**Disarmed Ti plasmid derivative vectors SLJ, pBIN19 or pGreen/pSoup and strains GV3101, AGL1 and LBA4404 of Agrobacterium tumefaciens will be used for infiltration into leaves of Arabidopsis, N.tobacum, N.benthamiana, Lycopersicon spp., and Solanum spp, as a mean of transient assays for gene targeting. The transient assay will be performed to assess efficiency of gene targeting for visual marker genes like GUS and GFP, with subsequent experiments to target endogenous plant genes.**

Dipping procedure for Arabidopsis transformation will be performed to generate stable transformants with selectable markers like NPTI or NPTII for kanamycin resistance, bar for BASTA herbicide resistance, hyg gene for hygromycin resistance and aadA gene for spectinomycin resistance, and visual markers like GUS and GFP. Derivatives of plant endogenous plant genes will be used to induce gene targeting.

**Recipient or parental organism**

As plant expression vectors and constructs these vectors would not cause a human health hazard. Agrobacterium strains, Arabidopsis, Nicotiana spp., Lycopersicon spp.,...
and Solanum spp. Plants would survive in the environment but none are likely to cause damage to the environment, and neither disarmed Agrobacterium, or transgenic Arabidopsis, Nicotiana spp.; Lycoperscion spp., and Solanum spp. Would cause disease. Infiltrated plants containing high concentrations of Agrobacterium will be held in a category B greenhouse to prevent escape. The Arabidopsis plants could cross with naturally occurring plants, although the level of cross-fertilisation in this species is extremely low, especially out of controlled conditions. Therefore no harmful effects are foreseen.

**Host/vector system**

Wild type or transgenic plants of Arabidopsis, tobacco, tomato or potato with visual marker genes (GUS, GFP) will be used to assess gene targeting in transient assays or stable transformants.

Agrobacterium strains GV3101, AGL1 and LBA4404 will be used for plant transformations or infiltrations.

Disarmed vectors pBIN19, pGreen/pSoup, SLJ and pRK290 derivatives will be used for delivery of transgenes into plants.

**Origin & function**

The majority of genes used for transformation have bacterial origin. They are NPTI, NPTII for kanamycin resistance, addA gene for spectinomycin resistance, bar for BASTA resistance, hyg for hygromycin resistance and uidA (GUS) as a visual marker. GFP is an eukaryotic gene from jellyfish and is used as a visual markers. Plant endogenous genes like maize Spm transposable element and tabacco Tnt1 retrotransposon will be used to facilitate gene targeting in plants. Disarmed vectors pBIN19, pGreen/pSoup, SLJ generated at the John Innes Centre and Sainsbury Laboratory, as well as pRK290 derivatives will be used for delivery of transgenes into plants.

**Evaluation of foreseeable effects**

Arabidopsis: this is a small short-lived species of no economic importance, either as a weed or crop and of limited environmental significance (being primarily a weed of waste ground). It does not cross breed with any crop species and there are no known bridging species. Therefore, even in the event of an escape, the GMO is highly unlikely to present an environmental threat.

Nicotiana species: The Nicotiana species used (tabacum, benthamiana) are not native species in the UK. However Nicotiana spp are used as ornamental varieties in the UK. We are unaware of any such commercial activities in the local area. In the event of an escape, GM Nicotiana species are unlikely to overwinter and survive more than one growing season.

Lycoperscion species: GM Lycopersicon species are unlikely to overwinter in the UK. All fruit is bagged in the glasshouse and processed within the laboratory, so seed escape to the environment is highly unlikely.

Potato: Solanum species: a major local crop but does not generally propagate itself by seed in the UK, so escape by pollen or seed is highly unlikely. All plant material is destroyed by autoclaving, so tuber escape is also highly unlikely.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Genetically modified plants (GMP) of Arabidopsis are produced either in culture by co-cultivation with Agrobacterium or by particle bombardment or by dipping flowering plants into Agrobacterium cultures. Where Agrobacterium is used in co-cultivation experiments, as for Nicotiana spp., Lycoperscion spp. And Solanum spp., the GMM will be removed using antibiotics before planting out in Cat A greenhouses. Where dipping is used, dipped plants will be contained within Cat B glasshouses. Theses glasshouses facilities are designed to contain microbes and plant pathogens and operate under strict MAFF DEFRA approved guidelines. Briefly, access is limited by an ID card-operated double door containing foot dips, biological waste leaves by a double-doored autoclave, waste water is treated by a verified chemical treatment before release into the waste water system, the entire facility operates at positive pressure to prevent insect entry (this is supplemented by a rigorous control program) and air is filtered on release.

Transgenic plants that are free of GMMs may be grown in Cat A or B glasshouses. These have insect screens in place over vents and doors and have a systematic insect...
control program to prevent pollen dispersal. Where pollen or seed dispersal may provide an escape route for the GM plant, plants are either prevented from flowering or are bagged to contain the seed. Greenhouses are surrounded by a gravel strip that is sprayed on a regular basis with a broad spectrum herbicide.

As IFR has a limited space in greenhouse facilities transgenic or wild type plants will be grown for generation of leaf biomass only which will be subsequently used for molecular biological analyses. The Agrobacterium infiltration or dipping of plants for transformation will be performed at JIC greenhouse facilities.

We consider that our procedural and cultural precautions will minimise the risk of GM escape into the environment and that level 1 containment is sufficient to reduce the hazard to effectively zero.

Genetically modified Arabidopsis
Plants will be transformed by infiltration with Agrobacterium and grown in containment level B glasshouse. Seeds will be collected in glasshouse, double contained in the bags before transferring to the laboratory and stored in the locked up laboratory. Remaining plant material between glasshouses and laboratory will be controlled and limited as far as possible. The transgenic material will be double contained in bags and transported in rigid container. The progeny of these plants will be selected with antibiotics under sterile conditions in the laboratory before transfer to a glasshouse or growth chambers at containment level B as appropriate. Alternatively the progeny plants will be grown under containment level B and selected with a herbicide such as BASTA. After harvesting plant material will be autoclaved. In category B conditions disinfectant foot dip is provided for workers entering and leaving the glasshouse. Arabidopsis is predominately self-fertilising. This, together with the strict control of insect pests maintained in the glasshouse restricts the possibility of sexual transfer of novel genetic material. All matting and plant material is autoclaved after use.

Genetically modified Nicotiana species.
Only ornamental varieties of Nicotiana species are grown in the UK. Normal Cat. A glasshouse practice (bagging of flowering plants) is considered sufficient to contain any seed that might be produced.

Genetically modified Solanum and Lycopersicon species.
Transgenic plants of these species will be produced in tissue culture within the laboratory and mature plants grown under Cat. A containment. Plants will be grown in screened glasshouses (to prevent insect transfer of pollen). For Solanum spp. Flowers will be removed or bagged if seed set seems likely. For Lycopersicon spp. All fruit will be bagged and is processed within the laboratory. All material will be autoclaved after experiments are finished. Cat A glasshouses are considered sufficient to contain all risk.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste Disposal procedure at the Institute of Food Reasearch (IFR) site.
1. Introduction
This code of practice (COP) covers the disposal of biological waste at Algentech Ltd in accordance with Institute of Food Research general procedure. Biological waste is defined here as that contaminated with micro-organisms (ACDP Hazard Groups 1 and 2 and ACGM Genetically Manipulated (GM) Organisms Classes I and II), mammalian cells, human body fluids/wastes or transgenic plant material.
All such waste will be inactivated before final disposal, i.e. release to the environment. The inactivation procedure will be one (or more) of chemical treatment, autoclaving or incineration.

2. Inactivation by autoclaving
Waste in re-usable items such as glass bottles will be placed in the stainless steel containers available from the Media Laboratory of the Institute of Food Research. These
containers will be labelled with the number of the room generating the waste, and will be collected by support staff for autoclaving.

Non-re-usable solid or semi-solid wastes (e.g. Petri dish cultures) will be put in a transparent/blue autoclave bag (the recognised colour coding for biohazard waste for autoclaving), and contained within a white polypropylene bucket. Care will be taken that no sharp items that might penetrate the bags are included. Such items will be placed in a dedicated 'sharps' container in a separate autoclave bag. Buckets will be labelled on a piece of tape with the number of the room generating the waste, and the lid clipped on to the bucket ready for collection. Buckets will be routinely collected from the laboratory by support staff. After sterilisation, waste in autoclave bags will be further bagged by the support staff using yellow incinerator bags (see below), and dispatched for incineration.

Note that other safety requirements, such as COSHH, will also be met.

3. Chemical inactivation

Chemical inactivation will use an approved disinfectant such as alcohol at concentration 70-85% for 10-30 minutes, VIRCON at concentration 1% for 10 minutes, and chlorine compounds like bleach or hypochlorite at the concentrations 5-10% for 15-20 minutes. Although chemically-inactivated waste no longer presents a biological hazard, other requirements of COSHH will be met when considering further disposal.

4. Inactivation by incineration

Waste for incineration will be double-bagged and the outer bag will be yellow (the recognised colour coding for biohazard waste for incineration). Sharp items will be placed in a dedicated 'sharps' container in a separate bag. Bags will be sealed with tape, and will then be routinely collected from the laboratory by support staff. Bags of waste for incineration will be transported by a licensed contractor in secondary containment appropriate for transport on public roads.

Note that other safety requirement, such as COSHH, will also be met.

5. Transgenic plant material

As noted in 1 above, in general, waste containing genetically modified material will be inactivated prior to leaving the laboratory site. However, as an exception, genetically modified plant waste originating only from IFR glasshouses, and which IFR Genetic Manipulation Safety Committee consider to be Containment Level A or B, will be sent off-site direct for incineration without prior inactivation, via an approved contractor, using yellow bags held inside rigid transport bins.

6. General Administration

All waste bins will be clearly labelled. All staff (particularly visiting workers) will be instructed on the disposal procedures for biological waste, particularly the differences between biological waste for autoclaving and ordinary non-hazardous waste e.g. office material (black bags).

Waste Disposal procedure at the John Innes Centre (JIC) Site.

Only genetically modified plant waste originating from JIC glasshouses, and which JIC Genetic Manipulation Safety Committee consider to be Containment Level A or B, will be disposed at JIC site. All JIC genetically modified plant waste will be autoclaved and subsequently composted on the site in accordance with JIC Safety Procedure.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
More details on genes and bacterial strains which will be used for research should be introduced;
Nicotiana spp have a commercial crop in the UK as ornamental varieties, and this issue should be taken in consideration.
The final version of the risk assessment was modified in accordance with comments and was accepted as adequate for the project.

### Project Additional Information

**Purposes of the contained use**
Potex and Gemini - viruses will be used as vectors for expression of plant and bacterial genes in dicot and monocot plants.
The following geminivirus will be used: members of the Begomovirus (Tomato Golden Mosaic Virus, TGMV), Curtovirus (Beet Curly Top Virus, BCTV) and Mastrevirus (Maize Streak Virus, MSV; Wheat Dwarf Virus, WDV) genera.

The following potexvirus will be used: Potato Virus X (PVX).

Recipient or parental organism

Studies will use a range of plant hosts including Nicotiana ssp. Arabidopsis, Tomato, Maize, Barley, Rice and Wheat. E.Coli strains DH5a, DH10B and SCS110 will be used for cloning viral vector sequences into disarmed Ti plasmid derivatives (pRK290, pBIN19, Bin 400 and pGreen/pSoup derivatives).

The Agrobacterium strains GV3101, AGL1 and LBA4404 will be used to inoculate plants or cultured explants for transient and stable expression of virus derivatives.

Host/vector system

The investigation will include the construction of virus derivatives for plant inoculation and transformation:

1. Full length double stranded (dsDNA) derivatives of PVX, BCTV, TGMV, MSV, WDV and part thereof.
2. Recombinant viruses for expression of cloned genes from plants and bacteria (aadA for spectinomycin resistance; visual marker genes uidA (GUS), GFP, luciferase, amturase genes and intron sequences).

None of the genes to be used will be associated with toxic effects or genes known to affect virus virulence, and if such genes become of interest we will submit a separate or modified proposal, as appropriate.

Origin & function

Potential scenarios include the construction of virus derivatives for plant inoculation and transformation:

1. Geminiviruses:

With the exception of horticulturally desirable ornamentals that are propagated vegetatively (e.g. honeysuckle, abutilon), geminivirus diseases do not occur in the UK. All geminiviruses are transmitted by either whitefly, leaphopper or treehopper vectors. These vectors do not occur in the UK, hence the viruses could not become established in the environment even if released. Some begomoviruses are mechanically transmissable but no accidental transmission between adjacent touching plants has been observed under glasshouse conditions. In addition, the viruses do not gain access to the germ - line and hence are not seed transmissable.

-GM Geminiviruses: no harmful effects should occur because neither the wild-type virus nor the genetically modified viruses would be able to survive if released. In the worst case, it is conceivable that recombination could occur between viral DNA and plant chromosomal DNA, but as the viruses are unable to gain access to the germ line, such events would be limited to individual cells of infected plants and would be transmitted vertically. In the event of pollen release from transgenic plants, the possibility of recombination between a geminiviral transgene and an endemic virus is considered to be extremely remote (no such events have been reported).

2. Potexvirus (Potato Virus X):

PVX is transmitted mechanically. It has a narrow host range infecting potato, tomato, Brassica campestris and Nicotiana species. Experiments will be carried out with an indigenous UK isolate that is normally causing mild symptoms in infected plants. PVX is not seed transmissable. There is no known vector for transmission of PVX. We intend to use mainly sequences from the chloroplast and mitochondrial genome, these are not known to affect the virulence of PVX, and will minimise the risk of producing a more virulent form of the virus.

The most severe consequence of survival, establishment and dissemination would be the mild disease caused by PVX in potato and tomato. Given the use of containment facilities and the known fact that PVX is not transmitted by invertebrate vectors or true seed there is only low likelihood of hazard from these experiments.

3. The virus and host plants used in this project are not known as hazard to human health and nor is there any
The Agrobacterium infiltration or dipping of plants for transformation and growth of transgenic plants carrying viral sequences will be performed at the John Innes Centre (JIC) category B (level 2) greenhouse facilities where access is limited by an ID card-operated double door containing foot dips, biological waste leaves by a double-doored autoclave, waste water is treated by a verified chemical treatment before release into the waste water system, the entire facility operates at positive pressure to prevent insect entry (this is supplemented by a rigorous control program) and air is filtered on release.

The glasshouses facilities at JIC are designed to contain microbes and plant pathogens and operate under strict MAFF DEFRA approved guidelines.

The most likely routes of escape of geminivirus and potexvirus sequences into the environment is via pollen from transgenic plants. For this reason, all infectively studies in which cloned viral genome components are infiltrated into plants will be conducted under category 2 containment. Transgenic plants carrying virus sequences will be grown in category 2 containment and will be allowed to flower only when seed is to be collected, and plants will be suitably bagged to minimise pollen release.

We consider that our procedural and cultural precautions will minimise the risk of genetically modified virus escape into the environment and that plant growth level 2 containment is sufficient to reduce the hazard to effectively zero.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Transgenic plant waste:
the glasshouses facilities at JIC are designed to contain microbes and plant pathogens and operate under strict MAFF DEFRA approved guidelines: access is limited by an ID card-operated double door containing foot dips, biological waste leaves by a double-doored autoclave, waste water is treated by a verified chemical treatment before release into the waste water system, the entire facility operates at positive pressure to prevent insect entry (this is supplemented by a rigorous control program) and air is filtered on release. All JIC genetically modified plant waste will be autoclaved and subsequently composted on the site according to JIC Safety Procedure.

E.coli and Agrobacteria cultures carrying viral constructs:
Standard IFR waste disposal practises will be strictly adhered to.

All materials coming in contact with the GMM and all biological waste is activated by autoclaving, incineration or verified chemical means before leaving the building. Waste in re-usable items such as glass bottles will be first inactivated by approved chemical means (e.g 1% Virkon for 10 minutes) placed in stainless steel containers and autoclaved. Non-reuseable waste (e.g Petri dish cultures) will be autoclaved and dispatched for incineration. Bags will be transported by a licensed contractor in secondary containment appropriate for transport on public roads.

Personnel are trained in GMO/GMP and the uses of appropriate protective clothing (lab coats, gloves etc) to enable effective decontamination of personnel in the event of an accident.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N
Comments of the GM Safety Committee on the risk assessment:
1) Your description of growth of transformed plants implies that there will be no soil transferred to the laboratory from the greenhouse. Is this so? If soil will be transferred, can you detail how this will be made safe and subsequently disposed of?
2) Please include details of the double containment procedures you will use when transferring plants and plant samples between greenhouse and laboratory.
3) Seeds must also be transferred under double containment: they must also be stored in a locked, designated container/refrigerator (either in the greenhouse or laboratory).
4) Please be aware of which greenhouses will be suitable for different aspects of your work (Particularly if your work progresses to a different stage). Those at JIC operate under both DEFRA and the HSE licences; those at JIC operate under both Defra and HSE licences; those at IFR only have an HSE licence, so cannot be used for e.g plant virus work.
5) Nicotiana spp do have a commercial crop in the UK, as ornamental varieties. We are unaware of any such commercial activity in the locality, but it might be useful to be aware of this possibility.

The final version of the risk assessment was modified in accordance with comments and was accepted as adequate for the project.

FluMist vaccine contains two cold-adapted (ca), temperature-sensitive (ts) and attenuated (att) influenza strains of type A (ie A/H1N1 and A/H3N2), and one ca, ts and att influenza strain of type B. Seeds used to produce FluMist are 6:2 reassortant viruses, which are produced by a process of genetic reassortment between a contemporary wild-type virus to produce the appropriate 6:2 vaccine strain is currently achieved using classical techniques, in which the initial steps are co-infection of cells which the MDV and a wild-type virus, followed by antibody selection and screening to identify the appropriate 6:2 vaccine strain. Recent advances in reverse genetics have made it possible to significantly improve the reassortment process using the plasmid rescue technique. Transfection of certain mammalian cells with plasmids, designed to produce each of the eight viral gene segments containing unmodified genetic sequences derived from the wild-type virus HA and NA genes and the remaining six genes derived from the MDV, results in the derivation of a specific 6:2 vaccine strain. Details regarding the two reassortment methods (classical co-infection or plasmid rescue methods) and the biological and genetic properties of 6:2 vaccine strains prepared using either of these two reassortment methods are provided in Risk Assessment. Because the viruses that are the subject of this application are attenuated vaccine viruses, Medimmune believes that it is reasonable that they should be classified below Hazard Group 2, ie as representing no hazard to human health. All waste materials containing vaccine virus are either thermally or chemically inactivated by validated procedures prior to removal from the facility. Alternatively contaminated material is sealed in clinical waste drums and incinerated at approved off-site facility.
The risk assessment has been discussed and agreed as valid and correct by all members of the safety committee and by Corporate oversight committee. The committee agree with the report conclusions that:

Rescue of infectious 6:2 reassortants by plasmid rescue methods yields MVSs that are indistinguishable from those generated by classical methods. Classically derived reassortants and plasmid rescued 6:2 reassortants have been shown by several criteria to be comparable vaccine strains. Regardless of the method used, 6:2 reassortants created by either method have highly consistent genomic sequences, express the ca, ts, and att phenotypes, and have the appropriate antigenicity.

All of the testing and characterization currently performed on the MVS of the licensed vaccine will be continued for MVS produced by plasmid rescue. Because the plasmid rescue method uses controlled reagents (use of reagents that have no animal-derived materials) and cells (complete testing for adventitious agents and tumorigenicity) no additional testing or characterization of plasmid rescued MVSs appears to be warranted. Because creation of the 6:2 by plasmid rescue is more predictable, reliable and may potentially produce vaccine with greater similarity to the wild type HA and NA antigens, it may become the preferred approach for the production of MVS. However, plasmid rescue is intended to supplement, not necessarily replace, the classical reassortment procedures. Both methods are adequate and both should be acceptable to produce vaccine in a timely manner. In addition to the above described advantages of the plasmid rescue method, rescue by plasmids may enable use of wt strains that were not originally isolated in eggs to produce reassortants (because the methodology would be expected to eliminate adventitious agents present in the original wt isolate). In summary, plasmid rescue of 6:2 reassortants should enhance the overall availability and choice of vaccine strains, should increase the genetic and antigenic authenticity of the reassortant, and should improve the predictability and reliability of production of new MVSs.

Historical Significant Changes

Historical Date of Additional Info

Project Additional Information

Purposes of the contained use

The subject of the current application is commercial-scale manufacturing of pandemic live attenuated influenza vaccine (P-LAIV) using reassortant vaccine seeds prepared...
using either classical reassortment techniques or plasmid rescue techniques. P-LAIV is similar to the seasonal FulMist® vaccine (Influenza Virus Vaccine Live, Intranasal); however, whereas seasonal FulMist contains antigens that protect against seasonal epidemic influenza strains, P-LAIV contains antigens to protect against pandemic influenza strains.

**Recipient or parental organism**

Each live, attenuated influenza vaccine (LAIV) strain is produced by genetic reassortment of a master donor virus (MDV) and a wild-type (wt) influenza virus. The pandemic vaccine strains have a genetic composition similar to that of the seasonal vaccine strains in the licensed LAIV product, FulMist®. The Type A MDV was originally derived from wild-type A/Ann Arbor/6/60 (H2N2).

**Host/vector system**

Each pandemic vaccine strain has a 6:2 gene constellation; the six gene segments encoding internally-located viral proteins, (PB1, PB2, PA, NP, M and NS), are derived from the MDV, and the two gene segments encoding the surface glycoproteins (HA and NA) are derived from a contemporary wt strain.

**Origin & function**

All of the production of the GMO (Master Virus Seed) is performed in the United States of America. The UK site only expands the Master Virus Seed by growing the Master Virus Seed in SPF eggs to produce the Virus Harvest. The Virus Harvest is tested by Genotypic and Phenotypic methods to confirm that it is identical to the MVS. A detailed explanation of the GMO preparation process is given in the risk assessment and annex 1 of the attached document.

The Virus Harvest produced in the UK is commercial-scale manufacturing of pandemic live attenuated influenza vaccine (P-LAIV) using reassortant vaccine seeds prepared using either classical reassortment techniques or plasmid rescue techniques. P-LAIV is similar to the seasonal FulMist® vaccine (Influenza Virus Vaccine Live, Intranasal); however, whereas seasonal FulMist contains antigens that protect against seasonal epidemic influenza strains, P-LAIV contains antigens to protect against pandemic influenza strains.

**Evaluation of foreseeable effects**

The final vaccine seeds are used to produce a live attenuated influenza pandemic vaccine, which is designed to prevent influenza in humans. Therefore, the final P-LAIV vaccine seeds are not hazardous to humans. Furthermore, results of studies of seasonal vaccine in a variety of domestic and farm animals support the conclusion that the vaccine strains do not represent a hazard to the environment. We would expect the P-LAIV strains to behave in a similar way. Available shedding data for the H9N2 pandemic vaccine suggests that the median human infectious dose is greater than 10^7 TCID 50 whereas adults shed lower than 10^1 TCID 50 for less than one day; therefore in the unlikely event that the manufacturing staff would be infected by P-LAIV, it is extremely unlikely that secondary transmission outside the facility could occur. The relatively low replication of the H9N2 pandemic vaccine strain in humans and its expected inability to replicate in avian species or in farm animals (e.g. pigs) suggests that reassortment between influenza strains and the pandemic H9N2 pandemic vaccine would be unlikely to occur in either humans or in animals. The H5N1 pandemic vaccine is also highly attenuated in animals; it does not replicate in chickens and its replication is attenuated in mice and ferrets. Based on the clinical results for the H9N2 pandemic vaccine we expect the H5N1 vaccine to be highly attenuated in humans. Based on these considerations we are confident that, even in the event of a total breach of containment, the P-LAIV vaccine seeds covered by the assessment would not be hazardous to humans or the environment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All waste materials containing vaccine virus are either thermally or chemically inactivated by validated procedures prior to removal from the facility. Alternatively...
contaminated material including "sharps" are sealed in Clinical waste drums and incinerated at approved off-site facility. Liquid waste is thermally inactivated in an inactivation tank at a minimum temperature of 80°C for 15 minutes and the resultant liquid is further pH neutralised. The temperature of the cycle is monitored throughout the process. The inactivation achieves 100% influenza virus kill. Metal, glass, paper and plastic materials are inactivated by autoclaving at a minimum load temperature of 121°C for a minimum of 15 minutes. The autoclave cycle loads are validated and the temperature and pressure is monitored throughout the process. The inactivation achieves 100% influenza virus kill. Plastic materials including sharps and all laboratory biological test reagents are placed in Clinical Waste drums and incinerated. This achieves 100% influenza virus kill at an approved off-site facility.

Eggs - Eggs are macerated, and in a sealed system, the solid material is initially thermally inactivated for viruses at above 80°C for 15 minutes. The temperature is monitored throughout the process. The resultant dry material is placed in sealed drums and incinerated to ensure 100% kill of influenza virus at an approved off-site facility.

Although MedImmune believes that designation of this vaccine as Class 1 provides more than adequate assurance of safety of our employees and the environment., the company accepts the WHO classification of Class 2 for the manufacturing process.

Please enter comments on the GM safety committee on the risk assessment

Although MedImmune believes that designation of this vaccine as Class 1 provides more than adequate assurance of safety of our employees and the environment, the company accepts the WHO classification of Class 2 for the manufacturing process.

**Project Additional Information**

**Purposes of the contained use**

The aim of these studies are to generate reassortant attenuated influenza viruses (H1, H3 and B subtypes) using reverse genetics. These reassortant viruses are engineered to express the hemagglutinin (HA) and neuraminidase (NA) genes from seasonal influenza isolates on the master donor virus (MDV) backbone (A/Ann Arbor/6/60 or B/Ann Arbor/1/66).

**Recipient or parental organism**

Seasonal influenza virus of human origin - A strains (restricted to H1 and H3) and B strains which are classified as ACDP hazard group 2

E. Coli (strains NEB 5-alpha F'Iq competent E.coli, Veggie NovaBlue Singles Competent Cells or Invitrogen Top 10 Cells) - Disabled non-pathogenic, ACDP category 1

Continuous cell lines such as MDCK (CL1) or SPF eggs (CL1) (RA17722 – hazard group 1 cell lines)

Primary chicken or human cells (CL2) (RA 14917- working with primary cells)

**Host/vector system**

Reassortant viruses are engineered to express the hemagglutinin (HA) and neuraminidase (NA) genes from seasonal influenza isolates on the master donor virus (MDV) backbone (A/Ann Arbor/6/60 or B/Ann Arbor/1/66). Master donor virus is an influenza virus that was modified to confer cold-adapted (ca), temperature sensitive and attenuated phenotype and is the backbone for the FluMist/Fluenz vaccine. Attenuated viruses will be generated by reverse genetics (generally 6:2, occasionally 5:3 or 7:1 reassortants) from plasmid rescue. Novel viruses may also be engineered using single point mutagenesis of viral genome. The rescued viruses will then be characterized in vitro to confirm attenuated phenotype.

**Origin & function**

Host Organism

Seasonal influenza virus of human origin - A strains (restricted to H1 and H3) and B strains which are classified as ACDP hazard group 2

E. Coli (strains NEB 5-alpha F'Iq competent E.coli, Veggie NovaBlue Singles Competent Cells or Invitrogen Top 10 Cells) - Disabled non-pathogenic, ACDP category 1

Continuous cell lines such as MDCK (CL1) or SPF eggs (CL1) (RA17722 – hazard group 1 cell lines)

Primary chicken or human cells (CL2) (RA 14917- working with primary cells)

Source and nature of genes

Hemagglutinin (HA), neuraminidase (NA) or internal genes from seasonal influenza clinical isolates.

Source and nature of Vector

pAD 3000 plasmid - non-mobilisable
**Influenza A/Ann Arbor/6/60** - attenuated, cold adapted and temperature sensitive ACDP category 1

**Influenza A/Ann Arbor/1/66** – attenuated, cold adapted and temperature sensitive ACDP category 1

**Evaluation of foreseeable effects**

**Potential for Harm to human health**

For 6:2 and 7:1 reassortant viruses containing all Ann Arbor internal genes - The Ann Arbor master donor virus internal genes are well characterised and have been shown to confer attenuated phenotype for a large number of different 6:2 LAIVs in cells, eggs, ferrets and human safety studies. For reassortant viruses containing wildtype virus internal genes – the impact of wildtype virus internal genes on the attenuated phenotype of reassortant viruses cannot be predicted and a wildtype virus phenotype may be seen.

There is therefore the potential to develop flu-like symptoms following exposure. Personnel at risk of developing severe disease following influenza infection (e.g. pregnant women, asthmatics, immune compromised) should seek occupational health advice and undertake an individual risk assessment prior to undertaking work covered by this risk assessment.

**Potential for Harm to the Environment**

none – HA and NA genes from wild-type seasonal influenza viruses already circulating in the environment

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All GMO waste must be inactivated prior to disposal as Non-hazardous Biological waste or where inactivation is not possible as Hazardous Biological waste. Inactivation should be by autoclaving or by chemical treatment with 1% final Virkon for at least 30 minutes (or other validated method). Detail: All waste from the handling of this material will be inactivated at source by chemical treatment and/or autoclave. All material is further treated by incineration.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

The Risk assessment was reviewed and approved by the organisation’s Biological Safety Committee which oversees GMO safety onsite in Nov 2016

The aims of these studies are to generate and work with 6:2 reassortant influenza viruses containing the hemagglutinin (HA) and neuraminidase (NA) genes from low pathogenic animal origin influenza viruses and the internal genes from the cold adapted, temperature sensitive, attenuated master donor virus (MDV) backbone A/Ann Arbor/6/60. Animal origin means isolated from an animal (for example, avian or swine) as well as isolated from a human with a zoonotic infection.

Live attenuated 6:2 reassortant viruses will be generated by reverse genetics and plasmid rescue. Novel LAIV may also be engineered using single point mutagenesis of the viral genome.

Recipient or parental organism

Wild-type animal origin low pathogenic influenza viruses do not have the multi-basic amino acid peptide insertion at the HA cleavage site (PENPKTR*GLF), are not pathogenic to chickens and are not therefore designated a SAPO agent by DEFRA. As such the wildtype viruses are handled at CL2.

Host/vector system

HOST Wild-type animal origin low pathogenic influenza viruses do not have the multi-basic amino acid peptide insertion at the HA cleavage site (PENPKTR*GLF), are not pathogenic to chickens and are not therefore designated a SAPO agent by DEFRA. As such the wildtype viruses are handled at CL2.
VECTOR E. Coli (strains NEB 5-alpha F'Iq competent E.coli, Veggie NovaBlue Singles Competent Cells or Invitrogen Top 10 Cells) - Disabled non-pathogenic, ACDP category 1
pAD 3000 plasmid - non-mobilisable
Influenza A/Ann Arbor/6/60 - attenuated, cold adapted and temperature sensitive ACDP category 1

Live attenuated 6:2 reassortant viruses will be generated by reverse genetics and plasmid rescue. Novel LAIV may also be engineered using single point mutagenesis of the viral genome.

Origin & function

Wild-type animal origin low pathogenic influenza viruses do not have the multi-basic amino acid peptide insertion at the HA cleavage site (PENPKTR*GLF), are not pathogenic to chickens.

Hemagglutinin (HA) genes from low pathogenic animal origin influenza isolates. The HA protein on the surface of the virus is responsible for virus/cell attachment and fusion. The HA protein does NOT contain the 7 amino acid multi-basic peptide insertion at the HA cleavage site (PENPKTR*GLF), characteristic of highly pathogenic influenza viruses.

Neuraminidase (NA) genes from low pathogenic animal origin influenza isolates. The NA of influenza viruses has enzymatic activity and is responsible for cleaving the HA from the cell receptor thus releasing new virus particles budding from the cell surface. There are no known regions or sequences that have been shown to be solely responsible for a highly pathogenic phenotype.

Internal genes PB2, PB1, PA, NP, M or NS from Influenza A/Ann Arbor/6/60 - these are all well characterised genes that are used in the commercial vaccine and have been shown to be safe.

E. Coli (strains NEB 5-alpha F'Iq competent E.coli, Veggie NovaBlue Singles Competent Cells or Invitrogen Top 10 Cells) - Disabled non-pathogenic, ACDP category 1
pAD 3000 plasmid - non-mobilisable
Influenza A/Ann Arbor/6/60 - attenuated, cold adapted and temperature sensitive ACDP category 1

Evaluation of foreseeable effects

The wildtype viruses are designated CL2 by HSE and DEFRA as long as they meet the following:

- presence of a HA cleavage site consistent with low pathogenic influenza viruses
- shown in assays not to cause pathogenicity in the chickens

Combination of the wildtype HA and NA genes with the internal genes of A/An Arbor/6/60 is known to result in highly attenuated cold adapted temperature sensitive viruses.

Potential for harm to human in the event of exposure - Potential for limited and mild upper respiratory tract infection

Potential to harm and disseminate to the environment - The HA and NA genes may be from low pathogenic animal origin influenza strains that are NOT currently circulating in the UK. In this case there is a low risk to the environment if the 6:2 virus was accidently released because the HA and NA genes could potentially reassort with genes from currently circulating wild type influenza to generate an influenza virus with a novel HA that is not currently in the UK environment.

This risk assessment therefore takes into consideration the differing level of risk to the environment depending whether the HA and NA genes originate from a wildtype virus that is in current circulation in the UK or not.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

### Project Additional Information

#### Purposes of the contained use

The seasonal influenza viruses produced by reverse genetics will be used in experiments to determine the mechanism of action of vaccine viruses. These experiments will include in vitro cell culture work as well as in vivo animal model work.

#### Recipient or parental organism

The combination of the 8 gene segments will produce seasonal influenza virus which is capable of causing illness in humans.

#### Host/vector system

The viruses will be rescued in cell culture using continuous cell lines such as MDCK and 293T cell lines. The virus will be grown in specific pathogen-free (SPF) embryonated chicken eggs according to standard protocols.

#### Origin & function

The genetic material used originates from seasonal wild type influenza virus segments (HA, NA, PB2, PBi, PA, NP, M and NS). These wild type genes are restricted to currently circulating subtypes of influenza (Hi, H3 and B viruses). These segments will be used to produce wild type seasonal influenza viruses by reverse genetics. In addition to this, mutations that have been previously shown to produce a temperature sensitive phenotype will be introduced into the segments either by point mutagenesis or via replacing one or more internal gene segment (PB2, PBi, PA, NP, NS, M) with that of the cold adapted, temperature sensitive, attenuated master donor virus that is currently used for live attenuated vaccine production.

Site-directed mutagenesis will also be employed to introduce mutations into the wild type virus that have been shown to impact key characteristics of live attenuated influenza virus such as immunogenicity, antigenicity and viral fitness on human nasal epithelial cells.

#### Evaluation of foreseeable effects

As the viruses to be rescued will contain wild type influenza internal genes there is a risk of developing influenza after exposure. All procedures will be undertaken by appropriately skilled and experienced staff who have completed site biosafety training. All work will be performed at BSL2 containment. Personnel at risk of developing severe disease following influenza infection (eg pregnant women, asthmatics, immune compromised) should seek occupational health advice and undertake and individual risk assessment prior to undertaking work covered by this risk assessment.

The influenza viruses generated by reverse genetics will contain gene segments from viruses that are already circulating in the environment and so pose no additional risk to seasonal influenza strains.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All BSL2 waste will be handled as per on site procedures (listed below).
All GMO waste will be inactivated prior to disposal as non-hazardous biological waste (EWC 1801 04)
Liquid culture will be treated with a suitable disinfectant for the contact time outlined according to the manufacturer,
e.g. 10 minutes for presept, minncare or biocide x.
Eggs will be handled in a BSL2 safety cabinet with any waste being double bagged in biohazard bags containing
disinfectant powder (e.g. virkon or presept). The bags will be sealed and placed into biohazard bins. The biohazard
bins are incinerated off site.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The GMO risk assessment (attached) was reviewed and approved at the June 2018 biosafety committee meeting at
AstraZeneca, Liverpool.

02/03/2022
The seasonal influenza reassortant A/Ann Arbor/06/1960 (wtAA60) viruses produced by reverse genetics will be used as controls in experiments to determine the mechanism of action of seasonal vaccine reassortant A/Ann Arbor/06/1960 viruses with a cold adapted, temperature sensitive and attenuated phenotype (caAA60). These experiments will include in vitro cell culture work as well as in vivo animal model work.

Recipient or parental organism

The combination of the 8 gene segments will produce seasonal influenza virus which is capable of causing illness in humans.

Host/vector system

The viruses will be rescued in cell culture using continuous cell lines such as MDCK and 293T cell lines. The virus will be grown in specific pathogen-free (SPF) embryonated chicken eggs according to standard protocols.

Origin & function

The genetic material will originate from two sources:
1) HA and NA gene segments from currently circulating seasonal influenza viruses (pdm09H1N1 and H3N2)
2) PB2, PB1, PA, NP, M and NS gene segments from the wt A/Ann Arbor/06/1960 isolate (H2N2)

Reassortant viruses will be generated by reverse genetics which will contain HA and NA from seasonal circulating viruses and PB2, PB1, PA, NP, M and NS from wt A/Ann Arbor/06/1960.

Live Attenuated vaccine candidates are produced using reverse genetics with a cold adapted (ca), temperature sensitive (ts) and attenuated (att) A/Ann Arbor/06/1960 virus. Therefore the function of the genetic material is to generate reassortant viruses to be used as controls for the live attenuated vaccine candidates to determine how ca, ts, and att relate to the mechanism of action of live attenuated vaccine candidates.
As the viruses to be rescued will contain wild type influenza internal genes there is a risk of developing influenza after exposure. All procedures will be undertaken by appropriately skilled and experienced staff who have completed site biosafety training. All work will be performed at BSL2 containment.

Personnel at risk of developing severe disease following influenza infection (e.g. pregnant women, asthmatics, immune compromised) should seek occupational health advice and undertake an individual risk assessment prior to undertaking work covered by this risk assessment.

The influenza viruses generated by reverse genetics will contain HA and NA gene segments from viruses that are already circulating in the environment and so pose no additional risk to seasonal influenza strains.

PB2, PB1, PA, NP, M and NS gene segments are from a non circulating influenza subtype (H2N2) and present a risk of reassortment with other influenza viruses if there was accidental exposure. This could generate novel influenza viruses with unknown phenotypes. Although, it is unlikely that these novel viruses would have increased pathogenicity when compared to the currently circulating isolates. This is supported by the fact that risk assessments carried out on H2N2 viruses of which A/Ann Arbor/06/1960 is a part of, show that there is a low to intermediate risk of non reassorted isolates from this subtype (Risk Assessment of H2N2 Influenza Viruses from the Avian Reservoir: Jones et al, 2014. Journal of Virology).

Only class one organisms and bacterial waste will be produced on site. Waste will be disposed of by appropriate routes as detailed in CBT-Standard operating procedures. Solid waste will be collected in double containment waste bags and inactivated by autoclaving, prior to disposal as clinical waste destined for incineration (contractor Vetspeed). Liquid waste will be collected in suitable containers and inactivated overnight with either Presept disinfectant tablets (dichloroisocyanurate sodium salt, Johnson and Johnson) or Virkon and autoclaved. Inactivated waste will then be disposed of to the drain.

Please enter comments of the GM safety committee on the risk assessment
All GMM will be genetically modified recombinant E. coli (these will always be attenuated strains such as JM101, DH5a, XL1 blue or similar lines). These lines will be for the purpose of producing plasmid constructs for transfection into animal cell lines to create recombinant cell lines. Examples of typical plasmid cloning vectors include: pCMVScript(Stratagene), pcDNA3 (Invitrogen), TOPO TA(Invitrogen). These constructs will have minimal anticipated detrimental effects on human health and the environment, as they will be non-oncogenic, non-viral, non-transmissible genes of human or animal origin. As such they pose virtually no risk to the individual researcher, to the environment either as naked DNA, a gene or gene product within a transfected prokaryotic or eukaryotic cell or as a translated protein. These genes also have either no or minimal anticipated combinatorial effects in the host bacterium. Examples of tenes used in such construct include GPCRs, metabolic enzymes and receptors, none of these will be for the purpose of protein production for purification. Each construct will be assessed prior to manufacture by the GM safety committee and considered class one if it meets the criteria detailed below:

II) The inserted genetic material. The inserted genetic material is already present in living cells and is unlikely to significantly change the properties of the host organisms. Overall risk: High/Medium/Low/EFFECTIVELY ZERO.

IV) Vector. The vectors are considered non-mobilisable, with negligible risk of transferring to insect, plant or human cells. Overall risk: High/Medium/LOW/Effectively Zero.

V) the resulting genetically modified micro-organisms are non-pathogenic and non-infectious. Overall Risk: High/Medium/LOW/Effectively Zero.
Project Additional Information

Purposes of the contained use

The aim of this project is to use retroviral, lentiviral, and baculoviral delivery systems to introduce various mammalian DNA sequences into mammalian cells in culture. These sequences direct expression of either (i) RNA species (siRNAs or antisense RNAs) that interfere with the expression of various mammalian proteins or (ii) the corresponding mammalian proteins themselves; for in vitro use and for the generation of stable mammalian cell lines (and subsequent use of such stable lines in vitro) with the aim of generating stable cell lines expressing fluorescent proteins, potential drug targets or therapeutic proteins, etc.

Recipient or parental organism

systems (and in the case of baculovirus - also for the transposition of inserts into Bacmid) will take place in K12 strains of E. coli (with a history of safe use).

Insect cells (e.g. sf21 - with a history of safe use) will be used for amplification of infective baculovirus.

Mammalian cell lines (e.g. immortalized lines derived from human cancer tissues) fall into two types:

a) Packaging/helper cell lines into which plasmids containing lenti- or retroviral DNA will be introduced, and from which infectious virus will be secreted into the medium to high titre. The media from these cell-lines poses a risk because of the high viral titre. As such this could provide a risk of infection to personnel working with the media.

b) Recipient cell lines in culture. These cells will initially be exposed to a high titre of virus to permit infection (virus derived from (a) above). However the infected cell lines will be incapable of themselves producing active virus and as such are no more dangerous than the parental cell lines, i.e. a negligible risk.

Host/vector system

The gamma-RETROVIRAL vectors which will be used are derived from either Moloney Murine sarcoma Virus (MoMLV), Mouse Mammary Tumour Virus (MMTV) or Feline Leukaemia Virus (FeLV), all of which are ACDP Hazard Group 1 biological agents. On the other hand, the virus will be packaged by transfecting transfer vector into specific amphoteric ‘helper’ cell line (gag, pol and env stably incorporated into host chromosome cells). NOTE: amphotropic packaging will widen the host range of the virus and allow it to infect a wide range if mammalian species (including humans) and cell types. This means that the viruses produced for this experiment could potentially infect a number of species, including man.

However, bearing this in mind we should consider that the viruses that will be used have been modified in a number of ways which will make them safer to handle:

- The genes encoding structural and other components of the viral genome have been separated. These genes have been engineered to minimise the risk of recombination that could lead to production of a replicationcompetent virus.
- The packaging cell lines allow expression of proteins, required to produce progeny virus: But the transfer vector is the only genetic material transferred to the target cells, consequently these cells cannot produce the proteins which are essential for viral assembly and infectivity.
- Second, third generation or Self INactivating vectors retrovirus vectors will be used in all experiments (see SACGM compendium of guidance part 2, section 2.11 (Retroviruses) pp117

The LENTIVIRAL vectors that will be used are derived from HIV-1 , which is an ACDP Hazard Group 3 biological agent. However, second and third generation lentiviral vectors have several of the lentiviral accessory genes (required for pathogenesis only) deleted to increase biosafety and viral packaging is achieved by providing three helper
constructs in trans containing gag, pol and rev sequences.

For example, second and third generation Lentiviral Expression Systems include the following key safety features:

In the second and successive generation lentiviral vectors several lentiviral accessory genes (vif, vpr, vpu and net) are deleted from the transfer plasmid since they are not required for in vitro replication and the products they encode have cytotoxic activities.

In addition to this in the third generation lentiviral vectors:

- The Lenti expression vectors contain a deletion in the 3'LTR (IIM3) that does not affect generation of the viral genome in the producer cell line but instead results in "self-inactivation" of the lentivirus after transduction of the target cell (Yee et al., 1987; Yu et al., 1986; Zufferey et al., 1998). Once integrated into the transduced target cell, the lentiviral genome is no longer capable of producing a packageable viral genome.

- The number of genes from HIV-1 that are used in the system has been reduced to three (i.e. gag, pol, and rev).

- Genes encoding the structural and other components required for packaging the viral genome are separated onto four plasmids. All four plasmids have been engineered not to contain any regions of homology with each other to prevent undesirable recombination events that could lead to the generation of a replication-competent virus (Dull et al., 1998).

- Although the three packaging plasmids allow expression in trans of proteins required to produce viral progeny (e.g. gal, pol, rev, env) in the 293FT producer cell line, none of them contain LTRs or the 4' packaging sequence. This means that none of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. No new replication competent virus can be produced.

Despite the above safety features, use of these lentiviral vectors (which include WPRE) falls within SACGM 2 criteria due to the potential biohazard risk of possible recombination with endogenous viral sequences to form self-replicating virus, or the possibility of insertional mutagenesis. Also, the virus will be packaged by transfecting transfer vector into specific amphotropic "helper" cell line (gag, pol and env stably incorporated into host chromosome cells). NOTE: amphotropic packaging will widen the host range of the virus and allow it to infect a wide range of mammalian species (including humans) and cell types.

This means that the viruses produced for this experiment could potentially infect a number of species, including man. The BACULOVIRAL vector technology that we will use is based on double-stranded DNA insect viruses (baculovirus - which are ACDP Hazard Group 1 biological agents) as vehicles to efficiently deliver and express genes in mammalian cells. Bacmid/baculovirus particles are taken up by endocytosis, released for transcription and expression following migration to the nucleus. Gene expression begins within 4-6 hours of transduction and is at near maximum level within 24 hours of transduction. The baculovirus have been modified by engineering of a mammalian expression cassette for transgene expression in mammalian cells. Baculoviruses are non-replicating in mammalian cells and thus have an excellent safety profile combined with being well-tolerated by cells. Baculovirus transduction of mammalian cells is transient in nature as the foreign DNA does not integrate into the host genome.

### Origin & function

**Selectable markers - examples (but not restricted to):**

- Ampicillin resistance: E.coli derived
- Neomycin resistance: bacteria derived aminoglycoside phosphotransferase gene

**Health and Safety Executive**

Puromycin resistance (PAC): Puromycin acetyl transferase is derived from Streptomyces alboniger

Reporter proteins such as (but not restricted to):
• Fluorescent proteins as reporters:
  o GFP derived from the jellyfish Aequorea victoria and variants of this
• Luciferase - class of oxidative enzymes used in bioluminescence
  o renilla luciferase derived from the Sea pansy (Renilla reniformis)
  o firefly luciferase derived from the firefly Photinus pyralis.
Open reading frames, cDNAs and gene sequences encoding potential drug targets or therapeutic proteins and l or
shRNAs (designed to knockdown the expression of Open reading frames, cDNAs and gene sequences encoding
potential drug targets or therapeutic proteins) - all human derived.
This could include the expression of potentially harmful genes e.g. encoding known proto-oncogenes or genes with
known oncogenic mutations that can contribute to cellular transformation.

Evaluation of foreseeable effects

All viral vectors employed in this protocol exhibit broad tropism and potential to infect humans. Risks conferred
fo llowing infection are identified as:

i) genetic insertion of viral sequences with potentially deleterious effects on endogenous genes: we will
employ transgene promoters and other viral sequences that may affect host gene function in a wide
range of cell types (e.g. CMV promoter). We assess retro-, lenti- or adenovirus infection might induce
permanent changes in infected cells including a risk for tumorigenesis. Risks conferred are previously
described and categorised under Class 2 risks [SACGM compendium of guidance part 2, page 121]:
..... The effects of integration upon the infected cell should be considered. For instance, promoter
sequences present in the provirus might activate genes adjacent to the integration site or,
alternatively, insertion may disrupt genes and prevent their expression.”

ii) expression of human-derived or homologous transgenes with potentially deleterious effects: various
transgenes may be employed, wherein intrinsic function of the transgene confers potentially
deleterious effects. For example, expression human oncoproteins could induce transformation of
infected cells. Beyond endogenous homeostatic mechanisms that may lessen this risk (e.g. apoptosis
and other host tumour suppression responses), we assess that standard precautions under Class 2
risk mitigation procedures are adequate to address such risks.

iii) expression of exogenous transgenes directed to host genes with potentially deleterious effects: multiple
transgene technologies (antisense, RNAi, CRISPR or related gene conversion) may be employed to
modify the function of endogenous genes with potentially deleterious effects. For example, RNAi or
antisense RNA could reduce the function of genes necessary to control cell apoptosis, potentially
resulting in tumorigenesis. As above, we assess that Class 2 risk management procedures
adequately address these risks.

iv) expression of heterologous genetic sequences with potentially deleterious effects: we will employ diverse
collections of non-human derived, exogenous transgene sequences that carry potential risks
following infection. Risks from expression of these collected transgene sequences are mitigated and
attenuated through several means. First, known pathogenic transgenes systemically removed, and
other exogenous gene products are fragmented or rearranged, such that potentially pathogenic or
other biologically deleterious genetic functions are not recapitulated in their complete endogenous
configuration. Second, potentially deleterious transgenes in any infectious viral preparation are highly
titrated, such that any single deleterious sequence comprises less than 1 part in 100,000 parts of an
inoculum with infectious potential. In total, we assess these risks are adequately managed via the
same Class 2 risk precautions employed above.

We assess environmental hazards are adequately addressed through the proposed personnel risk management
measures. We employ multiple attenuation strategies and protocols to severely limit independent virus
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)  

| Not applicable |

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)  

| Instead of autoclaving waste in the building we propose to follow the procedure used by the Babraham Institute described in their disposal notification GM105/4.1 (see also section 6 above for description). Reasons for adopting this method of waste disposal are:  
1. We do not have access to an autoclave within our area of the building  
2. The waste disposal system used by the Babraham Research Campus is safe and has been running since October 2004.  
All liquid waste material will be inactivated by treatment with 1 % (w/v) Virkon solution prior to disposal. Solid waste material will be placed in sealed bins and incinerated by an off-site incineration company (Vetspeed - Their GM authorization is GM898) according to disposal notification GM105/4.1.  
Waste from our GM work at Class 2 will be placed into suitably labelled hermetically sealable (red lid to distinguish them from Class 1 waste) 60 litre UN approved (to Class 3) Type 3H21Y30/S/2003 bins. Sealed bins are placed into secondary 210 litre yellow labelled "Eurobins". Contents of the bin are recorded and collections by the local registered clinical/GM waste incinerator contractor will be made three times a week to prevent a build-up. The site has 24/7 Security. The contractor uses solid bodied transport and carries portable disinfection equipment in case of any spillage. Autoclave facilities will be available in an adjacent building, as required by the Regulations, in case of loss of the contractor's facilities. The type of container and the secondary Euro container means that the risk of any spillage of active GM waste on site is negligible. However, as active waste will leave the site, the risk to the environment and health is possibly marginally higher than autoclaving prior to incineration. The only real risk of release would be as a result of a major RTA, however, the containers are designed to withstand this. This disposal method is expected to achieve 100% inactivation of the GMM.  

