR’CS-G and their derivatives, Drug inducible expression vectors, pLVX-Tight-Puro (Clontech) co-transfected with the regulator pLVX-Tet-On Advanced or pLVX-Tet-Off Advanced. Virus particles in this system are produced by the Lenti-X HT Packaging Mix which utilises a trans-lenti viral vector system.

Lentiviral vector systems in which shRNA constructs can be directly cloned, e.g. pKLO.1.

MSCV-pmiR30, pPRIME-CMV-GFP-FF3, pPRIME-CMV-dsRed-FF3 or pPRIME-TET will be provided by Dr Stephen Elledge (Department of Genetics Center for Genetics and Genomics Harvard Medical School).

MSCV-MigR1 will be provided by Dr. Warren Pear (Abramson Family Cancer Research Institute University of Pennsylvania).

MSCV-Ires-hCD2t will be provided by professor Meinrad Bussligner (IMP, Vienna).

pHIV7-GFP will be provided by professor John J. Rossi (Beckman Institute, CA, USA).

pLL3.7 will be provided by Tyler Jacks (MIT).

A full list of components (inserts, vectors and eukaryotic cell lines) can be found as a separate attached document (Manipulation of the regulatory state of haematopoietic cells COMPONENTS.doc).

Host/vector system

Human and mouse cell lines including haematopoietic, fibroblastic, hepatic cells. Mouse primary cells including embryonic stem cells, haematopoietic cells and embryonic fibroblasts from wild type transgenic or knock out animals. These are categorised as belonging to biological hazard group 1.

Primary human cells such as CD34+ cells, leukaemic blast cells, myeloid cells and lymphoid cells from normal donors and patients. These are biological hazard group 2 due to the potential risk of infection from endogenous pathogens.

Origin & function

Generation, propagation and use of these retro- or lenti-viral expression vectors aim to introduce the coding sequence of transcription factors, oncoproteins, inhibitory RNA molecules or peptide aptamers into murine or human primary cells or established cell lines. The objective is to over-express or knock down the expression of targeted molecules or to interfere with their function into cells, and analyse alterations in the expression and structure of the target genes and cellular phenotypes.

Evaluation of foreseeable effects

The E.coli bacteria used are not pathogenic to humans or animals and are not expected to survive in the environment, they therefore belong to hazard group 1.

The cells which will be transduced in the project are either established cell lines, mouse primary cells or human haematopoietic cells. They are highly unlikely to be able to survive outside the culture vessel and are non-transplantable due to immuno-incompatibility. The use of Class 1 containment with good laboratory practice will be sufficient to limit hazards to human health and the environment from these cell lines. Primary cell lines are categorised as requiring containment level 2 due to the potential for adventitious agents to be present.

Packaging cells for retroviral production are either HEK 293T or NIH-3T3 derivatives and HEK 293T for lentiviruses. Prior to the induction of viral vectors or packaging
vectors, they do not produce any viral products and are considered in the same way as an established cell line. Once virus vectors and packaging vectors are transfected into packaging cells, these cells are capable of producing viral particle which can infect human cells and have to be used at containment level 2.

Once transduced, viral sequences are integrated into the host genome, and occasionally integrate in a position adjacent to oncogenes which thereby leads to a constitutive increase in the level of expression of these oncogenes due to the promoter/enhancer in the Long Terminal Repeat (LTR). Depending on the position, virus integration can cause the aberrant silencing or disruption of the endogenous genes. Lentiviral systems described in this assessment have a self-inactivating (SIN) mutation which abolishes LTR promoter activity so as to prevent the aberrant activation of endogenous genes. With third generation retrovirus systems, the retroviral structural genes are encoded on two different plasmids and contain additional proteins, and at least 3 non-homologous recombination events are necessary to generate replication competent virus. Consequently, they are highly unlikely to acquire a replicative ability in cells. Lenti-vector particles are generated by co-expressing the virion packaging elements and the vector genome in a cell used as a producer. In the case of HIV-1-based vectors, the core and enzymatic components of the virion come from HIV-1, while the envelope is derived from a heterologous virus. To decrease the probability of generating replication competent recombinant (RCR) virus a second generation vector was created which has deletions in its crucial virulence factors. In order to further improve their safety a third generation of lentiviral vectors was developed in which the transgene vector contains a deletion in the 3' LTR U3 region making it self-inactivating in target cells and the packaging vector is a split genome construct with the tat gene deleted and the rev gene expressed by a separate non-overlapping construct. This vector achieves transduction of target cells as well as that observed with the previous generation. To date, neither second nor third generation lentiviral vectors have been found to generate RC virus.

Some of the inserts described in the risk assessment have been shown to have transforming activities when overexpressed. The major risk of generating viral vectors expressing normal transcriptional regulatory proteins therefore comes from either introducing abnormally high levels of a normal or mutated factor into normal cells or from the downregulation of endogenous proteins by RNAi. In some cases, this could lead to aberrant cell differentiation, proliferation, apoptosis or in rare cases, oncogenic transformation. However, the expression of these proteins is highly unlikely to change the natural immunogenic characteristics of the cells they are expressed in, which are therefore very unlikely to colonize humans due to immuno-incompatibility. Consequently, the transfection of these cells and expression of the transfected genes will not significantly alter the capacity of these cells to persist in the environment or cause harm to either humans, animals or other aspects of the environment.

The work will be undertaken in accordance with containment level 2. This includes culture of primary cells, retroviral infection protocols and subsequent culture of any cell-lines produced that have not been screened for the presence of retrovirus. Screening of the cell-lines will be by assay of reverse transcriptase activity. The assay will be carried out within the laboratory designated for Class 2 work until cell culture-derived material has been dissociated using lysis buffer (50mM Tris, 80mM KCl, 2.5mM DTT, 0.75mM EDTA, 0.5% Triton-x-100), after which time it can be continued outside of the facility providing the principles of Good Laboratory Practice are followed. Cell-lines in which no retroviral activity has been found can be de-rated to Class 1. Access to cell culture facilities such as incubators or safety cabinets in which Class 2 work is being performed will be restricted to users registered for Class 2 work. The University Occupational Health Department will be given a list of names of all workers with access to the facility and will give these workers appropriate health surveillance.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not Applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All plastic ware that has come into direct contact with viral supernatants or cell material that has been transfected or infected, e.g., pipettes, tubes etc., will be decontaminated either by immersing in 1% Virkon or trypsin prior to autoclaving, or be taken directly for autoclaving in a sealed, watertight container. All other consumables will be autoclaved.

Tips and tubes will be placed in a plastic, sealable disposable jar in the hood that will be sealed immediately after use. The outside will be sprayed with a disinfectant, put into an autoclave bag, closed, then removed from safety cabinet, put into another autoclave bag and subsequently autoclaved. The tips/tubes will not be soaked in virkon or trypsin as the disposable jar provides an extra layer within the autoclave bag separating workers from the potentially hazardous material.

Serological pipettes will be rinsed with disinfectant by aspirating the solution a few times before disposal into a two-layered autoclave bags. Immediately after the
procedure, the autoclave bag will be sealed and subsequently autoclaved. Used culture flasks, plates, and dishes will be put into an autoclave bag, closed, the outside of the autoclave bag will be sprayed with a disinfectant, then put in another autoclave bag and subsequently autoclaved. The final route for all solid material that has been contaminated is incineration.

Liquid waste will be rendered biologically inactive by adding virkon or trigene to give a final concentration of 1% and leaving overnight before discarding down the sink. It can either be emptied aspirated in a beaker of concentrated virkon or trigene in the hood or by using a vacuum aspirator directly into a reservoir of concentrated virkon or trigene. Should the latter option be employed, the vacuum pump system must be fitted with the appropriate filters (changed once a month) and the nozzle and hose will be rinsed with 1% virkon or trigene at the end of each day.

Please enter comments on the GM safety committee on the risk assessment

The application for this connected program of work was considered by the LIMM Local GM Safety Committee at its 6 monthly meeting on the 14th July 2008. Copies of the risk assessment had been sent to the members of the Committee approximately 10 days in advance of the meeting. The Committee felt that the project had been well set out with a clear description of the (second and third) generation retro and lentiviral vector and host systems presented, along with a description of the potential risks associated with their proposed use. Furthermore, there was a very detailed description of the inserts proposed to be investigated.

Discussion mainly centered on where the work would be undertaken and the routes of waste disposal. The bulk of the work would be undertaken in the tissue culture room on Level 6 Wellcome Trust Brenner building. However, viral stocks would sometimes require centrifugation in an ultracentrifuge based in a different ancillary room. It was felt that so long as the centrifuge tubes containing the viral cultures were both sealed and opened in the tissue culture hoods then there was not a problem with this procedure. However, emergency decontamination provision must be put in place in the event of a tube failure. The main topic of conversation regarding waste disposal related to tip disposal. It was decided that the safest route of disposal of the tips would be via collection in Dispo-SAFE P.E.T. jars (Microbiological Supply Company) that would then be (double) bagged in autoclave bags by workers registered at Class 2 and then transported to Level 3 WTBB for autoclaving. After autoclaving this waste is sent for incineration as a matter of course. The consensus of the Committee was that the work described was a Class 2 project and that the group of individual projects merited the title ‘a connected program of work’. They felt that the project could now be submitted to HSE for approval.

**Project Additional Information**

**Purposes of the contained use**

The work involves the use of constructs called sub-genomic replicons derived from a cDNA copy of the picornaviral genome. These constructs lack the coding sequence for the structural proteins and thus are unable to undergo a complete viral lifecycle. Viral particles are therefore not produced. Permission has been granted previously to use a variety of different picornaviral sub-genomic replicons to study viral genomic replication under category 2 containment and we would like to extend this to include studies with another picornavirus, foot-and-mouth disease virus (FMDV). It is only recently that FMDV replicons have been available, allowing academics to study the genome replication of this important pathogen.

We wish to use the replicon to study the biochemistry of FMDV genome replication within cells. We will also undertake a cell biological approach by using indirect fluorescence microscopy to localise viral proteins in fixed cells.

We expect that this work will lead to a better understanding of FMDV genome replication and may lead to the development of novel therapeutic approaches in the future.

**Recipient or parental organism**

Sub-genomic replicon RNA or cDNA will be introduced into two immortalised cell lines of non-human origin - BHK21 (hamster embryonic fibroblasts) and EBL (an embryonic bovine lung cell line). Both cell lines have been shown to support the genome replication of FMDV derived sub-genomic replicons [McInerney et al. (2000) Replication-competent foot-and-mouth disease virus RNAs lacking capsid coding sequences. J. Gen. Virol. 81, 1699-1702].

**Host/vector system**

The sub-genomic replicon cDNA is cloned into a standard non-mobilisable DNA plasmid (pUC based), and will be grown in laboratory-adapted strains of Escherichia coli that do not survive in the human gut (ACGM/HSE/DOE Note 7, annex 1). Standard in vitro mutagenesis protocols (e.g. Quikchange) will be used to introduce defined
mutations into the replicon.

**Origin & function**

The replicon includes sequences derived from foot-and-mouth disease virus genome, however, NO structural protein sequences are included. The replicon is thus unable to generate virus particles or mediate cell-to-cell spread. It is limited to the cell into which it is introduced by transfection (electroporation) and maintained episomally.

Three forms of reporter/selection protein will be employed. Such proteins are non-toxic and are not predicted to alter the nature of the construct.

(i) a fluorescent protein (green fluorescent protein, GFP and different colour derivatives thereof) will enable the identification of cells in which RNA replication is occurring and measurement of replication.

(ii) luciferase proteins (Luc; Renilla or firefly) will provide easy, highly sensitive, biochemical assays for RNA replication and

Since Lpro plays important roles in replication (e.g. ‘shut-off’ of cap-dependent translation, we will also re-insert the deleted Lpro sequences restoring the full complement of genome replication proteins. As none of these modifications will restore the structural proteins they will not enable the replicon to generate infectious virus.

**Evaluation of foreseeable effects**

The replicon is non-hazardous for the following reasons.

i) It does not encode any structural proteins and therefore lacks the ability for replicon-derived RNA to be packaged. It is therefore impossible to produce FMDV particles from this construct. Naked replicon RNA is highly unstable and cannot survive in the extracellular environment. Furthermore, it can only be transmitted to naïve cells using sophisticated laboratory-based techniques.

ii) Trans-encapsidation with structural proteins from other viruses would be extremely unlikely as this would need to have arisen from a) the presence of both the replicon and a replicating virus within the same cell and b) the ability of the coat proteins produced by the other virus to recognise and package FMDV subgenomic replicon-derived RNA. Even if both of these events were to occur, the resulting particles could not set up an infection as they would lack any genes encoding structural proteins and thus would only be able to undertake cell entry and replication of non-structural proteins. Furthermore, the absence of the structural protein coding sequences would prevent packaging and cell-cell spread.

iii) A recombination event between the replicon and another virus (termed X) could only theoretically occur if these were very closely related (e.g. another picornavirus) and if both were present in the same cell. The lack of any other picornavirus research in the laboratory, together with the containment precautions proposed for this work, mean that this event is extremely unlikely to occur. However, even if this highly unlikely event were to occur, recombination involving incorporation of viral structural genes into the replicon would result in the presence of structural proteins from virus X, not from FMDV. Even if the resulting construct was able to make RNA and proteins successfully, the capsid proteins of virus X are highly unlikely to be competent to package the RNA. But even if this was to occur, any particles would have the capsid of virus X (not FMDV) and therefore, due to inability to bind to appropriate receptors, would not duplicate the pathogenic profile of FMDV. Furthermore, as picornaviruses do not replicate via a DNA intermediate and replicate entirely in the cytoplasm, there could be no host cell mediated homologous DNA recombination. Recombination between host RNA molecules is not a possible route for the provision of structural protein sequences.

There is no impact on antibody testing for FMDV due to the absence of FMDV structural proteins.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

n/a
Our colleague, Professor Martin Ryan (St Andrews) has been involved in extensive discussions with HSE and The Scottish Executive (Scottish equivalent of DEFRA) concerning the safe use of the FMDV construct. These regulatory bodies concluded that level 2 containment would be appropriate providing that studies on the replicons are carried out in a different location to any work with picornaviral structural proteins.

For only GMM - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All FMDV capsid sequences will be removed from Leeds (they will be transferred to IAH, Pirbright).

Work will be carried out in laboratory Garstang 8.54d in the University of Leeds. This will allow complete segregation from all other Picornaviridae experiments. The room has recently been refurbished to a high standard.

The use of a dedicated class II cabinet for all cell culture manipulations and measures to prevent formation or escape of aerosols from samples taken outside of the cabinet (e.g. samples contained in plastic screw-capped vials, centrifugation carried out in sealed rotors etc.) will be implemented. All liquid waste will be discarded directly into Virkon (2%) within the Class II cabinet and inactivated by overnight treatment with Virkon prior to autoclaving. Spent plastic-ware will also be autoclaved (130°C, 20 minutes). Class II cabinets are tested every 6 months, as recommended by HSE guidelines.

The GMSC was happy to accept the risk assessment and the project was approved.

Project Ref 559/09.3

Date Ackn'd CU2 Project Title

Class CultureVolClass2 CultureVolumeClass3-4

02/03/2022
We are engaged in studies to understand the development of antibiotic resistance in Pseudomonas aeruginosa, and in particular, the role played in this process by mutation. Specifically, we will examine the genetic and environmental conditions which are conducive to the rise of hyper-mutator variants during growth in biofilm, since such isolates have been implicated in the development of antibiotic resistance and persistence during in vivo infections (Oliver et al. [2000], Science, 288, 1251-1253).

Recent work from this laboratory demonstrated increased mutability (as determined by increased frequency of antibiotic-resistance) in biofilms compared to planktonic cultures of Ps. aeruginosa PAO1, correlative with a decrease in the expression of key oxidase-type enzymes which offer protection to the organism from oxidative stress (Driffield et al. [2008] Journal of Antimicrobial Chemotherapy, 61, 1053-1056). Thus, the proposed work is a natural extension of the previous study and aims to establish the role of oxidase-type enzymes in mutability in biofilms, as well as whether the inactivation of one or more of the genes encoding oxidase-type enzymes would lead to the rise of hyper-mutators.

Ps. aeruginosa PAO1: ACDP hazard group opportunistic human pathogen which is widely used for research, and has a history of safe use in research laboratories. Strain PAO1 is a strain of choice in Ps. aeruginosa research, with in excess of 1000 Pubmed basic search hits (citations and/pr publications) at the time of writing this application.

Recipient or parental organism
Ps. aeruginosa PAO1: ACDP hazard group opportunistic human pathogen which is widely used for research, and has a history of safe use in research laboratories. Strain PAO1 is a strain of choice in Ps. aeruginosa research, with in excess of 1000 Pubmed basic search hits (citations and/pr publications) at the time of writing this application.

Host/vector system
E. coli K-12-based cloning hosts (e.g. DH5α, JM109, XL1 Blue) will be used to carry out gene manipulations and vector construction in the first instance, before introduction into Ps. aeruginosa. These E. coli host strains are commercially available and the most widely used hosts for gene cloning and/or expression.

Vectors to be used in this study include standard cloning vectors (e.g. pUC19 and comparable available vectors) in standard E. coli cloning hosts (e.g. DH5-alpha, JM109, XL1 Blue, and comparable cloning hosts), as well as shuttle vectors (e.g. pUCP19) which can be maintained in either E. coli or Ps. aeruginosa PAO1 hosts (e.g. pUCP19).

Origin & function
The genetic material involved in the proposed study includes:

1. Vectors/plasmids
1.1. pUC19 (and other standard, commercially-available E. coli cloning vectors; New England Biolabs, UK)
1.2. pUCP19: a shuttle vector for E. coli/Ps. aeruginosa (West et al. [1994] Gene, 128, 81-86.
1.3. Other comparable shuttle E. coli/Ps. aeruginosa vectors as may be necessary in the course of the work.
1.5. Plasmid pMDGF carrying a non-functional GFP (+1 frameshift mutation) to be used for the isolation of potential hyper-mutators in Ps. aeruginosa biofilms (Conibear et al. [2009] PloS One, 4, e6289), and parent vector pMF36 (Franklin and Ohman [1993] Journal of Bacteriology, 175, 5057-5065).

2. Inserted sequences
2.1. Frameshifted and point lacZ mutants will be amplified from E. coli strains CC101-CC111 (Cupples et al. [1990] Genetics, 125, 275-280), and cloned in E. coli/Ps. aeruginosa shuttle vectors, and subsequently introduced into Ps. aeruginosa.
2.2. Insertional inactivations in Ps. aeruginosa PAO1 oxidase-type genes katA, ahpC, tsaA, sodA, and in relevant genes bfrA (encodes bacterioferritin and a positive regulator of katA) and acnA (encodes aconitate hydratase and is up-regulated during growth in biofilm; Driffield et al., 2008). These mutant strains already exist and are available from the Department of Genome Sciences at the University of Washington (Seattle) as part of a transposon mutant collection (containing either a lacZ and/or a phoA insertion linked to the gene encoding tetracycline-resistance; Jacob et al. [2003] PNAS, 100, 14339-14344).
2.3. Insertional inactivation of DNA repair genes (e.g. rec and mut genes), or acquisition of such mutant strains to work with from other laboratories.
2.4. Re-introduction and overexpression in strain PAO1 endogenous genes encoding oxidase-type enzymes (katA, ahpC, tsaA, sodA), and other relevant genes (e.g. bfrA, acnA, rec, and mut genes).

Evaluation of foreseeable effects

None of the genes used in this study contain harmful adventitious sequences or oncogenic properties, and are not likely to promote allergen/toxin production or increase host pathogenic/infective ability.

None of plasmids proposed for use encode toxins or otherwise dangerous products, and have a history of safe use and/or are already in use in other laboratories for similar purposes to those described here, and will not be used in strains containing conjugative plasmids/transposons that may accidentally mobilise them in trans.

The final GMMOs are unlikely to be more harmful than the un-modified host. Inserted and/or modified sequences should not increase the ability of the host to colonise humans, plants or animals and should not increase the mobility of the vector. The modified host, in the event of escape from containment, is not expected to have any advantage over parent strain which exists naturally in the environment. In the highly unlikely event of escape from containment, the small volume of cultures used and the modifications introduced are unlikely to support the modified host to establish itself in the environment. The GMMOs would not be predicted to cause significant economic or ecological consequences in the case of a major escape.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMOs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All contaminated liquid waste is autoclaved under high pressure steam at 121C (or more) for 20 min, ensuring complete killing of all living agents. Solid waste is similarly treated before disposal as clinical waste.

Emergency spill procedure:

Liquid spill – treat with Virkon granules until deep pink, or add an equivalent volume of 2% Virkon – will be left for at least half an hour before being mopped up with plenty of water.
Wearing strong gloves of the “Marigold” or similar type, solid spills will be gathered into an autoclave bag, the area affected will be wiped liberally with 2% Virkon. The treated area will be left for half an hour for the disinfectant to have time to act and the area will then be mopped up with plenty of water. Immediately after it has been collected and the affected area has been treated with Virkon, the solid waste will be taken for autoclaving, as above.

For spills inside centrifuges or incubators the local Standard Operating Procedure as indicated on the equipment will be followed.

All spills of genetically modified microorganisms (GMMOs) will be reported immediately to the local Biological Safety Officer, or local Safety Supervisor in the absence of the BSO: all spills and their mode of treatment will be recorded.

Any personal injury where an infection by a GMMO may be involved will be reported immediately to one of the local BSO’s or Safety supervisors and the immediate advice of Occupational Health will be sought.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment Y

Please enter comments on the GM safety committee on the risk assessment

The Committee were happy that the controls identified in the risk assessment adequately addressed the risk

Project Ref 559/09.4

Date Ackn’d 19/11/2009

CU2 Project Title Manipulation and expression of mouse and human gene sequences using lentiviral and adenoviral vectors, to alter gene function and cellular responses in primary and transformed cells in order to study effects on healthy and diseased states

Date Project Ceased

Class 2

Consent Granted

Project notified under transitional arrangements N
### Project Additional Information

#### Purposes of the contained use

The aim of this project is to investigate gene function and cellular responses in healthy and diseased states of cancer and atherosclerosis specifically in relation to intracellular signalling.

#### Recipient or parental organism

This project is essentially split into two connected programmes of work, the first part being a standard molecular biology approach using tissue culture and molecular biology techniques, and the second part involving in vivo studies using mice. See attached assessment which give complete details of the contents of the project.

#### Host/vector system

<tbody>
<tr>
<td>Small hairpin RNAs (shRNAs) targeting transcripts of mammalian genes that regulate cellular responses in vascular and non-vascular cells will be used. For example, the LOX-1 scavenger receptor, VEGF receptors, insulin and insulin-like growth factor receptors, p53, FAK, PI3-kinase-AKT signalling pathways are relevant to our current research. In addition, the phospholipases (cPLA2alpha, iPLA2) as well as cyclooxygenase enzymes that are downstream of growth factor (e.g. VEGF) stimulation will also be analysed (see Appendix 2). cDNAs encoding the above as well as point and deletion mutants thereof will also be cloned in the vectors (see Appendix 2).</td>
</tr>
<tr>
<td>Briefly, the genes to be targeted/expressed are as follows; LOX-1, VEGFR1-3, cPLA2α, iPLA2, p53, p14/ARF, p19/ARF, FAK, AKT, PI-3-Kinase subunits, RHEB, IGF-1, IGFBPs, iASPP, LC3, zyxin, Insulin receptor, IGF-1R, and linked signalling gene products. Constructs expressing constitutively active mutants of AKT, PI-3-kinase and</td>
</tr>
</tbody>
</table>
RHEB and those directing knock-down of p53, p14/19/Arf are likely to contribute to immortalisation and transformation of the target host cell. Another question is the role of different factors in regulating blood clotting and we can test the role FXIII-A, transglutaminase 2 (TG2) or GLO-II gene products using viral-based transgene expression to manipulate synthesis, secretion, localisation and biological activity in cultured cells.

**Evaluation of foreseeable effects**

Bacterial E.coli strains used for standard molecular biology have a history of safe use, they are unable to establish and colonise the gut, have auxotrophic requirement that will not be met in the environment, the genetic lesions are well documented. Even in the event of failure of containment it is highly unlikely that harm would occur to humans or the environment.

Vectors

The viral vectors used will be previously described replication defective lentiviruses or adenoviruses engineered to contain mouse shRNA sequences to inhibit gene expression. These will be checked for effectiveness in immortalised mouse cells in culture (e.g. RAW647 mouse macrophage line) before delivery into mice using approved procedures.

Lentiviral vectors:

These 3rd and 4th generation viral gene transfer system are well-characterised, have a history of safe use, are widely-used, non-replicating and are unlikely to generate replication competent virus. The SIN versions of these vectors have higher biosafety when compared to the standard versions.

Adenoviral vectors:

The non-replicating first generation and high capacity adenoviral vectors have been well-characterised. The wildtype adenovirus itself is not associated with any tumour formation in humans. The vector system is very well-characterised and cannot replicate in the absence of the adenoviral E1 gene products.

Virus-transformed cells:

Although some of the virus-transformed mammalian cells created in this project will likely have altered growth properties, eukaryotic cells, even when transformed, are highly disabled and unable to propagate in the environment. Thus the likelihood of harm to humans, animals or the environment is considered to be low.

Mice: Mice injected with the viral vectors are not expected to be any more harmful to humans or the environment than the host mice. Wild-type, ApoE -/- and LDL-R -/- knockout mice cannot support replication of infectious lentivirus (based on HIV-1 genes). As a result, the potential for shedding of recombinant virus from such animals is very low. We are using viral vectors with a negligible risk of becoming replication-competent viruses.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

- Rodent control external to the building to prevent ingress of wild type mice
- Use of door barriers to prevent escape of mice from holding rooms
- Mice housed in home office approved caging system which is resistant to escape
- Animal technicians are trained in the correct technique for animal handling
- Only approved SOPs are used for cage changing tasks
- All waste is autoclaved prior to leaving the animal facility, final disposal of waste from the facility is via incineration
- Access to the facility is restricted via an electronic access system to approved personnel

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

To minimise any residual risk to workers or the environment procedures adhering to a GM Class 2 safety manual for recombinant viral work will be followed. This includes the use of a tissue culture class II hood that is cleaned after each use, prompt decontamination and disposal of biological waste, use of lids on centrifuge rotors and
wearing gloves for all gene manipulations. In addition, easily identifiable colour coded labcoats (e.g. blue coloured) and equipment such as centrifuges, pipettors, incubators and tissue culture class II hoods designated for use in viral work will minimise biosafety risks. Routine cleaning and waste management will be carried out by the named person (SLS) and additional trained people working to Class 2 standard.

Facilities to be used:
All work with cell culture and viral particles will be done in the designated GMO Class 2 room and all equipment will be designated as available for GMO class 2 work only.

Safety precautions:
The work will be undertaken in accordance with the requirements for GMO containment level 2. This includes culture of primary cells, viral infection protocols and subsequent culture of any cell lines produced that have not been screened for the presence of virus. Screening of the cell lines will be by assay of reverse transcriptase activity, for example, by using the Roche reverse transcriptase assay, colorimetric (catalogue number 11 468 120 910). The assay will be carried out within the Class 2 facility until cell culture derived material has been put into the lysis buffer (isotonic buffers containing non-ionic detergents (0.5-1% TX-100 or NP- 40) or ionic detergents (2% SDS)), after which time it can be continued outside of the facility providing the principles of Good Laboratory Practice are followed.

Access:
Only named persons will have access to the facility. Viral vector particles will be stored in a locked freezer. Prior to being given access, any named staff must receive training via local induction involving the experienced virologist (SLS) and the local safety officer in LIGHT (Dr. S. Futers). Thorough decontamination of any potentially affected areas will be completed before maintenance staff are granted access.

All contaminated liquid waste is autoclaved under high pressure steam with a temperature of at least 121C for 20 min, ensuring complete killing of all living agents. Solid waste is similarly treated before disposal as clinical waste.

Emergency spill procedure:
Liquid spill – treat with Virkon granules until deep pink, or add an equivalent volume of 2% Virkon – will be left for at least half an hour before being mopped up with plenty of water.

Wearing strong gloves of the “Marigold” or similar type, solid spills will be gathered into an autoclave bag, the area affected will be wiped liberally with 2% Virkon. The treated area will be left for half an hour for the disinfectant to have time to act and the area will then be mopped up with plenty of water. Immediately after it has been collected and the affected area has been treated with Virkon, the solid waste will be taken for autoclaving, as above.

For spills inside centrifuges or incubators the local Standard Operating Procedure as indicated on the equipment will be followed.

All spills of genetically modified microorganisms (GMMOs) will be reported immediately to the local Biological Safety Officer, or local Safety Supervisor in the absence of the BSO: all spills and their mode of treatment will be recorded.

Any personal injury where an infection by a GMMO may be involved will be reported immediately to one of the local BSO’s or Safety supervisors and the immediate advice of Occupational Health will be sought.
1. This one is a very well written and appropriately detailed assessment.

2. P2, under Host(s) – class II ACDP oppo paths… should read ACDP hazard group 2 opp paths.

3. P4, Final GMM, can you make this plural as you have two hosts i.e. GMMs, also in text can you make GMMO plural. Same again under next section, make GMM plural.

4. Under section on “environmental and activity” level 1 containment facilities should read level 2. Also GMMO should be plural.

5. P8, under training & authorisation please describe your training in GM work, can be experience and/or formal courses. Have you registered for the faculty’s on-line Gm training course?

6. I’m ok about FBS9024aon – Although Ps aeruginosa is a mild pathogen they seem to have all safety considerations in place and it seems quite well thought out.

7. This project looks OK to me. I presume it is Category II on the basis of the recipient organism?

8. OK by me.

Large Scale Activities

Human Clinical Applications
**Project Additional Information**

**Purposes of the contained use**

The aim of this project is to use gene delivery technology to characterise the roles of both viral and cellular proteins in viral replication, pathogenesis and immune evasion.

These genes (viral and host) will be expressed, or their expression reduced with shRNA, (delivered by non-replication competent retroviral and lentiviral vectors). The modified cells will then be tested for changes in various signalling pathways associated with growth, stress and the immune response. Once changes have been identified, the mechanism of action of the viral or host protein will be characterised. Mutants of the expressed proteins will be made to inform which parts of the protein are important for activity. Understanding the mechanisms by which viruses cause pathogenesis will enable us to block these responses and may alleviate human diseases.

In addition, this technology will be used to extend the lifespan of primary cells in culture for biochemical studies.

**Recipient or parental organism**

**Host(s)**

Bacteria

E. coli K12 strains such as XL-1 blue, DH5 alpha and similar commercially available GM strains for plasmid propagation and gene manipulation.

Mammalian

Mammalian primary cells and immortalised cell lines (such as HeLa, SiHa, Caski, HEK-293, HEK-293T, HEK-293 derivatives, NIH-3T3, HaCaT, Vero, Cos-7, Huh-7, Huh-7.5, Hep-G2, CHO and RAW264.7).
Vector

Retroviral

In the first instance we will be using pBabe-Puro retroviral vector (commercially available from Cell Biolabs Inc.), derived from Moloney Murine Leukaemia Virus (MMLV). This vector provides a viral packaging signal, transcription and processing elements and a multiple cloning sequence for cloning of the gene of interest. The vector also contains a bacterial origin of replication, ampicillin resistance gene and a puromycin resistance gene for the growth of infected mammalian cells to select stable cell lines. Other 2nd (and later) generations of safety modified retroviral vectors may be used in this project.

Lentiviral

Amphotropic lentiviral self-inactivating (SIN) lentiviral vector expression system. This system includes p8.91 (pCMVD8.91) which is a HIV-1 plasmid encoding gag-pol tat and rev and deleted for the other accessory gene, pCSGW (pHRSIN-cPPT-CEW) which is a HIV-1 vector encoding green fluorescent protein, which will encode the gene of interest pMDG, which encodes VSV-G envelope protein.

Host/vector system

Retroviral packaging system

In the first instance we will utilize the well characterised Phoenix packaging cell line. Phoenix is a second-generation retrovirus producer cell line for the generation of helper virus free amphotropic retroviruses. These lines, generated in the Nolan laboratory (Stanford University, USA) and now available through the ATCC, are in routine use in over 2500 laboratories worldwide. They are based on the HEK293 cell line (a human embryonic kidney cell line, transformed with adenovirus E1A carrying a temperature sensitive T antigen). For biosafety purposes both the gag pol and envelope constructs utilize non-Moloney promoters to minimize recombination potential with introduced retroviral constructs, and different promoters for gag-pol and envelope are used to minimize their inter-recombination potential. Importantly, this cell line has been tested extensively by the Nolan laboratory for helper virus production and has been established as being helper virus free. The viruses do not contain DNA that encodes virus proteins and so this system cannot produce replication competent virus. Other packaging cell lines compatible with 2nd and later generation retroviral gene delivery technology may also be considered.

Lentiviral delivery system

SIN vectors have a deletion in viral promoter region (U3) of the long terminal repeat (LTR) and following reverse transcription have no viral promoter in the provirus and so are safer than non-SIN vectors. The other gene products (Gag-pol and the envelope) are provided in trans from different plasmids so as to minimise any risk of replication competent lentiviruses. In this system replication-competent viruses can be produced only after three separate recombination events. Co-transfection of the plasmids including one carrying a viral glycoprotein (VSV-G) into a designated human packaging cell line (e.g. HEK293T) enables production of replication-incompetent viral-like articles that retain the ability to deliver the viral genome to a broad range of host cells.

The accessory genes essential for wild-type lentivirus replication are absent in this system. Additionally, the vesicular stomatitis virus envelope glycoprotein (VSV-G) is encoded by a separate plasmid that enables coating of the replication-defective particles with VSV-G, enabling delivery of virions to a wide-range of host cells in culture. For biosafety purposes, the integrated lentiviral construct within the genome of the host lacks the capability of excision or VSV-G gene sequence to enable packaging and export of infective virions.

Purified plasmids will be transfected into Phoenix or HEK293T cells, media collected and retroviral / lentiviral virus-like particles purified by high-speed centrifugation in sealed tubes. Alternatively, commercial kits are available for viral purification (e.g. Invitrogen, Clontech)

Origin & function

Inserted sequences.

This project is concerned with the expression of four kinds of inserted sequences, which in combination will be used to dissect viral pathogenesis and cellular processes. These inserts include; viral genes cellular genes, shRNAs and libraries created from cell lines and each will be discussed in more detail below

Viral sequences.
The inserted sequences consist of both structural and non-structural proteins, some of which are potential transforming proteins, derived from:

- human adenoviruses (E1A, E1B, E3-14.7K, fibre)
- human papillomavirus (HPV) (E5, E6, E7)
- hepatitis C virus (HCV) (NS2, NS3/4A, NS4B, NS5A).

We will PCR amplify the sequences for these cDNAs and clone wild-type, point and deletion mutants thereof into the viral expression plasmids.

Cellular sequences.

We are interested in proteins associated with signalling. Briefly, the genes to be targeted/expressed include protein kinases, ubiquitin ligases, phosphatases and adaptor proteins. In particular we will work with proteins associated with nuclear factor kappa B (NFkB) signalling (e.g. NEMO, optineurin and TRAF ligases), interferon (IFN) signalling (e.g. TBK1 and IKK epsilon), mitogen activated protein kinases (MAPks) (e.g. ERK and p38 MAPK), pattern recognition receptor signalling (e.g. RIG-1 and Mda-5), energy balance detection (e.g. AMPK) and beta catenin signalling (e.g. GSK3 beta and beta-catenin). Introduction of some of these constructs is expected to change the growth properties of the cell lines, increasing or decreasing growth rate and ability to survive indefinitely in culture, or abrogation of this ability, depending on the host genotype and the particular construct.

shRNA sequences.