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)  

| All liquid waste material will be inactivated by treatment with 1 % (w/v) Virkon solution prior to disposal. Solid waste material will then be placed in sealed bins and incinerated by an off-site incineration company (see derogation application above). Waste from our GM work at Class 1 will be placed into suitably labelled hermetically sealable bins. They will be sealed by our staff and removed to a central collection point where they will be placed into 210 litre yellow labelled "Eurobins". Collections for incineration will be made by the local registered clinical/GM waste incinerator contractor. This disposal method is expected to achieve 100% inactivation of the GMM. The data sheets describing inactivation by Virkon are attached. |

Give brief details of the genetic modification safety committee

Genetic Modification Safety Committee was formed on 17/10/05. The committee comprises of the health and safety committee members. The members include: Vice President Science and Technology (supervisor of GM activities). Office Manager, Quality Assurance Manager, Facilities Manager, Analytical Chemist, Senior Scientist Molecular Diagnostics (Biological Safety officer), Customer Services Manager, Operations Manager. Meetings will be held monthly in conjunction with health and safety meetings. Updates on GM activities and analysis of risk assessment forms will take place in these meetings. Risk assessments will be reviewed individually and discussed as a group.

Significant Change ID

Date of Significant Change
**Project Additional Information**

**Purposes of the contained use**

The genotypic drug resistance assays will consist of a nested RT-PCR amplification of the drug target gene followed by direct sequencing. Run off transcripts will be used as templates for the optimisation of the nested RT-PCR. A panel of constructs will also be generated to provide positive controls for the assay; their inserts will cover the viral gene of interest (e.g., NS3/4A or NS5B) under the control of a promoter such as T7 to generate in vitro transcripts. This panel of positive controls will represent different genotypes and sequences containing drug resistance mutations. If necessary, known drug resistance mutations will be introduced by site-directed mutagenesis to construct appropriate positive controls.

**Recipient or parental organism**

Disabled E. coli (JM109, XL-1 Blue, DH5alpha, TOP10 or HB101)

**Host/vector system**

Non-mobilisable plasmid vectors pUC8 and pGEM

**Origin & function**

Pre-existing HCV clones containing up to 90% of the genome and lethal mutations within the open reading frame (both making them non-infectious) will be used as PCR templates to provide positive controls for the assay. Additional positive controls representing other viral genotypes will be generated by cloning the drug target gene from clinical samples.

**Evaluation of foreseeable effects**

All experiments will be undertaken with incomplete genomic clones which are incapable of generating infectious virus. No harmful proteins will be encoded within the inserts. E. coli carrying plasmid coding for HCV proteins do not pose any significant risk to human health and safety or to the environment. Recombination and gene transfer to other microorganisms are highly unlikely.

**Containment and control measures for GMOs that are not microorganisms (e.g., GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste will be decontaminated by treatment with 10,000 ppm chlorine overnight (100% kill) and all solid waste will be autoclaved at 134 degrees Celsius for 20 minutes.

### Project Additional Information

Purposes of the contained use

Analysis of clinical samples for in vitro susceptibility of antiviral drugs against HBV. The work will involve cloning viral gene sequences amplified from clinical samples into a plasmid containing the HBV genome from which the gene of interest was deleted. The resulting construct will contain a full-length HBV genome. Only after transfection of...
the resulting construct into host cells, such as HepG2, an infectious recombinant virus can be generated. All full-length HBV transfection experiments will be carried out in a biosafety category 3 laboratory.

**Recipient or parental organism**

Disabled E. coli hosts such as DH5α, Top10, or HB101.

**Host/vector system**

Non-mobilisable plasmid vectors based around, pBluescript, pUC or pGEM will be used as vectors in the cloning procedures in E. coli

**Origin & function**

A pre-existing construct of full length HBV lab strain is used as a backbone to clone the antiviral drug target from clinical samples. The final construct will be transfected into human hepatoma cells, such as HepG2. The transfected DNA will not be inserted into the genome of the host; instead it will result in viral replication equivalent to HBV infection of the cells. System like the one described in Tenney et al: Antimicrob Agents Chemother. 2004 September; 48(9): 3498-3507.

**Evaluation of foreseeable effects**

HBV full-length constructs used in this study could be accidentally administered. Although no evidence exists to suggest that this would cause infection, all staff handling these clones will be vaccinated against HBV and checked for protective levels of antibody prior to initiation of experiments. Moreover, handling of all HBV infectious virus stocks will be carried out in a designated Category 3 laboratory under strict operating procedures.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All liquid waste will be de-contaminated with 2500ppm chlorine, 10% TriGene ADVANCE, 3% (w/v) Virkon or an equivalent disinfectant which ensures 100% kill. All solid waste will be autoclaved at 135°C for 30 min providing 100% kill.

**For activities involving GMMs, describe the waste management measures which will apply to the activity**

All biological waste will be autoclaved prior to disposal. Randomly selected autoclaved cultures will be used to inoculated fresh growth medium to check viability.

All GM plant material to be autoclaved, including the soil they were grown in.

All biologically contaminated sharps will be soaked in 10% bleach for a minimum of 20 minutes before disposal via the sharps waste system.

Any biological spills (e.g., E. coli and Agrobacterium cultures) will be bleached in freshly made 10% bleach for a minimum of 20 minutes.

**Tick to confirm that you are attaching a summary of the risk assessment**

**Tick if you are claiming exemption from disclosure for sections of the risk assessment**

**Please enter comments of the GM safety committee on the risk assessment**

All committee members were satisfied with the containment level and the measures that will be employed to minimise any risks.

**Premises Conditions**

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Give brief details of the genetic modification safety committee

Y
The Safety Committee already established at one of the hospitals involved (St James's university Hospital) has conducted the risk assessment:

Leeds Teaching Hospitals NHS Trust Biological Safety Committee
Trust Headquarters
St James's University Hospital
Beckett Street
Leeds
LS9 7TF

Composition:
For composition, operating procedures and frequency of meetings see separate sheet.

Information on separate sheet:
Committee composition:
Associate Director of Trust (Chair), Microbiologist, Senior Research Nurse, Post Doctoral Scientist, Medical Oncologist, Pharmacist, Virologist, Infection Control Respresentative, Pharmacist, HSE Representative, Clinical Oncologist.

Operating Procedures:
A Biological Risk Assessment Form is completed for proposed study. This details background to study, Principal Investigator (PI), where the work will be carried out, details of biological agent, details of construct, details of cell line, containment level, risk to human health and environment. This form is sent to the Chair of the committee along with SOPs detailing the specifics of how the study will be conducted within the Trust (where it will be done, who will do what), protocol, Investigator Brochure, GTAC Submission if available and PI's CV. The committee ensures the study has been submitted to the necessary bodies and all the necessary approvals are in place.
The PI attends the meeting itself, presents the study and answers any questions before leaving the room to allow the committee to discuss freely. Following discussion, the PI rejoins the meeting and any issues raised are discussed. A letter is issued to the PI detailing the outcome of the meeting and giving feedback. Any necessary amendments to SOP's are made based on this feedback.

Frequency of meetings:
3 monthly but can be arranged more frequently if necessary.

Yes

All needles and syringes will be discarded into a designated sharps bin. This will be sealed and disposed of using normal hospital procedures.

All other materials will be treated as clinical waste and disposed of in yellow clinical waste bags under normal hospital procedures.

Unused vials will be returned to Pharmacy and stored in the refrigerator until they are collected periodically by courier.

If a spill occurs use absorbent materials to soak up spill and discard with spent vials in Biological Waste. Clean area with cleaning agent to remove residue. No specific disinfectants are required.

**For activities involving GMMs, describe the waste management measures which will apply to the activity**

Date of meeting: 10th October 2005
Present: Associate Director of Trust (Chair), Microbiologist, Senior Research Nurse, Post Doctoral Scientist, Medical Oncologist, Pharmacist, Virologist, Infection Control Representative.

Apologies: Pharmacist, HSE Representative, Clinical Oncologist.

Note: The Senior Research Nurse (Debbrie Berine) and Medical Oncologist (Dr John Chester) on this committee will be working on this project. Dr Chester is the principal investigator at St James's University Hospital.

Y

Give brief details of the genetic modification safety committee

The GM ethics and safety committee consists of internal members of staff, two of whom are not involved in GM work, together with a lay representative of the Board of Governors. The committee is required to consider applications to conduct GM work and to address ethical, safety, security and propriety concerns arising in the conduct of such work.

For activities involving GMMs, describe the waste management measures which will apply to the activity
All waste and glassware will be autoclaved at 121 degrees C for 15 minutes. Steam sterilisation will be monitored using cycle verification indicators (TST Class 6) (degree of kill 100%).

All surfaces will be cleaned after use with 1% Virkon (degree of kill greater than 99.999%).

Tick to confirm that you are attaching a summary of the risk assessment Y

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The GM ethics and safety committee meeting of the 9th December 2005 reviewed the attached risk assessment. The committee agreed to the following statement:

The genetic transformation is deemed to have no perceived hazard to humans, animals or the environment over and above an equivalent microbiology procedure using a non-modified, non-pathogenic micro-organism.

The genetic transformation can be performed in a laboratory suitable for the use of Hazard Group 1 micro-organisms. Procedures must comply with “Good Microbiological Practice” as detailed in the Harper Adams University College Code of Practice for the use of microbiology and molecular biology laboratories.
## Project Additional Information

### Purposes of the contained use

The purpose of the contained use is to safely propagate fungal spores and use such spores to inoculate detached leaves or whole plants to assess the plant pathogenic ability and virulence of various knockout mutants and wild-type Fusarium isolates, on small grain cereals. Mutants have specific genes implicated in pathogenicity knocked out. Comparison to wild-type isolates in pathogenicity assays will identify role of specific genes within pathogenicity of the Fusarium species.

### Recipient or parental organism

<table>
<thead>
<tr>
<th>GMO</th>
<th>Parental organism</th>
</tr>
</thead>
<tbody>
<tr>
<td>GMO1</td>
<td>Fusarium graminearum</td>
</tr>
<tr>
<td>GMO2</td>
<td>Fusarium langsethiae</td>
</tr>
</tbody>
</table>

Both GMOs are natural pathogens of small grain cereals such as wheat, barley and oat and are endemic within Europe.

### Host/vector system

- **No vector systems have been identified for any of the GMO listed**

### Origin & function

**GMO1** carries a mutation in an endogenous gene encoding a hydrophobin protein. Selectable marker is the gene carrying hygromycine resistance (hph). Deletion of the hydrophobin gene is expected to reduce surface hydrophobicity of the fungus.

**GMO2** carries a mutation in an endogenous gene encoding the first enzyme (Tri5) in the biosynthetic pathway for trichothecene mycotoxins, including HT-2 and T-2. Selectable marker will be the gene carrying hygromycin resistance (hph). Deletion of Tri5 will abolish trichothecene toxin production.

### Evaluation of foreseeable effects

Both GMO1 and 2 are deletion mutants, hence reducing the risk of reversion to a minimum.

**GMO1**: Reduced surface hydrophobicity is expected to reduce pathogenicity and maybe also spore production. These are known effects from other studies. Reduced spore production will reduce the ability to disseminate if, accidentally, released into the environment.

**GMO2**: Abolished toxin production might reduce pathogenicity/aggressiveness of the GMO. The aim of the research is to test the function of HT-2/T-2 toxins as fungal virulence factors in F. langsethiae. Similar studies with Tri5 deletion in F. graminearum abolished production of deoxynivalenol (DON) and reduced pathogenicity drastically. The probable effect of deletion of Tri5, if any, is therefore a weakened pathogen. Additionally, if GMO2, accidentally, should be able to spread in the environment, the threat to human and animal health would be negligible as it would not produce toxins.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Fusarium species will be used to inoculate detached leaves and/or leaves of seedlings of small grain cereals. As such they are plant-associated GM micro-organisms.

All operations will be conducted in a Class 2 Microbiology Research Suite. The Microbiology Suite has swipe card controlled restricted access.

All manipulations of fungal cultures will be performed in a Class II Microbiological Cabinet.

Inoculated plants will be contained in a laboratory plant growth cabinet within the Class 2 Microbiology Research Suite (S25).
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

All work will be conducted in a Level 2 Containment Facility, no derogation requested

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All work will follow the Harper Adams University College code of practice for working in the microbiology research laboratory S25 - attached.

Waste will be in the form of fungal spores and mycelia on agar plates, and remains of spore suspensions in shake flasks, tubes, filters, pipette tips, microscope slides, plant material, plant growth medium and containers.

Glass flasks with spore suspensions will be put in autoclaveable biohazard bags and sterilized by passage through a waste autoclave cycle (121 C for 1 hour) before washing (degree of kill 100%).

Glass slides will be placed in a beaker containing fresh 1% Virkon solution for a minimum of 10 minutes before disposal with general waste (landfill) (degree of kill greater than 99.999%).

All surfaces will be wiped with fresh 1% Virkon solution (degree of kill greater than 99.999%).

All other consumables and plant material will be placed in autoclaveable biohazard bags and sterilized by passage through a waste autoclave cycle (121 C for 1 hour) before disposal with general waste (landfill) (degree of kill 100%). Waste is autoclaved in a certified autoclave, load temperatures are recorded throughout the autoclave cycle and checked before waste disposal.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

Please enter comments on the GM safety committee on the risk assessment

The College Genetic Modification Ethics and Safety Committee met on the 1st June 2009. There was a thorough review of the application and the Committee concluded there are satisfactory facilities and procedures available in college to conduct the experiments detailed within this application. A full discussion of the risk assessment was conducted and key issues of containment, disposal and decontamination were addressed. The Committee agreed that a requirement for dedicated technical staff should be clarified with the laboratory manager. On the basis of the considerations detailed above the Committee approved the submission for Class 2 GM contained use activity.

For activities involving GMMs, describe the waste management measures which will apply to the activity.
Liquid waste: 5% hypochlorite solution for 16 hours prior to disposal via appropriate sinks 100% kill.

Solid waste: Surfaces decontaminated with 70% ethanol, 1% Virkon used for 16 hours to decontaminate glassware. Autoclave to sterilise agar plates etc. prior to sealing in clinical waste bags for specialist disposal off site (arranged via Microbiology department). Above methods provide 100% kill.

Monitoring: Quarterly monitoring by attempting to grow up host bacteria following decontamination procedure.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

It was felt that the assessment would cover the work currently planned. However, if work with complete oncogene sequences were required a further risk assessment specifically for these sequences may be needed.

### Purposes of the contained use

Propation of vectors containing fragments of human genomic DNA, in competent E. coli. Vectors are extracted, purified and labelled with fluorochromes. Labelled human genomic DNA fragments are then hybridised to human metaphase chromosomes to provide clarification of chromosome rearrangements.

### Recipient or parental organism

DH10B E Coli

### Host/vector system

- pBACe3.6
- pCYPAC2
- pPAC4

### Origin & function

Human genomic DNA
To be used as region specific fluorescently labelled probes for molecular cytogenetic analysis of human metaphase chromosomes.

### Evaluation of foreseeable effects

No ill effect foreseeable, vectors are non-expressing and inserts do not encode complete genes. Vectors are non-mobilisable.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

![Yes]

Give brief details of the genetic modification safety committee

We will use an existing Genetic Modification Safety Committee based at the Waltham Centre for Pet Nutrition (WCPN), Waltham-on-the-Wolds, Leicestershire - a different division of Masterfoods, UK. This committee consists of three WCPN associates (Head of Research, Laboratory Manager, Site Safety Manager) and an expert Molecular Biologist from Mars Symbioscience. The committee meet as necessary to discuss new work as requested whether it falls within the current containment level or if an increase in containment level is required. The committee also meets quarterly to review the progress of GMO studies, whether new work has been requested or not.

As work will be conducted with commercially available attenuated strains. All material resulting from studies with GMMs will be autoclaved or treated with a suitable antibacterial detergent (e.g., Trigene) and then transported for incineration by a registered waste carrier and disposer or disposed of to the sewage system respectively. GMM material undergoing inactivation procedures will be periodically tested for viability using standard counting methods.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The genetic modification safety committee (GMSC) considers that the work outlined in the risk assessments will be confined to specified laboratories and falls well within the existing safety protocols. As a result, the work poses minimal risk to individuals working with the genetically modified micro-organisms. As the work involves commercial attenuated strains, there will be minimal risk to the environment following accidental release. Equally, as this work is confined to the laboratory and will be used as a laboratory tool, it poses minimal risk to the employees. Therefore, the GMSC considers that this work requires level 1 containment.

Significant Change ID

02/03/2022
### Project Additional Information

#### Purposes of the contained use

The aim of the work is to use small hairpin RNA (shRNA) Lentiviral particles to silence SNARE expression via RNA interference (RNAi) in mammalian cell lines to cause knockdown of the SNARE proteins and to generate data to investigate the relationship between the inactivation of specific SNARE proteins and inhibition of cellular secretion.

#### Recipient or parental organism

#### Host/vector system

A number of vectors used are TRV vectors, the RNAi consortium (TRC) is a collaborative effort based at the Broad Institute of MIT and Harvard, and includes six MIT and Harvard associated research institutions and five international life science organizations. These vectors contain a pUC origin of replication and U6 promoter. Each MISSION™ shRNA clone will be constructed within the Lentivirus plasmid vector pLKO.1-Puro or TRC2-pLKO-Puro. The pLKO.1-Puro and TRC2-pLKO-Puro vectors contain bacterial (Ampicillin) and mammalian (Puromycin) antibiotic resistance genes. The MISSION™ Lentivirus particles use the third generation of Lentivirus system and is a three-plasmid system consisting of three main components:

1. The packaging vector, which contains the minimal set of Lentiviral genes required to generate the virion structural proteins and packaging functions.
2. The vesicular stomatitis virus G-protein (pCMV-VSV-G) envelope vector, which provides the heterologous envelope for pseudotyping.
3. The shRNA transfer vector, which contains the sequence of interest as well as the cis-acting sequences necessary for RNA production and packaging. The multi-plasmid approach results in no single plasmid containing all the genes necessary to produce packaged Lentivirus.

The pLKO.1 vector is a Lentiviral (HIV)-based plasmid. The vector is regarded as a Biosafety Level 2 material and safe to use due to its modified features (deletion of a number of accessory genes implicated in the virulence of HIV, minimal genome of the viral particles, non-replicating and self-inactivation features), making it incapable of producing virus once infected into the host cell. The only change between the pLKO.1 vector and the TRC2 vector is the addition of the WPRE (Woodchuck Hepatitis Post-Transcriptional Regulatory Element). This allows for enhanced expression of transgenes delivered by Lentivirus.

#### Origin & function

The lentiviruses will encode shRNA sequences that cause knock-down of SNARE proteins in mammalian cells

#### Evaluation of foreseeable effects

The most hazardous Lentiviruses will encode shRNA sequences that cause knock-down of SNARE proteins in mammalian cells but as the replication deficient viral particles will be used to stably transduce mammalian cell lines, after a short period of culture the GMM cell lines created from Lentiviral transduction will be free of any functional virus and will not therefore be of any harm to human health and the environment.

The lentiviruses are replication deficient so secondary infections should not occur. The cell lines that will be infected require complex media and controlled conditions for survival so escape into the environment is not expected.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

TriGene ADVANCE will be used as the general disinfectant/decontaminating agent and has been shown by the manufacturer to be effective against bacteria, viruses and cells. TriGene ADVANCE is certified Sporicidal, Mycobactericidal, Virucidal Fungicidal and Bactericidal under EN and HIRL protocols. It breaks down and inactivates DNA/RNA. TriGene ADVANCE is included on the DEFRA list of approved disinfectants.

For general disinfection on non-soiled surfaces, TriGene ADVANCE will be used at 2 parts concentrate in 100 parts water (2% v/v). 2% Trigene will be sprayed over the surface, the surface wiped with tissue, then rinsed with milliQ water and wiped followed by spraying with 70% v/v ethanol and wiped.

All spent contaminated growth media containing mammalian cells or serum within plasticware will be decontaminated by adding Trigene ADVANCE to 5% v/v and allowed to stand for 24h before disposal down the drain. All plasticware will be placed after decontamination in yellow clinical waste burn bins.

Is an emergency plan required according to regulation 20? N

Yes

Give brief details of the genetic modification safety committee

GMSC approves all risk assessments in Glycoform. No work can commence unless it is authorised by GMSC. The committee is staffed by senior managers and scientists with a wide range of experience and education. Signed copies of risk assessments are filed/scanned and kept for 10 years. COSHH assessments must be carried out in addition to any GMM assessments. In case of uncertainty over risk an external body/contractor will be consulted and HSE informed. GMSC members have wide range of experience and training covering biology, microbiology, medicine, chemistry and engineering: Research Manager, Clinical Manager/Consultant, Research Scientist, Head of Protein Manufacturing.

For activities involving GMMs, describe the waste management measures which will apply to the activity
Any equipment that come into contact with GMM will be inactivated using validated autoclave (6 log kill). All areas in which GMM work is done will have 70% aqueous solution of ethanol and 1% Virkon solution (validated for E. coli inactivation). Fresh Virkon solutions will be made daily after each use. All work surfaces on completion of work or after any spill will be wiped with a 1% Virkon and sprayed with 70% ethanol, then allowed to air dry. In case of spillage, the area will be covered with Virkon powder, left for 10 min then scraped using paper towels, then disposed into biohazard waste container. Virkon provides ~5 log kill. During all times protective clothing will be used. Care will be taken to minimise aerosol formation.

Risk assessment approved by the GM Safety Committee.

Y

Give brief details of the genetic modification safety committee

A genetic modification safety committee comprising the Safety and Environment Officer, Director of Research Operations and a Biologist will review and advise on risk assessments, good microbiological practice, containment and control measures and waste management as necessary. All other employees will be consulted on the safety issues associated with the GMO activities through the Tripos safety committee.

The storage and small scale culture of established genetically modified containment level 1 cell lin

For activities involving GMMs, describe the waste management measures which will apply to the activity
Solid waste will be autoclaved before off site incineration with existing Tripos hazardous solid wastes. Liquid wastes will be treated with Virkon and then autoclaved before off site incineration with existing Tripos bulk hazardous liquid wastes.

The cells are thought highly unlikely to readily survive for significant durations outside their precise culture conditions and temperatures and autoclaving will be 100% effective. Autoclave cycle records will be filed and autoclave efficacy will be tested once a year.

Regular biological testing of the autoclave operations will be carried out at a suitable frequency.

Tick to confirm that you are attaching a summary of the risk assessment  Y

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

Satisfied that the cell culture work proposed presents a suitably low risk to humans or to the environment and the containment and waste management arrangements are suitable and appropriate for the genetically modified organisms involved. The work does not involve genetic modifications and the cell lines involved are not readily viable outside their laboratory culture conditions. Employee safety should be adequately controlled by the operation of the biology laboratory at containment level 1.

All liquid waste resulting from bacteriological procedures or activities involving the propagation of cells or non-pathogenic viruses will be treated with Virkon tablets to a final concentration of greater than 1% (weight/vol). Virkon is recommended by the manufacturer for the treatment of liquid waste.

All solid waste resulting from bacteriological procedures or activities involving the propagation of cells or non-pathogenic viruses will be placed in designated waste bags or bins. Waste will be clearly labelled as biohazard. Bags will be closed but not sealed and autoclaved prior to incineration. The autoclave is sited in building 405, Babraham Institute. The location of the autoclave in the vicinity of the laboratory complies to containment level 2 operation. The autoclave is routinely tested on a six monthly basis to confirm working temperatures and pressures are achieved. Autoclave waste is transported to an off site facility. Vetspeed, (GM Ref. GMGM898) for incineration.

Project Additional Information

Purposes of the contained use

To develop safer and more immunogenic vaccines against Mycobacterium tuberculosis using cell lysate preparations obtained from the recombinant Mycobacterium bovis strain rBCG AFR-O. The lysates will be enriched in heat shock proteins and antigens cross reactive with Mycobacterium tuberculosis.

Recipient or parental organism

The parental organism is Mycobacterium bovis, strain Danish 1331 (Staten Serum Institute Lot No. #103063) ACDP Classification 2. This strain is a commercially available vaccine strain and as such is used as a live vaccine.

Host/vector system

Mycobacterium bovis BCG strain Danish 1331 has been modified by site specific recombination into the UreC site and transfection with the plasmid pAF105. Plasmid pAF105 was synthetically derived and encodes the Kanamycin gene and promoter, the OriM, which will permit plasmid replication, Mycobacterium bovis antigens Ag85a, Ag85b and TB10.4 controlled by the Ag85b promoter and does not contain E. coli derived sequences required for plasmid mobilisation.

Origin & function

Mycobacterium bovis BCG strain Danish 1331 is modified by site specific Recombination into the UreC site and transfection with the plasmid pAF105. The combined affect of the expression of the selected inserts is to enhance immunogenicity of the Mycobacterium bovis BCG strain by the over-expression of selected secreted antigens and the expression of a cytolysin which will facilitate the availability of antigens to the immune system.

The pfo A cytolysin gene from Clostridium perfringens (GenBank Accession No. CPE0163) was integrated into the genome of the host organism by site specific recombination at the UreC locus. The pfo A gene encodes perfringolysin O (Pfo), a cytolysin, cloned from Clostridium perfringens (ACDP Class 2). Cytolysin mediates escape of the organism from phagosomal vacuoles into the cytoplasm of host cells, following ingestion of the organism by the host macrophage. Phagosomal escape represents a unique mechanism to facilitate MHC class 1 antigen presentation of mycobacterium antigens. The pfo A gene, has been modified by substitution of a cystine at position 137 to a glutamine, to limit the inherent cytotoxicity of cytolysin in mammalian cells. The mutant pfoAg137q demonstrates a shortened half life in the host cytosol and is more sensitive than the unmodified protein to proteolytic degradation, these properties combined render the cytolysin less toxic than the native protein in mammalian cells. Experimental evidence suggests that cells exposed to mutant pfo Ag137q are not killed when mutant pfo Ag137q is expressed by a comparable intracellular pathogen, Listeria monocytogenes.

The 'homologous' antigens Ag85a, Ag85b and TB10.4 are encoded by the plasmid pAF105. Antigens Ag85A (Genbank Accession No. P0A4V2) and Ag85B (Genbank Accession No. P12942) from Mycobacterium bovis possess a mycolyltransferase activity required for the biogenesis of trehalose dimycolate (cord factor), a dominant structure necessary for maintaining cell wall integrity. Ag85a and Ag85b are secreted proteins and represent major antigens in the host response.
TB10.4 (Genbank Accession No. AF2122/97) of Mycobacterium bovis has been identified as a major antigen in human immune responses to Mycobacterium tuberculosis and is listed in the genbank database as an uncharacterised protein of 10kDa, and is highly conserved in bacteria, ESAT-6 like and of unknown function. This protein is not a known toxin or oncogene and has previously been over expressed in E. coli. The plasmid sequence, pAF105 is maintained in the host organism using antibiotic (Kanamycin) selection.

Evaluation of foreseeable effects

ALTERATIONS IN HOST RANGE; Hazards from the alteration of existing pathogenic traits (eg alteration of host range or tissue tropism):

* expression of the 'homologous' Ag85B and Ag85A and TB10.4 in the host organism is unlikely to modify the host range or tissue tropism of BCG Mycobacterium bovis. Although the proteins will be expressed at higher than normal levels, the majority of the protein will be secreted and the antigens will be highly enriched in the culture supernatants (in culture) or cellular cytosol. Over expression of the antigens Ag85A and Ag85B and TB10.4 is likely to increase the immunogenicity of Mycobacterium bovis as has been previously shown. No changes in tissue tropism or alterations in host range are anticipated.

* the pfo Ag137q protein is secreted, is susceptible to proteolytic degradation, and the consequences of expression are understood and have been studied extensively in other recombinant host organisms. No changes in tissue tropism or alterations in host range are anticipated.

ALTERED PATHOGENESIS: altered interactions with the human immune response:

* the overexpression of the 'homologous' antigen Ag85A has previously been shown to increase the immunogenicity of Mycobacterium bovis. Immunogenicity is commonly linked to pathogenicity, and it is unlikely that a 'more immunogenic' organism will be more pathogenic in the immune competent animal.

* The mutant pfoAg137q gene from Clostridium perfringens has previously been expressed in the intracellular pathogen Listeria monocytogenes. Both the parental strain of Listeria monocytogenes and the strain expressing the mutant cytolsin, pfoAg137q, had similar LD50 values in a virulence model in mice. No increased pathogenesis is anticipated in the selected host organism, Mycobacterium bovis.

LOSS OF DRUG SUSCEPTIBILITY. AFR-01 is resistant to Kanamycin however in the event of infection with this recombinant strain it is anticipated that the antibiotics rifampicin and isoniazid derivatives which would be the antibiotics of choice in cases of infection with Mycobacterium bovis, would remain effective.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste resulting from bacteriological procedures involving the propagation, disruption and analysis of the GMO will be treated with Virkon tablets to a final concentration of greater than 1% (weight/volume). Virkon is recommended by the manufacturer for the treatment of liquid waste. Detailed information is available at www.antechh.com. Laboratory benches and equipment will be wiped down with 1% (weight/volume) Virkon solution or where this is inappropriate a solution of 70% ethanol in water on absorbent paper and then paper will be disposed of as solid waste. Spills will be treated with Virkon as above and soaked up on absorbent paper, and treated as solid waste.

All solid waste resulting from bacteriological procedures involving the propagation, disruption and analysis of the GMO will be placed in waste bags, which will be closed but not sealed, the bags will be placed in designated bins. Waste will be clearly labeled as biohazard. Bins will be closed but not sealed and autoclaved prior to incineration. The autoclave is sited in Building 405 Babraham Institute. The location of the autoclave in the vicinity of the laboratory complies with containment level 2 operations. The autoclave is routinely tested on a six monthly basis to confirm working temperatures and pressures are achieved. Autoclaved waste is transported to an off site facility, Vetspeed, (GMRef. GMGM898) for incineration.
The risk assessment has been reviewed and containment level and activity class are deemed appropriate to the procedure.

Give brief details of the genetic modification safety committee

Given the low containment level of the work to be done, the genetic modification safety committee overlaps with the biological safety committee. This committee currently consists of:
- Departmental Safety Officer
- Biological Safety Officer
- Safety Officer for the School of Biological Sciences
- Technician and Chief Electron Microscopist

The committee will initially meet every 6 months. Should substantially more biological/GM work be done, this frequency will increase. Should the work carried out on the premises change to a higher containment level, a separate genetic modification safety committee will be set up.

All solid waste will be autoclaved on site and subsequently disposed of with normal waste. All liquid waste will be sterilised using Virkon or another, similarly effective, reagents following the manufacturer's guidelines in terms of dosage and exposure times. Waste will subsequently be disposed of as normal, non-contaminated, non-dangerous liquid waste.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

The members of the genetic modification safety committee have studies the attached risk assessment and are happy that all foreseeable risks have been identified. The preventative measures contained within the risk assessment are deemed adequate for the hazards associated with the proposed work.

Project Ref 939/17.1

Date Ackn’d 19/01/2017

Date Project Ceased

CU2 Project Title Study of GM P. falciparum parasites using optical microscopy to understand the invasion mechanism of parasites in the blood-stage of malaria disease

Consent Granted Yes

Non-GMM

Consent Granted

Project notified under transitional arrangements No
### Purposes of the contained use

To investigate by live optical imaging the molecular details of human-parasite host-pathogen interactions during the *P. falciparum* blood stages, with a particular focus on erythrocyte invasion and how that process is influenced by natural genetic variation in both host and parasite. A better understanding of critical interactions during the invasion process may lead directly to the development of new prevention and control measures such as drugs and or vaccines. This work is linked to work at the Wellcome Trust Sanger Institute which seeks to develop and apply methods for genome-scale genetic manipulation of *P. falciparum* parasites, which has been approved by HSE.

### Recipient or parental organism

**Plasmodium falciparum**

### Host/vector system

Host: standard lab-adapted *Plasmodium falciparum* parasite strains will be used, primarily 307, as that is the strain from which the *P. falciparum* reference genome sequence was generated. In certain limited circumstances other lab-adapted strains, such as 7GB, HB3, Dd2, or strains recently adapted from clinical isolates will be used in place of 307.

Vector system: vectors will be obtained from ATCC through the Malaria Research and Reference Reagent Resource Center (www.mr4.org) and then adapted by Dr Julian Rayner's group (Wellcome Trust Sanger Institute, Hinxton, Cambridge CB10 1SA) to contain the gene or gene fragments of interest. Essentially all vectors consist of three elements: antibiotic resistance gene with associated expression elements to allow propagation in *E. coli* (usually encoding Ampicillin or Kanamycin resistance); drug resistance cassette with associated *Plasmodium* expression elements to allow positive selection in *P. falciparum* (usually anti-folate drug resistance encoded by *T. gondii* or *H. sapiens* DHFR; Blasticidin and Gentamicin resistance are also used); an expression or gene targeting cassette to either express the gene of interest in *Plasmodium falciparum* or direct insertion of the construct to a specific genomic location in order to ablate or modify the endogenous gene.

### Origin & function

We expect that the majority of modified lines tested at the Physics Department will focus on genes predicted to be involved in *P. falciparum* erythrocyte invasion, estimated to be approximately 400 genes and covering several broad classes of proteins including invasion ligands (EBL family, RBL family, AMA1), merozoite surface proteins (MSPs), invasion motor proteins (MyoA, MTIP, GAP45, GAP50), cytoskeleton components (IMCs, GAPMs) and regulatory enzymes (kinases and palmitoyl transferases). However, as larger-scale screens expand, other classes of genes may be included.
Fluorescent protein fusions and other marker proteins will also be inserted in some strains to facilitate fluorescence imaging, and these have no biological action.

**Evaluation of foreseeable effects**

The recipient organism does not contain any disabling mutations and is classified by the ACDP as a Hazard Group 3 organism. If altered from the wild-type, there is no available evidence to suggest that any of the proposed engineered mutations could increase the virulence, infectivity or stability of the pathogen. There is no available evidence that any disabling mutation in the recipient organism could be overcome e.g. due to insertion of a foreign gene or reversion. The GMOs have no altered tissue tropism and drug resistance to frontline prophylactics should not arise. The GMM would not elicit any alteration in the immune response of the host. The fluorescent and marker protein insertions are not expected to have biological activity in humans. GM *P. falciparum* parasites tend to grow more slowly, and are rapidly outgrown by wildtype parasites under experimental conditions. Therefore GM *P. falciparum* strains are expected to pose no increased hazard to human health or the environment relative to non-GM *P. falciparum* strains. The GM and wild-type *P. falciparum* will be handled in restricted access laboratories. Access will only be given to workers that have undergone induction and training to work in the derogated CL3 laboratory (CL3*). It is derogated for air handling aspects as there is no evidence for aerosol based transmission (see Section 11). All workers are instructed to seek medical attention immediately if they experience flu-like symptoms or an unexplained fever. Infection would be readily treatable with anti-malaria Is. Infection by *P. falciparum* occurs solely by inoculation into the bloodstream. Sharps will be banned in the laboratory, apart from the use of glass slides to assess culture growth. There is no evidence for aerosol based transmission, therefore the risk of infection by *P. falciparum* will be low. There are no natural non-human hosts of *P. falciparum* in the environment surrounding the laboratory, therefore *P. falciparum* would not be able to subsist outside of the laboratory environment. Therefore the risk of foreseeable effects through work with GM *P. falciparum* is judged to be low.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Does not apply here.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

The same derogations that apply to non-GM *P. falciparum* (and which follow primarily from the fact the parasite is not airborne) will apply to the culturing and experiment procedures with these GM strains. These derogations are:

- The requirement that the laboratory is sealable for fumigation
- The requirement that the laboratory is at negative pressure relative to the pressure of the immediate surroundings
- The requirement that an autoclave be sited in the laboratory suite
- The requirement for HEPA filtered extract and input air

The derogations are justified as there is no air-borne infection route and the parasites cannot survive dessication. Infection of personnel in the absense of a vector requires contact with the blood stream, which is unlikely as sharps use is restricted in the laboratory.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All solid waste that has contacted GM *P. falciparum* will be immersed in Distel disinfectant and then double bagged in unmarked autoclaved bags to be autoclaved in an autoclave validated for waste to reach 135°C for 10 minutes. Once autoclaved, provided that the autoclave is displaying a completed autoclave cycle, waste is removed from the autoclave by trained personnel and taken to the landfill waste stream.

Liquid waste containing the GM *P. falciparum* parasites will have Distel added at a 10% concentration, and will be left...
overnight, before being poured down the sink and flushed with tap water.

The GM safety committee considered this application on the 5th October 2016 and commented that 'as there is no airborne route of infection, the activity can be carried out at derogated CL3' and that 'no sharps are permitted in the laboratory, apart from the use of glass slides for the assessment of parasites that have been inactivated by the staining process'.

### Project Additional Information

#### Purposes of the contained use

Bacteria are simple life forms, whose understanding of their basic processes will begin to allow us to unravel those processes that underpin all life. They are made more important by the fact that some of them can cause human disease and that existing antibiotics are becoming useless due to the spread of resistance.

**Aim:** The aim of the project is to understand how the bacterium Staphylococcus aureus is able to grow and divide.

**Objectives:**
1. To use fluorescent reporters to map cellular components during growth and division.
2. To determine the role of specific components in growth and division.
3. To elucidate the mechanisms of antibiotic action and associated resistance.

#### Recipient or parental organism

- **Staphylococcus aureus**

#### Host/vector system

We will use Staphylococcus aureus SH1000, a rbsU+ derivative of S. aureus 8325-4 (Horsburgh et al., 2002) which we will refer to as the wild-type, and its methicillin resistant mutants (MRSA), some of them carrying markers for erythromycin, kanamycin and ampicillin.

For localization experiments, derivatives of pMUTIN4 vector (Vagner et al., 1998). This vector harbours E. coli origin of replication and kanamycin and ampicillin resistance markers. Also, the derivatives of this vector that will be used in the study will carry transcriptional fusion of fluorescent proteins’ genes (mNeonGreen and eYFP) with gene of RNA polymerase β’ s.u. (thought to be involved in meticillin resistance) for localization experiments.

None of the vectors used will encode resistance to antibiotics routinely used in the treatment of infections caused by S. aureus. None of the vectors used are hazardous and they are very unlikely to confer any advantage to the host bacterium.

#### Origin & function

Genetic material modified in the bacteria will include

1. inserted fluorescent reporter fusions, mNeonGreen derived from Branchiostoma lanceolatum and eYFP a mutant of GFP originally derived from the jellyfish Aequorea victoria) to allow subcellular localisation of components
2. inactivation of existing genes involved in bacterial physiology, particularly in cell wall homeostasis, to determine biological function.

#### Evaluation of foreseeable effects

The S. aureus strains considered here are capable of causing treatable disease in humans. Symptoms vary depending on infection site. Laboratory practices that could lead to infection are those that have the potential of causing trauma of the cutaneous barrier and contact with aerosols. Good laboratory practice and the specific containment level 2 control measures including use of containment laboratories, appropriate handling of sharps and avoidance of sample treatments that may produce aerosols will minimise both the risk to the worker and escape of the organisms.

In the event of accidental exposure, the worker will be advised to seek immediate medical advice and will be provided with information on strain characterisation, including...
antibiotic susceptibility. Some of the donor strains will contain resistance markers to erythromycin and some vectors to be used encode for resistance markers to kanamycin and ampicillin.

Uncontrolled dissemination of genetic material containing antibiotic resistance markers might theoretically lead to increase of antimicrobial resistance in other bacterial species. Good laboratory microbiological practice and the specific containment level 2 control measures will provide a Contained Use of the organisms that will minimise the risk to the environment.

All alterations in the genetic material will have no impact on the level of harm that the used strains may cause to human health or to the environment. All the vectors that will be used in the experiments have no known negative impact on human health and are stably inserted to the bacteria before arrival in Cambridge. The fluorescent proteins that will be synthesized from the fusion constructs are considered as non-hazardous for human health or the environment.

It is therefore highly unlikely that the generated strains will be able to harm human health or the environment to a greater degree than the parental strains.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not Applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not Applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All contaminated solid waste (agar plates, disposable plasticware, etc.) will be autoclaved in an autoclave validated to reach 135 degrees celsius for 10 minutes and subsequently disposed via the standard waste route.

Liquid cultures will be chemically-inactivated (Virkon 5% for a minimum of 30 minutes) or autoclaved as for solid waste prior to disposal down the sink.

All contaminated glassware and reusable plasticware will be decontaminated as above.

In the event of the waste autoclave breaking, either a spare autoclave will be validated to deactivate waste, while the waste autoclave is fixed, or alternatively waste will be chemically decontaminated and transferred in sealed containers to an alternate autoclave at the nearby Department of Veterinary Medicine for final destruction.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

The initial draft of this GM project and attendant GM assessment and related Risk Assessment for the base organism were provided to the Committee on 12th May 2020.

Requests were made to the researchers submitting the assessments to provide more details on the organisms used, details of certain equipment and their safety measures and the role of certain genes mentioned.

The researchers added these to the assessments which were returned to the Committee for re-review on the 4th June 2020.

On the 9th July 2020, after no further changes or details were requested by any member of the Committee, the assessments were passed locally to move this Notification.

02/03/2022
The project will attempt to visualise the growth patterns of microorganisms on materials.

Aims:
1. Visualise the bacterium on glass slide alone and validate microscopic techniques.
2. Use the pre-validated methodologies to visualise the growth patterns of PA on materials.

Recipient or parental organism

Pseudomonas aeruginosa and Burkholderia thailandensis
Pseudomonas aeruginosa is a Gram-negative bacterium principally found deep in tropical soils. In immunocompetent individuals, it can only cause eye infections but in immunocompromised people, it can cause skin and lung infections. It is the prototypical organism for studying bacterial biofilms.

Burkholderia thailandensis is also a Gram-negative bacterium principally found deep in soils. It rarely causes disease in animals or humans. It is being used here as a low risk model for more dangerous Burkholderia bacteria species.

We will be using laboratory adapted, highly characterised and sequenced wild-type strains both with modifications and unmodified controls.

Wild-type PA has been transduced with the pSEDQS plasmid, facilitating constitutive expression of genes for various fluorescent proteins. Wild-type BT has been transduced with a combination of pk18mocsacB (Schafer, et al., 1994) and pSLC plasmids (Eshaghi, Mehershahi, & Chen, 2016) or transposon libraries to allow expression of fluorescent reporter protein markers.

The plasmids also carry genes for carbenicillin, kanamycin and no resistance, respectively. None of the vectors used are hazardous and they are very unlikely to confer any advantage to the host bacterium.

Host/vector system

Genetic material modified in the bacteria may include
1) inserted fluorescent reporter fusions,
2) antibiotic resistance (Kanamycin and carbenicillin) markers

The bacteria were modified by transducing the vectors named above into the specified bacterial strains. The P. aeruginosa strain was modified in the lab of Professor Marvin Whiteley, then at UT Austin. The B. thailandensis was modified in the lab of Associate Professor Gan Yunn When at NUS.

These modifications are intended to allow easy detection and localisation of bacteria in experiments on their growth and survival on material surfaces.

Origin & function

The P. aeruginosa strains considered here are capable of causing disease in humans. Symptoms vary depending on infection site. Laboratory practices that could lead to infection are those that have the potential of causing trauma of the cutaneous barrier and contact with aerosols. Good laboratory practice and the specific control measures including appropriate handling of sharps and avoidance of sample treatments that may produce aerosols will minimise the risk to the worker. In the event of accidental exposure, the worker will be advised to seek immediate medical advice and will be provided with information on strain characterisation, including antibiotic susceptibility.

The B. thailandensis strains considered here are not considered capable of causing disease in immunocompetent humans.

In the event of accidental exposure, the worker will be advised to seek immediate medical advice and will be provided with information on strain characterisation, including antibiotic susceptibility. Some of the donor strains will contain resistance markers to kanamycin or carbenicillin.

Uncontrolled dissemination of genetic material containing antibiotic resistance markers might theoretically lead to increase of antimicrobial resistance in other bacterial species. Good laboratory microbiological practice and the specific containment level 2 control measures will provide a Contained Use of the organisms that will minimise the risk to the environment.

All alterations in the genetic material will have no impact on the level of harm that the used strains may cause to human health or to the environment. It is therefore highly unlikely that the generated strains will be able to harm human health or the environment to a greater degree than the parental strains.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not Applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not Applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All contaminated solid waste (agar plates, disposable plasticware, etc.) will be autoclaved in an autoclave validated to reach 135°C for 10 minutes. Autoclaved material disposed via the standard waste disposal route. The autoclave is calibrated and validated yearly. Autoclave runs are run regularly through the year with bio-indicator test systems (e.g. 3M’s Attest, a Geobacillus spore tube system). Liquid cultures will be chemically-inactivated (Virkon 5% for minimum 30 min) or autoclaved prior to disposal down the sink. All contaminated glassware and reusable plasticware will be decontaminated as above.

In the event of the waste autoclave breaking, waste will be chemically decontaminated and sent to an approved contractor for incineration (Novus).

Give brief details of the genetic modification safety committee

The genetic modification safety committee consists of Advanced Courses Programme Manager, Advanced Course Laboratory Manager, Wellcome Trust Sanger Institute Biological Safety Adviser, 2 x guest instructors who teach on the course that will use containment level 1 organisms.

The lab manager and the two instructors will be responsible for ensuring that containment level 1 regulations are not breached and that all waste disposal regulations are complied with.

The committee will meet annually (the course is held annually) to discuss any changes to the protocols and to review the risk assessments.

For activities involving GMMs, describe the waste management measures which will apply to the activity
PPE
Laboratory coats must be worn in the laboratory and removed when leaving the laboratory suite.
Personal protective equipment including protective clothing must be
i) stored in a well defined place
ii) checked and cleaned at suitable intervals
iii) when discovered to be defective, repaired or replaced before further use.

Personal protective equipment which may be contaminated by biological agents must be
i) removed on leaving the work area.
ii) kept apart from uncontaminated clothing
iii) decontaminated and cleaned or if necessary, destroyed.

Waste disposal.
The chemical waste from the Advanced Course Laboratory is disposed of by a registered contractor.
Incinerated waste and culture waste (including that relating to organisms classified as containment level 1) is disposed of by the Sanger Centre core facility.

**Chemical Waste:**
Dispose of waste chemicals in the labelled waste containers and under no circumstances tip any waste chemical down the sink.
Do not mix different chemicals in the waste containers; use separate containers for each chemical as mixing may cause chemical reactions to occur.
If in doubt about disposal ask a member of the Advanced Courses team.
Chemical containers are then stored in chemical cabinets until collected by a registered chemical disposal contractor.

**Clinical waste:**
Clinical waste should be placed in the yellow clinical waste bags. This includes items such as disposable gloves and azole wipes.
The yellow bags are then collected and stored in UN approved transport containers to await regular collection and incineration by a designated waste contractor.

**Single use disposable items:**
Single use disposable items such as pipette tips, toothpicks, universal bottles, falcon tubes, appendorf tubes should be discarded into disposable plastic (sweet) jars.
When full the jars are sealed with biobazard tape, collected by the waste team and placed in UN approved containers (for collection by a designated waste contractor and final inactivation by incineration).
Biological agents are 100% inactivated using this method.

**Recyclable items**
Any items such as glassware which have been in contact with biological organisms including those subject to containment level 1 regulations should either be treated with disinfectant at the appropriate concentration and exposure time or autoclaved at an appropriate cycle prior to being sent for wash up.

**Sharps**
Sharps for example blades, scalpels, needles, small items of glassware, must be discarded into an approved sharps bin. Never try to retrieve an item placed into a sharps bin. Only fill sharps bins to that approved level (usually the three quarters line, at this point the lid must be secured and the bin put in a designated waste collection point. Bins are disposed of via incineration with residues going to landfill. This method is 100% effective at inactivating biological agents.

**Solid biological agent waste.**
Solid waste including that produced at containment level 1, ie biological organisms grown in Petri dishes, contaminated paper towels or gloves, should be placed in the grey leak proof plastic autoclave boxes lined with an autoclave bag and put in the designated waste collection point. These are collected by the Sanger waste handling team for inactivation by autoclaving. After autoclaving waste is 100% inactivated in terms of biological agents, inactivated material is then placed in yellow incineration bags for storage in UN approved transport containers (to await regular collection and incineration by a designated waste contractor).

**Liquid biological**
Liquid biological waste including that produced at containment level 1 is inactivated using disinfectant eg Virkon, Presept, Tegodyne) at a concentration and contact time appropriate to the level of contamination, which is known to be effective for sterilisation. Where this is not possible (eg chemical incompatibility from a constituent of the liquid waste) then a suitable autoclave cycle will be used. Both of these methods are 100% effective at inactivating biological agents. Where chlorine based disinfectant has been used then liquid waste must not be autoclaved.

Page 12114 of 15326
The Advanced Courses Genetic Modification Safety Committee believes that this project should be designated containment level 1. They do not consider the genetically modified organisms covered by this assessment to have any harmful properties associated with the recipient strain, the vector or the inserted material and they are confident that none of the final genetically modified organisms could be hazardous to humans or the environment.

Project Additional Information

Purposes of the contained use

We will use classical gene replacement technology, based on PCR or suicide vector mediated gene conversion, to generate specific mutations in specific genes encoded within the genomes of selected enteric bacteria. Also we will introduce genes encoding non-toxic reporter molecules including Green Fluorescent Protein, Luciferase, Chloramphenicol acetyl transferase, beta-galactosidase and non-toxic vaccine antigens into different enteric bacteria. These reporter genes will be expressed from either constitutive or regulated bacterial promoters. The aim of the work is to use the reporter gene products to (1) track bacteria to different cells or sub-cellular locations within tissue culture cell lines or tissue derived from eucaryotic hosts; (2) to detect the activity of different promoters under different conditions.

Recipient or parental organism

The reporter genes will be supplied from existing plasmids as cloned DNA sequences or purchased from commercial suppliers. They will be introduced into any enteric bacteria other than those classified as Class II or above. Examples will be Escherichia coli (other than verocotoxigenic forms), Shigella spp. Salmonella enterica (other than class II agents such as S.Typhi and S.Paratyphi), Citrobacter spp etc.

Host/vector system
The host bacteria will be any enteric bacteria. The genes will either be introduced directly into the chromosome of the bacteria (via suicide vectors or PCR methodologies). Alternatively the genes will be cloned onto non-transferable plasmids such as those based on Col1E1 replicons or pAYC184 (pUC plasmids for example).

**Origin & function**

The genetic material involved is from a variety of sources such as jelly fish (Green Fluorescent Protein), bacteria (beta-galactosidase, luciferase, chloramphenicol acetyl transferase) but will not be cloned from these sources. We will use well-defined existing plasmids or genes from commercial sources. The DNA is simply to be used to report gene expression activity in enteric bacteria under different conditions.

**Evaluation of foreseeable effects**

The genes we have selected are all extremely well characterised and have been used without incident in thousands of research laboratories around the world. We will only use the named reporters associated with this application. If we decide to use any novel reporters we will amend the local risk assessment. To our knowledge there have been no foreseeable effects of these reporters other than high level expression could cause toxicity to the host bacteria (as with over expression of many proteins).