We will also utilise the Phoenix delivery system to introduce small hairpin RNAs (shRNAs) targeting transcripts of the above viral and cellular targets.

In addition, we will extend the lifespan of primary cells in culture by the expression of the HPV E6 and E7 proteins using viral delivery. Over-expression of HPV E6/E7 has been demonstrated to be effective as a means of prolonging growth in the laboratory of different primary cells (Maeda et al., 2005).

Evaluation of foreseeable effects

The main environmental and safety hazard from these inserts would be the transmission of oncogenes to a wild-type animal or person. This is an extremely unlikely event. However, if this occurred then the worst-case scenario (transmission of an oncogene), would be limited to primary contacts in a wild-type population. However, any viral vector would have to evade the host immune system; the human oncogene would have to be transcribed correctly, and the resultant oncogenic event would also need to evade the host immune system. The likelihood of harm to the environment and safety of workers from the inserts is therefore assessed as negligible. Individuals involved with project are instructed to declare changes to their immune status (caused by e.g. antirejection drugs, chemotherapy, radiotherapy etc), where this is identified then individuals will have a personal risk assessment.

Final GMM

Virus: This project specifically excludes the use of viable Wild-type viruses. All viral vectors used are replication deficient and cannot propagate in any organism except in the producer cell line used for packaging and production of virus-like particles that are replication-defective.

Cells: Virally infected cells are not expected to be more harmful to humans or the environment than the untransduced host cells. They will still be highly unlikely to survive outside tissue culture conditions as eukaryotic cells, even when transformed, are highly disabled and unable to propagate in the environment.

There is no cancer risk associated with human adenoviruses; high risk HPV (such as HPV16 and 18) is associated with cervical cancer and ano-genital cancers with HCV is associated with hepatocellular carcinoma; however transformation frequencies of human cells are very low and multiple open reading frames are often required to stably transform primary human cells. All experiments utilising the recombinant replication defective viruses will be performed under containment level 2 conditions (cell culture laboratories 8.51b, 8.54d and 8.61j). The Phoenix cell lines used to produce recombinant viruses are currently employed in at least 2500 laboratories world-wide for the delivery genes into cells for biomedical research. Additionally, we have consulted with colleagues in Belfast (who provided the pBabe-Puro plasmid) and University College London (who provided the lentiviral vectors) who use this delivery system for similar purposes and they work at Containment Level 2. Similarly, consideratons apply to the use of cells infected with viruses expressing oncogenes. For example, studies on colon cancer have documented that many oncogenes, tumour suppressors and
mis-match repair enzymes must be mutated or inactivated in order to generate a malignant phenotype in vivo. Therefore, cell lines generated are unlikely to be harmful to the operator. Furthermore, accidental infection of the operator with retrovirus expressing viral oncogenes is very unlikely to cause harm.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

To minimise an residual risk to workers or the environment procedures adhering to a GM Containment Level 2 safety manual for recombinant viral work will be followed. This includes the use of a tissue culture class two hood that is cleaned after each use, prompt decontamination and disposal of biological waste, use of aerosol tight lids on centrifuge rotors and wearing gloves for all gene manipulations. In addition, easily identifiable colour coded lab coats and equipment such as centrifuges, pipettors, incubators and tissue culture class two hoods designated for use in viral work will minimise biosafety risks. Routine cleaning and waste management will be carried out by the named person (KHR) and additional trained people working to Class Two standard.

Facilities to be used.
All work will be performed in the laboratories in FBS, level 8. All work with cell culture and viral particles will be done in designated GMO Containment Level 2 rooms and all equipment will be designated as available for GMO Class two work only.

Safety precautions.
This work will be performed in accordance with requirements for GMO containment level two. This includes culture of primary cells, viral infection protocols and subsequent culture of any cell lines. Cells cultured for biochemical experimentation will be lysed within the GMO class two facility, after which time it can be continued outside the facility providing the principles of Good Laboratory Practice are followed. The major risk of working with retrovirus vectors is associated with needlestick injuries. To prevent contamination of workers by virus, no glass or sharps will be used in the cell culture facilities and a lab coat and nitrile gloves will protect workers. Skin lesions will be covered with a bandage in addition to the protective wear described in this application. People with severe skin conditions or wounds will be prevented from working with infectious virus.

Access
Only named persons will have access to the cell culture facility. Viral vectors will be stored in a freezer. Prior to being given access to cell culture staff must receive training via local induction involving the experienced virologist (KHR). Thorough decontamination of any potentially affected areas will be completed before maintenance staff are granted access.

Spillage/accidents.
All spills of genetically modified microorganisms (GMO) will be reported immediately to the local Biological Safety Officer, or local Safety Supervisor in the absence of the BSO: all spills and their mode of treatment will be recorded. In case of spillage, aerosols will be allowed to settle for 30-60 mins before decontaminating the area with 10% Virkon or Trigene. Any contaminated clothing should be removed and autoclaved. Any personal injury where an infection by a GMMO may be involved will be reported immediately to one of the local BSO's or Safety supervisors and the immediate advice of Occupational Health will be sought. In the event of an injury, wounds should be thoroughly washed with soap and warm water before being bandaged. If material has entered the eye, it should be washed thoroughly from the eye wash stations.

Training
An experienced retrovirologist (KHR) will train others in appropriate use of viral gene delivery techniques.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not reequired

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste generated as part of standard procedures containing viable organisms will be inactivated prior to removal from site by a licenced clinical waste contractor. Inactivation will either be the use of a validated biocidal agent (Virkon or Trigene) or autoclaving using a cycle with sufficient load heat and dwell time to achieve sterilisation.
Members of the Faculty of Biological Sciences, Biological Safety Committee discussed the technical aspects of A M's risk assessment. Two questions were raised: one was the need to test for replication competent viruses in the lentiviral vector preparations. It was thought that the safety features built into the systems being used were well tried and tested so there was no need to test for RCVs unless primary cell lines were used that could possibly be infected with retrovirus. Secondly, could transmission of oncogenes by lentivirus vectors into workers be described as low risk? The committee thought this was the case and agreed with the risk assessment on this (to include non-use of sharps).
**Project Additional Information**

**Purposes of the contained use**

The aim of the project is to understand the role of oncogenes, tumour suppressor, developmental and cellular signalling genes and pathways in the development and progression of cancer. This includes construction of viral vectors to introduce gene sequences in human cell lines or primary cultures to induce over-expression or knock-down of target genes.

Three expression cassettes will be used:

1. Inserts coding for reporter genes including eGFP and derivatives, dsRed and derivatives.
2. cDNAs encoded by wild-type or mutant known or potential oncogenes, tumour suppressor genes and other genes involved in cell signalling and/or development under the control of cloned promotor fragments. These cDNAs may be unmodified or expressed as fusions with a fluorescent dye such as eGFP or dsRed for identification of cells expressing constructs.
3. Cassettes containing and expressing sequences to effect gene knockdown using RNA interference under the control of human or viral promoters as above. RNA interference would be targeted primarily but not exclusively to genes involved, or thought to be involved, in development and progression of tumours. These may be transient or stable knockdowns.

Any of the above (cassettes 1, 2 and 3) may also include transfer of a drug resistance marker to select recombinant cells.

**Recipient or parental organism**

For propagation of plasmid DNA

E.coli K-12 derived plasmids because of their safe history of use

E. coli XL-Blue (recA1 enA1 gyrA96 thi-1 hsdR17 supE44 relA1 lac [F' proAB lacIqZΔM15 Tn10 (Tetr)]) because of its safe history of use and efficient cloning of methylated DNA. Although XL1-Blue is able to mobilise plasmids, none of the vectors to be used are mobilisable therefore minimizing risk.

Retrovirus packaging cell lines

e.g. Phoenix amrho, derived from human embryonic kidney cell line HEK293T by introduction of separate gag-pol and env constructs [two plasmids with different selectable markers] designed to minimise potential recombination.
Established human cell lines

Primary human cells

Human cell lines, primary cells and packaging cell lines are not capable of survival outside the laboratory and are non-transplantable due to immunoincompatibility. They are therefore considered to be highly disabled hosts. Established cell lines with a history of safe use may be considered hazard Group 1, however primary cells may contain endogenous pathogens and must be treated as Group 2.

Host/vector system

Retrovirus (including MMTV, MoMLV) - ACDP1

Lentivirus (including safety modified HIV-1)

No work is proposed which would involve using intact wild-type retrovirus, HIV-1 or HVS. Lentivirus backbones to be used are considered safer than wildtype HIV-1 because of modifications which reduce probability of live virus production significantly. The non-human adenoviral vectors (Herpesvirus saimiri - HVS) to be used are non-pathogenic, deletion of the transforming genes Stp and Tip removing any oncogenic potential of the virus.

1) Viral vectors from collaborators and commercial sources -

a. Retrovirus - vectors include FB series (Stratgene), RETROSUPER (Netherlands Cancer Institute), RetroTET system (Clontech). Retroviruses infect dividing cells and integrate into the host cell genome. Integration is random but preferentially into transcriptionally active chromatin and thus carries a risk of insertional mutagenesis. The retroviruses used for vector construction are based on murine retroviruses MMTV, MoMLV and MSCV in ACDP hazard Group 1, however amphotropic virus is produced which can infect human cells, potentially increasing the hazard. The retroviral vectors to be used are replication-defective, requiring transfection into special packaging cell lines to produce infectious virus and have a long history of safe use. Viruses are capable of infecting cells but once integrated, virus genomes lack the sequences necessary for production of infectious virions. Stable retrovirus producer cells cannot be made. Packaging cell lines (Phoenix Ampho) have been developed which carry two plasmids encoding the viral gag-pol and env genes separately to minimise the possibility of multiple recombination events regenerating wild type virus. Vectors carry drug resistance markers for selection of transduced cells - these genes are non-hazardous to human helath.

b. Lentivirus (see Appendix for examples)

Lentiviruses are a sub-group of retroviruses that can infect both dividing and quiescent cells. The lentiviral vectors to be used in the proposed study are based on HIV-1 (e.g. Invitrogen pLenti6 series, Clontech pLVX). However these 3rd generation self-inactivating vectors are multiply-deleted and lack the ability to replicate or re-create an intact virus genome once integrated into the host cell genome, and would thus pose a much reduced risk compared to the parent genome once integrated into the host cell genome, and would thus pose a much reduced risk compared to the parent virus. The vectors typically contain less than 30% of the wild type HIV-1 genome. Safety is increased by the use of commercial packaging systems such as the Clontech Lenti-X or Open Biosystems Trans-Lentiviral Packaging System in which the functions required for virion production are separated and carried on 4 or 5 co-transduced plasmids. These contain minimal virus sequence to minimise the potential for recombination. Stable producer cell lines cannot be made with the modified vectors to be used. Virions produced from lentivirus vectors will be pseudotyped with VSV-G structural proteins to allow entry into multiple cell types, however recent work has shown that amphotropic lentiviruses rapidly lose infectivity at 37°C. Commercially available 3rd generation lentiviruses with ORF or siRNA inserts ay also be used. The vectors carry drug resistance markers for selection of transduced cells; these are non-hazardous to humans.

SACGM Compendium of Guidance Jan 2007 pp116-125
2) Plasmid vectors obtained from collaborators or commercial sources, including but not limited to pFB series. All are mobilisation-defective. All contain antibiotic resistance genes for selection with ampicillin, kanamycin or chloramphenicol in bacteria. Resistance to these antibiotics is not clinically relevant due to widespread resistance or antibiotic toxicity.

All vectors and viruses received from external sources (commercial or from collaborators) will be handled in a designated labelled restricted access class 2 biological safety cabinet by experienced trained laboratory personnel, and checked for contamination with bacteria, yeast or mycoplasma prior to preparation of stocks and use. Receipt of vectors and viruses, source and details of subsequent handling will be recorded and dated (written record).

Origin & function

ORIGINS:

i) Human DNA, including cloned cDNA, shRNA, siRNA prepared in-house, from collaborators or commercial sources.

ii) Low hazard for plasmid DNA or human cell line DNA

Risk of infection in preparation of DNA from primary cell cultures; if donor known to be HIV or HBV +ve on basis of medical history they are excluded to minimise this hazard.

FUNCTIONS:

1. Inserted sequences coding for reporter genes including eGFP and derivatives, dsRed and derivatives, luciferase, beta-galactosidase.

2. cDNAs encoding wild-type or mutant known and candidate oncogenes, tumour suppressor genes and other genes involved in cell signalling and development. Expression is under the control of cloned tissue-specific huma promoter sequences, constitutive viral promoters (e.g. MoMV 5’ LTR) or inducible promoters (e.g. TET ON or TET OFF system, inducible lacZ promoter). cDNAs may be unmodified or expressed as fusions with eGFP or similar for fluorescent detection of protein expression.

3. Expression cassettes encoding shRNA or siRNA molecules under the control of human or viral promoter. shRNAs or siRNAs will be targeted primarily but not exclusively to genes that may be, or are known to be, involved in cancer development and progression. Stable expression of shRNA has the potential for off-target effects on other genes that can deliver an antiviral response resulting in altered cellular metabolism and local inflammation following accidental exposure to RNAi-expressing GMOs. This will be minimised by careful selection of target sequences using sequence databases.

Evaluation of foreseeable effects

Retroviruses are hazard group 1 and are les hazardous than the parent organism. The replication defective system consists of a packaging cell line and the vector; structural genes are removed from the vector to prevent it replicating once it has entered the cell. Infection with retroviruses can lead to insertional mutagenesis adjacent to the site of insertion, although it is only capable of one round of infection. Infection with retrovirus has the potential to transcriptionally activate cellular oncogenes. However, this is partly titre-dependent and unlikely to occur with the small amount of virus handled within this laboratory assessment. The inserted genes code for known or potential oncogenes, tumour suppressor or developmental genes that may be under the control of strong promoters. Theoretically these changes may contribute to cellular transformation if expressed in the cells of the operator, although several further genetic changes would be required for progression to malignancy. Furthermore removal of structural genes from the vector prevents it from replicating after it has entered the cell.

Lentiviruses are no more harmful than the parent virus, and frequently pose a lower risk reflecting deletions in the virus backbone and inability to replicate or re-create an intact virus genome when integrated into the host cell genome. In the proposed study the high infectivity rates and long-term persistence of vectors, combined with the ORF 73 regulatory region to overcome promoter silencing, may be utilised. Additional vectors are HIV-1 based but multiply-deleted and unable to replicate or cause disease. The
main theoretical risk, as for retroviruses, is from insertional deleted and unable to replicate or cause disease. The main theoretical risk, as for retroviruses, is from insertional mutagenesis and expression of inserts in the host cell leading to cellular transformation. Lentiviral vector systems that include specific genes (gag, pol, env) for virulence or pathogenicity on 2, 3 or 4 plasmids lower the risk for recombinaton and the production of replication-competent HIV, thereby providing greater safety to the researcher.

E. coli strains and human primary and established cell lines are disabled and cannot survive outside laboratory growth conditions.

Retroviruses and lentiviruses are enveloped and could not survive in environment and no modifications of the viruses will be made that would be likely to alter this property. All virus vectors contain multiple deletions and can only be propagated in specialised laboratory cell lines. Any infected cells would be targeted and destroyed by the immune system. Furthermore the retrovirus genomes lack the sequences necessary for production of infectious virions limiting infectivity following cellular integration.

Lentivirus based on HIV: In theory it would be possible for lentivirus to recombine with wild type HIV in a person infected with HIV, however this would require that infectious virus reaches and infects CD4 cells where HIV exists. Since the lentivirus-recipient cells are non-permissive for wild type HIV maintenance and replication, this should not arise.

There are no economic or ecological consequences of major release of any of the GMOs; the work is small-scale and non-hazardous to the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All work to be carried out in accordance with LIMM safety manual rules for work with Biological Agents and GMOs.

All work with cell lines, virus production and handling of virus to be performed in designated Class 2 biological safety cabinets using designated, labelled equipment to minimise aerosols and risk of accidental infection. Centrifugation to be carried out in closed buckets opened only inside Class 2 safety cabinet.

Minimise risk of ingestion by good laboratory practice, hygiene procedures, hand washing, wearing of gloves and laboratory coat (see LIMM safety manual).

No use of sharps with virus or virus-infected cell cultures or naked DNA (gel excision tips to cut DNA bands form gels).

Immuno-compromised individuals or those with skin conditions such as eczema will be advised to consult occupational health before working with live virus.

All waste to be disposed of according to LIMM safety manual procedures.

Liquid waste will be treated with Virkon granules or an equal volume of 20% Trigene Advance or 10% Virusolve+ and left for at least 30 minutes before disposal down the drain with copious amounts of water.

Solid waste (culture or cells) will be autoclaved at a minimum of 121°C (load temperature) for 15 minutes before being disposed as clinical waste.

Emergency spill procedure:

Liquid spill - Wearing gloves treat with Virkon granules until deep pink, or add an equivalent volume of 20% Trigene Advance or 10% Virusolve+; leave for at least 30 minutes before mopping up with paper towels and wash area with plenty of water.
Solid spill - Wearing appropriate gloves, solid spills will be gathered into an autoclave bag, the area affected will be wiped liberally with 2% Virkon or 5% Trigene Advance. The disinfectant to remain in contact with the treated area for at least 30 minutes to allow the disinfectant to act; the area will then be mopped up with paper towels and washed with plenty of water. Immediately after it has been collected and the affected area has been treated with Virkon, the solid waste will be taken for autoclaving, as above.

For spills inside centrifuges or incubators the local Standard Operating Procedure is indicated on the equipment will be followed.

All spills of genetically modified microorganisms (GMMOs) will be reported immediately to a safety supervisor: all spills and the mode of decontamination and disposal will be recorded in the GMO incident book.

Any personal injury where an infection by a GMMO may be involved will be reported immediately to a safety supervisor and the advice of Occupational Health will be sought. Such incidents will be recorded in the accident book.

The identity of any vectors and viruses received will be confirmed by restriction enzyme digest to authenticate the suitability of clones received from external sources for work under the current licence application.

Please enter comments on the GM safety committee on the risk assessment

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N
I have passed the application around members of the LIMM GMAG Safety Committee asking for any comments. A few responses were received. The only negative comment related to the generic feel of the application re the inserts to be employed.

1. Section 12 - There was concern over the phrase 'cDNAs encoding wild-type or mutant known and candidate oncogenes, tumour suppressor genes and other genes involved in cell signalling and development'. It was felt that this phrase was very generic and could encompass half the genes in the genome. For previous applications, details of specific genes and the consequences of over-expressing or knocking them out were asked for. Are we now going back down the generic route? Will the HSE accept this? Would it be wise to include one or two examples as worse case scenarios to compare the rest with e.g. The over-expression of mutant RAS may be more hazardous than the over-expression of polo kinase’

2. Section 11 - For lentiviral production: are third generation packaging systems always going to be used? Are the ones in the attachment the chosen systems? Additional systems could be included at a later date if required.

3. Perhaps a brief comment re the process of accepting viruses from collaborators may be in order with respect to evaluation of the hazards of the system.

Comments?

Section of Opthalmology and Neuroscience

Leeds LS9 7TF
West Yorkshire
UK

In response to comments
1. Generic nature of the application - I have added some examples of potential effect of some specific inserts. Most importantly though the constructs are not anticipated to change the host range for the viruses. (Section 12)

2. These are examples as stated in text (Section 11).

3. I have added a comment about handling viruses from collaborators. (Section 12)

Are you both happy that we submit this now?
Do you have any additional comments?

I had not noticed before that HVS (I assume this is herpesvirus saimiri) appears inappropriately under the heading of Lentivirus. This monkey gamma herpes virus does not appear to be described in the vectors to be used. Is this the AW's vector that has had the transforming oncogene bits removed (perhaps including one of A's appropriate references). On its own, I assume this is classified as a Class 1 vector anyway as its host is monkey? I seem to remember that it infects some (primary) human cells but does not replicate?

I also cannot see where a comment is made re analysis of the safety of vectors being imported from collaborators. Can you add a sentence after the comment about logging in clones something along the lines that 'The potential hazards of clones from external sources will be evaluated to check for their suitability under the licence being applied for' This is one of the points I wanted to be addressed and commented upon in the application as it was raised by the Safety Committee. The other point was the request for examples of the potentially most damaging inserts (worse case scenario) that was addressed.

UK

Tel 0113 3438419
Fax 0113 3438603

Thank you for these helpful comments.
Yes the HVS non-human viral vectors are especially disabled by deletion of Stp and Tip to remove the oncogenic potential of the virus. We have previously used Herpesvirus saimiri (from A) in the lab- that was Class 1 (low risk). We are likely to use this again and potentially other similar class 1 vectors that A is developing that have modifications to the promoters to prevent methylation. However as this is class 1 I have removed this from the text. Have inserted additional text on receipt from collaborators as you requested.

Please can you insert the information for section 2, 6 and 16, and any information that might be needed in Section 15 from the genetic modification safety committee.

Please can we submit this to HSE now?

02/03/2022
V(D)J recombination generates diversity of immunoglobulin and T cell receptor genes, a reaction that is catalysed by the recombination activation gene (RAG) proteins, RAG1 and 2. During this reaction, the DNA that lies between the recombinating V, D and J gene segments is excised out of the genome. Previously, this excised DNA was thought to be lost during cell division but recent evidence indicates that RAG1 and RAG2 can catalyse an aberrant V(D)J recombination reaction in which these by-products are reinserted back into the genome. This re-integration reaction is thought to be a very frequent reaction during lymphocyte development and has been proposed to have pathogenic effects by triggering genome instability. The non-core regions of RAG proteins have been shown to inhibit the re-integration reaction in vivo. The aim of the activity described here is to purify full-length wtRAG1 and wtRAG2, and mutant form(s) of these RAG proteins. These will be used in subsequent in vitro experiments to further analyse the biochemistry of the reintegration reaction to thus better characterise how the re-integration reactions are inhibited. The longer term goal of this work is to develop specific small molecule inhibitors of these potentially pathogenic reactions.

It is not possible to purify active forms of full-length RAG1 and RAG2 when expressed in E. coli or insect cells, so early biochemical studies of these proteins made use of truncated versions, where residues non-essential for the basic V(D)J recombination reaction are removed to give "core" RAGs. However, the "non-core" regions are now known to be essential for the correct regulation of recombination as well as re-integration reactions. Previous studies (e.g. Elkin et al., 2003, EMBO J 22, p1931 and McBlane et al., 1995, Cell 83, p387) indicate that expression by vaccinia virus in HeLa cells is the only method of expressing and purifying catalytically-active full-length
RAG1 and RAG2 proteins. These full-length proteins are thus essential to characterise the mechanism by which the inhibitory non-core regions regulate re-integration.

Protein expression using the vaccinia virus/T7 RNA polymerase hybrid system

The most efficient procedures for expression of genes in mammalian cells utilize a recombinant vaccinia virus encoding the bacteriophage T7 RNA polymerase (Fuerst et al 1986 PNAS 83, 8122). Two main variations of this system exist. In the first, cells are infected with a recombinant vaccinia virus expressing the T7 RNA polymerase (vTF7-3), and then transiently transfected with a plasmid construct containing the gene of interest situated 3’ to a T7 promoter. However, according to the developers of the system, the level of expression achieved using this method is not high enough to make a large stock of purified protein, that we require for our subsequent biochemical analyses (Moss and Elroy-Stein, 1998, Curr Prot Prot Sci, Unit 5.15; Elroy-Stein et al 1989, PNAS p87). To achieve the level of expression required for mass protein production, the preferred method is to make a second recombinant virus containing the gene of interest situated 3’ to the T7 promoter (Fuerst et al 1987, Mol Cell Biol 7, p2583; Moss et al 1990, Nature 348, P91; Barrett et al 1989, AIDS res. Human Retroviruses 5, 159-171). This is because the efficiency of viral infection is much greater than the efficiency of transfection by the calcium phosphate of liposome methods. In a typical experiment, 99% of infected cells are observed to express the desired protein, compared with as little as 60% in transfected cells (Moss and Elroy-Stein, 1998, Curr Prot Prot Sci, Unit 5.15).

Recipient or parental organism

HeLa S3 cells will be used to produce wild-type vaccinia stocks and also in the expression and purification of RAG1 and RAG2. These cells are non-pathogenic to humans or animals, non-toxic and non-allergic. BSC-1 cells will be used for the production and screening of recombinant vaccinia virus. HeLa S3 and BSC-1 cells are of human and primate origin respectively, and both are well characterised, authenticated continuous cell lines that have essentially zero risk of endogenous infection and as such are both categorised as ACDP Hazard level 1.

Host/vector system

The hybrid vaccinia/T7 RNA polymerase expression has been described above. Full-length RAG genes will be subcloned into the plasmid transfer vector pTM11, which is non-mobilisable and poses no hazard in itself (Moss et al 1990, Nature 348, p91). pTM1 is then inserted into the genome of WR vaccinia virus via homologous recombination in BSC-1 cells. This recombinant virus is then used as the vector for transfer of RAG genes in HeLa S3 cells. Transfer of genetic material is achieved by infection of mammalian cell culture. The Western Reserve strain of vaccinia virus in not attenuated, and is replication competent in human cells. However, the risk posed by vaccinia infection is low, and level 2 containment procedures are sufficient to minimise the risk posed to workers (see “Evaluation of foreseeable effects” below).

Origin & function

The full length RAG1 and Rag2 cDNAs will be subcloned from plasmid vectors available in the lab.

The DNA sequence will not be isolated from a donor organism, therefore there are no associated hazards.

Two recombinant vaccinia viruses will be made, one containing the mammalian RAG1 gene, and the other containing the mammalian RAG2 gene, as well as mutant derivatives of these proteins. Both wild type and mutant proteins will be cloned 3’ to a T7 promoter and these vectors will be used to individually infect HeLa cells to produce high levels of RAG proteins. Rag1 and RAG2 must work as a complex to trigger recombination or re-integration and thus these proteins pose no hazard when expressed on their own. Likewise, the mutant derivatives also pose no hazard when expressed as individual proteins. Thus, the risk to personnel should they become infected, is negligible and if infection with both viruses should occur, the risk is still very small, such that it is close to negligible (see “evaluation of foreseeable effects”)

Evaluation of foreseeable effects

Production of recombinant vaccinia virus involved the use of the Western reserve (WR) strain of vaccinia virus. To healthy individuals this virus poses no possible threat of serious disease, with typical symptoms being the development of a small pustule on the skin at the site of infection. Mild systemic disease may accompany the skin lesion, such as mild fever and general malaise. The low risk posed by vaccinia virus infection is demonstrated by the fact that this virus has been used in vaccination protocols against smallpox virus since the late 18th century. Furthermore, all individuals who grew up in the UK and are now over the age of 40 are likely immune due to previous
Immunization with vaccinia virus to protect against smallpox. However, vaccinia virus has been known to cause skin irritation and lesions in individuals with severe eczema and psoriasis, or individuals who are severely immune deficient or pregnant. For this reason, class 2 containment practices will be employed at all times, including the use of class 2 microbiology safety cabinets within a laboratory designed specifically for class 2 activities. A fraction (10-15%) of vaccinia virus can survive for up to 24 hours in the environment. However, handling of, or work with, virus will be performed in a Class II safety cabinet where the surfaces will be wiped with 2% Virkon after virus use, thereby minimising the risk of virus escape. Nucleic acid from the recombinant vaccinia virus will be extracted and stored at -20°C. This DNA will be analysed to confirm the production and isolation of recombinant virus, and will then be disposed of. The DNA in isolation in non-mobilisable and poses no risk. The RAG1 and RAG2 proteins are non-toxic to humans. Furthermore, expression of the RAG proteins in human cells would also require concomitant infection with vTF7-3, as the RAG gene is under the control of a T7 promoter. As explained above, the RAG1 and 2 proteins are responsible for cutting DNA during V(D)J recombination. Since they are both required for cutting, infection with all three recombinant viruses would be necessary to pose a risk of DNA cutting. The RAG1 and RAG2 infections will be carried out separately, so the risk of infection with all three viruses is reduced to close to zero. In the event of a triple infection, the antigen receptor loci where cutting occurs are not accessible to the RAGs in any cells except B and T cells, giving a very small chance of any potentially harmful DNA cutting. Moreover, in the absence of recombination, the potentially pathogenic re-integration reaction does not occur. Therefore, the modified vaccinia viruses would be no more harmful than the unmodified recipient.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

| N/A |

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

| Liquid waste will be treated with an equal volume of 2% Virkon and left overnight to give 100% inactivation of vaccinia viruses before disposal down the drain with copious water. Solid waste (culture or cells) will be autoclaved at a minimum of 121°C (load temperature) for 15 minutes to give 100% kill before being destroyed as clinical waste. Emergency spill procedure: Liquid spill - Wearing appropriate gloves treat with Virkon granules until deep pink, or add an equivalent volume of 2% Virkon - leave for at least half an hour before mopping up with plenty of water. Solid spill - Wearing appropriate gloves, solid spills will be gathered into an autoclave bag, the area affected will be wiped liberally with 2% Virkon. The treated area will be left for half an hour for the disinfectant to have time to act and the area will then be mopped with plenty of water. Immediately after is has been collected and the affected area has been treated with Virkon, the solid waste will be taken for autoclaving, as above. For spills inside centrifuges or incubators the Standard Operating Procedure as indicated on the equipment will be followed. All spills of pathogens or genetically modified microorganisms (GMMOs) will be reported immediately to a safety supervisor: all spills and their mode of treatment will be recorded. Any personal injury where an infection by a pathogen or GMMO may be involved will be reported immediately to a safety supervisor and the immediate advice of Occupational Health will be sought. |

02/03/2022
Dear S,

Thank you for forwarding the risk assessment for work with vaccinia by Dr B. I confirm that the Biological Safety Committee is happy for this to be submitted to the HSE.

The aim of the project is to understand the role of a variety of genes including oncogenes, tumour suppressor genes and genes encoding components of cellular signalling pathways in renal disease (renal cancer, renal injury and renal failure).

This involves the construction and use of viral vectors to allow targeted over-expression or knock-down of genes of interest in human and mammalian cell lines. Viral vectors will contain expression cassettes that harbour:
- Reporter genes or
- cDNA or
- Interfering RNA

These vectors carry drug resistance markers to allow selection in E. coli and human/mammalian cells.

**Recipient or parental organism**

E. coli K12 strains such as:
- XL-1Blue (recA1 endA1 gyrA96 thi-1 hsdR17 supE44 relA1 lac [F’ proAB lacQZΔM15 Tn10 (Tetr)])
- DH5α (F− Φ80lacZΔM15 Δ(lacZYA-argF) U169 recA1 endA1 hsdR17 (rK−, mK+) phoA supE44 λ− thi-1 gyrA96 relA1)

will be used for propagation of plasmid DNA.

E. coli K12 strains are attenuated, non-colonising, non-pathogenic strains, unlikely to survive outside the laboratory and have a long history of safe use, and are regarded as non-hazardous.

**Cell lines**

Retrovirus packaging cell lines such as Phoenix Ampho (Orbigen; www.stanford.edu/group/nolan) which are derived from the human embryonic kidney cell line HEK293T by introduction of separate gag-pol and env constructs [two plasmids with different selectable markers] designed to minimise potential for recombination will be used for virus production.

Lentivirus packaging systems such as the HEK293T-based Lenti-X™ HTX (Clontech; www.clontech.com) or Open Biosystems Trans-Lentiviral™ GIPZ (Thermo Scientific; www.openbiosystems.com) systems in which the functions required for virion production are separated and carried on multiple co-transfected plasmids will be used for virus production.

Primary and established human cell lines and mammalian cell lines.
The cell lines used are not capable of survival outside the laboratory and are non-transplantable due to immuno-incompatibility. They are therefore considered to be highly disabled hosts. Established cell lines with a history of safe use may be considered hazard group 1, however primary cell lines may contain endogenous pathogens and are treated as hazard Group 2.

## Host/vector system

Viral vectors to be used are from collaborators and commercial sources:

a. **Retrovirus** – vectors such as pFB-Neo (Stratagene), pPRETROSUPER (Netherlands Cancer Institute), pBABE-puro (addgene) and pMSCVhyg (Clontech)

Gamma-retroviruses (such as MMLV) only infect actively dividing cells and integrate into the host cell genome. Integration is random but preferentially into transcriptionally active chromatin and thus carries a risk of insertional mutagenesis. The retroviruses used for vector construction are based on murine retroviruses Moloney Murine Leukemia virus (MMLV) and Murine Embryonic Stem Cell virus (MSCV) in ACDP hazard Group 1; however amphotropic virus is produced which can infect human cells, potentially increasing the hazard. The retroviral vectors to be used are replication-defective, requiring transfection into special packaging cell lines for production of infectious virus and have a long history of safe use. Once integrated, virus genomes lack the sequences necessary for production of infectious virions; stable retrovirus producer cells cannot be made. Packaging cell lines (such as Phoenix Ampo; www.stanford.edu/group/nolan) have been developed which carry two plasmids encoding the viral gag-pol and env genes separately to minimise the possibility of multiple recombination events regenerating wild type replication competent virus.

b. **Lentivirus** – vectors such as pLOC/pGIPZ (Thermo Scientific), pLenti6 series (Invitrogen), pLVX-Puro (Clontech)

Lentiviruses are a sub-group of retroviruses that can infect both dividing and quiescent cells. The lentivirus vectors to be used are based on HIV-1 which is listed in ACDP Hazard group 3. However these 3rd and 4th generation self-inactivating vectors are multiply-deleted and lack the ability to replicate or re-create an intact virus genome once integrated into the host cell genome and thus pose a much reduced risk. The vectors typically contain less than 30% of the wild type HIV-1 genome. Safety is increased by the use of commercial packaging systems such as the Lenti-X HTX (Clontech; www.clontech.com/products) or Open Biosystems Trans-Lentiviral GIPZ (Thermo Scientific; www.openbiosystems.com) packaging systems in which the functions required for virion production are separated and carried on multiple co-transfected plasmids. These contain minimal virus sequence in order to minimise the potential for recombination. Stable producer cell lines cannot be made with the modified vectors to be used. Virions produced from lentivirus vectors are usually pseudotyped with VSV-G structural proteins to allow entry into multiple cell types (VSV-G allows entry in to a very broad host range, i.e. most mammalian cells).

Recent work has shown that amphotropic lentiviruses rapidly lose infectivity at 37oC. Commercially available 3rd generation lentiviruses with ORF or siRNA inserts may also be used.

References:

All contain drug resistance markers to allow selection in E. coli and human / mammalian cells. Resistance to these antibiotics is not clinically relevant due to widespread resistance or antibiotic toxicity.

## Origin & function

The following will be delivered to target mammalian (including human) cell lines predominantly by viral vectors:

1. Reportor genes including GFP and derivatives, luciferase and β- galactosidase.
2. cDNAs encoding wild-type or mutant known and candidate oncogenes, tumour suppressor genes and other genes involved in cell signalling, apoptosis and/or development of renal diseases including cancer. Expression is under the control of cloned human promoter sequences, constitutive viral promoters (such as CMV or SV40 early promoters, MoMLV 5’ LTR) or inducible promoters (such as TET ON/OFF system, inducible lacZ promoter). cDNAs may also be expressed as fusions with GFP and derivatives to allow fluorescent detection or with epitope tags such as haemagglutinin (HA) or FLAG or with poly-histidine tags to facilitate protein detection and purification.
3. shRNA or siRNA (interfering RNA) molecules under the control of human or viral promoters targeted to genes thought to be involved in renal disease.

In terms of hazard, loss of tumour suppressor or gain of oncogene function may contribute to the development of a malignant cell phenotype and loss of normal growth and survival controls. Certain inserts may immortalise cells. It is highly unlikely that inserts will alter the host range of the virus or result in a GMO capable of replicating outside the laboratory.

High levels of interfering RNAs can trigger the antiviral response, resulting in altered cellular metabolism and local inflammation following accidental exposure to interfering RNA-expressing GMOs. Expression of interfering RNAs has the potential for off-target effects on other genes. This will be minimised by careful selection of target sequences using sequence databases.

In E. coli, Inserts will be under the control of eukaryotic promoter sequences and would not be expressed in bacteria and thus are of no or low hazard.

DNA
Human/mammalian DNA isolated from tissues, primary or established cell lines; cloned cDNA or shRNA/siRNA from collaborators or commercial sources.
Plasmid DNA and DNA isolated from established cell lines and mammalian primary cell lines and tissues is low hazard.

There is a risk of infection in preparation of DNA from human tissue samples and primary cell lines, however samples are not collected from patients known to be high risk or positive for HIV or HBV on basis of medical history to minimise this hazard.

All personnel handling human tissue must show hepatitis B virus (HBV) immunity.

**Evaluation of foreseeable effects**

Modified retrovirus – is less harmful than the parent organism. The replication defective system consists of a packaging cell line and a vector; the vector is not capable of replicating once it has entered a cell thus virus is only capable of one round of infection. Infection with retroviruses can lead to insertional mutagenesis adjacent to the site of insertion. This has the potential to transcriptionally activate cellular oncogenes. However, this is partly titre-dependent and unlikely to occur with the amount of virus handled within this assessment (<50ml supernatant at any one time). The inserted genes/interference RNAs include those that code for/target known or potential oncogenes or tumour suppressor genes and could potentially lead to cellular transformation if expressed in an operator's cells although several further genetic changes would be required for progression to malignancy.

Lentivirus – less harmful than the parent organism. The vector is HIV-1-based but multiply-deleted and unable to replicate or cause disease. It would in theory be possible for lentivirus to recombine with wild type HIV in a person infected with HIV, however this would require that infectious virus reaches and infects CD4 cells where HIV exists, followed by multiple recombination events. The lentivirus-recipient cells (human and rodent cell lines derived from epithelium or stroma) are non-permissive for wild type HIV maintenance and replication. The main risk, as for retroviruses, is from insertional mutagenesis and expression of inserts in the host cell leading to cellular transformation.

Hazard identification in respect of the environment:
E. coli strains and human primary and established cell lines are disabled and cannot survive outside the laboratory.

Retro- and lentiviruses are enveloped and could not survive in the environment and no modifications of the viruses will be made that would be likely to alter this property. All virus vectors contain multiple deletions and can only be propagated in specialised laboratory cell lines.

Infected cells would be destroyed by immune system.

Work is small-scale thus there is no chance of major release of any GMO, and the work is non-hazardous to the environment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A
All work to be carried out in accordance with LIMM safety manual rules for work with Biological Agents and GMOs.

All work with cell lines, virus production and handling of virus to be performed in designated Class 2 biological safety cabinets using designated, labelled equipment to minimise aerosols and risk of accidental infection. Centrifugation to be carried out in closed buckets opened only inside Class 2 safety cabinet.

Minimise risk of ingestion by good laboratory practice, hygiene procedures, hand washing, wearing of gloves and laboratory coat (see LIMM safety manual).

No use of sharps with virus or virus-infected cell cultures or naked DNA (gel excision tips to cut DNA bands from gels).

Immuno-compromised individuals or those with skin conditions such as eczema will be advised to consult occupational health before working with live virus.

All waste to be disposed of according to LIMM safety manual procedures.

Liquid waste will be treated with Virkon granules or an equal volume of 20% Trigene Advance or 10% Virusolve+ and left for at least 30 minutes before disposal down the drain with copious amounts of water.

Solid waste (culture or cells) will be autoclaved at a minimum of 121°C (load temperature) for 15 minutes before being disposed as clinical waste.

Emergency spill procedure:
Liquid spill – Wearing gloves treat with Virkon granules until deep pink, or add an equivalent volume of 20% Trigene Advance or 10% Virusolve+ ; leave for at least 30 minutes before mopping up with paper towels and wash area with plenty of water.

Solid spill – Wearing appropriate gloves, solid spills will be gathered into an autoclave bag, the area affected will be wiped liberally with 2% Virkon or 5% Trigene Advance. The disinfectant to remain in contact with the treated area for at least 30 minutes to allow the disinfectant to act; the area will then be mopped up paper towels and washed with plenty of water. Immediately after it has been collected and the affected area has been treated with Virkon, the solid waste will be taken for autoclaving, as above.

For spills inside centrifuges or incubators the local Standard Operating Procedure as indicated on the equipment will be followed.

All spills of genetically modified microorganisms (GMMOs) will be reported immediately to a safety supervisor: all spills and the mode of decontamination and disposal will be recorded in the GMO incident book.

Any personal injury where an infection by a G MMO may be involved will be reported immediately to a safety supervisor and the advice of Occupational Health will be sought. Such incidents will be recorded in the accident book.

The identify of any vectors and viruses received will be confirmed by restriction enzyme digest to authenticate the suitability of clones received from external sources for work under the current licence application.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

02/03/2022
The committee were happy that the hazards of the project have been correctly identified, and that appropriate safe systems of work will be used to control those risks identified. The project was approved by the committee without further comment.

### Project Additional Information

**Purposes of the contained use**

In order to understand tumour, endothelial and stem cell processes that contribute to cancer it is necessary to perform functional analyses by overexpression and knockdown of genes of interest identified in genetic screens. The groups aim to use viral gene delivery systems to achieve high efficiency of transduction and stable expression in cell types of interest. The following inserts will be used:
1) Reporter genes.
2) shRNAs and micro-RNA derivatives to knockdown of genes involved in cell signalling, angiogenesis, immunity, cancer or normal development.
3) cDNAs encoded by wild-type or mutant genes involved in cell signalling, angiogenesis, immunity, cancer or normal development.
4) Antibody fragments, function-blocking peptides and peptide aptamer sequences to inhibit the function of proteins involved in cell signalling, angiogenesis, immune responses, cancer or normal development.

Recipient or parental organism

Prokaryotic host:
Well established laboratory E. coli K-12 derivatives strain will be used for propagation of plasmid DNA. These are recognised as non-colonising and disabled, have an extensive history of safe use and the genetic mutations are well understood. They have been categorised as belonging to ACDP Hazard Group 1 and are not considered harmful to humans.

Eukaryotic host:
Host cells will be tumour cell lines, mouse and human primary cells. Human cell lines, primary cells and packaging cell lines (see Section 11) cannot survive away from laboratory culture conditions, they are allogeneic and therefore non transplantable. For these reasons they are categorized as belonging to ACDP Hazard Group 1. Unscreened primary human cells would be handled in tissue culture hoods at ACDP Hazard Group 2.

Lentivirus packaging systems such as the HEK293T-based Lenti-X™ HTX (Clontech; www.clontech.com) or Open Biosystems Trans-Lentiviral™ GIPZ (Thermo Scientific; www.openbiosystems.com) systems in which the functions required for virion production are separated and carried on multiple co-transfected plasmids will be used for virus production.

Primary and established human cell lines and mammalian cell lines.

The cells lines used are not capable of survival outside the laboratory and are non-transplantable due to immuno-incompatibility. They are therefore considered to be highly disabled hosts. Established cell lines with a history of safe use may be considered hazard group 1, however primary cell lines may contain endogenous pathogens and are treated as hazard Group 2.

Host/vector system

Replication-defective retroviral vector system:
The Phoenix ecotropic and amphotropic retroviral transduction systems (packaging producer line is derived from 293T human embryonic kidney cell-line), or equivalent, 3 plasmid packaging system will used. The transducing particles produced are simple enveloped RNA virus vectors that consist of gag (coding for the core proteins), pol (coding for the viral RNA reverse transcriptase) and env (coding for the viral envelope). Long terminal repeats (LTRs) harbour sequences that aid viral genome integration and transcription of the inserted genes. The ecotropic particles cannot transduce human cells and are therefore categorized as ACDP Hazard group 1. The amphotropic particles can transduce human cells and therefore are categorized and Hazard group 2. In the 3 plasmid packaging system one construct harbour gags and pol and a separate construct harbour env. A third construct is then transfected into the producer cells that contains: (a) the gene of interest plus the retroviral packaging signal to allow production of particles capable of transducing human target cells; and (b) sequences within the Long Terminal Repeats (LTRs) that aid viral genome integration and transcription of the inserted genes. Only sequences within the LTRs are integrated in the genome of target cells. In this packaging system, the functions required for production of transducing units are separated in three different plasmids making the potential for recombination and virus production in the target cells virtually impossible.

The retroviral vectors to be used with this system are pBABE and pBabe derivatives or equivalent MLV-derived retroviral vectors. The plasmids are non-mobilisable but are designed to be integrated into the host genome. Vectors carry drug resistance markers or reporter genes that are non hazardous to humans.

Replication-defective lentiviral vector system:
Where mitosis-independent transduction is required lentiviral systems will be used. These systems are based on HIV-1. However, viral genes such as vpr, vif, vpu and nef are deleted and the HIV envelope gene is replaced with Vesicular stomatitis virus G protein (VSV-G) to increase the host range of the virus. Replication defective transducing units are produced by co-transfection of a transgene vector harbouring the gene of interest together with at least two separate non-overlapping packaging constructs containing gag, pol and env making the potential for recombination virtually impossible. Biosafety is further increased by the use of self-inactivating vectors. The particles can transduce human cells therefore they are categorized and Hazard group 2 and will be handled under Containment level 2 conditions.

The plasmids to be used with the lentiviral system pLKO.1 (addgene), pGIPZ, pLEX (Open Biosystems)5 or equivalent self-inactivating (SIN) lentiviral vectors due to deletion of part of the HIV-1 3' LTR – upon integration the provirus lacks a promoter so full-length vector sequence can no longer be transcribed. Vectors carry drug resistance markers or reporter genes that are non hazardous to humans.

Ori9n & function

Retroviral and / or lentiviral vectors will harbour the following sequences:

1) Inserts encoding reporter genes such as EGFP and derivatives, dsRed and derivatives, Firefly luciferase (Fluc), β-galactosidase under the control of mammalian or viral promoters (eg CMV or MLV 5' LTR) to enable tracking of cells.
2) Inserts encoding wild-type or mutant genes involved in normal development, cell signalling, angiogenesis or cancer. cDNAs may be expressed as fusions with a fluorescent molecules EGFP or dsRed; in non tagged or tagged form (N- or C-terminal MYC, HA, FLAG, or HIS-tag); cDNA libraries may be used. Expression will be constitutive via mammalian or viral promoters (e.g. CMV or MLV LTR) or inducible (e.g. TET ON or TET OFF systems).
3) Small hairpin RNA molecules (shRNAs) or derivatives of microRNAs to knockdown genes involved in normal development, cell signalling, angiogenesis or cancer under the control of U6 or H1 promoters. shRNA and miRNA libraries may be used.
4) Inserts encoding function-blocking peptides, antibody fragments or aptamers to inhibit the function of proteins involved in normal development, cell signalling, angiogenesis or cancer.

Small hairpin RNAs (shRNAs) and micro-RNA derivatives, function blocking antibody sequences, and aptamer sequences will be synthesized commercially or obtained from collaborators. Mammalian expression vectors harbouring cDNAs and reporter genes will be obtained from commercial sources and collaborators. Retroviral and lentiviral vectors will be obtained from commercial sources and collaborators (lentiviral vectors will be SIN vectors. Plasmids will be propagated in E. coli K-12 derivatives

Evaluation of foreseeable effects

Occasionally a sequence may integrate in an adjacent position to oncogenes, leading to an increase in their transcription driven by enhancer/promoter elements found in the LTR. Alternatively, integration may cause disruption of a TSG leading to a loss of their activity. Loss of tumour suppressor or gain of oncogene function as result of random integration or over-expression or knockdown of potential oncogenes or tumour suppressor genes may contribute to the development of a malignant cell phenotype. However, target cells will allogeneic and therefore not immunologically viable.

The infection of a worker with replication-defective transducing particles resulting in expression of an oncogene or tumour suppressor gene is possible but highly unlikely. Since viral particles cannot replicate, only a finite number of cells could be infected. This is undesirable since theoretically it increases the risk of cancer albeit to a very small degree. The workers’ immune system in healthy workers provides protection against this risk.

Hazard identification in respect of the environment:

E. coli strains and human primary and established cell lines are disabled and cannot survive outside the laboratory.

Retro- and lentiviruses are enveloped and could not survive in the environment and no modifications of the viruses will be made that would be likely to alter this property. All virus vectors contain multiple deletions and can only be propagated in specialised laboratory cell lines.

Infected cells would be destroyed by immune system.

Work is small-scale thus there is no chance of major release of any GMO. and the work is non-hazardous to the environment.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All work to be carried out in accordance with LIMM safety manual rules for work with Biological Agents and GMOs.

All work with cell lines, virus production and handling of virus to be performed in designated Class 2 biological safety cabinets using designated, labelled equipment to minimise aerosols and risk of accidental infection.

Minimise risk of ingestion by good laboratory practice, hygiene procedures, hand washing, wearing of gloves and laboratory coat (see LIMM safety manual).

Immu-no-compromised individuals or those with skin conditions such as eczema will be advised to consult occupational health before working with live virus.

All waste to be disposed of according to LIMM safety manual procedures.

Liquid waste will be treated with Virkon granules or an equal volume of 2% Virkon solution, 20% Trigene Advance or 10% Virusolve+ and left for at least 30 minutes before disposal down the drain with copious amounts of water.

Solid waste (culture or cells) will be autoclaved at a minimum of 121°C (load temperature) for 15 minutes before being destroyed as clinical waste.

Emergency spill procedure:
Liquid spill – Wearing gloves treat with Virkon granules until deep pink, or add an equivalent volume of 20% Trigene Advance or 10% Virusolve+; leave for at least 30 minutes before mopping up with paper towels and wash area with plenty of water.

Solid spill – Wearing appropriate gloves, solid spills will be gathered into an autoclave bag, the area affected will be wiped liberally with 2% Virkon or 5% Trigene Advance. The disinfectant to remain in contact with the treated area for at least 30 minutes to allow the disinfectant to act; the area will then be mopped up paper towels and washed with plenty of water. Immediately after it has been collected and the affected area has been treated with Virkon, the solid waste will be taken for autoclaving, as above.

For spills inside centrifuges or incubators the local Standard Operating Procedure as indicated on the equipment will be followed.

All spills of genetically modified microorganisms (GMMOs) will be reported immediately to a safety supervisor: all spills and the mode of decontamination and disposal will be recorded in the GMO incident book.

Any personal injury where an infection by a GMMO may be involved will be reported immediately to a safety supervisor and the advice of Occupational Health will be sought. Such incidents will be recorded in the accident book.

### Project Ref 559/13.1

**Date Ackn'd:** 06/03/2013

**CU2 Project Title:** Functional analysis of proteins of Human Respiratory Syncytial Virus (HRSV) using a variety of methods including gene deletion viruses, and viruses containing reporter genes (e.g. GFP) to infect both primary and continuous cells in culture

**Class:** Class 2

**Culture Volume:** < 1 Litre

**Non-GMM Consent Granted:** Consent Granted

**Project notified under transitional arrangements:** N

**Withdrawn:** N

**Tick if notifying a connected programme of work:** N

### Project Additional Information

**Purposes of the contained use:**

The aim of the project is to functionally analyse the proteins of the human respiratory syncytial virus (HRSV), the genome of which contains 10 genes encoding 11 proteins.

We will examine how protein expression during virus infection affects key cellular activities, as well as taking a proteomics approach to study the changes in total cell
proteins in response to infection with both wild-type and specific gene deletion viruses. The strategy of using a genetically modified HRSV will allow us to examine the effects of protein expression in a system that is highly relevant in terms of virus biology, as all other virus-encoded gene products will be expressed at appropriate times, locations and abundances within infected cells.

Alternative methods that do not involve the use of genetically modified HRSV do exist, however, these methods are flawed, as they often result in overexpression of viral proteins within inappropriate cellular locations, which are likely to lead to the generation of cellular artefacts.

The initial focus of the project will be to investigate the function of the small hydrophobic (SH) protein, which forms part of the viral coat. Previous work has shown that HRSV lacking the SH gene is attenuated in both cell culture and in small animal models, indicating the SH protein contributes to virus growth and overall pathogenicity. The underlying mechanism behind the altered phenotype is not understood, although there is increasing evidence to suggest that SH acts as a membrane channel, resulting in alteration of the ion balance within HRSV infected cells. The proposed membrane channel activities of SH suggest that it may be involved in multiple cellular processes including innate immune signalling, apoptosis, and cell cycle regulation.

Recipient or parental organism

The recipients of the genetically modified HRSV will be mammalian cells. These will be either from continuous cell lines such as A549 or BHK-21, or alternatively primary cells derived from human lung or tracheal tissue. These cells do not belong to a hazard group. These cells require specialized culture conditions and growth supplements, and these conditions are not present outside of the laboratory. Therefore, accidental release of the recipient will pose no threat to the environment. HRSV infected cells do release infectious virus particles, although the majority of released virus remains cell-associated. Any released virus that is not cell-associated will be contained within the nutrient media that covers the cells, and thus is highly unlikely to be released as an aerosol. HRSV infected cells will be grown and maintained in dedicated incubators within the CL-2 laboratory space. Cross infection of cells contained within a incubator is possible, although unlikely due to the presence of liquid media covering all cells, and the use of vented cell culture flasks.

Host/vector system

The wild type vector is human respiratory syncytial virus (HRSV), laboratory strain A2. HRSV is a ubiquitous human pathogen that is responsible for a generally mild respiratory infection. Most humans are infected at least once with HRSV by the age of 2 years. The consequences of HRSV infection are a generally mild and localized upper respiratory tract infection, with associated headache and rhinitis, and infected individuals generally recover within 1-2 weeks. Infection by HRSV is protective to subsequent exposure, although repeat infections are possible due to variation in circulating strains in different geographic locations and in different years. In the context of the proposed work, all individuals handling the virus will have encountered HRSV multiple times, and no contact with infants is anticipated. The accidental release of wild-type HRSV will have negligible impact due to the massive scale of natural transmissions. Despite this, laboratory acquired infection of HRSV is undesirable, and provided all the CL-2 procedures are adhered to, will be extremely unlikely.

HRSV is classified as a hazard level 2 pathogen.

Genetic modification of the HRSV genome will be achieved by PCR-mediated mutagenesis of a cDNA encoding the entire HRSV genome sequence. The resultant cDNA can then be transfected into mammalian cell culture systems along with supporting cDNAs expressing specific HRSV structural proteins, resulting in the generation of infectious virus. This strategy can be used to engineer nucleotide insertions, deletions or modifications into the HRSV genome.

The three modified viruses initially required for this research project have previously been generated from altered cDNAs by collaborators Dr. Michael Teng and Dr. Peter Collins, who have kindly agreed to supply these altered viruses.

In the eventuality that other gene deletions within the HRSV genome are required for completion of this project, a cDNA encoding the entire HRSV genome will be modified using PCR-based mutagenesis. Infectious viruses will be generated from this cDNA as described above.
We will be using the HRSV genome which is responsible for encoding the virus, the genome is made up of 10 open reading frames (encoding 11 proteins). The work will involve creating deletion mutants as well as mutants containing reporter genes such as GFP.

The work will primarily focus on the SH protein, in order to do this we will initially use three genetically modified HRSV variants:

1) Delta-SH HRSV, in which the SH gene has been completely removed from the wild type HRSV genome.
2) A derivative of the Delta-SH virus, in which a gene expressing enhanced green fluorescent protein (eGFP) has been inserted in place of the SH gene.
3) A derivative of the wild-type HRSV, in which the eGFP gene has been inserted.

These viruses have previously been generated by others and have been shown to be attenuated in cell culture and small animal models (Bukreyev A., Whitehead S. S., Murphy B. R., Collins P. L. (1997) Recombinant respiratory syncytial virus from which the entire SH gene has been deleted grows efficiently in cell culture and exhibits site-specific attenuation in the respiratory tract of the mouse. J. Virol. 71:8973–8982).

**Evaluation of foreseeable effects**

For the initial work on the SH gene, deletion of the gene from the HRSV genome is known to result in attenuation of HRSV growth in cell culture systems, and reduced symptoms in small animal models (see above). A consequence of these reduced growth characteristics is that the titre of released altered virus is lower than wild-type. Smaller deletions within the SH gene will be predicted to reduce SH protein function, and so will also be predicted to result in reduced growth and disease compared to the unmodified virus. Taken together, these data strongly suggest the resulting SH-deleted and SH-modified viruses would be less harmful to humans than the wild-type.

The insertion of reporter gene coding sequence into the HRSV genome is predicted to attenuate virus growth due to reduced expression of viral gene products. Therefore the resulting GFP-expressing virus is predicted to be attenuated compared to the wild-type. In addition, the titre of released altered virus will be lower than wild-type due to its reduced growth characteristics, which further reduces potential harm.

Transfer of reporter gene transgenes to other genetic systems is extremely unlikely. HRSV possesses a negative sense RNA genome, and such viruses are widely regarded as being resistant to recombination with other nucleic acid sources within cells. Furthermore, as described above, no adverse consequences of reporter gene expression have been identified, and so even if transfer did occur, no risk is currently associated.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

No application is sought.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Treatment of HRSV containing liquid waste fluids will be performed under the Faculty of Biological Sciences SOP for CL-2 waste treatment, which are summarized as follows: HRSV-infected liquids from cell culture flasks and plates will be aspirated using both vacuum lines and manual pipettes. All liquid handling procedures involving infectious HRSV will be performed inside a laminar flow hood to prevent risk of aerosolized virus spread outside the work area. All aspirated liquids containing virus will be immediately treated with 2% virkon, and incubated overnight to allow complete virus killing.

Plastic ware exposed to HRSV, including pipette tips, plastic universal bottles, cell culture flasks and plates, will be treated with 2% virkon, and incubated overnight. Following this treatment, plastic ware will be autoclaved to ensure complete virus killing.

Infected cells and cell lysates required for further analysis are rendered non-infectious by denaturation by detergents of chaotropic agents prior to removal from laminar flow hoods within the CL-2 containment facility.
All surfaces potentially in contact with HRSV droplets and aerosols are decontaminated by contact with 2% virkon and, where possible, UV treatment for 30 minutes.

Project Additional Information

Purposes of the contained use

The purpose of the contained use is to allow the study of the polyomaviridae family of virus, in both wild type and genetically modified forms in a variety of research conditions including cell based as well as for study in model host organisms. Members of the polyomaviridae family are able to infect humans (although for the vast majority of the population the affects are sub-clinical) and have therefore been categorised as hazard group 2 agents. Containment level 2 laboratories and animal facilities will be used in order to control the risk of infection to workers and the wider community.

A) General description of polyomavirus

Polyomaviruses are ubiquitous, species-specific family of viruses that infect mammals and birds with varying clinical significance. The family was named from the founding virus, polyoma virus, meaning “many tumors,” which was discovered in mice, followed later by the prototypical primate polyomavirus, simian virus 40 (SV40), from the rhesus monkey.

In 2010, the polyomaviridae study group of the International Committee on Taxonomy of Viruses recommended revision of the polyomaviridae family by the division of the polyomavirus genus into three genera:

• Orthopolyomavirus, containing the “classic” mammalian polyomaviruses (e.g., JCPyV, BKPyV, SV40, mouse polyomavirus, etc.);
• Wukipolyomavirus, containing the novel human polyomaviruses including the Karolinska Institute polyomavirus (KIPyV) and the Washington University polyomavirus (WUPyV);
• Avipolyomavirus containing the avian polyomaviruses.

Individual species making up each genera are usually named after either the patient they were first isolated from (e.g. the human polyomaviruses BK and JC) or the host species in which they were first identified (e.g. mouse MPyV). High throughput DNA sequencing technology is continuing to identify new family members, resulting in a number of viruses classified as Polyomaviruses that are yet to be categorised into one of the three new genera. Appendix 3 (attached) shows the phylogenetic relationships between the members of the polyomaviridae family.

B) Distribution

Members of the polyomaviridae family have been isolated from a broad range of mammals (humans, primates, elephants, horses, bats, rodents etc) and birds. There are currently 12 identified human polyomaviruses, five viruses that are associated with disease in birds, and many others that infect mammals other than humans (Van Ghelue et al, 2012). Most species of polyomavirus have very narrow host ranges, infecting only a small number of closely related hosts. The exception to this is avian polyomavirus which has a much broader host range within birds.

C) Structure

Polyomaviruses virions are non-enveloped, approximately 45nm diameter icosahedral particles. There are 3 capsid proteins, VP1-3, which form 72 pentameric capsomers, 60 hexagonally co-ordinated and 12 pentamERICally co-ordinated (at the vertices). Each virion contains 360 copies of VP1 (i.e. 72 x 5) and 30-60 copies each of VP2 and
VP3, i.e. approximately 1 copy per pentamer. Each copy of VP1 has a sialic acid binding site on the surface and these form the receptor-binding site for the virus; hence the particles have haemagglutinating properties. VP2/3 have overlapping sequences with VP2 containing the entire sequence of VP3 at its C-terminus, and 115 amino acids at the N-terminus.

Polyomavirus genomes are double stranded, circular DNA molecules, ~5kb in size. The entire nucleotide sequence of all the viruses so far discovered in the family is known and the architecture of their genomes (i.e. number and arrangement of genes and regulatory signals and systems) has been studied in detail. Within the particles, the DNA assumes a supercoiled form (like plasmid DNA), and four cellular histones H2A, H2B, H3 and H4 are associated with it.

Polyomavirus genomic organisation is designed to pack maximal information (6 genes) into minimal space (5kbp), which is achieved by the use of both strands of the genome DNA and overlapping genes.

The genome is divided into three regions:

Early: encodes non-structural proteins (i.e. not present in virus particles), these are expressed early in virus infection, i.e. before genome replication and continues into the late stage of infection.

Late: encodes structural proteins which are expressed later in virus infection, i.e. during and after genome replication.

Regulatory region: contains transcriptional promoters and enhancers as well as the unique origin of DNA replication.

D) Replication

On encountering a host cell, a number of distinct steps are seen:

1. Attachment of the viral proteins to host receptors mediates endocytosis of the virus into the host cell.
2. Virion transits through endoplasmic reticulum where host protein disulfide isomerases rearrange its capsid structure.
3. Export of misfolded virion to the cytoplasm (possibly through host endoplasmic-reticulum-associated protein degradation pathway).
4. Loss of VP1 in the low-calcium conditions of the cytosol
5. Import of genomic DNA into host nucleus.
6. Transcription of early genes (large Tumour and small Tumour antigens, and middle T antigen for mouse virus)
7. Replication of the DNA genome in the nucleus.
8. Transcription of late genes encoding for structural proteins (VP1, VP2 and VP3).
10. Virions are released by lysis of the cell.

The polyomavirus non-structural proteins, Tumour antigens (T-antigens), expressed by the early coding region are of interest because of their role in modulating host cell function to facilitate efficient genome replication. The early region of viral cDNA is transcribed/translated by host cell apparatus to express a number of T-antigens variants through alternative splicing. The number of different polyomavirus T-antigens varies between species but their function is similar, that is to facilitate viral replication and ultimate lytic release. T-antigens exert influence over host cells through interactions with a variety of cellular proteins; in particular, the large T-antigen has been implicated as the master regulator in influencing host cell processes for the benefit of viral proliferation and is absolutely required for viral genome replication as well as regulation of viral gene expression. This protein is expressed by all Polyomaviridae family members identified to date with key DNA and protein binding domains clearly identifiable through sequence conservation across the family.

A consequence of the action of large T-antigen is the potential for cellular transformation because of the modulation of cellular function to drive the cell into S-Phase promoting viral DNA replication and inhibiting apoptosis thus ensuring efficient viral replication and assembly of progeny. As their name suggests, expression of these proteins has a long association with oncogenesis; however, expression does not guarantee transformation. The particular actions that lend themselves to transformation to an oncogenic state (e.g. attachment independent growth) include binding and inhibition of p53 which results in proliferation of DNA errors (the cell cycle would ordinarily be paused to facilitate repair) and sequestering of Retinoblastoma, resulting in uncontrolled transcription of cell cycle promoters.

Additional non-structural proteins expressed by polyomaviruses include:

- small T-antigen which is ubiquitous in family members identified to date,
- middle T-antigen which appear to be specific to mouse polyomavirus, and has a strong oncogenic potential
- and agnoprotein which is expressed in some species.

The exact function of these and other non-structural proteins is has not been elucidated but it is probable that these have an accessory function in virally mediated host cell modulation.
E) Pathogenesis
Polyomavirus is highly infectious, and is likely to have a number of modes of transmission:

- Body fluids (saliva, blood etc)
- Aerosol route (coughs)
- Faecal-oral route
- Surface contact
- Transplacental transmission (mother to foetus)
- Consumption of contaminate food or water
- The virus has been found to survive for up to a month in sewage, and the live virus has been found in shell fish

Infection of host cells by polyomavirus can result in two outcomes:

- Productive (lytic) infection
- Non-productive (abortive) infection

The outcome appears to be determined primarily by the cell type infected. However, after infection, some (unknown) determinant in the intracellular environment determines the outcome of the infection. The factors responsible for the transformation of latent polyomavirus infection to a lytic infection are not well understood. The intensity of immunosuppression is widely believed to be an important risk factor for viral reactivation.

F) Role of polyomavirus in disease

Humans

Polyomaviruses are not associated with clinically significant disease in healthy individuals. The general population exhibits high seroprevalence for each of the human polyomaviruses identified to date. There is variation depending on species, with approximately 70% of people over the age of 10 years being seropositive for each of the human polyomavirus species.

However, human associated polyomavirus are the causative agents of significant diseases in immunocompromised individuals (e.g. organ transplant patients, people with active HIV/AIDS) as viral replication and dissemination in the body is permitted by an altered immune system. Polyomaviruses have been shown to be the causative agents of at least two major diseases in immunosuppressed individuals through reactivation from a persistant subclinical state to a lytic infection. Polyomavirus mediated disease is typically associated with individuals who are HIV positive or those undergoing organ transplantation. Any condition where treatment is through medical disruption of the immune system can make individuals vulnerable including Multiple Sclerosis, Psoriasis and Crohn’s Disease. Reactivation of virus is detectable through an increase in viral loading in many individuals with a compromised immune system but progresses to serious disease in only a small percentage of cases. This process stimulates significant viral replication and lytic release followed by translocation to many different tissues in the body which can result in serious illness and often death.

The human polyomavirus JC virus discovered in 1971 has been linked with Progressive Multifocal Leukoencephalopathy (PML) which is a viral infection of the CNS resulting in cell death and cerebral lesions and is frequently fatal. PML is very rare despite the high frequency of JCPyV infection indicated by seroepidemiological studies, however, the incidence of PML caused by JC virus has risen significantly as the global HIV-AIDS epidemic has spread.

BK virus is the causative agent of Polyomavirus-Associated Nephropathy (PVAN) which is a condition resulting in necrosis and cell damage in the key structures in the kidney; typically encountered in kidney transplant patients.

A common feature of human polyomavirus is that the occurrence of viral-associated disease in the population is very rare and yet antibodies to virus can be detected in a large percentage of people, indicating that infection is widespread. For example, most people have antibodies to BKPyV and JCPyV by the second decade of life, but viremia is rarely detected (except in patients with PVAN and PML).

With the increased use of Biological drugs (also called “Biologics”) as immunomodulators in the treatment of conditions related to an abnormal immune response it has been found that patients are becoming more susceptible to polyomavirus-associated disease because of increasing efficiency of medication in suppressing the immune system. Examples include reactivation of JC polyomaviruses and subsequent onset of PML in Multiple Sclerosis or Crohns Disease sufferers being treated with the immune modulators Natalizumab or Psoriasis patients undergoing treatment with Adalimumab or similar biological drugs.

Despite the clear potential for cellular transformation and therefore a link with the development of human cancers there has not been a clear association made with oncogenesis in otherwise healthy individuals. The International Agency for Research on Cancer classify BK and JC Virus as category 2B carcinogens (possibly cause cancer, see IARC). Expression of BK virus in human fibroblasts has been shown to cause cellular transformation. Experimental work where polyomaviruses have been inoculated to animals (or expressed in cells in tissue culture) which are outside of the normal host range (so-called non-permissive cells) results in a stronger tumorigenic
The recently discovered Merkel Cell Polyomavirus has been associated with tumours in humans, a very rare but aggressive form of Skin Cancer (Merkel Cell Carcinoma). Epidemiological studies have revealed a striking correlation with immunocompromised individuals, older people or those who expose their skin to significant levels of UV light. However, Merkel Cell Polyomavirus does not appear to be a causative agent of cancer in otherwise healthy people. Researchers have found that otherwise healthy women in the second and third trimester of pregnancy can undergo an asymptomatic viral reactivation which results in detectable levels of polyomavirus within urine (viruria). A small number develop a clinically significant disease, however, it has been postulated that this is due to the hyperoestrogenic state during pregnancy and the subsequent alterations to the immune system allowing polyomavirus reactivation rather than from the effects of primary viral infection after conception. Despite the clear link with disease in immunocompromised individuals and a high seroprevalence in the general human population, the mode of transmission remains unconfirmed. This has clear implications on the protection of laboratory workers using polyomaviruses as all exposure routes must be assumed to pose a risk of exposure.

Avians
There are at least 5 species in the avipolyomavirus genus including the archetypal Avian Polyomavirus (formally called Budgerigar Fledgling Disease Virus) which has a surprisingly broad host range infecting a wide range of bird species. Other distinct polyomaviruses have been isolated from geese, crows and finches. The mode of transmission to birds remains unknown (suspected to be via shed virus in dander and droppings). Infection in fledglings can be detrimental to brood sizes and has significant impact in commercial bird flocks. None of the avian polyomaviruses has so far been shown to have tumourogenic activity.

F) Research aims
The aim of our research is to further our understanding of the role of polyomavirus in disease, and in particular oncogenesis:

a) Initially, greater emphasis will be placed on the mechanism of action and role in pathogenesis (and potential oncogenesis) of the non-structural proteins expressed by the polyomavirus early coding region. Research will focus on structure and function studies of these non-structural proteins (e.g. Large T-Antigen) to elucidate their role and mechanism of host cell interactions and cell modulation, viral genome replication and facilitation of viral gene expression. The means by which structure and function of non-structural proteins will be investigated is through the generation of modified virus particles carrying specifically targeted mutations, deletions or insertions. Mutant viruses will be subjected to detailed in vitro characterisation in eukaryotic cells.

b) By analysing genetically modified viruses insight will be gained into the function of the wild type pathogen (e.g. binding to key cellular partners to modify host cell function) and therefore potential vulnerabilities that could be targeted for therapeutics. A primary objective would then be to exploit those therapeutic targets to reduce disease in immunocompromised individuals as well as gaining an insight into the oncogenic action in case a stronger link is identified in the future.

c) Because polyomaviruses have very narrow host ranges and only small differences in the non-structural proteins expressed by different viral species (e.g. variations on the Large T-Antigen structure and function), we will engineer host cells to express the receptor required to allow infection by a virus that would not normally infect that species (e.g. expression of a human polyomavirus in Chinese Hamster Ovary (CHO) cells). This technique is a safer alternative to engineering viruses (i.e. pseudotyping to alter host tropism) to express in a different range of cells because of the increased risk of infection.

d) Other components of the virus will also be subject to detailed study with respect to their involvement in disease, the virus’s ability to evade the immune system, and its ability to become dormant.

e) A further research aim will be the co-expression of reporter genes (e.g. Green Fluorescent Protein) with wild type and modified viruses to allow study of cellular location during the viral infection-replication-release cycle.

f) The research will also include the infection of rodents with either wild type or genetically modified viruses, and will extend to the use of transgenic mice (e.g. expression of a human cell surface marker to allow viral infection). The work will be carried out in the University’s new (construction completed 2011) dedicated animal unit which as well as being built for containment of transgenic animals, has purpose built containment level 2 facilities to support the safe use of infectious material in animal studies, including provision for where material is shed by the animal after initial inoculation (e.g. in skin, urine or faeces into bedding).