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable other than to disabled S.Typhi derivatives specifically derogated to CL2

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All the experiments will be performed in a well maintained CL2 facility. A copy of the protocol for handling enteric pathogens in these facilities is enclosed for inspection and has been approved by the local safety committee. Briefly we have detailed policies for handling contaminated liquid and solid waste that involved the contained removal of materials for autoclaving. Hence, all contaminated material is autoclaved or incinerated using chemical disinfection procedures using a variety of accepted and validated disinfectants including phenolics (hycolin etc), Virkon S or chloros. All disinfectants are made up and utilised as described in the enclosed protocol. We routinely validate inactivation using a viable count method based on the killing of control cultures of bacteria within accepted ranges. All inactivated waste material is removed using approved clinical waste disposed by incineration.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

02/03/2022

Page 12116 of 15326
The aim of the project is to utilise specific strains of Staphylococcus aureus derivatives in an Advanced training course designed to train Research Staff to perform research on the modular basis of infection.

Staphylococcus is an ACDP hazard group 2 pathogen and is consequently able to cause disease in humans and domestic animals. Inserted DNA normally comes from hazard group 2 bacteria with the exception of the non-toxic biological reporter genes.

Inserted genes can encode potential virulence genes but during the construction of the GMMs virulence genes may be inactivated and attenuated variants may be generated. It is unlikely that the manipulation procedures will enhance the virulence of any of the GMMs to a higher level than that of the donor, as a consequence all work will be carried out at containment level 2. Although antibiotic resistance genes such as Kanamycin will be used in the experiments the GMMs will be sensitive to appropriate therapeutic antibiotics. Such as cephalosporins and fluoroquinolones.
Although active genes may be used initially in E.Coli K12, they are unlikely to cause harm out if the context of their natural bacteria. However, it should be recognised that deliberate large scale production of some of the cloned proteins could be hazardous but this is not the aim of these experiments or within the remit of this assessment. Thus, the risk is negligible. Plasmids used in the experiments are non-conjugative and should not promote the transfer of DNA to unintended recipient bacteria.

Origin & function

The genetic material for reporter functions or antibiotic resistance is from a variety of sources such as jellyfish (Green Fluorescent Protein), bacteria (beta-galactosidase, luciferase, chloramphenicol acetyl transferase) but will not be cloned from these sources. We will use well defined existing plasmids or genes from commercial sources. The DNA is simply to be used to report gene expression activity in enteric bacteria under different conditions.

Evaluation of foreseeable effects

In most cases genetic modifications that will be carried out will result in loss of function and therefore is likely to result in attenuation of pathogenesis. Reporter genes we have selected are all extremely well characterised and have been used without incident in thousands of research laboratories around the world. If we decide to use any novel reporters we will amend the local risk assessment. To our knowledge there have been no foreseeable effects of these reporters.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not Applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All the experiments will be performed in a well maintained CL2 facility. Give brief details of the genetic modification safety committee

Two members of MTS Cryostores Ltd plus one external person (with experience in Biological Safety) make up the Committee who will ensure that the facilities are fit for purpose, that all equipment is adequate and properly maintained. All local rules and procedures will be prepared and staff are correctly trained and that emergency plans are in place. The said Committee will meet on a monthly basis and minutes will be recorded, signed and archived. The Committee will meet on each consideration of a client's request.

For activities involving GMMs, describe the waste management measures which will apply to the activity:

All liquid waste will be deactivated in a Virkon trap (1%) and disposed of after 24hr, as per manufacturer's instructions; all solid waste will be autoclaved at 121°C for 30 minutes prior to incineration by validated means through a licensed contractor. Accidental spillages of liquid waste will be cleaned with 2% Virkon.

Y

Give brief details of the genetic modification safety committee

Composition of the Genetic Modification Safety Committee:
Technology Director, Microbiological Safety Officer, Safety, Health and Environment Committee representative, at least two laboratory based research staff.

Mode of operation:
The committee will meet monthly as part of the overall safety, health and environment review and will review ongoing projects. Ad-hoc meetings will be arranged as required due to changes in existing projects and the emergence of new projects. The outcome of the GMSC meeting will be shared with the whole research and development team through the monthly R&D review and more widely through the site Safety Committee.

</tbody>
</table>
All laboratory liquid microbiological waste will be treated either by autoclaving in a validated autoclave, by chemical disinfection according to manufacturers instructions or by a method validated to give at least a 5-log reduction in viable count. Solid laboratory microbiological waste will be disposed of by incineration off site by a licensed contractor according to the site standard procedure. All solid waste destined for off-site incineration will be transported in labelled, sealed, unopenable plastic incineration bins. Microbiological waste derived from large scale activities will be inactivated by validated heat treatment, or under exceptional circumstances if heat treatment is not possible then treatment with acid and base will be used to inactivate prior to disposal via the site effluent treatment plant.

Waste will be generated during the preparation of Cerepro by the appropriately trained pharmacy staff and following the injection of Cerepro into the tumour bed of patients with high grade Glioma.

The waste will be disposed of in the following manner:
Disposable equipment will be placed in biohazard bags or sharps bins and autoclaved.
Any spillages in the safety cabinet or in open areas will be covered with 2% Virkon or 2% sodium hypochlorite for a minimum of 30 minutes. Any clothing, gloves, cleaning materials or any other material suspected of being contaminated with Cerepro will be autoclaved.
The theatre will be washed with 2% Virkon or 2% sodium hypochlorite after the surgery in which Cerepro was delivered.
All surgical instruments will be autoclaved as per normal hospital procedures.

Give brief details of the genetic modification safety committee

The Genetically Modification Safety Committee (GMSC) within Cyprotex is a sub-committee of the main safety committee and consist of four members of staff. These include, the chief scientific officer, the operations manager and other scientists who are exposed to working with the GMM as well as an office-based scientist (qualified to PhD level). The committee will oversee the applicability of the GMO regulations and advise the end users on the risk assessments. The committee will meet every six months to review the risk assessment document.

Waste generated within Cyprotex falls into two main categories, solid and liquid waste. All waste material that has been in contact with cells or exposed to the microbiological cabinet is treated as a potential biological hazard and/or clinical waste. Solid waste covers generally, disposable plastic wares with no electrical connections (e.g. tissue culture flasks, tissue culture plates and gloves. All plastic disposable wares (including gloves) are treated as clinical waste and disposed of in yellow clinical bin bags secured with tape highlighting the types of waste. Once full, the waste is placed in a secured (assess restricted) bin and transported offsite by a contracted waste disposal company; Ideal Solutions Ltd
152 Brookland Road
Wythenshaw
Manchester
M23 9HD
Sharps are placed in the sharps bin and considered as clinical waste.
Liquid waste generated from cell culture is treated with Virkon or effective alternative disinfectant for at least 1hr prior to disposing to drain. Solvent waste is collected in Duran bottles and is secured in an access restricted area for collection by a contracted waste disposal company; P&R Waste Disposal Services Ltd
Brindley Road
St Helen's
WA9 4HY

For activities involving GMMs, describe the waste management measures which will apply to the activity

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Give brief details of the genetic modification safety committee

The GMSC comprises a Chairman who is on the company board (Company Secretary), a GM Safety Officer who is an experienced scientist (Associate Director), the head of process development, and a member of the admin staff (as a non-expert). Other technical staff may attend meeting as required. The GMSC meets quarterly or as required to review new GM work proposals.

The GMSC oversees all GM work and operating procedures to ensure they comply with all current legislation and reviews all GM work prior to it beginning - it forms part of the Company Health and Safety organisation and the key members also sit on the H&S committee.

There are two main methods of waste inactivation in operation at TMO’s labs.

1. Autoclaving: The bulk of waste generated is preferentially inactivated by autoclaving using a discard cycle of 121°C for 15 mins with full steam penetration to the load. This cycle is electronically monitored and controlled to ensure correct temp and pressure are maintained throughout the run. The effectiveness of the cycle is further monitored by the addition of a steam cycle verification indicator (TST strip, 121°C, 15 mins). The autoclave cycle performance is checked and validated on an annual basis during maintenance by competent contractors following relevant manufacturers guidelines.
   EFFECTIVE KILL: 100%

2. Chemical Inactivation: where waste cannot be inactivated by autoclaving, e.g. treating spills or for soaking sensitive equipment, then chemical inactivation is used. TMO use 1% (w/v) solution of Virkon (Antec International) which is used in accordance with the manufacturers instructions. Contact time is a minimum of 10 minutes. For soaking, the solution is discarded once the pink colour has faded or after 7 days (whichever is soonest).
   EFFECTIVE KILL: >1 x 10e7 reduction in viability.

For activities involving GMMs, describe the waste management measures which will apply to the activity
All needles and syringes will be discarded into a designated sharps bin. This will be sealed and disposed of using normal hospital procedures.

All other materials will be treated as clinical waste and disposed of in yellow clinical waste bags under normal hospital procedures.

Unused vials will be returned to pharmacy and stored in the refrigerator until full accountability has been conducted by the monitor of the study and approval to destroy has been received from sponsor.

If a spill occurs use absorbent material to soak up spill and discard with spent vials into Biological Waste. Clean area with cleaning agent to remove residue. No specific disinfectants are required.

Date of meeting: 10th October 2005
Present: Associate Director of Trust (Chair), Microbiologist, Senior Research Nurse, Post Doctoral Scientist, Medical Oncologist, Pharmacist, Virologist, Infection Control Representative

Apologies: Pharmacist, HSE Representative, Clinical Oncologist

Note: The senior Research Nurse (Debbie Berine) and Medical Oncologist (Dr John Chester) on this committee will be working on this project. Dr Chester is the principal Investigator at St James's University Hospital.

For activities involving GMMs, describe the waste management measures which will apply to the activity
Although advised that level 2 will apply, a full risk assessment is enclosed with this application; data on efficacy of povidone iodine is also supplied.

Controlled scientific studies at the University of Washington have demonstrated the safety of the Lentivirus vector in the transfer of c G-CSF into the target muscle tissue, using a standard protocol of operation pre-peri-and post administration of the vector by deep intra-muscular injections. Studies on the dog and rat by a team totally devoted to its research and safe development have enabled a gene therapy to be developed specifically to treat children with Cyclic Neutropaenia for a 30 year period.

The Collie dogs involved in the study have demonstrated the efficiency and safety of the gene transfer as they are a very good research tool showing classic probability-inherited cyclic neutropaenia.

Peer-reviewed papers describing virus generation & use in rats and dogs have been frequently published.

Collie and normal dogs successfully treated this way have been returned to the community as they have been considered to be of no risk to the families concerned - on a par with the use in similarly affected children. In excess of 100 rats have received lentivirus vectors and have been handled and routinely bled by investigators. These studies only required precautions normal employed in handling rodents.

Virus is generated in a biosafety level 2 laboratory and after virus administration, the staff are only required to house the animals at biosafety level 1. This also means that they can be returned to the community with no restrictions on their movements.

We are fully prepared to apply the risk assessment SOP in full as good veterinary medical practice, as well as making this request for derogation, in the earnest understanding of a fast-track result that will enable us to treat a client's puppy who is at risk from a common infection that could totally overwhelm her defences when around the Neutrophil Nadir.

The method of treatment proposed for the puppy will conform exactly to the standard operating procedure used on the dogs at the University of Washington.

**Project Additional Information**

**Purposes of the contained use**

First treatment by gene therapy of an immunologically deficient young working collie suffering from Cyclic Neutropaenia, and who carries a very grave prognosis if the situation is not treated. We do not anticipate any further Lentivirus administration.

**Recipient or parental organism**

Expression plasmid pRRL-cPPT-CMV-cGCSF-PRE-SIN was constructed by inserting the canine G-CSF cDNA into the multiple cloning site of pRRL-cPPT-CMV-X-PRE-SIN.

**Host/vector system**

A well-established Lentivirus vector is used, with non-replicating characteristics, generated by Calcium Phosphate cotransfection of the above plasmid plus 3 other "packaging" plasmids. Assays for replication-competent lentivirus continue to be negative.

**Origin & function**

Sustained delivery of cG-CSF to the target cells (muscle tissue) to permit long-term gene expression. The intended aim is to allow the dog to generate a sustained, elevated therapeutic neutrophil production, thereby allowing in turn normal growth rate to resume and no further recurrent cycles of potentially-fatal persistent infections that would be rapidly and spontaneously resolved in healthy immuno-competent dogs.

**Evaluation of foreseeable effects**

We remain confident that the use of this gene therapy presents no risk to other animals and people associated with the puppy. We have established a treatment SOP (attached with this form) to provide sensible medical safeguards to the patient, operator and client. Regular blood tests will be continued to provide simple data for on-going statistical analysis.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

This is specific canine gene therapy for a specific canine genetic immuno-deficient disease. For the sake of complete identification, the patient will be uniquely micro-chipped and will be spayed when considered well enough following achievement of a satisfactory and sustained response to the therapy. Please refer to PCR and southern blot checks in the risk assessment on tissue harvested from animals involved in the university study which demonstrates that there is no spread of any virus vector material to other body tissues apart from the intended target thigh muscle tissue.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Controlled scientific studies at the University of Washington have demonstrated the safety of the lentivirus vector in the transfer of c G-CSF into the target muscle tissue, using a standard protocol of operation PRE-,PERI and post administration of the vector by deep intra-muscular injections. Studies on the dog and rat by a team totally
devoted to its research and safe development have enabled a gene therapy to be developed specifically to treat children with cyclic neutropaenia for a 30 year period. The collie dogs involved in the study have demonstrated the efficiency and safety of the gene transfer as they are a very good research tool showing classic probably-inherited cyclic neutropaenia. Peer-reviewed papers describing virus generation and use in rats and dogs have been frequently published. Collie & normal dogs successfully treated this way have been returned to the community as they have been considered to be of no risk to the families concerned - on a par with the use in similarly affected children. In excess of 100 rats have received lentivirus vectors and have been handled and routinely bled by investigators. These studies only required precautions normally employed in handling rodents. Virus is generated in a biosafety level 2 laboratory and after virus administration, the staff are only required to house the animals at biosafety level 1. This also means that they can be returned to the community with no restrictions on their movements. We are fully prepared to apply the risk assessment SOP in full as good veterinary medical practice, as well as making this request for derogation, in the earnest understanding of a fast-track result that will enable us to treat a client's puppy who is a risk daily from a common infection that could totally overwhelm her defences when around the Neutrophil Nadir.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Procedure will leave little or no vector on the skin surface post-needling due to depth, angle and choice of min. needle gauge cosistant with safe practice.
1. Povidone Iodine will be applied to saturate the area with virucidal activity.
2. The treated, virus free area will be covered by suitable dressings for at least 24 hours.
3. Pre-treatment assay on the quality and safety of that batch of non-replicating lentivirus.
4. All materials used will be placed in 10% bleach then transferred to clinical waste bags and sharps bins for transfer to the approved incineration plant of our licensed clinical & hazardous waste disposal contractor.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The method of treatment proposed for the puppy will conform exactly to the standard operating procedure used on the dogs at the University of Washington.

Give brief details of the genetic modification safety committee

The GM safety committee consists of a founder of Smart Holograms, the BSO and the Deputy BSO of Smart Holograms. All are trained to PhD level and the BSO and deputy BSO are experienced in the safe handling and genetic modification of class 1 and class 2 micro-organisms. The GM safety committee convene on a quarterly basis. Experiments involving the genetic modification of micro-organisms are discussed on an individual basis and assessed on individual merit. The necessity of the experiment is discussed, as are the safety implications of the experiment and how GMO's will be disposed of safely. Only if all members of the GMSC agree that all safety issues have been addressed will the experiment be given the go ahead.

Laboratory bench top surfaces are thoroughly cleaned with a 1% Virkon solution before and after any potential exposure from GMO. Virkon solution is prepared and replaced on a weekly basis. Virkon solution has been shown to effectively kill a wide range of micro-organisms in both vegetative and spore forms. Protective items that have come into contact with GMO's e.g. gloves, are disposed of in yellow biological waste bins. Agar plates containing GMO's are also placed in yellow bin. Yellow bins are sealed when three quarters full and collected by an external licensed company for disposal by incineration. Flasks that have been used in the cultivation of GMO's are sterilised by addition of 1% Virkon solution before autoclave treatment.

Sharps that have come into contact with GMO's e.g. pipette tips, syringes, are disposed of in biological waste sharp bench bins. These are sealed when three quarters full and collected by an external licensed company for disposal by incineration.

For activities involving GMMs, describe the waste management measures which will apply to the activity

After discussion of the experiment no sources of unnecessary risk were identified. The methods of disposal of organism, lab-ware and sterilisation of equipment were deemed as suitable. No foreseeable increase in Bacillus Subtilis pathogeneisis could be identified by the attempted increase in spore sensitivity to Ca2+ DPA.

THE RISK ASSESSMENT HAS BEEN ENDORSED BY THE GMO SAFETY COMMITTEE.

Project Ref 301/05.1

Date Ackn'd 05/07/2006

CU2 Project Title Testing of human antibodies developed from phage libraries for therapeutic use of assessing their effect on a variety of cell lines grown in the laboratory.

Date Project Ceased

Class CultureVolClass2 CultureVolumeClass3-4

Class 2 < 1 Litre

Non-GMM Consent Granted Not Applicable

Project notified under transitional arrangements N
### Project Additional Information

#### Purposes of the contained use

To minimise the risk of infection from class II cell lines, in accordance with good microbiological practice and the protection of both work and worker. Work carried out at the premises will be limited to research activities.

#### Recipient or parental organism

The cell lines used may include adenovirally transformed lines (eg HEK-293) or cells classed as Biosafety level 1 that have been transfected with mammalian expression vectors or via adenovirus. The cell lines themselves are not infectious.

#### Host/vector system

The GM cell lines may be virally transformed, adenovirally transfected or stably transfected using expression vectors. Adenovirus has been identified by the ACDP as a Level 2 Biosafety Hazard. However, the risk of transmission to humans in this activity is considered negligible. In some cases the inserted product may be expressed as a membrane bound protein. The antigens under study are not in themselves pathogenic but should be handled according to good microbiological practice.

#### Origin & function

Adenovirus has been used to transform some commercially available cell lines, in order to render them immortal for long-term culture. Adenovirus is also as a means of introducing a gene of interest for over-expression, usually at the cell surface, for use as a selection target. The product may occasionally be released into the medium as a soluble protein, or purified from the cell, but will then be captured for use as a selection target or for in vitro characterisation and testing of the antibodies under development.

#### Evaluation of foreseeable effects

Biosafety level 2 hazard is introduced to the proposed work by use of adenovirally transformed or transfected cell lines. Other cell lines or products are currently evaluated at level 1. The risk of transmission of adenoviruses from these systems to humans is negligible and the cell and genetic material will not survive in the external environment. Standard level 2 decontamination and containment facilities are in operation. Overall, the foreseeable effects are considered negligible.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Cell lines will be cultivated in disposable plasticware at a scale from 50ul to 500ml under aseptic conditions and harvested by centrifugation. All waste resulting from these procedures will be either chemically inactivated or autoclaved prior to disposal. All equipment and materials used within the procedures will also be sterilised by autoclaving for 20 minutes at a temperature of 121 degrees C or chemically disinfected (eg with Virkon, TriGene, or Proceine40) prior to disposal or re-use. All operations will be performed in laboratory facilities in which spillages can be effectively disinfected so the wider environment is unlikely to become contaminated.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

This project has been approved as a class 2 GM activity on the basis of the attached risk assessment.

<th>Function</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>To assess mechanism of action for any given antibody candidate - specifically internalisation using a variety of cell lines.</td>
<td></td>
</tr>
</tbody>
</table>

**Evaluation of foreseeable effects**

As a disabled E. coli strain, the GMM has limited potential for survival outside laboratory culture conditions and would therefore be unlikely to become established in the environment.

The risk of exposure to a scientist would be for eg. By a splash on an open wound or through the eye and where the antibody is directed against a human antigen, the result would be hazardous if the antigen was expressed. However the risk of transmission to humans in this activity is considered unlikely.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

- Not applicable as work will not involve GM animals or plants.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

- No derogation from class 2 containment will be allowed.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

- Equipment and materials - to be decontaminated by autoclaving at 121C for 20 minutes. This will result in a 100% kill. Following decontamination, waste will go to landfill.
Liquids - to be decontaminated by autoclaving as above. Following decontamination liquid will be disposed of down the sink. References supporting decontamination route: "Full length toxin has enzymatic activity identical to that of Diphtheria toxin" - Merck KGaA - Chemicals - Merck Biosciences (www.merckbiosciences.com).

GMSC discussed the risk assessment at a meeting on Monday 30 July 2007. Some amendments were made to the assessment, following which the committee were satisfied with the assessment and signed it off on Monday 6 August 2007.

### Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Give brief details of the genetic modification safety committee
The duties of the Genetic Modification Safety Committee are fulfilled by the Gentronix Health and Safety (H&S) Committee. There is no provision within Gentronix for a separate Genetic Modification Safety Committee at this time, due to the small size of the organisation.

The H&S committee is comprised from members of staff from different tiers of the organisation:

H&S Co-ordinator & Chair
Scientific or other Director
Laboratory Manager
Member of the Technical Staff
Researcher/ Student (by invitation)

Operating Procedures & frequency of meetings
1. Chair invites members to a quarterly meeting to discuss H&S matters and to review either new, or current, risk assessments.
2. During the meeting the relevant risk assessments will be discussed and any amendments required will be made with the consensus of the committee, after liaison with the staff involved in drafting the original risk assessment.
3. The amended risk assessment will then be approved by the committee and circulated to all staff.

The Chief Scientific Officer of Gentronix is also a member of staff in the Faculty of Life Sciences at the University of Manchester. Some university research students will also be working within the Gentronix Laboratory using the same panel of organisms and procedures and the laboratory is based within the University of Manchester. Hence, the Gentronix Health and Safety Committee will solicit advice on matters concerning GMMs from the local, University of Manchester, Genetic Modification Safety Sub-Committee. This Modification & Biohazards Safety Sub-Committee and the University of Manchester Genetic Modification and Biohazards Safety Advisory Group. The Genetic Modification & Biohazards Safety Sub-Committee comprises a Chairman and representatives of the local University Genetic Modification Safety Sub-Committee associated with the various faculties and buildings within the University, as well as other University Health & Safety representatives.
H&S Co-ordinator & Chair

</table>
The GMMs proposed for use in this study are as follows: (Also see accompanying Working Practices document).

- Specially-disabled strain of Saccharomyces cerevisiae (FF18984), ACDP Classification - Class 1
- Disabled strains of mammalian cell lines, principally human lymphoblastoid line (TK6) and human hepatocellular carcinoma (Hep G2), ACDP Classification - Class 1
- Disabled strains of Escherichia coli (K12 derivatives), ACDP Classification - Class 1

Standardised Working Procedures will be adopted when handling Class 1 GMMs, consistent with, and often exceeding, those required for Class 1 containment.

Inactivation and disposal of items contaminated with Class 1 GMMs

- All re-useable items contaminated with Class 1 GMMs, such as laboratory glassware and small pipetting troughs, will be disinfected by total immersion in freshly prepared 1% (w/v) Virkon solution (Antec International) for 24 hours (see note 1). Items will then be washed and autoclaved following standard laboratory procedures.
All disposable items contaminated with Class 1 GMMs, such as polypropylene pipette tips, sample vials, microplates and gloves, will be sealed in small bags containing absorbent material, labelled as “biohazard” and either inactivated via autoclave before appropriate disposal by conventional routes (see note 2), or sent for incineration by approved contractors. Materials sent for incineration will be further encapsulated in one-way sealed burn units, appropriately labelled with details of their contents and the sender's contact details.

Stock cultures of Class 1 GMMs, when no longer needed, will be sealed in small bags containing absorbent material, labelled as "biohazard", and either inactivated via autoclave before appropriate disposal (see note 2), or sent for incineration by approved contractors. Materials sent for incineration will be further encapsulated in one-way sealed burn units, appropriately labelled with details of their contents and the sender's contact details. Alternatively, larger volumes of culture can be inactivated by autoclave whilst contained within culture flasks, before appropriate disposal by conventional routes (see note 2).

Work areas will be disinfected after use using 70% ethanol/water solution (see note 3).

Liquid spills of Class 1 GMMs on the bench or floor will be contained with absorbent paper tissue, or Virkon powder. Absorbent paper and powered Virkon waste will be sealed in small bags containing absorbent material, labelled as "biohazard", and either inactivated via autoclave before appropriate disposal by conventional routes (see note 2), or sent for incineration by approved contractors. Materials sent for incineration will be further encapsulated in one-way sealed burn units, appropriately labelled with details of their contents and the sender's contact details. The affected floor/bench area will be disinfected with 70% ethanol/water solution (see note 3).

Contamination broken glass will be inactivated by total immersion in freshly prepared 1% Virkon solution for 24 hours before appropriate disposal by conventional routes (see note 1). The affected bench/floor area will be disinfected with 70% ethanol/water solution (see note 3).

Note 1: Virkon is a peroxygen compound that was found to be effective against strains of Saccharomyces cerevisiae, bacteria and viruses after 5 minutes contact time at 1% (see www.antecint.co.uk and references therein). It has minimum environmental impact and a red colour in solution indicating its activity. 99.999% degree of kill is assumed after 24 hours with 1% virkon solution.

Note 2: Items sterilised, and GM cells inactivated, by autoclave are subject to a temperature of 121°C for a duration of 20 minutes. 100% degree of kill would be achieved. A boxer autoclave is to be provided by the University of Manchester Incubator Company (The Buildin Managers) in an area adjacent to the laboratory. The autoclave is maintained regularly under a service contract with Lab3 Ltd, 1 Dragon Court, Crofts End Road, Bristol BS5 7XX.

Note 3: Alcohols give a very rapid kill of micro-organisms, but do not provide sustained microbial action. 99.999% kill would be achieved.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment
All members of the current Gentronix Health and Safety Committee were involved in the drafting of risk assessments for this work. The Committee has subsequently approved the final risk assessment as an accurate account of the risks inherent to the work and a correct description of the protocols, sufficient for safe containment and use of GMMs in these projects, within the Gentronix laboratory. The risk assessments will be reviewed annually and as any significant variations in protocols arise.

In addition, the work described in this form, in the associated risk assessment and in supporting documentation has been carried out over the previous 15 years in the laboratory at the University of Manchester (formally University of Manchester Institute of Science and Technology - UMIST). Over the past 7 years this research work has been largely on behalf of Gentronix Limited. This application concerns the movement of activities to a new laboratory adjacent to the University premises. During the previous 15 years, whilst working within University premises, the work was subject to approval by the various UMIST/University of Manchester Biological Safety Committees. All work, containment procedures and risk assessments were approved by these committees.

For activities involving GMMs, describe the waste management measures which will apply to the activity

All contaminated waste and cell culture waste, disposable plastics, laboratory glassware, or other contaminated materials, including waste destined for incineration, will be autoclaved at 121°C for at least 15 minutes to inactivate GMOs (100% kill) prior to disposal or cleaning and recycling. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored using TST sterilisation control strips with colour change dot to show successful autoclaving. The dot changes from yellow through brown to purple when exposed to steam at 121°C for 15 minutes. Periodic swabs shall be taken from the culture media after autoclaving to ensure effective operation. Inactivated autoclaved waste will be removed from the premises and disposed of by incineration by a commercial contractor.

Tick to confirm that you are attaching a summary of the risk assessment  

Tick if you are claiming exemption from disclosure for sections of the risk assessment  

Please enter comments of the GM safety committee on the risk assessment

The comments on the risk assessment were all positive and it was decided that the risk assessments met the criteria that were set down in the ACGM Compendium of Guidance.

Issues such as security, biohazard and GMO signage on the door of the room, information on the qualifications and the training of staff in standard operating procedures were also discussed:

Access to the GMO laboratory will be restricted and the laboratory area will only be accessible through the use of a swipe card.

Biohazard and signs will be displayed on the doors to the laboratory.

Staff will be trained on all standard operating procedures relating to GMO procedures and waste disposal before commencement of any work involving GMO. These standard operating procedures will be reviewed on an annual basis.

---

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Composition: Chair, biological safety officer, line managers (or their delegates) representing each laboratory covered by the committee, a national blood service health and safety advisor (ex-officio capacity), representatives from each level of researcher working in the laboratories where GMM are used (eg. Post-doctoral scientist, Ph.D. student), external experts as required (eg: The Oxford Radcliffe Trust biological safety officer).

Meetings: At least every 6 months, and more often as required. Between meetings, email will be used to discuss issues that arise and can be dealt with without a formal meeting of the committee.

Procedural note: Risk assessments can only be approved following review by at least 3 members of the committee that are not directly involved in the work proposed.

Other(s)

For activities involving GMMs, describe the waste management measures which will apply to the activity

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The GMSC is happy with the risk assessment in its current form. It was noted that the work poses low or very low risks, and that both containment and waste disposal measures are well established.

This work was initially presented as a CL1 activity. However the committee decided it should be upgraded to a CL2 due to the reported association of vectors containing WPRE and murine liver cancer.

Date Ackn’d | CU2 Project Title
07/07/2006 | To produce self-inactivating (SIN) HIV-1 based Lentiviral Vector (LV) particles as vehicles for gene transfer into mammalian cells.

Date Project Ceased

Consent Granted

Project notified under transitional arrangements N

Tick if notifying a connected programme of work N
### Project Additional Information

#### Purposes of the contained use

The work will involve the production of lentiviral vector particles as vehicles for gene transfer into mammalian cells. Transient and stably transfected cell lines expressing the chosen transgene will be expanded for the purposes of further study such as gene and protein analysis. Transfected cells may also be assessed in vitro assays related to cell proliferation and cell migration/adhesion.

#### Recipient or parental organism

Disabled E. coli strain used for cloning and propagation of the plasmids represent negligible risks. Mammalian cell line used to produce the lentiviral vector particles (e.g., HEK 293T cells) contain the SV40 T antigen and therefore present a medium risks under COSHH. Primary human cells represent negligible risks, since they are naturally occurring, unless they are from blood. All blood will be screened by PCR for HIV and HSV. All recipients are unlikely to survive outside the laboratory and therefore the GMOs will carry no additional hazard.

#### Host/vector system

The plasmids described in the attached risk assessment will not produce stable transfection. The lentiviral vector (LV) systems described in the same risk assessment are disabled, minimal, self-inactivating vectors that will be unable to establish an infection or propagate to other cells.

#### Origin & function

All transgenes described in the risk assessment will be of human origin.
- LacZ, Luciferase and GFP are markers used to assess transduction efficiency.
- The Nkx2.5 transcription factor is required for heart formation during development. Nkx2.5 is expressed during adult life in cardiac tissue, and it is more abundant in ventricular than atrial cardiomyocytes. Therefore its function is likely to be induction of cardiac muscle phenotype and cardiac-specific gene expression.
- The receptors CD164, PZR, JAM-A, LSP-1, CXCR4 and EPHA3 may be involved in cell adhesion and cell migration. Their overexpression may enhance cell motility and cell adhesion in human primary cells.
- Similarly, the scaffolding protein HEF-1 may be involved in cell proliferation and cell migration/motility.
- The EDG-1 (endothelial differentiation gene) is a member of the sphingosine-1-phosphate family of receptors involved in the regulation of essential cellular processes such as proliferation, migration, cytoskeletal organisation, adherens junction assembly and morphogenesis.

#### Evaluation of foreseeable effects

The expression of a standard marker gene such as LacZ, which is naturally occurring in high levels in mammalian cells due to its stability, mean that even in the unlikely event that accidental exposure occurs that no harmful effect will follow. Similarly the other transgenes are transcription factors, receptors and enzymes that naturally occur in mammalian cells, reducing the risk of harm.
Furthermore, although the potential exists that almost any gene that is involved in processes such as cell-to-cell or intracellular signalling, cell cycle control, differentiation or apoptotic control, could become an oncogene under certain circumstances e.g. Overexpression, it is rare that a single oncogene would cause cancer. The worst case scenario will occur if the overexpression of the transcription factor includes the expression of several oncogenes or inhibits the expression of tumour suppressor genes. None of the trangenes chosen are known to have harmful physiological or pharmacological properties. They are not known to be oncogenic and as they are naturally occurring they are not expected to affect host or normal human defence mechanisms. There is no evidence in literature that any of them cause an adverse effect. Gene transfer would not seem to be hazardous and the resulting GM cells are not expected to carry any additional risks to that of the unmodified recipients. The inserts code for genes which are not expected to have harmful physiological or pharmacological properties or to affect animals, plants or other organisms should they be accidently released. Classification: Class 1. There is no evidence in the literature that any of them cause an adverse effect, neither would they be likely to impact the environment should they accidently be released. It is highly unlikely that the vector system will be hazardous to animals, plants or the environment should accidental exposure occur.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable. This work will not involve the use of GM plants or animals in the premises.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The work will be carried out avoiding sharps and with the appropriate Personal Protective Equipment (PPE). All GMO and GM waste must be inactivated before disposal. Waste inactivation will either be by Virkon at 2%, for a minimum of 2 hours, or by autoclaving. All waste to be autoclaved must be placed in grey boxes, sealed and placed in the metal wheelie-bin in the Blood Research Laboratory (BRL) for inactivation in the JRH Trust’s autoclave and subsequent disposal. This is in agreement and is already well established.

Following inactivation, waste is to be placed in yellow biohazard bins, which must be sealed and dated before being passed to Grundon for removal/disposal.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

Page 12175 of 15326
The work will involve the production of retroviral and adenoviral vector particles as vehicles for gene transfer into mammalian cells. Transient (adenovirus) and stably (retroviral) transfected cell lines expressing the chosen transgenes will be expanded for the purpose of further study such as gene and protein analysis. Transfected cells will also be assessed in in vitro assays related to stem cell phenotype, proliferation and differentiation into various lineages.

Recipient or parental organism

Disabled E. coli strain used for cloning and propagation of the plasmids represent negligible risks. Mammalian cell lines used to produce the lentiviral vector particles (eg: HEK 293T cells) contain the SV40 T antigen and therefore present a medium risk under COSHH. Primary human cells represent negligible risks, since they are naturally occurring, unless they are from blood. All blood will be screened by PCR for HIV and HSV. All recipients are unlikely to survive outside the laboratory and therefore the GMOs will carry no additional hazard.

Host/vector system

The plasmids described in the attached risk assessment will not produce stable transfection. The adenovirus vector (AdS) system described in the same risk assessment
are disabled, minimal, non-replicating vectors that will be unable to establish an infection or propagate to other cells. The retrovirus vectors used in this study are also also packaging deficient and non-replicating virus unable to establish infection or propagate to other cells.

Origin & function

All transgenes described in the attached risk assessment will be of human origin. LacZ, Luciferase and GFP are markers used to assess transduction efficiency. The pluripotency associated genes Oct4, Nanog, Sox2, and Klf4 are highly expressed in embryonic stem cells, and with varying expression profiles in other more committed multipotent stem cells. The intended function of these genes is to use them in combination, to induce a stem cell phenotype from human tissues of varying origins.

Evaluation of foreseeable effects

The expression of a standard marker gene such as LacZ, which is naturally occurring in high levels in mammalian cells, is expected to be safe due to its stability. Even in the unlikely event that accidental exposure occurs, no harmful effect will follow. Similarly, the other marker transgene GFP, has no reports of adverse reactions associated with it. Furthermore, although the potential exists that almost any gene that is involved in processes such as cell-to-cell or intracellular signalling, cell cycle control, differentiation or apoptotic control, could become an oncogene under certain circumstances e.g. overexpression, it is rare that a single oncogene would cause cancer. The worse case scenario will occur is the overexpression of the transcription factor induces the expression of several oncogenes or inhibits the expression of tumour suppressor genes.

Some of the transgenes used in this study are thought to have oncogenic characteristics, in specific cell types: Oct4 is associated exclusively with germline tumours; and Nanog can induce a lymphoproliferative disorder- However, these effects have been observed only causally, and it is not known whether they mediate oncogenesis directly, and is unlikely that exposure to these viruses will occur, given that correct PPE and Class 2 procedures will be employed. Gene transfer to target cultured cells would not seem to be hazardous and the resulting GM cells are not expected to carry any additional risks to that of the unmodified recipients. The inserts code for genes that are not expected to have harmful physiological or pharmacological properties or to affect animals, plants or other organisms should they be accidentally released. Classification: Class 2. There is no evidence in the literature that any of them cause and adverse effect, neither would they be likely to impact the environment should they accidently be released. It is highly unlikely that the vector system will be hazardous to animals, plants or the environment should accidentally exposure occur.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable. This work will not involve the use of GM plants or animals in the premises.

Give brief details of the genetic modification safety committee

Our GM Safety Committee comprises the Director of Research & Development and a Research Scientist. This meets on an ad hoc basis in addition to the regular safety meetings. For handling specific client samples, whereupon we refer to the findings and recommendations of the GM safety committee at the client organisation and act appropriately on the information provided. We do not foresee the need for us to handle any GM materials greater than Category 1 at this stage and therefore the risk to our staff is minimal. Since there are no trade unions represented in our company (we have only 4 employees), all staff will be consulted prior to the possible handling of such materials.

For activities involving GMMs, describe the waste management measures which will apply to the activity
We currently dispose of all laboratory waste as though it were clinical waste (EWC 18 01 03) in accordance with the recommended UK government procedure for the disposal of wastes whose collection and disposal is subject to special requirements in order to prevent infection. We have a contract with Cliniserve Ltd. Who dispose of the waste by incineration in accordance with The Environment Protection Act (1996). This includes our providing a description of the waste in accordance with European regulations (EPA 1990 SEC 34). Our premises have been registered as being "low risk" since we produce less than 200kg of hazardous waste per annum. We understand that for disposal of Class 1 GM waste, our current procedure is sufficient to cover this.

Tick to confirm that you are attaching a summary of the risk assessment  Y

Tick if you are claiming exemption from disclosure for sections of the risk assessment  Y

Please enter comments of the GM safety committee on the risk assessment

For the activities we wish to carry out at Biopharma Technology Ltd., we have identified the activity risks relating to the handling of the Category 1 GM material itself as being minimal, since we would be handling dilute liquid formulations, freeze-drying the material and sealing the resulting material in containers under negative pressure, thereby minimising the risk of any direct contact with our staff or the environment.

All handling operations will be carried out in a Class II microbiological safety cabinet (HEPA filtered air under laminar flow) with the operators using the following personal protective equipment: gloves, safety spectacles, laboratory coat. Additionally, a face mask will be used if it is necessary to handle powders.

Our freeze-dryers' vacuum pumps are fitted with filters to minimise the risk of organisms or oil mist being emitted into the laboratory. All accessible potential equipment contact surfaces will be disinfected using bacteriocidal solution and swabbed with 70% ethanol or isopropanol solution after use, in accordance with our standard operating procedures.

Laboratory waste will be treated by heat inactivation. Disinfection may also be employed. Inactivation will be by validated means where and to the extent the risk assessment shows it to be required.

For larger scale processes the cells will typically be removed by centrifugation or filtration for further processing. Disinfection or chemical treatment with caustic solution may also be employed.

Inactivation of GMM's in contaminated material and waste including those in the process effluent before discharge will be validated where and to the extent the risk assessment shows it to be required.

For activities involving GMMs, describe the waste management measures which will apply to the activity:

Laboratory waste will be treated by heat inactivation. Disinfection may also be employed. Inactivation will be by validated means where and to the extent the risk assessment shows it to be required.

For larger scale processes the cells will typically be removed by centrifugation or filtration for further processing. Disinfection or chemical treatment with caustic solution may also be employed.

Inactivation of GMM's in contaminated material and waste including those in the process effluent before discharge will be validated where and to the extent the risk assessment shows it to be required.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment:

The risk assessment fully considers the laboratory operations and correctly identifies the risks and the containment level required. The NIBF Development Laboratory more than meets the requirements for the containment level 1 such that the risks to humans and the environment are minimised.

### Project Additional Information

#### Purposes of the contained use

Storage in - 80 degrees Freezer and shipping (logistical distribution) of GM material on behalf of the client. In some cases materials may need to be discarded as per client's request. No GM manipulation will be undertaken as part of this contained use.

Client notification number for contained use: GM3392/18.1.

Title: "rMV manufacture and rMV Process Development"

#### Recipient or parental organism

Non applicable as storage and cold chain logistical distribution only.

Performed by the client as per:

Client notification number for contained use: GM3392/18.1.

Title: "rMV manufacture and rMV Process Development"

#### Host/vector system

Non applicable as storage and cold chain logistical distribution only.

Performed by the client as per:

Client notification number for contained use: GM3392/18.1.

Title: "rMV manufacture and rAAV Process Development"

#### Origin & function

Non applicable as storage and cold chain logistical distribution only.

Performed by the client as per:

Client notification number for contained use: GM3392/18.1.

Title: "rMV manufacture and rAAV Process Development"

#### Evaluation of foreseeable effects

Non applicable as storage and cold chain logistical distribution only.

Performed by the client as per:

Client notification number for contained use: GM3392/18.1.
### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Non applicable as storage and cold chain logistical distribution only. Performed by the client as per:

Client notification number for contained use: GM3392/18.1.

#### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Non applicable

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Class 2 GMM waste is only generated as per client's request of material disposal, as result of a faulty container or breakage of container.

The Class 2 GMM waste is autoclaved at 123°C for 30 minutes, 2 bar pressures, prior to disposal to landfill by a registered waste contractor (Veolia). Spore strips are included in each Class 2 GMM waste load for purposes of validation of destruction. The autoclaved waste is then stored in a sealed wheele bin with biohazard symbols displayed, for 48 hours, while the spore strips are incubated to validate destruction. After 48 hours and a positive destruction result with the spore strips, the inactivated waste is removed by a registered waste contractor to landfill.

The autoclave is validated annually. Class 2 sharps containers are autoclaved in accordance with an SOP for Class 2 GMM waste inactivation before being removed by a registered waste contractor (Veolia) for disposal.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

---

**Please enter comments on the GM safety committee on the risk assessment**

FBS UK bio-repository is equipped with the appropriate safe systems to store and distribute the AAV - Multiple recombinant Adeno Associated Vector material safely. These include appropriate waste and spill procedures. No laboratory manipulation will be performed for this material.

In order to undertake this contained use work, FBS UK will be required to follow notification requirement as per under The Genetically Modified Organisms (Contained Use) Regulations 2014 - GMO(CU), using CU2 form available on the Health and Safety Executives website.

This proposed contained use work is low risk. Please also refer to Product Risk Assessment FBS-P-368.

Please also refer to GMO Risk Assessment performed under:

Client notification number for contained use: GM3392/18.1.

Project Additional Information

Purposes of the contained use
Provide storage, labelling, secondary packaging and logistical services to clients carrying out Research, Development, Clinical Trials and Manufacturing of Biotechnology and Therapy Solutions, including Cell Gene Therapy.
Storage is performed in temperature conditions ranging approximately between:
Ambient
Cold: +2 to +8 °C Fridge/walk-in fridge
Ultra Cold -20 to -30°C walk-in freezer
- 40 to -80 °C Upright freezer/Robotic freezer
-150 to -200°C vapour phase Liquid Nitrogen
Primary Labelling: Performed on closed sealed vials in ambient temperature (performed in GMP packaging suite or CL2 laboratory), cold and ultra cold (with the use of dry ice trolley or inside cold rooms).
Secondary Packaging: GM may be packaged in singular containers or multi container depending on clients request.
Secondary Labelling: External labels applied upon request of the client.
Logistical Distribution : Shipping of GM material is performed on behalf of the client using UN3245. Staff performing the task are fully trained on related shipping regulations.
Discard: GM may need to be discarded as per client's request. In these occasions material will be autoclaved prior to disposal.
No open laboratory work with GM will be undertaken as part of this contained use notification.

Recipient or parental organism
Non applicable as storage, labelling, secondary packaging and cold chain logistical distribution only.

Host/vector system
Non applicable as storage, labelling, secondary packaging and cold chain logistical distribution only.

Origin & function
Non applicable as storage, labelling, secondary packaging and cold chain logistical distribution only.

Evaluation of foreseeable effects
Non applicable as storage, labelling, secondary packaging and cold chain logistical distribution only.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Non applicable as storage, labelling, secondary packaging and cold chain logistical distribution only.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Non applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Class 2 GMM waste is only generated as per client's request of material disposal, as result of a faulty container or breakage of primary container.
The Class 2 GMM waste is autoclaved at 123,C for 30 minutes, 2 bar pressures, prior to disposal to landfill by a registered waste contractor (Veolia). Spore strips are included in each Class 2 GMM waste load for purposes of validation of destruction. The autoclaved waste is then stored in a sealed whee lie bin with biohazard symbols displayed, for 48 hours, whi le the spore strips are incubated to validate destruction. After 48 hours and a positive destruction result with the spore strips, the inactivated waste is removed by a registered waste contractor to landfill. The autoclave is validated annually. Class 2 sharps containers are autoclaved in accordance with an SOP for Class 2 GMM waste inactivation before being removed by a registered waste contractor for disposal.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
FBS UK bio-repository is equipped with the appropriate safe systems to store and distribute Class 2 GMO safely. These include appropriate waste and spill procedures. No laboratory manipulation will be performed for this material. In order to undertake this contained use work, FBS UK will be required to follow notification requirement as per under The Genetically Modified Organisms (Contained Use) Regulations 2014 - GMO(CU), using CU2 form available on the Health and Safety Executives website.

This proposed contained use work is low risk, as no laboratory work is undertaken. This contained use notification will cover:
1. All Class 2 GMO materials from clients that have already notified their Class 2 GMO activity to the HSE as far not listed on:
   a. the Counter-Terrorism and Security Act 2016
   b. the Specified Animal Pathogen Order 2008

Important notes below:

All GMO microorganisms listed on the Counter-Terrorism and Security Act 2015 will be risk assessed by the Biosafety/GMO Committee. The committee will decide if additional notification will be required on an individual basis.

All GMO microorganisms assigned Activity Class 2 or BSL2 listed on the Specified Animal Pathogen Order 2008 will be risk assessed by the Biosafety/GMO Committee. Additional CU2 notification will be required and SAPO License application will be completed and submitted to the HSE.

All GMO assigned as BSL2 or equivalent (e.g. Risk Group 2) from international non-UK clients, whom do not have a contained use notification with the HSE, will be risk assessed by the Biosafety/GMO Committee. The committee will decide if additional GMO notification will be required on an individual basis.

Any laboratory manipulation of GMO Activity Class 2 will be risk assessed by the Biosafety/GMO Committee. Additional CU2 notification will be required.

Y

**Give brief details of the genetic modification safety committee**

The company currently numbers 26 personnel. The GMO safety committee comprises 3 persons:

1. Cambridge Biostability H&S appointed person.
2. Laboratory scientist (with previous experience of research project management of molecular biology projects and membership of GMO safety committees in 2 previous employments).
3. Laboratory scientist (previous experience in molecular biology).

The committee meets at 6 monthly intervals or as required.

All decisions taken in GMO safety committee meetings are also reported at general Company H&S committee meetings (Company H&S committee comprises 5 members including a senior management representative).

Disposable waste:
All contaminated disposable waste is steam sterilised (on site) using an autoclave. Sterilised waste is then disposed of by incineration (of site) through a contract waste disposal company. The sterilisation (autoclave) process is monitored by use of temperature indicating tape and vials included in each run.

Recycled waste;
Recycled waste e.g. glassware, is chemically disinfected using a proprietary disinfectant with quoted virucidal activity (e.g Trigene ® 2% v/v).

For activities involving GMMs, describe the waste management measures which will apply to the activity

### Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Give brief details of the genetic modification safety committee

- Chairman - (CEO)
- Health and Safety Officer - (Head of R&D)
- Secretary - (Principal Scientist)
- Biological Safety Officer - (Senior Scientist)

Committee formed 11/7/06, and will meet at least on a quarterly basis, with a brief to review all GM risk assessments and procedures.

Laboratory  | Animal Unit  | Growth Room  | Glass House  | Large Scale
---|---|---|---|---
Level 1 (GMMs) | Yes | | | |
Level 2 (GMMs) | | | | |
All liquid cultures will be autoclaved and/or treated with Virkon-S (2% w/v) prior to discarding. Contaminated areas will be treated with wiping with 2% Virkon-S (contact time > 5 minutes). All contaminated materials will be inactivated (100% kill) by autoclaving prior to disposal or recycling. The autoclave will be validated by annual thermocouple mapping and each run monitored by digital recording of the temperature/time profile. All test output will be signed off and stored for reference. A notice describing the status of the validation will be attached to the instrument. Material to be autoclaved will be placed in autoclave bags which are tied and placed in autoclave bins. Prior to autoclave taking place, the bags will be opened to allow steam to penetrate efficiently. The autoclave will be set such that the temperature in the coolest part of the chamber reaches 121°C for 30 minutes. The effectiveness of the sterilisation will be monitored by TTS tape added to each bag, and the temperature profile monitored by the use of a dedicated data printer attached to the autoclave. Once the run is complete, all bags will be identified and sealed with autoclave tape. A record of each autoclave run will be completed, signed off and filed. A Log Book of autoclave usage will require to be filled in and signed off for each run. This will be retained in the laboratory. These steps are laid out in detail in our Standard Operating Procedure ONL1.1 (Disinfection and Sterilisation of GMO material). (See attached document).

Virkon-S at 1% w/v with a contact time of 5 minutes has been shown to be effective (>5 log orders kill) against both E.coli and S. aureus (http://relyon.dupont.com/myRelyOn/activated.htm).

Work areas will be swabbed on a regular basis to check for residual bacterial contamination.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment
The GM Safety Committee reviewed the notification documents, risk assessments and standard operating procedures relevant to the GMO work being proposed, and have formally given approval for the application to proceed.

- **Date Project Ceased**: 11/02/2014
- **Withdrawn**: Y
- **Historical Significant Changes**: Notification withdrawn

#### Project Additional Information

**Purposes of the contained use**
- Production of recombinant protein
- Cleaning returned flow cells that have been used with collaborator samples

**Recipient or parental organism**
- E. coli

**Host/vector system**
- PT7

**Origin & function**
- Growth of recombinant DNA
- Production of plasmid DNA
- Analysis of purified DNA
**Evaluation of foreseeable effects**

- Contained use will limit any pathogenic effects - PPE and mechanical procedures in place
- E. coli cell lines used are incapable of colonising the human gut
- Contained Use (MSC containment hood class 2) will limit any environmental effects

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

- All items used with GMMs will be cleaned with 1% Virkon (1 hour exposure) and autoclaved.
- Disposable items will be cleaned with 1% virkon (1 hour exposure), autoclaved and disposed of in 60L yellow clinical waste bins - our current waste disposal contractor is Grundon Clinical Waste.
- Autoclaves are checked by our external maintenance engineer every 6 months to ensure kill/inactivation temperatures are reached.
- Bowie Dick tests are carried out weekly.

**Project Containment**

- The majority of the work will be Cat 1, however all work will be carried out to Cat 2 standard.
- In the case of returned flow cells, collaborator will advise us of any sample used before receipt so potential Cat 2 samples can be segregated so that staff involved will be fully aware.
- Full staff training and supervision will be carried out by the company Health & Safety Officer and the Biological Safety Officer.