</tr>
</tbody>
</table>
Permissive cell lines will be genetically modified to facilitate infection by polyomaviruses where the wild type cell line would not normally be infected (e.g. modification of mouse cells with human cell surface receptor genes to facilitate infection by human polyomavirus).

Murine Host for study of infection
Murine host organisms (mice) will be used in this research.

Host/vector system

Cloning vector system
Viral DNA will be maintained, manipulated and propagated in simple cloning vectors such as the pUC series or pBR322.
Viral DNA cloned into these vectors will be manipulated using molecular biological techniques (e.g. PCR using mutagenic primers) to generate cDNA encoding modified viruses to facilitate structure and function studies as detailed above. Mutagenesis will be site directed to introduce either precise point mutations or targeted deletions or insertions or to generate fragments for recombinant expression.
For transfection into permissive cells, the cDNA fragment encoding polyomavirus will be excised and recircularised using restriction and ligation enzymes before being transfected using a lipid-based transfection reagent (e.g. Lipofectamine) into cells in tissue culture.
Mammalian Cells containing polyomavirus
Permissive cells (mammalian and avian), primary and established, modified and unmodified will be transfected / infected with polyomavirus (GM and WT).
Murine host containing polyomavirus
Murine host organisms (mice) will be infected with Polyomavirus (GM and WT).

Origin & function

Polyomavirus
Double stranded viral DNA (usually isolated from respiratory tract samples and faeces/urine samples) will be obtained from collaborators and cloned into a simple expression vectors as detailed previously. The following techniques will be used:
a) Mutations will be introduced (e.g. point mutations and larger scale deletions) to systematically investigate the structure and function of elements of the polyomaviridae family.
b) cDNA encoding non-structural proteins from selected members of the polyomavirus family will be substituted for cDNA expressing equivalent proteins in other family members to generate hybrid polyomaviruses to allow the study of differences between different viral species. For example, useful insight would be gained in understanding non-structural protein function through expression of hybrid mutants of the Large T-antigens expressed by human and mouse polyomavirus species.
c) Insertion of reporter genes (e.g. GFP) to allow tracking of proteins during infection.
d) The virus particles produced by infected cells will be isolated from tissue culture media, concentrated using centrifugation before use for further studies such as reinfection of naïve cells or lysis for protein or DNA extraction for further analysis.

Evaluation of foreseeable effects

Risks associated with manipulation of viral cDNA
As polyomaviruses use host transcription and translation apparatus to replicate themselves it is not possible to generate a live virus during propagation of plasmid DNA in bacteria or during molecular manipulation to generate recircularised DNA for transfection.
Viral cDNA will be manipulated (e.g. deletions, point mutations, insertions) using techniques such as PCR to generate cDNA to produce mutant virus genomes. This work poses no risk of viral expression as the cellular apparatus required to make virus particles are not available.
There is a very low probability of polyomavirus infection if viral cDNA is inoculated into a worker, e.g. by a needlestick, during molecular biological work with DNA. However naked DNA is likely to be detected by the immune system and destroyed as part of the bodily response to an injury.
Polyomavirus T-Antigen expression has been shown to generate oncogenic effects without viral replication, especially through recombinant expression in non-permissive cells (species outside of the host range e.g. SV40 infection to human cells has been shown to cause transformation in tissue culture although SV40 is not thought to be an oncogenic virus in humans) and therefore accidental introduction of viral protein must be considered in the risk assessment process. While it is theoretically possible for a worker to accidentally inoculate themselves with cDNA encoding a polyomavirus or viral protein (e.g. through a needle stick) the likelihood of expression of viral protein or an introduced protein causing an oncogenic effect is unlikely because of the immune response triggered by the body.
As viral expression is not possible in a bacterial host and the potential for harm following inoculation to a researcher is negligible, this element of the work has been
assessed as being suitable for work at containment level 1.

Cloning vector system
Viral DNA will be maintained, manipulated and propagated in simple cloning vectors such as the pUC series or pBR322. Viral DNA requires host transcription and DNA replication apparatus that are not available in bacteria to generate infectious material so there is no risk at this stage, and this work is therefore assessed as being suitable for containment level 1.

Viral DNA cloned into these vectors will be manipulated using molecular biological techniques (e.g. PCR using mutagenic primers) to generate cDNA encoding GM viruses to facilitate structure and function studies. Mutagenesis will be site directed to introduce either precise point mutations, or targeted deletions or insertions or to generate fragments for recombinant expression. Any modified mutant virus is expected to be less able to infect and modulate cell function and so therefore is expected to present less of a hazard than wild type viruses.

There is a remote risk of mobilisation of vectors containing viral DNA from lab strains to other microbes such as commensal microbiota or soil bacteria in the external environment. However, the use of containment level 1 laboratory procedures (such as no eating or drinking, good hand hygiene, disinfection of live cultures prior to disposal, e.t.c.) reduces this risk to a negligible level. It is expected that even if mobilisation of polyomavirus in a vector to other families/species of bacteria were to occur the likelihood of harm (e.g. production of infectious virus or a recombination event leading to pathogenic bacteria) is assessed as being highly unlikely.

For transfection, the cDNA fragment encoding polyomavirus will be excised and recircularised using restriction and ligation enzymes before being transfected using a lipid-based transfection reagent (e.g. Lipofectamine) into cells in tissue culture. In this form (viral DNA in lipid vesicles) there is a risk of infection (albeit with lower infectivity than the wild type); this procedure therefore requires containment at an appropriate level, in this case containment level 2.

Risks associated with production of virus in tissue culture
Following transfection with viral cDNA, cells grown in tissue culture will produce live polyomavirus (wild type or genetically modified) that will be shed into the tissue culture following lytic release from infected cells. Because the media will become enriched with infectious material this may be a source of infection; especially during cell manipulations (e.g. passage of cells). The use of Containment Level 2 procedures are considered suitable for reducing this risk. In particular, application of the principles of good lab practice, the confinement of high risk procedures (e.g. where aerosols could be produced) to microbiological safety cabinets, disinfection of liquid cultures prior to disposal and treatment of consumables (e.g. cell plates) prior to consignment to the waste processing system will reduce the risk of infection to staff or students who enter the facility or transfer of infectious material outside of the containment area.

Live wild type and modified virus particles shed into tissue culture media will be collected and concentrated using techniques such as centrifugation. Centrifugation poses a risk from aerosol production and will be considered as a high risk procedure and therefore key steps of the process will be carried out within a microbiological safety cabinet (i.e. opening and closing tubes within the cabinet) so that potential aerosols are controlled.

Typically, live virus that has been concentrated will be lysed for protein and DNA extraction for further studies (e.g. PCR or Western blot). The chemicals/enzymes used for this will inactivate the virus and so subsequent analyses can be carried out in a standard Containment Level 1 laboratory.

Viral isolates will also be used (following concentration to increase titre) for live infection of naive cells for further studies. This will require inoculation of virus isolates into tissue culture media to allow cells to become infected and subsequently produce virus by lytic release. However, this process will be controlled using the same Containment Level 2 control measures which will control the risk.

Some immortalised cell lines that could be used for research contain (or may contain) fully integrated viral sequences (e.g. human papillomavirus found in HeLa Cells) which could in theory mobilise to generate infectious material. However, after many years of use (over 60 years in the case of HeLa), there have been no documented cases of harm occurring to researchers using these stable cell lines.

Due to the fact that only a small number of members of the polyomaviridae family are listed on the Approved List of Dangerous Pathogens as belonging to Hazard Group 2; we will be taking a precautionary approach and will require that work with any infectious polyomavirus material will be handled under Containment Level 2 conditions.

Research with live virus will therefore be carried out in a dedicated Containment Level 2 laboratory with established local procedures and safe working practices as detailed in the attached appendix.

Host cell lines will be genetically modified to facilitate infection by polyomaviruses where the wild type cell line would not normally be infected (e.g. modification of mouse cells to facilitate infection by human polyomavirus). In this example the modifications required will allow those cells to express a human cell surface receptor which will not present any hazard to laboratory workers (unless those cells are subsequently infected with human polyomavirus).

Work with recipient organism (i.e. cell lines) in their uninfected state is assessed as being low risk and the likelihood of harm to workers or the environment is negligible.

Effects of genetic modification
Modified viruses designed to facilitate investigations into the structure and function of non-structural proteins expressed within the host cell (e.g. T-antigens) will be
engineered with mutations that are designed to disable a specific function. Because mutations will be designed to disrupt the action of non-structural proteins (e.g. investigate key protein residues in a binding site by systematically altering them) it is anticipated that mutant viruses will be less able to infect cells and modulate host cell function. This will therefore reduce the likelihood of viral replication/lytic release and lower the probability of cellular transformation (e.g. attachment independent growth) of cells expressing mutant viruses; these factors therefore reduce the risk in the event of a failure of control measures resulting in exposure to live material. It should be noted that there is no intention to attempt to engineer viruses with increased pathogenesis.

Point mutations will be introduced into viral cDNA based on careful analysis of the protein sequence e.g. to identify key protein or DNA binding motifs that are likely to be associated with virus activity. Specific mutations will be introduce using site directed mutagenesis to obtain very specific alterations which rather than random mutagenesis (e.g. with chemicals), the latter which would generate unknown mutants where the phenotype cannot be predicted. Insertions or deletions will be engineered into cDNA using standard molecular biological techniques such as PCR and ligation of DNA fragments. It is in the interests of the research to ensure the fragment of interest has been inserted/deleted properly (e.g. no frame shifts resulting in truncated protein) and so DNA Sequencing will be used to confirm that the expected DNA construct is being used to express a GM virus therefore avoiding expression of modified viruses with unexpected characteristics.

The co-expression of reporter proteins (such as GFP) in place of a deleted non-structural protein is similarly not predicted to have an adverse effect on human or animal health in the event of accidental exposure compared to the wild type virus. Reporter genes have a long history of safe use as a co-location marker and therefore level 2 containment measures in place to protect workers from the virus itself will be sufficient. Cells expressing reporter gene-labelled viruses will only be removed from the containment facility (e.g. for observation by microscopy) once they have been inactivated. For example, Cells will be fixed with Formaldehyde (or suitable alternative) to inactivate viruses before removal from containment. There is no intention to carry out live imaging studies without fixation of cells before removal from containment.

Murine host containing polyomavirus

Both wild type and modified viruses will be inoculated into rodents as part of this research to assess in vivo effects and to further aid structure and function studies. For the containment of infectious material and animals inoculated with infectious/GM material all such work will be conducted in the dedicated animal unit facility. Handling of infectious/GM material within the animal unit will be carried out under the same strict containment conditions as detailed above for laboratory work with equivalent control measures (e.g. disinfection, waste streaming and personal/workplace hygiene measures).

Animals will be infected with virus in a Microbiological Safety Cabinet within the animal unit’s CL2 facility before transfer to containment in Individually Ventilated Cages (IVCs; e.g. Techniplast system). Animals are housed within IVCs set to negative pressure in relation to the holding room which provides protection for both workers and other animals as well as containing GM material. Polyomavirus will be shed in rodent urine and onto the skin (as well as being present in blood and other body fluids); cage bedding will therefore pose a risk to workers. Husbandry of animals housed within the Category 2 animal suite is carried out under strict containment measures to protect researchers, husbandry technicians and facility technicians (e.g. cage cleaning staff). Briefly, cage changes are carried out within Microbiological Safety Cabinets and all contaminated material such as cages and bedding is autoclaved to inactivate infectious material prior to handling to consign to the healthcare waste route.

The programme will additionally involve generation of transgenic animals to facilitate studies of altered viral tropism (e.g. expression of a human cell surface protein in rodents to allow expression of a human virus in rodents). Animals expressing the necessary cell surface protein to facilitate viral infection (e.g. an integrin or glycoprotein) will be highly unlikely to cause additional harm to workers than wild type animals (e.g. through a bite) when not infected with Polyomavirus. Following infection it is probable that Polyomavirus will be shed as detailed above. However, the precautions noted above for use of animals will be applied equally to transgene animals for the protection of workers.

Research animals are housed in a state of the art modern animal facility such that escape (and therefore loss of containment of GM material) would be highly unlikely. Animals are maintained within IVCs within climate controlled holding rooms within a secure unit with only 3 exits to the outside. Escapees from holding cages would be detected very quickly and are unlikely to get to the outside. However, while the environmental risks from production of transgenic animals in this work are negligible because alterations are unlikely to confer any benefit there may be risks to the local rodent population should a rodent infected with GM polyomavirus escape to the environment. GM polyomavirus are likely to be less able to express and replicate and so will represent a reduced hazard compared to wild type polyomaviruses.

Polyomavirus work that is specifically excluded

• It should be noted that there is no intention to attempt to engineer viruses with increased pathogenesis.
• There is no intention to increase the lethality of the virus e.g. by cloning interleukin-4 into polyomavirus genome.
• Insertion of genes coding for toxins is specifically excluded
• There is no intention to carry out live imaging studies without fixation of cells before removal from containment.

Function of the Biological Safety Committee

Researchers wanting to carry out research under this broad notification will be required to obtain consent from the University biological safety committee using the
University biological risk assessment process. If in the committees opinion the research falls within the remit of this notification and there is no increase to the overall risk associated with the work then the work will be approved. The biological safety committee has been given executive authority by senior managers at the University to grant or deny approval for a project to begin.

In applying to the biological safety committee the researcher are expected to have determined the risks associated with any new Polyomavirus research with particular attention given to factors such as potential links with human disease, percentage of the population that are seropositive by adulthood (for human viruses) and the proximity and possibility of transmission to an animal host. Should the use of a virus increase the level of risk to a level greater than that indicated for this notification then a new notification will be made to the HSE.

It is probable that new Polyomavirus species or additional serotypes of known species will be identified in the future and cDNA encoding them will become available from our collaborators. Should the research programme require the use of a Polyomavirus species that is not included in Appendix 1 then the risks associated with the virus will be carefully defined and our internal process to obtain approval for the research from the biological safety committee will be followed. Where there is an increased potential for harm to human or animal health or damage to the environment then the committee will not grant approval unless a new notification is made the HSE.

All infectious material containing polyomavirus will be handled under the Containment Level 2 Standard Operating Procedure for polyomavirus detailed in Appendix 2. Appendix 1 shows an example internal application for work with BK, JC and Merkel Cell Polyomaviruses.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not required

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

See the attached Standard Operating Procedure for polyomavirus work at containment level 2 appendix 2 (sections 9 to 13) for details on waste treatment.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The internal assessment (FBS13078) was reviewed by the local committee (25th October 2013) and approved as appropriate for work at containment level 2. The committee noted that a notification to the HSE would be needed.

02/03/2022
This application seeks to establish virus-encoded epitope libraries (VEEL) as a research platform to investigate potential therapeutic benefit and associated immune responses to VEEL-derived tumour vaccines. These will be utilised both in vitro and in pre-clinical animal models of human/murine/hamster cancer.

Specifically, we will utilise the following platforms:

- Wild-type adenovirus or replication competent, attenuated Adenovirus of various serotypes obtained by collaboration (Dr Iain McNeish, University of Glasgow);
- Replication-defective Adenovirus (various serotypes), obtained commercially (Clontech/Invitrogen) or in collaboration (Dr Iain McNeish, University of Glasgow; Dr Eric Blair University of Leeds);
- Attenuated Maraba Virus (Vesiculovirus genus) obtained by collaboration (Dr David Stojdl, CHEO Research Institute, Ottawa); replication-defective VSV (VSV-∆G);
- Replication competent, attenuated vaccinia virus.

Virus platforms will be used to harbour fragment cDNA libraries, generated via random hexa-nucleotide priming in an unbiased fashion or via oligo-dT primers. Libraries will be sourced from either human/murine tumour cell lines or ex-vivo normal/cancerous human tissue, obtained with ethical approval and appropriate consent. This has been formerly demonstrated in the VSV system*. Resultant expression therefore comprises proteins derived from each source.

The primary objective of research projects carried out under this assessment is to use VEEL, both in vitro (immune priming assays) and in murine/hamster models (syngeneic models for e.g. Prostate cancer: C57BL6/TC2), to stimulate anti-tumour immunity. This will aid one of the principal research aims, namely “defining the molecules involved in human diseases and using this knowledge to develop novel therapies and new drugs”.

Generation of VEEL from various cell line/primary cell sources will be followed up using a series of investigative PCRs to confirm the presence of pre-determined “indicator”
cDNA fragments pertaining to their origin. Stocks of VEEL encoding libraries will be deliberately maintained as heterogeneous mixed populations, without the purification/expansion of individual clones, although PCR and immune-cell expansion will be used to identify antigens selected by the induction of immunity*.

Recipient or parental organism

Bacterial cells
Laboratory strains of E.coli such as XL1-Blue and BL21 will be used to maintained, propagated and manipulated polyomavirus cDNA. Laboratory strains of E.coli have a long history of safe use. Growth of plasmid vectors is assessed as harmful neither to the environment nor people and can be carried out at containment level 1.

Mammalian cells (un-infected)
Mammalian cell lines both primary/tumour and established will be grown in nutrient media in temperature controlled incubators within a tissue culture suite.

Murine Host for study of infection
Murine host organisms (mice) will be used in this research.

Host/vector system

All proposed viral vectors have either a long history of safe clinical use, or gene deletions and/or attenuation mutations that render them either tumour cell specific in terms if replication, or dependent on (helper) cell lines for propagation. cDNA libraries will be directly transferred into viral vectors for the most part, but may also be cloned via “shuttle” plasmid vectors where appropriate – these are non-mobilisable.

Animals vaccinated using VEEL will be kept in appropriate isolation conditions as standard for level 2 animal procedures.

Maraba virus is a Rhabdovirus originally isolated from south American sandflies. It is a negative strand, ssRNA virus comprising a “bullet-shaped” nucleocapsid and a lipid envelope, populated by the viral glycoprotein (G).

Maraba virus is listed as a distinct species (ICTV: http://ictvdb.bio-mirror.cn/ictv/fs_rhabd.htm) within the Rhabdoviridae and, whilst closely related to strains of VSV such as Indiana, does not cause vesicular disease with symptoms overlapping with FMDV in cattle or other ruminants*.

Toxicity experiments conducted by colleagues in Canada demonstrate that systemically delivered MG1 displays no overt dose-limiting toxicity in immune-competent mice, with minimal associated symptoms. Direct cranial injection does result in neurotoxicity and fatal encephalitis, but this is only occurs via this invasive route of delivery shedding and spreading of MG1 from infected Macaques is minimal, viral genomes only being detectable in tissues via PCR, not by the less sensitive IHC or plaque assay (personal communication D. Stojdl, CHEO Research Institute, Ottawa).

Maraba virus has been shown to have limited spread outside of sandflies* and no natural mammalian host has been identified, with only one documented example of human seropositivity. Vectors based on Maraba virus contain two attenuating mutations in the glycoprotein (G) and matrix (M) proteins. The M mutation limits evasion of innate antiviral immunity but the mechanism of action of the G-protein mutation is not known+. Genetic modification of MG1 comprises an insertion site between the G and M ORFS, resulting in expression from an internal transcription initiation site. Attenuations mean that high titre growth of MG1 and derived VEEL is only possible in tumour cell lines. This property has resulted in MG1 being proposed for use as a highly selective oncolytic virus.

between the M and the deleted G ORFs. G-deleted VSV is commonly licensed by the HSE in the UK for work under a class 2 bio-containment.

Adenoviruses (Ad)
Ad systems to be used under this notification will be:

- Wild-type Ad
- Replication competent, attenuated Ad
- Replication-defective Ad, deleted in the E1 ORF; unable to replicate except in specialised, E1-expressing cell lines (e.g. HEK293).

Wild-type adenoviral vectors are replication competent and could infect humans. Wild-type virus infection in humans with an intact immune system leads to a mild and self-limiting flu-like illness.

The replication competent adenoviruses contain mutations within the viral genome that attenuates replication in normal cells and tissues. The deletions occur in regions of the viral genome that are necessary for replication in normal cells but are complemented by the altered gene expression in cancer cells. The tumour selective mutants can infect normal cells but the ability to replicate is highly attenuated.

Replication-deficient viruses are incapable of replication in cells lacking adenovirus E1 function. Infection of normal human cells as well as malignant cells results in no infectious virion production.

In the absence of replication, long-term viral gene expression can occur only following integration into the host cell genome which is extremely rare – this can occur with a frequency of 1 in 105 in exponentially growing human cells and thus presents a minimal risk.

Vaccinia Virus
Various replication competent forms of the Western Reserve, Wyeth and Lister strains of vaccinia virus.

Insertion of the cDNA libraries leads to disruption of the viral thymidine kinase (tk) gene which results in attenuation of the virus as it is then dependent on tk expression in the host cell. Tk is transiently expressed during S-phase in proliferating normal cells but is constitutively expressed at high levels in most cancer cells, hence the attenuation limits vaccinia virus infection of normal tissue.

Like Adenovirus, vaccinia virus does not integrate into the host genome and hence risk of mutagenesis is very low.

Origin & function
Sequences selected for virus-mediated expression in either cell culture or pre-clinical murine models will derive from both cancerous and "normal" human/murine tissue. Libraries will be sourced from either human/murine tumour cell lines or ex-vivo normal/cancerous human tissue.

Fragment cDNA libraries will be generated via random hexa-nucleotide priming in an unbiased fashion or via oligo-dT primers. However, sequences are unlikely to comprise complete ORFs due to viral coding capacities.

Evaluation of foreseeable effects
GM viral particles or transduced mammalian cells are expected to pose no additional risk to safety. Production of replication-competent VSV-∆G by transduced cells is highly unlikely.

Helper Cell Lines
The mammalian cells produced after transfection for production and packaging of replication-defective virus particles are not expected to be more harmful than the unmodified cell line, with the exception of risks from production of virus covered elsewhere in this assessment.

Generation of a cell that is capable of producing wild type, replication-competent VSV-∆G is highly unlikely due to the safety features incorporated into the design of the systems as described in Section 3.2.

Transduced cell lines and primary cells
Following viral transduction, cell lines and primary cells will not be considered any more hazardous than the parental helper lines in which vectors are expressed/pseudotyped. Monitoring for the generation of replication-competent VSV-∆G will be carried out periodically, and initially for each cell combination employed, using either PCR for viral genome components or direct assay for live virus (e.g. plaque assay). Expression of virus from transduced cells or the generation of replication-competent VSV-∆G is highly unlikely (as described in Section 3.2).

The exception to this concerns work with cells derived from clinical samples as these may harbour existing viruses such as HIV or hepatitis viruses. The main risk to operators handling such cells would be infection with the adventitious agent via needle-stick injury. To reduce the risk, such samples will only be taken from low risk groups or patients screened by physicians with knowledge and experience of the patients to exclude high risk samples. Workers handling clinical material should be vaccinated against HBV. Samples later found to be from high risk individuals must be destroyed or re-evaluated to determine whether any adventitious agent can be inactivated.

02/03/2022
Human health hazards

• Replication-competent Ad vectors have a long history of use as a therapeutic oncolytic agent both as wild-type virus and as a gene therapy vector. They have an excellent safety record with many cancer patients having been treated at high doses without adverse effects3-5

• Replication-defective Ad vectors contain deletions in their E1 region, thus requiring helper cell lines which are modified to encode these regions (e.g. HEK293) in order to complete a full infectious cycle. In all other cells, these vectors are limited to single-round infections.

• MaraV MG1 vectors contain two stable attenuations6, one in the glycoprotein (G) ORF, and one in matrix (M). These have been demonstrated to render MG1 capable of replicating only in tumour cell lines.

• VSV-∆G vectors have had their glycoprotein (G) ORF deleted and so are also dependent on modified helper cell lines for replication. Thus, these are limited to single-round infections in all other cell types.

• Replication-competent vaccinia virus has a long history of safe use as a live vaccine in human smallpox vaccination programs7, and in addition a good safety record in clinical immunotherapy trials8-11. The level of vaccinia-induced human toxicity is strain-dependent7. Usually: minimal grade 3 and no grade 4 toxicity (observed across immunotherapy trials in a wide variety of cancers with administration via intramuscular, intratumoural, intravesical and subcutaneous routes).

The risk to human health arising from the use of any of the above vectors is assessed as being very low. There is a risk that mammalian cells may carry adventitious agents such as human immunodeficiency virus (HIV), or hepatitis B/C viruses (HBV, HCV). To reduce this risk, patient samples will only be taken from low risk groups or patients screened by physicians with knowledge and experience of the patients to exclude high risk samples. Workers handling clinical material will be vaccinated against HBV. Samples later found to be from high risk or infected individuals must be destroyed or re-evaluated to determine whether any adventitious agent can be inactivated.

Immunocompromised individuals should be identified and assessed individually in conjunction with UoL Occupational Health to determine whether it is safe to undertake work.

Hazard identification in respect of the environment

Mammalian cells producing viral components (producer/packaging cell lines) or those that have been stably transduced (target cell lines) are highly unlikely to survive outside a tissue culture laboratory due to rapid dehydration and specialised growth and nutritional requirements.

Primary cells derived from human blood (e.g. PBMC) have extremely limited viability and would not survive environmental exposure outside of laboratory conditions. It is highly unlikely that cultured mammalian cells would survive in a “host” organism unless the host was severely immunocompromised and therefore unlikely itself to survive in the environment. Immunocompromised individuals working in LICAP will be individually risk-assessed before undertaking work with viruses.

(Pseudo)-infectious viral particles:

• Engineered viruses are unable to replicate outside of helper cell lines (VSV-∆G, Ad-∆E1) so infections would be self-limiting.

• Attenuated viruses are able to infect normal cells but do not replicate in them, they replicate efficiently only in tumour cells.

• Rhabdovirus particles are membrane coated and would be quickly degraded in the environment through UV exposure and dehydration.

• Both vaccinia and Ad wild type particles are already present in the environment. Accidental release would therefore increase the risk of exposure to potential hosts (rabbits, rodents, cattle (vaccinia), rodents, rabbits, pigs (adenovirus)), but immune recognition and activation would control viral pathogenesis in all cases.

• The host range for all viruses is well defined.

The hazard to the environment from accidental release of cells or virus is assessed as negligible. As MaraV does not cause vesicular disease in cattle, it does not require SAPO classification.

The worst case scenario of an individual worker being exposed to replication-competent virus via e.g. needle-stick injury would result in a mild febrile illness which would be self-limiting as a result of activation of the immune system. Even less likely would be the transfer of MG1 or VSV-∆G via an insect vector as insect tropism is highly limited and would not include hosts present in Northern Europe.

This work does not alter the overall risk to workers and/or the environment in our laboratory since:

• Work will only be carried out in laboratory facilities meeting requirements for containment level 2

• All work is managed to comply with the requirements for containment level 2

• Standard operating procedures for this type of work are in place in LICAP (see attached). These are the minimum requirement within the Institutes: local rules may be more stringent.
• Animal experiments are conducted in a highly regulated and well established level 2 animal facility.
• The scope of the notified activity is restricted to the connected buildings Wellcome Trust Brenner Building, Clinical Sciences Building, Cancer Research Building and Robert Ogden Building on the University of Leeds St James’s University Hospital site.

Activities specifically excluded from this assessment
Projects that will be specifically excluded from this system of work will be those for which the risk to worker and/or the environment is increased over that posed by the work outlined here.

Inserts that could increase pathogenicity compared to wild type.
Deliberate infection of humans with viruses. Such applications e.g. for gene therapy purposes or clinical trials, are outside the scope of this assessment and would require separate notification.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Infected murine hosts (including GM variants) will be housed the purpose built (2006) animal unit located on site. The animals are housed in IVC's (mainly Techniplast but also Optimice housing system).

A variety of standard operating procedures are used within the unit and govern how work is carried out.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not required

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
Submitted assessment discussed at GM and Biological Safety Committee meeting 21.7.2014. Committee requested more information on methodology and clarification of various points but agreed that assessment should be approved subject to these changes being made. This revised assessment incorporates these changes

### Project Additional Information

**Purposes of the contained use**

We seek to establish a research portfolio to investigate aspects of the molecular mechanisms of virus genome replication and assembly of the arthropod-borne viruses (also known as Arboviruses) classified in the two virus genera - Flaviviruses and Alphaviruses. Flavivirus work will be limited to the hazard group 3 pathogen Dengue virus (DENV). Alphavirus work will include the re-emerging hazard group 3 pathogen chikungunya virus (CHIKV), as well as Sindbis virus (SINV) and Semliki Forest Virus (SFV); two viruses that are less pathogenic than CHIKV and thus classified at hazard group 2. A number of viruses are considered within the non-taxonomic group Arboviruses as they are transmitted by mosquitoes, midges, ticks and fleas to susceptible vertebrates including humans and other mammals.

Work will be performed by two research groups involving three PIs (Harris, Tuplin and Stockley), all of which have extensive experience of research involving infectious viruses both within the Faculty of Biological Sciences at University of Leeds but also drawing on previous experience at other Institutions (Tuplin joined the University of Leeds in 2013 having previously worked in the Universities of Edinburgh and Warwick as well as the NERC Institute of Virology, Oxford).

DENV is a member of the genus Flavivirus (Family Flaviviridae) that includes a number of important human pathogens including Yellow fever virus, West Nile virus and tick-borne encephalitis virus. DENV is the aetiological agent of dengue fever and dengue shock syndrome and is considered the most important arbovirus. Four serotypes have been described (DENV 1-4), these emerged separately from a sylvatic ancestor (infecting primates) and the virus is now transmitted in a human urban transmission cycle. An estimated 2.5 billion people are considered to be at risk from infection, and annually 50-100 million cases are infected with 500,000 hospital admissions in some years.

Dengue-associated disease manifests as a number of syndromes, often as fever, headache, muscle and joint pain but in the most severe cases as dengue haemorrhagic
fever (DHF)/Dengue shock syndrome (DSS) which is characterised by vascular leakage; a range of intermediate syndromes are also possible. Cases of severe dengue often increase following exposure to different DENV serotypes as a result of infection-enhancing antibodies.

DENV is principally transmitted by Aedes aegypti mosquitoes but A. albopictus can also act as vector. This is becoming an issue due to the widespread distribution of A. albopictus, including in Europe. Indeed, autochthonous transmission of DENV has been described in the South of France.

DENV has a positive sense single stranded RNA genome of approximately 11 kb in length, containing one open reading frame (ORF) that encodes a single polyprotein (see Figure 1 below). This polyprotein is cleaved by viral and cellular proteases into three structural proteins (C, prM, E) located at the N terminus, and seven non-structural proteins at the C terminus (NS1, NS2A, NS2B, NS3, NS4A, NS4B, NS5). The non-structural proteins are involved in virus replication and also antagonism of host responses. The 5’ end of the DENV genome is capped and highly structured, and the 3’ end is also highly structured but not polyadenylated.

CHIKV is a member of the genus Alphavirus (Family Togaviridae) which also includes a number of highly pathogenic human and animal pathogens (eg Venezuelan and Eastern equine encephalitis viruses). Infection with CHIKV can cause fever, headache, myalgia, rash, as well as acute and persistent arthralgia. CHIKV disease can cause severe morbidity and, as more recently described, fatality. The virus is vectored by Aedine mosquitoes, mainly A. aegypti in Africa, but both A. aegypti and A. albopictus in Asia. Urban cycles occur in Asia and the virus has been imported into many countries by returning travellers, including Europe. Several large outbreaks have occurred in recent times, especially in the Indian Ocean (Reunion Island) (Morrison TE (2014) J.Virol 88:11644-11647). Most interestingly, the outbreaks in the Indian Ocean were caused by an African strain with a mutation (A226V) in the E1 glycoprotein, which results in better dissemination in A. albopictus. This mutation is also found in CHIKV in India. Pertinently, outbreaks of CHIKV in Southern Europe (Italy) where the virus was presumably imported by travellers and amplified by A. albopictus (this mosquito is also now present in parts of S. Europe) have shown the same mutation in E1. CHIKV outbreaks have also been reported in France.

A significant development in the re-emergence of CHIKV was the report in Dec 2013 of the first case in the Americas - on the Caribbean island of Saint Martin. Some 7 months later there were 440,000 cases of CHIKV infection reported across the Caribbean and Central/South America and a few cases in Florida. Given the scale and geographical distribution of these outbreaks, more research on CHIKV is urgently needed.

CHIKV also has a positive sense single stranded RNA genome which is 12 kb in length and encodes two ORFs which are translated from 5’ capped mRNAs (Figure 1). The first ORF encodes the virus non-structural proteins that are co- and post-translational cleaved into mature proteins. The second ORF is translated from a sub-genomic RNA molecule and encodes the virus structural proteins.

In addition to work with CHIKV we also plan to work with less pathogenic Alphaviruses - Semliki Forest virus (SFV) and Sindbis (SINV). Although both of these viruses can infect humans they are classified as hazard group 2 pathogens by the ACDP. SINV has a broad distribution, although originally isolated in Egypt it has been found as far afield as Scandinavia and Australia. It is generally asymptomatic in humans but can cause rash and arthritis. It is transmitted from the natural host (wild birds) via both Aedes and Culex species of mosquitoes. SFV is naturally found in Central and Southern Africa and is transmitted between animals and birds mainly by Aedes aegypti and Aedes africanus. SFV has been linked to human disease on only two occasions but serological surveys present evidence for widespread human infection.

There are three specific reasons for experiments with these CL2 viruses in addition to our work with CHIKV and DENV at CL3. Firstly, as part of the training programme for work at CL3; the procedures for the propagation and titration of all Alphaviruses will be very similar (CHIKV, SINV and SFV), it is logical for new members of staff to be initially trained by working with SINV or SFV at CL2. This will allow staff to become familiar and competent with these techniques, prior to being trained for work at CL3 and applying those protocols under those more stringent containment conditions. We have a rigorous training regime for work at CL3 and this would form part of that process for those staff involved in Alphavirus work.
Secondly, it will be important to extrapolate results obtained with CHIKV to other Alphaviruses to determine if the molecular mechanisms under study are conserved across the genus. This would provide valuable information about the processes of genome replication and pathogenesis. For example, if we identify specific RNA structures in the CHIKV genome, or amino acid residues in CHIKV proteins, that are required for virus genome replication, homologous sites could be mutated in SINV or SFV to determine if the phenotype of the mutant was the same.

Thirdly, Stockley's studies seek to understand the genome-nucleocapsid organisation of Alphaviruses, building on his recent identification of putative packaging signals (PSs - short regions of secondary structure in the virus genome that are involved in packaging of virus genomes into infectious particles) in other positive strand RNA viruses (Borodavka et al (2012) PNAS 109:15769; Dykeman et al (2014) PNAS 111:5261; Patel et al (2015) PNAS 112:2227). This will involve technically challenging biochemical approaches such as CLIP-SEQ which will be impractical to perform at CL3. Thus these experiments will be conducted with SINV or SFV. These techniques will be complemented with in vitro approaches such as SELEX to identify PSs, and preparation of nucleocapsids for analysis of molecular mechanisms of RNA release. Mutation of PSs in infectious cDNA clones and observation of the phenotype will validate the existence of PSs. An additional strand will be to screen libraries of small molecular weight clinically approved drugs that bind in vitro to PSs for effects on virus assembly.

Studies will focus on two broad aspects of virus biology:

1) The role of RNA structures within the genomes in controlling virus replication, translation and assembly and interactions with host cell factors.
2) The role of the viral proteins in virus RNA replication, translation, assembly and interactions with the host cell.

Details of the GM approach are discussed in the following sections. Briefly, cDNA clones of infectious viruses will be manipulated to generate mutants in which either the conformation of essential RNA structures have been destroyed or specific mutations are introduced into the coding sequence of the viral proteins. The effect of these mutations will be assayed by translation of marker genes incorporated into the virus construct (eg luciferase or GFP), or virus titration. Mutations will be incorporated by conventional site directed mutagenesis. Downstream a range of biochemical and cell biological approaches will be used to understand the phenotypes of these mutations and determine the role(s) of both viral RNA structures and proteins in the lifecycle. These will include imaging procedures such as confocal microscopy (for CHIKV or DENV this would involve utilising the unique facilities available within our CL3 laboratory) but also proteomic analysis and the study of protein-protein and protein–RNA interactions by immunoprecipitation and affinity purification.

Recipient or parental organism

Viruses of the Flaviviridae family:
- Dengue virus (serotypes 1-4), for example DENV2 New Guinea C. ACDP3.

Viruses of the Togaviridae family:
- Chikungunya virus (strain RL2006 OPY1 [ICRES clone], other strains). ACDP3.

Complementary DNA encoding DENV (termed an infectious clones) principally the DENV-2 New Guinea C strain, will be obtained from Dr Andrew Davidson at the University of Bristol and the CHIKV infectious clones from Dr Alain Kohl at the University of Glasgow Centre for Virus Research and Dr Andres Merits, University of Tartu, Estonia. The CHIKV infectious clone is based on strain RL2006 OPY1 (constructed by Dr Merits laboratory as part of an EU FP7 consortium). This clone and derived viruses are based on CHIKV sequences from the East/Central/South African (ECSA) genotype and contain the E1-A226V mutation.

DENV and CHIKV listed additionally under Anti-Terrorism Crime and Security Act.

Plasmids containing either SINV or SFV cDNAs will be obtained from either Dr Alain Kohl (CVR, Glasgow), Dr Andres Merits (University of Tartu, Estonia) or Professor William Gelbart (UCLA).

Host/vector system

Reverse genetics systems for both DENV and the alphaviruses (specifically CHIKV, SINV and SFV) are well established in many laboratories. In these systems,
complementary DNAs (cDNA) of the complete genomes of both viruses have been cloned into plasmids which can be amplified and manipulated in standard bacterial systems. Following linearisation of the plasmid at the 3' end of the inserted viral sequences in vitro transcription of the plasmid cDNA using either T7 or SP6 bacteriophage RNA polymerase produces RNA which, when transfected into eukaryotic cells can give rise to infectious virus. Viral RNA must be capped at the 5' end, thus it is necessary to use a commercial in vitro transcription kit (Life Technologies mMessage mMachine) to ensure efficient capping of in vitro transcripts. Plasmids contain an origin of replication followed by a prokaryotic selectable marker (ampicillin or kanamycin resistance) and are non-mobilisable vectors in a disabled prokaryotic host. No live virus is produced during this process.

RNA generated from these constructs in vitro will be transfected into a range of transformed mammalian cell lines (including HEK293, A549 and Huh7 human cells, C2C12 murine muscle cells and BHK21) and Aedes mosquito cell lines (including A20 and Aag2 from A. aegypti and C6/36 from A. albopictus) by lipofection or electroporation for analysis of virus replication. No work with live vectors (i.e. mosquitos) will be undertaken as part of these projects.

The established protocol for this work (as determined by consultation with other investigators) is that cells will be transfected with RNA encoding CHIKV or DENV at CL* and then immediately transferred to the CL3 lab. From discussions the consensus in the field is that no virus is released from transfected cells for at least 4 hours after transfection. We propose that the first experiment once approval is granted will be to test this statement. Susceptible cells will be transfected with either CHIKV or DENV RNA, transferred to CL3 and supernatant harvested every hour from 1h post-transfection for virus titration. This will allow us to accurately determine the early time-scale of virus infection and validate the experimental procedure. Cells transfected with RNA encoding SFV or SINV will be maintained within our CL2 lab.

Our approach is to generate defined site directed mutants of the target before expressing and characterising mutant viruses along with reporter genes in mammalian or invertebrate cells in tissue culture.

DNA constructs to facilitate the production of viral cDNA will be constructed and/or manipulated to generate mutant viruses using standard molecular biological techniques. In prokaryotic cells, only selectable (e.g. antibiotic resistance) genes will be translated; prokaryotic cells may also be used for protein expression and subsequent purification.

Transcription of cDNA to capped RNA will be carried out using a commercial kit (Life Technologies mMessage mMachine), which will then be transfected into transformed mammalian or invertebrate cell lines using electroporation or commercially available reagents such as Lipofectamine or FuGene.

Following transfection, where necessary, cells will be transferred to the CL3 laboratory. Once viral production is established mutant viruses will be characterised. Research will focus on key areas detailed here:

Research thread 1: Analysis of RNA structures:

Our strategy will involve generating specific mutations (generally synonymous in the protein coding regions), which will disrupt RNA secondary structures within both protein coding and non-translated regions of the genomes. Synonymous – or silent - mutations do not change the amino acid sequence encoded by the virus and as such viral proteins will not be mutated. Although it is known that both viruses encode RNA structures vital for translating and replicating their genomes their mechanisms of action and interaction with host cell factors is not understood.

In preliminary studies utilising subgenomic replicons a number of RNA stem-loops in the open-reading frame of CHIKV have been shown to act as host dependent cis-replicating elements (CREs) during early stages of virus genome replication (manuscript in preparation). Disrupting the CREs inhibited replication in human cells and stimulated it in mosquito cells. Utilising mutant infectious virus systems and intracellular RNA structure mapping we will define host-specific genetic and structural determinants of CRE function, precise roles during early virus replication and specific protein trans-activator interactions. Comparison of results between in human and mosquito cell systems will enhance detailed dissection of mechanisms involved, which we expect to have direct application in identification of novel therapeutic targets. Furthermore, mechanistic understanding of CRE-mutant attenuation will have direct application in studies towards a genetically stable attenuated vaccine.

Similar approaches will be used in SINV/SFV to examine the roles of putative PS sites in viral assembly. The two known clades of alphaviruses contain distinct, although interchangeable, single-copy, high affinity PS sites (Kim et al (2011) J. Virol. 85, 8022–8036), but the mechanism by which they regulate nucleocapsid assembly is
unknown. We will determine if there are secondary PS sites and what their roles are in assembly.

Research thread 2: Analysis of protein function:

Mutations will be introduced into the infectious clones to change specific amino acids. These will be predicted to disrupt specific functions or protein-protein interactions, for example by alanine substitution of charged amino acids or potential phosphorylated residues (serine/threonine/tyrosine). Mutations will potentially be generated in the coding sequences of all the viral proteins however initially a particular focus will be the CHIKV non-structural protein nsp3.

This protein contains an N-terminal macro-domain which has been described to possess ADP-ribose binding and ADP-ribose-1"-phosphate phosphatase activity (Malet et al (2009) J.Virol. 83:6534), however the role of these functions in genome replication has not been determined. Specific mutations that are predicted to ablate these functions will be generated and the replication of the resulting viruses will be analysed in both mammalian and mosquito cell lines. As the macro-domain is conserved in all Alphaviruses (as well as Coronaviruses and hepatitis E virus) it is highly likely that it has a functional role in the virus lifecycle, and therefore unlikely that putative inactivating mutants would enhance either replication or pathogenicity of the virus. Indeed, this statement is supported by the recent observation by our collaborator Dr Andres Merits that mutations in one of the other viral non-structural proteins, nsp2, that reduce one of its enzymatic activities (RNA helicase) result in a non-cytopathic phenotype and allow persistence of subgenomic replicons (Utt et al (2015) J. Virol. 89:3145).

We will also generate mutations in other regions of nsp3, for example the C-terminal polyproline motif which has been shown by our collaborator Prof Kalle Saksela (University of Helsinki) to interact with the SH3 domain of amphiphysin (Neuvonen et al (2011) PLoS Pathogens e1002383), again the details of how this interaction (and interactions with other cellular SH3 domains) is involved in genome replication remains elusive. The functions of nsp3 are poorly understood and we plan to complement our mutagenic studies by introducing either fluorescent (eg GFP or mCherry) or affinity (eg One-Strep or FLAG) tags into the C-terminus of nsp3 to facilitate downstream microscopic or proteomic approaches to study nsp3 function. The viability of this strategy has previously been demonstrated by other laboratories, including that of our collaborator, Dr Andres Merits (University of Tartu).

As described previously, findings from work with CHIKV will be replicated in work with SFV or SINV to provide valuable information about the processes of genome replication and pathogenesis. This will require the generation of mutations in SFV or SINV cDNA followed by expression and characterisation under Category 2 containment.

Evaluation of foreseeable effects

Cloning into bacterial vectors and growth in Escherichia coli: the E.coli strain used (DH5a) is a laboratory adapted multiple auxotroph and is unlikely to survive in the human gut (ACGM/HSE/DOE Note 7, annex 1). All plasmids will be non-mobilisable – derived from the pUC or pBluescript series. These procedures can therefore be carried out at CL2 within standard research laboratories.

Production of viral RNA: Viral RNA is transcribed in vitro using a commercial kit (Life Technologies mMessage mMachine). This procedure will generate RNA which is capped at the 5' end and will result in the generation of live virus when transfected into susceptible cells. A standard in vitro transcription produces approximately 20 ug of RNA at a concentration of approximately 100ng/ul. It is extremely unlikely that handling this material could result in uptake into susceptible cells and production of infectious virus because the naked RNA is labile and highly susceptible to degradation by serum nucleases. An additional safeguard is that there is no requirement to purify the RNA before transfection, thus limiting the downstream processing and handling. This procedure will therefore be carried out at CL2.

Transformation of viral RNA into susceptible cells: appropriate susceptible cells (see list above) will be propagated under standard tissue culture conditions at CL2 and transfected with viral RNA using reagents such as lipofectamine or FuGene or by electroporation. Transfected cells will be placed into complete media (therefore containing serum and nucleases) following treatment cells will be either transferred immediately to the CL3 laboratory for studies using DENV or CHIKV or maintained at CL2 for work with SFV or SINV. Control experiments using subgenomic replicons of CHIKV have shown that viral genome replication (as measured by detection of firefly luciferase expressed from the subgenomic RNA) is not apparent until 4 hours post transfection in either mammalian or mosquito cells and then continues to increase by 1000-fold up to 24 hours post transfection. Thus no infectious virus will be produced until after 4 hours.

Expression in mammalian or invertebrate cells: mammalian or invertebrate cell lines transfected with infectious DENV or CHIKV RNA, or infected with DENV or CHIKV, will
be confined to our CL3 facility and processed according to the Standard Operating Procedures (SOPs) for that laboratory. This SOP has been updated to reflect the use of DENV and CHIKV to account for control of insects in particular. Briefly, the lab is sealable to enable fumigation and is leak tested every 12 months. Penetration to the lab to allow inward air flow contain a course filter. The lab is in a large research building in an urban environment. The lab is not open to the outside and there are 2 doors between the corridor immediately adjacent to the lab and the outside external environment (i.e. 4 doors between work area and the outside). Therefore the potential for a vector (e.g. mosquito) entering the laboratory and moreover becoming infected with live virus is very small. However, an insect control device will be placed in the corridor outside the lab and periodically monitored to check insect activity in the area.

SINV and SFV will be used under category 2 containment. The containment labs within the Virology group is a very well established lab for the study of viruses at Containment Level 2 and work is carried out under a Faculty-based protocol which establishes requirements for the lab design and operation and is translated into local requirements by a strict SOP and supervision by academic members of staff and a Laboratory Manager. Work with SINV will additionally be carried out in a newly established laboratory in an adjoining building but procedures have been established which mirror those in place in the established virology area. The Laboratory Coordinator has indeed spent time working within the established virology lab.

Within the CL2 containment labs strict practices are enforced on users to ensure containment of infectious material and to protect users themselves from infection. Access is limited to those who are suitably trained and all new users are given an initial induction and training. All processes involving the generation of aerosols are contained within safety cabinets which are serviced and tested in accordance with COSHH requirements for Local Exhaust Ventilation. Agents are grown in specific incubators and are inactivated using suitable disinfectants. Waste is processed through the faculty autoclave system before removal by our waste contractor. University cleaning staff are forbidden from entering the area and so cleaning is carried out by users on a rota basis. Spill procedures are in operation, although volumes are kept to a minimum where possible.

Removal of samples from CL3: Samples that require CL3 containment that need to be taken out of the containment laboratory will be inactivated by detergent treatment or fixation (paraformaldehyde). The only exception to this is the temporary removal of samples for virus concentration by ultra-centrifugation. In this case, as outlined in the SOPs, virus is contained within a sealed centrifuge rotor which is only re-opened inside the safety cabinet to control aerosols. A spillage procedure is in place within the laboratory SOP. However, the cell lines containing infectious virus would be unable to survive outwith tissue culture medium and so present no risk either to the environment or to human health and safety.

It is theoretically possible for members of viral families to undergo recombination events to produce a hybrid virus. Therefore, work in the CL2 laboratory with cDNA encoding CHIKV and SINV/SFV will be kept entirely separate. Subsequently, culture of cells infected with virus will be carried out in laboratories that are several floors apart where strict containment procedures are in place. This spatial separation will exclude any possibility of recombination.

Generation of mutant viruses: as discussed above any GMO generated by mutagenesis would most likely be less harmful than the wildtype viruses from which they were derived. Although it is formally possible that some mutations might enhance in vitro infectivity, as all viruses are treated as potentially infectious and handled at CL2 or 3 respectively, the resulting standard safety protocols will ensure that any viruses with enhanced infectivity will not represent an increased risk.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

For in vitro transcription of viral RNA and initial transfection into mammalian or invertebrate cells we are seeking to undertake this element of the work at Containment Level 2.

This is in line with the SOP (attached) for the CL3 facility – these have been reviewed recently by an HSE Biological Agents Specialist Inspector. Transfected cells will be immediately transferred to the CL3 facility.

Previous control experiments using subgenomic replicons have shown that virus genome replication cannot be detected before 4 hours post transfection and therefore no
infectious virus can be produced until this time at the earliest. As discussed previously, a revalidation experiment will be conducted once approval is granted – cells transfected with full length virus genomes will be transferred to the CL3 facility and sampled at 1 hour intervals for virus titration to demonstrate that virus is not detectable within the first four hours of transfection.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

For work at Containment Level 3:
Routine waste disposal: Both DENV and CHIKV are susceptible to a wide range of disinfectants as well as moist heat.
Liquid waste will be treated with an equal volume of 2% Virkon and left overnight before disposal down the drain with copious water.

Solid waste (culture or cells) will be autoclaved at a minimum of 121°C (load temperature) for 15 minutes within the CL3 laboratory before being processed again in the Faculty autoclave waste system and discharged from the Faculty as Healthcare Waste (Contractor is GW Bulter, Bradford).

Emergency spill procedure:
The CL3 laboratory SOP has detailed systems for spillages. The laboratory can be made ready for fumigation within a few minutes in the event of a spill outside of a safety cabinet and an emergency egress procedure is in place.

For work at Containment Level 2:
The Faculty of Biological Sciences has documented standard procedures for working with ACDP Hazard Group 2 materials. This stipulates that local procedures must be in place to deal with the waste generated by a particular project.

Briefly, the following procedures are in place.
All solid waste (e.g. plastic-ware, tubes, tips and gloves) from Category 2 projects is collected in autoclave bags which are packed into tins with a close fitting lid. These are collected from labs by a waste processing technician and taken to a dedicated facility for treatment. The waste discard autoclaves undergo regular servicing and validation using the 12-point thermocouple test to ensure a holding temperature of 121°C for 20 minutes to achieve a suitable kill.

Liquid cultures are treated with a suitable disinfectant (e.g. 2% final volume Virkon) and left in situ (such as in a tissue culture hood) for at least 30 minutes before disposal to the drain.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Comments attached and highlighted.

Page 9882 of 15326
The aim of the project will be to analyse the interactions of arthropod-borne viruses (so-called arboviruses) with the mammalian immune system. As model systems, we study positive-stranded RNA viruses of the Togaviridae (genus Alphavirus), and Flaviviridae families, and negative-stranded RNA viruses of the Bunyaviridae. These viruses include; Semliki Forest virus (SFV), Ross River virus (RRV), o’nyong-nyong virus (ONNV); Bunyamwera virus (BUNV), Schmallenberg virus (SBV); and the Langat virus (LGTV). We also plan to use replicons derived from these viruses or related alpha- and flaviviruses. The response to virus infection by mammalian immune responses will be studied by infecting mice (including genetically modified mice). The use of genetically modified mice will enable hypothesis testing and will provide an important route by which mechanisms of disease can be determined. The project covered by this notification will use cell lines derived from vertebrates and arthropods (e.g. mosquitoes) as well as mice (including genetically modified mice).
systems are commonly used at ADCP level 1, but to avoid confusion we will use all material, both replicons and viruses as if they are all ADCP2. See below for a full description of these systems and further justification for the use ADCP level 2. The use of replicons is also discussed in section 3.2.

The following models will be used in these studies:

**Arboviruses and derived replicons used will be of the Flaviviridae, Bunyaviridae and Togaviridae (genus Alphavirus) virus families.**

**Model for Togaviridae:**
- Semliki Forest virus prototype (SFV4), SFV6, A7 and A7(74) strains.
- Semliki Forest virus-derived replicons and virus-replicon particles.
- O’nyong-nyong virus (ONNV).
- Ross River virus (RRV).

**Other arthropod-borne alphavirus replicons.**

**Model for Flaviviridae:**
- Langat virus (strain TP21, the most commonly used lab strain, or others).
- Langat virus-derived replicons.
- Other arthropod-borne flavivirus replicons (for example derived from tick-borne encephalitis virus or dengue virus).

**Model for Bunyaviridae:**
- Bunyamwera virus (genus Orthobunyavirus), and derived recombinant viruses.
- Schmallenberg virus (genus Orthobunyavirus), and derived recombinant viruses.

**Health hazards associated with virus and replicon infection**

**SFV:**
In Africa, natural infections have been associated with mild febrile illness (Mathiot et al., 1990). Various laboratory strains of SFV including prototype-SFV4, L10, A7 and A7(74) have been used extensively in many laboratories and even (in the past) for student practical classes. There is one report of laboratory based human disease. Death of a laboratory worker in Germany was associated with infection by the Osterrieth strain of SFV (Willems et al., 1979). This (Osterrieth) strain of SFV is no longer used experimentally. Whilst the above case report is noted, it dates back over 30 years and is difficult to reconcile with the extensive use of other strains of SFV with no reported adverse effects over a 50-year period. This case report makes the unpublished observation that antibodies against SFV can be demonstrated in the serum of many laboratory personnel working with it. It is generally considered that the individual who died was probably immunosuppressed and therefore highly susceptible to infection. Anecdotal reports and reported laboratory incidents indicate no human clinical signs after accidental inoculation with various laboratory strains of SFV. The classification into ACDP hazard group 2 indicates current expert opinion that containment level 2 precautions are considered adequate for controlling the risks associated with working with SFV.

**ONNV:**
This virus is classified as ACDP hazard group 2. In endemic areas of Africa, Anopheles species mosquitoes spread ONNV. Outbreaks of this virus are infrequent, although they can be large in scale (Uganda 1959-1962, spreading to Tanzania and Zaire; Uganda 1996-1997). Person to person transmission is not documented and by 1980 only two laboratory-acquired infections had been described. Symptoms include polyarthritis, rash and fever, occasionally eye pain, chest pain, lymphadenitis and lethargy. No fatalities have been recorded, and three strains of the virus are known (Braault et al, 2004).

**RRV:**
Although classified as an ADCP group 2 pathogen, there have been continuing outbreaks of infection in Australia that have caused disease in humans. RRV is spread to humans by infected Aedes aegypti mosquitoes and can cause a febrile illness. In some cases virus disseminates to the joints where it causes arthralgia. Symptoms can include polyarthritis, rash and fever, occasionally eye pain and lethargy. No fatalities have been recorded (Jacups et al., 2008).

**LGTV:**
LGTV is a tick-borne flavivirus of the Flaviviridae family. It was first isolated from Ixodes granulatus ticks in 1956 in Malaysia (Smith, 1956). The natural transmission cycle
of the virus is believed to involve rats in areas such as Thailand, Malaysia and Russia. LGTV can cause encephalitis in experimentally infected mice (Webb et al., 1968) but is not very neuroinvasive compared to other more virulent members of the tick-borne flavivirus group (Thind & Price, 1966) and is considered the non-pathogenic member of the Tick-borne encephalitis complex. Indeed, under normal conditions LGTV is only very rarely pathogenic to humans. The naturally attenuated Malaysian strain TP21 (the most common laboratory strain), is not associated with human disease (Rumyantsev et al., 2006) and LGTV has been used as a live attenuated vaccine in humans (Dubov et al., 1972). Development of this vaccine was stopped in the 1980s because of rare (1 in 20,000) occurrences of post-vaccinal neurological disease (Rumyantsev et al., 2006). LGTV is not listed on the ACDP list but should be classified as hazard group 2 (current use in the UK and internationally, see http://www.healthsafe.uab.edu/pages/biosafety/biosafetymanual.pdf)

BUNV:
Bunyamwera virus (BUNV) is the prototype virus of the family. Originally isolated in Uganda from infected mosquitoes, most of our understanding of bunyavirus biology is due to studies on this model bunyavirus (Elliott, 1989). Infection with this virus can cause a febrile illness with headache, arthralgias, rash and infrequent central nervous system involvement (Gonzalez and Georges, 1988). The classification into ACDP hazard group 2 indicates current expert opinion that containment level 2 precautions are considered adequate for controlling the risks associated with working with BUNV.

SBV:
This an animal pathogen that is widely distributed in Northern Europe (Gibbens, 2012), including the UK, and not likely to be a risk to human health by current guidelines (http://ecdc.europa.eu/en/publications/Publications/Forms/ECDC_DispForm.aspx?ID=795).
SBV was recently isolated from cattle in Germany and leads to disease (fever, diarrhoea, malformations, abortion) in cattle and sheep. SBV is not listed on the ACDP or SAPO list but has been recommended to be classified as hazard group animal pathogen 2. We propose to treat SBV like BUNV in terms of risk for human infections and health unless other regulation is in place for a particular pathogen. In addition, advice will be given to lab personnel that they should not be in contact with susceptible animals or visit farms/zoos where they could potentially come into contact with susceptible species for a period of 48 hours following work with SBV.

Genetic modification of all these viruses as proposed here (e.g. addition of reporter genes) is highly unlikely to add or increase the risk to human health. The viral envelope glycoproteins and capsid protein sequences are the major determinants of host range and cell tropism will not be changed beyond the addition of marker genes such as GFP (as fusion or cleavable inserts into this coding region) into the structural open reading frame; host range and cell tropism are therefore unlikely to be altered.

Personnel working with these viruses must be registered with Occupational Health and are expected to inform Occupational Heath should they become pregnant or immunosuppressed.

Virus-derived replicons and virus-like particles
In addition to infection with virus, it is possible to use virus-derived replicons (VRPs). The system exploits the wide cell tropism of e.g. SFV, but has no potential for virulence since genes for the viral structural proteins are prevented from being incorporated into new virus, or are simply deleted and replaced with marker genes e.g. GFP. This system is deemed extremely safe and can be used at ADCP2 level containment (Smerdou and Liljestrom, 1999). In VRPs, the structural genes can be replaced by a polylinker which allows insertion of foreign sequences. In the absence of genes encoding the viral structural proteins in replicons, new infectious virus particles capable of initiating a propagating infection cannot be regenerated in VRP-infected cells; VRPs are thus also referred to as ‘suicide particles’. Replicons can be used to express reporter genes or other genes of interest. See Atkins et al 2008 for a recent review of Alphavirus vectors and their replicons.
VRPs can be generated by transfecting host mammalian cells with either two, or potentially three, distinct plasmids. Each plasmid contains a different section of the viral genome. These additional plasmids are referred to as helper plasmids. Most commonly one plasmid will express the replicase genes, whilst the second and third will express either structural genes or a foreign gene that has been inserted. Transfection and translation of these plasmids results in the production of ‘suicide’ VRPs that are able to infect susceptible cells, but are limited to only one round of multiplication because they lack the viral structural protein genes that have been supplied by the helper plasmids (Atkins et al, 2008). This system has been specially engineered to prevent the possibility of plasmid recombination and has been well tested. This includes the use of two helper plasmids to decrease the probability of a successful recombination, and the inclusion of a mutated capsid protein cleavage site e.g. in SFV, that in the unlikely event of recombination would result in a defective virus.
In addition, we plan to carry out comparative studies with arthropod-borne alphavirus replicons such as those derived from chikungunya virus; those replicons are not covered by schedule 5 and no sequences for the complete genome (i.e. sequences that encode structural genes that complement the viral protein set to potentially give infectious virions) will be stored in-house. Those replicons will not be packaged into VRPs, only RNA will be introduced into cells to study replication; replicons will not be mixed in the same cells (either by co-infection/transfection, or by superinfecting spreading virus) with related viruses from within the same genus to avoid recombination events during co-infection.

Host/vector system

Plasmid vectors and bacteria:
All viruses and plasmids will be sourced from Dr Alain Kohl (Centre for Virus Research, University of Glasgow), Prof John Fazakerley (Pirbright Institute) and Prof Andres Merits (University of Tartu). Viral sequences (including full length clones or partial sequences of SFV, ONNV, RRV, LGTV, BUNV and SBV) and other genes (cellular, viral or reporter) are available in plasmid-encoded cDNA form. Plasmid vectors are based on bacterial plasmids and contain an origin of replication for prokaryotic cells and selectable antibiotic/drug resistance (pro- or eukaryotic) markers (Atkins et al 2008).

By themselves these vectors present no risk to human health. Plasmid vectors have no selective advantage and would soon be lost from the bacterial population. The bacterial systems are non-mobilisable vectors in a disabled prokaryotic host. Transcription of even complete viral cDNA will result in no infectious RNA since the promoters are not active in prokaryotic hosts. Systems for prokaryotic gene expression are under control of an inducible prokaryotic promoter. Systems for eukaryotic RNA or protein expression are under the control of promoters of viral (such as CMV or SV40), eukaryotic (eg actin promoter, pathway inducible promoter such as STAT) or prokaryotic (such as T7 or SP6 promoter for in vitro transcription) origin. Plasmids with eukaryotic promoters such as the CMV promoter can be transcribed in human and rodent cells. None of the genes used in these studies are oncogenes. The hazard of expressing ‘foreign’ genes from these eukaryotic promoter plasmids would depend on the expected physiological effects of the foreign gene product and is discussed in more detail below.

Hosts

Prokaryotic organisms: All strains will be disabled, commercially available E. coli derivatives classified as ‘especially disabled hosts’ by ACDP. These strains cannot colonise humans and are known not to cause harm to humans.

Eukaryotic cells: Cell lines to be used would not survive inside the human body (immune rejection) and are not known to carry harmful pathogens. Addition of DNA or RNA will confer no growth or survival advantage in or outside the laboratory to cell lines of vertebrate or arthropod origin.

Mice (including genetically modified mice): These will be sourced from commercial suppliers (Charles River and Harlan) and collaborators. Mice (including genetically modified mice) will be housed and handled in designated areas approved by Biomedical Services and the Home office. Upon infection with viruses, mice will be housed in filter cages that keep the mice in a sealed environment. Work with virus replicons and VRPs will be done under the same procedures and containment as work with infectious virus (wild type or genetically modified). Mice act as dead-end hosts and cannot actively infect humans, although biting arthropods that take a blood meal from a viraemic mouse can theoretically become infected. Measures to prevent human or accidental arthropod infection include; use of filter cages to house infected mice; work in designated rooms with restricted access; and wearing of gloves. Once housed at biomedical services in filter cages, an encounter with a biting arthropod is highly unlikely. Live mice and samples (dead mice or material from these) will be transported to biomedical services or our CL2 laboratory according to standard regulations.

Animal work utilising class 2 organisms will be carried out following established, approved level 2 protocols at SBS

The use of genetically modified mice does not pose any additional risks to human health above and beyond that associated with infection of non-genetically modified mice

Origin & function

Sequences to be inserted into arboviruses genomes:

Genes: Reporter genes of prokaryotic or eukaryotic origin (e.g. luciferase, fluorescent proteins etc.) and antigenic peptides e.g. ovalbumin (OVA).

Non-coding RNA sequences: non-viral RNA (e.g. mammalian miRNA recognition elements), or viral RNA sequences (e.g. flavivirus 3' untranslated regions) to study
mechanisms of roles of non-coding sequences in replicative processes, immune responses and dissemination of virus in vivo.

Sequence changes in viral sequences: These (through mutation or deletion) will target disruption of non-structural protein functions or non-coding viral sequences.

All of these sequences have no inherent hazard and it is very unlikely that these RNA or proteins would have any harmful toxin-like effect outside cells.

Evaluation of foreseeable effects

Hazard associated with receiving genetic material

Reporter genes: No harmful properties have been attributed to reporter genes of prokaryotic or eukaryotic origin (e.g. luciferase, fluorescent proteins etc.). There would be no altered physiology expected if any of these genes were expressed; eGFP for example is a spontaneously fluorescent protein isolated from Aequorea victoria a coelenterate and has no known detrimental effects. Luciferase is another commonly used reporter gene and is derived from the firefly Photinus pyralis or the jellyfish Renilla reniformis. It is an enzyme which catalyses production of light from luciferin and ATP; the light produced is used as a measure of gene activity. The enzyme has no other biological function.

Antigenic peptides: Most individually expressed proteins (e.g. OVA) are unlikely to have harmful effects in eukaryotic cells, however some could perturb cellular metabolism, predispose or protect against cell death or render cells more or less susceptible to other infections.

Non-coding, non-viral RNA sequences: Individually expressed RNA sequences to be used as described are unlikely to pose a risk. They may suppress gene function or have effect on replication in individual cells but are unlikely to lead to whole body physiological effects in humans as they do not code for the production of secreted bioactive molecules. Viral non-coding RNA sequences too are likely to have minimal effects on virus replication, and do not encode biologically active molecules that are likely to induce physiological effects in humans.

Sequence changes in viral sequences: Mutation or deletion will target disruption of non-structural protein functions or non-coding viral sequences are likely to have no or deleterious effects on viral replication. Thus there is no increased risk or hazards associated with viruses modified as described.

Genetic changes that will be introduced into the virus sequences will be targeted at disrupting or changing specific functions of virus RNA or virus proteins and can be expected to attenuate virus fitness; such changes are highly unlikely to increase virus virulence as they modify virus sequences, or change genome length, or lead to expression of additional sequences such as reporter genes which confer no advantage to virus replication. The viral glycoprotein amino acid sequences that are the major determinants of host range and cell tropism will not be changed beyond the addition of marker genes as fusion or cleavable markers.

In summary, genetic changes that will be introduced into the arbovirus nucleic acid sequences as described above can be expected to attenuate virus fitness; such changes are highly unlikely to increase virus virulence as they modify virus sequences (which are optimized for replication), or change genome length, or lead to expression of additional sequences such as reporter genes which confer no advantage to virus replication.
This work does not alter the overall risk to workers and/or the environment in our laboratory since:

- Work will only be carried out in laboratory facilities meeting requirements for containment level 2
- All work is managed to comply with the requirements for containment level 2
- Standard operating procedures for this type of work are in place in LICAP (see attached). These are the minimum requirement within the Institutes: local rules may be more stringent.
- Animal experiments are conducted in a highly regulated and well established level 2 animal facility.
- The scope of the notified activity is restricted to the connected buildings Wellcome Trust Brenner Building, Clinical Sciences Building, Cancer Research Building and Robert Ogden Building on the University of Leeds St James’s University Hospital site.

Projects that will be specifically excluded from this system of work will be those for which the risk to worker and/or the environment is increased over that posed by the work outlined here.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**Work with infected mice:**

- The SBS animal unit is relatively new (extensive refurb completed 2007) and is built to a high standard, with all animal holding or procedure rooms meeting the requirements for containment level 2 (although the vast majority of work is level 1).
- Mice are housed in independently ventilated cages (IVC’s) which are HEPA filtered to prevent movement of particles (including viruses) between IVC’s.
- Infected mice are further isolated from uninfected mice in a quarantine/holding room that is physically isolated from other animal holding rooms.
- Routine husbandry with infected mice outside of IVC’s (e.g. cage changing) is carried out in Class 2 cage change cabinets.
- All task are assessed and animal workers follow standard operating procedures which are designed to maintain consistency and minimise risk.
- Animal workers receive specific training and are supervised until such a time that they are identified as competent.

### Waste disposal

In addition to standard default procedures described below:

- **Liquids** (e.g. samples, culture supernatants, tissue culture media) – add Virkon or other validated disinfectant to final concentration of 1% (w/v) for a minimum of 12 hours, then discharge to drains.
- **Liquids** (E. coli culture medium) - add Virkon to final concentration of 1% (w/v) for a minimum of 12 h, then discharge to drains.
- **Sharps** (in sharps bin, e.g. needles, syringes, scalpels) – autoclave by using a make safe cycle of 121°C for a minimum of 15 minutes.
- **Mouse cadavers, tissue samples and other solids** will be disposed of by Biomedical services.
- **Mouse cadavers** are bagged, and frozen (-20degC) before collection for incineration.
- **Tissue samples and other solids waste samples** will be placed in sealed autoclave bags, disposed of by autoclaving using a make safe cycle of 121-123°C for a minimum of 15 minutes and then incinerated.

**Degree of kill:**

Chemical Sterilization by Virkon, or other validated disinfectant - effectively 100% kill.

Autoclaving - effectively 100% kill (annual validation)

02/03/2022
Comments from the local Biological Safety Committee (20/07/2015)

- McKimmie Project: the Committee discussed the form submitted and various points were raised, as follows:
  - Information provided needs to be expanded.
  - Animal work will require a project license – discussions should take place with [the unit manager] in SBS.
  - It is important to provide more details on the vectors being used.
  - Line management details need to be amended on the form.
  - Section 5 should be completed.
  - Some of the viruses [Dengue replicon] involved will attract the attention of counter terrorism and therefore notification needs to be made to the CTSA.

It was agreed that the form should be circulated to the Committee after amendments have been made.

[The committee agreed the classification of the project, Class 2, and that notification to the HSE should be made once the above points had been addressed].

Project Additional Information

Purposes of the contained use

The principle aim of this project is to study Bunyamwera virus (BUNV) inside infected host cells as it progresses through its replication cycle.

BUNV is the prototypic member of the Bunyaviridae family, which comprises over 300 related viruses that infect a broad range of hosts including humans, animals, insects and plants. Several of these viruses are classified by ACDP as hazard level 3 and 4 pathogens, however BUNV is classified as a hazard level 2 pathogen.

BUNV is known to share many fundamental aspects of its molecular and cellular biology with other Bunyaviridae family members, and thus is a well-established model system with which to study the more dangerous pathogens within the family. The BUNV genome comprises three strands of negative sense RNA, which each encode a single mRNA that are translated to yield a total of 6 proteins. Four of these are structural proteins that are found in the virus particle, namely N, L, Gn and Gc, whereas NSs and NSm proteins are non-structural and are only present within the cytosol of the infected cell. These six virus proteins are also expressed by most other bunyaviruses.