Give brief details of the genetic modification safety committee

Entire organisation has 12 employees in total, so there is frequent, open dialogue particularly between those lab staff performing contained use activities, and their line management. Company director and Medical projects Manager meet on a regular basis to discuss laboratory matters, including risk assessment of contained use activities. Office and laboratory managers are both trained in health and safety issues, and ensure that staff complete risk assessments of contained use activities.

All material that has been in contact with GMM's will be disposed of in house via autoclaving of double bagged clinical waste bags. These bags are taped before disposal in such a way that successful sterilisation can be guaranteed, i.e. by use of autoclave tape and keeping the neck of the bag open for steam penetration. At the end of the autoclave process on site, sterilisation is confirmed by a paper printout of the temperature reached and the duration at this temperature during the autoclave process. These printouts are archived on site.

**For activities involving GMMs, describe the waste management measures which will apply to the activity**

The risks associated with performing the described protocols do not represent a significant hazard to those members of staff involved. The Breener scheme results in a calculation of 10 (-18) clearly placing this at containment level 1 activity.

All bacteria used are K12 derived and as such are incapable of surviving outside containment if this was breached by accident. None of the vectors used produce substances of any hazard, the vectors themselves are based on vectors considered non-hazardous by the ACGM and all methods are standard laboratory techniques.

Good laboratory practice should still be used at all times, and appropriate COSHH and risk assessments performed.

Other(s) Use of a genetically modified cell-line to test for the presence of dioxins in our products.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Contaminated solid waste such as plastic disposables, tissue paper etc. will be collected in autoclave bags. These will be autoclaved at 121 degrees C for 22 minutes. Contaminated liquid wastes will be autoclaved under the same conditions. Any materials that cannot be autoclaved will be treated as medical waste and incinerated. Spillages of contaminated material will be treated with a full spectrum disinfectant (Vircon) and wiped up with tissue. Wipes will be autoclaved as above. The autoclave will be validated and serviced annually. Indicator disks will be used with every operation to show that appropriate conditions have been achieved. The expected level of kill for these treatments is 100 percent.

Tick to confirm that you are attaching a summary of the risk assessment Y

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The risk assessment of the organism shows that it is a class 1. Staff will be appropriately trained, follow approved procedures and use specified personal protective equipment and containment measures. Inactivation methods will give an expected 100 percent kill of the organism. The genetic modification safety committee considers that risks to humans and the environment from the use of this organism at our premises will be negligible.

Y

Give brief details of the genetic modification safety committee

St George's University of London's Genetic Modification Safety Committee (GMSC) and Biological Safety Officer for Genetic Modification (BSO-GM) provide risk assessment review and approval in an advisory capacity to St George’s NHS in accordance with regulation 8 of the Genetically Modified Organisms (Contained Use) Regulations 2014. The GMSC has representation from biological and lab safety, health and safety, microbiology/virology, infection control, clinical infectious disease and cellular biology.

No class 1 activity at this time. First use will be at Class 2.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

The St George's GMSC were all asked to review the risk assessment on the 18/07/06. This was completed by 30/08/06; there were no outstanding issues of concern from the GMSC.

Project Ref 963/06.1

A Phase 2, Randomized, Double-blind, Placebo-controlled, Multicentre, Dose-Selection Study of AD/2 Hypoxia Inducible Factor (HIF)-1alpha/VP16 in Patients with Intermittent Claudication. Protocol No: PADHIF00704.

Class 2

< 1 Litre

Consent Granted

Not Applicable

Project notified under transitional arrangements N
Project Additional Information

**Purposes of the contained use**

For 300 patients (up to 10 patients at St George's) with intermittent claudication, where they can only walk between 1 and 10 minutes before having to stop with severe leg pain. This phase 2 clinical study will examine the safety and efficacy of an experimental gene transfer agent (via a single treatment of 40 injections). And its ability to stimulate the growth of new blood vessels from existing blood vessels (angiogenesis) in an attempt to improve the blood flow in the patients' legs. To evaluate if patients have improvement in their walking ability, 6 months after receiving the study drug standardised walking treadmill tests will be performed.

Potential patients after signing informed consent and having thorough screening will be randomised to receive either 1 of 3 doses of Ad2/HIF-1a/VP16 or placebo in a 1:1:1:1 ratio. The study treatment for each patient will consist of a single dose administered intramuscularly to both legs in the Vaccine Institute at St George’s Trust a level 2 biosafety area. The drug will be stored in the locked –70C freezer in the restricted area of the Vaccine Institute S2 facility. Trial drug will be drawn up under antiseptic conditions in a BL2 biosafety cabinet in the Vaccine Institute at St George’s NHS Healthcare Trust. The syringes with prepared drug will then be placed in a closed metal container and taken to an adjacent room within the S2 facility for the patient injections. The patient will be treated with study drug in the S2 facility and will rest for at least an hour post injections to minimise any risk factors. All waste products from the preparation and treatment doses of the study drug will be contained, packaged under biohazard conditions prior to autoclaving and/or incinerating. As per risk assessment.

Recipient or parental organism

The HIF-1 sequence (1-390) amino acids within the Ad2/HIF-1 a/VP16 vector were derived from the full length HIF-1 a sequence (aa1-826) generated by polymerase chain reaction (PCR) from a HeLa cell cDNA library (available commercially from Clontech). The correct sequence was verified by DNA sequencing performed by the sponsor Genzyme Corporation.

The patient will receive the gene therapy agent as intramuscular injections to the legs. In theory growth of new blood vessels in unintended areas may occur. However the patients will be screened rigourously as per protocol. The gene is attached to an adenovirus; this may survive in the environment in the event of accidental release. However the Ad2 vector used in this study is replication deficient, so it is unlikely.

Host/vector system

Ad2/HIF-1 a/VP16 is a replication-deficient Type 2 Adenovirus (Ad2) used to express the Ad2/HIF-1 a/VP16 gene. The Ad2 DNA, used to derive the AD2/hif-1a/vp16final product, was obtained from American Type Culture Collection (ATCC). All recombinant DNA cloning and virus construction steps were completed at Genzyme Corporation (USA). The upstream manufacture of Ad2/HIF-1 a/VP16 involves cell culture. Adenovirus infection, harvest and upstream processing. The downstream
purification of Ad2/HIF-1 a/VP16 consists of several chromatography steps. After sterile filtration, the formulated bulk undergoes final dilution and is filled into glass tubing vials (3ml solution in 5ml vials). Although the wild type adenovirus type 2 naturally can infect and replicated in the respiratory tract, eye, gastrointestinal tract and bladder, the Ad2 viral vector used to express the HIF-1 a/VP16 gene is replication deficient. Therefore there is minimal risk to an individual if exposed.

## Origin & function

### Source of the HIF-1a gene.

The HIF-1 sequence (1-390) contained within the Ad2/HIF-1 a/VP16 vector was derived from the full length HIF-1 a sequence (aa1-826) generated by polymerase chain reaction (PCR) from a HeLa cell cDNA library (available commercially from Clontech). The correct sequence was verified by DNA sequencing performed by the sponsor. The study requires 300 patients (a maximum of 10 patients at St George’s Healthcare NHS Trust) male or female between the ages of 40-80 years of age who have a diagnosis of peripheral arterial disease in both lower limbs. Symptoms of severe intermittent claudication which manifests as a pain, cramping, discomfort or fatigue in various muscle groups. The patient must have had these for at least 6 months. All patients will as part of the protocol is only able to walk for no longer than 10 minutes using a standardised exercise treadmill test. Only once the patient has given informed consent and has had a vigorous cancer screening, will the patient be randomised to one of three treatment doses or placebo.

## Evaluation of foreseeable effects

### Direct Therapeutic Effect: Angiogenesis and Therapeutic Angiogenesis

Angiogenesis, the formation of new blood vessels from existing blood vessels, is a complex physiologic process involving numerous mediators including the angiogenic growth factors.

The term “therapeutic angiogenesis” has been used to describe a strategy employing gene transfer or protein formulations of angiogenic growth factors, which stimulate or augment new blood vessel development, to target vascular inefficiency. Gene transfer, when administered into ischaemic tissue, permits targeted delivery of the therapeutic transgene, and maintenance of a concentration of the angiogenic protein in that region for days to weeks following a single administration. The patients will have repeat standardised treadmill tests to assess their ability to walk further. Also repeat standardised quality of life questionnaires, to assess if their quality of life has changed since their treatment dose.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

#### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

The syringes and vials containing the inoculated material will be placed in a sharps container, with 10% sodium hyperchlorite and then placed in a Denley container to be transported via trolley to be autoclaved via the SAL autoclave in an adjacent building within the hospital site, (1st floor Jenner Wing). After autoclaving, a completed form from the medical microbiology dept will be issued to verify destruction of the material.

Any used bed-linen will be cleaned using routine hospital procedures. However if there is any blood/faecal contamination then a high temperature wash will be used. The linen being placed in red bags, the contents will not then be handled again as the bags are placed directly into the laundry machines. According to the Draft copy of Guidance on the use of genetically modified micro-organisms in a clinical setting.

#### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Used vials and other miscellaneous materials (mat, gloves, syringes) used in the preparation of the test material will be placed in a plastic bag which is then sealed. The sealed plastic bag will be removed from the biosafety cabinet, and placed into a biohazard waste container. The contents will be autoclaved and incinerated. After each intramuscular injection any refluxed fluid must be wiped clean with sterile gauze, which will immediately be placed in biohazard bags for autoclavin and
incineration.
The used treatment syringes will be placed directly in a container with 10% sodium hypochlorite, autoclaved and disposed of in biohazard bags.
All waste from the trial patient after treatment will be treated as potentially infected. The biosafety workspace should be cleaned with 10% sodium hypochloride (bleach) solution, followed by a rinse with water and ethanol.

The autoclave is located in an adjacent building within the hospital site, (1st floor Jenner Wing ext 5738) and is a SAL autoclave. This has daily Bowie Dick checks, weekly extensive checks by hospital engineers and quarterly servicing and checks by the autoclave installers. The department of Medical Microbiology where the autoclaving occurs will also complete a confirmation form of the destruction of any waste products for research records.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N

Give brief details of the genetic modification safety committee

A Genetic Modification Safety Committee (GMSC) has been established and is based at 21 Ellen's Glen Road, Edinburgh. The committee comprises six members of staff from various representative functions and scientific expertise as well as staff side representation. Meetings are currently held on a monthly basis.

For activities involving GMMs, describe the waste management measures which will apply to the activity

a) Inactivation of liquids containing the biological agent to an appropriate disinfectant at a known concentration.
b) Disposable items of equipment/materials will be heat treated.
c) As clinical waste in a yellow bag, properly labelled and identified, to incinerator or other appropriate end process.
d) Additionally, process waste is disposed if by flushing to drain using excessive amounts of water. The drainage system of the facility is directly linked to a 100,000 US gallon (378,00 litres) reservoir before being directed to the environmental drainage system.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The GMSC have reviewed the Risk Assessment and agree that the GMO activities performed at either of Albs Bioscience's premises at both 21 Ellen's Road, Edinburgh and Pentlands Science Park, Bush Loan, Penicuik and find that the overall risk factor is low for the following reasons:
1) No genetic modification is performed within either of the premises.
2) The gene product is deemed to be non-toxic and synthesised as a fusion product and is unlikely to be hazardous.
3) The gene product will be stored, grown and expanded using standard monoclonal procedures and equipment for use in the manufacture of in vitro diagnostic reagent only (21 Ellen's Glen Road site only).

Other(s)

Cell culture expansion from small scale to large scale fermentation.

Y

**Give brief details of the genetic modification safety committee**

Our GMSC is comprised of: - a) A management representative; b) chairman/BSO; c) A senior employee representative and d) An employee representative.

When we relocate to our new premises we intend to meet once per month to specifically discuss any new projects or amendments to our current risk assessments (as appropriate). There will also be a more general discussion concerning laboratory safety matters with an emphasis on the GMO work.

Solid waste such as plastics, agar, contaminated paper etc. and liquid volumes below 50 mls are placed into open-necked autoclave bags (double thickness) and sterilised at 126°C for 20 minutes. As a means of validation a Brown "Black-dot" glass sterilisation indicator is taped to the inside of the autoclave bag (in addition to the quickly visualised autoclave tape which is taped to the outside of the bag) these two indicators are routinely checked after each autoclave run. The autoclave has its physical parameters (pressure, temperature and chamber integrity) checked 2x per year by external qualified technicians.

Solution volumes above 50 mls (bacterial culture supernatants) are disinfected chemically with commercially available "Persept" or "Klorsept" chlorine releasing tablets. Our internal validation experiments have determined that a final available chlorine concentration of 1000ppm (freshly made) for at least 3 hrs is entirely adequate. This level produces 1 100% kill rate with our supernatants.

To deduce this ppm level a ppm titration was used on bacterial supernatants, for specified periods of time, followed by spreading the disinfected solution onto agar plates with no antibiotic added; No colonies grew after an overnight incubation at 37°C.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

The Cytocell GMSC has carefully considered all the risk assessments and is content that they correctly assign the procedures to containment level 1 / activity class 1.

To use reverse genetics to create attenuated influenza virus. We will use an attenuated virus strain such as PR8 as the background strain and replace the neuraminidase and Haemagglutinin with those from current influenza A and B strains. Mutations…….

### Project Additional Information

**Purposes of the contained use**

To produce an attenuated influenza virus that could be used as a live attenuated vaccine against current strains of influenza virus. Current influenza virus vaccines are only about 70% effective, live attenuated virus vaccines like those we are trying to develop may be more effective.

**Recipient or parental organism**

The extensively studies PR8 strain of the influenza virus will be used as the recipient Influenza strain. The PR8 strain of influenza virus is highly attenuated and does not cause disease in humans. Influenza viruses are classified as ACDP category 2 pathogens.

**Host/vector system**

Plasmids containing the cloned genes of Influenza virus strain. PR8 are being generously donated to us by Professor Brownll (Sir William Dunn School of Pathology, University of Oxford). The plasmids are PPOLY-PB1-PR8, PPOLI-PA-PR8, PPOLI-PA-PR8, PPOLI-PR8, PPOLI-M-PR8, PPOLI-NS, PR8, PPOLI-Sapl-Rib, pcDNA-PBI-PR8, pcDNA-PB2-PR8, pcDNA-PA-PR8, pcDNA-NP-PR8. These plasmids are all Puc18 derivatives. These will be transfected into either Vero (African Green Monkey) cells or 293t (Human Kidney) cells. Recombinant virus will then be retrieved from these transfected cells (see Fodor E etal. Rescue of influenza A virus from recombinant DNA, J Virol 1999;73:9679-9682).
The introduced genetic material will be the influenza virus neuraminidase and Haemagglutinin genes cloned from recent strains of the influenza virus such as A/New Caledonia/11/99. Mutations will be added to these cloned genes to attenuate the virus. Alterations to the neuraminidase gene have been shown to lead a reduction of virulence (see Solorzano et al. Reduced levels of neuraminidase and Haemagglutinin which will come from recent strain of the influenza virus. The introduced gene products will be expressed on the surface of the recombinant influenza virus and are intended to act as antigens to provoke a protective immune response to any later challenge by the wild type influenza virus.

Evaluation of foreseeable effects

The influenza virus normally causes an upper respiratory infection in humans, however, the attenuated PR8 strain is non-pathogenic in humans. The mutations we add to the influenza virus genome are intended to be stable and to attenuate the virus. The haemagglutinin and the neuraminidase proteins have been shown to be non-toxic to humans and have been used extensively in vaccines. Vaccine are available to protect against Influenza virus infection and there are antiflu drugs such as Tamiflu and Relenza.

Influenza viruses pose limited environmental risk as they are degraded quickly in the environment (UV, dessication) the genetic modifications we perform will not change this.

Work with the mutated influenza virus being conducted in Microflow Biological Safety Cabinets in category 2 GLP laboratory.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No application for derogation.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste produced containing recombinant influenza virus will be treated with Basol, a quaternary ammonia compound based detergent. This detergent is known to very rapidly destroy lipid encapsulated viruses such as influenza. To ensure a one hundred percent kill the waste containing the recombinant virus will be left in the basol for 24 hours. The waste will then be disposed of down the sink. This is a standard technique for disposing of Influenza waste.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Both the parent virus and the neuraminidase and haemagglutinin proteins from recent strains have a history of safe use in humans.

To use reverse genetics to create attenuated influenza virus.

Purposes of the contained use

To produce an attenuated influenza virus that could be used as a live attenuated vaccine against current strains of influenza virus. Current influenza virus vaccines are only about 70% effective, live attenuated virus vaccines like those we are trying to develop may be more effective.

Recipient or parental organism

The extensively studied PR8 strain of the influenza virus will be used as the recipient Influenza strain. The PR8 strain of Influenza virus is highly attenuated and does not cause disease in humans. Influenza viruses are classified as ACDP category 2 pathogens.

Host/vector system

Plasmids containing the cloned genes of Influenza virus strain, PR8 are being generously donated to us by Professor B (Sir William Dunn School of Pathology, University of Oxford). The plasmids are PPOLY-PB1-PR8, PPOLI-PA-PR8, PPOLI-HA-PR8, PPOLI-NP-PR8, PPOLI-NA-PR8, PPOLI-M, PR8, PPOLI-NS, PR8, PPOLI-Sap1-Rib, pcDNA-PB1-PR8, pcDNA-PB2-PR8, pcDNA-PA-PR8, pcDNA-NP-PR8. These plasmids are all Puc18 derivatives. These will be transfected into either Vero (african Green Monkey) cells or 293 (Human Kidney) cells. Recombinant DNA, J. Virol 1999;7.3:9679-9682).
The introduced genetic material will be the influenza virus neuraminidase and Haemagglutinin genes cloned from the recent strain of the influenza virus, A/California/7/2009(H1N1)sw1. Mutations will be added to these cloned genes to attenuate the virus. Alterations to the neuraminidase gene have been shown to lead a reduction of virulence (see Solorzano et al. Reduced levels of neuraminidase of Influenza A viruses correlate with attenuated phenotypes in mice. J. Gen Virol 2000: 81 Pt3:737-742). The recombinant virus will thus contain all the PR8 gene segments except those encoding the neuraminidase and HAEmagglutinin which will come from a recent strain of the influenza virus. The introduced gene products will be expressed on the surface of the recombinant influenza virus and are intended to act as antigens to provoke a protective immune response to any later challenge by the wild type influenza virus.

Origin & function

The influenza virus normally causes an upper respiratory infection in humans, however, the attenuated PR8 strain is non-pathogenic. The mutations we add to the influenza virus genome are intended to be stable and to attenuate the virus. Project Containment
Project Additional Information

Purposes of the contained use

Four Genetically Modified (GM) viruses will be used in the assay. They were produced by reverse genetics using established techniques (Neumann et al., 1999) to create and attenuated influenza virus consisting of the HA and NA gene segments from recent strains and the six internal gene segments from a cold adapted Master Donor Virus (MDV). This MDV has previously been used to generate commercially available influenza vaccines, this is described in more detail in Section 7.

The assay itself will consist of the mixing of serial dilutions of human sera with the GM virus across a 96 wells-microplate coated with the fetuin substrate. After a suitable incubation period, the enzymatic reaction will be read colorimetrically.

This assay has been very well described and is widely used to measure NA protein activity (Aymard et al., 2003).

Stocks of the GM viruses will be received at RVL ready for use and there will be no further propagation of the virus onsite.
Influenza viruses are classified as ACDP category 2 pathogens. The GM influenza viruses we will use are highly attenuated, cold adapted vaccine strains. The methodology used to generate the GM virus for use in these assays is the same as used to produce Live Attenuated Influenza Vaccine (LAIV) that is currently licensed and marketed in the USA and has recently received approval for use within the EU. Over 40 million doses of vaccine have been manufactured.

The level of attenuation of the GMO virus for use in the assay will be similar to that for the LAIV.

Host/vector system

In the assays RVL will use four different GM viruses representing different subtypes of influenza and different NA proteins. These four viruses are summarised in Table 1. The six internal gene segments of the MDVs impart the cold adapted (ca), temperature-sensitive (ts) and attenuation (att) phenotype to the vaccine strains.

Reassortant viruses such as these, carrying the six internal genes of MDV-A or MDV-B and the wild type HA and NA segments of another virus, consistently maintain three key characteristics:

1) They are cold adapted and replication is limited to the upper respiratory tract.

2) They do not replicate in the lungs of ferrets,

3) They are safe and attenuated in children and adults

(Massab et al., 1982; Monto et al., 1982; Odagiri et al., 1982; Wright et al., 1982)

</tbody>
</table>

Abbreviations PB2, PB1 and PA are the three polymerase subunits, PB for polymerase basic

HA Hemagglutinin, NA neuraminidase, NP nucleoprotein

Origin & function

Origins

A/Ann Arbor/6/60 (MDV-A) and B/Ann Arbor/1/66 strain (MDV-B)

The MDV viruses were generated by cold adaptation of an influenza type A strain (A/Ann Arbor/6/60 H2N2) and a type B strain (B/Ann Arbor/1/66) by serial passage at sequentially lower temperatures in specific pathogen-free primary chick kidney cells (Jin et al., 2003).
Influenza type A GMO viruses (Table 1)

These viruses contain 6 internal genes from the MDV-A, the HA segment of A/teal/HK/W312/97 (H6N1). The Neuraminidase (NA) genes are cloned from the influenza virus A/South Dakota/6/06 (H1N1) for the first GMO and from A/Uruguay/716/07 (H3N2) for the second.

Influenza type B GMO viruses (Table 1)

These viruses contain 7 genes from the MDV-B. The Neuraminidase (NA) genes are cloned from the influenza virus B/Florida/4/06 for the first GMO and from B/Malaysia/2506/04 for the second.

A/South Dakota/06/06 (H1N1), A/Uruguay/716/07 (H3N2), B/Florida/4/06

These are vaccines strains contained in the vaccine formulation.

B/Malaysia/2506/04

This strain is used in this project to check the cross protection of the vaccine against another type B neuraminidase.

A/teal/HK/W312/97 (H6N1)

In this project the HA of the virus (subtype H6) is used to avoid non-specific neutralisation of the NA by the antibody directed against the H1 and H3 contained in sera after vaccination.

Intended function.

The intended function of the GMO described here is to provide the NA protein, which acts enzymatically on the fetuin substrate in the assay. The assay is then used to titrate anti NA antibodies in sera from people pre and post vaccination.

Evaluation of foreseeable effects

Influenza virus normally causes an acute self-limiting upper respiratory infection in healthy humans with no underlying health conditions.

The GM viruses intended to be used in the assays are attenuated strains with limited ability to replicate in human upper respiratory tract. In general cold adapted vaccine strains, as the ones that will be used in this study, are highly restricted in there replicative ability and virus is rarely recovered by culture from the nasal wash after inoculation for volunteers (Belshe et al., 2008; Talaat et al., 2011)

The viruses have been sequenced and do not possess any known mutations that would give rise to drug resistance to the anti-neuraminidase compounds.

Influenza viruses pose limited environmental risk as they are degraded quickly in the environment due to UV radiation and desiccation.

All work with the live GM influenza viruses will be conducted in Microflow Biological Safety Cabinets in category 2 GLP laboratory.

Please see risk assessment attached to this application for more details

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No application for derogation

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste produced containing GM influenza virus will be treated with 5% (v/v) Biocleanse (final concentration), a quaternary ammonia compound based detergent. This detergent is known to very rapidly destroy lipid encapsulated viruses such as influenza. The GM virus will be left fully immersed in the 5% (v/v) Biocleanse ™ (final concentration) for 24 hours. The liquid waste will then be autoclaved and the final liquid will be disposed of via normal drainage.

Solid wastes such as 96 well microplate, pipettes tip, empty vials, etc will be treated first with biocleanse solution as mentioned above. After 24 hours being fully immersed, solid waste will be autoclave on site and then treated as clinical waste i.e. incinerated

Is an emergency plan required according to regulation 20? N

Please enter comments on the GM safety committee on the risk assessment
The RVL GMO Committee met on 12th May 2011, chaired by Prof J O, and reviewed the use of the proposed GM influenza viruses at the Company’s facility.

The following key points were considered:

**VIRUS PROVIDENCE:**
Both the MDVs, and the NA and HA proteins, are from characterised strains. The MDVs have a history of safe use in humans.

**GMO VIRUS BACKGROUND:**
These recombinant viruses are generated from cold adapted virus back-bone. For all recombinant virus evaluated here, both NA and HA segments are from well described strains and have been completely sequenced. The parental MDVs are well characterised and not known to be resistant to zanamivir and oseltamivir.

**CONDUCT OF THE ASSAY**
During the assay the 96 well plates will be washed repeatedly with PBS-Tween. Tween is a detergent and will inactivate the influenza virus.

**HANDLING OF H6 RECOMBINANT VIRUS at RVL:** There is no poultry farm in the vicinity of the RVL facility, H6 viruses tend to be of low pathogenicity.

Type B viruses are generally accepted to be less pathogenic than type A viruses and are not known to have pandemic potential.

Retroscreen’s GM committee did not believe that there was a risk associated from working with different GMO strains concurrently as there will be no culture of virus ongoing in the laboratory during the conduct of this assay and no cell culture will be conducted in the incubator dedicated to this project. All equipment will be very clearly labelled to state its dedicated use.

All virus samples will be used only within a safety cabinet. Plates will be removed from the cabinet once washed with PBS-Tween to inactivate the virus.

The committee considered the following aspect of health monitoring.

Health Monitoring (Tick relevant boxes)

<table>
<thead>
<tr>
<th>Yes</th>
<th>No</th>
</tr>
</thead>
<tbody>
<tr>
<td>Is an effective vaccine/prophylaxis available?</td>
<td>v *</td>
</tr>
<tr>
<td>Are staff encouraged to be vaccinated?</td>
<td>v **</td>
</tr>
</tbody>
</table>

* If required, Oseltamivir can be used prophylactically
** Vaccination of staff is encouraged, this will protect against current seasonal strains of influenza

Conclusion of the RVL GMO committee
The committee concluded that the H6N1, H6N2 and B GMO viruses could be used within the RVL labs

### Project Additional Information

**Purposes of the contained use**

Seasonal influenza strains produced by reverse genetics using established techniques (Neuman et al, 1999) will be:
1. used as challenge agents in human volunteer studies
2. investigated in standard laboratory assays.

The human volunteer studies will be used to improve understanding of influenza infection, illness and host response, in addition studies may be conducted to evaluate novel IMPs (all clinical studies subject to ethics approval).

Stocks of the GM virus will be received at hVIVO ready for use. There will be no further modification of the virus on hVIVO’s premises.

**Recipient or parental organism**

Not applicable (work to be outsourced).

**Host/vector system**

An eight plasmid system will be prepared each containing the influenza genes and transfected into a qualified cell line and recombinant virus rescued (Hoffmann E, et al., Eight-plasmid system for rapid generation of influenza virus vaccines. Vaccine 20(25-26):3165-70 2002; Hoffmann E and Webster RG, Unidirectional RNA polymerase
I-polymerase II transcription system for the generation of influenza A virus from eight plasmids” J Gen Virol. 81(12):2843-7 2000. This work will be outsourced and not take place at the applicant's premises.

Origin & function

The influenza strains from which the plasmids will be derived will be seasonal influenza strains, classified as ACDP Hazard Group 2, that naturally circulate in the human population. The seasonal influenza strains selected will be well characterised and cause mild to moderate influenza like illness. The full nucleotide sequences will be obtained from Genbank. The recombinant virus seed stocks will contain the same gene sequences as the original wildtype viruses and will be used to produce challenge virus stocks under Good Manufacturing Practice (GMP) conditions at an outsourced facility.

The recombinant virus seed stock and/or the manufactured virus will be used in laboratory assays (e.g. virus titre determinations; haemagglunination inhibition assays).

The recombinant manufactured virus may be investigated in animal models (e.g. ferret studies) to assess virus replication, clinical symptoms, pathology and biomarkers.

The recombinant GMP manufactured virus will be used in human challenge studies.

Evaluation of foreseeable effects

Influenza viruses generally cause upper respiratory tract infections in humans. Symptoms are usually resolved after 4-5 days but complete recovery can take up to 10 days or longer. The GMM will be representative of clinical isolates that naturally circulate in the human population globally. The influenza viruses to be produced by reverse genetics are classified as ACDP category 2 pathogens. The sequences will be based on recent circulating seasonal influenza strains which have been extensively studied. The use of reverse genetics for the production of influenza virus rather than the propagation of a clinical isolate will enable far greater control of the virus sequence (influenza viruses exist as a heterogeneous population of quasi-species) and hence the properties of the virus stock.

One strain of virus that may be produced by reverse genetics is H1N1. A GMM H1N1 influenza strain has previously been shown to cause mild to moderate influenza disease with no severe complications in human challenge studies (Memoli et al., Validation of the wild-type influenza A human challenge model H1N1pdmMIST: an A(H1N1)pdm09 dose-finding investigational new drug study. Clin Infect Dis. 60(5):693-702 2015).

There are no additional hazards associated with the GMM compared to that of the parental wild-type strain from which it was derived; the pathogenic traits of the GMM virus will not be increased by reverse genetics; the severity of infection is expected to be the same as for the parental wild-type. The GMM will be screened to ensure the virus sequence is consistent with the parental sequence and no known virulence associated mutations present. In addition the GMM will be checked to confirm that no mutations associated with drug resistance to neuraminidase inhibitors are present. Susceptibility testing to one or more classes of approved anti-influenza drugs may be conducted if necessary. The GMM will be no more hazardous than the parental seasonal circulating influenza strain from which it was derived.

There are two aspects to the work outlined in this application: The first involves laboratory work involving the GMM; the second is the use of the GMM in human challenge studies.

The standard procedures used for handling influenza ACDP category 2 pathogens will also be appropriate for handling the GMM. Laboratory work will take place in containment level 2 laboratories; these have restricted access and hand wash basins. Only trained personal will work with the GMM; training records will be retained. All laboratory work with the GMM will be performed in Biological Safety Cabinets (BSC) to contain aerosols. All workers will wear appropriate PPE in accordance with category 2 laboratories. Centrifugation will take place using sealed rotors.

Work on different viruses will not be performed in the same cabinet or work space to negate cross contamination. All equipment used for GMM work will be designated for work involving the particular GMM only and will be cleaned thoroughly before the equipment is used with other work. A fresh solution of an appropriate quaternary ammonia compound based detergent (5% (v/v) Biocleanse (final concentration) and 70%(v/v) Industrial methylated spirits(IMS) will be used for cleaning BSCs, benches, centrifuges and other surfaces at the end of each working session and dealing with spillages. Sealed centrifuge buckets and small items of equipment will be swabbed prior to removal from cabinets. A period of at least 30 minutes will be allowed before work with a different influenza virus commences. Once work is completed for the day, the Ultra Violet
The second aspect is the use of the GMM in human challenge studies. The hazards associated with the GMM is seen as representing an equivalent risk to those challenge studies conducted using wild-type influenza virus strains of the same ACDP Hazard Group 2. All human challenge studies will be carried out under 'contained use' conditions. Human challenge studies will be conducted within hVIVO’s specialised quarantine facility (Virus Challenge Unit, VCU). The VCU has restricted access with a mechanical air handling system and hand wash facilities. Only trained personal work within the VCU; training records will be retained. Infection control measures are in place to prevent secondary transmission and transfer of virus to outside of the VCU. As per hVIVO’s documented procedures, VCU staff will wear PPE (scrubs, apron, full face respirator or mask with eye protection and gloves). All VCU staff will change from outer clothes into PPE before entering the VCU, including a change in footwear or the use of shoe covers; and will disrobe prior to departure within the VCU’s changing area before exit; showers are available in the changing area.

Human volunteers participating in challenge studies will reside within the VCU. The GMM inoculum dose will be based on the minimum titre required to achieve infection with adequate virus shedding and symptomology. The minimal volume of GMM will be taken into the secure VCU for volunteer challenge. As such, it is expected that the GMM titres handled within the VCU to be low and the volume of virus used small (<50 mL at any one time) thereby minimising the risk of potential contamination. Volunteers are inoculated intranasally via a pipettor using a filter pipette tip to minimise the risk of aerosols.

Post volunteer inoculation, the GMM virus is expected to replicate and the new progeny virus will be representative of the season influenza parental virus from which the GMM was derived. All volunteer samples obtained post virus challenge, which may contain infectious virus (e.g. nasal washes), will be treated as clinical samples and will be handled under the parental virus ACDP category.

Volunteers will remain in the VCU for the duration of the clinical study, usually a minimum of 7 days post-inoculation (to cover the virus replication and clearance stages of influenza infection) and discharged on Day 8 or later. All volunteers must have a negative result for influenza by a rapid viral antigen test conducted on the day of discharge (or earlier) to confirm they are no longer shedding virus. Any volunteers who remain symptomatic will only be discharged from the VCU at the discretion of the study Principal Investigator. Prior to exiting the volunteers will be instructed to disinfect their rooms and personal effects with disinfectant wipes. They will then shower and change into clean clothes for departure. The clothes worn by the volunteer within the VCU are double bagged using an inner water soluble laundry bag and outer protective bag. Volunteers are instructed to wash all worn garments and are provided with disinfectant wipes and hand sanitizers to maintain infection control on departure. In accordance with the Clinical Protocol, volunteers are asked to refrain from interaction with vulnerable individuals for a fixed period post-discharge.

Floors in the VCU are steam-cleaned twice each day and following viral inoculation of volunteers. There will be at least a 24 hour period between discharge and admission of another volunteer cohort. At the end of a study the VCU is decontaminated using disinfectant (Dettol or 1% Virkon). Mops and non-disposable cloths are disinfected overnight in a mild hypochlorite (bleach) solution prior to use (2% or one part bleach to four parts warm water).

During an emergency reasonable effort is made to adhere to existing infection control measures. If external teams require access to the VCU, they will be fully briefed regarding risks and appropriate infection control measures prior to entering. Procedures are in place in the event of an emergency evacuation from the VCU during a quarantine study or in the event a volunteer requires hospitalisation. During an evacuation of the VCU, volunteers will be provided with PPE (face mask, gloves). Where possible, staff will be supplied with portable hand sanitisers for themselves and volunteers.

As a result of these precautions, release of the GMM once the volunteer has left the VCU is considered negligible. It should be acknowledged that any virus shed by an infected individual could be considered analogous to a clinical isolate and therefore pose no increased risk over those posed by seasonally circulating influenza strains.

All external transportation will be performed using approved couriers. The GMM virus will be shipped on dry ice and temperature monitored with chain of custody documentation. Large quantities of GMP virus will be shipped in accordance with Good Distribution Practice (GDP). The bulk of the GMP GMM challenge virus stocks will be retained at off-site facilities in accordance with the requirements for a ACDP category 2 pathogen and a GMM. Limited GMM stocks will be retained at hVIVO’s GMO licensed premises in secure, locked -80 oC freezers in areas with restricted access. All freezers are continually temperature monitored and linked to an alarm system. In the event of a temperature deviation that would affect the integrity of the GMM, the GMM will be transferred to another similarly secure and monitored freezer.
records will be held indicating the storage location of the GMM in accordance with hVIVO's documented procedures. These records are updated following removal of GMM stocks from the freezer enabling full traceability.

hVIVO staff are offered the annual influenza vaccination. Vaccination is not viewed as a primary control measure but as a supplementary precaution. hVIVO's infection control policy recommends staff to monitor their own health and when respiratory or influenza-like illness is recognised are advised not come into the workplace, thus minimising transmission of influenza by staff and reducing the possible risk of co-infection for those staff working with different influenza strains and possible reassortment. It is an employer’s responsibility to ensure that a worker’s health or immune status is sufficient for the activity in question. A system for the monitoring of health and immune status should therefore be implemented where the nature of the work demands it. Periodic monitoring of immune status may be required.

The GMM will be transmissible by an airborne route. The most likely routes for the release of the virus into the environment are via aerosol dissemination and contaminated waste. The survivability and stability of the GMM can be assumed to be comparable to wild-type. Influenza viruses are enveloped RNA viruses; the envelope (lipid membrane) is sensitive to desiccation, heat, UV exposure and detergents. The virus degrades quickly in the environment. The GMMs detailed here will not have been modified in any way to change this.

In common with some wild-type strains, the GMM may have the ability to infect humans and other animals (e.g. ferrets, pigs and birds). The infectivity and host-range of the GMM can be assumed to be the same as the parental wild-type. The effects of accidental exposure could result in influenza illness in humans and animals. The severity of illness with the GMM can be assumed to be the same as the parental wild-type strain. Some humans will have previously been infected with influenza and may have developed protecting antibodies. There is some evidence of cross-protection between influenza viruses of the same subtype. In general, immunity to a specific strain is thought to be life-long. In addition, some humans will have received annual vaccination against circulating influenza strains which may offer a level of protection against the GMM. Exchange of genetic material is possible between the GMM and wild-type strains in the environment. The exchange of genetic material is extremely unlikely as this would require co-infection of the GMM with another influenza virus in the same host. As detailed above, adequate control measures are in place for both the handling of the GMM in the laboratory and within the VCU, and appropriate management of study volunteers to mitigate the risk of GMM release.

Not applicable.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Request derogation for virus challenge in the VCU which do not operate under containment level 2.

Human challenge studies will be conducted in hVIVO's purpose built access controlled VCU. All staff will be appropriately attired in PPE. Infection control measures will be in place to prevent secondary transmission and transfer of virus to outside of the VCU. Surface decontamination is used to clean the VCU.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Disposable, heat resistant plasticware and heat resistant glassware (borosilicate) will be used for the handling of GMMs in the laboratory.

A quaternary ammonium compound (Biocleanse, 5% v/v final concentration) will be used for GMM inactivation. This detergent is known to very rapidly destroy lipid encapsulated viruses such as influenza. Flasks/bottles/tubes containing GMM virus will be filled with the quaternary ammonium compound (5%(v/v) final concentration) within a BSC and sealed overnight (10 hours). All liquids, solid waste and other items that may have been contaminated with the GMM (e.g. pipette tips and gloves) will be discarded into the quaternary ammonium compound (5% (v/v) final concentration) within a BSC and soaked overnight (10 hours). After overnight inactivation, the liquid will be separated from the solid waste by decanting the liquid waste into glass Duran bottles. The solid waste, along with clinical waste and sharps (disinfected in alcohol within Cinbins) from the VCU will be placed in sharps bins and sealed. GMM waste will be stored separately from all other waste. All GMM associated waste and recyclable materials (e.g. glass bottles and waste pots) will be autoclaved for sterilisation. Post autoclaving (and confirmation of a successful autoclave run), liquid waste will be disposed via normal drainage and glassware cleaned. Solid waste will be transferred to clinical waste bags, labelled appropriately, and incinerated. All waste will be handled in accordance with hVIVO’s documented procedures.
Biocleanse (5% v/v), Dettol Antibacterial Surface Wipes, industrial methylated spirit (70% v/v) and/or Virkon will be used to disinfect medical equipment and surfaces. Gowns, scrubs and linen used within the VCU will be contained within soluble laundry bags and placed in Cinbins, sealed and transferred to external laundry facilities.

Please enter comments of the GM safety committee on the risk assessment

The safety committee, after a review of the risk assessment, recommends that all work will be class 1 and that the assessment describes all work using GMM's to be undertaken on the premises.
The purpose of the contained use application is to produce an intermediate compound in a chemical process, which will instead be produced in a biological system, where the finite nature of the chemical industry is removed. It is believed that the constructed strain will have no greater affect on humans and the environment than is seen already in the parental wild type strain.

The parental organism is a Burkholderia strain, and is available for purchase from DSMZ.

The vector system being used are pBBR1 derivative plasmids harbour a mobilization region required to mediate the transfer of the plasmids only when the IncP group transfer functions are supplied in trans from the vector pRK2013. This work was described previously by Antoine et al: Isolation and molecular characterization of a novel broad-host-range plasmid from Bordetella bronchiseptica with sequence similarities to plasmids from Gram-positive organisms Antoine et al. Mol. Microbiol 1992, 6, 1785-1799.

The target gene will be produced synthetically by a third party company.

The affects of the alterations to the parental strain are expected to result in the production of the compound of interest. The projected production levels are low with no more than 1 g/L of the compound being produced.

The engineering steps to be performed on the Burkholderia cepacia strain described above will result in diversion of carbon flux from a well characterized endogenous compound into the compound of interest which is not naturally produced by the strain. Previous deletion of the gene encoding the key enzyme involved in the synthesis of the endogenous compound did not result in any other phenotype changes than the alteration of the compound synthesis. The gene to be inserted in the deletion strain is present in a wide range of organisms from bacteria to single cell eukaryotic organisms, mammals and plants. The natural product of the reaction is a known intermediate in an ubiquitous synthesis pathway and therefore do not represent any hazards or potential risk for increased pathogenicity.
Previous work on the generation of a compound similar to the target compound using the gene of interest in yeast did not result in any detectable toxic effect for the cells and the environment.

Therefore we predict that Burkholderia cepacia pathogenicity will not likely be affected by either the deletion of the endogenous gene or the introduction of the heterologous target gene.

| The main method of inactivation is through sterilisation using an autoclave where the water is heated under pressure to a temperature of 122 oC for 1 hour. This system has previously been validated for the Class I work that is currently performed in the laboratory. Upon receipt of a Class II licence tests will be performed to determine whether the current inactivation method completely kill the Class II organism that will be grown before any genetic modification takes place. Following validation of the inactivation process liquid waste will be disposed of into the local drainage system while a national waste disposal company will remove solid waste. The integrity of the microbiological safety cabinet, in which the organisms will be manipulated, will be maintained through thorough cleaning using a biocide spray, a further bactericidal, fungicidal, virucidal, mycobactericidal, sporocidal spray which also inactivates and breakdown DNA/RNA. Finally surfaces are wiped with 70 % IPA solution. |

Please enter comments on the GM safety committee on the risk assessment
The safety committee wanted a statement inserted into the risk assessment to confirm that Class II work will be performed with laboratory operators wearing Blue lab coats, while Class I work will continue to wear white lab coats.

The committee also requested that the risk assessment clarifies that Class II work is performed in a dedicated safety cabinet, incubator and fermentor separate from all Class I work.

All operators must risk assess the tasks that are required to be performed and should understand that immunocompromised personnel should refrain from performing work which involves Class II organisms. No laboratory work can be performed until the risk assessment has been reviewed and issued.

An additional point that was raised by the Biological Safety Committee, following their review of the risk assessment is that one way in which it can be attempted to show that mobilization has been reduced is to ensure that IncP stays in the donor host (a Class I organism) and is not transferred to Burkholderia cepacia as the presence of IncP would increase the ability to mobilise foreign DNA. To ensure that IncP has been removed from Burkholderia cepacia the committee has requested IncP is tested for removal either by a marker selection test or a PCR test. The absence of IncP should confirm that mobilization to other strains is reduced.

It was agreed by all members of the Biological Safety Committee that the work be assigned to Class II.

- Gene Therapy
For activities involving GMMs, describe the waste management measures which will apply to the activity

- Any samples containing the original cell culture material or its processed products should be disposed of into 1% Virkon. This includes unstopped assay plates, eg "BCA".
- Virkon-treated paper waste etc can be disposed of in the normal waste.
- Dry contaminated items should be autoclaved unlidded, and then disposed of in the yellow bin, from which an approved agent then takes them for incineration. Our autoclave process is not accredited for complete pathogen removal but decreases it substantially so that the waste may be stored before collection.
- Contaminated sharps, broken glass etc should go into the sharps bin.
- Polyacrylamide must not be autoclaved; this is hazardous as acrylamide monomer can be generated. Gels and disposable items contaminated with polyacrylamide which have been used for plasma fractions, whether or not treated with SDS, should be incinerated by an approved agent with an incinerator which works at a temperature suitable for the safe degradation of polycrylamide, eg that at Addenbrookes. Place in the bin provided, when full this is transferred to the yellow skip.
- ELISA plates which have been "stopped" using 2M Sulphuric acid may be considered non-infective. The wall contents are flushed down the sink with plenty of water and the rinsed plates disposed of in normal waste. NB these must not be autoclaved because acid may damage the autoclave.

Tick to confirm that you are attaching a summary of the risk assessment  

Tick if you are claiming exemption from disclosure for sections of the risk assessment  

Please enter comments of the GM safety committee on the risk assessment

The committee has reviewed the proposed work and does not consider the elements of this activity to be of significant risk.

Give brief details of the genetic modification safety committee

The iQur GM Safety Committee comprises:

- The Head of Scientific Operations who is a member of the company Management
- The Health and Safety Coordinator (the company does not have a Biological Safety Officer)
- The Laboratory Manager, to represent the technical staff
- The Immunotherapeutics team leader from iQur (Southampton) (Chair)
- A Senior Research Scientist from 1Qur (Southampton) to represent the Immunotherapeutics team.
- A Research Scientist from 1Qur (Leeds) to represent the Vaccine Research and Development team.

The first meeting of the iQur GMSC was held on 19th December 2006 at which the chairperson was elected. It is anticipated that a meeting will be held annually to review existing risk assessments and containment measures. Additional meetings will be scheduled as and when risk assessments for new activities are submitted. Since the company is small, the GMSC will also take responsibility for ensuring that staff are appropriately trained and that full SOPs are prepared for activities involving GMMs.

Project Ref 969/07.1
The use of recombinant influenza virus to test if immunisation with virus-like particles carrying a haemagglutinin insert, induces specific and protective immunity.

Purposes of the contained use

The GMM in question is an existing recombinant influenza virus, which will be obtained through a Material Transfer Agreement with Reading University. It will be used to test if immunization with non-replicating virus-like particles (VLPs) carrying a protein domain from influenza haemoglobin (HA), induces specific immunity and protects against infection with the recombinant influenza virus.

Recombinant virus will be propagated by culture in Madin Darby canine kidney (MDCK) cells, the TCID50 will be determined and the virus will be concentrated and stored frozen. The virus will be used as follows:

• inactivated virus will be used in in vitro assays e.g. haemagglutination assays and to coat plates for the detection of HA-specific serum antibodies by ELISA.
• Viable virus will be used in in vitro micro-neutralisation assays.
• Viable virus will be used to determine if immunisation with HA-VLPs induces protective immunity against influenza infection.

Recipient or parental organism

The recombinant virus to be used comprises the 6 gene segments that encode for the internal proteins of influenza A/PR/8/34 recombined through reserve genetics with the haemagglutinin (HA) and neuraminidase (NA) genes from A/Panama/2007/99. For the purpose of the following discussion, A/PR/8/34 is regarded as the recipient microorganism and A/Panama/2007/99 as the donor of the insert.

Influenza A/PR/8/34 is a laboratory strain of influenza A, favoured for its high growth in embryonated chicken eggs and in mammalian cells. It is, however, completely attenuated for man and although antigenic, is not infectious. Because of these properties it is the backbone strain of choice for the manufacture of human influenza vaccines. A/PR/8/34 is, however, virulent in some animal models, including mice.

Host/vector system
The PR8 x Panama recombinant virus already exists. All steps requiring plasmids and vectors for the construction of this recombinant virus by reverse genetics have already been undertaken at the University of Reading.

**Origin & function**

The PR8 x Panama recombinant was produced at the University of Reading using reverse genetics. DNA corresponding to the haemagglutinin (HA) and neuraminidase (NA) genes of wild-type (wt) circulating influenza A virus H3N2 A/Panama/2007/99 was recovered by RT-PCR and cloned into appropriate mammalian transcription vectors. Plasmids containing these two genes were then pooled with six other plasmids that carried the remaining internal influenza virus genes (PA, PB1, PB2, NP, M and NS) from strain A/PR/8/34, which is attenuated for infectivity in humans. Each of these eight plasmids contained the relevant influenza gene in a negative sense between an RNA polymerase I promoter and RNA polymerase I terminator sequence, yielding eight vRNA-like negative sense RNA segments in the transfected cell. All eight RNA and pol I plasmids were co-transfected with an additional four expression plasmids, each containing one of the influenza genes PA, PB2 and NP from strain A/PR/8/34 in a positive sense under the control of RNA polymerase II promoters. These four genes encode the proteins that form the viral ribonucleoprotein complex of influenza viruses and are minimally sufficient to promote transcription, replication and packaging of the viral genome. Together, all 12 plasmids yielded infectious recombinant influenza virus that displays the HA and NA surface proteins of A/Panama/2007/99 and is attenuated for man by the A/PR/8/34 backbone. The virus produced by this reverse genetics approach is genetically similar to reassortant viruses produced in eggs during the manufacture of influenza vaccines.

Recombinant influenza PR8 x Panama virus infects and replicates in Madin Darby canine kidney (MDCK) cells and is shed into the culture supernatant. This will be the source of recombinant virus for the proposed experiments.

Recombinant influenza PR8 x Panama expresses Panama H2N2 at its surface. It thus mimics the cell binding and entry properties of native A/Panama/2007/99, without the associated virulence and risk to human health, making it more suitable for laboratory investigations.

For the purpose of the current study, the PR8 x Panama virus has been chosen because it expresses the H3 haemagglutinin subtype, as does the insert in the HA-VLPs that will be used for immunisations. Immunisation with the HA-VLPs is expected to induce an immune response directed against the H3 insert, which should afford protection against infection with an H3 influenza A virus. The PR8 x Panama recombinant has been chosen for this purpose because it offers a safer alternative for handling in the laboratory than wild-type A/Panama/2007/99.

**Evaluation of foreseeable effects**

Influenza reassortants, comprising the 6 genes encoding the internal influenza proteins from the PR8 strain with only the HA and NA derived from another influenza strain, have been used routinely for production of influenza vaccines for over 25 years. According to the WHO, there have been no reported infections among production workers exposed to an environment that harbours substantial aerosols of reassortant virus, arguing in favour of the very low risk of PR8 reassortant viruses to human health.

The recombinant PR8 x Panama virus to be used in this study was produced by reverse genetics rather than reassortment, but this is not expected to alter the fact that the resulting GM virus will be of low virulence to man. It has been chosen for these studies in preference to the wild-type A/Panama/2007/99 strain, because of its predicted attenuation for man compared to the wild-type. It is not considered to pose a significant risk to human health. At worst it might cause a mild respiratory infection with local symptoms such as nasal congestion.

The wild-type A/Panama/2007/99 strain is already circulating within the human population and there can be expected to be some level of immunity through:

- the presence of residual protective immunity to A/Panama/2207/99 as a result of prior infection
  A/Panama/2007/99 was prevalent between 1999 and 2003, or
- the presence of residual protective immunity to A/Panama/2007/99 as a result of prior vaccination.

Influenza viruses readily exchange genes by the process of reassortment. Therefore, there is a theoretical possibility that the recombinant PR8 x Panama virus could form secondary reassortments if replicating in the presence of a naturally occurring influenza virus. Depending on the nature of the reassortment this could theoretically give rise
To a more virulent virus. However, given the laboratory containment measures that will be taken and the low virulence of the PR8 x Panama in man, the risk of a secondary reassortant event occurring is minimal.

Effects on the Environment

For the in vitro laboratory work the containment measures that will be taken to safeguard human health should also serve to reduce any attendant environmental risk to negligible levels.