Very little is known about how BUNV and other related bunyaviruses gain entry into cells and then alter the host cell environment to favour their own multiplication. Being able to visualize individual virus particles as well as sub-viral components will provide us a tool kit with which to dissect many virus activities that together make up the replication cycle. A better understanding of these processes will aid in the development of anti-viral therapies to prevent bunyavirus-mediated human and animal disease.

This project focuses on BUNV for three reasons:
1) highly-efficient 'reverse-genetics' systems are currently available for rescue of infectious wild-type BUNV from cDNAs, which also permits the site-specific manipulation of the BUNV RNA genome, described below;
2) BUNV replication cycle is the best characterised of any bunyavirus and many reagents are already available that will facilitate our studies;
3) BUNV is a hazard level 2 pathogen, which allows the manipulation of its genome and subsequent analysis within the relatively amenable confines of containment level 2 facilities.

Similar 'reverse genetics' systems have also recently become available for the manipulation of two other hazard group 2 bunyaviruses, namely Uukuniemi virus (UUKV; Rezelj et al, 2015, J. Virol. 89(9) 4849-4856) and Hazara virus (HAZV; unpublished). We are aiming to generate modified viruses based on these and other hazard level 2 bunyaviruses in order to better understand the replication cycle of the Bunyaviridae family as a whole.

Therefore, our work will be restricted to the modification of members of the Bunyaviridae family which:
• are classified as hazard level 2 pathogens (i.e. able to infect humans)
• are not identified by DEFRA as a specified animal pathogen
• and specifically no work will be performed on viruses classified as ACDP hazard level 3 or 4 pathogens.

One of the key methodologies we will be using to study bunyaviruses replication in live cells will be to generate infectious viruses that have been modified such that their proteins or genomes are appended to fluorescent molecules that can be detected using confocal microscopy. These fluorescent molecules can be incorporated into the virus in one of three ways:
1. by genetically altering the open reading frames (ORFs) of viral proteins to include the ORF of a fluorescent protein such as eGFP, or one of its derivatives.
2. by incorporating a specific amino acid sequence into a viral protein ORF that has high affinity for a fluorescent molecule, which can be introduced into the infected cell.
3. by altering a non-translated region of the bunyavirus genome to incorporate RNA structures that have high affinity for a fluorescent molecule, as above, that can be introduced into the infected cell.

In addition to adding heterologous sequences, we will also be modifying sequences within the bunyavirus genome by deleting or altering nucleotides within regions of
defined functions.

All of these genetic manipulations will involve site-specific modification of the bunyavirus RNA genome, and this is achieved by first manipulating corresponding plasmid DNAs that encode its genome. This will be achieved according to procedures described in relevant publications. For BUNV these are Bridgen and Elliott, 1996, PNAS 93(26) 15400-4; Lowen et al, 2004, Virology, 330(2) 493-500, and for UUKV these are (Rezelj et al, 2015, J. Virol. 89(9) 4849-4856).

Procedures for HAZV are currently unpublished, but follow the same general principles as the BUNV systems. The basis for these systems is a set of cDNA plasmids that encode the virus genome. As the bunyavirus genome is separated into three individual RNA strands called segments, the complete BUNV genome can be encoded by three separate plasmids. These plasmids are designed such that they possess promoter sequences that drive transcription of the viral RNAs using a variety of DNA-dependant RNA polymerases, and popular choices include bacteriophage T7 RNA polymerase (T7-pol), and cellular DNA polymerase I (Pol-I). The three plasmids are transfected into cells in culture that express T7-pol or Pol-I, and the viral genome is transcribed. If additional plasmids expressing virus structural proteins N, L, Gn and Gc are also supplied to these cells, infectious virus particles can form, which are independent of further plasmid-derived components. These viruses can then be purified and used to infect further cells for the intended analysis.

Recipient or parental organism

The recipients of the genetically modified virus will be mammalian or insect cells. These will be continuous cells lines such as A549, BHK, SW13, Vero or C6-36. There are no hazards currently associated with these cell types. These cells do not belong to a hazard group.

Host/vector system

The vector will be the bunyavirus genome, primarily BUNV, UUKV or HAZV. All modifications to the bunyavirus genome will be designed using high-resolution structural models of viral proteins or their homologues (eg. Ariza et al, 2013, Nucleic Acids Research, 41(11) 5912-26; Gerlach et al, 2015, Cell, 161(6) 1267-79), or previous functional analysis of cis- and trans-acting viral components (reviewed in: Walter and Barr, 2011, J. Gen. Virol, 92(11) 2467-84). In addition to constructing new recombinant viruses, we also have access to a variety of previously generated genetically modified BUNV variants from the laboratory of Professor Richard Elliott. One of these possesses a V5 epitope within the L ORF (Shi et al 2009, J. Gen. Virol, 90(2) 297-306), and the other expresses a modified version of Gc, which is fused to either eGFP or mCherry (Shi et al, 2010, J. Virol, 84(17) 8470-9).

The growth characteristics of these viruses have been characterised, which revealed they all exhibited approximately 100-fold reduced virus titres compared to the wild-type. This is not surprising given that RNA viruses such as BUNV are able to rapidly evolve in order to perform their replication cycles with optimal efficiency; extraneous and non-advantageous protein or RNA-encoding elements reduce this efficiency, and have not been documented to enhance virus growth. Consequently, we anticipate that all modifications we make to the genome of BUNV, or other bunyaviruses, will either result in a reduced or unchanged virus growth and infectivity.

BUNV, UUKV and HAZV are arthropod-borne pathogens classified by ACDP within hazard level 2. The principle arthropod hosts of BUNV are midges of the Culicoides species, whereas both UUK and HAZV are associated with ticks of the Ixodes species. These viruses can be transmitted to humans by the bite from an infected arthropod host.

Infected domestic mammals can sustain a viremia, and exhibit neurological symptoms (Chung et al, 1990, Vet. Micro, 21, 297-307). No definitive association between BUNV, UUK or HAZV infection and human disease has been made. In the case of BUNV, closely related viruses within the Bunyamwera serogroup, such as Cache Valley virus, have been linked to a febrile illness that is known collectively as Bunyamwera fever (Tauro et al, 2012, J. Clin Virol, 54, 98-99).

Origin & function

The genetic material involved has several sources. As described above, various genetic modifications to the bunyavirus genome will be made, most of which will comprise sequence insertions. One of these inserted sequences will be the gene encoding enhanced green fluorescent protein (eGFP) derived from the jellyfish Aequorea Victoria. Another will be the TR sequence derived from bacteriophage MS2, as well as the translational operator sequence from bacteriophage PP7, both of which binds their respective viral coat proteins. Other inserted sequences we may use include V5 and FLAG epitopes, tetracysteine motifs, or ACP and MCP-tags that are based on the E. coli Acyl Carrier Protein. It is highly likely that other molecules with more favourable characteristics will in future supersede these sequences and associated ligands, and if
so we will adopt the best possible system for our intended applications.

**Evaluation of foreseeable effects**

The insertion of eGFP ORF and V5 epitope sequences into the BUNV genome is known to attenuate virus growth by approximately 100-fold, as described in the previously cited references (Shi et al 2009, J. Gen. Virol, 90(2) 297-306; Shi et al, 2010, J. Virol, 84(17) 8470-9). Similarly, we predict that all other nucleotide insertions that we make to the BUNV, UUKV or HAZV genomes will reduce or have no effect on resultant virus growth and infectivity compared to the unmodified parental wild-type virus.

In addition, the titre of released altered virus will be lower than wild-type due to its reduced growth characteristics, which further reduces potential harm.

Transfer of the transgenes to other genetic systems is extremely unlikely. Bunyaviruses possess a negative sense RNA genome, and such viruses are widely regarded as being resistant to recombination with other nucleic acid sources within cells. Furthermore, as described above, no adverse consequences of inserts such as eGFP expression have been identified, and so even if transfer did occur, no risk is currently associated.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

No application is sought

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Treatment of bunyavirus containing liquid waste fluids will be performed under the Faculty of Biological Sciences SOP for CL-2 waste treatment, which are summarized as follows:

Bunyavirus-infected liquids from cell culture flasks and plates will be aspirated using both vacuum lines and manual pipettes. All liquid handling procedures involving infectious virus will be performed inside a biological containment cabinet to prevent risk of aerosolized virus spread outside the work area. All aspirated liquids containing virus will be immediately treated with 2% virkon, and incubated overnight to allow complete virus killing.

Plastic ware exposed to bunyaviruses, including pipette tips, plastic universal bottles, cell culture flasks and plates, will be treated with 2% virkon, and incubated overnight. Following this treatment, plastic ware will be autoclaved to ensure complete virus killing.

Infected cells and cell lysates required for further analysis are rendered non-infectious by denaturation by detergents of chaotropic agents prior to removal from laminar flow hoods within the CL-2 containment facility.

All surfaces potentially in contact with virus-containing droplets and aerosols are decontaminated by contact with 2% virkon and, where possible, UV treatment for 30 minutes.

**Is an emergency plan required according to regulation 20?**

Yes

**If yes, tick to confirm that it is attached to this form**

Yes

**Tick to confirm that you have attached a risk assessment to this form**

Yes

**Tick if you are claiming exemption from disclosure for section of the risk assessment**

No
The attached version of the risk assessment form was passed by the local safety committee of the Faculty of Biological Sciences, University of Leeds.

### Project Additional Information

**Purposes of the contained use**

The aim of this project is to gain a deeper understanding of how individual herpesvirus-encoded proteins enhance virus replication and also how they modulate host cellular processes to produce an environment conducive for virus replication.

To investigate the role of herpesvirus-encoded proteins we will compare the molecular and cellular biology of wild type viruses with genetically modified virus recombinants.
which lack herpesvirus-encoded proteins or contain site-directed mutations with specific regions of the herpesviral proteins. We aim to assess the contribution of each herpesvirus-encoded protein on virus replication using various techniques such as:

- qRT-PCR to assess virus gene expression,
- qPCR to assess viral DNA load,
- immunoblotting to assess viral protein production
- western blotting for virus structural proteins

Other laboratory techniques will be used to examine genomes and proteomes.

We will be exploring how herpesvirus-encoded proteins manipulate cellular processes to produce a cellular environment to enhance their own replication. These host cell pathways include cell signalling, cell proliferation and transformation, immune evasion and intracellular trafficking. We will examine how virus-encoded proteins, which function in regulating viral gene expression and genome replication, affect these cellular pathways using various techniques such as high-throughput Next Generation Sequencing (NGS) and quantitative proteomic approaches to analyse changes in host cell gene expression profiles and protein expression levels in response to virus infection (both wild type and genetically modified members of the Herpesviridae family).

Analysis will be performed on various Hazard Group 2 members of the 3 sub-families of Herpesviridae, which are:

- Alpha-herpesvirinae (e.g. Herpes Simplex Virus type I)
- Beta-herpesvirinae (e.g. Human cytomegalovirus, Human Herpesvirus 6 etc.)
- Gamma-herpesvirinae herpesviruses (e.g. Epstein Barr virus, Kaposi's sarcoma-associated herpesvirus, etc).

For these studies we will engineer genetically modified herpesvirus recombinants which lack specific herpesvirus-encoded proteins or contain site-directed mutations with specific functional regions of the viral proteins.

Recipient or parental organism

Recipients of both wild type and genetically modified members of the Herpesviridae family of viruses will be various mammalian cell types. These will either be from continuous cell lines such as Vero, HEK 293, HEK293T, or alternatively commercially sourced primary cells derived from kidney, skin, blood or endothelial tissue. These require specialised culture conditions and growth supplements, and these are not readily available outside of the laboratory. Therefore, accidental release of the recipient will pose no significant threat to the environment.

Infected cells do release infectious virus particles, although the titre of virus from these cells is low (Virus titres of <1x10^8 pfu/ml are expected). Any released viruses will be contained within the nutrient media that covers the cells, and thus will not be released as droplets. Cross infection of cells contained within an incubator is has been considered, but is unlikely due to the presence of liquid media covering all cells, and the use of filter-lidded cell culture flasks. Any laboratory procedures that may cause droplets or aerosol generation (such as use of vortex or pipette) will be performed inside a safety cabinet to prevent risk of infection. Following use or spillage of media containing herpesviruses, all surfaces will be decontaminated with both 2% virkon washing and where possible, exposure to UV light.

In addition, cloning will be performed in the E. coli laboratory strains such as DH5α; which are non-pathogenic disabled bacterial hosts that cannot survive in the human gut, belonging to hazard group 1.

Host/vector system

Vectors will be various Herpesviridae member genomes representing the three sub-families, such as:

- Herpes Simplex Virus type 1 (HSV-1);
- Human Cytomegalovirus (hCMV);
- Human Herpesvirus 6 (HHV-6A);
- Epstein Barr Virus (EBV);
- Kaposi's sarcoma-associated herpesvirus (KSHV).

Modifications will be performed on the viral genome prior to infection of host mammalian cell lines. Genetic modifications that will be used include the deletion or site-directed mutation of specific regions of the viral genome to enable studies of the interaction between viral proteins and host cell proteins.
Mutations to be generated are intended to disrupt the function of viral proteins and in the majority of cases are therefore likely to reduce the effectiveness of the virus to replicate.

The deletion of herpesvirus non-structural genes results in attenuation of virus growth in cell culture systems. Moreover, mutation of non-structural encoded viral proteins will not affect host or tissue tropism of modified viruses. In addition the titre of released altered virus will be lower than wild type due to its reduced growth characteristics. Similarly, smaller deletions and site-directed modifications within non-structural proteins will also reduce its function, and so will also be predicted to result in reduced growth and disease compared to the unmodified viruses. Taken together, these data strongly suggest the resulting virus bearing deletions and other modified viruses would be less harmful to humans than the wild type.

Knock outs or deletions in those genes involved with viral latency may cause an increase in pathogenicity of herpesviruses, for example deletion of the latency-associated nuclear antigen (in Kaposi's sarcoma-associated herpesvirus) leads to an increase in viral titre (https://www.ncbi.nlm.nih.gov/pmc/articles/PMC2626151/). Increase in viral titre is an expected outcome following this type of modification as cells will no longer be able to harbour latent viruses and instead all virus infected cells will produce virus particles (this effect is also seen when treating infected cells with sodium butyrate). In terms of risk, this is seen as a slight increase in overall risk, but still falls within the requirements for hazard group 2 categorisation. Controls identified for working at containment level 2 are sufficient to mitigate the small increase in risk.

Deletions or modifications to structural genes are expected to result in reduced viral viability and infectivity.

Origin & function

The various genetic modifications to members of Herpesviridae family genomes will be made, mostly comprising mutations to disrupt the function of viral proteins. Genetic modifications that will be used include the deletion or site-directed mutation of specific regions of the viral genome to enable studies of the interaction between viral proteins and host cell proteins. These will focus on non-structural encoded viral proteins which will not affect host or tissue tropism of modified viruses, specifically non-structural proteins which function in regulating viral gene expression and genome replication.

Evaluation of foreseeable effects

Herpesviruses are spread by close contact, saliva or a sexual route. Therefore, potential routes of transmission include inoculation by sharps, contact with open wounds and exposure to droplets. Local rules of Category II work preclude the use of sharps and the compulsory wearing of gloves, and protection of droplets will be controlled by the use of a Class II biological safety cabinet. Furthermore, infection which subsequently results in clinical disease is more unlikely, firstly because the human immune system restricts the ability of the herpesvirus to generate a lytic infection; herpesviruses establish a persistent, latent infection and secondly because a high percentage of the population is seropositive for these human herpesviruses and so a second exposure to a seropositive individual is not likely to establish a persistent infection.

However, a key hazard that will be addressed through procedures associated with the work is the risk of infection in immunocompromised individuals. Staff, students or lab visitors (including contractors and cleaners) who have an immunocompromised condition (e.g. HIV or treatment with immunosuppressive drugs) are no less likely to be seropositive from an early age than an immunocompetent individual and so are vulnerable to viral reactivation that is independent of exposures through research activity. However, a primary infection stemming from research samples may trigger a lytic infection which leads to disease. Such individuals will therefore be managed under a specific risk assessment.

The Herpesviridae family cause a range of diseases, which in the vast majority of cases are mild (e.g. HSV-1 causing localised lesions). In rare cases members of the Herpesviridae can cause significant infections, potentially with severe consequences for the infected individual (e.g. CMV linked to Guillain–Barré syndrome). These extreme cases are very rare and often arise as a result of the immune system being compromised. People involved with work on herpesviruses undergo University Occupational Health screening, and are asked to inform the University if they become aware that their immune status has changed (i.e. that they are immunocompromised).

A potential hazard associated with contained use of these viruses is accidental release outside of the containment facility. However, infection of persons either through entering the containment facility or by contact with infectious material (e.g. waste being removed from the lab) is unlikely.

Some members of the Herpesviridae family, Gamma-herpesviruses, are specifically known to be oncogenic (e.g. EBV and KSHV), and in general members of this sub-family have the potential to cause host cells to evade the immune system and elements of cellular control (e.g. apoptosis and proliferation). Therefore one worst case scenario for this virus family is accidental inoculation leading to infection followed by an oncogenic event. However, these cancers are restricted to those with particular risk factors such as significant UV exposure or an immunocompromising condition and therefore exposure from research activity is unlikely to cause ill health. Standard
CL2 controls will prevent accidental inoculation.

We predict that the proposed mutations which disrupt the function of viral proteins will reduce the effectiveness of the virus to replicate, a deletion of herpesvirus non-structural genes results in attenuation of virus growth in cell culture systems. Importantly, mutation of non-structural encoded viral proteins will not affect host or tissue tropism of modified viruses. In addition the titre of released altered virus will be lower than wild type due to its reduced growth characteristics. Similarly, smaller deletions and site-directed modifications within non-structural proteins will also reduce its function, and so will also be predicted to result in reduced growth titre and disease compared to the unmodified viruses. Taken together, these data strongly suggest the resulting virus bearing non-structural deletions and other modified viruses would be less harmful to humans than the wild type.

Final GMO:
The genetically modified viruses we intend to use are able to infect cell culture systems, although at a substantially reduced rate compared to wild type. Therefore, it is likely that they will also be able to infect humans. Cells infected with modified viruses will also release clonal progeny viruses. However, as described above, the titre of altered viruses, with exceptions (alteration to latent genes), is expected to be lower than wild type. Therefore, we acknowledge that there is risk that accidental release may result in human infections. However, as most intended modified viruses described exhibit attenuated growth, and will be present with lower titres, these viruses pose less risk than the unmodified form and will be subject to containment under category 2 conditions.

Controls
Work with Human herpesviruses will only be performed within a CL-2 laboratory with restricted access and virus samples will be stored in a lockable freezer. All manipulations will be performed by staff wearing disposable gloves. No sharps will be permitted in the virus handling area and all unwanted infected media will be aspirated by vacuum directly into 2% Virkon and stored overnight before disposal. Viruses will be grown in tissue culture vessels provided with filters to prevent escape of aerosols. All pipette tips will be disposed of vial plastic ‘sweetie jars’. All materials (e.g. pipettes and culture flasks) that have potentially been in contact with live viruses will be treated with Virkon before being placed in disposable autoclave plastic bags and placed within metal autoclave tins before being passed on to cleaning/waste disposal staff. These measures will be applied at the end of each session of handling live virus. Standard BCL2 waste disposal and Faculty Cat 2 spill containment procedures will minimise the chance of virus release.

Herpesviridae that are covered by this notification must be classified as belonging to ACDP hazard group 2 and will be used under a containment level 2 standard operating procedure.

Herpesviridae belonging to higher hazard groups (e.g. Herpes B virus, also known as Macacine herpesvirus 1) are specifically excluded from this notification. No members of Herpesviridae currently fall under SAPO.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No application is sought

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Treatment of herpesvirus containing liquid waste fluids will be performed under the Faculty of Biological Sciences SOP for CL-2 waste treatment, which are summarized as follows:

Herpesvirus-infected liquids from cell culture flasks and plates will be aspirated using both vacuum lines and manual pipettes. All liquid handling procedures involving infectious virus will be performed inside a biological containment cabinet to prevent risk of aerosolized virus spread outside the work area. All aspirated liquids containing virus will be immediately treated with 2% virkon, and incubated overnight to allow complete virus killing.

Plastic ware exposed to herpesviruses, including pipette tips, plastic universal bottles, cell culture flasks and plates, will be treated with 2% virkon, and incubated overnight. Following this treatment, plastic ware will be autoclaved to ensure complete virus killing.
Infected cells and cell lysates required for further analysis are rendered non-infectious by denaturation by detergents of chaotropic agents prior to removal from laminar flow hoods within the CL-2 containment facility.

All surfaces potentially in contact with virus-containing droplets and aerosols are decontaminated by contact with 2% virkon and, where possible, UV treatment for 30 minutes.

The attached version of the risk assessment form was passed by the local safety committee of the Faculty of Biological Sciences, University of Leeds.

Investigation of interactions within gut microflora including those identified as belonging to Hazard Group 2

Date Ackn'd: 15/02/2018

Date Project Ceased: 15/02/2018

Consent Granted: Not Applicable

Project notified under transitional arrangements: N

Tick if notifying a connected programme of work: N
The aim of this work is to improve our overall understanding of how microbial ecosystems in a host gut function, particularly within the human gut. The study of isolated discrete components of gut ecosystems is unlikely to yield comprehensive results, hence the need to work with complex systems in their entirety. The human gut microbiota consists of a complex mutualistic community of microorganisms. Bacterial species within the gut microbiota communicate amongst themselves to coordinate various processes, such as biofilm formation, and exchange of genetic material e.g. antibiotic resistance determinants.

Areas of research will include:
- microbe-to-microbe interactions within the gut and gut models during healthy and diseased states
- investigating the natural transfer of genetic material between bacterial communities by horizontal gene transfer.
- interaction of gut pathogens within the residual bacterial community during disease
- host-cell-to-microbiota interactions,
- host-to-microbiota interactions (e.g. effect of the host immune system on the microbiota and vice versa)
- effect of bacteriophages on a microbial gut ecosystem,
- quorum sensing and microbiota coordination,
- effect of external factors such as diet on microbiota,
- identifying targets for therapeutic intervention,
- studying the effect of gut microbiota on therapeutic interventions including those interventions unconnected to the gut microbiota (e.g. cancer chemotherapy or radiotherapy treatment).

There are numerous genetic manipulation techniques that can be used to do this, including:
1. Allelic exchange to construct defined gene deletions & complementation to probe the role of specific genes.
2. Targeted intron insertion to construct gene disruptions to probe the role of specific genes where allelic exchange is not possible.
3. Random transposon mutagenesis to construct libraries for high-throughput analysis to identify genetic pathways involved in a biological process, such as colonisation.
4. Plasmid manipulation techniques for studying expression, such as complementation or interference RNA, or genetic transfer studies, such as the addition of reporter genes e.g. fluorescent markers.
5. Use of naturally occurring plasmids harbouring antibiotic-resistance determinants, such as carbapenemases. Once isolated and sequenced, a fluorescent reporter can be inserted within plasmids to aid in investigating the dissemination of such plasmids to other micro-organisms in the absence or presence of antibiotic-selective pressure.
6. Studying the effect of the host genetic background on microbiota or specific bacteria in the gut. This would involve use of host organisms (e.g. mice) with specific genetic modifications using conventional GM techniques.

Recipient or parental organism

Recipient/Parental organisms will be members of normal and disease associated gut microflora such as:

</table>

All the hazard group 2 organisms listed above are capable of causing disease in their host, usually as self limiting opportunistic infections often where the immune system has been compromised. For example Staphylococcus aureus is able to cause a number of conditions including:

- food poisoning resulting from the consumption of food contaminated with enterotoxins,
- local infections from bites leading to cellulitis, erythema, tenderness, mild fever, adenopathy, and lymphangitis
- Scalded skin syndrome is caused by exfoliative toxins secreted on the epidermis
- necrotizing fasciitis in immunocompromised individuals
- superantigen TSST-1 producers are responsible for 75% of toxic shock syndrome cases

Whilst Clostridium difficile is the main cause of nosocomial antibiotic-associated diarrhea. C. difficile can also cause; bacteremia, intra-abdominal abscess, osteomyelitis, visceral abscess, empyema, toxic megacolon, colonic perforation, and reactive arthritis.

All of these bacteria have been identified as naturally occurring in and on humans, with worldwide carriage rates ranging from a few percent to 100% for bacteria such as Bacteroides fragilis and Escherichia coli. For the most part they coexist as part of a wider bacterial ecosystem within the host without causing harm, infact research clearly shows that removal or limiting diversity of the gut microbiota is damaging to the human (or animal) host.

Genetic modifications will include:

For complementation studies, deleted genes can be complemented back on the bacterial chromosome. These may be tagged e.g., a watermark codon may be used to denote complemented allele. The nature of these genes will vary, however, as they will be restored under their own promotor no enhanced virulence is expected. In certain cases, the transgenic sequence for genes to be complemented will come from wild-type donor strains isolated from human faeces.

2. Generation of single insertion sites using targeted introns
For example the insertion of the Group 2 intron from the ltrB of Lactococcus lactis may be used. Owing to the addition of an ermB cassette (a selectable marker), the insertion of this intron in the genome confers resistance to marcolide antibiotics (namely erythromycin, clindamycin and lincomycin).

3. Generation of random insertion immobilised transposon libraries
For example the Mariner-family transposable elements are active in a wide variety of organisms with the himar1 transposon, harbouring an ermB cassette, being able to randomly insert into the chromosome of a number of bacteria. The insertion sequence for this transposon occurs at any AT sequence. This transposon system is under the control of a tetracycline promoter and derepression of this system occurs in the presence of tetracycline or homologues of tetracycline.

4. Addition of reporter proteins
For example GFP and LOV derivatives or SNAP tags (based on O6-alkylguanine-DNA alkyltransferase). Once expressed these proteins confer fluorescent properties in the recipient.

Where bacterial genes are disrupted (targeted insertions, transposon mutagenesis, etc.) it is expected that in the vast majority of cases the disruption will either be of no effect on the recipient or will result in reduced survivability or attenuation of virulence properties.

However, there are a number of examples where disruption of a single gene can increase virulence, e.g. disruption of the tcdC gene in C. difficile causes loss of regulation of the tcdA and tcdB, two genes involved in the production of cytotoxins.

For gene tagging using a variety of reporters - these genes have previously been expressed in a range of bacterial species without any enhanced virulence being observed. In fact, many reports have shown that pathogens harbouring some of these genes have attenuated virulence properties. Although considered unlikely, the addition of a fluorescent protein to candidate proteins could alter the cellular location or enzymatic properties of the candidate gene potentially causing increased virulence in recipient strains.

We will also be making use of in vivo animal models which will include colonising the guts of both wild type and genetically modified animals with WT and genetically modified bacteria. Animals will be small mammals (e.g. mice, rats, hamsters, etc.) which can be housed, isolated, and maintained in specialised animal caging (such as the Tecniplast isocage system). Genetically modified small mammals (on their own) are unlikely to be of increased risk to humans or the environment as most modifications tend to reduce viability or have no phenotypic effect. However, there are a small number of modifications which can increase the potential for harm:

- Modifications to genes associated with behaviour resulting in increased aggression
- Modifications that allow the animal to act as a novel reservoir for human (or other) pathogens

**Host/vector system**

A variety of vector systems will be used including:

- Plasmid based (e.g. pMLT series of Clostridium shuttle vectors) mutated alleles, or alleles containing fluorescent / metabolic proteins. Allele exchange plasmids are pseudo-suicide plasmids meaning they have a poor replication efficiency, and harbours ermB, an antibiotic resistance marker. Mutations created in this way are stable chromosomal mutations.
- Transposon based shuttle vectors e.g. mariner-like elements (such as the himar1 transposon) harbouraged on suicide shuttle plasmids such as pRPF215 and pYAA023.
- Targeted introns to create single insertion sites, e.g. pMLT007C contains the re-targeted L. lactis ltrB intron with ermB resistance cassette along with catP gene, conferring resistance to chloramphenicol/thiamphenicol.
- Manipulation of naturally occurring plasmids harbouring antibiotic resistance determinants isolated from wild-type strains (e.g. plasmids harbouring blaKPC resistance determinant). Plasmids will be genetically manipulated with the inclusion of reporter genes (e.g. GFP) and inserted in to the original strain using an appropriate method. This will enable the examination of horizontal gene transfer to other microbial species.
- Constitutive or inducible expression constructs (e.g. tetracycline inducible systems).

Manipulation of vector systems will be carried out using laboratory strains of E.coli, this element of the work is categorised as requiring containment level 1. Most of these vector systems will be transferred to target bacterial populations by conjugation with E. coli (lab adapted strain containing the F plasmid). Conjugation in this way requires deliberate co-culturing of donor and recipient organisms. However, other methods may also be used to transfer vectors (e.g. electroporation, chemical...
Many (or most) of the organisms found in the gut microflora are identified as hazard group 2 pathogenic agents able to cause disease (usually opportunistic infections). The host vector systems described above are generally unlikely to increase the pathogenicity of the potential hosts described in the previous section. However, there are a small number of exceptions where inactivation or induction of already present genes can result in more harmful phenotype. Even with a more harmful phenotype these organisms are still expected to be categorised within hazard group 2 (i.e. they can cause human disease and may be a hazard to employees; they are unlikely to spread to the community and there is usually effective prophylaxis or treatment available).

Genetic material will be derived from a variety of gut microflora (described previously) and will include all coding and non-coding regions of their chromosomes as well as other genetic elements (such as plasmids and transposons). These genes will have an extensive range of functions including:

- DNA metabolism
- RNA metabolism
- Protein processing, folding, and secretion
- Cellular processes
- Energetic and intermediary metabolism
- Signalling
- Transport
- Chemotaxis
- Housekeeping
- Pathogenicity (colonisation, adhesion, cytotoxins etc.)
- Resistance (antibiotic, restriction endonucleases, sporulation)

Alterations (inactivation or activation) to the vast majority of these genes will result in either no change to the phenotype or a reduction in the organisms viability. However, in a limited number cases inactivation or activation of particular genes can increase the potential for harm by some, but not all, of these bacteria.

The overall aim of this research is to gain a better understanding of the gut ecosystem, there is no deliberate intention to specifically engineer enhanced pathogenic phenotypes or to increase virulence of any of the bacteria forming gut microbiotas.

Hazard to humans
Many species form part of a humans/animals gut flora and are usually beneficial to the host, however, given the right set of conditions many of these bacteria can become pathogenic, for example, disease casing infection by C. difficile usually occurs following perturbation of the gut flora by antibotic exposure.
Given that healthy individuals have a natural barrier to colonising microflora, in general, the vast majority of GM isolates are not expected to overcome this barrier, thus the risk factors associated with wild-type strains and GM strains are expected to be the same, and is not expected to change the overall hazard rating of this research.

For the most part, genetic manipulation will result in a loss of an important phenotype, either cell-cell communication, environmental signalling or other infection-related processes.

There are examples where modification of a gene (inactivation or activation) can enhance a pathogenic trait (e.g. inactivation of tcdC of C.difficile results in unregulated cytotoxin production), however, for harm to occur there would also need to be an accidental inoculation event:
- for the percutaneous route this would always be hazardous for an individual worker almost regardless of whether the bacteria was GM or not.
- for the oral route, the modified bacteria would need to become established within the natural barrier of the already present host gut bacteria.

For the vast majority of bacteria identified previously the main routes for transmission are oral (e.g. hand-to-mouth) or infection of wounds (i.e. contact with pre-existing wounds or innoculating wounds such as needlestick). The use of physical and management controls identified at CL2 (e.g. wearing gloves, hand washing etc.) will reduce the potential for infection to a very low level (i.e. negligible).

The use of physical and management controls identified for GM work at containment level 2 is sufficient to prevent accidental inoculation.
With regard to specific modifications:

• Alterations to microbiota genes (i.e. inactivation or activation) – it is expected that in the vast majority of cases these alterations will either have no effect on the gut bacteria or will result in reduced survivability or attenuation of any pathogenic/virulance properties.

• Use of reporter genes – The production of fluorescent proteins in the resultant GMOs is not expected to alter virulence properties of the microorganisms, in fact several studies have shown that expression of fluorescent proteins can attenuate the host, potentially through steric hindrance of associated protein. Although the risk is considered low, fusion of a fluorescent protein could potentially change the cellular location of the fusion leading to enhanced virulence.

• Use of transposons – In a worst case scenario, the construction of transposon libraries has the potential to enhance the virulence of target bacteria potentially altering virulence determinant expression (through mutation of regulator genes) or cell tropism.

• Use of antibiotic resistance genes – these may make it harder to treat an infection, however, most laboratory vector based resistance markers are for antibiotics that are generally not clinically useful. These resistance genes are already present in the environment and readily move between bacteria (horizontal gene transfer).

• Construction of vector systems – E.coli strains used for plasmid propagation/conjugation are lab-adapted strains unable to cause disease in humans & animals, this work is categorised at containment level 1.

It should be noted that workers undergoing certain types of pharmacological interventions (e.g. taking a course of antibiotics) are likely to have altered susceptibility to some of the organisms listed previously. People involved with this research will be instructed to inform senior researchers if they are affected, an individual assessment of risk will then be undertaken. The same principal will be applied to workers that become significantly immunocompromised, or have conditions that have a major impact on innate defences such as the skin or mucus membranes (e.g. psoriasis or eczema resulting in broken skin).

Combined animal and bacterial work

The combination of a modified host animal and modified bacterial population in general is not expected to increase the risk of the activity, most modifications will result in either no phenotypic alteration, or reduced viability of the host and or the bacteria. However, there are a small number of examples where there is a potential increase in risk to workers, these are:

• Increased shedding of modified bacteria through alterations to the host
• Increased overall bacterial load in the host
• Generation of more aggressive animals which could increase the likelihood of being bitten (and introduction of modified bacteria to a worker via the wound).

The increased risk of the first two examples is mitigated by the use of good laboratory practices and decontamination procedures (as is already required for work at containment level 2). For the third example, increased risk of being bitten is mitigated by: animal handling is reduced to the minimum possible, remaining handling is carried out by experienced workers, keeping infected animals alive only for the duration of the associated experiment, using incapacitation techniques that reduce the potential for being bitten (e.g. restraining devices, anaesthetics, etc.).

Hazard to the Environment

The gut microbiota identified above can be described as ubiquitous within the environment, some are spore formers, and most are able to survive in the environment. With the exception of vector systems all the genetic material is derived from the natural environment, if a laboratory release were to occur it would be of material that was already present in the environment.

With respect to accidental release of GM gut bacteria, these are expected to have the same or reduced viability when compared to the wild type, i.e. modifications are not expected to confer any selective advantage for survival outside of the host.

Use of animal gut models – potential for hazard to humans or the environment

The potential for hazards to arise from the use of animal models such as mice and rats are:

• Percutaneous route (animal bites) and direct transmission of microorganisms into the wound – animal workers receive extensive training on the correct handling of animals and wear surgical gloves (these will not provide protection for anything other than a minor nip). Various restraining devices (e.g. tube restrainers) will be used for higher hazard activities (e.g. tail injection).

• Faecal oral route – animal workers follow good animal husbandry techniques as well as good occupational hygiene techniques which will limit the potential for accidental transmission to virtually zero. Animal workers wear surgical gloves which are routinely changed between study group animals and holding rooms.

• Transmission of microorganisms to other animals in the animal facility – animals are housed in independently ventilated cages (currently techniplast), facilities operate a "clean-to-dirty” regime with “dirty” animals being separated (different holding rooms) from “clean” animals. Staff will follow a clean to dirty regime (i.e. only move from clean
to dirty and not the other way around). These measures as well as measures identified above reduce the potential for transmission to other animals to virtually zero. In addition, animals are regularly screened for opportunistic infections using accredited testing companies (e.g. Charles River).

- Escape of GM pathogen to the environment e.g. incorrect disposal of soiled bedding. Facilities work to strict SOPs, all waste is inactivated by autoclaving, and autoclaved waste is sent for incineration. The potential risk to the environment is assessed as negligible. Work with animals (mainly mice and possibly rats) will only take place in home office approved facilities which also meet the requirements containment level 2 work. The risk to the environment is reduced by using either IVCs or filter top cages to prevent the escape of contaminated dust/aerosols. The escape of an infected animal is considered unlikely as these cages are sealed when the animals are housed. In addition, all rooms are fitted with rodent barriers to prevent animals escaping from the room. All procedure/husbandry work will be done in a class 2 safety cabinet with a HEPA2 filter. This helps to reduce environmental exposure, protecting the immediate area and human workers from GMO contamination. Any staff handling animals will be required to wear PPE, such as, the use of autoclaved lab coats and double gloves. This will minimise the risk of scratches and bites, and potential transmission of the GMO.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste is disposed of in accordance with local procedures to insure inactivation of biologically hazardous waste. In general this involves a minimum of:

Liquid waste is treated either by:
- for low concentration and low organic load, mixing with an approved biocidal product (e.g. virkon, sodium hypochlorite etc.) at a concentration that is able to achieve a 5 to 6 log reduction may be used, or
- for high concentration or high organic load contaminated liquid waste (waste collection bottles/sample pots/falcon tubes/tissue culture flasks) are placed in autoclave bags. These are then autoclaved (with minimum parameters being identified as 121DegC and 15psi (1Bar) for at least 15 minutes). Autoclaved waste is then collected by an authorised healthcare waste contractor for final offsite disposal by approved methodology (e.g. incineration, rotoclave, etc.).

Solid waste (agar plates, used plastic consumables etc.) is treated by:
- Contaminated materials are placed in autoclave bags, these are then autoclaved (with minimum parameters being identified as 121DegC and 15psi (1Bar) for at least 15 minutes). Autoclaved waste is then collected by an authorised healthcare waste contractor for final offsite disposal by approved methodology (e.g. incineration, rotoclave, etc.).

Disinfectants are used as per the manufacturers’ instruction and are selected in accordance with their documented efficacy. Autoclaves are validated on a minimum of a yearly basis by 12 point thermocouple test under load conditions by an approved validator.

Is an emergency plan required according to regulation 20? No

If yes, tick to confirm that it is attached to this form No

Tick to confirm that you have attached a risk assessment to this form Yes

Tick if you are claiming exemption from disclosure for section of the risk assessment No

Please enter comments on the GM safety committee on the risk assessment
Campus BioSafety Committee 24th October 2017
FBS17138 Cell-cell interactions of human gut microbiota – A. Buckley
NC reported that he advised that the SoP be incorporated into plans, which SB had chased up. Draft SoPs have been provided and another meeting will be arranged in order to finalise details. Final details will be checked with PB and MB. 
PB reported on a risk of exposure to anyone on antibiotics. 
NC asked clarification regarding carcass disposal. Should carcasses be double bagged and frozen or autoclaved? 
MH confirmed that the project will need to be submitted to HSE. 
Action: NC to confirm details and report back to Committee.

Campus BioSafety Committee 16th January 2018
FBS17138. Cell-cell interactions of human gut microbiota – A. Buckley – Class 2 submission
Various concerns had been raised regarding adequacy of SoPs and the animal element [these have now been addressed and the project approved] 
Action: MB to send complete broad application for HSE. This should be successful in future-proofing work as similar projects will be covered by the same notification.

Influenza virus is a negative sense RNA virus within the Orthomyxoviridae family and its genome comprises eight separate RNA strands known as segments. Influenza viruses are classified within four subtypes A, B, C and D, with all the human pathogen strains falling within the A and B groups.

Influenza A virus (IAV) is an important pathogen of humans, birds and several other mammalian species, causing widespread seasonal infections, as well as occasional pandemics within the human population. Repeat infections of IAV are common, as a result of the high mutation rates of the virus, and consequently many strains of IAV exist.

Influenza B virus (IBV) has a limited host range and is only known to infect humans and seals, and has not been implicated in pandemics. Whilst IBV mutates at a rate 2 to 3 times slower than type A, it is accepted that Influenza B virus causes significant morbidity and mortality worldwide.

The overarching aim of this research is to identify and understand the role of virus and host interactions during the various stages of the influenza virus infection and replication cycle.

The planned work will use strains of IAV as well as strains belonging to the IBV group classified within hazard group 2. Strains of virus will be studied at the containment level appropriate to the hazard group of the virus (i.e. HG2 at CL2). In particular, much of our focus will be on the well-studied and laboratory cell culture adapted WSN strain of IAV, A/WS/33 (H1N1; ATCC VR-1520).

The scope of our planned experiments is very broad and may include:

- analysis of the overall effect of IAV or IBV multiplication on host cell processes
- the interaction between host and viral proteins
- location of IAV or IBV proteins within the cell during various stages of the replication cycle
- and also the dependence of IAV or IBV on various cellular processes for efficient virus growth.

To this end, we will infect cells in culture with infectious and replication-competent IAV or IBV, and examine the subsequent viral and cellular processes that occur using biochemical and biophysical techniques.

While much of our work can be performed using wild type strains of IAV or IBV, we also wish to generate genetically-modified IAV or IBV, in which specific genetic changes have been engineered. The roles of the genetic changes that we are planning fall into two categories:

1. Genetic changes that result in alteration of specific amino acid or nucleotide sequences, with the intention of causing a corresponding loss of viral function. This is the principle of reverse genetics and it will allow us to define and assign functions to any genetic element within the IAV/IBV genome. The major benefit of using reverse genetics in the context of infectious IAV/IBV is that it will allow us to determine the role of specific sequences and corresponding functions in the context of the full IAV/IBV replication cycle. Design of such changes will be made by rational methods including the use of structural models of viral proteins, sequence alignments followed by identification of regions of nucleotide and amino acid conservation, as well as previously identified amino acid or nucleotide sequence motifs.

2. Genetic changes that result in the addition of sequences to the IAV/IBV genome, specifically to facilitate the visualization of IAV/IBV particles or components as they are generated within infected cells. A typical example of this activity is the modification of an IAV/IBV gene segment by the addition of the coding sequence for a fluorescent protein such as eGFP, allowing its fusion to a native viral protein. On infection of new cells, the resulting IAV/IBV particles will express the viral protein fused to eGFP, which will thus be made visible within the infected cell. An example of such a modification is the fusion of eGFP to the viral protein PA (Lakdawala et al, 2014; doi: 10.1371/journal.ppat.1003971), allowing detection of IAV PA gene expression and polymerase location within infected cells, and many similar insertions have been reported (Reviewed in Breen et al, 2016; doi: 10.3390/v8070179).

All of these genetic manipulations will involve generating infectious IAV or IBV using plasmid-based reverse genetics systems.

For IAV the most efficient of these comprises eight individual plasmids that each encode one of the eight IAV segments. These segment sequences are flanked at one end by the promoter sequence for cellular DNA-polymerase-I (Pol-I), and at the other end by cellular DNA polymerase II (Pol-II). Pol-I drives the transcription of a negative sense copy of each IAV segment, thus generating the complete IAV RNA genome, whereas Pol-II transcribes each IAV segment as a positive sense mRNA molecule, which subsequently is translated to yield the IAV proteomes. Transfection of these eight plasmids into suitable mammalian cells (eg MDCK and HEK293T cells) leads to co-expression of the eight IAV segment RNAs along with the corresponding viral proteins, and subsequently allows assembly of IAV particles that can autonomously infect new cells. To generate a IAV bearing a specific genetic change, the modification is engineered into the corresponding plasmid cDNA, so as to result in the transcription of a
modified RNA bearing the desired nucleotide change. The complete reverse genetics system and the associated protocols are described in Hoffmann et al (2000) PNAS May 23;97(11):6108-13 (DOI: 10.1073/pnas.100133697).

The following Influenza viruses fall under SAPO or are Pandemic and are outside the scope of this notification:

A. We will not work with any avian influenza that are:
   o uncharacterised
   o Type A viruses which have an intravenous pathogenicity index in six week old chickens of greater than 1.2
   o Type A viruses H5 or H7 subtype for which nucleotide sequencing has demonstrated multiple basic amino acids at the cleavage site of haemagglutinin.

B. Influenza viruses identified as newly emergent pandemic strains as per ACDP’s Advice on Experimental working with Influenza Viruses of Pandemic Potential section 10 a. and b. (www.hse.gov.uk/biosafety/diseases/acdpflu.pdf)

There is no intention to work with any of the viruses listed (A and B) above.

Recipient or parental organism

The recipients of the genetically modified virus will be mammalian cells. These will be either from continuous cells lines such as MDCK, A549, BHK, SW13, Calu-3 human lung carcinoma cells. In addition, we will use primary lung cells as well as cells derived from human bronchial progenitor cell lines (e.g. BCi-NS1 and NHBEC-BMI-1) to provide a more authentic cell system. The cells identified above are not identified as hazardous, do not belong to a hazard group, and therefore are estimated to be of negligible or no risk.

Host/vector system

The vector will be the influenza virus genome. As described above, this will primarily be IAV, but also possibly IBV if working with this virus is deemed beneficial to our research aims. As described above, the design of such changes will be made by rational approaches such as using structural models of viral proteins, sequence alignments to identify regions of nucleotide and amino acid conservation, as well as searching influenza virus sequences for previously identified functional motifs.

Foreseeable effects from the host vector system:

Viral infection of staff or others: The consequence of infection with IAV and IBV to human health is strain-dependant. For example, the main laboratory cell culture adapted WSN strain of IAV that we intend to use, A/WS/33 (H1N1; ATCC VR-1520), is not associated with severe human disease. In general, infections with seasonal influenza is characterized by a sudden onset of fever, cough (usually dry), headache, muscle and joint pain, general malaise, sore throat and a runny nose. Most people recover from fever and other symptoms within 7-10 days without requiring medical attention. A vaccine based on the circulating strains of seasonal IAV and IBV is made available each year and is broadly effective in preventing disease.

Origin & function

The genetic material involved will originate from several sources. As described above, various genetic modifications to the influenza virus genome will be made, most of which will comprise sequence insertions. One of these inserted sequences will be the gene encoding enhanced green fluorescent protein (eGFP) derived from the jellyfish Aequorea Victoria. Another will be the TR sequence derived from bacteriophage MS2, as well as the translational operator sequence from bacteriophage PP7, both of which binds their respective viral coat proteins. Other inserted sequences we may use include V5 and FLAG epitopes, tetracysteine motifs, or ACP and MCP-tags that are based on the E. coli Acyl Carrier Protein. It is highly likely that other molecules with more favourable characteristics will in future supersede these sequences and associated ligands, and if so we will adopt the best possible system for our intended applications.

Evaluation of foreseeable effects

The insertion of the eGFP ORF and other exogeneous sequences into the IAV genome is known to result in minor attenuation of virus growth as described in previous work (Reviewed in Breen et al, 2016; doi: 10.3390/v8070179). Similarly, we predict that all other nucleotide insertions that we make to the IAV or IBV genomes will reduce or have no effect on resultant virus growth and infectivity compared to the unmodified parental wild-type virus.

In addition, the titre of released altered virus will be lower than wild-type due to its reduced growth characteristics, which further reduces potential harm.
Transfer of the transgenes to other genetic systems is extremely unlikely. Influenza viruses possesses a negative sense RNA genome, and such viruses are widely regarded as being resistant to recombination with DNA sources within cells. Furthermore, as described above, no adverse consequences of inserts such as eGFP expression have been identified, and so even if transfer did occur, no risk is currently associated.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No application for derogation is sought

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Treatment of influenza virus containing liquid waste fluids will be performed under the Faculty of Biological Sciences SOP for CL-2 waste treatment, which are summarized as follows:

Influenza virus-infected liquids from cell culture flasks and plates will be aspirated using both vacuum lines and manual pipettes. All liquid handling procedures involving infectious virus will be performed inside a biological containment cabinet to prevent risk of aerosolized virus spread outside the work area. All aspirated liquids containing virus will be immediately treated with 2% virkon, and incubated overnight to allow complete virus killing.

Plastic ware exposed to influenza viruses, including pipette tips, plastic universal bottles, cell culture flasks and plates, will be treated with 2% virkon, and incubated overnight. Following this treatment, plastic ware will be autoclaved to ensure complete virus killing.

Infected cells and cell lysates required for further analysis are rendered non-infectious by denaturation by detergents of chaotropic agents prior to removal from laminar flow hoods within the CL2 containment facility.

All surfaces potentially in contact with virus-containing droplets and aerosols are decontaminated by contact with 2% virkon and, where possible, UV treatment for 30 minutes.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The attached version of the risk assessment form was passed by the local safety committee of the Faculty of Biological Sciences, University of Leeds (10/09/2019). Comments were made with respect to future proofing the project and the potential for work at CL3, however for the purposes of the current work CL2 and the use of HG2 influenza virus is currently sufficient.

Project Containment
We aim to use a replication defective human adenoviral vector to introduce the following genes into primary cultures of human cardiac myocytes, vascular smooth muscle and endothelial cells:

(i) the angiotensin type 1 receptor (AT1)  
(ii) matrix metalloprotease 9 (MMP9) in both sense and antisense orientations, and also dominant negative mutants of MMP9 may be expressed.  
(iii) peroxisome proliferation activation receptor (PPAR) gamma isoform 1 in both sense and antisense orientations.  
(iv) Reporter expression cassettes consisting of the bacterial beta-lactamase gene (obtained from Aurora Biosystems) under the control of either the human AP-1, CRE or NF-AT response elements.  
(v) A reporter expression cassette in which expression of either the enhanced yellow (EYFP) or enhanced green fluorescent protein (EGFP) (available from Clontech) is driven by the upstream regulatory region of human angiotensin receptor type 1 or type 2.
The bacterial Reverse Tetracycline Transcription Activator (rtTA) under the control of the human Cytomegalovirus (CMV) immediate early promoter.

By placing genes (i-iii) under the control of the tetracycline response element, the levels of expression of recombinant proteins can be regulated enabling a better understanding of the role of signal transduction pathways in cardiac pathologies.

Recipient or parental organism

The recombinant adenoviral vector will be introduced into primary cultures of human cardiac myocytes, vascular smooth muscle and endothelial cells.

Host/vector system

All transgenes are integrated into an adenoviral genome (using the AdEasy system from Stratagene) from which the early genes essential for replication, contained in the E1 region of the viral genome, have been deleted, to generate replication defective viruses which can only be propagated in human 293 cells. This is a helper cell line (human embryonic kidney cells) which express the leftmost 11% of the Ad5 genome containing the E1 region in trans thus reducing the ability of the virus to evade a host immune response.

Origin & function

**pAdEasy-1 vector**

The pAdEasy-1 vector (Stratagene) is a modified versions of human Adenovirus 5 in which the genes in the E1 region of the viral genome, essential for replication, are deleted to generate a replication defective virus. In addition the E3 gene is deleted which significantly reduces the ability of the virus to evade detection by the host immune system.

**Human angiotensin receptor.**

The peptide agonist angiotensin II activates this receptor to produce a variety of regulatory actions on the cardiovascular, renal, endocrine and neural systems including vasoconstriction, hypertension and aldosterone release. It is not envisaged that expression of this gene will be oncogenic or have adventitious effects in host cells at the levels of expression used. Expression of the gene will be placed under the control of a tetracycline inducible promoter system that levels of expression of the transgene can be finely regulated by the addition of tetracycline. The full coding sequence of the angiotensin type 1 receptor is available as a cDNA in our laboratory.

**Peroxisome Proliferation Activation Receptor (PPAR) Gamma**

PPARgamma is a transcription factor which is expressed in all of the major tissues of the vasculature including endothelial cells, vascular smooth muscle cells (VSMCs) and monocytes and macrophages. Drugs which activate PPARgamma have been shown to inhibit the proliferation and migration of VSMCs in cell culture. Current data suggests that the antiproliferative effect of PPARgamma on the cell cycle is due to an increase in the levels of cyclin-dependent kinase inhibitors such as p27. Again, as stated in the case for the angiotensin receptor, it must be borne in mind that in all cases, PPARgamma transcripts whether sense or antisense will be under the strict control of a Tetracycline-inducible promoter. A cDNA encoding full length human PPAR gamma isoform 1 was obtained from Laboratory of Molecular Hematopoiesis, Sloan-Kettering Institute, New York.

**Matrix Metalloprotease 9**

MMP9 (also known as Gelatinase B) is responsible for basement membrane degradation essential for tissue remodelling in a number of key developmental and growth processes. MMP9 is found to be up-regulated in many forms of cancer, as its role in basement membrane degradation facilitates malignant cell invasion and metastasis. Transformation of a cell to a full malignant phenotype however, is dependent on a number of changes in expression in genes controlling signal transduction/gene expression cascades within the cell or genes involved in regulation of the cell cycle. It is highly unlikely therefore that alteration of levels of MMP9 expression alone would confer an oncogenic phenotype upon a mammalian cell and to the best of my knowledge there is no case of this being documented in the research literature. In addition, as has been stated for both the case of the angiotensin receptor and PPARgamma above, all transcripts whether sense, antisense or dominant negative mutant will be under the strict control of a Tetracycline-inducible promoter. A cDNA encoding full length human MMP9 was obtained from Department of Immunology and Oncology, Universidad Autonoma de Madrid).
AP-1/CRE/NF-AT Reporter Constructs

These constructs consist of the bacterial beta-lactamase gene under the control of either the AP-1, CRE or NF-AT response element. The activity of each response element can be measured by assaying the activity of the protein product of the beta-lactamase gene through a simple optically based assay. It is not envisaged that introduction of the beta-lactamase gene into mammalian cells should pose a significant safety risk as mammalian cells are routinely exposed to commercially available ampicillin resistant plasmids containing the beta-lactamase gene with no adverse effects.

Upstream Regulatory Region of Human Angiotensin Type 1 and Type 2 Receptor

The reporter cassette in this virus will contain either a fragment of DNA encompassing approximately 1300bp immediately upstream of the transcriptional start site of human angiotensin II type 2 receptor (GenBank Acc No X87722) or a fragment encompassing approximately 2700bp upstream of the initiation ATG of human angiotensin II type 1 receptor (GenBank Acc No. U07144 - detailed in 'Molecular cloning and expression of the gene encoding human angiotensin II type 2 receptor' Guo et al. Biochem Biophy Res Commun. 1994 May 16; 200(3):1449-54).

Reverse Tetracycline Transcription Activator (rtTA)

The rtTA gene was obtained from the plasmid pTet-On which is commercially available from Clontech. It is necessary to make a recombinant virus which express this protein so that expression of genes under the control of the Tetracycline response element can be activated when a co-activator ligand such as Doxorubicin is added.

Evaluation of foreseeable effects

All strains of AD5 are non-oncogenic. Wild type AD5 may cause mild respiratory diseases in children. Because the recombinant virus will lack the E3 gene this may produce a virus that will evoke a stronger inflammatory response in a host, but this should also lead to more rapid clearance of the virus from a host system. Primary infection of adenovirus is thought to generate life-long immunity and it is thought that the majority of the adult population are likely to have antibodies to the wild-type virus.

Although replication has been shown to occur in the lungs of experimentally infected cotton rats administered with high doses of virus, there is no evidence that adenoviruses can naturally colonise non-human hosts and therefore pose no significant harm to animals, plants or ecosystems.

Human angiotensin receptor.

The peptide agonist angiotensin II activates this receptor to produce a variety of regulatory actions on the cardiovascular, renal, endocrine and neural systems including vasoconstriction, hypertension and aldosterone release. It is not envisaged that expression of this gene will be oncogenic or have adventitious effects in host cells at the levels of expression used. Expression of the gene will be placed under the control of a tetracycline inducible promoter system that levels of expression of the transgene can be finely reguylated by the addition of tetracycline.

Peroxisome Proliferation Activation Receptor (PPAR) Gamma

PPARgamma is a transcription factor which was initially characterised as an adipose-tissue specific facgtor that played a role in the differentiation of this tissue and regulated a number of adipose specific genes. PPAR gamma is also expressed in all of the major tissues of the vasculature including endothelial cells, vascular smooth muscle cells (VSMCs) and monocytes and macrophages. Drugs which activate PPARgamma have been shown to inhibit the proliferation and migration of VSMCs in cell culture. Current data suggests that the antiproliferative effect of PPARgamma on the cell cycle is due to an increase in the levels of cyclin-dependent kinase inhibitors such as p27. Again, as stated in the case for the angiotensin receptor, it must be borne in mind that in all cases, PPARgamma transcripts whether sense, antisense or dominant negative mutant will be under the strict control of a Tetracycline-inducible promoter.

Matrix Metalloprotease 9

MMP9 (also known as Gelatinase B) is responsible for basement membrane degradation essential for tissue remodelling in a number of key developmental and growth processes. MMP9 is found to be up-regulated in many forms of cancer, as its role in basement membrane degradation facilitates malignant cell invasion and metastasis. Transformation of a cell to a full malignant phenotype however, is dependent on a number of changes in expression in genes controlling signal transduction/gene expression cascades within the cell or genes involved in regulation of the cell cycle. It is highly unlikely therefore that alteration of levels of MMP9 expression alone would confer an oncogenic phenotype upon a mammalian cell and to the best of my knowledge there is no case of this being documented in the research literature. In addition, as has been stated for both the case of the angiotensin receptor and PPARgamma above, all transcripts whether sense, antisense or dominant negative mutant will be under the strict control of a Tetracycline-inducible promoter.
AP-1/CRE/NF-AT Reporter Constructs
These constructs consist of the bacterial beta-lactamase gene under the control of either the AP-1, CRE or NF-AT response element. The activity of each response element can be measured by assaying the activity of the protein product of the beta-lactamase gene through a simple optically based assay. It is not envisaged that introduction of the beta-lactamase gene into mammalian cells should pose a significant safety risk as mammalian cells are routinely exposed to commercially available ampicillin resistant plasmids containing the beta-lactamase gene with no adverse effects.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All work will be performed in tissue culture (Category II) facilities with restricted access. The flow cabinet in which work will be performed is equipped with a UV light source which enables sterilisation of the work area upon completion of work. Liquid waste will be virkon treated. Plasticware will be disinfected prior to autoclaving and then incinerated. All work surfaces will be treated with 70% ethanol and 1% Virkon spray prior to and upon completion of work. Kill rate by virkon or autoclave treatments is 100%.

Is an emergency plan required according to regulation 20? N

02/03/2022
Maximum volume of culture is 500 ml.

All liquid cultures are deactivated by addition of Virkon, or Presept according to manufacturers instructions. Following deactivation, liquid is disposed by washing down sink.

All solid waste is decontaminated by autoclaving. Laboratory autoclaves are serviced and calibrated once a year.

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

Project Additional Information
**Purposes of the contained use**
Small scale production of Herpes Simplex type-1 virus for further biologic testing with the aim of optimising production methods.

**Recipient or parental organism**
Herpes Simplex type-1 virus (strain JS-1 ECACC Accession Number 01010209)

**Host/vector system**
Herpes Simplex type-1 virus deleted for neurovirulence factor ICP34.5 and culture in BHK cells in vitro. GM-CSF, a cytokine involved in the stimulation of T-cells, is under control of the human cytomegalvirus immediate early promotor (HCMV IE).

**Origin & function**

**Evaluation of foreseeable effects**
The design of the facility and the category 2 handling and waste inactivation procedures utilised mean that release of vector outside of contained use is highly unlikely. If such release was to occur then it is unlikely that the vector will be harmful to humans, animals or plants. The vector is modified so that replication only occurs in rapidly dividing cells and not non-dividing cells. Considerable literature shows that HSV 1 deleted for ICP34.5 is non-pathogenic in animals and humans. Approximately 80% of the human population are seropositive for HSV-1. Infection is by contact and transmission by the aerosol route is not though to occur. The therapeutic gene delivered, human GM-CSF is present in normal, healthy humans. The virus is fragile, and is rapidly inactivated by desiccation, lipid solvents and mild detergents. The fact that contact is required for transmission attests to the instability of the virus outside the host.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**
Not applied for.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**
All waste materials (eg. liquid waste, flasks and pipettes) are inactivated by autoclaving (126 degrees C for 45 minutes) before disposal to effectively give 100% kill of the GMM. The autoclaving procedure is performed according to formal written standard operating procedures (KPBT0161 and KPBT0162) and has been validated. The inactivation of waste by autoclaving is monitored/validated by the following means:
* chemical indicators (eg autoclave tape) are used on all autoclave runs and the temperature and pressure for each run is recorded and verified against requirements.
* Once a week correct autoclave operation is verified by the use of chemical indicators.
* Once every two months correct autoclave operation is verified by the use of biological indicators.

**Is an emergency plan required according to regulation 20?**
N

**If yes, tick to confirm that it is attached to this form**
N

**Tick to confirm that you have attached a risk assessment to this form**
Y

**Tick if you are claiming exemption from disclosure for section of the risk assessment**
N
Standard level 2 containment procedures should be employed for this work.

For activities involving GMMs, describe the waste management measures which will apply to the activity:

- Plates and broths of GMMO are placed in the autoclave (120 degrees C for 15 mins).
- Any paper waste etc. is bagged and autoclaved as normal.
- Immobilised films and 96 well plates (liquid culture) are completely submerged in a strong (10%) solution of Hibitane and left for at least 24 hours to kill the bacteria.
- The 96 well plates are then emptied and put into general waste.
- Films are removed still attached to the glass slide and placed in a bag for autoclaving and disposal whilst the containers are washed and recycled.

Tick to confirm that you are attaching a summary of the risk assessment

Please enter comments of the GM safety committee on the risk assessment.
**Project Additional Information**

### Purposes of the contained use

- The lux operon will be delivered to the recipient chromosome by mating, and the recipients will be used as bioluminescent biosensors for toxicity evaluation or pollutant detection.

### Recipient or parental organism

- Recipient organisms are isolates from industrial wastewater treatment plants, and clean and contaminated soils.

### Host/vector system

- **pUTmini-Tn5 luxCDABEKm2**: Carries an unpromoted luxCDABE operon from the terrestrial bacterium Photorhabdus luminescens, located within the 1 and O elements of a disarmed min-Tn5 transposon, together with a Km resistance gene for insertional selection into the recipient chromosome. The disarmed vector is maintained in E. coli S17/1pir. Transfer is via conjugation.

### Origin & function

- **pUTmini-Tn5 luxCDABEKm2**: Carries an unpromoted luxCDABE operon from the terrestrial bacterium Photorhabdus luminescens. The vector is a suicide vector as it needs the R6K-specified p protein for replication. Thus, it has to be propagated in E. coli lpir strains, and the recipients will be lpir … negative. The pUT plasmid carries the tnp* gene which allows the transposon to jump from the plasmid to the chromosome of the recipient, but as the transposon itself is disarmed, and the recipients will be lpir … negative, the plasmid cannot replicate in the recipient and the kanamycin selection will select strains in which the transposon has integrated with the chromosome.

- An alternative is the use of the transposome technology of Epicentre (Goryshin & Reznikoff, 1998), which would involve the introduction of lux genes to the transposon, and electroporation of the transposome system. This contains the Tn903 derived kanamycin resistance gene. The introduced DNA is linear and non-replicative.

### Evaluation of foreseeable effects

- It is possible that the insertion of the DNA in this random mutagenesis strategy could alter the expression of flanking sequences either up- or down-regulating expression and it is a theoretical possibility that such an insertion could result in the increased expression of a virulence factor. However, such an insertion is unlikely to generate a mutant of increased virulence since pathogenicity is multifactorial.

- Kanamycin resistance…... Kanamycin is used in the treatment E. coli, Proteus (both indole-positive and indole-negative). Enterobacter aerogenes, Klebsiella pneumoniae, Serratia marcescens, Acinetobacter species. However, chromosomal integration reduced the risk of transfer to negligible.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

- **N/A**

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

- Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All class 2 waste (liquid and solid) will be autoclaved - 100% kill. A brownes tube is included in each load to indicate correct operation ensuring a temperature of 121°C for 15 min. The autoclaves are serviced annually.

Historical Significant Changes

Historical Date of Additional Info
The objectives of this project are to understand the biology of Salmonella spp. and gain insights into virulence and disease pathogenesis to identify potential antimicrobial targets. This will involve cloning, expression and disruption of Salmonella genes. This research will be conducted using plasmids in disabled E. coli K12 hosts, and also reintroducing cloned DNA sequences back into strains of Salmonella.

Escherichia coli K12 strains (md. DH5alpha, JM101, JM1O & S17-1 lambda-pir), in the ACGM 2000 disabled hosts category, part 2A, annex II.

Well characterised attenuated Salmonella: S. Typhimurium (5L3261) attenuated by lesions in genes of the aromatic amino acid biosynthetic pathway. This strain carries the same attenuating mutations as the strains listed in the ACGM 2000, part 2A, annex II as disabled hosts. The only wild type hosts to be used are S. Typhimurium SL1 344 & WG49 which have both been used extensively and are well-characterised in the literature.

Cloning & expression vectors: All derived from those listed in the ACGM 2000, part 2A, annex II as ‘nonimobilisable’ (eg pUC series, pGEM series & derivatives) or ‘mobilisation defective’ (pBR322 & derivatives).

Only DNA sequences constituting genes or parts of genes from Salmonella or E. coli that encode non-toxic products of known function will be inserted into the vectors for introduction into Salmonella. These products will contribute to basic cellular physiology such as essential metal ion homeostasis (including metal-transporting P-type ATPases and metal-sensing proteins). Introduced DNA will be expressed either individually as full-length proteins or sub-regions, and/or as fusions to other genes (within the vector) encoding non-toxic products, including the reporter genes lacZ (encoding beta-galactosidase), gfp (encoding green fluorescent protein from jelly fish), luxCDABE (encoding luciferase from Vibrio fischeri).

All sequences will be well characterised prior to introduction into Salmonella strains and will be generated by PCR using specific primers designed to amplify known DNA sequences (no random sequences will be introduced).

Introduced DNA sequences will either (i) remain on self-replicating plasmids to drive reporter gene expression or for expression of genes from their natural promoter or from vector promoters, or (ii) be integrated into the genome to generate gene disruption mutants of Salmonella.

Human health:
The attenuated Salmonella strains employed are specifically designed to be given as oral vaccines. They can survive in and colonise the host gut sufficiently to induce an immune response however the ability to colonise the host is very dose dependent, and requires large numbers. There are no recorded instances of aro mutants spreading between hosts. The wild-type S. Typhimurium strains to be used are only likely to cause food poisoning if ingested in a large dose. These strains have been safely used for 20 years and the likelihood of hazard can therefore be considered low. We will only introduce very short (<4 kb) DNA sequences into Salmonella using well characterised harmless vectors. Introduced DNA will be well defined genes (or parts of genes) that encode non-toxic products that contribute to basic physiology (such as the sensing and transport of essential metal ions).

Environment:
The disabled host strains will not replicate in the environment. Infectious doses for man and animals are high and
the probability of accidental infection low. The host strains are not known to be infectious for plants. The wild-type S Typhimurium strains may be able to replicate in the environment. The chance of transfer of the vectors to other organisms in the environment can be considered low. It is difficult to envisage how any of the genetic manipulations proposed in this project could confer a harmful phenotype or competitive advantage to the host strains. The environmental hazards associated with the project are therefore considered no greater than those associated with handling non-GM Salmonella. The project involves small-scale work for research purposes and all contaminated material will be completely inactivated by autoclaving prior to disposal. In the highly unlikely event of release into the environment no risks are envisaged.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All contaminated waste materials (bacterial liquid cultures/agar plates) will be completely inactivated (100% kill) by autoclaving: All autoclave runs are validated by monitoring with a chart recorder and the autoclaves are validated annually by thermocouple testing. All solid waste will subsequently be incinerated.

Project Ref  564/09.1

02/03/2022  Page 9936 of 15326
The objectives of this project are to understand the biology of L. monocytogenes and gain insights into virulence and disease pathogenesis to identify potential antimicrobial targets. This will involve cloning, expression and disruption of Listeria genes. This research will be conducted using plasmids in disabled E. coli K12 hosts, and also re-introducing cloned DNA sequences back into strains of L. monocytogenes.

Recipient or parental organism

Escherichia coli K12 strains (incl. DH5alpha, JM101, JM109 & S17-1 lambda-pir), in the ACGM 2000 disabled hosts category, part 2A, annex II. The L. monocytogenes strain EGD-e has been used extensively by a number of research groups and is well-characterised in the literature.

Host/vector system

Cloning & expression vectors: All derived from those listed in the ACGM 2000, part 2A, annex II as 'non-mobilisable' (eg pUC series, pGEM series & derivatives) or ‘mobilisation defective’ (pBR322 & derivatives). The Gram positive/negative shuttle vectors pAUL-A and pUNK1 possess tempertaure sensitive origins of replication to facilitate insertion into the L. monocytogenes chromosome.

Origin & function

Only DNA sequences constituting genes or parts of genes from L. monocytogenes that encode non-toxic products of known function will be inserted into the vectors for introduction into L. monocytogenes. These products will contribute to basic cellular physiology such as essential metal ion homeostasis (including metal-transporting P-type ATPases and metal-sensing proteins) and vitamin B12 synthesis. Introduced DNA will be expressed either individually as full-length proteins or sub-regions, and/or as fusions to other genes (within the vector) encoding non-toxic products, including the reporter genes lacZ (encoding beta-galactosidase), gfp (encoding green fluorescent protein from jelly fish), luxCDABE (encoding luciferase from Vibrio fischeri).

All sequences will be well characterised prior to introduction into L. monocytogenes and will be generated by PCR using specific primers designed to amplify known DNA sequences (no random sequences will be introduced).
Introduced DNA sequences will either (i) remain on self-replicating plasmids to drive reporter gene expression or for expression of genes from their natural promoter or from vector promoters, or (ii) be integrated into the genome to generate gene disruption mutants of L. monocytogenes. Plasmid vectors used in L. monocytogenes do not encode resistance to ampicillin or penicillin which are often the therapeutic antibiotics of choice for L. monocytogenes infection.

**Evaluation of foreseeable effects**

**Human health:**
L. monocytogenes is capable of causing infection in humans although infection of healthy individuals is rare. The infectious dose remains unknown and may be lower in immunocompromised individuals. Thirteen serovars are associated with L. monocytogenes however serovar 4b is more commonly associated with invasive disease. L. monocytogenes EGD-e to be employed in this work is a serovar 1/2a strain.

Strain EGD-e is the sequenced reference strain and has been used in laboratories worldwide safely used for over 20 years and the likelihood of hazard can therefore be considered low. We will only introduce very short (<4 kb) DNA sequences into L. monocytogenes using well characterised harmless vectors. Introduced DNA will be well defined genes (or parts of genes) that encode non-toxic products that contribute to basic physiology (such as the sensing and transport of essential metal ions).

For reasons outlined above, the likelihood of harm in the event of exposure would be no greater than that with non-GM L. monocytogenes and can be considered negligible.

**Environment:**
L. monocytogenes is not a respiratory pathogen hence accidental infection via aerosol contamination is considered to be negligible. The host strains are not known to be infectious for plants. The wild-type L. monocytogenes strains may be able to replicate in the environment. The chance of transfer of the vectors to other organisms in the environment can be considered low. It is difficult to envisage how any of the genetic manipulations proposed in this project could confer a harmful phenotype or competitive advantage to the host strains. The environmental hazards associated with the project are therefore considered no greater than those associated with handling non-GM L. monocytogenes. The project involves small-scale work for research purposes and all contaminated material will be completely inactivated by autoclaving prior to disposal. In the highly unlikely event of release into the environment no risks are envisaged.