Despite being attenuated for man, influenza A/PR/8/34 is virulent in some animals, including mice. The recombinant PR8 x Panama virus is considered to be of similar virulence to the PR8 parent and thus poses a risk of adventitious infection of mice or possibly other small mammals in the environment. During the protection experiments the possibility of inadvertent transmission of the PR8 x Panama recombinant virus will be minimised by adherence to strict class 2 containment measures.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None requested.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Influenza A viruses are inactivated by heat (>71°C) and by chemical treatments including formalin, oxidising agents, dilute acids and ammonium ions. Virkon® is a virucidal disinfectant containing an inorganic peroxygen compound that oxidises proteins within the influenza virus, thus destroying its physical structure and activity. Virkon® retains its activity in the presence of organic matter and is recommended for the inactivation of micro-organisms in tissue culture supernatants.

Waste will be treated as follows:

Spent cell culture supernatants that have been in contact with the recombinant virus, will first be chemically inactivated by soaking for 15 minutes in a 1% solution of Virkon® (final concentration). Spent liquid will then be flushed down the drain with copious amounts of water.

Contaminated tissue culture plasticware will be soaked in a 1% solution of Virkon® for 15 minutes. It will be drained and thoroughly flushed with water terminal inactivation by autoclaving.

All waste generated during the protection experiments will be loaded into an autoclave integral to the class 2 suite. It will be inactivated by autoclaving at 121°C for 20 minutes. Biological waste will then be removed for terminal inactivation by incineration. The empty containers will be autoclaved a second time, ready for re-use.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment Y

Please enter comments on the GM safety committee on the risk assessment
The risk assessment was reviewed by the iQur GMSC on 19/12/2006.

The committee discussed the designation of this contained use as a class 2 activity. Bearing in mind that both parental organisms are hazard group 2 pathogens and that the predicted activities of the recombinant virus will remain similar to those of the A/PR/8/34 parent, it was agreed that the work required containment level 2 was justified as a class 2 activity. Evidence was given where in similar situations, recombinant viruses which retain the same virulence as the parental strain, also retained the same GM classification.

The possibility for secondary reassortment events to take place was discussed. Given that the recombinant virus is expected to be of low virulence in man, and the containment measures that will be taken, the chances of a laboratory worker harbouring a wild-type influenza infection becoming dually infected with the recombinant virus were slim. Some members of the committee felt this risk was so small that special measures were unnecessary, others suggested that measures should be taken to prevent workers with influenza-like symptoms from handling the recombinant virus. The risk assessment has been modified to include this latter measure.

Other minor comments were made about sections of the risk assessment as follows. These have all been amended in the attached version (version 2).

- Factual errors in the overview, about how the recombinant virus was generated required correction
- Further clarification was required about how the virus would be inactivated for some in vitro assays
- Clarification was required about whether viable or inactivated virus would be used in the in vitro assays.

For activities involving GMMs, describe the waste management measures which will apply to the activity

All solid waste to be autoclaved prior to incineration. Thermolog strip used in autoclave to validate each run, as well as digital print out of each run. Autoclave serviced annually.

Liquid waste to be inactivated by the use of Virkon to manufacturers standards (1% solution, see manufacturers killing data).

Decontamination of work benches with Virkon, tissue culture hoods with Proline Biocontrol (see manufacturer for killing data), followed by 70% IMS. All tissue culture waste to be autoclaved.

Any contaminated equipment or spills to be treated with either Proline (for metal equipment) or Virkon (particularly for spills) followed by 70% IMS. Contamination of murine and human cells to be kept at a minimum by the use of hoods, aseptic technique and spraying with IMS everything prior to the entry into hood.

From information supplied by the supplier, it is expected that the GMM will be completely inactivated under the reaction conditions employed for its use. The reaction medium is both corrosive and highly toxic to the organism.

After reaction, the biomass will be filtered off, drummed up and sent for off-site disposal using a licensed waste contractor. The liquid filtrate will undergo further chemical processing including distillation at around 160°C.

The biomass will be tested using an approved and validated method by a contract microbiology lab to confirm that no living GMM remains after reaction.

Live GM waste will be disposed of in a rigid plastic (meeting UN 3921 transport requirements) clinical waste bins (sometimes called cliniwaste bins).

Full bins will be collected by an Environment Agency approved clinical waste contractor.

The Clinical waste contractor has HSE approval to collect, transport, store and dispose (via incineration) of GM waste.

Controlled incineration at high temperature has been well validated to achieve a 100% kill rate of viable organisms (viable organisms not detected in plume or ash).

Validation is undertaken by the waste contractor and results will reported to Diamond as per the "duty of care".

See the attached Waste Disposal Policy.

Comments from the Biological Safety Committee (14/12/2006)

Review of Risk Assessment

Brief discussion of TC work. Question regarding other types of CL1 work to be assessed; other CL1 work will be assessed as/when required. Emailed comments from external consultant relayed to committee. Committee agreed the project had correctly been assessed as Class 1.

Review of DLS Biological Safety Handbook

Transport of biological material, how are DLS employees protected when material sent by non DLS staff, in the process of completing DLS biological material transport policy - this will be communicated to individuals intending to send material to DLS.

Why waste covered in two separate documents; brief description of waste disposal in handbook to allow personnel to correctly follow procedures, in-depth description in supporting document detailing DLS policy toward biological waste.

Laboratory coat colour - suggested need to specify colour to distinguish different jobs (also allows separation of laundry) (bio-workers/chemists/workshop/cleaners etc.).

ACTION - to investigate lab coat colours and report back to committee. First aiders not currently trained to deal with injuries arising from work with biological material. CL 1 organisms will not cause harm, two new first aiders to be trained (both with a history of working in a standard biological laboratory). Own is validation of disinfectants to be done, and does assessment of incorrect use of disinfectant need to be carried out. For hazard group 1 organisms the manufacturers instructions sufficient, plus, a complete breach of containment for HG1 organisms would not present risk to humans/environment.

Committee agreed to handbook.

Comment (13/12/2006)

On the risk assessment, I have no qualms that things are under-assessed - my major feeling is that in several places the most remotely possible risks are being discussed, where I think that it would be fully justified to simplify things. As an example, it is normal to consider standard t.c. cell lines as HG 1, without needing any further justification - they are simply too disabled to present any hazard, so the discussion can move directly on to possible hazards from the vector (s) and inserts.

If the vectors are non-mobilisable and do not increase the pathogenicity of the host cells (in fact, pretty unlikely), then the only consideration becomes whether or not the transgene could increase the pathogenicity of the host or, if highly expressed, the coded protein could present any hazard. My feeling is that the vectors do not present any risk, nor do the transgenes increase the pathogenicity. The question of expressed proteins is more than adequately discussed - in typical practice if there is no mammalian promoter being used one can usually take it that there will be little expression and so negligible hazard.

I hope these comments are helpful.

Project Ref 972/19.1

Date Ackn'd 18/07/2019

CU2 Project Title Generation, usage and storage of material, including genetically modified material, from Hazard Group 2 agents

Class 2

CultureVolClass2 < 1 Litre

CultureVolumeClass3-4

Non-GMM Consent Granted

Date Project Ceased 02/03/2022
Purposes of the contained use

To work with Hazard Group 2 (HG2) organisms which include those that may be genetically modified. The work would involve the generation, growth, imaging and storage of material. Expression of the material (i.e. protein) will be in either prokaryotic or eukaryotic organisms which will be no greater than HG2 and maybe GM material. The expressed material is prepared for usage, primarily imaging. Imaging will be completed at DLS or RCaH. Storage of the material will also take place in DLS and RCaH.

There are 2 routes for these samples, SS1 and SS2. The samples could be any of the following:
- Non-hazardous proteins genetically modified with a tag for structural and bio-chemical characterisation
- Non hazardous proteins originating in higher than Hazard Group 2 agents classification
- Prokaryotic material from no greater than HG2 classification
- Eukaryotic material from no greater than HG2 classification
- Virus no greater than HG2 classification

For SS1: Diamond Light Source (DLS) is a user facility where external people use the facilities at DLS. The Research Complex at Harwell (RCaH) is also a user facility used by external scientists. Samples which may include GM samples are generated and prepared before arrival to DLS or RCaH. This work will be assessed by their home institution. The home institution will be responsible for the transport to DLS and RCaH. Sample and experimental details must be submitted via the User Administration System (UAS) prior to bringing anything on site. Diamond Safety, Health and Environment (SHE) will assess the risk of the proposed work and can accept or deny the application to complete the work at DLS. The samples arriving at DLS or RCaH will be handled on DLS beamlines and/or RCaH facility. Only short term storage of up to a week will be permitted, followed by either inactivation of the sample or transport of the sample back to the home institution.

For SS2, samples will be generated, stored and transported on site between DLS and RCaH. Assessment will be completed at a local level for every sample. This assessment will detail the experiment to be completed, including details of hosts, vectors, inserts and mutations to be used. This completed assessment be submitted to the GMS management committee for review and approval/rejection of the proposed work.

Work will be rejected if:
- Any biological agent to be used is classified as HG3 or HG4
- Any biological agent to be used is a SAPO agent
- Any biological agent is listed on ATCSA Schedule 5

In the case of an experiment using multiple live bio-material, this should not have more than one biological agent from the same domain carrying a genetic modification (i.e. The experiment will be rejected where a GM virus is used in co-infection with a non-GM/GM virus but an experiment will be accepted using a GM virus infecting a GM.
mammalian cell line.
If the genetic modification confers potentially harmful biological activity (e.g. virulence factor, toxin, determinant of immune evasion)
If the genetic modification increases the pathogenicity and/or fitness of the sample.

Recipient or parental organism
Any prokaryotic or eukaryotic organism.

Host/vector system
Any prokaryotic or eukaryotic organism.
Vectors used will be commercially available non-mobilisable vectors

Origin & function
The genetic material will originate from either a prokaryotic or eukaryotic organism.

Health and Safety
Executive
The inserted genetic material will be expressed in either a prokaryotic and eukaryotic system and will not
• Confer potentially harmful biological activity (e.g. a virulence factor, a toxin, an allergen or determinant of immune evasion)
• Increase its pathogenicity and/or fitness.
• Alter the host range
• Alter the susceptibility to prophylaxis
• Confer potentially harmful activity to the environment
• Increase its survival fitness.

Any work to be completed must not increase the virulence, pathogenicity or robustness of the recipient host (classification up to HG2 prokaryotic or eukaryotic organism)
Manipulation using sharps will be avoided at all times, however the use of sharps is unavoidable in some cases (e.g. some imaging tools) These must be handled only by members of staff with experience in using these tools
Any manipulation of an organism that can cause harm by the airborne route must be able to be handled in a microbiological safety cabinet or the proposed work will be rejected

Evaluation of foreseeable effects
No hazards are specified due to no existing pathogenic traits. Any mutation must not confer any pathogenic traits or alter the host range. If any alteration of the host range is likely further assessment must be completed.

No hazards are envisaged as the inserted material must not code any hazardous products.
Additionally, to avoid transfer of genetic material, in the case of an experiment using multiple live bio-material, there will not be more than one biological agent from the same domain of life carrying a genetic modification.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
No use of larger GMOs will take place

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
No derogation measures required

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
The work will produce both solid waste and liquid waste.

**Health and Safety**

**Executive**

Solid waste: Will be treated by disposal into autoclave bags or bins and autoclaved at 121°C for 15 mins prior to either off site incineration or disposal to landfill. In the case of lab coats, they will be treated by autoclaving at 135°C for 25 mins. Autoclaves are available for use at both DLS and RCaH. Autoclaves are serviced and validated annually.

Liquid waste: Will be treated in one of the following ways depending on the concentration and organism in use.

- Immersion in 70% ethanol for 5 mins
- Immersion in 1% virkon for 15 mins
- Immersion in Sodium hypochlorite for at least 30 mins. Concentration dependent on organism used and work being completed
- Immersion in Distel for 15 mins. Concentration dependent on organism used and work being completed.

Autoclaving at 121°C for 15 minutes for disposal

Surfaces and tools will be decontaminated with one of the following depending on the concentration and organism in use, along with the surface and tools to be treated:

- 70% ethanol
- 1% virkon
- Sodium hypochlorite. Concentration dependent on organism used and work being completed.
- Distel. Concentration dependent on organism used and work being completed.

The use of antibiotics that are used as a treatment for that infection must be avoided for work involving that organism.

All waste will be deactivated in a Virkon trap (1%) and disposed of after 24 hours as per manufacturers instructions. All GMM solid waste will be incinerated by licenced contractor. All waste from retrovirus work will be handled seperately from other tissue culture waste. Accidental spillages of liquid waste will be cleaned up with 2% Virkon solution. We do not expect the scale of low viral work to exceed more than 200ml for amphoteric viruses and 1 litre for ecotropic viruses.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Please enter comments of the GM safety committee on the risk assessment

It is the view of the CRI committee that, all GMM's handled in these facilities are regarded as relatively safe. There is a very low risk to humans as the host vector systems have been specifically designed to be of a non-transmmisable form and are replication incompetent. These organisms are mostly unstable and cannot survive outside of the environment in which they grown.
The GM work undertaken in these facilities is regarded as safe and without threat to the users or the environment.

## Project Additional Information

### Purposes of the contained use

To use somatic cell line knockout technology to generate assay reagents for combinatorial libraries of potential therapeutic compounds and for pathway analysis of potential new therapeutic targets.

This project requires gene disruption through homologous recombination in human epithelial cells in vitro; rAAV (adeno-associated virus) vectors permit such knockouts in human cells.

Inserts will encode LoxP sites, human genomic targets and positive selectable marker genes (e.g., neomycin or hygromycin). Target cells are human epithelial cell lines, including HCT-116, DLD1, A549, CAL51 and MT3 cell lines. These cells will be infected with rAAV (e.g., AAV-293).

Target genes are those of the pathways regulating DNA repair, apoptosis, histone acetylation, including BRCA2, HDCA1, SIRT1 and ADA3.

### Recipient or parental organism

Tissue culture cells of human origin.

### Host/vector system

Laboratory strains of E. coli K12 derivatives;

Tissue culture cells of human origin.

Human t.c. lines both for recombinant virus production (e.g., AAV-293 cells derived from HEK 293 cells will be used as producer cells) and for subsequent infection to produce recombinant t.c. cell lines.

pUC-based plasmid vectors; Moloney Leukaemia virus based vectors.

AAV Helper-Free system (Stratagene) (pCMV-MCS for initial cloning, pAAV-LacZ to produce the ssDNA for encapsidation, pAAV-RC and pHelper to provide the adenoviral proteins required for encapsidation); the resulting recombinant adeno-associated viral vectors will be used for transduction of human cells.

### Origin & function

Target genes are those of the pathways regulating DNA repair, apoptosis, histone acetylation, including BRCA2, HDCA1, SIRT1 and ADA3.

### Evaluation of foreseeable effects

The planned knockout of the target genes in human t.c. cell lines is not foreseen as increasing their pathogenicity from its negligible level for the cell lines.
The one significant hazard arises from the rAAV produced from the packaging cells. This is capable of infecting human cells and contains inserts designed to knockout target genes in the pathways regulating DNA repair, apoptosis, histone acetylation, including BRCA2, HDCA1, SIRT1 and ADA3. Their effect is therefore considered as potentially oncogenic.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The planned knockout of the target genes in human t.c. cell lines is not foreseen as increasing their pathogenicity from its negligible level for the cell lines.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

The planned knockout of the target genes in human t.c. cell lines is not foreseen as increasing their pathogenicity from its negligible level for the cell lines.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Containment level 2 waste will be autoclaved (136 degrees C for 10 min), before subsequent discharge down the drain into the public sewer or incineration. It is expected that this will give effectively 100% killing.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

The work involves the cloning of inserts to knockout various genes, their incorporation into recombinant adeno-associated virus (rAAV) and the subsequent infection of human epithelial cell lines, in order to establish stable cell lines with the appropriate genes knocked out. The target genes are those in the pathways regulating DNA repair, apoptosis and histone acetylation, including BRCA2, HDCA1, SITR1 and ADA3. The host cells are all highly disabled and the modifications will not increase their pathogenicity. With the exception of the rAAV, the vectors are non-mobilisable and present no risk. The exception is the AAV, which can infect human cells.

Knocking out the target genes is potentially oncogenic and, while this is highly unlikely to increase the pathogenicity of the intended host cells, it does present a risk to workers who might become infected with the rAAV.

For this reason the packaging and infection steps are considered as Class 2, while the preliminary cloning steps and subsequent propagation of any modified cells are Class 1.

(Note from BSO: I have taken advice from HSE and the Inspector, to whom I was referred, agreed with this assessment.)

**Non-GMM Consent Granted**

Not Applicable

**Project notified under transitional arrangements**

N

**Withdrawn**

N

**Tick if notifying a connected programme of work**

N

**Historical Significant Changes**

TRANSFERRED FROM GM 678 - 23/5/07.

**Recipient or parental organism**

**Characterisation of novel Tissue inhibitor of metalloproteinase (TIMP) 1, 2, 3 and 4 mutants and chimeras and their comparison with wild-type TIMPs in a variety of mammalian cell models to assess their affects on cellular processes dependent on metalloproteinase activity.**

**Host/vector system**

Plasmid DNA will be produced in E. coli K12 strains which are class 1 pathogens and are assessed to be containment level II microorganisms.
TIMP-Ad5 adenovirus are to be made by Flp dependent recombination by co-transfection of plasmid vectors pDC515 or pDC516 with pBHGfrt(triangle)E1E3, 3flp in HEK293T cells. Vectors pDC515/6 are non mobilisable and contain the TIMP gene and CMV promotor. pBHGfrt(triangle)E1E3,3flp encodes the Ad5 genome and can only produce adenovirus in mammalian cells which express adenoviral proteins E1 and E3, such as HEK293T after transfection. Further information can be obtained from www.Microbix.com who are the manufacturers of the vector system. TIMP-Ad5 will be used to infect a variety of mammalian cell lines and primary cells. These are not expected to contain the adenoviral genes E1 and E3 and should not produce viral particles after infection.

**Origin & function**

TIMPs 1, 2, 3 and 4 are from human cDNA and are inhibitors of metalloproteinases. Chimeras are made from the cDNAs encoding parts of human Furin, murine TACE and GFP, or the polypeptides KDEL, [Leu]17, V5 epitope and [His]6. These are to target TIMPs to particular cellular organelles (Fur, TACE, KDEL, (Leu)17, or to aid detection (GFP, V5, [His]6).

Plasmid vectors pDC515/6 and pBHGfrt(triangle)E1E3,3flp are derived from vector pUC18 and recombinant adenovirus Ad5.

**Evaluation of foreseeable effects**

Replication deficient Ad5 are unlikely to cause disease for purpose of group II classification. However the nature of the inserted gene should be considered in the context of the recombinant virus. Work with adenovirus carries risk of allergy after repeated exposure. This effect is idiosyncratic and may manifest as conjunctivitis and rhino-tracheo-bronchitis. Ad5-CMV based virus are not known to cause these symptoms. However although the virions lack E3 protein and are compromised in their ability to establish and maintain an infection in human cells, should infection occur, the effect of elevated TIMP expression is difficult to predict due to the varied functions of these proteases they inhibit. However, decreases in ECM turnover through MMP inhibition, or inhibition of shedding of growth factors, receptors and cytokines, on balance, is likely to decrease cell survival. All TIMPs have been shown to decrease tumour survival in murine models when expressed by adenoviral infection (variety of transformed cells including epithelial derived cells). The Ad5 adenovirus is non-oncogenic and TIMPs, GFP, ADAM17 and Furin are not recognised as oncogenes. The oncogenic potential of short peptide sequences consisting of the V5 epitope, KDEL and the 17 amino acid Leucine rich peptide is not known.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None applied for

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be treated for 24hrs with 2% Virkon or Presept tablets before disposal into the laboratory drainage system. Alternatively disinfected waste will be gelled with Vernagel in sealed containers and removed for incineration. Solid waste such as plastics will be double bagged before transfer to a waste autoclave within the building, and then disposed of by incineration on site.

Is an emergency plan required according to regulation 20? N

Project notified under transitional arrangements

### Purposes of the contained use

The use of co-culture of tumour epithelial cells with tumour stroma (fibroblasts and endothelial cells) to mimic aspects of tumour cell-cell interactions in vitro.

### Recipient or parental organism

Human Mammary Fibroblasts (HMF clones A to D) and Human Mammary Microvascular Endothelial Cells (HMME clones 2 and 7) were obtained from Ludwig Institute for...
Cancer Research, London. The characteristics of the cells are described in the publication by O'Hare et al, PNAS, 2001, 98 p646-51. In brief, primary cells derived from breast tissue were immortalised by separate transduction with helper-free amphotropic murine-lukaemia-virus (MLV) encoding the catalytic subunit of human telomerase (hTERT) and a heat labile mutant of the simian virus 40 large tumour antigen (U19tsA58). The resulting cells are immortal, yet retain most genetic and phenotypic characteristics of the primary parental cells. The cells only retain immortality when cultured at the permissive temperature of 34 degrees C, and senesce after 15 passages at 37 degrees C. These cells have the hTERT and U19tsA58 genes stably integrated into the host cell genome by MLV retroviral transduction. They have been tested negative for the presence of LMV and are unlikely to produce LMV containing hTERT and U19tsA58 in the future. However as hTERT and U19tsA58 genes are potentially oncogenic, it is advised that the cells are cultured under containment level II conditions and the cell lines are classified as Class II organisms.

Host/vector system

Cells are derived from primary fibroblasts and microvascular endothelial cells obtained from breast tissue explants.

The vector system used originally used to transform these cells is described in the publication by O'Hare et al, PNAS, 2001, 98p646-51. In brief the vectors used were helper-free amphotropic murine-lukaemia-retrovirus (MLV) containing resistance genes for antibiotics hygromycin and G418 to aid selection of clones which had integrated MLV stably into their genome.

NB. Only the cells derived from this vector system are to be used by the applicants. NOT the vector system itself.

Origin & function

The human telomerase catalytic domain (hTERT) is derived by removal of the regulatory domains of human telomerase. Human telomerase maintains telomere length which is a means of regulating cell life-span. HTERT prevents telomere shortening and can lead to immortalisation of cells which express it.

The simian virus 40 large tumour antigen is a known oncogene and induces DNA synthesis by by-passing key cell cycle check points through interacting with regulatory proteins (c-myc, Ras). It also blocks p53 dependent apotosis U19tsA58 is a temperature sensitive mutant of SV40LTA which is inactive at 37 degrees C yet is active at the permissive temperature of 34 degrees C.

Expression of these constructs individually does not always lead to cell immortalisation, although expression of both will usually lead to complete transformation and immortalisation.

Evaluation of foreseeable effects

Due to the nature of the hTERT and U19tsA58 genes stably inserted into the genome by MLV transduction there exists a very small but finite risk of a recombination event which could lead to production of amphotropic replication competent MLV containing either the hTERT or U19tsA58 genes should the cells come into contact with MLV or a derivative thereof. To further reduce the risk of recombination, the following will be adhered to.

1. Culture in Containment Category II facility following CIMR Containment II Code of Practice.
2. The cells are not to be cultured in the presence of murine cells.
3. All human cell lines which will be co-cultured with the immortalised fibroblasts or endothelial cells will be tested for the presence of MLV by PCR.
4. The fibroblast and endothelial cells will be tested monthly for the presence of MLV by PCR.

Date of Significant Change

Project Additional Information

**Purposes of the contained use**

We will produce viral particles using the FLP recombinase kit from Microbix. The gene of interest is cloned into pDC515 or pDC516, which contains a CMV promotor or pDC511 and 512 containing the SV40 promotor, allowing expression to be checked under Containment Level 1 conditions prior to generation of virus. Virus is made by co-transfection of the pDC vector with pBHGfrDE1E3, 3FLP in NautCell 293T cells, where FLP recombination occurs producing viral particles. This will be performed under Containment Level 2 conditions in compliance with the institute code of practice.

**Recipient or parental organism**

E.coli: All strains are K12 derived thus disabled and non-colonising. Vectors are mobilisation defective. Mammalian cells: pDC515/6. Vector is non-mobilisable.

Adenovirus: Microbix adenovirus and all commercially prepared adenoviral genomes are based on Ad5 which is replication deficient but can enter a variety of human cells.

**Host/vector system**

E. coli, K12 pBr322 based
Mammalian Cell pBR322 based
Mammalian cell Ad5 based virion post infection (E1 deficient).
NautCell293T Ad5 based virion.

**Origin & function**

Human origin
SiRNA is synthetically derived- used to inhibit expression
cDNAs - used for over expression

**Evaluation of foreseeable effects**

Replication deficient Ad5 are unlikely to cause disease for purpose of group II classification. However the nature of the inserted gene should be considered in the context of the recombinant virus. Work with adenovirus carries risk of allergy after repeated exposure. However although the virions lack E1/E3 proteins and are compromised in their ability to establish and maintain and infection inhuman cells. Over expression of MMPs through inadvertent infection by RAd5 virus expressing the enzymes via a CMV or SV40 promotor may result in increases in ECM degradation and hence increases in cellular proliferation and migration. High levels of over expression of most MMPs in tumour cell lines in mouse models of subcutaneous xenotransplantation results in increased tumour growth. It is possible therefore that increased rates of cell growth may occur on adenoviral expression. Although increased MMP expression is increased on neoplastic transformation in most tumour types,increased MMP expression itself is not thought to cause cellular transformation at the genetic level, hence MMPs are not considered oncogenes. Effects of ADAM knock down are even harder to predict in vivo through inadvertent infection of sirRNA expressing adenovirus. With the exception of ADAM10 (embryonic lethal due to lack of Notch/Delta processing) or TACE (EGF like knockout phenotype due to poor shedding of EGF ligands) all other mouse knockouts made so far as ADAMs are viable and have no severe phenotypic differences from their wild type litter mates which have been defined as yet.
The virus is physically relatively stable, so need good practice to ensure it isn't spilled and left to present a hazard at some future point; the host range of Ad5 is naturally limited to man and therefore the virus will not infect animals or plants nor, due to its disablement, spread to the wider human community. Bacteria and mammalian cells are unable to survive outside of laboratory culture conditions.

See attached protocol for further details.

In summary, there is little evidence that either knock down of MPs or their over expression would have long term effects, should any pathology result from inadvertent infection by adenovirus. Adherence to the code of practice for containment 2 facilities should be adequate for preventing inadvertent infection.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applied for.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste will be treated with either 2% virkon overnight in labelled containers. Liquid post disinfection will be gelled with Vernagel and placed in sealed containers and taken to room 1.23 for incineration. Solid waste will be placed in double autoclave bags, secured with autoclave tape labelled with room no and user name, followed by autoclaving and incineration. Liquid spills will be treated with 2% Virkon (non metallic surfaces) or 10% Trigene (metallic surfaces), absorbed with paper towels which will then be autoclaved. Surfaces will be routinely cleaned with 10% Trigene.

Animal Units | Large Scale Activities | Human Clinical Applications
### Project Additional Information

**Purposes of the contained use**

To study the activities and mechanisms of suppressor gene function by recombinant means in human and mouse cell lines.

**Recipient or parental organism**

Established human (IMR90, W138 & BJ), and 293T human embryonic kidney cells transformed with E1a and carrying a temperature sensitive T antigen, also mouse embryonic fibroblasts cell lines.

**Host/vector system**

Retroviral vectors based on Moloney Murine Leukaemia Virus, ecotropic (for mouse cells) or amphotropic (for human cells) packaging system. Mobilisation-defective Lentiviral vectors will be used for non-dividing cell lines.

See attached project proposal.

**Origin & function**

cDNAs and shRNAs, tumour suppressors (p53, Rb, p16) and over expression of oncogenes (HMGA, ras, mdm2, etc) involved in tumourigenesis.

See attached project proposal.

**Evaluation of foreseeable effects**

None of the cell lines used are capable of colonising a healthy individual and we do not expect any of our proposed manipulations to change this. The amphotropic
retrovirus and lentivirus would be able to infect human but could not replicate unless the improbable event occurs that it recombines with endogenous retroviruses. Even then it is unlikely the expression of a single oncogene or suppression of a tumour suppressor causes tumours, as multiple genetic alterations (between 4 and 6) are required for inducing tumours and safeguard mechanisms exist impeding the accumulation of these alterations in the organisms (i.e. single events like ras or myc expression instead of unrestrained proliferation induce growth arrest or apoptosis).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

| All work, where directed by the Biological Safety Committee, will be carried out in the higher containment level 2 facility. Other work will be conducted with good laboratory practice and in accordance with the biosafety local rules. All virus production will be undertaken in the CL2 facility. Liquid waste will be rendered harmless by treatment with Virkon (1%) over 16 hours and in accordance with recommended manufacturers instruction. Spills will be treated with an excess of 2% Virkon or other approved validated disinfecting agent. All solid waste loads from CL2 will be autoclaved at 121C for the requisite time, validated and bagged for disposal by incineration through an approved, validated, licensed contractor (White Rose). Solid waste arising from Class 1 work will be bagged and collected in containers for incineration by the above named contractor. Staff undertaking collection of waste will be trained to deal with the clean-up of accidental spills. Autoclaves are subject to regular routine maintenance, insurance inspection and annual validation. |

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The project was submitted for comment was considered at the meeting of the Biological Committee on Friday 15th December 2007. The committee agreed that the project assessment was correct and parts of this proposal would need to be carried out at Containment Level 2. All virus production work ecotropic or amphotropic would be done in the CL2 facilities. Staff engaged in work at CL2 would need to be made familiar with the requirements and local rules and sign acknowledgement that training had been provided, evidence of past experience would also be required.

Should treated cells need to be removed from the CL2 laboratory, evidence would be needed to demonstrate absence of virus in the cells and supernatant.

The committee agreed that this proposal should be submitted under the requirements of the Genetically Modified (Contained Use) Regulations 2000 activity notification.

**Project Additional Information**

**Purposes of the contained use**

Translational research on cancer pathology and treatment

**Recipient or parental organism**

Human or mouse cell lines, including both primary and established cultures

**Host/vector system**

- 'Third generation' lentiviral vector systems, and also second generation lentiviral vector systems only if derived from non-human viruses. *Second generation* retroviral (other than lentiviral) vector systems. Adenoviral vector systems. Herpes simplex 1 'amplicon' vector systems.

02/03/2022
A wide variety of inserts will be used, according to the different areas of research across the institute, many of them essentially harmless, but will sometimes include inserts that are inherently oncogenic, that activate oncogenes, that repress tumour suppressor genes, that promote the expression of growth factors, or are otherwise potentially harmful.

**Evaluation of foreseeable effects**

All vectors are well characterised, with a history of safe use, and are inherently safe. The lentiviral vectors are self-inactivating, replication incompetent, with the genes for assembly of live vector viral particles on three different plasmids, with viral accessory genes deleted, and with expression of vector contingent on upstream elements and trans complementation. However, the lentiviral vectors may also carry enhancements to host range & stability and/or to vector titre & transgene expression. The retroviral vectors are self-inactivating, replication incompetent, with the genes for assembly of live vector viral particles on two different plasmids, with packaging signals and 5'LTR typically deleted, and with expression of vector contingent on trans complementation. However, the retroviral vectors may also carry enhancements to host range & stability and/or to vector titre & transgene expression. The adenoviral vectors non-replicative and non-mobilisable with the E1 gene cassette deleted, in most cases the E3 cassette deleted, and in many cases the E2 cassette deleted, and the insertion site is at the site of disablement (E1). The HSV-1 amplicons are generated using a bacterial artificial chromosome but with the packaging signal, origin of replication and the ICP27 gene (essential for replication) all deleted and with 'stuffer' sequence inserted to render the HSV sequence too large to be packaged into viral particles, and with the missing elements supplied from separate BAC's/plasmids, and then the final amplicon containing largely only insertion sequence with little or no room for viral sequence and thus non-infectious. The risk to human health will be very low in most cases, but in some cases, with potentially harmful inserts, and/or enhanced vectors, and/or human primary material, the risk to human health may become significant. The risk to the environment is very low in all cases because of the highly attenuated and disabled nature of all the vectors and recipient cell lines used.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

n/a

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Liquid waste is inactivated with the peroxygen disinfectant DuPont RelyOn Virkon at a freshly prepared overall concentration of 1% for at least 20 minutes prior to disposal to drain. Based on the manufacturer's efficacy data, this will inactivate all cell lines and viral vectors used with effectively 100% kill. Solid waste is autoclaved prior to removal from site by a suitably approved carrier to a suitably approved disposal site for final incineration. The autoclave is regularly serviced and tested. This will inactivate all cell lines and viral vectors used with 100% kill.

Any spills are treated with Virkon as above. All work is carried out in a class II microbiological safety cabinet conforming to BS EN 12469:2000, and regularly serviced and validated.

**If yes, tick to confirm that it is attached to this form**

N

**Tick to confirm that you have attached a risk assessment to this form**

Y

**Tick if you are claiming exemption from disclosure for section of the risk assessment**

N
Four risk assessments are attached, one for each vector type. All were approved by the GM safety committee as GM Class 2 and/or 'COSHH' Hazard Group 2 (although certain aspects may be at GM Class 1 and/or 'COSHH' Hazard Group 1 as indicated in the assessments. These risk assessments represent generic templates, and the committee require that a detailed specific risk assessment be submitted to them for approval for every new/separate project. These specific assessments may be based on these generic assessments, but must clearly show that the proposed work (ie, the specific cell-lines, vectors, inserts and procedures to be used) fall within these generic risk assessments and give a level of risk consistent with the generic assessments, or else a further notification under regulation 10 will be made.

### Project Additional Information

**Purposes of the contained use**

Mice will be infected with influenza Strain A virus isolates including some previously GM virus (altered to express peptide epitope marker) and their ability to raise effective
Immune responses will be monitored. The model uses well characterised and commonly used laboratory mouse-adapted strains of Influenza A virus (H1N1 isolates A/WS/N/33 (WSN) and A/PR/8/34 (PR8) and H3N2 isolate A/HK/X31) to study immune response to virus infection and rechallenge.

Recipient or parental organism

Parental organisms: Influenza virus strain A/WSN/33 (WSN;H1N1) and A/PR8/34 (PR8;H1N1).

Host/vector system

Orthomyxoviridae, Influenza virus type A, Subtype H1 N1, strains A/WSN/33 (WSN;H1N1) and A/PR8/34 (PR8;H1N1) containing the OVA 257-264 peptide was generated by reverse genetics.

The host organism will comprise of either:
(a) characterized mammalian cell lines (such as canine cell line, MDCK) maintained in tissue culture for viral plaque assays.
(b) C57BL/6 and transgenic mice for virus immunity studies.

Origin & function

Ovalbumin sequence 257-264 (SIINFEKL) as a peptide epitope marker. To allow virus-specific immune cell responses to be monitored using MHC-tetramer technology and transgenic T cell receptor (TCR) expressing mice (such as OT1 mice).

Evaluation of foreseeable effects

We classify the work with these H1 N1 influenza virus strains as GM Containment Level 2 for the following reasons:
Strain A/WSN/33 is classified as BSL-2 by the ATCC
Strain A/PR8/34 is classified as BSL-2 by the ATCC

The OVA 257-264 is a MHC I Kb restricted epitope and is presented on the surface by antigen presenting cells to activate a CD8+ T lymphocyte response specific for the OVA peptide (Walker et al., J. Immunol. 1997, 159:2563-2566; Topham et al., J. Immunol. 2001, 167:6983-6990). The insertion of OVA is not predicted to increase the virulence or pathogenicity of the virus.

The viral influenza model involves the exposure of mice to live virus to give a subclinical infection. The parental influenza virus strains WSN and PR8 are well characterised and have a low or no pathogenicity in human. They are highly passaged isolates used routinely in laboratories are considered non pathogenic. The virus required direct intranasal administration of viral particles to infect cells of the respiratory tract. There is no evidence of transmission between mice or from mouse to human (Lowen, A.C., Mubareka, S., Tumpey T.M., Garcia-Sastre, A. & Palese P. (2006). The guinea pig as a transmission model for human influenza virus. Proc Natl Acad Sci USA 103, 9988-9992). For mouse infections all work will be carried out in a containment 2 area within the biological services unit. Mice will be handled within MSC II cabinets and housed in individually ventilated (HEPA filtered) sealed cages. As such, the risk of spread to the wild murine population is very unlikely.

The viral particles cannot survive outside of the mouse, and are rapidly inactivated by dehydration or other environmental insult, and so scope for spread via the environment is severely limited. The virus is fragile and is quickly inactivated by detergents, lipid solvents, phenolic disinfectants or chlorinating agents. The virus is to be stored in sealed labelled vials within an -80:°C freezer, as such the environmental risk is correspondingly extremely low. No production of viral stocks will be undertaken, existing GM virus will be used..

The Advisory committee on dangerous pathogens document - ‘Advice on Experimental working with Influenza
Viruses of Pandemic Potential" states that, 'Viruses with pandemic potential should be handled at higher containment (at CL3 or above as determined by risk assessment). These include subtypes H2, H1 and H3 if, in the case of the latter two, the viruses being handled are sufficiently different from currently circulating human viruses to warrant an assumption of little or no cross-reactive immunity in the human population.' The viruses to be used in this case are predicted to be antigenically similar to components of the currently available seasonal human influenza vaccine and this indicates containment level 2 will be adequate.

The GM insert is known to be harmless.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be treated for 24 hrs with 2% Virkon or Presept tablets before disposal into the laboratory drainage system. Alternatively disinfected waste will be gelled with Vernagel in sealed containers and removed for incineration.

Solid waste such as plastics or cage waste will be double bagged before transfer to a waste autoclave within the building, and then disposed of by incineration.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Risk Assessment was approved by the GM safety committee on 2nd February 2017 as GM Class 2 and/or 'COSHH' Hazard Group 2.

Y

Give brief details of the genetic modification safety committee

We have 5 members in our newly established committee with between 12 and 30 years practical experience in the following disciplines; Microbiology, molecular biology, production of recombinant proteins, cell culture and diagnostics development. 3 members have PhD's, 1 a MSc and another BSc Hons. The group aims to meet 2-3 times a year or as required to look at risk assessments.

One of the members has several years training and experience as a safety advisor whilst working in a class 2 facility at Unilever Research, and is responsible for organising meetings.

Laboratory waste is placed into autoclave bags which sit in autoclavable boxes. At the end of the day a lid is placed on the box and it is transported to the autoclave. The lid is removed and autoclaved along with the box containing the waste, an automatic discard cycle is used. Each run is monitored by thermocouples that are placed in the waste load and chamber to record temperatures reached. This is recorded and registered. The bags and boxes also carry autoclave tape that is thermosensitive.

Any spill that occur in the lab during work are treated with 70% ethanol and cleaned up with absorbent paper. This waste is also autoclaved. The degree of kill has been determined by testing the viability of microorganisms in heat. Class 1 heat sensitive organism show a 1 log kill per second at 70°C.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The GM safety committee agree that the activities under assessment fall into the Class 1 category.

Comment 30/11/2006
On the specific documents you sent, I am happy with both risk assessments. One minor point on both is that I am a "former member of ACGM", not being on its successor SACGM.

Review by the BSC 3/12/2006
The risk assessments were discussed and it was suggested that a list of workers should be included in the risk assessment. However, the procedure for access to the Bio Lab is addressed in the Biological Safety Handbook. Access will only be given to trained and competent persons.

There was a discussion about record keeping for expressed proteins which will be appropriately catalogued.

Asked that in section 3 1 litre was changed to 2 litres.

Stated that the risk assessment will be available in the Bio Lab.

Concern was expressed that the risk assessments did not clearly state that the work was class 1 and that a qualifying table should be included. Explained that this format is only used for hazard group 1 organisms but that he would add a table into the risk assessment. Action.

There was a discussion about generic risk assessments for the Bio Lab.

Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Give brief details of the genetic modification safety committee

The genetic modification safety committee consists of five members who meet annually and on a Ad Hoc basis if a new project assessment is required. The members include two company directors, the Operations Manager, the research pharmacologist who will be conducting the work on site and an external biological safety advisor from the University of Nottingham. Meetings will involve a review of all risk assessments for our operating procedures and a discussion of any further safety aspects.

Laboratory | Animal Unit | Growth Room | Glass House | Large Scale
---|---|---|---|---
Level 1 (GMMs) | | Yes | | |
Level 2 (GMMs) | Yes | | | |
Level 3 (GMMs) | | | | |
Level 4 (GMMs) | | | | |
Non-microbial | | | | |
Other (please specify) | Tick if confidential | |
Bacteriology | Parasitology | Transgenic Birds | Microbiology Research | Yes |
All work will be conducted using the appropriate safety equipment and the aseptic technique to prevent contamination. All bacterial plates (used and unused) will be rinsed in 70% IMS before temporary storage in a sealed metal container. All waste will then be autoclaved on a discard cycle to achieve complete disinfection prior to transport for incineration in sealed biohazard bags by a licensed contractor. There is an autoclave present in the same building, which can be used for this purpose. This incinerator is validated for this purpose on an annual basis.

Any liquid bacterial cultures or tissue culture medium will be treated overnight with 2% Trigene to kill off any living micro-organisms (as per manufacturers instructions and data sheet), after which they will be discarded down the sink. Tissue culture flasks and plates where cells may be living will be treated with 2% Trigene for 24 hours to kill any remaining culture after which they will be discarded into sealed biohazard bags and sent for incineration. All gloves will be discarded into the incineration waste bags. All pipette tips, which may have come into contact with GMO's, will be treated with 2% Trigene and then discarded into a sealed sharps bin, which will be incinerated when full.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

Two risk assessments (CA-07-1 and CA-07-2) were considered by the genetic modification safety committee at its meeting on the 22nd February 2007 (copies attached). These were both approved as Class 1 activities.

Immediately prior to the meeting the Chairman and external Biological Safety advisor from the University of Nottingham, undertook an inspection of the laboratories and confirmed that the physical condition, safety procedures and administration of the laboratories complied with level 2 containment.

Yes

Give brief details of the genetic modification safety committee

A joint GM Safety committee is held between the Marine Biological Association and Plymouth Marine Laboratory. Both sites have their own Biological Safety Officer and GMSO who are on the committee, a union representative, postdoctoral researcher and a student representative. There is also an external advisor from the University of Plymouth. All members of the committee are required to look at the risk assessments of new and reviewed projects. The committee will meet 4 times a year and will feedback to the Joint Health and Safety Management Committee.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Waste is bagged within the lab using suitable autoclave bags, these are transported in an aluminium box to the autoclave (this is situated along the corridor and down one floor in the lift) this is done using a trolley. The waste is autoclaved at 121°C for 40 minutes. The autoclave is validated on a monthly basis using bioindicators within the load, which are incubated for 72 hrs to make sure they have been killed. This is carried out in house. Annually the autoclave is pressure tested by an engineer as part of planned maintenance, as part of this a 12 point test will be carried out on a test load.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

"With the addition of the method of deactivation of any waste as well as making clear the assessment of risk to the environment, as recommended during the HSE visit, the committee are happy with the risk assessment for the project and agree that it is a class one activity.

The risk assessment should be reviewed in a year, or sooner if there are any significant changes"

Give brief details of the genetic modification safety committee

The NovaBiotics Genetic Modification Safety Committee consists of the Health & Safety Officer, Deputy Health & Safety Officer, Fire Officer, Biological Safety Officer, First Aid Representative, Laboratory Staff Representative and Chief Scientific/Chief Executive Officer. At present, NovaBiotics Ltd Genetic Modification Safety Committee meets on an ad hoc basis, but once GM work begins it is anticipated that the committee will meet monthly, at least initially, with meeting frequency requirements under constant review.

Laboratory | Animal Unit | Growth Room | Glass House | Large Scale |

Virology | Transgenic Animals | Transgenic Fish | Gene Therapy | Yes |
For activities involving GMMs, describe the waste management measures which will apply to the activity

All GM waste will be inactivated by autoclaving. GM activity in Novabiotics' Molecular Biology laboratory will be limited to routine cloning and expression work using attenuated Escherichia coli strains. All work will be carried out in small volumes (<50ml) using disposable plastic-ware at all times. All GM-contaminated plastic-ware will be inactivated by autoclaving, and none will be re-used following autoclaving. No unautoclaved GM waste of any description shall be kept in the Molecular Biology Laboratory for more than 48 hours. All GM waste must be autoclaved prior to disposal. Any waste in the GM Biohazard waste bins on Friday afternoon must be autoclaved rather than being left over the weekend, where practicable. If this is not possible, for example due to breakdown or malfunction of the autoclave, then the bags should be clearly labelled, sealed with autoclave tape and left in water-tight container in the Molecular Biology Laboratory to wait later treatment. An agreement is in place with Sterile Technologies Ltd to dispose of all BioHazard waste (including GM waste) on an ad hoc basis in the event of a breakdown of the Varioklav 135S Autoclave.

All GM waste must be autoclaved in the Varioklav 135S Autoclave in the "Wet" Laboratory. The correct cycle, "destruction EV" applies a vacuum to the load before heating it to 134°C for 15 min. This is cycle P2 on the front panel of the autoclave. A separate Standard Operating Procedure is available for operation of this autoclave, as is a risk assessment for the use of autoclaves in general.

Waste bags (marked "Biohazard") will, when full, be placed inside larger clear plastic autoclaveable bags and these bags will be sealed with autoclave tape, leaving a small opening to permit the ingress of steam. The top of the bag will be folded over and taped down with a small piece of tape for transport to the autoclave. Bags will be placed in securely lidded plastic boxes and taken to the "Wet" Laboratory for autoclaving. Once the bag is placed in the autoclave, this small piece of tape will be removed and operators should ensure that the unsealed hole left in the top of the bags is left open to allow air to be evacuated and for the ingress of steam during the autoclave cycle. After autoclaving, the waste bag and contents will be placed inside the orange clinical waste bag provided and loaded into the waste storage bin prior to collection and disposal by Sterile Technologies Ltd.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The members of the Genetic Modification Safety Committee agreed unanimously that the Risk Assessment was entirely adequate for the purposes for which it was designed, and will be implemented.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Class 1 GMM waste is disposed of by autoclaving. Autoclave cycles are validated to ensure waste reaches the required criteria. The criteria to pass a cycle are that the contents of the waste must undergo a sterilisation cycle greater than or equivalent to sterilisation at 121°C for at least 15 minutes.

Autoclaved waste is then disposed of via the clinical waste route, using an authorised contractor to dispose of it by incineration.

Tick to confirm that you are attaching a summary of the risk assessment  

Tick if you are claiming exemption from disclosure for sections of the risk assessment  

Please enter comments of the GM safety committee on the risk assessment

The risk assessment has been studied by the GM committee who agree that the GM work to be carried out by Lumora is designated as class 1 GM activity.

Gene Therapy
Although not required for class 1 activities, two autoclaves are available in the laboratory where the work will be carried out for inactivation of waste material as well as a class 11 safety cabinet.

All waste material containing viable GMMs, including spent culture fluid and other media, will be inactivated by heat inactivation (autoclave) or chemical means (where appropriate).

Contaminated waste and contaminated items will be autoclaved using a validated cycle, e.g. at 121 degrees C for 20 minutes before disposal and may include a holding time.

The autoclaves used for waste disposal will be validated regularly for performance.

Contaminated laboratory glassware and other materials awaiting disinfection will be stored in a safe manner and pipettes will be totally immersed in disinfectant, where necessary.

Spillage is treated by chemical methods such as spraying the contaminated area with 70% ethanol and Virkon if required.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Tick to confirm that you are attaching a summary of the risk assessment  

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

This will be a continuation of class 1 activities previously approved by Manchester Interdisciplinary Biocentre. No additional risks to human health or the environment are indicated. The laboratory where the work is proposed to be carried out, has both autoclaves and a class 11 safety cabinet available in the same room.

For activities involving GMMs, describe the waste management measures which will apply to the activity

The GM safety committee were satisfied that the correct protocols were in place for handling class 2 GMO. The disposal of contaminated material was discussed and it was found to be acceptable to use the disinfection methods described as approved by the manufacturer for retrovirus culture. Additional comments relating to the format and content of the risk assessment have been integrated into the supporting document enclosed.

Project Ref 981/07.1

Date Ackn’d 23/05/2007

CU2 Project Title Conditional Immortalisation of Primary Human Bronchial Epithelial Cells using Retroviral delivery of / and integration of Thermolabile SV40 Tantigen, or C-MYC.

Class 2

Culture Volume Class 2 < 1 Litre

Consent Granted Not Applicable

Non-GMM Consent Granted

Project notified under transitional arrangements N

Historical Significant Changes

Historical Date of Additional Info
### Project Additional Information

#### Purposes of the contained use

Generation of conditionally immortalised cell lines derived from Bronchoscopic brushings taken from well characterised individuals for research purposes.

#### Recipient or parental organism

Retrovirus - MoMLV based retrovirus vector (pZIP-Neo or NIT-Tag) (pBABE or pLNCX-2). Recipient cells are human primary bronchial epithelial cells and carry a risk of T.B. infection, the risk is considered low in choice of donors.

#### Host/vector system

**Packaging cell lines**

1) BING/CAK 8 A 293T derived (human kidney epithelial origin) cell line expressing amphotropic envelope protein.
2) TEFLY A Human sarcoma derived cell line expressing amphotropic envelope protein, gag and pot genes.

**Origin & function**

The pZIP-Neo vector and TEFLY A cell line originated from the Ludwig Research Institute and will be supplied by Lonza Nottingham Ltd.

The NIT-TAG vector originated from research at the University of Michigan and Laboratory of Genetics, Salk Institute, La Jolla, California and will be supplied by the latter.

The BING/CAK 8 cell line will be purchased from ATCC Cell biology cell cultures collection (Teddington, TW11 0LY, UK).

The intended function is to generate retroviral packaging, delivery and integration of thermolabile SV40 T antigen, into primary human bronchial epithelial cells. The generation of stable conditionally immortalised cell lines from well characterised donors.

To the same purpose C-MYC will be introduced in the commercially available vector pLNCX-2 (Clontech) (a format licenced from Reneuron Ltd).

#### Evaluation of foreseeable effects

The GMO produced will be amphotropic retrovirus capable of delivering and integration of heat sensitive T antigen. The GMO is replication deficient.

Infected cells will be resistant to the amphotropic neomycin and have extended proliferative potential at permissive temperatures below 32C.

Accidental exposure to retrovirus carries a potential risk of infection. Inoculation with significant viral titre may cause infection with tumorigenic potential. The risk is deemed low as proviral integration would be required a site deleterious and oncogenic to the cell or there would need to be conversion of the T antigen to wild type (now thermolabile) and co-expression of oncogenic RAS (Thomas M 2002 Neoplasia 4: 493-500). All work will be carried out in class 2 microbiological safety hoods and designated incubators and equipment, routinely disinfected will be used to minimise exposure risk.

Transformed cells will not be derived from the operator or other laboratory personnel. If inoculation due to sharp injury occurred it would be likely to invoke a strong allogenic immune response resulting in rejection of injected transformed cells.

The retrovirus is replication deficient and susceptible to degradation on dehydration. Host cells are unable to survive outside cell culture conditions these characteristics mean accidental release into the environment carries negligible risk of hazard, particularly as likely exposure would be from small quantities.

The GMO produced will be amphotropic retrovirus capable of delivering the oncogene C-MYC. The retrovirus is replication deficient itself.