Project Additional Information

Purposes of the contained use

ADAM17 (a disintegrin and metalloproteinase) is a sheddase, a membrane bound enzyme involved in the cleavage of proteins from cell surfaces. Some of the proteins shed, such as TNF, are implicated in the disease process of multiple sclerosis (MS). Our work has also shown that ADAM17 is increased in active MS lesions suggesting a role in MS (Plumb et al (2006) Multiple Sclerosis 12, 375-385).

The purpose of this project is to determine the functional role of ADAM17 in CR-EAE, an animal model of MS, to gain further insight into its role in MS pathogenesis and as a potential therapeutic target. The project involves using lentiviral vectors expressing shRNA targeted against ADAM17 to knockdown ADAM17. The lentiviral vectors will be developed in the laboratory of Prof Mimoun Azzouz at the University of Sheffield. The effectiveness of the developed vectors to knockdown ADAM17 at the mRNA and protein level will be studied in the Biomedical Research Centre (BMRC) at Sheffield Hallam University, initially in a murine brain endothelial cell line, bEND3, then in primary murine astrocytes and microglia.

The vector which produces maximal knockdown will be used to treat mice with CR-EAE to see if their symptoms are ameliorated. This animal work will be done in the laboratory of Dr Chris Bolton, the William Harvey Research Institute, St Bartholomews Hospital London and he will obtain the relevant permissions for this. Tissues from these mice will be analysed for ADAM17 knockdown and inflammatory changes at the BMRC, Sheffield Hallam University.

Recipient or parental organism

Lentiviral vectors produced in Prof Azzouz's laboratory will be used to infect the bEND3 cell line and primary murine CNS derived cells including astrocytes and microglia. In vitro studies will be carried out at containment level 2. Snap frozen tissues from Biozzi mice with CR-EAE, treated with lentiviral vectors, will be analysed at the BMRC, Sheffield Hallam University.

Host/vector system

We intend to use both primate and non primate derived replication defective lentiviral vectors. We will be testing HIV-1 based vectors, the self inactivating (SIN) HIV-based lentiviral system which will be provided by Dr Nicole Deglon (France). We also propose to use Equine infectious anaemia virus (EIAV)-based lentiviral vectors which will be provided by Oxford BioMedica Ltd (Oxford, UK)

HIV-derived lentiviral vectors:

We propose to use the self inactivating (SIN) HIV-based lentiviral system which will be provided by Dr Nicole Deglon under MTA from Commissariat a L'Energie Atomique (CEA) CNRS URA2210, Service Hospitalier Frederic Joliot and ImaGene Program Orsay Cedex, France. Vector-based on lentiviruses have been refined to a very high safety and efficiency levels. Any system used will incorporate the safety features outlined below.

SIN-lentiviral vector system (from Nicole Deglon)

Viral vectors will be generated with a four-plasmid system ("fourth generation" HIV-based vectors (Zufferey et al. (1997) Nat Biotechnol 17:871-875; Hottinger et al. (2000) J Neurosci 20:5587-5593). The four plasmids are as follows:

1) SIN-cPPT-PGK-W, gene transfer vector.
2)pCMVΔR-8.92, packaging construct
3)pRSV-Rev, the accessory protein rev plasmid
4) pMD.G, Vesicular stomatitis virus-G envelope protein. It may be necessary to use other envelope proteins such as rabies-G glycoprotein to achieve specific tropism.

Features that prevent generation of live virus, recombination with endogenous retroviruses and viable HIV.

1) Production of the viral vectors form the promoter cell line requires the transfection of 4 plasmids (SIN-CpPT-PGK-W, pCMVΔR-8.92, pRSV-Rev, pMD.G) in a transient transfection. All four plasmids have been designed, through lack of common sequences, to avoid the possibility of recombination with each other. The plasmids expressing the structural and packaging genes are not packaged with the produced virus, since none of them contain LTRs or the packaging RNA sequence. Thus, replication-competent viruses cannot be produced, nor can the packaging.

02/03/2022
Vector genome SIN-cPPT-PGK-WPRE: A 400-bp fragment of the U3 region of the 3' LTR was deleted to obtain self-inactivating (SIN) transfer vector. The mouse phosphoglycerate kinase 1 (PGK) promoter was used as internal promoter. This plasmid was further modified by insertion of the posttranscriptional 1cis-acting regulatory element WHV.

pRSV-Rev is rev cDNA-expressing plasmid in which the joined second and third exons of HIV-1 rev are under the transcriptional control of the RSV U3 promoter. The HIV promoter has been deleted and replaced by the RSV U3 promoter for safety.

pCMVAR8:92 (packaging construct): The Vpu, Vpr, Nef and Rev coding sequences, required for viral packaging etc have been deleted. The accessory protein Rev, which is required for the transport of RNA from the nucleus to the cytoplasm, is expressed on a separate plasmid. Expression of gag/pol is under the control of the CMV promoter rather than the viral promoter for safety.

EIAV- based lentiviral vector system (generated by Oxford BioMedica Ltd)

The EIAV minimal vector system

Equine infectious anaemia virus (EIAV) is a non-primate lentivirus that causes a self-limiting, lifelong but rarely fatal infection of all Equidae, and is a world-wide disease of horses, most prevalent in warmer climates. The aim when designing an EIAV-based lentiviral vector system is three-fold. The first is to minimize the amount of viral sequence in the transfer vector, thus increasing the capacity for transgenes and associated regulatory elements. The second is to eliminate the expression of viral sequences in the target cells. Viral genes may elicit immune responses that result in destruction of transduced cells and may have undesirable effects per se. The third is to express, in the production system, only those viral proteins required for efficient production of transduction competent vector. All three components, vector genome, Gag/Pol and envelope necessary to generate EIAV-base lentiviral system are being optimized by Oxford BioMedica Lts and the current status is summerised below.

The safety profile of the EIAV vector system

EIAV vector system was modified with safety in mind making use of the strategies used in the murine leukaemia virus (MLV) vector field to avoid the production of a replication competent retrovirus (RCR). The most important features for safety are:

The partition of the components of the vector system in three independent expression cassettes: vector genome, gag/pol and envelope plasmids.

The minimal sequence homology between the vector, gag/pol and env components.

The use of human cell lines with low levels of engogenous retroviral sequences as the basis for producer cell lines.

Some additional features that will reduce the potential for recombinant formation and the potential pathological consequences arising from the presence of such recombinants in the EIAV vector system are: These features provide a high safety margin.

The use of a heterologous envelope component. Recombination events can not generate wild type EIAV;

The use of vectors which have SIN or conditional SIN configurations and therefore are almost transcriptionally silent in transduced cells;

The elimination of accessory proteins from the system. Tat, Rev and S2 can be eliminated from the system without affecting transduction efficiency; however, Rev is maintained in the producer system since it improves titre by increasing cytoplasmic levels of vector RNA. Expression of Rev is from an independent expression cassette, in which rev is 'codon-optimised' to minimize the chances of its involvement in recombination reactions.

Transcription of the vector genome is driven by the human CMV enhancer/promoter fused to the R region of EIAV so that the first base of the transcript is the same as that formed as a result of transcription from the EIAV U3 region. This configuration allows high titres to be obtained in the absence of Tat protein which would normally serve this function.

The codon-optimised gag/pol gene (pESYNGP) is now being utilized for construction of EIAV packaging and producer cell lines. The coden-optimisation process increases the safety of the system in two ways. First, gag/pol/mRNA is unlikely to be packaged as efficiently as the wild type gag/pol RNA. Secondly, due to the lack of significant homology with the vector in the region of the packaging signal, it is unlikely to be involved in recombination reactions which might result in generation of an RCR, even if it was incorporated into the vector particle. The optimization process makes the expression of gag/pol Rev-independent, possibly as a result of removing RNA instability sequences.

Vectors will be produced in the laboratory of Prof Azzouz who has the appropriate permissions. Viral stocks will be received as aliquots in PBS which are stored frozen at -70C.

Origin & function

Vectors will express shRNA targeting the expression of ADAM17 or a missence sequence as a control. DNA sites for RNAi targeting will be determined using online algorithms (Dharmacon). The viral vector will also contain the RNA Pol III H-1 promoter, derived from human embryonic kidney 293T cell line and cloned into the lentiviral
vector. They will also contain a reporter gene for green fluorescent protein (GFP) or luciferase.
The vectors will be used to knockdown ADAM17 in murine bEND3 cells and primary murine CNS-derived cells in vitro. They will also be used in vivo to treat Bioxxi mice with CR-EAE in Dr Bolton's laboratory in London.

Evaluation of foreseeable effects

Environmental assessment:
The replication defective viruses, as stocks or in cultured cells, culture media or tissues would be inactivated prior to disposal and given their inability to replicate, they have no significant additional environmental hazard.

Worst case scenarios:
The above protocols should minimize any risk of exposure to personnel using, or in the vicinity of, work using these lentiviral vector systems. The worst scenario would be exposure to a main stock of virus, resulting from the centrifuge failure or spillage. Risks of centrifuge failure-associated contamination (the only readily conceivable mechanism likely to generate a substantial aerosol of many infective particles) should be minimized by good microbiological practice and steps outlined in section 12. The major exposure routes would be cutaneous, mucocutaneous and respiratory. Effective infection of intact skin is unlikely as skin is a very effective barrier and would be minimized by good laboratory safety and hygiene. The viruses may infect mucocutaneous surfaces and respiratory epithelia and macrophages with which they came into contact. Again this would be minimized by strict adherence by trained personnel to proper laboratory procedures e.g. use of microbiological safety cabinet class II, masks, eyes protection and gloves will be observed. However the particles are replication defective and have many safety features preventing generation of replication competent viral particles. The vectors are replication defective hence spread from an initially infected cell is very unlikely. Some vectors to be used for this project may contain wild type or truncated forms of woodchuck post-transcriptional regulatory element (WPRE) sequences. Following the recommendation from HSE and the SACGM measures will be taken to minimize the risks when using these sequences:
- Good microbiological practice by using safety cabinet class II
- Adopt procedures that reduce the likelihood of exposure, such as wearing gloves, mask and eye protection, etc.
- Accidents would be minimized by strict adherence by well trained personnel to good standards of safety and hygiene. Professor Azzouz has successfully used this technique in the past, and will provide training for staff using lentiviral vectors.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Anti-viral disinfectants (virusolve, virkon, bleach) will always be available prior to starting work involving handling of viral particles, in identified containers easily to hand (e.g. spraygun)
- All culture will be performed using a Class 2 hood, in a designed Class 2 laboratory. All cells exposed to the virus will be handled in the category 2 hood. After infection, viral supernatant will be removed and the cells washed. Once the media has been changed on at least one further occasion (after which active viral particles should not be present), then functional assays may involve handling transfected cells for brief periods on the bench using acceptable good practice but any cells taken out of the laboratory for analysis (e.g. flow cytometry) will be fixed or rendered fully non-viable (e.g. treated with formaldehyde solutions prior to flow cytometry).
- Where large volumes of supernatants containing, or potentially containing, viral particles require centrifugation, individually sealable buckets will be used in the relevant centrifuge. The buckets and contents will be inspected before opening (in the Class 2 hood). Buckets would be cleaned appropriately using virusolve, virkon or bleach after use. Supernatants from virally-transfected cells which had been cultured for more than one media change over several days would not be regarded as being likely to contain significant numbers of active virus, but would be handled according to accepted good practice and neutralized prior to final disposal.
- Hoods will be carefully cleaned after each session in which culture with virus particles takes place and after each session, when cells that have been transduced by virus on a previous, occasion are handled.
- Viral particles and supernatants from infected cells will be handled using filtered pipettes and pipette tips.
- All murine tissues, supernatants, plastic ware and cells that have come into contact with virus particles or viral infected cells will be treated with virusolve, virkon or
bleach, at concentrations recommended by the manufacturer, for 20-30 minutes prior to discard.
- Solid waste from this project will be segregated from containment level 1 waste in appropriate leak-proof containers and inactivated on-site by autoclaving or off-site by an appropriately licensed contractor.
- Safe practice will be rigorously enforced (lab coats, eye protection, gloves, etc).
- Other lab personnel will be made aware of the use of lentiviral systems in the laboratory.

Containment management
1. Where spills occur in contained environments such as Class 2 hoods, neat virusolve, bleach or virkon will be added and left for 20-30 minutes to neutralize viral particles prior to wiping, cleansing and disposal.
2. If a small contained spill occurs outside of Class 2 hoods, management will be as above. Any spills outside of Cat 2 hood will be reported to a principal investigator, and assessment made to determine whether avoidable features are present to prevent future accidents.
3. Where aerosolized contamination is suspected to have occurred outside of Class 2 hoods (e.g. as a result of centrifuge failure), the lab will be cleaned immediately to prevent aerosol inhalation. The air conditioning system will replace the air within the room within 10 min and will serve to desiccate and dilute the hazard. A single designated worker will return to the lab after 15 min and apply appropriate disinfectant to liquid traces.

Is an emergency plan required according to regulation 20?  N
If yes, tick to confirm that it is attached to this form  N
Tick to confirm that you have attached a risk assessment to this form  Y
Tick if you are claiming exemption from disclosure for section of the risk assessment  N

Please enter comments on the GM safety committee on the risk assessment

The risk assessment for class 2 activity was considered by the Genetic Modification Safety Committee on 3/11/2008. This was approved subject to minor amendments which have now been made.

Project Ref 565/10.1

Date Ackn'd 08/07/2010
CU2 Project Title Expression of functional recombinant peptides found naturally in scorpion venom
Class Class 2
CultureVolClass2 1-50 Litres
CultureVolumeClass3-4

Since these peptides are typically found in small quantities as part of a complex venom mixture, the ability to produce a pure peptide in sufficient quantities to enable its full characterisation is essential.

The aim of the project is to express functional recombinant peptides found naturally in scorpion venom. These peptides can be broadly divided into four groups:

i) Sodium channel toxins
ii) Potassium channel toxins
iii) Chloride channel toxins
iv) Other peptides

We propose to express these peptides in E.coli as indicated in Table 1 below:

This proposal also covers the expression of the above peptides in Pichia pastoris.

Sequences will either be amplified directly from scorpion genetic material or synthetic sequences will be generated by back-translation of known peptide sequences. These sequences will be inserted into E. coli maintenance vectors and P. pastoris expression vectors. After transformation of the host, proteins will be expressed in <5L per culture.

**Recipient or parental organism**

Non-pathogenic E. coli K-12 or B derivatives (e.g. DH5, JM109, TB1); Top 10; DH5alpha and BL21 (DE3) derivatives (e.g. NEB express, origami-2, origami B, Rosetta-gami-2, Rosetta-gami-B) or laboratory strains of yeast Pichia pastoris will be used.

E. coli K-12 or B derivatives are unable to colonise humans and are not considered pathogenic to humans or animals. They are expected to have limited survivability in the environment and often have auxotrophic requirements, which are unlikely to be satisfied outside laboratory culture. E. coli DH5 alpha and BL21 (DE3) derivatives lack necessary pathogenic mechanisms required by strains of E. coli to cause enteric infections (Chart et al. (2000) J. Applied Microbiol. 89, 1048-1058 and can be considered broadly equivalent to E. coli K12 strains.

Laboratory strains of yeast Pichia pastoris will be used. This is a non-pathogenic disabled host which is unlikely to persist in the gut, lung or survive outside the culture media. It is not normally infectious nor able to colonise humans and the main biological characteristics are known.

**Host/vector system**

For expression in E. coli, standard commercially available, well-characterised vectors that are neither non-mobilisable (e.g. pUC series and their derivatives) or mobilisation-defective (e.g. pBR322 and its derivatives) in bacteria will be used. They will contain only selective markers that are already in routine use in standard cloning vectors. All expression systems will be induced by IPTG.

Example vectors include:

- **pMal**: E. coli plasmid cloning vectors designed for recombinant protein expression and purification using the pMal protein fusion and purification system. pMal vectors (e.g. pMAL-c5X, pMALp5X, pMALp5G, pMALp5E, pMALp2X) are derived from PBR322 (a mobilisation defective bacterial plasmid vector) and expression is inducible and directed either to the cytoplasm or the periplasm.

- **pGEX**: E. coli plasmid expression vectors designed for cytoplasmic expression of glutathione S-transferase (GST) fusion proteins. pGEX vectors (e.g. pGEX-P series, pGEX-T series, pGEX-X series, pGEX-2TK) are non-mobilisable bacterial plasmid vectors. Expression is inducible and catabolite repression possible.

- **pET SUMO**: Inducible expression vectors designed to express small ubiquitin-like modifier (SUMO) fusion proteins in the cytoplasm, pET vectors are mobilisation defective bacterial plasmid vectors.

For expression in P. pastoris, standard commercially available, non-conjugative, non-mobilisable or mobilisation defective expression vectors which utilise the AOX1 gene promoter will be employed (e.g. pPICZ series vectors, pPink series vectors). These vectors exhibit tight regulation by induction mechanisms and repression/derepression (Daly & Hearn (2005) J. Mol. Recognit 18, 119-138) for tight cytoplasmic or secreted expression of proteins in methanol containing media.

Sodium channel toxins will only be cloned using non-mobilisable vectors.
There inserted gene products will be derived from scorpion DNA/cDNA. Sequences will either be amplified directly from scorpion genetic material or synthetic sequences will be generated by back-translation of known peptide sequences. The expressed peptides will be purified and used in structure/function studies.

The gene products can be divided into four broad groups:

i) Sodium channel toxins:
ii) Potassium channel toxins:
iii) Chloride channel toxins:
iv) Other peptides:

Evaluation of foreseeable effects

Toxicity of product:
All peptides discussed below are unlikely to have significant oral toxicity because of their inability to escape the lining of the stomach. Ion channel toxins derived from venom have a high density of positive charges and are therefore extremely unlikely to cross cell membranes. As peptides, they will be susceptible to proteases in the gut.

The four groups of gene products will be considered separately:

i) Sodium channel toxins:
This group of toxins is primarily responsible for the clinical effects of scorpion venoms when individuals are stung and the venom enters the bloodstream. The most toxic scorpion venom (Leirus quinquestriatus has LD50 0.25mg/kg via subcutaneous injection (Simard & Watt (1984) J. Physiol (Paris) 79, 185-91). The most toxic sodium channel toxins have approx 10 fold higher toxicities when injected directly into the brain (e.g. LD50 10μg/kg intracebroventricular, toxin AaHI vs 25μg/kg subcutaneous toxin Cs11 (Kharrat et al (1989) European Journal of Biochemistry 181, 381-90, Martin (1987) Journal of Biological Chemistry 262, 4452-9). However, the likelihood of administering a significant dose subcutaneously during our use in the lab is extremely low. Extrapolation by weight from the subcutaneous LD50 for Cs11 in mice would suggest a subcutaneous LD50 of 1.75 mg for a 70 kg human (equivalent to 1.1L of E.coli culture or 17.5 ml Pichia pastoris culture (see below). Although the risk of colonisation is low, the toxicity of this group of toxins has influenced our restricted use of mobilisation-defective vectors for this particular class of peptides and the decision not to express these toxins in E.coli via secretory pathways (see Table 1). Native sodium channel toxins are used routinely in our laboratory.

ii) Potassium channel toxins:
Compared to sodium channel toxins these toxins are essentially non-toxic via intraperitoneal injection (LD50 30mg/kg, (Harvey & Karlsson (1980) Naun-Schmied. Arch Pharmacol. 312, 1-6)). They are only lethal via direct injection into the brain (LD50 4μg/kg (Schweitz et al (1989) Biochemistry 28, 9708-14)). The likelihood of administering these toxins directly into the brain is negligible. Native potassium channel toxins are used routinely in our laboratory.

iii) Chloride channel toxins:
Although a recombinant chloride toxin from a Chinese scorpion venom has extremely surprisingly been quoted to have a mouse LD50 of 4.3mg/kg (Fu et al (2005) Biotechnol Letts. 27, 1597-1603), the overwhelming majority of papers contradict this finding and indicate that this group of toxins are not toxic to mammals, including chlorotoxin from Leiurus quinquestriatus (Soreceanu et al (1998) Cancer Research 58, 4871-9) and chloride channel toxins from Mesobuthus tamulus (Dhawan et al (2002) FEBS Letts 528, 261-66; Wudyagiri et al (2001) BMC Biochemistry 2, 16 (Epub)). Indeed, synthetic chlorotoxin is now in clinical trials (Mumelak et al (2006) J. Clin. Oncol. 24, 3644-3650). As with the sodium channel toxins, the likelihood of administering a significant dose subcutaneously during our use in the lab is extremely low. Native chloride channel toxins are used routinely in our laboratory.

iv) Other peptides:
Molecules from scorpion venoms are primarily characterised based on toxicity assays. We can therefore confidently predict that the molecules with the highest toxicity that are present in our venoms of interest have been characterised (as sodium channel toxins). Native scorpion venom is used routinely in our laboratory (Newton et al (2007) Rapid Commun. Mass Spectrom. 21, 3467-76).
Expression levels of scorpion venom peptides obtained previously are typically 1-10 mg/L culture (1mg/L for a chloride channel toxin expressed in P. pastoris (Trung et al (2006) BMC Biotechnology 6, 18); 1.6mg/L for a sodium channel toxin expressed in E.coli (Fu et al (2004) Protein Expression and Purification 38, 45-50); 8-10mg/L for a potassium channel toxin expressed in Saccharomyces cerevisiae (Wu et al (2002) Biochemistry 41, 2844-2849); 5mg/L for a sodium channel toxin expressed in Saccharomyces cerevisiae (Shao et al (1999) Protein Expression and Purification 17, 358-365), although expression of 100-120mg/L culture has been reported for a sodium channel toxin expressed in P. pastori (Wang et al (2006) Biotechnol Lett 28, 1767-1772). These expression levels suggest that accidental intoxication to the level of the lethal dose via these cultures is highly unlikely.

It is difficult to envisage how the cloned sequences described above could enhance the ability of the disabled E. coli K12 strains or the yeast strains to colonise humans or otherwise cause disease.

The specific function of any individual scorpion toxin is highly dependent on its sequence and these sequences have evolved and been selected for during the evolutionary process. It is therefore probable that this sequence has been optimised for biological activity and any unintentional sequence alteration is likely to reduce activity.

Environmental assessment:
Use of disabled E. coli or yeast strains which have very limited ability to survive outside the laboratory, with non-mobilisable or mobilisation-defective vectors, will ensure that in the very unlikely event of escape the GMM will be unable to survive, disseminate with and/or displace other organisms and the vectors will be unlikely to transfer to related microorganisms.

The GMM will be unable to colonise or otherwise cause harm to animals. The expressed product is unlikely to cause a problem to human health or harm other mammals. The greatest risk will be posed by subcutaneous injection of a sodium channel toxin. The published expression levels for similar peptides suggest that the likelihood of sufficient toxin entering the blood stream to cause harm to human health is extremely low.

Some scorpion toxins exhibit toxicity to invertebrates. An insect-specific chloride channel toxin from Mesobuthus tamulus is toxic toward insect larvae (LD50 5μh/100mg, Dhawan et al (2002) FEBS Letts 528, 261-66) However, these toxins are "normally effective when injected into insects and are typically ineffective when administered orally because they are unable to access the central nervous system or other target sites where they are active" (Fitches et al (2010) Pest Manag Sci. 66, 74-83). A second insect-specific chloride channel toxin from Mesobuthus tamulus has been characterised (Wudyagiri et al (2001) BMC Biochemistry 2, 16 (Epub)) and although it has been reported to account for almost all the insect lethality of the crude venom toward some invertebrates when directly injected, Fitches et al (2010) (Pest Manag Sci. 66, 74-83) demonstrated that this toxin exhibits no oral activity in these species. The most toxic insect-selective scorpion venom toxins is the sodium channel toxin AaIT (LD50 of 10μg/100 mg body weight (Zlotkin et al (1992) Arch Insect Biochem Physiol. 21, 41-52), however, the toxin is inaccessible by oral and topical applications (Zlotkin et al (2000) Biochimie 82, 869-81). Since all insect toxicity is obtained by direct injection of toxins, it is extremely unlikely that this situation will be replicated outside the laboratory.

There is no evidence to suggest that scorpion venom proteins are able to cause harm to plants. Use of only disabled host strains which have very limited ability to survive outside the laboratory, combined with cloned sequences that will not express a product that could have toxic or other detrimental effects if delivered to plants, will ensure that in the very unlikely event of escape, the GMM will be unable to cause harm to plants.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

• All manipulations involving GMC/O will be undertaken within a level 2 containment laboratory where access is restricted to authorised personnel/students using good laboratory practice. Only staff/students trained in the safety aspect of this work will be involved.
• Workers will wear dedicated laboratory coats that will remain in the laboratory at all times These coats will be laundered "in house".
• All GM solid waste material will be disposed of on-site by autoclaving or by incineration off-site by a contractor licensed for disposal of GM waste. Before inactivation, solid GM waste will be bagged and then stored or transported in leak-proof containers. Liquid GMO waste will be inactivated by adding bleach tablets according to the manufacturer's instructions to give an available chlorine concentration of at least 1,000 ppm and left to stand for 30 minutes before disposal; alternatively, liquid GM waste will be sterilised by autoclaving. GMC/O waste is autoclaved on a sterilising cycle for which a printed record of the conditions is logged after each run. Twice yearly, a temperature indicator strip, a Browne's tube and a spore tube are incorporated into the autoclave run to comply with HSE regulations. Following this run, the spore tube is incubated at 55°C for 48 hours with a non-autoclaved control tube. The autoclaved tube should remain yellow in colour indicating a 100% kill rate and the control tube will turn purple indicating spore growth.
• In the event of a significant spillage of GMC/O the area concerned will be flooded with disinfectant and left for at least 10 minutes. The spillage will then be mopped up using disposable paper towels which will be placed into and autoclave bag for sterilisation by autoclaving. The incident will be recorded on the GM accident notification form AND in the departmental accident book and the Faculty Biological Safety Officer will be notified.

The risk assessment for class 2 activity was considered by the genetic modification safety committee on 05/02/10. This was approved subject to amendments which have now been made.

Project Ref 565/15.1

Date Ackn'd 21/10/2015

CU2 Project Title Periodontal pathogens and interactions with human epithelial cells

Class 2 CultureVolClass2 1-50 Litres

Non-GMM Consent Granted

Date Project 02/03/2022

Page 9951 of 15326
The study aims at elucidating the mechanisms underlying cellular responses triggered in oral epithelial cells following infection with the periodontal pathogens, Tannerella forsythia and/or Porphyromonas gingivalis.

The methods used in this study include growth of bacteria under anaerobic conditions, culture of immortalised human cell lines, infection of these human cell lines with the pathogens, protein extraction and analysis using a range of techniques (including western blotting, ELISA, protein assays/mass spectrometry) as well as DNA and total RNA (RNA, miRNA, LnRNAs) extraction for analysis (e.g. PCR and qPCR). Infected cells will also be analysed by immunofluorescence methods (e.g. immunofluorescence microscopy, confocal microscopy or flow cytometry).

The studies described here do not aim to generate or introduce new genetic modification within the pathogens and cell lines used, rather they will involve the use of genetically modified oral anaerobic bacteria: Porphyromonas gingivalis and Tannerella forsythia that have been generated by collaborators in Sheffield and Buffalo, NY. All of these mutations reduce the virulence of the pathogens as they lack specific virulence factors.

Recipient or parental organism

(1) Tannerella forsythia is a Gram-negative, anaerobic bacterium, which is frequently isolated from patients with periodontal disease. It was formerly known as Bacteroides forsythus and in some literature is referred to as T. forsythis. It has extremely fastidious growth requirements and requires N-acetyl neuramic acid supplementation in media to enable growth. It falls into Hazard Group 2 with other Bacteroides spp. The strains used in this study will be the type strain Tannerella forsythia ATCC 43037 and the following mutants:
   - Tannerella forsythia nanH (lacking sialidase)
   - Tannerella forsythia ed1 (aberrant surface glycosylation)

(2) Porphyromonas gingivalis is a Gram-negative, anaerobic black-pigmented bacterium that is frequently isolated from patients with periodontal disease. Hazard Group 2. The strains used in this study will be NCTC 11834, W50 and 381 containing null mutation.
   - Porphyromonas gingivalis rgpA, rgpB, kgp (containing null mutations in arginine and lysine proteases)
   - Porphyromonas gingivalis PG0352 (lacking sialidase)
   - Porphyromonas gingivalis ompA (lacking a surface protein)

Host/vector system
On occasion, complemented Porphyromonas strains transformed with the plasmid pT-COW will be used. It is a non-transferrable shuttle vector for expression in E.coli and Porphyromonas and carries a tetracycline resistance cassette- again these strains will be generated by our collaborators at TuOS (The University of Sheffield).

**Origin & function**

The bacterial pathogens Porphyromonas gingivalis and Tannerella forsythia will be used to infect oral epithelial cell lines (H357 or OK-F6 cells; see below) to study host-cell interactions. These will include determining which cellular pathways are being triggered following infection (e.g. apoptosis, autophagy) as well as validating proteins which were found to be dysregulated in previous proteomic studies.

**Evaluation of foreseeable effects**

Porphyromonas gingivalis and Tannerella forsythia can cause periodontal disease in certain individuals, but the site of infection is limited to periodontal pockets. The organisms are strictly anaerobic, nutritionally fastidious and unable to survive for longer than a few hours in air. They are ACDP Hazard Group 2 biological agents.

Complemented Porphyromonas strains transformed with the narrow host-range plasmid pTCOW will be used. It is a non-transferrable shuttle vector for expression in E.coli and Porphyromonas and carries a tetracycline resistance cassette- again these strains will be generated by our collaborators at TuOS.

Gene products inserted in pTCOW will be complementation constructs of the genes that have been deleted, they are expressed from natural promoters and only restore gene expression to wild-type levels, thus not increasing virulence of strains.

The strains will either have reduced (mutant strains) or wild-type traits (complementations), in no cases do we intend to increase pathogenic potential.

Oral anaerobes are strictly anaerobic, nutritionally fastidious organisms that do not survive well in the environment and potential hazards of sequences within the GMM being transferred to related micro-organisms are negligible.

The likelihood that the GMM could cause harm to human health in the event of exposure is negligible. It is not likely to be released under the requirements of the containment level to protect human health.

These pathogens are strict anaerobes with fastidious growth requirements (such as Hemin, cysteine and menadione). Whilst both P. gingivalis and T. forsythia have been linked to the oral disease of periodontitis, this condition has a complex, multi-factorial aetiology and acquisition of single species is not thought to predispose to disease. Additionally, host response, risk factors (including smoking, immune health) as well as the oral microbial community present all contribute to disease. As the pathogens are strict anaerobes, they are unlikely to survive in the aerobic atmosphere of the buccal cavity; they normally survive in periodontal pockets.

The likelihood that the GMM will be released into the environment under the requirements of the containment level to protect human health is negligible. The consequences of GMM dissemination in the environment are negligible since the aerobic survival time of the organisms is short. Due to their short survival time, the GMM are not likely to displace other organisms. These pathogens are also strict anaerobes with fastidious growth requirements (such as hemin, cysteine and menadione).

As the pathogens will not survive in the environment, they will not cause any harm to animals.

No harm will be caused to plants by these strictly anaerobic and nutritiouslly fastidious pathogens, so will not survive in the environment.

They are unlikely to cause harm to other cells/organisms.

Risk of transfer of genetic material between the GMC/O and other cells/organisms are negligible.

These pathogens have been in use for a while with no known risks of phenotypic or genetic instability.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

- All manipulations involving GMC/O will be undertaken within a level 2 containment laboratory where access is restricted to authorised personnel/students only using good experimental practice and hygiene. Only staff/students trained in the safety aspect of this work will be involved.
- Workers will wear dedicated laboratory coats that will remain in the laboratory at all times. These coats will be laundered "in house."

All GM solid waste material will be disposed of off-site by a contractor licensed for disposal of GM waste. Solid GM waste is stored and transported in leak-proof containers (biohazardous waste bins) before being taken to the outside store holding area ready for collection by the contractor. Liquid GMO waste will be inactivated by adding bleach tablets according to the manufacturer’s instructions to give an available chlorine concentration of at least 1000 ppm and left to stand for 30 minutes before disposal; alternatively, liquid GM waste will be sterilised by autoclaving. All microbial waste is autoclaved on a sterilising cycle for which a printed record of the conditions is logged after each run. Twice yearly, a temperature indicator strip, a Browne’s tube and a spore tube are incorporated into the autoclave run to comply with HSE regulations. Following this run, the spore tube is incubated at 55°C for 48 hours with a non-autoclaved control tube. The autoclaved tube should remain yellow in colour indicating a 100% kill rate and the control tube will turn purple indicating spore growth.

Outline any additional measures regarding disposal route:
- Liquid Waste from GM mammalian cell culture should only contain culture media plus expressed secreted proteins and possibly cell waste.

Outline any additional control measures:
- Personal protective equipment in the form of gloves and lab coats should be worn at all times.

Liquid Waste:
Cell culture liquid waste under 50 ml is disposed of in a sealed falcon tube and then placed directly into yellow clinical waste bins. Waste over 50 ml is emptied into an old media bottle containing half a pre-sept tablet. This is left overnight and then emptied down the sink and the bottle disposed of in the black bin.

Vacuum pumps can be used but these must be cleaned and maintained by the user. There is only one pump available for use.

Any flasks that are infected with fungi/bacteria or mycoplasma are sealed in a bag and placed in an almost full yellow bin, so that sealing of the yellow bin and removal from the lab is imminent.

Solid waste:
Any solid waste will be disposed of in the yellow clinical waste bin along with used pipettes, tips, gloves and other consumable items.
- Liquid waste can be directly aspirated into the waste reservoir from culture dishes or flasks using the vacuum pump.
- Liquid waste collected in a beaker should be carefully aspirated into the waste reservoir using the vacuum pump.
- Do not fill the reservoir past the marked fill line.
- The liquid waste must be inactivated for 30 minutes using bleach tablets according to standard operating procedures for disposal of cell culture waste before disposal down the sink in the Tissue Preparation room.

If the reservoir is full to the fill line, excess waste must be inactivated with presept (bleach tablets) for 30 minutes and disposed of down the sink in the Tissue Preparation room.

Outline any additional control measures:

Personal protective equipment in the form of gloves and lab coats should be worn at all times.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y
This project has been reviewed by the genetic modification safety committee, and was approved following minor amendments concerning clarification of specific details of the host organisms and likelihood of interacting with humans.

**Project Additional Information**

**Purposes of the contained use**

To rescue recombinant ovine adenovirus (OAV) from a plasmid in an ovine cell line and to propagate OAV in this cell line for human therapeutic use.

**Recipient or parental organism**

OAV623 is an OAV that contains the full viral genome and a prokaryotic transgene. OAVs are capable of infecting human cells but have been shown to unable to complete their full cycle of replication (Khatri, A et al [1997]: Virology 239 226-237), resulting in an abortive infection. Infection is still abortive in the presence of co-infected human adenovirus suggesting minimal risk to the worker when propagating this virus. It is expected however that there will be an immune response in humans on exposure to this virus.

**Host/vector system**

A plasmid that contains the whole OAV623 viral genome and is therefore a GMM, though of similar or lower risk to the parental virus. The host cells and viral vector are both ovine and the virus is incapable of effective replication in humans. In addition, the expression of the transgene is under the control of a human tissue specific promoter.

**Origin & function**

Virus and cell line are ovine. The cell line is to allow efficient propagation of the recombinant ovine virus. The virus carries a prokaryotic transgene and is intended to deliver the transgene to human cells via an infective but non-replicative action. Expression of the transgene is under the control of a human tissue specific promoter. The gene product is a human enzyme that will only be expressed in target tissues and will be capable of generating a toxic product from a prodrug that is administered separately.

**Evaluation of foreseeable effects**