The activity of CMYC is regulated by cellular localisation and the fusion gene introduced will produce a chimer of C-MYC and a modified estradiel receptor. The chimeric protein must dimerise to enable nuclear translocation and subsequent C-MYC activity. Dimerisation is controlled by ligand binding where the ligand is 4-Hydroxy Tamoxifen (4-OHT).

Accidental exposure to the retrovirus carries a potential risk of infection, however the tumorigenic risk is negligible without the coincidental use of 4-OHT.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

---

02/03/2022
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Disinfection of biohazardous tissue culture waste in liquid form or contaminated plastics will be performed by treatment with chemical disinfectant Virkon. Virkon is DEFRA approved disinfectant active against a broad range of viruses including retrovirus.

UV irradiation and disinfection of class 2 microbiological safety cabinets where biohazardous cultures are opened and where aerosols can potentially form will be routine procedure.

In addition to disinfection, solid waste will be double bagged and sealed autoclaved and incinerated - by clinical waste contractors appropriately trained.

It is noted that retroviruses are susceptible to dehydration, transformed cells only survive in controlled tissue culture conditions, the inserted gene product is thermolabile.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Details of the proposed GM project, Risk assessment and code of practice for handling retrovirus and related class 2 material was circulated to members of the GM safety committee for consideration on 23/4/07. The comments of the committee have been incorporated into the supporting documents to this application regarding risk assessment and code of practice for handling GMO.

The committee reviewed the disposal of contaminated waste and were satisfied with the manufacturers stipendation that Virkon was suitable for disinfection of retrovirus contaminated material. Additional steps ensuring containment during disinfection, use of UV and autoclaving to sterilise materials and work space were approved.

Give brief details of the genetic modification safety committee

The HPA is located at the Institute of Cell and Molecular Sciences (ICMS), Barts and the London School of Medicine, Queen Mary College. A GMO safety committee has been constituted within the ICMS and this proposal has been reviewed by it. We now have created a joint ICMS-HPA GMO committee with representatives of the HPA MRU to provide a single site-wide oversight. The GMO committee has a chairman (a senior virologist at this time) and a secretary (a bacterial molecular biologist) plus bacteriologists and virologists with scientific, medical training and direct experience of the handling and containment of pathogenic microorganisms at cat. 1, 2 and 3 including GMOs.

For activities involving GMMs, describe the waste management measures which will apply to the activity

All disposable waste, disposable labware, gloves and materials used for treatment of spillages are treated by autoclaving on a validated sterilisation cycle of 121°C for a minimum of 15 minutes. The degree of kill is expected to be 100%. Standard autoclave indicators are used to verify that the cycle has completed successfully.

Prior to autoclaving all re-usable laboratory glassware is also treated with commercially available sodium dichlorosocyanurate based liquid disinfectant.

Surfaces are routinely disinfected with commercially available propan-1-ol based surface disinfectant. Laboratory environmental monitoring is carried out monthly, surfaces are sampled and any contaminants isolated. Environmental monitoring records indicate routine sanitation procedures are sufficient to eliminate any bacterial contaminants that might occur.

Following autoclaving all materials are removed from the premises by a licensed contractor for disposal via incineration.

Please enter comments of the GM safety committee on the risk assessment

The proposed procedures are considered to be low-risk with regard to the health and safety of personnel involved in the work, those working within the same laboratory space, and to the environment. There is no known pathogenicity attached to the organism to be used in the GMM work, and the gene fragments to be inserted will not produce functional proteins, therefore the modified organism is considered to pose a very low risk.

02/03/2022
Two GMOs will be used at the NeuTec facility, both class I: Escherichia coli K-12 and Saccharomyces cerevisiae.

Waste Management: All waste material containing viable GMMs, including contaminated disposable plastics, spent culture fluid and other media, are inactivated by chemical treatment (Trigene Advance Laboratory 2.5% final concentration, exposure overnight) prior to incineration. Chemically inactivated waste is stored in leak-proof, sealed containers prior to collection by Astec Waste Services. Contaminated laboratory glassware and pipettes are totally immersed in Trigene Advance Laboratory (2.5% final concentration) and incubated overnight. Decontaminated glassware is washed in water and reused. Our waste disposal policy document detailing processing of different types of waste is attached. Attachment 1.

Validation of Inactivation: This has been performed by the manufacturer of Trigene Advance Laboratory, and certificates of testing and microbial inactivation for different microorganisms are available. Attachment 2.

Degree of Kill: No Test certificate is available for Saccahromyces. However data for Candida albicans (a similar non-spore forming yeast) is available. Here Trigene (1% final) added to a fungal suspension containing albumin (3 mg/mL) and erythrocytes 3 mL/L) resulted in a >106 reduction in viable yeast cells after 15 min at 20 deg C. The test method used was BS EN 13624 “Candida Quantitative suspension test for the evaluation of fungicidal activity of chemical disinfectants used in medical areas”.

For E.coli, a >106 reduction in viable E.coli cells was observed under similar conditions. Test method used was EN1276. “Bactericidal activity of Trigene Advance using phase 2 step 1 suspension test”

Monitoring Measures: No monitoring is planned. However, by September 2007 an autoclave will be available in our facility and contaminated waste will be subject to sterilization using standard autoclave conditions. This autoclave will be subject to “under load” measurements of temperature and pressure, autoclave tape indicators and in some instances spore strip tests.
The assessment was considered by our GM safety committee on the 7th June 2007. There were no specific comments from our GM safety committee. There were minor changes in the wording of the assessment.

| 04/10/2018 | Gene therapy product RP1 (Common name rHSV_1hGM-CSF/GALV-GP) for the | Class 2 | < 1 Litre |  

02/03/2022
RP1 will be administered to subjects as an anti-tumour therapy, as part of a Phase I clinical trial to treat a wide range of solid tumour types. RP1 has a particular utility in combination with immune co-inhibitory pathway blockade. Intended indications to study include soft tissue sarcoma, breast cancer including triple negative breast cancer (TNBC), lung cancer including non-small cell lung cancer (NSCLC), melanoma, non-melanoma skin cancers, head and neck cancer, primary liver and kidney cancer and colorectal cancer. The initial clinical trial protocol intends to test RP1 in several indications as a monotherapy and in combination with anti-PO-1 therapy.

Recipient or parental organism

RP1 (rHSV_1hGM-CSF/GALV-GP) is a selectively replication competent Herpes Simplex Virus-1 (HSV-1). The virus contains a codon-optimised sequence for human granulocyte macrophage colony stimulating factor (hGM-CSF) and a codon optimised sequence for the gibbon ape leukemia virus surface glycoprotein (GALV-GP) with the R- sequence deleted (R-)[GALV-GP-R-]. GALV-GP-R- expression leads to cell to cell fusion (syncytial) formation in infected tumour cells through binding to the constitutively expressed PIT-1 receptor for GALV. This results in the death of the cells by membrane fusion and is also intended to enhance the spread of the virus through the tumour. Since the RP1 selectively replicates in tumour cells, the expression of the GALV-GP-R- is minimised in normal tissues. The oncolytic destruction of tumour cells leads to the release of tumour associated antigens that are intended to engender an antitumour immune response, enhanced by the local expression of GM-CSF. This is intended to be further enhanced through GALV-GP-R- mediated killing, fusion associated cell death which also results in the production of the highly immunogenic exosomes, which is expected to contribute to this immune effect. The immune response generated may then lead to immune destruction of distant, uninjected tumours, and/or delay the progression of distant disease, and/or vaccinate against relapse. RP1 is intended for direct injection into solid tumours.

Host/vector system

RP1 (rHSV-1 hGM-CSF GALV-GP) is derived from the RH018A strain of Herpes Simplex Virus-1. RP1 is produced in the Vero cell and released into the culture media during cell lysis, prior to purification.
RP1 was constructed using a new strain of HSV-1 (strain RH018A). Replimune obtained and compared 30 clinical strains of HSV-1 on a panel of human tumour cell lines and selected the most promising of these (strain RH018A) for further development.

RP1 expresses the immune stimulatory protein GM-CSF, which augments therapeutic activity. GALV-GP-R- binds to the Pit1 receptor, which is widely expressed on mammalian cells including human tumour cells. Pit1 is also critical for cell proliferation, and its expression is therefore unlikely to be lost or down-regulated in response to cancer treatment. The truncated R- version of the protein provides constitutive fusion activity without GALV (i.e. the virus) itself. Expressing GALV-GP-R- together with GM-CSF is expected to increase clinical activity as compared to only expressing GM-CSF. As well as causing direct tumour cell death by cell to cell fusion, cell to cell fusion followed by death is highly immunogenic and includes the release of immunogenic tumour antigen-containing exosomes. Expression of GALV-GP-R- from an oncolytic virus is therefore expected to improve systemic, immune mediated, effects, as well as effects in the directly treated tumour thereby increasing synergy with other immunemediated approaches to cancer therapy such as immune co-inhibitory pathway blockade.

**Origin & function**

As described above (under Recipient or Parental Organism), the oncolytic destruction of tumour cells (upon transduction with RP1) leads to the release of tumour associated antigens that are intended to engender an antitumour immune response, enhanced by the local expression of GM-CSF. This is intended to be further amplified through GALV-GP-R- mediated killing, fusion associated cell death which results in the production of the highly immunogenic exosomes and is expected to contribute to this immune effect. The immune response generated may then lead to immune destruction of distant, uninjected tumours, and/or delay the progression of distant disease, and/or vaccinate against relapse. RP1 is intended for direct injection into solid tumours.

**Evaluation of foreseeable effects**

As described above (under Recipient or Parental Organism), the oncolytic destruction of tumour cells (upon transduction with RP1) leads to the release of tumour associated antigens that are intended to engender an antitumour immune response, enhanced by the local expression of GM-CSF. This is intended to be further amplified through GALV-GP-R- mediated killing, fusion associated cell death which results in the production of the highly immunogenic exosomes and is expected to contribute to this immune effect. The immune response generated may then lead to immune destruction of distant, uninjected tumours, and/or delay the progression of distant disease, and/or vaccinate against relapse. RP1 is intended for direct injection into solid tumours.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

No derogation is requested

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All used and unused RP1 and diluent vials used in preparation and syringes will be destroyed per institutional policy. As per the wild-type HSV-1 virus, the recombinant HSV-1 vector particles that represent RP1 are highly susceptible to dehyration, rapidly inactivated outside the host and easily inactivated (for example with 1 % Virkon solution). As part of phase I of the clinical trial, biodistribution and shedding will be monitored. RP1 DNA levels in blood and urine will be determined at time-points outlined in the Schedule of Assessments of the clinical protocol (day 1, day 3/7/10, day 14, day 21, day 28, day 35, day 42, day 49, day 56 and as part of the follow up, 30 days after the last dose). Blood will be collected after the first, second and third RP1 injections at the following time-points: 1 (±15min), 2 (±15min), and 4 (±15min) hours and also immediately prior to dosing at the second and third dose. RP1 DNA levels and virus from saliva/oral mucosa, injection sites, injection site dressings, and lesions that appear to be herpetic will be determined on the same days.
The feedback was around notification of the laboratory staff for routine bloods for participants on study. These are marked with a red identifier and the lab staff are notified of a participant on study. The risk assessment designated a class I for this GMO in line with a similar study. The Chair has sent a letter on behalf of the Committee for the study to proceed.

Project Ref 985/19.1

Date Ackn'd: 24/10/2019

CU2 Project Title: RP2 is a selectively replication competent herpes simplex virus 1 (HSV-1) which expresses exogenous genes, and is administered by intratumoural injection

Class: Class 2

CultureVolClass2: ≤ 1 Litre

Non-GMM Consent Granted

Withdrawn: N

Tick if notifying a connected programme of work: N

Historical Significant Changes

Historical Date of Additional Info

02/03/2022
### Project Additional Information

#### Purposes of the contained use

RP2 is an interlesionally delivered oncolytic immunotherapy comprised of a genetically engineered HSV-1 (herpes simplex virus type 1) that selectively replicates in tumour cells as part of the Replimune Clinical Trial: An Open-Label, Multicenter, Phase 1 Study of RP2 as a Single Agent and in Combination with PD1 Blockade in Patients with Solid Tumours.

#### Recipient or parental organism

RP2 is a selectively replication competent herpes simplex virus 1 (HSV-1) which expresses exogenous genes, and is administered by intratumoral injection. RP2 was constructed using a new strain of HSV-1 (strain RH018). The neurovirulence factor (ICP34.5) encoding genes and the ICP47 encoding gene are deleted from the virus. The ICP34.5 deletion allows the virus to replicate selectively in tumours. The virus contains a codon-optimised sequence for human granulocyte macrophage colony stimulating factor (hGM-CSF), a cytokine involved in the stimulation of immune responses. In addition, the virus contains a codon-optimised sequence for the gibbon ape leukemia virus surface glycoprotein (GALV-GP) with the R- sequence deleted (R-). GALV-GP-R- causes cell to cell fusion resulting in cell death. The truncated R- version provides constitutive fusion activity, which is intended to be beneficial for tumour treatment. RP2 has been engineered to express anti-human CTLA-4 antibody-like molecule. Anti-human CTLA-4 interferes with the interaction of CTLA-4 (expressed as a subset of activated T cells) with B7 (CD80/CD86) molecules on professional antigen presenting cells. The design and mode(s) of action is similar to that of the previous RP1 trial.

#### Host/vector system

RP2 was constructed using a new isolate of HSV-1 (strain RH018; ECACC Accession Number 1612904). RP2, rHSV-1 hGM-CSF/GALV-GP-R-/ahCTLA-4 RP2 consists of (a) a lipid bilayer envelope derived from host cell membranes, including polyamines, lipids and glycoproteins; (b) a tegument of amorphous material; (c) a capsid made of capsomers arranged in icosapentahedral symmetry; (d) an internal core containing double-stranded DNA of ~160 kilobase pairs.

#### Origin & function

RP2 is a selectively replication competent HSV-1 intended for direct injection into suitable solid tumors. All herpes viruses are comprised of a large double-stranded linear DNA genome that is packaged into an icosahedral nucleocapsid which is approximately 100 nm in diameter. The herpes virus family is classified into different groups based on biological properties such as host cell range, length of replication cycle, and the cell type in which they become latent. Wild type HSV-1 is an alpha herpes virus with a wide host cell range. RP2 is a modified HSV-1 containing the genes coding for hGM-CSF, GALV-GP-R- and anti-hCTLA-4. RP2 was constructed using a new isolate of t1SV-1 (strain RH018; ECACC Accession Number 1612904). The neurovirulence factor ICP34.5 genes and the ICP47 gene are deleted from the virus. The ICP34.5 deletion renders the virus non-pathogenic and allows the virus to replicate selectively in tumor tissue. The role of ICP47 is to block antigen presentation to MHC class I and II molecules by blocking the transporters associated with antigen processing (TAP). This deletion also allows the increased and earlier expression of US11, a gene that promotes growth in tumor
cells without decreasing tumor selectivity. The virus contains the coding sequence for human GM-CSF, a cytokine involved in the stimulation of immune responses. GM-CSF expression is under the control of the hCMV IE promoter. The virus also contains the coding sequence GALV-GP-R-. The truncated R- version provides constitutive fusion activity, which is intended to enhance the spread of virus through the tumor. GALV-GP-R-expression is under the control of the RSV L TR promoter. RP2 also expresses anti-hCTLA-4 with the intent to enhance anti-tumor activity. As stated above, anti-hCTLA4 interferes with the interaction of CTLA-4 (expressed on a subset of activated T cells) with B7 (CD80/CD86) molecules on professional antigen presenting cells. This is intended to result in enhanced T-cell activation due to blockade of the inhibition otherwise mediated by the CTLA-4/B7 interaction. The resulting enhanced local anti-tumor T-cell activation, proliferation, and lymphocyte infiltration into tumors, is intended to lead to improved local and systemic anti-tumor effects both alone and in combination with antibodies targeting PD-1 or PD-L1. Intratumoral expression of the anti-hCTLA4 antibody-like molecule would also be expected to reduce toxicity as compared to the systemic administration of an anti-hCTLA4 antibody, including in combination with antibodies targeting PD-1 or PD-L1.

Evaluation of foreseeable effects

No studies have yet been conducted with RP2 and therefore no data is available. However, as previously described RP2 is an oncolytic immunotherapy product intended for the treatment of solid tumors and is identical to RP1 other than the expression of anti-CTLA-4 from RP2 which RP1 does not express. Whilst no studies have yet begun with RP2, approximately 26 patients have been treated in a phase 1 trial of RP1 in the UK. Patients have been treated with up to 10 mL of 108 PFU/mL in superficial and deep (visceral) cohorts at dose levels of between 104 and 108 PFU/mL. One patient in the low dose deep cohort had a dose limiting toxicity (DLT) of a clinically asymptomatic lipase increase after the third virus dose was administered (106 PFU/mL). Although this resolved without intervention, an additional three subjects were enrolled at the same dose and no further DLTs were observed. Side effects otherwise have been as expected for an oncolytic immunotherapy with low-grade febrile and constitutional symptoms with mild injection site reactions having been seen. The RP2D for use by superficial injection was determined to be a first dose of 106 PFU/mL followed by subsequent doses of 107 PFU/mL.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

We would need a derogation as we do not have an autoclave on site.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Ali used and unused vials will be disposed of as per eee policies and procedures and in line with the IB for RP2. Spills will be treated with a virucidal agent such as 1% sodium hypochlorite or Virkon. All materials contaminated with RP2 will be disposed of in compliance with local institutional eee policies and SOPs. Incineration is appropriate. In the event of exposure to broken skin or needle stick, the site will be cleaned thoroughly with soap and water or a skin disinfectant. A physician for monitoring for signs of infection, occupational health will be contacted for support. Acyclovir or other anti-viral drugs may be administered prophylactically. Our patients will be given full instructions and support from our designated Principal and Co-Investigators and Research Practitioner Team which will include care of any -lesions and advice on any shedding. Our patients will be provided with spare dressings, instruction for use and safe disposal equipment which they can return to eee, they will be given out of hours contact numbers and advice will be on hand by the eee Team if needed and all advice will be in line with Sponsor instruction and the study protocol.
The committee felt that this is an important follow on study to RP1 supported at CCC. The committee felt that the risk assessment for class 1 was appropriate for RP2 as we will only be handling small quantities of virus and not any large mixing as per Sponsor IB; this in our assessment substantially reduces risk and given the structure and attenuation of the IMP, we feel becomes class I. The Chair has sent a letter to the effect that the committee supports the study proceeding.

Please enter comments on the GM safety committee on the risk assessment

The committee felt that this is an important follow on study to RP1 supported at CCC. Give brief details of the genetic modification safety committee

The genetic modification safety committee comprises one member of the senior management team and two members of the laboratory scientific team. The committee meets every two months to discuss the new arising GMO assessments or more frequently should this be required by the Biologics Safety Officer and the initiation of work programmes.

For activities involving GMMs, describe the waste management measures which will apply to the activity

All spent liquid waste that has come into contact with the cell lines or the cell product will be treated with Virkon to a final concentration of a minimum of 1%. The Virkon treatment will last a minimum of overnight approx. 10 hours prior to being disposed of through the normal Babraham drainage system. Virkon is the EPA approved disinfectant. Liquid spillages will be dealt with by the use of an approved spillage kit. Solid waste including plasticware from procedures and laboratory work with the GMO will be placed in a plastic autoclave bag which will be sealed but not completely closed. The waste will be autoclaved and labelled clearly as a biohazard. The autoclave used is sited in the same building as the laboratory. The autoclave is routinely tested every six months ensure the reading of temperature and pressure are correct. The autoclaved waste is transported off site for incineration by Vet Speed (GM ref 98).

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The host and vector systems being used are all standard and as the inserts are unlikely to cause or enhance any pathogenicity the work is assessed as a Class 1 activity.

The GMSC has cleared the work to start on receipt from the HSE that this is applicable.
GM Centre Number: 987

For activities involving GMMs, describe the waste management measures which will apply to the activity

All plastic and glassware and microbiological plates and cultures will be autoclaved at 134°C for 30 mins (waste decont cycle) prior to disposal. This autoclave cycle is designed to give 100% kill of all bacteria and GMMs. All work surfaces and spills will be disinfected with 1% Virkon solution in accordance with the manufacturers recommendations.

Autoclaves are validated annually for insurance purposes and will be serviced annually. NB the autoclaves were purchased in Jan 2006 therefore the first service will be Aug/Sept. 2007 after the end of the warranty period.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The Genetic Modification Safety Committee (GMSC) met on 20-06-07 to evaluate the risk assessments for the proposed GMO activities (see attached documentation). The committee reviewed and approved both risk assessments following minor modifications.

1. Include details about disinfecting surfaces and spill where GMM activities are performed (section 4 applications GMO001 & GMO002)
2. Provide further details of associated hazards relating to work with bacteriophages (section 2 application GMO002)

All GMO activities were approved as class1.

NB - the project supervisors for these applications are members of the GMSC. However neither supervisor was present when the committee discussed or approved their risk assessment. Likewise, for GMO001, relinquished the role of Biological Safety Officer so as not to be involved in the approval of there own risk assessment. For this application only a suitably qualified member of the GMSC acted as Biological Safety Officer.
Purposes of the contained use

To enable the generation of self-inactivating third generation recombinant lentiviral particles that encode:
- Specific open reading frames (ORFs)
- encoding for wild type proteins involved in DNA replication and repair
- mutated / truncated forms of above proteins
- tagged forms of wild-type and mutated / truncated forms of above proteins
- Short hairpin (shRNA) sequences for the knockdown of expression of ORFs by RNA interference
- The generation and in vitro use of stable mammalian cell lines for the purpose of
- studying the cellular effect of knockdown of gene expression of above proteins
- studying the cellular effect of overexpressing ORFs
- establishing cellular / in vitro disease models
- identifying druggable targets in DNA replication and repair pathways
- verifying such druggable targets

Recipient or parental organism

i) E. coli K12 strains for facilitating cloning and propagation of plasmid DNA:
- DH5alpha, SURE for generic use
- STBL3 for cloning and propagating shRNA sequences
E. coli K12 strains are attenuated, non-colonising, non-pathogenic strains, unlikely to survive outside the laboratory and have a long history of safe use, and are regarded as non-hazardous
ii) the HEK293T packaging cell line for the assembly and packaging of lenticiral particles. Infectious viral particles are generated by the packaging cell line and secreted into the medium at high viral titre. Risk is associated with the high titer of infectious viral particles.

iii) recipient cell lines. These cells are exposed to the high titre virus suspension generated in the packaging cells. The viral genome is integrated into the genome of the recipient cell line but because of the design of the system (third generation lentiviral vectors) the virus is incapable of further replication. The transduced cell lines, therefore, pose no further risk compared to the recipient cell lines.

Host/vector system

Third generation lentiviral vectors will be used throughout the work, which are replication incompetent and self inactivating (SIN). The systems separate the packaging signals and viral LTRs on the expression plasmid from the viral structural and expression genes (gag, pol and rev from FIV or HIV and viral envelope glycoproteins such as the VSV-G gene from Vesicular Stomatitis Virus, in place of HIV or FIV env). The viral structural and expression genes and the envelope glycoprotein genes are separated on at least two additional plasmids. Deletion of accessory genes vpr, vpu, vif and nef mean that the vector is unable to replicate once it has transduced the target cell. In addition third generation lentivirus are deleted for the tat gene and carry a SIN deletion of the 3' LTR (ΔU3) which results in "selfinactivation" of the lentivirus following transduction of the target cell, precluding adventitious activation of the vector by endogenous retroviruses and minimising the risk of recombination with ERVs. In particular, the pLKO.1, pLenti6, and pLenti-DEST vectors will be used.

The packaging cell line HEK293T (and its derivatives) is generated from the well-characterised 293 human embryonic kidney cell line (Pear et al., PNAS 1993; 80; 8392; ATCC CRL-11268). This cell line stably and constitutively expresses a temperature-sensitive version of the SV40 large T antigen.

The recipient cell lines are well established laboratory cell lines (for example, but not exclusively, HeLa, U2OS); normal / transformed / immortalised fibroblasts (for example, but not exclusively, MRC5, GM00637, WI38, HS68tert); normal and immortalised mesenchymal stem cells

Origin & function

i) The cDNA fragments of ORFs will be produced from RNA prepared from laboratory cell lines, reverse transcribed with reverse transcriptase (e.g. AccuScript, Agilent) and PCR amplified with purpose designed primers (for truncation, mutagenesis or Gateway cloning). PCR amplified cDNA fragments will be inserted into suitable primary cloning vectors (Gateway or TA cloning vectors). Insert from the primary constructs will be transferred into suitable expression vectors with or without tagging.

ii) shRNA -encoding DNA fragments will be chemically synthesised and inserted into pLKO.1 vector. Transduction with shRNA-bearing vectors will result in siRNA mediated knockdown of target genes. Physiological effect of knockdown will be studied in vitro using microscopic and molecular biology techniques. The effect of overexpression of wild type and mutated / truncated forms of proteins will be studied in similar techniques. Expressing of wild type and mutated / truncated forms in the background of knocked-down expression will permit ‘rescue’ of the knock-down phenotype, and will provide a functional map of the re-expressed protein.

Evaluation of foreseeable effects

i) Characteristics of the host, virus or viral vector and any hazards associated with it

The transfer vector systems are derived from FIV or HIV (feline or human immunodeficiency virus, respectively) and have been specifically engineered for biosafety by separating the packaging signals and viral LTR's on the expression plasmid from the viral structural and expression genes (gag, pol and rev from FIV or HIV and the VSV-G gene from Vesicular Stomatitis Virus, or similar alternatives, in place of FIV or HIV env) encoded on three or four separate
plasmids, which remain in the packaging cell line, effectively precluding the production of replication competent virus in the target cell or should the viral vector escape containment. FIV vectors are included as they may be more efficient for some cell types. It does not imply any different containment or risk considerations than HIV based vectors. The plasmids expressing these gene products carry no packaging signals or LTRs and so cannot themselves be mobilised with the vector and have been engineered not to contain any regions of homology to each other or to the viral vector, to prevent undesirable recombination events that might result in replication competent virus being produced. Reversion to wild type is extremely unlikely given that several recombination events would be needed to reconstitute an active viral genome, the viral genes are present on three different plasmids, which have minimal sequence homology and the viruses are self-inactivating following insertion (i.e. the LTR’s are destroyed upon genome insertion).

The viral vector would be able to transduce many tissues should it come in contact with them. The major hazard is therefore represented by the packaged virus prior to infection of the target cells and residual virus in the medium of infected cells. The two potential transmission routes are by external exposure (either skin lesions or mucous membranes; only in the case of very high titres and aerosol production) and by accidental injection/inoculation using sharps. The following safety measures will be employed to minimise these risks:
- The work will be carried out in a restricted area in a designated Class II laminar flow safety cabinet.
- The usage of sharps of any kind is strictly forbidden.
- Researchers working with active viral particles will be wearing double-gloves
- Additional PPE: safety goggles, labcoat, disposable plastic sleeve covers will provide additional barrier for the protection of experimenters.
- Liquid waste will be disinfected with 1% Virkon solution, which is a widely used disinfection reagent capable of inactivating all known viruses.
- Culture vessels and other plasticware that has been in contact with live virus particles are collected in Biohazard bags inside the cabinet. Closed bags are decontaminated with 70% ethanol on the outer surface and autoclaved.
- All centrifugation step is conducted in an aerosol tight container and rotor; contaminated liquids and solids are treated as above.

Severity of harm is MINOR given that infection of human tissue if achieved would be with non-replicable virus and low-efficiency. Likelihood of harm is deemed to be LOW. The Standard Operating Procedures document set out rules for safe working with lentiviral vectors, in particular for avoiding contamination. The usage of sharps is strictly forbidden. Viral titre is expected to be between 0.5-5x10^6 IU/ml. The virus is generally weak and does not survive long outside of buffered solutions. Infection requires optimal conditions and the use of additives in cell culture. Immune competent mice show sterilising immunity with wild-type virus infection; humans would also show such sterilising immunity. Risk is generally speaking no greater than that of handling human tissue or bodily fluids i.e. relatively safe given that proper precautions are taken to avoid infection.

ii) Characteristics of the inserted sequences, and any hazards associated with it

Ectopic expression / overexpression of ORFs will be driven by strong constitutive promoters. Lentiviral transfer of such constructs is associated with hazards of modifying cells, including those of the researchers should accidents happen. However, due to the very low infecting efficiency of the virus, and its inability to replicate, the risk is low unless the viral vectors carry oncogenes / proto-oncogenes. ORFs with known oncogenic potential will be excluded from the work.

There is further risk associated with lentivirus vectors carrying shRNA cassettes. Here the major risk is knockdown of expression of tumour suppressors. ORFs with known tumour suppressor activity will be excluded from the work. In addition, target sequences that may affect virulence genes or associated regulatory pathways will also be excluded. Off-target effect of shRNA cassettes are minimised by careful design of the target sequence that includes database searches to exclude sequences with effective homology to other targets.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

There is not intention to use larger GMOs.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be disinfected using Virkon (oxone (potassium peroxymonosulphate), sodium dodecylbenzenesulfonate, sulphamic acid; and inorganic buffers) which is expected to give 100% kill of any organisms. Virkon is widely accepted as the correct agent to disinfect bacteria, viruses, fungi and cultured cells, and approved for use against HIV. Solid waste is collected in Biohazard bags inside the biological safety cabinet. Closed bags are sprayed with 70% ethanol on the outside surface, then transferred for autoclaving. Autoclaving is performed at 134 deg C at 15 psi for 45 minutes to give 100% kill of organisms.

This project has been considered by the full GMSC and following revisions recommended by the committee, has been approved at containment level 2.

Y

Give brief details of the genetic modification safety committee

The Genetic Modification Safety Committee (GMSC) consists of the Chief Executive Officer, the Biological Safety Officer and VP Engineering.

The GMSC meets on a quarterly basis with additional meetings as and when necessary. The committee seeks to understand the risks both to human health and the environment. The GMSC advise, discuss and judge on all GMO risk assessments, which supersedes other laboratory risk assessments. The committee will seek and appoint extra sources of advice, where necessary. The committee is also responsible for consulting all staff on health and safety issues. The committee will discuss and act upon any recommendations by the Biological Safety Officer.

Laboratory | Animal Unit | Growth Room | Glass House | Large Scale
---|-------------|-------------|-------------|-------------|
Level 1 (GMMs) | Yes         |             |             |             |
Level 2 (GMMs) |             |             |             |             |
Level 3 (GMMs) |             |             |             |             |
Level 4 (GMMs) |             |             |             |             |
Non-microbial |             |             |             |             |
Work surfaces are wiped down with chemical disinfectants (Virkon or equivalent) at the end of each procedure. Spillages are decontaminated with powder chemical disinfectants (Virkon or equivalent). As much as practically possible, the work will be done in a class 2 biological safety cabinet (serviced annually) to reduce contamination to samples and reduce the aerosol exposure to workers and the environment. The solid and liquid waste generated from the GMO work is deactivated by autoclaving at 121°C for 22 mins. The autoclaving process is validated via use of commercial autoclave tape which gives a visual indication that it has been exposed to the correct sterilisation conditions. The autoclave equipment is serviced annually to ensure that performance of the sterilisation equipment. The degree of kill via a correctly-operating autoclave is 100%. Treated waste are then collected and disposed by licenced laboratory hazardous waste companies.

Tick if you are claiming exemption from disclosure for sections of the risk assessment □

Tick to confirm that you are attaching a summary of the risk assessment Y

Please enter comments of the GM safety committee on the risk assessment

The risk assessment is appropriate and has considered all potential hazards to humans and the environment. The committee agrees with the classification of the activity as class 1.

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Give brief details of the genetic modification safety committee

A Genetic Modification Safety Committee (GMSC) has been established within the Trust, reporting through the Risk Management Committee of the Renal Unit within the South West Thames Institute for Renal Research (SWITRR) co-locates, from here to the Clinical Networks Division Risk Management Committee and finally into Epsom and St. Helier University Hospitals Trust Health and Safety Committee (HSC) who are responsible for Health & Safety within the Trust, reporting to the Trust Executive Board. The GMSC comprised Scientific Director (SWITRR) as Chair and Biological Safety Advisor, Deputy Scientific Director (SWITRR) as Biological Safety Officer, Trust Risk Management Advisor and HSC liason, Microbiology Medical Scientist, Consultant Immunologist, R&D Manager, post-doctoral research scientist and PhD student working in this area, and two external scientific advisors available as necessary. The committee meets 3x annually to assess proposals, risk assessments, incident reports, assign containment levels and to monitor GM work in the Trust to ensure safe and best practice.

Yes

All procedures will follow the standards of Good Microbiological Practice and Good Occupational Safety & Hygiene. All work will be conducted to the requirements for containment level 1. The bench surfaces in the laboratory are easily cleaned, impervious to water, resistant to acids, alkalis, solvents, disinfectants and other decontamination agents in use. A spill tray with disposable covers will be used to provide environmental and personal protection and ease of decontamination should such a need be identified. Routine disinfection will use 1% hypochlorite solution on all surfaces except metal and equipment where 70% aqueous alcohol will be used in accordance with the Trust Infection Control Guidelines. At least a 5log kill in the treated areas is expected. Hand washing facilities and a supply of soap are provided in the laboratory. The laboratory is equipped with a dedicated safety cabinet and all associated equipment for experimental procedures involving GMM. An autoclave and dishwasher are also located in the laboratory for safe decontamination and disposal of GMM waste at source. The autoclave is serviced routinely under contract to ensure calibration and proper working order. All contaminated material, including waste destined for incineration, will be inactivated by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Each run will be monitored using TST (Time, Steam and Temperature) test strips (Albert Browne Ltd., TST class 6 emulating indicator 121°C for 20 min). All inactivated waste will then be disposed of through Trust clinical waste management procedures. Work surface and equipment contamination will be tested quarterly by Microbiology excepting in the event of a spill where affected areas will be tested by Microbiology for the presence of relevant organisms after appropriate decontamination. The laboratory will be inspected on a quarterly basis. Remedial action will be identified and enforced as necessary.

Tick to confirm that you are attaching a summary of the risk assessment Y

Tick if you are claiming exemption from disclosure for sections of the risk assessment

The committee accepted that the organism and vectors under discussion fell under the category of a recognised disabled micro-organism and that the vectors were not mobilisable. The modifications proposed were considered unlikely to alter these characteristics. The appropriate and due diligence had been paid to the potential risk of harm to personnel and the environment and that appropriate control measures had been described. The committee accepted the proposal for and assigned an activity class 1 and containment level 1 status for this proposal. The facilities provided were demonstrated to exceed the requirements for such a containment level and approval was given to the project subject to the Chair notifying HSE that this Institution was wanting to start work under the Genetically Modified Organisms (Contained Use) Regulations 2000 and acknowledgement by the HSE of receipt of that notification.

In our view there is no problem with this proposal. The vaccinia strain is highly attenuated and the data on its safety are impressive. That other sites have approved its use without significant modification and that it has already been given to my patients with renal and other cancers convinces us that we are happy for the study to go ahead.

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Y

Give brief details of the genetic modification safety committee

Comprises 5 individuals: (i) Operations Director, serving as senior management representative; (ii) Director of Virology, serving as acting Health & Safety Manager/BSO, and chair of committee; (iii) Molecular Biology Manager and (iv) Virology Manager serving as representatives from the two technical divisions; and (v) QA Manager, serving as representative for the non-technical, support staff who may be present in laboratory areas where GMO work conducted, and/or provide equipment maintenance etc. Individuals also provide relevant experience in the areas of virology, molecular biology, and microbiology. Meetings will be held every 2 months, and more often if required. Minutes will be reported to general safety committee, and made available to all staff, either electronically or by posting on H&S noticeboard.

</table>
Yes

Yes

See attached RA for further details.

Briefly: Liquid waste will be disinfected using a minimum of 1% Virkon, or by autoclaving (with/without prior chemical inactivation). Solid waste contaminated with GMMs will be autoclaved on site, prior to uplift for secondary inactivation (incineration). At least 5 log kill would be envisaged, based on manufacturers information, for Virkon. Surfaces potentially in contact with GMMs will be cleaned routinely using 2% virkon. Validation studies to confirm the effectiveness of procedures used for inactivation of model agents will be performed, once assays are in place. SOPs govern all working practices, and all equipment is maintained and checked / validated at regular intervals, including the autoclave.

Tick to confirm that you are attaching a summary of the risk assessment  

Tick if you are claiming exemption from disclosure for sections of the risk assessment  

Please enter comments of the GM safety committee on the risk assessment
The risk assessment is intended to cover the performance of all envisaged class 1 and 2 activities (form CU2 for class 2 activities also enclosed).

The RA was reviewed by the GMSC members, and comments incorporated. Comments were minor, and principles covered were agreed/approved by the committee. Committee noted for internal purposes that storage boxes for the transport of samples between laboratory areas should be sourced, and training in biological safety, including GM regulations, should be arranged.

**Historical Significant Changes**

**Historical Date of Additional Info**

**Significant Change ID** 992/07.1a

**Date of Significant Change** 28/04/2014

**Project Additional Information**

**Purposes of the contained use**

To perform biological safety testing of GMMs used in the production of biopharmaceuticals, or intended for use as vaccines, gene therapy vectors, or anti-cancer therapies. The majority of tests are designed to allow the detection of adventitious agents present within the client's materials, through the use of cell culture or PCR-based assays. These assays will form part of regulatory studies to support the safety of products at various stages of development (pre-clinical, clinical, licenced).

**Recipient or parental organism**

May include prokaryotic or eukaryotic cells, and plasmid or virus vectors (see also below). See The risk assessment for further details.

**Host/vector system**
Prokaryotic cells, such as E.coli, containing plasmid vectors (typically disabled or non-colonising host, with non-mobilisable / mobilisation defective vectors); mammalian cell lines containing stably inserted gene constructs:

- virus vectors (e.g., baculovirus, avipoxviruses, sendai virus, adenovirus, herpesvirus, retrovirus (usually based on simple oncoviruses), vaccinia, MVA)

See attached risk assessment for further details

**Origin & function**

The majority of samples submitted for testing will include: prokaryotic and eukaryotic cells expressing therapeutic proteins, including monoclonal antibodies; mammalian cells expressing helper functions to support the growth of replication defective virus vectors (helper and/or packaging cell lines); and virus vectors and attenuated viruses typically intended for use as vaccines, or for use in gene therapy or the treatment of neoplasia.

The inserted genes will therefore typically encode: therapeutic proteins (such as hormones (e.g., erythropoietin, growth factor, insulin), cytokines, coagulation factors) intended to replace normal human proteins deficient or absent in certain individuals or conditions; monoclonal antibodies; vaccine antigens, derived from various pathogens, often representing surface proteins; and detectable I selectable markers. Immune-modulatory genes may also be incorporated in some constructs, to enhance the immune response to the expressed immunogen.

See attached risk assessment for further details, and additional examples.

**Evaluation of foreseeable effects**

The majority of the GMMs submitted for testing will be derived from hazard group 1 or 2 agents, and contain inserts considered unlikely to significantly increase the risk of the construct, or containment level required, with respect to human health and the environment.

Most recombinant cells expressing therapeutic products would be expected to fall into GM activity class 1, although as many of the products may represent hormones or cytokines or novel constructs where the range of functions may not be known, additional precautions or higher containment may be required in some cases (e.g., pregnant women may be advised not to handle GMM5 expressing growth hormones where high level exposure could theoretically occur).

Vectors intended for use as live vaccines or for cancer! gene therapy are likely to be capable of entering, if not productively replicating, in human cells, and thus the potential for integration into the host cell genome, and/or long term expression, will be considered in deriving the final classification. For example, retrovirus vectors based on simple oncoviruses such as MLV, pseudotyped with an Env protein with tropism for human cells, will be classed as GM activity class 2, due to the potential for integration, and insertional mutagenesis. As replication competent virus (RCV) can be generated during the construction of most vectors, replication incompetent vectors will be classified at a similar level to the parent virus, as a minimum, unless evidence to show freedom from RCV is provided. Although in most instances it is unlikely that inserted genes would significantly increase the risk of a construct, there may be uncertainties with respect to the impact on pathogenicity (eg, inclusion of immune modulatory genes, or virus envelope proteins that could in theory alter the host range or tropism of the parent organism), and there may be some situations where additional precautions and/or higher containment is required.

Most processes are not envisaged to significantly impact on the containment requirements for most constructs, but some situations, e.g., tissue culture work where there may be a risk of recombination / rescue due to superinfection or the presence of endogenous virus sequences within a cell, may require additional precautions / higher containment.

Further discussion is contained within the attached risk assessment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

| n/a |

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

| n/a |

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

- Liquid waste will be inactivated by incubating overnight in a minimum of 1% virkon, or by autoclaving (with/without prior chemical inactivation). 5 log kill would be anticipated from the manufacturers’ information for virkon.
Solid waste contaminated with GMMs will be autoclaved on site, prior to uplift for incineration. Surfaces potentially in contact with GMMs will be cleaned routinely using 2% virkon. Spills will be disinfected using virkon (solid powder or 2% solution), and if necessary, biosafety cabinets may be disinfected by fumigation, using either formaldehyde or vapourised hydrogen peroxide (VHP).

Validation studies to determine the effectiveness of virkon, and fumigation, in inactivating a range of model agents will be performed once the relevant assays are in place. Initially, formaldehyde fumigation will be used for cabinets, as this is known to be effective for a broad range of organisms. However, it is intended to replace this with VHP, if this is shown to be effective in our hands.

Standard Operating Procedures govern all working practices, including the preparation of disinfectants, cleaning and spills policies, and disposal of waste. All equipment is validated and monitored on a regular basis, including the autoclave, air handling and biosafety cabinets. See attached risk assessment for further detail.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The risk assessment was reviewed by the GMSC members, and their comments incorporated. There were no major comments, and the committee was satisfied with the containment measures proposed. The principles I working practices described in the assessment were agreed / approved by the committee.

02/03/2022
All waste containing GMM's or exposed to GMM's will be treated according to the Company's standard operating procedure for biohazardous waste. It will be decontaminated by treatment with a suitable disinfectant prior to being securely bagged, sealed and sent for incineration by an approved contractor. Liquid waste will be decontaminated with disinfectant prior to disposal by a suitable route depending on the nature of the liquid. If these methods are deemed not to be suitable for particular items, they will be made safe by autoclaving in the company's on-site autoclave prior to disposal by incineration. The estimated degree of kill by these combined methods is extremely close to 100%.

### Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities: **Y**

Give brief details of the genetic modification safety committee:

The requirement for this notification has come about because of Medical Solutions acquisition of Geneservices Ltd and that some of the Geneservice business is being relocated to Nottingham. A GMSC had already been established at Geneservices and this will remain, incorporating those individuals from the previous GMSC still present within the new company (Medical Solutions) and all the present members of the Medical Solutions Safety Review Committee. The GMSC will meet concurrently with the Medical Solutions Safety Committee. The following members of staff constitute the GMSC: (Quality Assurance Manager), (Head of Operations), (Resource Development Manager, BSO), (Safety Officer), (Deputy Safety Officer), (Chief Laboratory Scientist),

Disposal of biohazard waste

Used tips, tubes and inoculating loops are to be placed in ‘sweetie jars’, these are then taped shut with biohazard tape and placed in the yellow biohazard bags. Items such as disposable gloves or paper tissues contaminated with low hazard waste should be disposed of as Biohazard waste. Solid microbial waste will be placed in yellow bags and disposed in the same way as biological waste. All biohazard waste will be placed in yellow bags (double bagged), these are then sealed and autoclaved prior to collection via a designated waste disposal agent for incineration.

The agent used is:
Polkacrest

Disposal of microbial cultures

Aqueous microbial cultures are to be treated with Virkon at a final concentration of 1% w/v, left for a minimum of overnight before discarding via the drain with copious amounts of water.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment
Risk assessment

The host vector systems and constructs satisfy the requirements for Group 1. The host strains are all K12 disabled, and the vectors are non-mobilisable. The likelihood of the hazard is therefore negligible and the environmental risk effectively zero.

Risk assessment Sequencing doc

This service aims to sequence already cloned DNA templates, which are sent in by customers. The cloned DNA is effectively random, as far as the service is concerned, but will already have been cloned into the appropriate host/vector system. Once received, the service grows up small volumes of the cells, to obtain a sufficient quantity to extract the DNA and then sequence it. The host/vector systems are all standard and since the inserts are highly unlikely to enhance the pathogenicity, the work is correctly assessed as Class 1.

One additional factor is that some DNAs could be potentially hazardous and it is recommended that all naked DNA should be handled appropriately to cover this hazard, ie DNA should be handled as set out in the ACGM Compendium of Guidance, Part 3A, Annex I, paras. 8-10; ie gloves should be worn, sharps avoided and all wastes be rendered harmless before disposal.

Clearance has been given by the GMSC that work can be started, pending receipt from the HSE.

02/03/2022
Yes

Prior to unloading an Isolator the contents will be decontaminated by gassing with a mixture of Hydrogen Peroxide and Peracetic Acid vapours.

Solid re-usable items of equipment will be subjected to further chemical decontamination (hypochlorite treatment) and dry heat sterilization.

Solid disposable items will be subjected to further chemical decontamination (hypochlorite treatment) and/or disposal as clinical waste (off site Incineration).

Liquid waste will be subjected to further chemical decontamination (hypochlorite treatment) prior to discharge from the facility. No active residues will be discharged into the facilities drainage system.

The facilities drainage system is "stand alone" there being no connection with the local mains drainage. Waste will be discharged into a bunded holding tank for disposal by a licensed contractor.

Risk Assessment agreed by Nova members of safety committee.

Project Ref 995/07.1

Date Ackn'd 09/11/2007

CU2 Project Title Aseptic filling of a human vaccine containing a modified HSV 1.

Class 2

Culture Volume Class 2

Culture Volume Class 3-4

Non-GMM Consent Granted

Not Applicable
**Project Additional Information**

**Purposes of the contained use**

To prevent filling operators being infected by live virus and to prevent product cross-contamination within the Nova “live biologics” facility (Building C).

**Recipient or parental organism**

Confidential customer information. Nova receives pre-modified bulk virus for filling into final containers that are used for human vaccination. No fermentation or modification of micro-organisms is performed by Nova.

**Host/vector system**

Modified
HSV 1. Nature of modification is commercially confidential.
Tests have
confirmed that modification does not increase the pathogenicity of the virus beyond Level 2.

**Origin & function**

For human vaccination.

**Evaluation of foreseeable effects**

The primary route of infection is oral.
Since aerosols are not believed capable of transmitting infective virus, normal cGMP handling including the use of isolator technology to maintain sterility of the product will provide protection for the operators.
For infection to occur the virus would need to enter cells that are capable of sustained rapid division, consequently "sharps injuries" are unlikely to lead to infection. Even so the process is designed to minimise the use of sharps during the filling procedures.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**
Heat treatment and/or disinfectant treatments to achieve 100% kill. Prior to unloading an isolator the contents will be decontaminated by gassing with a mixture of hydrogen peroxide and Per-Acetic Acid vapours. Solid re-useable items of equipment will be subjected to further chemical decontamination (hypochlorite treatment) and dry heat sterilization. Solid disposable items will be subjected to further chemical decontamination (hypochlorite treatment) and/or disposal as clinical waste (off site incineration). Liquid waste will be subjected to further chemical decontamination (hypochlorite treatment) prior to discharge from the facility. No active residues will be discharged into the facilities drainage system. The facilities drainage system is “stand alone” there being no connection with the local mains drainage. Waste will be discharged into a bunded holding tank for disposal by a licensed contractor.

Project Additional Information

Purposes of the contained use
Filling of an investigational, genetically modified adenovirus into vials for therapeutic use.
Full containment in a flexible film isolator to assure maintenance of mono-culture status (i.e. ensure purity) of the product during aseptic filling (i.e. to prevent ingress of contaminating organisms derived from personnel and the environment).

Recipient or parental organism
The therapeutic product is a genetically modified replication deficient, human adenvirus serotype 5.
It is ACDP level 2 requiring Containment level 2.

Host/vector system
The GMM was produced in HEK293 packaging cell lines and only infects CAR expressing cells.

Origin & function
The GMM was produced, purified and released in Switzerland in accordance with good manufacturing practice (GMP) regulations, and is fully characterised and safety tested. Nova Laboratories has the facility and capability to fill the virus into sealed vials, which are then intended for further human clinical trials in North America.
The material has been developed to activate immune cells to enhance the recognition of infection and viral resistance. Data from nonclinical and human clinical studies have shown acceptable safety profiles.

Evaluation of foreseeable effects
The therapeutic product has demonstrated a good safety profile with the effects of exposure to this and similar organisms well documented. Other than potential host organisms, it is considered that there are no environmental niches or habitats that would be affected, either directly or indirectly, by exposure to this product. The GMM is replication deficient, and is deemed a weaker pathogen than the native adenovirus. It is also susceptible to common disinfectants and cleaning agents (e.g. 1% sodium hypochlorite, 2% glutaraldehyde, 0.25% sodium dodecyl sulfate, and 70% ethanol) and is thermally unstable above 56°C, pH sensitive, and will be contained within an isolator during aseptic processing to protect the product and ensure its purity. The bulk drug substance and finished product will be frozen during storage and transportation. No laboratory manipulation or clinical administration will occur at Nova’s facility. There are systems in place to prevent the vaccine product or any waste associated with the manufacture from affecting the surrounding ecosystem.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
The containment for process requirements & good manufacturing practice (GMP) are more stringent than those required for protection of human health and the environment. In this case Class 2 activities requiring Containment Level 2 are performed at a significantly higher level in order to ensure product purity and prevent contamination from operators or the environment, hence the use of gassed isolators which are commonly used for such purposes at Nova Laboratories.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The isolator is pre- & post-sterilised by gassing using hydrogen peroxide/peracetic acid vapour that will be validated with respect to lethal efficacy against the virus dried on to various test substrates. All liquid waste is chemically inactivated prior to disposal through a contained drain into a holding tank. The virus is also sensitive to pH, common disinfectants (e.g. sodium hypochlorite, glutaldehyde, sodium dodecyl sulfate) and 1N sodium hydroxide (NaOH).

Is an emergency plan required according to regulation 20? [N]  
If yes, tick to confirm that it is attached to this form [N]  
Tick to confirm that you have attached a risk assessment to this form [Y]  
Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

Please enter comments on the GM safety committee on the risk assessment

The safety committee has taken note of the full risk assessment and the procedure to be deployed at Nova. The processes required to ensure aseptic manufacture in a gassed isolator are deemed more than adequate for handling a class 2 adenovirus in small batch quantities.

</tbody>
</table>
**Project Additional Information**

**Purposes of the contained use**

This is an aseptic fill and finish activity for manufacturing studies with view to developing patient-ready doses of an Investigational Medicinal Product, and later licensed drug product from a live attenuated viral vaccine in the future.

Full containment in a flexible film isolator is primarily to assure maintenance of mono-culture status of the product during aseptic filling (i.e. prevent ingress of contamination from personnel and/or the environment).

**Recipient or parental organism**

AAV2-hRPE65v2 employs the adeno-associated virus (AAV) as a delivery vehicle for the normal human RPE65 gene; the recombinant vector is a non-enveloped icosahedral virion of approximately 65nm in diameter. Recombinant AAV will be used to express human retinal pigment epithelial 65kDa protein (hRPE65).

**Host/vector system**

The AAV2-hRPE65v2 gene transfer vector is based on Adeno-Associated Virus (AAV), a non-pathogenic, helper virus-dependent member of the parvovirus family of small, non-enveloped viruses. AAV’s single-stranded DNA genome only contains two genes, the Rep gene that codes for proteins involved in DNA replication, and the Cap gene, which through a differential splicing mechanism encodes three amino-terminal variant virus proteins, VP1, VP2 and VP3, that make up the coat of the virus.

**Origin & function**

The drug substance is to be supplied from our U.S. based client. It is intended for manufacturing process development with view to launch of a medicinal drug product. As an Investigation Medicinal Product it has demonstrated an excellent safety profile in human clinical studies.

**Evaluation of foreseeable effects**

AAV is not known to cause any diseases in humans or animals. AAV viruses are not associated with any human disease; however, there is evidence of AAV infection in the human embryo and an association of AAV with male infertility.

Biosafety level 2 contaminant is required, however all handling of this material will be in fully contained isolators to prevent contamination of the product from organisms derived from personnel or the environment. Normal cGMP handling using isolator technology to maintain the monoculture status of the drug product will provide more than sufficient protection for operators.

Methods of inactivation have been identified and approved including chemical treatment with sodium hypochlorite for 20 minutes.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

02/03/2022
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None - Biosafety level 2 containment will be utilised throughout the process. In addition, product filling activities will be undertaken in an isolator in order to prevent contamination of the product from organisms derived from personnel or the environment. In addition, this will provide more than sufficient protection for operators.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The isolator is pre- & post-sterilised by gassing using hydrogen peroxide/peracetic acid vapour that will be validated with respect to lethal efficacy against the virus dried on to various test substrates. All solid waste is chemically inactivated prior to disposal by a specialist licensed contractor. All liquid waste is chemically inactivated prior to disposal through a contained, dedicated drain to a dedicated holding tank, which is emptied by a specialist licensed contractor.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form  

Tick to confirm that you have attached a risk assessment to this form  

Tick if you are claiming exemption from disclosure for section of the risk assessment  

Please enter comments on the GM safety committee on the risk assessment

The viral vaccine can be handled in accordance with standard operating procedures for handling live biologics in Nova Laboratories dedicated facilities. The GMM has demonstrated an excellent safety profile during use in Human Clinical Trials and can be readily deactivated via the use of Sodium hypochlorite (1-10% dilution)

The safety committee has taken note of the full risk assessment and the procedure to be deployed at Nova. The processes required to ensure aseptic manufacture in a gassed isolator are deemed more than adequate for handling a class 2 virus in small batch quantity

For activities involving GMMs, describe the waste management measures which will apply to the activity

Genetically Modified Material (GMM), double-bagged and labelled by the waste producer at the point of collection will be transported directly to our site in 660 litre double skinned galvanised lockable trucks. The material will be destroyed by incineration in a HS Thermal 500 incinerator at temperatures in excess of 550 degrees centigrade under Section 5.1 Part B of the Pollution Prevention Control Regulations 2000. The incinerator of a hot hearth design, is strictly operated under the Secretary of State’s Guidance for Animal Carcase Incineration. Temperatures and emissions are monitored and regularly inspected by Environmental Protection & the Local Authority- The inert ash remains will be transported by a Registered Waste Carrier to an approved landfill site.

Waste material will be transported under Environment Agency Waste Carriers Registration number AEA/792563. Biosecurity for the transport of the waste from the producer to the Peaceful Pets site is of the utmost importance. To minimise the risk of contamination whilst the waste is in transit the Biosecurity Guidance for the National Fallen Stock Scheme will be implemented. The Guidance covers specific vehicle design, safe handling of waste, use of disinfectants and vehicle signage. DEFRA through the State Veterinary Service visit the site on a regular basis to inspect incinerators, vehicles and relevant paperwork.

The double-skinned galvanised 660 litre bins containing the labelled, double-bagged GMM will be tail-lifted onto a specifically designed vehicle for transport. The driver will be competent and familiar with the biosecurity guidance. Bins will be mechanically tipped and loaded into the incinerator. Throughout transportation and loading into the incinerator a complete spillage containment kit will be close by. The galvanised bins are thoroughly washed and disinfected using a DEFRA approved chemical at the recommended concentration. Throughout the transport and disposal procedure appropriate protective clothing and footwear will be worn. Relevant records of collection, incineration and disposal of the inert ash will be maintained for traceability and Duty of Care.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The producer of the material’s genetic modification safety committee will consider the risk assessment to the environment appropriate for such a Class 1 activity. The Chair of the GM safety committee advises the inactivation or containment of the GMM’s in the infected animals is the responsibility of the waste producer who deposits the carcasses into hermetically sealed bags before transportation.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Amura will dispose of its materials using services provided by the Babraham Bioscience Technologies ("BBT"). In summary- Category 1 waste will be disposed of in hermetically sealed and labelled 30L or 60L yellow boxes with yellow lids. Boxes will be labelled and logged (on clipboards) before collection and disposal by BBT. The labels must show: The BRC registration number (NFK 619), the Company (Amura), Building number and Date. The box must be logged on the clipboard provided before placing in the external yellow bins located outside the above BBT buildings. Manual handling guidelines should be observed by all staff moving the bins. BBT has contracted VetSpeed (Royston) to remove materials off-site, treat materials to inactivate material (autoclaving) and subsequent disposal of materials.

Please enter comments of the GM safety committee on the risk assessment

Amura has adequately and appropriately addressed the health and safety assessment in relation to:
i. operators and non-operators (e.g. visitors and non-scientific staff)
ii. environmental issues (e.g. site access, storage, waste management, etc.) required to fulfil its objectives.
Amura is advised to continually and actively review its procedures to ensure that the processes and associated risk! assessment remains relevant for the use intended.

Yes

Only small scale liquid waste will be generated (cs litres at any one time). Liquid waste will be collected and inactivated using chlorine based disinfectant (eg. Chloros) prior to sink disposal.
Solid waste will either be collected as sharps solid waste and treated as described below, or will be collected in buckets lined with autoclave bags, which will be autoclaved in a cycle of 121 degrees Celsius for 15 mins, and will then be collected as hazardous waste by an external contractor. A fully calibrated autoclave will be used for the inactivation. Calibration will be carried out annually.
Sharp solid waste will be collected in sharpsafe bins and then sealed in a 60 litre burn-bins, which will be collected for off-site incineration by a hazardous waste disposal company.
Chlorination and autoclaving are accepted procedures which will result in complete killing.
The waste disposal company used would be either Grundon or Vetspeed.

**LIQUID WASTE**
Detail of type of waste — Liquid waste from cell culture
Inactivation — Chemical inactivation using Virkon. Freshly made Virkon will be made up with to give a final concentration & 1% (1000 parts per million of available chlorine) for at least 30 minutes.
Validation of treatment - Virkon has been independently validated to kill virus and a 5 minute exposure is enough to kill 5 to 6 logs of virus (Antiviral Research Volume 64, Issue 1, October 2004, Pages 27-33).

**SOLID WASTE**
Detail of type of waste - glass vials, rubber stoppers, plastic pipettes, cell culture flasks, 96 well cell culture plates
(other than - reusable glassware is soaked in 1% Virkon overnight, rinsed thoroughly, sent for washing and autoclaving)
Autoclave cycle — temp 131°C for 30 minutes.
Monitoring — monitored by chart recorder attached to the autoclave
Validation — no microbes can survive effective autoclaving. There will be an annual 12 point thermocouple testing of autoclave
Route of final disposal — incineration

Please enter comments of the GM safety committee on the risk assessment
Below are the comments of the Imperial College GM safety committee. Our alterations are in bold
Following the discussion of your proposal entitled “Freeze d.ylnq of Adenovirus with GEP and detection in HEK 293 cell culture” (GM1C -01675.1), the committee request that the following amendments are made to the proposal prior to approval:

Reviewer I
Please clartI the classification, is the pmject a containment level I or 2?

containment level 1 - see Part I - 1.4

Reviewer 2
Part I
I agree that this is a classi GMO and therefore part 2 does not need to be submitted to the committee with the assessment. The part 2 assessment is still a valuable exercise for the research team.

Part 2
Hopefully there is another separate access to the office from a non lab area.
Unfortunately access to the lab and office share the same entrance

Part 3
a i. la Please state that the final concentration of virkon including dilution with waste liquid will be no less than 1%.

It is advised that yukon is not allowed to come into contact with culture media for longer than necessary as chlorine gas has been observed to be evolved after prolonged exposure. The manufacturers recommended minimum contact time is 1% under ideal conditions. Therefore I would recommend 30 minutes as a generally effective, but not overly long, contact time.

This has now been changed to include final concentration. Virkon exposure has been reduced to 30 minutes ff11 is easily available autoclaving using a properly validated waste autoclave is the preferred mute lbr solid waste as it gives more reliable complete sterilisation. Solid waste can form air pockets especially in pipettes where the liquid agent may not reach.

We have access to an autoclave and disposal of solid waste has been changed to using this route-- see 3.I.lb

3.2a It is common practice in many other labs to use closed lunch box style containers for transport of the flat culture vessels as they have been known to split without warning (suspect that they are damaged during shipping). The bottom of the lunch box also provides a handy spill fray during incubation.

Agreed - amended

3.5a Virken should always be used such that the final concentration after dilution with any waste is no less than 1%.

Amended - final concentration should be at least 1% 

3.5b Mien and to whom will you report the incident?

Amended - safety officer

3.8 please tick the box if what you are saying is true.

Box ticked

Reviewer 3
No requirement for part 2 of the form.

Part 3:

Please confirm whether chemical disinfection only will be used to inactivate solki GM waste, if autoclaving is going to be used, please complete 3.1. lb.

Autoclaving is now included in part 3.1.lb

Reviewer 4

part 3 section 3.2
description of transport of any viable GMM to autoclave

Amended - Plastics containing GMMs will be double contained in plastic bag (not sealed to allow steam penetration) which will be placed Inside a plastic box for transport to the autoclave.
### Project Additional Information

**Purposes of the contained use**
To improve stability of the vaccine components at elevated temperature in either a liquid or lyophilised presentation

**Recipient or parental organism**
Vero cells

**Host/vector system**
DEN-2 PDK-53 virus (highly attenuated Dengue type 2 backbone) which has demonstrated safety and efficacy in man and grown in Vero cells

**Origin & function**
Origins of the genetic material is from the remaining three Dengue serotypes (1, 3 and 4)

**Evaluation of foreseeable effects**
Immunofocus assay in Vero cells
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Please see attached Risk Assessment for full details of the waste management procedures.
Basically all liquid waste will be decontaminated by contact with freshly made up virkon - final concentration will be 1% (1000 parts per million of available chlorine) – for a minimum of 30 minutes contact time. Solid waste soaked in freshly made up virkon prior to autoclaving (Holding temperature of 121°C for 15 mins autoclave serviced regularly (arranged landlord) a copy of service record held by Stabilitech

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
3. RISK EVALUATION OF THE DENVAX VACCINE

The DENVax dengue vaccine represents an important potential tool in the fight to address an infectious disease that threatens over half of the world's population. Inviragen is addressing this challenge with a novel tetravalent genetically modified chimeric vaccine. The design of this vaccine is based on careful consideration of needing to provide immunogenicity against all four serotypes while ensuring safety to patients and the environment.

As outlined in Sections 1 and 2 of this document, significant effort has gone into developing and manufacturing an attenuated chimeric tetravalent vaccine that provides a strong neutralizing antibody response in several animal models. Data have also been generated showing the parent attenuated virus (DEN-2 PDK-53) is safe while generating a strong immune response in humans in Phase 1 clinical trials. Based on this proof-of-concept of potential safety and effectiveness, the scientific effort was expanded to include the other serotypes and the DENVax tetravalent vaccine is now approaching clinical trials for evaluation of safety and immunogenicity in human volunteers.

The modifications to the viruses were designed to address the balance required between effectiveness and safety to patients and the environment. These effects of these modifications can be summarized as follows:

- **Reduced replication:** The modified viruses do not replicate as efficiently as wild type dengue viruses in mammalian cells (e.g., Vero, LLC-MK 2), mosquito cells or in mosquitoes. In addition, the replicative potential for the viruses is reduced by >90% at temperatures characteristic of a mild fever (i.e., 39°C).

- **Reduced pathogenicity:** As demonstrated in the neonatal mouse neurovirulence data and the plaque size test, the pathogenicity of the modified viruses is significantly attenuated compared to wild type dengue viruses.

- **Retained immunogenicity:** The data demonstrating immunoprotein in animal models (e.g., mice and monkeys) and neutralization of viral infectivity in the Plaque Reduction Neutralization Test clearly show that attenuation of the viruses for safety was achieved without compromising the ability to neutralize the viruses in the vaccine with an effective immune response.

- **Since all four DENVax components share the identical attenuating mutations, recombination between vaccine strains cannot generate more pathogenic viruses.**

Extensive controls have been implemented to ensure the vaccine meets the above characteristics of reduced replicative potential, attenuated pathogenicity and retained immunogenicity. As outlined in Section 1, an exhaustive effort went into thoroughly characterizing the genotype and phenotype of the candidate DEN-2 PDK-53 vaccine virus. This same rigor was applied in development of the subsequent research grade ChiDEN-1-V, ChiDEN-2-V, and ChiDEN-3-V viruses. Thereafter, Pre-Master, Master and Working Virus Seeds and the ultimate tetravalent vaccine, which are produced under cGMP conditions by a highly reputable vaccine manufacturer, are thoroughly tested and characterized to ensure fidelity to the genotypic and phenotypic requirements of this attenuated vaccine.

The DENVax vaccine has been designed to meet the challenge of balancing safety and effectiveness. The temperature sensitivity and reduced replicative phenotype of the vaccine viruses in mammals and mosquitoes significantly reduces the potential for spread between vaccinated humans by mosquitoes. Furthermore, the reduced pathogenicity of the vaccine viruses and strong immunogenicity they stimulate ensure that any viral replication subsequent to vaccine administration will be very short-lived, non-pathogenic and minor in terms of magnitude.

In summary, this combination of features makes this candidate dengue vaccine well suited for clinical testing in humans as the safety risk for both humans and the environment has been considered and the vaccine has been designed such that there is virtually no environmental risk associated with use of this vaccine in humans.

Yes
Consumables shall be inactivated by autoclaving at 134°C for 10-15 minutes, which achieves a 100% kill, and then disposed of through normal hospital clinical waste routes. The autoclave is located within an accredited laboratory in the hospital and is calibrated annually by Health Facilities Scotland. A record is maintained of all autoclave cycles. This waste is collected by a specialist waste disposal operative (Healthcare Environmental Group) for appropriate disposal.

Give brief details of the genetic modification safety committee:

Joint UCUUCLH/RFH Genetic Modification Safety Committee (clinical trials). The GMSC comprises a number of academic clinicians and clinical trials people from the 3 named centres with experience in the clinical application of GMOs. On such academic clinician from GOSH is already on this committee and the responsible person named below will also attend. The committee is a virtual one such that RAs are dealt with by email with face to face meetings as required.
**For activities involving GMMs, describe the waste management measures which will apply to the activity**

For routine cleaning all surfaces are wiped down with 70% ethanol after use. Liquid GMM waste is first disinfected using Sanichlor (effervescent chlorine tablets) to give a final concentration of 2500ppm chlorine overnight before being disposed of down a laboratory sluice. This is a standard procedure and viability is below detectable levels. 100% No specific testing for vector contamination. Environmental monitoring as routine for this laboratory. Waste will be taken by the dedicated personnel to be autoclaved at Camelia Botnar Laboratories or the Institute of Child Health (back-up) and this process logged in the batch manufacturing record. Solid materials are double-wrapped then autoclaved. The autoclaving cycle is carried out at 134 degrees celsius for 3 minutes. All sharps are placed in puncture-proof containers and disposed of through the central collection service for contaminated waste. All sharps are placed in puncture-proof containers and disposed of through the central collection service for contaminated waste. Waste is incinerated via a clinical waste process stream.

**Please enter comments of the GM safety committee on the risk assessment**

There has been a GMSC at UCL for many years with a long history of reviewing GM risk assessments and interaction with the HSE for approvals. The new committee has continuity of personnel and has separated the risk assessments with a clinical impact. Professor Wasim Qasim is on the committee and has a more than 10 years experience of submitting GM Risk Assessments for review.

Contaminated needles, syringes, used/unused vials and swabs will be discarded in a designated labelled sharps box in the treatment area. The sealed box will be stored in the designated treatment area or approved clinical waste area until collection for incineration. Drug destruction certificates will be completed. The local Labs will analyse the routine bloods and dispose of waste according to local procedures. The TRIOC protocol requires all staff who handle trial drug to wear gloves, apron, goggles and mask. Disposable PPE is recommended which will be available in pharmacy, in the treatment area and in spillage kits. Waste will be disposed of by incineration or other such locally approved method for GM waste. All waste potentially contaminated with GM culture material must be rendered non-viable (inactivated by a validated means) prior to leaving the site for final disposal. This includes GM material disposed of at the preparation of the gene therapy product stage, administration to patient stage, waste generated when removing and analysing samples.

For activities involving GMMs, describe the waste management measures which will apply to the activity

GMM defined as hazard group 1. Risks to human health from vector or gene insert are low. Risk of transfer to other organisms, animals or the environment are low. Drug tracking, storage and handling measures acceptable. Waste disposal measures appropriate. PPE (gloves, apron, mask and goggles) required for pharmacy and administering staff. Pregnant staff should not handle the drug. An appropriate emergency plan is in place.

Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Give brief details of the genetic modification safety committee

Salford Royal NHS Foundation Trust genetic modification safety committee - The committee consists comprises the following members: Chair - Principal Clinical Research Lead, Director of R & I operations, Biological Safety Officer, Pharmacist, R&I Nurse Delivery lead, carious other clinical/research staff, other staff as appropriate.

The remit of the committee is to advise on the adequacy of any risk assessments undertaken relating to GM activities at this site.

The committee will meet at appropriate intervals based on the level of activity of relevant work.

In order to fulfil this requirement the committee will:

- Receive and review each proposal for genetic modification work and judge the adequacy of the risk assessment and the identification of appropriate containment and other risk control measures.
- Periodically review risk assessments depending on the level of activity and level of risk.
- Act as a source of advice on the preparation of risk assessments.
- Consider any accidents or incidents relevant to genetic modification work.
- Consider and recommend arrangements for health monitoring or surveillance where appropriate.
- Act as a source of information relating to GM activity.
- Assist and advise the Authorised Person (in the first instance biological safety officer) to discharge the responsibilities for statutory notifications and record keeping.
- Provide an annual report to the relevant assurance committees and risk management team.
- Liaise with the University of Manchester where work at site is being conducted by University of Manchester employees at this site.

The committee has now met for the first time and will meet at least annually or as needed depending on level of activity on the site.

The activity to be undertaken is a clinical trial of an advanced therapeutic agent as defined by the

For activities involving GMMs, describe the waste management measures which will apply to the activity

Any disposable materials used will be immediately disposed of by incineration as clinical waste.
Syringes, cannulas and all contaminated procedure related material used in implantation will be placed in a single patient use, procedure specific biohazard sharps box for disposal by incineration. This will be a size 15 litre or 25 litre capacity to accommodate all related waste. All contaminated equipment will be cleaned as per local guidelines.
Waste management will be in line with local disposal procedures as used for clinical waste.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The genetic modification committee met and thoroughly discussed the risk assessment. Various suggestions were made and it was agreed that with the inclusion of these suggestions, the risk assessment was an appropriate reflection of the level of risk involved.
The Genetic Modification Committee will review future risk assessments relating to proposed studies.

Please enter comments of the GM safety committee on the risk assessment

The purpose of the assessment (from a GMSC perspective) is to consider risks to staff and other workers who could be exposed to the GM vaccine. The conclusion of the assessment is acceptable (a Class 1 GM trial activity, presenting no / negligible risk to human health and the environment, requiring the application of Containment Level 1 measures to limit contact with humans / environment) on the basis that the trial involves use of a replication deficient recombinant lymphocytic choriomeningitis vaccine vector (rILCMV) with a safe history of use, and use of vaccine antigens with no inherently harmful properties.

Give brief details of the genetic modification safety committee

Y
Membership
The membership of the School of Applied Sciences GMSC depends on the nature of the work to be undertaken. But the committee consists of the following core members or their delegated representatives. Additional members may attend meetings if their expertise are required, e.g., medical doctor, veterinary surgeon, or University Health & Safety Advisor.

1. Deputy Dean of School - management representative
2. Director of Operations - management representative
3. Academic representative and health & safety specialist
4. Technical staff representative
5. UCU representative
6. Unison representative
7. School Health & Safety Co-ordinator and Biological Safety Officer
8. Principal investigator

Responsibilities of the committee
a) To review new risk assessments relating to work involving the genetic modification of organisms (GMOs) in order to judge the adequacy of the risk assessment to protect the health of humans and the environment.

b) Consider whether the identified containment and other control measures are appropriate and available.

c) To advise on the requirements for training, equipment, facilities, and other resources necessary to undertake work involving the use of GMOs.

d) To review existing risk assessments if there is cause to do so.

e) Consider and approve reports from any inspections made of facilities or any compliance audits.

f) To keep under review the health and safety measures, such as local rules and standard operating procedures, relating to work involving the use of GMOs.

g) To scrutinise accidents or incidents related to work involving GMOs to ensure that control measures are appropriate to protect individuals and the environment.

h) To keep accurate records of the Committee's meetings. These must be consisting of:
   - Date of Meeting
   - Attendees
   - Apologies/absences
   - Title of the project(s) submitted to the committee, principal investigator, department, division, and location of work to be carried out in.
   - Reference number assigned to the project
   - Agreed classification of the project and whether notification to the HSE is required.
   - Containment level required
   - Any further control measures to be taken by the personnel involved with the project.
   - Amendments to be added to the risk assessment form.
   - Comments and concerns raised by the GMSC members regarding the project.
   - Dissenting opinion and agreed outcome.
   - Actions to be taken and the named responsible person.

h) The Biological Safety officer is responsible for keeping all records of the committee.

Frequency of meetings
Little work involving GMOs occurs in the school. Consequently, the Committee does not meet on a regular basis. The Biological Safety Officer will convene the committee when they have received GMO risk assessments or there is another reason for the committee to convene. However, the committee will meet at least once a year to review the work involving GMOs/GMMs within the School, including points B through G in section 3 above.

| Laboratory | Animal Unit | Growth Room | Glass House | Large Scale |
For activities involving GMMs, describe the waste management measures which will apply to the activity

Waste will be managed by autoclaving the GMMs at 126 for 15 minutes, before disposal of the material as clinical waste via a commercial contractor. Autoclave indicator tape will be included in each batch to the required conditions have been achieved.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment
Review risk assessment for genetically modified microorganisms ref. GMM/01

Risk assessment GMM/01

The committee was satisfied that the strains to be used were derived from E.coli strain K12 and that the strains themselves were not considered pathogenic (i.e. conforming to class 1) The committee accepted that the proposed modifications should not cause increased pathogenicity though the production of toxic gene products, altered metabolism and that the proposed modifications should not alter the allergenicity of the strains. The committee also accepted that the proposed modifications should not alter the allergenicity of the strains. The committee also accepted that the modified strains would still come under class 1 and that class 1 containment was adequate. The committee was satisfied that the risk to the health of humans or plants and animals in the environment was negligible. The facilities, staff training and containment and disposal measures in place were also considered acceptable. The risk assessment was therefore accepted without change.

Risk assessment GMO/01 & GMO/02

In the case of both risk assessments, the committee discussed the techniques, genes involved, the containment measures and possibility of the modifications causing increased harm to human health though the production of toxic gene products, altered metabolism and increased allergenicity. The committee discussed the potential for modified organisms to cause harm to the environment and concluded that the proposed modification should pose no threat to native species. The committee also accepted the facilities, expertise of staff, safety and containment measures were adequate, But asked that a second laboratory be added to the risk assessment as it was foreseen that the controlled environment facilities in that lab (room DG43B) would be required.

The committee agreed that the work involved class 1 GMMa and non-notifiable GM animals amd, therefore, new premises notification must be made to the HSE before the work outlined in all three risk assessments could take place.

Research
All sharps that have been in contact with the vaccine or vaccination site will be disposed of into sharps bins provided by Stericycle and all materials used will be disposed as clinical waste. All waste will be immediately placed into a suitable receptacle (e.g. sharps into a sharps box, swabs and dressings into a clinical waste bag) which will be located within the area where the GMO is being prepared. The clinical waste will be double bagged and tied before leaving the clinical area where the vaccine is being delivered. Sharps boxes will be locked before leaving the clinical area.

Sharps boxes and waste bags will be placed into a dedicated lockable GMO clinical waste bin and stored within a locked room in the NIHR Lancashire Clinical Research Facility (LCRF) until collected by the licensed waste contractor (Stericycle). Only trained staff will have access to the key for this lockable bin. This include any waste or sharps created to manage an accidental spillage in pharmacy or on transport from pharmacy to the LCRF. No GMO waste will enter the Lancashire Teaching Hospitals waste streams.

All GMO waste will be collected and removed from the sites by contractors (Stericycle) who are registered for handling GMO material. The waste management company contracted will be ultimately responsible for the disposal of the material as clinical waste (via incineration or any other validated means, according to current guidelines and regulations).

NOTE: Waste which has been fully chemically deactivated does not require further deactivation prior to disposal, e.g. swabs and paper towels used to mop up GMO spills using chlorine based disinfectants should still be treated as GM waste, items fully immersed in disinfectant do not need to be further deactivated prior to disposal.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Empty vials and used vials with needles and syringes, components used for collecting body fluid sample will be put in to a purple lid bin and sealed (as per local Trust policy). PPE and gauze will be put in to orange clinical waste bins and sealed for incineration following participant visit. Not inactivated at site prior to disposal is necessary. Sealed purple lid bins and orange clinical waste bags are incinerated. Standard disposal of samples by standard SOPs by local laboratories. Central laboratories will perform the safety analysis of complete blood count with differential, liver function test, renal function test and efficacy analysis (CMV PCR). Central laboratories will perform immunogenicity analysis. Central laboratories will dispose residual biosamples per their SOPs for disposing of biohazardous material.

Tick to confirm that you are attaching a summary of the risk assessment  

Tick if you are claiming exemption from disclosure for sections of the risk assessment  

Please enter comments of the GM safety committee on the risk assessment

The information available regarding the GMM supports the proposed Class 1 risk categorisation. On this basis containment level 1 with no additional measures is the appropriate containment necessary to control the risk. The arrangements described are entirely in line with containment level 1.

It is difficult to envisage any process by which this replication incompetent vaccine virus could prove any infective risk to the individual to whom it is administered to or to staff or other patients or to non-human animals. The very low risk that the replication incompetent vaccine virus could in theory reassort with wild type virus in a wild rodent reservoir and regain the ability to produce infectious virus is not in itself of significant consequence as there is no basis for the resulting virus to be of higher pathogenicity than wild type virus and the UK is already an endemic area for LCMV.

No special precautions are required for transport or disposal over and above what is normally done in clinical areas. Waste can be processed as clinical waste. No special precautions are required for dealing with spillage or accidents.

### Premises Conditions

- Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities: Y
- Give brief details of the genetic modification safety committee
Purpose:
1. To ensure that the structures and processes are in place for the safe conduct of gene therapy research on human subjects at Sheffield Teaching Hospitals NHS Foundation Trust.
2. Interface with the Gene Therapy Advisory Committee and comply with the recommendations of other agencies with statutory responsibilities including the Medicines and Healthcare Products Regulatory Agency and the Health & Safety Executive.
3. This Group will not consider the ethical or the scientific merits of the research projects which would have been assessed by the Research Ethics Committees and the Gene Therapy Advisory Committee.
4. This Group will not consider the Clinical Trials Application assessments by the competent authority which would have been assessed by the MHRA in the UK.

Accountability:
1. To report to the Director of R&D of STH
2. Informing the UoS Faculty MDH Research Committee
3. See reporting structure below

Frequency of meetings:
• Virtual meeting on an as needed basis for approval of studies
• Physical Meeting on an annual basis to review procedures

Areas of Expertise:
Pharmacy, including:
• Storage
• Disposal
• Staff Training
• SOPs
Laboratories, including:
• Virology
• Transport of specimens
• Personal Protection Equipment
• Staff Training
• SOPs
Waste Management, including:
• Spillages
• Disposal
• Personal Protective Equipment
• Staff Training
• SOPs
Patient pathway and staff involvement, including:
• Patient facilities
• Transport of specimens
• Infection Control
• Personal Protection Equipment

For activities involving GMMs, describe the waste management measures which will apply to the activity:

Storage of the modified herpes simplex virus HSV1716 at -70°C
Inactivation Methods:
The vials will be injected with 2% VIRKON solution and left for 1 hour to deactivate the virus. 2% VIRKON will be aspirated into the three-way valve and Rocket IPC drainage line. All the above equipment will be left in contact with the VIRKON for at least 1 hour to inactivate the virus.

After deactivation of residual virus the vials, needle, syringe three-way valve and Rocket IPC drainage line will be disposed of in a sharps box and local policy for disposal of this type of waste will be followed. All other solid decontaminated waste (e.g paper towels and gloves) will be disposed of in clinical waste bags.

Degree of kill:
When used as per the manufacturer's instructions, Virkon will provide complete inactivation of HSV1716.

Proposed process testing/monitoring measures:
Not required as validated by manufacturer.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

1. Waste Manager - In reference to page 9 of "The HSV1716 Handling and Administration Instructions Booklet", comments to point 2) are:
a) Disposal is to be carried out in accordance with the STH Waste Strategy and Policy
b) Vials, needles and syringes are to be disposed of in an approved sharps container with a yellow body and lid.
c) The 3 way Rocket IPC will contain a large volume of loose liquid and should be disposed of in a hermetically sealed container.  
d) The Herpes simplex virus not in a cultured form is classified as a category B infectious substance and should be disposed of as infectious Clinical waste for Alternative Treatment (orange lidded container).
e) Soiled PPE used in process should be disposed of as Infectious Clinical Waste In Orange bags.

2. Patient Safety Manager - potential risk to staff from splashes etc, what staff should do if they did get a splash to their eye/mouth etc - it shouldn't happen but if it does what are the contingencies.

Other reviewers provided confirmation of their review only. The above comments were followed up until resolution

Project Additional Information

Purposes of the contained use

Destruction of GMO via high temperature incineration

Recipient or parental organism

Information to be provided by waste producer and new risk assessment conducted for any new materials. Current requirement is for material contaminated with attenuated vaccine viruses (influenza). As attenuated vaccines they should not represent a hazard to human health so should be classified as below hazard group 2 in the ACDP Approved list of biological agents. In any event, in a complete breach of containment the virus would not survive long in the environment which greatly reduces the risk of infection. (evaporation rate of influenza-containing droplets under ambient conditions ranges from 3 to 30 seconds and Flumist undergoes a 100-fold loss in infectious titre following desiccation).

Host/vector system

Information to be provided by waste producer and new risk assessment conducted for any new materials. Current requirement is for Flumist vaccines which do not cause disease symptoms associated with the wild-type influenza virus (they actually prevent infection). If the virus did manage to survive in the environment, a simultaneous infection of the same cell with vaccine virus and wild-type virus would be required to transfer vaccine gene sequences to the wild-type strain. This event would not be expected to have adverse consequences, studies have shown the attenuated reassortants would be less virulent than the wild-type virus.

Bacterial host or viral vector studies have shown no environmental hazards — the plasmid rescue seed preparation method encodes the same human influenza viral proteins that are contained in seeds prepared using classical non GMO techniques.

Origin & function

Information to be provided by waste producer and new risk assessment conducted for any new materials. Current requirement results in the production of only unmodified human influenza genes — no GM material will be present in the material to be destroyed. It is the harvesting method — plasmid rescue technique — that brings this material under the umbrella of these regulations Material is intended for vaccine production

Evaluation of foreseeable effects

Information to be provided by waste producer and new risk assessment conducted for any new materials. Current requirement - Flumist vaccine seeds made either by non-GMM and GMM (the classical reassortment or by plasmid rescue) are genetically, biologically, and phenotypically comparable and do not contain detectable levels of plasmid cell culture DNA. Therefore there should be no adverse effects from the material resulting from this process.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Material will be presented in sealed containers which will be incinerated without being opened.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

All materials will be presented to the facility in sealed containers and will not be opened. We therefore wish to be exempted from the following schedule 8 measures:

Schedule 8 part II table 2:
- General — Paragraphs 1 — 9
- Equipment — Paragraphs 10 — 14
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Containers will be incinerated reaching a temperature of 1300°C using our High Temperature Incinerator, achieving a 100% degree of kill. Ultimate form will be vitrified slag and ash.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

Please enter comments on the GM safety committee on the risk assessment

The risk assessments have been carried out by the plant materials manager and safety advisor and cross referenced to relevant safety instructions and risk assessments.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Solid waste will be placed in unsealed bags placed in lidded but unsealed plastic boxes and removed from the laboratory to the John Innes Centre central autoclave service where it will be sterilized. The autoclave cycle will include heating the material to 120°C, for 15 minutes to ensure 100% kill for all material. Liquid waste and contaminated glassware will be treated with hycolin disinfectant, diluted according to the manufacturers instructions, overnight at room temperature. An initial check will be carried out the first time the process is carried out to check that no culturable cells remain before disposal. For low level risk this check will be repeated on an annual basis to ensure that the procedure ensures a 100% kill. Higher risk work may require more frequent monitoring.

Y

Give brief details of the genetic modification safety committee

The genetic modification safety committee (GMSC), is a subcommittee of the Selcia Health and Safety Consultative Committee, and consists of:

1. GM Biological Safety Officer (GMBSO) (Chair).
2. Selcia Health and Safety Officer (Secretary).
3. A General Staff Representative - to represent all persons who have access to genetic modification facilities e.g. technical staff, research workers, ancillary workers, students etc.
4. A member of the Selcia Management Team (General Manager and Head of Bioanalytics and Discovery Technologies to alternate).
5. Where necessary, a Technical Expert(s) - to provide expertise on particular work areas, e.g. on viral vectors, medical or environmental aspects.

The GMSC will meet six times a year, just prior to the main Selcia Health and Safety Consultative Committee. The GMBSO will circulate and archive written minutes of each meeting to the GMSC, the Selcia Health and Safety Consultative Committee, affected employees and the Management Team. A copy of the minutes will be posted on the Selcia Health and Safety Consultative Committee notice board in the tearoom.

The company GMBSO will chair the GMSC to ensure consistency in approach and outcome of risk assessments and will present a summary of key issues to the Selcia Health and Safety Consultative Committee at each meeting. The company’s notification for genetic modification work will be submitted to the HSE on this basis.

The GMBSO may refer matters to the Company Doctor and Occupational Health Adviser where appropriate.

The GMSC will advise on risk assessments and ensure that:

1. Proper and valid assessments have been made of the risks to human health and safety and to the environment
2. Satisfactory decisions about the appropriate containment and control measures have been made
3. The approach to risk assessment is in accordance with the guidance provided by ACGM taking into account the parameters detailed in the Regulations.
Live GM organisms must be inactivated by validated means. Usually, solid VirkonTNII (available from Antec International Ltd) will be added, to aqueous biological waste, to obtain a percentage of VirkonfM (usually 1%) that will render the OMO inactive. Alternatively media waste will be aspirated into Duran bottles containing TriGene (Medichem International). For each new cell line, the degree of kill will be determined at the first use of a cell line, either with a haemocytometer, after Trypan Blue staining, or with a NucleocounterTM (Chemometec). Waste will be treated overnight with the chemical agent before disposing of via a designated sink with copious amounts of water. Note: Detergent treated waste will not be autoclaved. Untreated aqueous biological waste, such as used culture media, may also be aspirated into 5L glass bottles and autoclaved2 on a regular basis to minimise build up of adventitious contaminants. Autoclaved aqueous waste will be disposed of down a designated sink with copious amounts of water. For each new cell line, the degree of kill will be determined after autoclaving, by counting the number of viable cells remaining. This will either be with a haemocytometer, after Trypan Blue staining, or with a NucleocounterTM (Chemometec). The degree of kill is expected to be 100%, if this is not the case, the autoclave cycle conditions will be modified to obtain 100% kill.

Plastic waste
Plastic waste such as disposable culture flasks, pipettes, tips and centrifuge tubes will be placed into appropriate autoclave bags (transparent with blue writing) and autoclaved.
autoclaved2 The autoclaved waste will then be treated as clinical waste: autoclaved bags will be put into yellow bags and, when full, the bag will be sealed with a numbered tag. The tag number will be written in the waste management book and on the print outs corresponding to the autoclaved waste. Details of the waste type will also be put in the waste management book. The yellow bags will be placed in a designated wheelie bin and taken to the waste store to be picked up by the designated waste contractor.

All empty reusable plasticware or glassware will be immersed in 1% VirkonTM overnight, after discarding down the designated sink with copious amounts of water; the plasticware will be rinsed and washed as normal.

Sharps

The use of sharps will be minimised, where possible. Hypodermic needles, glass pipettes and scalpels etc must be placed in square yellow sharpsafe bins, autoclaved1 then treated as clinical sharps waste. The bins will be numbered and details of the contents recorded in the waste management book. The sharps bins will be placed in a designated wheelie bin and taken to the waste store to be picked up by the designated waste contractor.

1. VirkonTM: “The Ultimate Broad Spectrum Virucidal Disinfectant” - independently proven effective against all seventeen virus families and bacteria and fungi including Mycoplasmae, Salmonallae, E. coli, Candida and Aspergillus.
2. Waste will be autoclaved at 121°C for at least 30mm. A printout generated for each run, will be recorded and filed. The autoclave has an internal load sensor to ensure the actual load reaches the required temperature. The autoclave will be serviced every 6 months and calibrated annually.

### Project Additional Information

#### Purposes of the contained use

- To maintain a small-scale (<8 litres) cell culture of GM cell lines for routine culture.
- To maintain small-scale (<100ml) cryopreserved samples of GM cell lines.
- To perform studies to determine the effect of compounds/reagents/drugs on GM cell lines using cell-based assays, such as cell viability, ELISA assays, adhesion and migration assays.

#### Recipient or parental organism

HCE-2 [50,Bl1 is a commercially available GM cell line, which can be purchased from the American Type Culture Collection (Number CRL-1135). It is a human corneal epithelial cell line generated by immortalisation of a primary culture of normal corneal epithelium with adenovirus I2-SV4O hybrid virus. This commercially available, GM cell line is epithelial in origin but contains Adeno-I2/SV-40 viral sequences. See attached risk assessment.

#### Host/vector system

See above and attached risk assessment

#### Origin & function

The aim is to perform studies to determine the effect of compounds/reagents/drugs on this cell line using cell-based assays, such as cell viability, ELISA assays, adhesion and migration assays. See attached risk assessment.

#### Evaluation of foreseeable effects

It is possible that accidental injection of the cells may be tumorigenic or cause an allergic or autoimmune response in humans although the risk of this happening is quite low. It is not considered to be pathogenic in humans, and would be expected to have limited ability to survive outside of the culture medium. The likelihood of the GMO getting into the environment is very low.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

#### For only GMOs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

n/a

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

**Treatment of Aqueous Waste**

Live GM organisms must be inactivated by validated means. Usually, solid Virkon®MI (available from Antec International Ltd) will be added, to aqueous biological waste, to obtain a percentage of VirkonTM (usually 1%) that will render the GMO inactive. Alternatively media waste will be aspirated into Duran bottles containing TriGene (Medicem International). For each new cell line the degree of kill will be determined at the first use of a cell line either with a haemocytometer, after Trypan Blue staining, or with a NucleocounterTM (Chemometec). Waste will be treated overnight with the chemical agent before disposing of via a designated sink with copious amounts of water. Note: Detergent treated waste will not be autoclaved.

Untreated aqueous biological waste, such as used culture media, may also be aspirated into 5L glass bottles and autoclaved2 on a regular basis to minimise build up of...
adventitious contaminants. Autoclaved aqueous waste will be disposed of down a designated sink with copious amounts of water. For each new cell line, the degree of kill will be determined after autoclaving, by counting the number of viable cells remaining. This will either be with a haemocytometer, after Trypan Blue staining, or with a NucleocounterTM (Chemometec). The degree of kill is expected to be 100%, if this is not the case, the autoclave cycle conditions will be modified to obtain 100% kill.

Plastic waste
Plastic waste such as disposable culture flasks, pipettes, tips and centrifuge tubes will be placed into appropriate autoclave bags (transparent with blue writing) and autoclaved. The autoclaved waste will then be treated as clinical waste: autoclaved bags will be put into yellow bags and, when full, the bag will be sealed with a numbered tag. The tag number will be written in the waste management book and on the print outs corresponding to the autoclaved waste. Details of the waste type will also be put in the waste management book. The yellow bags will be placed in a designated wheelie bin and taken to the waste store to be picked up by the designated waste contractor.

All empty reusable plasticware or glassware will be immersed in 1% VirkonM overnight, after discarding down the designated sink with copious amounts of water; the plasticware will be rinsed and washed as normal.

Sharps
The use of sharps will be minimised, where possible. Hypodermic needles, glass pipettes and scalpels etc must be placed in square yellow sharpsafe bins, autoclave& then treated as clinical sharps waste. The bins will be numbered and details of the contents recorded in the waste management book. The sharps bins will be placed in a designated wheelie bin and taken to the waste store to be picked up by the designated waste contractor.

1. Virko11: "The Ultimate Broad Spectrum Virucidal Disinfectant" - independently proven effective against all seventeen virus families and bacteria and fungi including Mycoplasmae, Salmonallae, F. coli, Candida and Aspergillus.

2. Waste will be autoclaved at 121°C for at least 30mm. A printout generated for each run, will be recorded and filed. The autoclave has an internal load sensor to ensure the actual load reaches the required temperature. The autoclave will be serviced every 6 months and calibrated annually.

Is an emergency plan required according to regulation 20? 

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

Please enter comments on the GM safety committee on the risk assessment

The risk assessment GMRA002 was approved unanimously by the Genetic modification Safety Committee on 28.02.08. Th1 were no further comments.

## Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Give brief details of the genetic modification safety committee

The committee is made up of the H&S Adviser/Biological Safety Officer and their deputy, as well as 2 volunteer scientists. The H&S adviser chairs the committee. The committee will meet formally once a year to review the procedures and inspect the laboratories, and meet on an ad hoc basis each time a new GM project is proposed. All meeting will be documented and minutes released to the staff.

Containment level 1 GM waste is disposed of following the Babraham Research Site waste policy (application GM1 05):

Solid waste is disposed of in hermetically sealable bins (UN approved Type 3H21Y30/S/2003). The bins are sealed and labeled (The BRC registration number: NFK 619; F-Star Biotechnology Ltd; Building 280 & date of disposal). The bins are then collected outside of building 280 in a central collection point where they will be placed into 210 liter yellow labeled “Eurobins”. Collections by the local registered clinical/GM waste incinerator contractor will be made three times a week to prevent a buildup. The site has 24/7 Security. The contractor uses solid bodied transport and carries portable disinfection equipment in case of any spillage. Autoclave facilities are maintained on site, if required.

Liquid Waste is inactivated by the addition of “Virkon” prior to disposal into the drainage system. Babraham Research site has its own sewage treatment plant which is closely monitored.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The Bacteria used are well characterized laboratory strains routinely used in molecular biology laboratories,
The bacteriophage M13 derivatives (KMIS, M13-K07) are only able to infect bacteria and not associated with human disease.
All work is classified as category Level I
Testing of human antibodies isolated from yeast, phage and ribosome display libraries. Antibodies are ultimately intended for therapeutic use and will initially be assessed for their affect on primary cells and a variety of cell lines grown in the laboratory.

Project Additional Information

Purposes of the contained use

To minimise the risk of infection from class II cell lines and blood borne infections, in accordance with good microbiological practice and the protection of both work and worker. Work carried out at the premises will be limited to research activities.

Recipient or parental organism

The cell lines used may include adenovirally transformed lines (e.g. HEK-293) or cells classed as Biosafety Level 1 that have been transfected with mammalian expression vectors or via adenovirus-retrovirus. The cell lines themselves are not infectious.

Host/vector system

The GM cell lines may be virally transformed, adenovirally transfected or stably transfected using expression vectors. Cell lines will be stably or transiently transfected with a gene encoding the antigen of interest. Transfection will be carried out using generic mammalian expression vectors, eg. pCEP4. Adenovirus has been identified by the ACDP as a Level 2 Biosafety Hazard. However, the risk of transmission to humans in this activity is considered negligible. The inserted products may be expressed as a soluble or membrane bound proteins. The antigens under study are not in themselves pathogenic but should be handled according to good microbiological practice.

Origin & function

Adenovirus has been used to transform some commercially available cell lines, in order to render them immortal for long-term culture. Transfection of cells is a means of introducing a gene of interest for over-expression, usually at the cell surface, for use as a selection target. The product may also be released into the medium as a soluble protein, or purified from the cell, but will then be captured for use as a selection target or for in vitro characterisation and testing.

Evaluation of foreseeable effects

Biosafety level 2 hazard is introduced to the proposed work by use of adenovirally transformed or transfected cell lines. Other cell lines or products are currently evaluated at level 1. The risk of transmission of adenoviruses from these systems to humans is negligible and the cell and genetic material will not survive in the external environment. Standard level 2 decontamination and containment facilities are being set up and will be in operation prior to commencing this work. Overall, the foreseeable effects are considered negligible.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Disposable waste material will not be autoclaved prior to incineration - this derogation follows the allowance specific for the Babraham Research Site. Waste material will be placed in sealed 30 or 60l eurobins and sent offsite for incineration by Vetspeed (Their GM authorization is GM898) according to Babraham Institute disposal notification GM105/4.1.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Cell lines will be cultured in disposable plasticware at a scale from 500ul to 5l under aseptic conditions and harvested by centrifugation. All liquid waste will be chemically inactivated (e.g. with Virkon, TriGene, or Proceine40) prior to disposal. All operations will be performed in laboratory facilities in which spillages can be effectively disinfected so the wider environment is unlikely to become contaminated. Disposable waste material will be placed in sealed 30 or 60l eurobins and sent offsite for incineration by Vetspeed (GM authorization ref. GM898) according to Babraham Institute disposal notification GM105/4.1.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

CU2 Project Title Retroviral Transduction of Mammalian Cells

Class 2 CultureVolClass 1-50 Litres

Project Title Class CultureVolume Class 3-4

Class 2 CultureVolClass 1-50 Litres

02/03/2022  Page 12466 of 15326
**Project Additional Information**

**Purposes of the contained use**
To create stable cell lines containing genes of interest

**Recipient or parental organism**
Mammalian cells classed as HG1 by the ACDP.

**Host/vector system**
2nd Generation lentiviral vector system. Replication deficient, but can still infect and integrate genome into a broad range of human cells.

**Origin & function**
Human oncogenes, with the potential for tumorigenesis.

**Evaluation of foreseeable effects**

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
No animals or plants will be used.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**
We would like to use the same derogation as the Babraham Institute, who are responsible for waste disposal for all companies on the research Campus, to not use an autoclave to deactivate waste but send it for incineration. The Babraham Institute use Vetspeed (GM authorisation GM898 and their derogation number is GM105/4.1)

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**
All culture work will be carried out in disposable plasticware. All liquid waste will be inactivated with Virkon (validated to fully inactive lentivirus) overnight before being disposed of to the drains. All solid waste will be sealed in 60L eurobins and sent for incineration by approved contractor, Vetspeed. Surfaces (Benchtop, safety cabinet interior etc) can be disinfected with Biocleanse or Trigene, both of which are validated to fully inactivate lentivirus.
The GMSC has reviewed the risk assessment and is happy that all preventative measures are in place, and have given their approval for the work to take place.

Please enter comments on the GM safety committee on the risk assessment

For activities involving GMMs, describe the waste management measures which will apply to the activity

The activity (secondary packaging and storage) is not expected to generate any waste. In case of an accidental release of damage to the primary containment, materials are collected and disinfected by treatment with a standard house-hold disinfectant or collected in a double sealed bag and disposed of as medical waste.

Tick to confirm that you are attaching a summary of the risk assessment  

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The material containing GMMO will be delivered to Pen in the primary packaged form, but sealed inside clear plastic bags. This will allow for safer opening of transit packaging without the risk of damaged primary packaging creating a spillage situation. All surfaces will be wiped clean using 70% IPA.

The handling of GMO material will be similar to that for handling any other primary packaged clinical drug at Penn. All staff are familiar in the handling requirements of primary packaged drug material, and receive initial and ongoing training Penn has well established spillage control procedures and these will be supplemented by the use of 70% IPA in the event of the release of the GMO material.

Following the review of the risk assessment Penn is confident that the procedures and training already in place are suitable for the safe handling of this material.
GM Centre Number: 3006

For activities involving GMMs, describe the waste management measures which will apply to the activity

Babraham Institute biosafety policy and guidance will be followed. In particular, GMM cell cultures will be inactivated overnight with 1% Virkon and working surfaces disinfected with 2% Trigene (see attached documents: SOP “Disinfection (Inactivation) in the Containment Level I Lab” and COP “Dealing with Biological Spills”). Waste will be disposed of in 30 or 60 litre eurobins in accordance with SI biosafety policy (see attached document: SOP “Clinical Waste Management: Level 1”)

02/03/2022
GMSC discussed all RAs associated with this CU1 form on 14 Feb 2008. Final approval given 14 May 2008.

Liquid waste will be inactivated by either autoclaving at 121°C for 15 mm (with or without prior chemical inactivation), or by incubation overnight in the presence of Virkon at a final concentration of at least 1% (w/v), prior to discard. Virkon has been demonstrated to be effective against a wide range of viruses and bacteria (Dupont Global Website) with published data demonstrating greater than 5 logs of inactivation of virus. Autoclaving of material will result in approximately 100% kill or inactivation of the agents.

The company is a cGMP compliant organisation for the outsourcing of vaccine and biological product.

All solid waste that has been in the microbiological safety cabinets (MSC) will be disposed of in dedicated waste containers in autoclavable biohazard bags. These bags will be autoclaved in order to kill off any infected cells. All cells in suspension will be killed by exposure to Perform (www.uk.schulke-mayr.com) according to the manufacturer’s instructions (2 % solution, over night), suspension will subsequently be poured out in the drain. All gloves used for work with infected cells will be autoclaved together with other solid waste. The MSC will be wiped with distilled water and 70 % ethanol before and after use. Autoclave will be validated for typical loads. Expected degree of kill: 100%.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Tick if notifying a connected programme of work

It is concluded that the work proposed offers a negligible risk to the environment as well as to the staff involved in the work.

Project Additional Information

Purposes of the contained use

Research and development of stem cell function and differentiation.

Recipient or parental organism

Well characterised human stem cell lines.

Host/vector system

Well characterised vector systems with a history of safe use, well characterised human stem cells. This notification does not include research to develop new viral vector systems or to investigate virus life cycles. Most commonly, adenoviral, retroviral and lentiviral vector systems will be used.

Origin & function

Tissue specific promoters, germ layer specific promoters, transcription factors, reporter genes, siRNA, shRNA, microRNA.

Evaluation of foreseeable effects

Significant risks to human health arise during the generation of cell lines: once established the cell lines are unlikely to cause harm to human health or the environment.

1. Risks arising from recombination/complementation events

The worst case scenario is that a replication competent virus expressing a harmful gene (e.g., oncogene) is generated either during manufacture of the infectious viral vector particle (i.e., between transfer vector and packaging cell line components) or through co-infection of a person with wild-type virus and viral vector. This scenario is unlikely given the number of recombination events required.

It is also possible that the transfer vector reverts to a replication competent virus. The level of risk depends upon the pathogenicity of the wild-type virus, and for high-risk viruses this possibility is unlikely given the number of recombination events required when packaging the transfer vector.

2. Risks arising from integration of viral vector into persons genome

It is possible that random insertion could lead to activation of cellular genes, disruption of important genes (e.g., tumor suppressor) or acquisition of a harmful gene (e.g., oncogene). The worst case is that permanent changes are induced in an infected cell resulting in tumorigenesis.

3. Risks arising from inserted genetic material

Wild-type and mutant forms of genes and genetic material may have harmful effects (as detailed in Section 2.2 SACGM compendium of Guidance) including known and putative oncogenes, growth factors, cytokines, non-coding regulatory elements, anti-sense constructs, and siRNA.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste will be autoclaved (expected degree of kill 100%), and then collected for further incineration. Liquid waste will be treated with 2% Perform over night before being autoclaved (expected degree of kill 100%) and then put to drain. Trace contaminated reusable labware and equipment with will be autoclaved if possible- if this is not possible then it will be disinfected with 2% Perform overnight before being rinsed to drain.

Please enter comments on the GM safety committee on the risk assessment

The foreseeable risks of this work using well characterised viral vectors with a history of safe use are controlled by dedicating a specific laboratory to this work. Access to these laboratories is restricted to staff who are directly involved in the work, and who have been instructed in Local Rules. Infectious viral vector particles (eq waste, samples for storage at low temperature) will only be removed from these laboratories when a safe method of transport has been agreed with the Biological Safety Adviser.

8. WASTE MATERIAL - DISINFECTION, AUTOCLAVING, DISPOSAL

8.1. Liquid cultures and liquid medium from which micro-organisms have been recovered should be sterilised by treatment overnight with Virkon powder (1% w/v) before being discarded via the sink.

8.2. GM Waste material should not be allowed to accumulate and placed promptly in the yellow clinical waste incineration bins. Used laboratory glassware and other materials awaiting disinfection must be stored in a safe manner in plastic boxes provided.

8.3. Re-usable contaminated glass and plastic vessels should be disinfected as described earlier, than rinsed and put in the washer. Eppendorf tubes, petri-dishes etc., should be placed directly into yellow clinical waste incineration bins.

8.4. Non GM waste, but chemically contaminated waste, except needles, scalpel blades and sharps, shall be disposed of in yellow waste incineration bags or bins. Sharp items should be placed in an appropriate container. Containers and bags for incineration must NOT be overfilled. Needles discarded into them must NEVER be re-sheathed.

5.4. Virkon powder - peroxygen compound proven to have a wide range of microbial, antiviral and antifungal activity. 'Used as a 1% solution, which is stable for 7 days. Must be discarded if pink colour is lost. Active agent is potassium monopersulphate. Contains anionic surfactant.
At the first meeting the committee approved the proposal as recommended. As this risk assessment is used for CU1 application and to further benchmark future proposals it was sent to the company’s Health and Safety Advisor, for comment. raised no significant comments

Give brief details of the genetic modification safety committee

The GMSC is a sub-committee of the Laboratory Health and Safety Committee. The GMSC is composed of six employees with significant experience and knowledge of molecular biology (Biological Safety Officer, Senior Product Development Manager, Senior Characterisation Scientist, Protein Expression Scientist, Cell Culture Scientist and two Development Scientists). All are qualified to degree level and 4 of the 6 hold PhDs in relevant subjects. The BSO/Senior Product Development Manager is on the management team of the facility.

The Laboratory Health and Safety Committee meets at least quarterly, with the GMSC meeting as required (e.g. as new risk assessments are submitted or when specific GM issues are raised by the main committee).
All laboratory solid waste and contaminated consumables (flasks! pipettes, etc) will be inactivated by autoclaving. This will be monitored for each run by a print-out and logs retained.

All liquid waste will be inactivated with a validated disinfectant according to manufacturers instructions (e.g. 1% final concentration virkon for at least 30 minutes).

Waste inactivated via the autoclave or by a validated disinfectant will be placed in sealable waste bins, distinctly from other waste, and processed by our waste contractor (whom are licensed to handle Class 1 GM waste)

Tick to confirm that you are attaching a summary of the risk assessment Y

Tick if you are claiming exemption from disclosure for sections of the risk assessment Y

Please enter comments of the GM safety committee on the risk assessment

The GMSC reviewed the risk assessment and no further comments were suggested.

<td>The production of recombinant proteins in mammalian cell lines</td>
<td>Class 2</td>
<td>&lt; 1 Litre</td>
<td>Non-GMM Consent Granted</td>
</tr>
</tbody>
</table>
**Project Additional Information**

**Purposes of the contained use**

The proposed objective of this project is to generate recombinant proteins, of mammalian origin, primarily for use in research as reagents. This will involve the batch production of protein (full length or fragment) using established cell lines in combination with CMV based vectors to produce milligram quantities of active proteins.

**Recipient or parental organism**

CHO cells and their derivates. CHO cells are classified as a Hazard Group 1 cell line, are well characterised and have a long history of safe use.

HEK293 cells and their derivates. HEK293 cells have been immortalised by transfection with adenovirus DNA and contain a partial virus genome, on this basis HEK293 cells are normally classified as Hazard Group 2. The cell line itself is well characterised and has a long history of safe use. Furthermore HEK cells do not shed active virus and will not be used for viral production in this project.

In addition, mammalian cell lines have very poor chances of survival outside of the nutrient rich and sterile cell culture environment, therefore they pose minimal environmental risk.

Disabled (auxotrophic for nutrients and non-colonising) lab strains of E. coli (e.g. DH5α, Novablue) will be used for cloning and vector generation. All strains have a long history of safe use, are unlikely to survive in the environment and will be sourced from reputable suppliers.

**Host/vector system**

All plasmids will be non-mobilising in bacteria, and will carry CMV and/or HTLV viral promoters to enable mammalian gene expression (e.g. pCMV6-AC)

**Origin & function**

All target proteins will be derived from mammalian sources, including humans, rabbits and mice. The cloned genes will include enzymes, structural proteins but, in the interest of safety, exclude more hazardous products such as oncogenes. The source material will be purchased as cDNA from a supplier or derived from tissues produced by a third party animal house.

End uses will include the production of lysates for screening by western blot and detection reagents/enzymes for assays such as ELISA.

**Evaluation of foreseeable effects**

The project scope allows for the cloning and expression of a wide range of functionally distinct genes. The most hazardous gene products will be those known to code for potentially harmful proteins; cytokines, growth factors. The production of cytokines and growth factors will, where possible, be restricted to non-functional fragments, with each protein requiring its own risk assessment. Furthermore, the use of sharps, in conjunction with any GMO work will further reduce operator risk.
The accidental transfer of cloned genes to humans is unlikely to present a high level of risk as the plasmids used will be naked DNA and, unaided, unlikely to cross a cell membrane to establish protein production within the cell.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste is to be autoclaved at 121°C for 15 minutes to sterilise prior to disposal via Abcam's established clinical waste disposal route. Solid waste is double-bagged in clear autoclave bags, prior to sterilisation and, post-sterilisation, placed in clearly marked-yellow clinical waste bags for disposal off-site. All clinical waste is kept in sealable yellow-bins, distinct from all other waste and is removed from the site for incineration by a licensed contractor. Our designated GM autoclave, keeps electronic records of each run, will display a warning alarm if a cycle fails, and is serviced by the manufacturer on a yearly basis.

Disinfection:
70% ethanol/industrial methylated spirits and blue roll is used in combination with Trigene to sterilise work surfaces by spraying and wiping down with blue roll both before and after Cell culture work.
Where necessary, liquid cultures are disinfected by mixing 1:1 with 2% Virkon and left overnight to ensure maximum killing time (in excess of manufacturer’s recommendations). The same Virkon solution is used to sterilise any spills that occur, and serological pipettes are soaked in 1% Virkon prior to disposal via the clinical waste route.
Both Virkon and Trigene have been shown to be broad spectrum and fast acting disinfectants by their manufacturers.

Please enter comments on the GM safety committee on the risk assessment
This project is broadly GM class 1 with the exception of a Hazard Group 2 host organism (HEKs). All work to be treated as Hazard group/GM class 2 and carried out in Class 2 laminar flow hood. A cell culture room within Abcam's existing facilities will be set aside for the GM work.

### Project Additional Information

**Purposes of the contained use**

To transform E. coli with genes derived from Hazard group 2 organisms to help antibody production or as an aid to protein production (e.g. receptors and chaperones) primarily for use in research as reagents.

**Recipient or parental organism**

The recipient strain will be a recognised disabled non-colonising E. coli, classified as an ACDP Hazard Group 1 organism. These strains of E. coli have a long history of safe use, are unlikely to survive in the environment and will be sourced from reputable suppliers.

Host/vector system

All plasmids will be non-mobilising in bacteria, and will not carry mammalian promoters. Example plasmids include:

pJ421 (DNA2.0) (pACYC-ori, KanR, T5 promoter)
pENTR™ 221 (Invitrogen) (pUC ori, KanR, attL, attL2)
pDONR™ 221 (Invitrogen) (pUC ori, KanR, attL, attL2)
pET300/NT-DEST (Invitrogen) (pBR322 ori, AmpR, CmpR, ccdB, lacO, T7 promoter, attR, attR2, ROP)
pQE-80L (and derivatives) (Qiagen) (pBR322 ori, AmpR, lacO, T5 promoter)
pET-19, pET-22 (and derivatives) (Novagen) (pBR322 ori, AmpR, lacI, lacO, T7 promoter)
pET-28 (Novagen) (pBR322 ori, KanR, lacI, lacO, T7 promoter)
pET200/D-TOPO (Invitrogen) (pBR322 ori, KanR, lacI, lacO, T7 promoter, ROP)

Origin & function

The majority of proteins will be derived from mammalian sources or non-verotoxic strains of E. coli. Hazardous mammalian products such as oncogenes and cytokines may be expressed and some sequences will be derived from pathogenic (but not verotoxic) E.coli. Where possible target selection will be restricted to proteins known to be non-hazardous when expressed in isolation. The source material will be purchased as cDNA from a supplier or derived from tissues produced by a third party animal house.

End uses will include the production of protein for use as antigens, lysates for screening by western blot and detection reagents/enzymes for assays such as ELISA.

Evaluation of foreseeable effects

The project scope allows for the cloning and expression of a wide range of functionally distinct genes. The most hazardous of which are potentially harmful proteins (such as cytokines, growth factors, oncogenes). The production of these proteins will, where possible, be restricted to non-functional fragments, with each protein requiring its own risk assessment. Furthermore, prohibiting the use of sharps, in conjunction with any GMO work will further reduce operator risk.

The accidental transfer of sequences to other hosts is highly unlikely due to the disabled nature of the host organism and non-mobilisable vectors used. The vector will not carry genetic factors for mobilisation and expression vectors will not contain eukaryotic promoter sequences (further reducing the risk to humans).

All genetically modified micro-organisms (GMMs) will originate from recognised, disabled, non-colonising E. coli strains, classified as ACDP Hazard Group 1 organisms. Therefore the GMM is highly unlikely to survive in the ‘outside environment’ (outside the media). The risk posed by expressed proteins will be minimised, as they will be expressed in small quantities (mg), and the likelihood of delivery to the site of action is minimal (no sharps).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Precautions for safe disposal:
All waste is to be autoclaved at 121°C for 15 minutes to sterilise prior to disposal via Abcam's established clinical waste disposal route. Solid waste is double-bagged in...
clear autoclave bags, prior to sterilisation and, post-sterilisation, placed in clearly marked-yellow clinical waste bags for disposal off-site. All clinical waste is kept in sealable yellow-bins, distinct from all other waste and is removed from the site for incineration by a licensed contractor. Our designated GM autoclave, keeps electronic records of each run, will display a warning alarm if a cycle fails, and is serviced by the manufacturer on a yearly basis. NB Containment: prior to inactivation all class 2 materials are to be handled in a class 2 biosafety cabinet (these are are maintained, and serviced on an annual basis, by an approved contractor).

Disinfection:
70% ethanol/industrial methylated spirits and blue roll is used in combination with Trigene to sterilise work surfaces by spraying and wiping down with blue roll both before and after Cell culture work.
Where necessary, liquid cultures are disinfected by mixing 1:1 with 2% Virkon and left overnight to ensure maximum killing time (in excess of manufacturer’s recommendations). The same Virkon solution is used to sterilise any spills that occur, and serological pipettes are soaked in 1% Virkon prior to disposal via the clinical waste route.
Both Virkon and Trigene have been shown to be broad spectrum and fast acting disinfectants by their manufacturers.

</table>
The proposed objective of this project is to generate recombinant antibodies, of mammalian origin, to small molecules, proteins and viruses in mammalian cells. These antibodies will be used primarily in research as reagents. This will involve the batch production of antibodies using established cell lines, in combination with CMV based vectors to produces milligram quantities antibody.

HEK293 cells and their derivates. HEK293 cells have been immortalised by transfection with adenovirus DNA and contain a partial virus genome. on this basis HEK293 cells are normally classified as Hazard Group 2. The cell line itself is well characterised and has a long history of safe use. Furthermore HEK cells do not shed active virus and will not be used for viral production in this project.

CHO cells and their derivates. CHO cells are classified as a Hazard Group 1 cell line, are well characterised and have a long history of safe use.

Mammalian cell lines, such as CHO and HEK293 cells, have very poor chances of survival outside of the nutrient rich and sterile cell culture environment. therefore they pose minimal environmental risk.

Disabled (auxotrophic for nutrients and non-colonising) lab strains of E. coli (e.g. DH5a, Novablue) will be used for cloning and vector generation. All strains have a long history of safe use, are unlikely to survive in the environment and will be sourced from reputable suppliers.

The adenoviruses which will be used in aspects of this work have been rendered replication deficient by deletion of the E1 region of the genomes. Purified adenovirus will be provided for us by a reputable supplier. and will not be propagated on-site. The adenoviruses which will be used in this work will not contain any genetic Insertion.

All plasmids will be non-mobilising in bacteria, and will carry CMV and/or HTLV viral promoters to enable mammalian gene expression (e.g. pCMV6-AC)

The source material will be plasmids or synthetic DNA obtained from a reputable supplier (e.g. Origene) or, in the
case of antibody production, B cells obtained from the PBMCs or spleens of immunized rabbits produced by a third-party animal house. In the case of antibody production B cells will be fused to create hybridomas and the antibody sequences from these cells will be subsequently cloned into antibody expression vectors. These will be transfected into HEK293 (and/or CHO cells, or similar mammalian cells) to allow expression and the secretion of the antibody. End uses will include the harvesting cell supernatant for screening by ELISA and, in some cases, Western blot, immunohistochemistry, immunocytochemistry and flow cytometry.

In the case of anti-viral antibody production, purified replication-incompetent virus adenovirus, provided by a reputable supplier will be used at the antigen in an ELISA assay to identify specific antibodies. Purified virus will either be adsorbed directly onto the surface of polystyrene microtitre plates or will be added to plates previously coated with anti-viral polyclonal antibody, in a standard sandwich ELISA method.

**Evaluation of foreseeable effects**

This project will involve cloning of a variety of functionally distinct genes and expressing them in mammalian cells. The most hazardous gene products will be those known to code for potentially harmful proteins; cytokines, growth factors. The production of cytokines and growth factors will, where possible, be restricted to non-functional fragments, with each protein requiring its own risk assessment. Furthermore, the use of sharps, in conjunction with any GMO work will be prohibited to further reduce operator risk.

In the case of recombinant antibody production, these antibodies will have been produced in rabbits, in response to immunisation, and therefore no potential hazards from the encoding plasmids is expected.

The accidental transfer of cloned genes to humans is unlikely to present a high level of risk as the plasmids used will be naked DNA and, unaided, unlikely to cross a cell membrane to establish protein production within the cell. In the case of anti-viral antibody production, purified replication-incompetent virus adenovirus, provided by a reputable supplier will be used at the antigen in an ELISA assay to identify specific antibodies. Purified virus will either be adsorbed directly onto the surface of polystyrene microtitre plates or will be added to plates previously coated with anti-viral polyclonal antibody, in a standard sandwich ELISA method. The adenoviruses which will be employed in this work are replication deficient and will not contain any genetic insertion. No replication competent viruses have been found following standard Replication Competent Adenovirus assays, so there is very minimal risk of any live virus being present in the final preparation. Purified virus will be provided by a reputable supplier and virus will not be propagated on site at any stage.

In the very unlikely event of exposure to replication competent adenoviruses, it should be noted that adenoviruses are ubiquitous pathogens of both mammals and birds, usually causing only mild self-limiting infection in human which does not require any specific treatment. No allergic or toxic effects are associated with these viruses.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Tick if confidential
Yes

All waste will be autoclaved at a minimum of 121 deg C for 20 minutes before removal from the premises for incineration. This procedure is expected to kill 99.999% of all GMO’s. A print out of each cycle will be kept on file for a minimum of two years. Virkon in a 1% solution for laboratory discard jars left for at least 12 hours in a 2% solution for laboratory spills.

For activities involving GMMs, describe the waste management measures which will apply to the activity:

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment:

It was decided that the procedures should be amended to the effect that all Activity Class 1 projects should be sent by e-mail to all members of the committee for interim approval, without the need for a formal meeting. This interim approval to be ratified by a formal meeting of the committee that should be held annually in the first instance. There was some discussion about how our risk assessments should be arranged. Originally each gene was given a different risk assessment for each cell type. After some discussion it was decided that putting a series of genes from a gene family into a series of cell types could go under one risk assessment provided each situation was considered on its merits and they all had the same classification. This would cut down on the paperwork considerably. It was emphasised that the committee should be aware of the potential for higher risks within these assessments. Risk assessments will be reviewed approximately annually, and those we are not actively working on will be designated as parked. Each completed risk assessment was examined. It was decided that a single assessment would suffice for all kinases in all expression systems. It was also agreed that all expression systems could be grouped together provided they all represented the same level of risk.

Date Ackn’d: 18/06/2010
CU2 Project Title: Genomic modification of human cells using lentiviral vectors
Project Ref: 3011/10.1
Purposes of the contained use

CRT undertakes focussed translational research on cancer pathology & treatment. This necessitates extensive use of human cells (established cell lines). These cells very often need to undergo genomic modification as part of the research. This GM includes use of shRNA or shRNAmir (microRNA-adapted shRNA) to perform gene knockouts, insertion of reporter genes to label and detect cellular processes, insertion of genes.

Lentiviruses are a type of retrovirus with more complex genomes than what are usually classified as 'retroviruses' for the purpose of GM work, and include the human immunodeficiency virus (HIV). The genome comprises the gag, pol, env genes (as do 'retroviruses') plus tat & rev genes that regulate viral gene expression and genes such as vif/vpr/vpu/nef needed for infectivity & pathogenesis. Lentiviruses, as per all retroviruses, are enveloped single-stranded RNA viruses. Lentiviruses infect both dividing and non-dividing cells. Lentiviruses are stably integrated into the genome of infected cells.

The lentiviral vectors that will be used for the work do not use the env gene but rather are pseudotyped with vesicular stomatitis virus membrane glycoprotein (VSV-G) to increase host range and stability. They will also include the woodchuck hepatitis B virus (WHV) post-transcriptional regulatory element (WPRE) to increase viral vector titre and genomic integration into, dividing and non-dividing human cells of a wide variety of tissue types with relatively high efficiency. Lentiviral vectors thus provide an excellent vehicle of great utility for achieving the genomic modifications needed for the research objectives of CRT. High titres of viral particles may be required. Examples of lentiviral vector systems used include TRIPZ and GIPZ with Trans-Lentiviral packaging system PTLA1-Pak, pTLA1-Enz, pTLA1-Env, pTLA1-Rev and pTLA1-TOFF (Open Biosystems), or pLENTI4 and pLENTI6 with ViraPower packaging system pLP1, pLP2, and pLP/VSVG (Invitrogen).

Given the nature & objectives of the research at CRT, the genetic targets are commonly oncogenes and tumour suppressor genes.

Recipient or parental organism

The bacterial strains used to produce the plasmid vectors are attenuated non-colonising strains that are harmless to Humans and cannot survive outside culture conditions, and are therefore harmless to the environment.

The producer cells that will package the virus after being transfected are harmless to humans. They are also unable to survive outside culture conditions, and are therefore harmless to the environment.

The recipient cells that will eventually receive and integrate the DNA are harmless to humans. They are also unable to survive outside culture conditions, and are therefore harmless to the environment.

Host/vector system

All the plasmids used are non-mobilizable
The lentiviral vectors used will all be well characterised, with a history of safe use, and inherently safe. These vectors will all be self-inactivating & replication-incompetent, that is, each lentiviral vector particle infects and gives genomic modification of one cell, and that cell will not (and indeed cannot) subsequently produce and release further viral particles. This is due to a deletion in the 3’ LTR (TATA deletion) which prevents excision after genomic integration.

These vectors will all be at least third generation, that is, the genes needed for packaging of the construct into live viral particles are present on at least three different vectors that cannot themselves be packaged into viral particles, and cannot recombine with each other or with the lentiviral vector. This means that cells can be infected with viral particles made in the packaging cell lines, but infectious viral particles cannot be made in the target cells. This then means that the probability of recombination events (especially with wild type lentivirus) generating a 'reverted' viral vector capable of inducing live viral production & release by infected cells is very unlikely - it would require three recombination events, each of which is very unlikely. Furthermore, the accessory genes (vif, vpr, vpu, nef) and the tat gene are deleted, and expression of the vector construct is contingent on upstream elements and trans complementation packaging acts as an inherent safeguard against generation of productive recombinants.

The lentiviral particles cannot survive outside of closed controlled cell culture conditions and are rapidly inactivated by dehydration or other environmental insults. They require close contact with body fluids or percutaneous inoculation for transmission. The virus could, in principle, in the unlikely event of it being introduced to the cells of a worker, give genomic modification of cells of the worker. The inserted sequences could be oncogenic, or could activate oncogenes, or could repress tumour suppressor genes, or could lead to other deleterious effects and dangerous changes to gene expression.

Origin & function

The bacterial strains used to produce the plasmid vectors are attenuated non-colonising strains that are harmless to Humans and cannot survive outside culture conditions, and are therefore harmless to the environment.

The recipient cell lines cannot survive outside the laboratory incubators and as such pose no threat to health or environment.

None of the plasmids, which are non-mobilizable, are harmful to health or to the environment. The packaging components are from the HIV-1 virus (harmful to Humans) but many components that are critical for HIV-1 infection have been removed. Only those essential for viral packaging remain in the vectors.

The most dangerous GMM is the lentiviral particles and the most hazardous steps are their collection, concentration and infection of recipient cells with them. However, the viral particles require close contact with body fluids or percutaneous inoculation for transmission. The virus could, in principle, in the unlikely event of it being introduced to the cells of a worker, give genomic modification cells of the worker. The inserted sequences could be oncogenic, or dangerous changes to gene expression.

The lentiviral particles cannot survive outside of closed controlled cell culture conditions and are rapidly inactivated by dehydration or other environmental insults. In order to minimize risks, all work involving viruses will be performed in Class 2 cabinets in containment level 2 laboratories specified particularly for viral GMM work. All DNA plasmids containing viral proteins will be grown separately to avoid opportunity for recombination. To avoid any contamination of workers by viral particles, no glass or other sharps will be used in the rooms where the virus is prepared and used, and workers will be protected by a lab coat and disposable gloves. Skin lesions will be covered by a bandage in addition to the protective wear described above. Specific guidelines will be in place to ensure all viral preparations are handled, labelled, stored transported and cleaned-up correctly. All those involved in the work will be made aware of the guidelines and the associated risks, as well as anyone else who may use the laboratory.

Evaluation of foreseeable effects

The genetic material included use of shRNA or shRNAmir (microRNA-adapted shRNA) to perform gene knockouts, insertion of reporter genes to label and detect cellular processes, insertion of genes (generated from IMAGE clones coming from human cDNA Libraries). Given the nature & objectives of the research at CRT, the genetic targets are commonly oncogenes and tumour suppressor genes.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

1-5% Virkon (v/v) will be used to treat liquid waste (18 hours) and to decontaminate any spills and for disinfection of any reusable bottles or other equipment and laboratory materials used. Liquid waste will be poured down the sink after treatment with 105% Virkon. Work surfaces will be wiped down with 5% TriGene Advanced and 70% ethanol treatment, solid waste will be double bagged in biological waste bags, sealed and autoclaved at 132°C with a hold time of 15 min by trained staff, then bagged according to UCL waste services procedure. Autoclave runs are regularly validated by waste management staff via thermocouple print out. Autoclave runs are regularly validated by waste management staff.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

Please enter comments on the GM safety committee on the risk assessment

University College London Genetic Modification Safety Committee:
This committee commented that the fact that sharps/glass etc was not used was mentioned on form CU2 it should be mentioned on the accompanying risk assessment.

Cancer Research Technology’s Biological and Genetic Modification Safety Committee.
This committee commented that we explain the abbreviation and include a reference to shRNA.
They ask for more explanation of a “third generation vector” this was added to section 2.06
In section 1.10 they requested we give some idea of the size, purpose and reference for the shRNA.
In section 1.15 they asked that we add “No likelihood of further cell to cell transfer”
In section 1.36 there was some discussion about the additional training required. It was decided that this was not needed at this level of risk.
A typographical error was corrected in section 2.07

**Project Additional Information**

**Purposes of the contained use**

The aim is to use 2nd generation or later lentiviral packaging systems in combination with 3rd generation Lentiviral transfer vectors to achieve single or multiple genetic mutations by utilising shRNA, CRISPR/Cas9 (and derivatives thereof) in genome wide screening efforts and in a range of mammalian cell lines in order to facilitate drug discovery projects. The extent of the planned work is limited to in vitro studies. Approaches include both transfection of plasmid vectors into eukaryotic packaging cell lines such as HEK-293T to generate replication-defective viral particles and, use of such replication-defective viral particles to transduce mammalian cell lines. The use of 2nd generation packaging systems will enable the generation of virus with appropriate virus titers required for whole genome wide pooled CRISPR screening in a wide range of mammalian cell lines. Virus titers from wholly 3rd generation lentiviral systems may not be suitable for a wide range of difficult to transduce mammalian cell lines. Restricting the use of of lentiviral systems to 3rd generation would therefore prevent successful genome wide screening in certain cell lines. 2nd generation lentiviral packaging systems will only be used if 3rd or 4th generation systems will not be suitable as described above. Additionally, close scrutiny of the transgene in the context of 2nd generation systems will be ensured in order to prevent the use of vectors containing packaged Tat and to minimize the likelihood of generating replication-competent viruses. Oncogenes and cytokines are not used as transgenes.

**Recipient or parental organism**

Lentiviruses are a type of retrovirus with more complex genomes than what are usually classified as ‘retroviruses’ for the purposes of GM work and include the human immunodeficiency virus (HIV). The genome comprises the gag, pol, env genes (as do ‘retroviruses’) plus tat & rev genes that regulate viral gene expression and genes such as vif / vpr / vpu / nef needed for infectivity and pathogenesis. Lentiviruses, as per all retroviruses, are enveloped single-stranded RNA viruses. Lentiviruses infect both dividing and non-dividing cells and stably integrate into the genome of infected cells. All vector systems will be split to minimise possibility of replication and where packaging cell lines are to be used these will be consistent with 2nd generation or later systems. Hence these viral vectors are extremely unlikely to be able to replicate in human cells or in the wider environment and are unable to present the pathogenesis associated with the originating pathogen. The lentiviral vectors that will be used for the work do not use the env gene but rather are pseudotyped with vesicular stomatitis
virus membrane glycoprotein (VSV-G) to increase host range and stability. They will also include the woodchuck hepatitis B virus (WHV) post-transcriptional regulatory element (WPRE) to increase viral vector titre and enhance expression of the transgenes (WPRE is similar to the post-transcriptional regulatory element found in human hepatitis B virus (HBV), which is closely related to WHV). Lentiviral vectors thus allow transfection of, and stable genomic integration into, dividing and non-dividing human cells of a wide variety of tissue types with relatively high efficiency. Lentiviral vectors thus provide an excellent vehicle of great utility for achieving the genomic modifications needed for the research objectives of CRT. High titres of viral particles may be required. Examples of lentiviral vector systems used include TRIPZ and GIPZ with Trans-Lentiviral packaging system pTLA1-Pak, pTLA1-Enz, pTLA1-Env, pTLA1-Rev and pTLA1-TOFF (Open Biosystems), or pLENTI4 and pLENTI6 with ViraPower packaging system pLP1, pLP2, and pLP/VSVG (Invitrogen), pMD2.G (https://www.addgene.org/12259/) and psPAX2 (https://www.addgene.org/12260/).

### Host/vector system

For lentiviral systems, viral particles will be generated by introducing plasmids containing elements of the virus genome into established packaging cell lines, e.g. human embryonic kidney (HEK293T) cells. There may be instances where the essential viral packaging genes will be expressed stably by the packaging cell, with a single plasmid carrying the vector backbone and transgene being introduced by transfection, and in other cases the viral functions and the vector backbone/transgene will be encoded on separate plasmids which will be transfected together.

Such viral vectors will then be used to transduce a range of human and animal cell lines. Target cell lines for transduction may comprise established and primary mammalian cell lines not known or suspected to contain pathogens at Hazard Group 3 or above. This could include human, rodent and primate sources.

### Origin & function

Given the nature and objectives of the research at CRT - TDL, the genetic targets are commonly oncogenes and tumour suppressor genes. Short hairpin RNA (shRNA) molecules intended to inhibit the expression of a range of genes including those known or suspected to be involved in pathways of oncogenesis, and genes intended to induce immortalisation and the extension of the proliferative lifespan of cells. CRISPR/Cas9 systems may be expressed which are intended to cause double-stranded breaks in DNA, leading to mutation by non-homologous end-joining or insertion of specific mutations or tags with homology-directed repair constructs. Variants of the CRISPR/Cas9 system include, S. pyogenes (sp) Cas9, spCas9-HF-1, saCas9, catalytically dead mutants of Cas9 fused to effectors such as cytidine deaminase or transcriptional/epigenetic regulators (CRISPRi/CRISPRa) and non Cas9 modifiers such as Cpf1. This work does not include the use of viral vectors expressing toxin genes or major pathogenesis factors (e.g. oncogenes as transgenes).

### Evaluation of foreseeable effects

For lentiviral vectors, use of second generation (or later) viral vector systems in which all accessory genes have been deleted, and where gag, pol, env and rev genes are provided in trans (either on additional accessory plasmids or integrated into the genome of packaging cell lines), means that the risk of production of replication-competent or infectious virus is extremely low. In addition the use of self-inactivating (SIN) viral vector systems in which promoter and enhancer elements have been removed from the long terminal repeats (e.g U3 deleted 3'LTR for lentiviral transfer vectors), reduces the risk of transactivation of genes proximal to the insertion site, but there remains the possibility gene activation by constitutive promoter/enhancer sequences within the inserted genetic material. Insertion of the viral genome could also result in disruption of genes involved in cellular regulation (e.g. tumour-suppressor genes). WPRE sequences used to increase the levels of expressed mRNA will be present in many vector systems. Although some versions of these elements also express a promoter fragment of the Woodchuck Hepatitis Virus X protein for which there is published evidence for its association with oncogenic activity (Hohne et al., EMBO 9, 1137-1145.1990; Schuster et al., Oncogene 19, 1173-1180. 2000), it is anticipated that this would not result in a need for a higher containment level (>CL2). Nevertheless to improve safety considerations, the preference will be for vectors devoid of the WPRE fragment or containing the mutated/deleted non X protein fragment containing form of WPRE.

In the instance of any transduction event, even by a viral vector that is non-infectious and replication-defective, the resultant integration of the inserted gene into the genome of the host cell means that expression will be permanent. Hence whilst the vector itself will not proliferate, cell division may result in a population of cells expressing the transgene. Specific hazards associated with inserted genes include:-

1. Expression/over-expression of known or potential oncogenes: while oncogenesis is known to be a multi-factorial process, the risk of insertional activation of other oncogenes by the vector, or of insertional inactivation of tumour suppressor genes is unpredictable, and could act in concert to contribute to oncogenic pathways.
2. Expression of short hairpin RNAs designed to knock down known or potential tumour suppressor genes
3. Intentional CRISPR/Cas9 modifications leading to inactivation of tumour suppressor genes or increased activity of endogenous oncogenes.
4) Expression of cytokines, growth factors and other bioactive molecules: these proteins have the potential to cause inappropriate growth, differentiation or apoptosis of cells, which are associated with oncogenesis. Growth factors and cytokines may also be teratogenic, and have other effects on the immune response. Such hazards may be associated with the viral vector or the final GMO (ie. cell line).

The highest level of risk associated with the viral vector or insert hazards is exposure by direct contact, self inoculation and aerosol generation. Controls measures required at Containment Level 2 include a no sharps policy, gloves and use of microbiological biosafety class II cabinet to reduce likelihood of exposure. The risks to workers associated with the plasmids used to generate the viral vectors are considerably less than the virus itself, as the passive uptake of circular DNA into human cells is a very inefficient process and chromosomal integration is much less likely.

All risk assessments for GM activities with retroviral vectors will continue to be subject to scrutiny and approval by the CRUK Research & Innovation (R&I) GM committee. The following activities will NOT be permitted within the work:-
1) Preparation of high-titre retroviral or lentiviral stocks by methods that require the use of needles to harvest the virus (e.g. density gradient centrifugation).
2) The use of sharps, including hypodermic needles and scalpels,
3) Expression of a major pathogenesis factor or a toxin gene (eg oncogenes and cytokines).
4) The use of lentiviral vectors for which there is evidence or potential for the presence of replication-competent virus.
5) Aerosol generation by ultracentrifugation of supernatants.
6) Any other activity which the R&I GM committee decides which constitutes one or more risks that might consign it to a higher Class.

According to the SACGM Compendium of Guidance, the risks are negligible 'where the cells do not incorporate any helper function and where residual virus titres have been reduced by replacing the potentially infectious cell supernatant medium'. Where validated procedures are not available or number of passages/dilution factors are unknown, screening (eg p24 ELISA for lentivirus) for presence of viral contamination in supernatant will be performed before any derogation of containment measures. Cells or samples shown to be free from viral vectors used after that may therefore be re-assigned to Class 1 GMMs for subsequent use, storage and transport, so long as the parental strain is Hazard Group 1.

No animals or plants to be used in this work

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No animals or plants to be used in this work

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be inactivated with a final concentration of 2% Virkon for a minimum of 20 minutes. (Dupont specification says it has been independently proven that 1% solution kills bacteria within 5 minutes and parvovirus within 10 minutes.) Surfaces are cleaned with a solution of 1% Virkon or Chemgene 1:10 spray. Chlorasept tablets are also used on some occasions at a minimum of one 2.5gm tablet per litre of solution, again left for a minimum of 20 minutes.

All solid Biohazard and GM waste is double contained in autoclave bags within autoclave bins, autoclaved on site at a minimum of 131deg C with a hold time of 20 minutes followed by offsite disposal. The autoclave runs are monitored for temperature and hold time automatically.

Procedures, relevant training, supervision and safety inspections are in place to ensure that all staff comply with waste protocols correctly as specified above

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

02/03/2022
Comments from CRUK R&I's GM committee. The proposed notification is an extension of TDL's existing class 2 GM notification to allow the use of 2nd generation lentiviral packaging systems with 3rd generation transfer vectors. Points discussed included:

1. General view was that risk assessment and notification were all within class 2.
2. There was discussion over the types of KO/KI being generated – the aim is to screen genome wide by creating pools of targeted insertions.
3. A question regarding whether additional signage was required whilst viruses are ‘actively in use’ – the existing signage and access control meets regulatory requirements and are sufficient.
4. A comment was made that re-assignment of cells or samples to Class 1 GMMs for subsequent use, storage and transport can only occur if the parental strain is Hazard Group 1.
5. A comment was made on ‘plates being lidded and sealed’ and if there would be secondary containment in the incubators? All the incubators are in CL2, the lidding and sealing of plates is to allow plates to be taken out of CL2 in secondary containers for reading on equipment in CL1 – out of scope risk assessments are in place to allow this.
6. A question was also raised around spillages and whether a procedure was in place to cover a spill on a person. This is not covered in the risk assessment but is included as part of the local Milner institute CL2 induction and standard procedures.

Spent liquid growth media to be sterilised by addition of 10% (v/v) £0.5 L Virkon for >60 mm. Treated waste to be discarded down designated sink (in containment level I laboratory where all work will take place) with copious water. All other waste to be sterilised by autoclaving following “waste procedure” with monitoring by way of TST Control Integrator Test Strips (Browne), to confirm effectiveness of each run. Inactivation effectiveness of the “waste procedure” for small volume cultures will also be confirmed by frequent (monthly) viability testing performed by plating 0.2 mL of a healthy 16 h culture of the strains used after inactivation by way of the “waste procedure”. During every small scale production run (1 L scale), the production of aerosols will be monitored using open agar plates containing (1) no antibiotic and (2) the selection antibiotic(s). The results of this monitoring will be recorded along with results from the “waste procedure” viability spread plate tests. Toxic materials will be disposed of by special contractor arrangement, as will sharps (collected in sharps bin for eventual incineration). However, toxic waste will be limited to very small quantities of ethidium bromide bound to a flow through cartridge, as per any small molecular biology laboratory. Sharps waste will be emptied annually, and this will only be to ensure the inside of the bin is free from any growth in the bottom.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

With reference to the attached class 1 activity risk assessment, it is reiterated that individual risk assessments will be performed in advance of the development / production of new recombinant enzyme / protein. It is also reiterated that a consensus is required before any practical work can begin with respect to the development! production of a new recombinant enzyme! protein. The GMSC is wholly satisfied that the restricted access purpose designed research and development! production laboratory at Prozomix is perfectly suitable for the small scale recombinant enzyme! protein development / production and other proposed operations as proposed. Notable features with respect to protecting human health and that of the environment and that all work falls into Class 1. Inactivation, monitoring and aerosol production are performed routinely and records kept, all autoclave runs (regardless of reason) are monitored with TST test strips and results logged in a record book, a clear and simple bacterial spill protocol is employed, and full training is provided even to previously experienced members of staff regarding safe performance of the microbiological, molecular biological and GMM aspects of the proposed activities (and records kept).

Give brief details of the genetic modification safety committee

The GMSC will meet at least once per quarter to discuss GM risk assessments, and other issues associated with GM and microbiological safety. The GMSC consist of people with training (to PhD level) and experience (many years academic and/or industrial) in molecular and microbiology, biochemistry and genetic manipulation, as well as HSE experts. The GMSC members have also been chosen from the managerial, scientist, and technical levels, and there will also be a representative from the site safety group. This combination of members has been chosen to ensure that all possible issues are raised, discussed, correctly assessed and documented at the GMSC meetings.

Bacteriology | Yes | Parasitology | Transgenic Birds | Microbiology Research Yes |
All GM work will be carried out in a class 2 laboratory, with autoclave facilities in a room within the class 2 laboratory suite. Liquid waste containing GMMs will usually be autoclaved for 1 hour at 121°C (15psi), except where significant amounts of solvent are present in the growth medium, in which case the GMMs will be inactivated with Virkon treatment for at least 1 hour at room temperature. Autoclave efficiency will be monitored during every autoclave run by checking the autoclave run data (from the internal thermocouple). In addition, inactivation efficiency will be screened on a regular basis by placing biological indicators in the samples being autoclaved, and by attempting to reculturing the autoclaved (or Virkon treated) material after inactivation. After inactivation, non-solvent waste will be disposed of down drains with copious amounts of water, whereas waste containing significant amounts of solvent will follow normal solvent disposal routes.

Solid waste will be put into autoclave bags in the laboratory (themselves contained in distinctive plastic bins to distinguish them from standard laboratory waste bins), and then autoclaved by trained staff. After inactivation, the solid waste will be treated as standard laboratory waste, and then taken for incineration by laboratory stewards.

Spills will be cleaned using standard microbiological spill kits, and if appropriate, surfaces will also be sterilized with 70% ethanol.

The GMSC was happy with this risk assessment, although a few minor changes were suggested, and these have been incorporated into the modified version (attached). These minor changes were around the use of ‘commercial’ vectors; it was felt that work on creating novel plasmid backbones was beyond the scope of this risk assessment, and should be risk assessed separately.

It was agreed that the GMMs would not pose an increased risk to human health. However, there was a discussion about the hazard that these organisms might pose to the environment. It was pointed out that GMMs expressing a whole suite of carbohydrolases might be able to degrade plant biomass, and thus thrive in the natural environment. Counter to this, it was pointed out that these organisms would endure a high metabolic load - due to the amount of protein that they are synthesizing - and would therefore likely be less fit in the natural environment than the wild-type organisms. To degrade natural, untreated plant biomass, these organisms would have to produce, and export cellulases and ligninases (5 or more enzymes in total), and it was agreed that with this metabolic load, they are unlikely to have increased fitness in the natural environment. Furthermore, the use of ligninases is beyond the scope of this work. In light of this, it was decided that treating the GMMs as HG2 organisms provided more than adequate containment measures.

WLGM-01 and WLGM-02 were reviewed by the GM safety Committee on 10th July 2008. There were some minor changes suggested to WLGM-02, to remove some of the abbreviations. The committee were in agreement that both risk assessments should be sent to the HSE as part of the notification of intention to use the premise for contained use activities.

To be advised.
Purposes of the contained use

Originating from early developing cells after fertilization, embryonic stem cells (ESC) are unique in their capacity to generate all differentiated cell types composing their original organism. The ability to cultivate ESC in vitro offers a tremendous opportunity to the scientific community to study fundamental mechanisms acting through embryonic development as well as opening exciting clinical perspectives by offering wide possibilities for in vitro pharmacological models and cell sources for regenerative medicine. Our global objective is thus to gain better knowledge in molecular factors and mechanisms controlling early ESC fate specification towards the three primitive embryonic germ layers (endoderm, mesoderm and ectoderm) and further differentiation towards mature functional cells. By bringing important insights in fundamental development processes, our project should allow us to gain in parallel a better control in ex vivo differentiation protocols from ESC and improve the production of therapeutically relevant cell types like cardiomyocytes, neurons, pancreatic cells or haematopoietic stem cells for instance.

This general perspective will develop into three leading projects implying genetic modification of various cell types:
- Project1. Factors controlling cell fate specification of pluripotent stem cells
- Project2. Transcriptional factor mediated reprogramming of somatic and embryonic stem cells
- Project3. Gene targeting in human embryonic stem cell

Since they are highly efficient vectors to genetically modify numerous cell types (notably ESC), we plan to use recombinant viral vectors derived from gamma-retroviruses, lentiviruses and adenoviruses to achieve our goal.

We will use recombinant retroviral particles (MuLV derived, from the company Vectalys, France) and recombinant lentiviral particles (HIV-1 derived, production in situ) which have amphotropic ranges of tropism (VSV-G pseudotyped). For some experiments, recombinant adenoviral particles (Ad5 derived, from the company Hybrid Systems, UK) will be also used. All recombinant viral vectors will be replication defective and each production batch
properly tested for absence of infectious particles. Inserts (cDNA, shRNA) will be cloned into these vectors, alone or in combination (through the use of independent promoters, IRES or 2A sequences) with GFP, antibiotic resistance gene or another insert of interest. In situ production of lentiviral particles will be achieved by transient co-transfection of 3 plasmids (vector, helper and envelope) into 293T/17 cells. All lentiviral particles will be produced from SIN (Self Inactivating) backbones using the 2nd generation production system (Vif, Vpr, Nef and Vpu deleted helper plasmid). Work involving recombinant virus handling (production, transduction) and human primary cell culture will be performed under containment level 2 conditions in compliance with institution practice.

Recipient or parental organism
1. Escherichia coli - K12 derived strains, disabled, non colonising
2. Gamma oncoretroviruses – MuLV derived, replication defective, amphotrope
3. Lentiviruses – HIV-1 derived, replication defective, amphotrope
4. Adenoviruses – Ad5 derived, replication defective, ecotrope
5. Mammalian cells (primary cells and cell lines) – considered as especially disabled
   - Human, murine embryonic stem cell lines (H9, H1, HSF6, ...)
   - Human, murine induced pluripotent stem cell lines (produced in situ)
   - Human, murine primary cells (embryonic and adult skin fibroblasts, keratinocytes, peripheral blood cells)
   - Human, murine somatic cell lines (HEK-293T, HCT-116, ...)

Host/vector system
1. E.coli K12 / pUC derived plasmids - no insert expression, plasmid non mobilisable.
2. HEK-293T / pUC derived plasmids – transient co-transfection, viral gene and insert expression, production of amphotrope replication deficient lentiviral particles (each batch to be tested).
5. Mammalian cells / Ad5 vectors – replication defective adenoviruses, transient genetic modification.

Origin & function
1. Human, murine, xenopus cDNA (+/- TAG sequences) coding for transcription factors, signal transducers, growth factors and surface receptors. These inserts are expected to play a role in pluripotency, cell fate decision and differentiation from pluripotent stem cells (PSCs). Their expression may enhance/block commitment and differentiation of PSCs towards one of the three primitive germ layers and further differentiated progeny.
2. shRNA and miRNA sequences against cell endogenous coding sequences. These inserts are non coding RNA sequences targeting cell endogenous mRNA from above mentioned factor families (in 1) in order to inhibit protein expression by RNA interference (RNAi). Their expression may enhance/block commitment and differentiation of PSCs towards one of the three primitive germ layers and further differentiated progeny.
3. Reporter genes (GFP, LacZ, Luciferase, possibly fused to cDNA (type1 inserts)). These inserts will code for proteins with fluorescent or enzymatic properties allowing easy identification of genetically modified (GM) cells. They are thought to have no deleterious biological effect on expressing cells.
4. Selection genes (NPT, PAC). These inserts will produce enzymatic proteins able to inactivate specific antibiotic families allowing selection of GM cells. They are thought to have no deleterious biological effect on expressing cells.
5. Functional non coding sequences. These inserts will act as promoters of transcription (promoters and enhancers), local chromatin structure modifiers (enhancers and insulators), RNA transcript stabilizers (WPRE) or translation regulators (IRES). They will be used (independently or in combination) into viral expression cassettes to achieve best
control of transgene expression depending on targeted cells.
6. Neutral non coding sequences (introns, isolated exons). These inserts will be used in particular for gene targeting projects to promote homologous recombination at defined genomic loci (intronic/exonic genomic sequences). They should not have biological effect by themselves.

**Evaluation of foreseeable effects**

**Human Health considerations -**

The most obvious risk for human health is linked to accidental infection of worker by recombinant viral particles. Indeed, because only replication defective viral particles (non infectious) will be used for experimental work through this project and inserts will not produce compounds with acute toxicity (like bacteria toxins), no additional risk will be associated with the final GMO itself (mammalian cells) compared to initial organism. Importantly, primary cells coming from human samples are uncharacterised and may contain adventitious agents: they will be handled at containment Level 2 (COSHH regs).

First, risks associated with the nature and design of recombinant viral particles has to be assessed. Retroviral recombinant particles (MuLV and HIV-1 derived) will be VSV-G pseudo-typed (protein G from the Vesicular Stomatitis Virus will replace the native envelope protein). VSV-G packaging alters the tropism of the retroviral particles, requiring interaction only with phospholipids present in the plasma membrane of all cells rather than interaction with a cognate receptor as occurs with ecotropic packaging. Thus, VSV-G pseudo-typed retroviruses acquire the ability to efficiently infect virtually all human cell types. Moreover, VSV-G pseudo-typing improves stability of the viral particle and may represent an aerosol means of transmission in addition to the expected percutaneous risk. Retroviruses stably integrate the host cell genome. This property is associated with a risk of insertional mutagenesis, i.e. ectopic activation/inhibition of host gene expression after colocorized provirus integration. Subsequent deregulation of endogene expression could theoretically lead to transduction associated detrimental effects like initiation of oncogenic processes. Moreover, the addition of the WPRE (Woodchuck Hepatitis Post-transcriptional Regulatory Element) to the expression cassette in several retroviral backbones could also enhance the oncogenic potential of such vectors (SACGM, annual report 2004). Importantly, among retroviral vectors, the use of lentiviral derived backbone is thought to be safer. First, genomic integration profile of lentiviral derived vectors do not show an integration bias toward the transcriptional start site region of host cell genes like MuLV ones. Moreover, we will use exclusively SIN (Self Inactivating) vectors devoid of viral enhancer activity which reduces further the likelihood of endogene activation. In contrast, recombinant adenoviral vectors are considered safer. Indeed, adenoviral genome is rarely seen to integrate into the host cell genome and transgene expression remains transient in host cells. Moreover, the disease caused by wild type adenovirus is usually just a mild and self limited common cold.

Risks associated with inserted coding sequences should also be assessed. cDNA (or shRNA/miRNA) inserts carried by viral vectors will direct ectopic expression (or inhibition) of transcription factors, signal transducers, growth factors and receptors which are expected to play a role in pluripotency, cell fate decision and differentiation from pluripotent stem cells. It is difficult to predict in vivo consequences of ectopic expression for all these genes on human health. However, since they are key regulator of cell identity, their overexpression could lead to pathological modifications of cell phenotype/function. Moreover, several of these genes have been involved in oncogenic processes and uncontrolled expression could subsequently initiate tumoral transformation. However, malignancy is a complex multistep process which involves multiple genomic alterations and a single “hit” is unlikely to trigger alone the oncogenic process. Experiments involving co-transduction or even co-expression by the same vector of several inserts should consequently be considered at higher risk for the worker. Notably, reprogramming experiments of somatic cells toward pluripotency (co-transduction with the 4 factors OCT4, SOX2, MYC, KLF4) could imply a specific risk since accidental genetic modification of worker cell could theoretically lead to teratoma formation.

Above mentioned risks will be tempered by the fact we will use strictly replication defective viral vectors unable to propagate further after transduction. For all viral vector type, in the likelihood of an accidental contamination...
(percutaneous, aerial), amount of viral vectors able to effectively contaminate worker cells will be smaller and transduction much less efficient compared to improved in vitro transduction protocols used on cultivated cells. Of note, MuLV derived vectors are only efficient in transducing proliferating cells that limits the number of potential accidental targets. Importantly, VSV-G pseudotyping of retroviral particles results also in complement sensitivity increasing the likelihood of immunological neutralisation in human hosts. Together, these considerations suggest that only low number of cells may be effectively transduced through accidental contamination. Moreover, malignancy is a complex multistep process which involves multiple genomic alterations and it is unlikely that any single “hit” corresponding to an accidental infection would initiate transformation. Notably, cells exposed to non percutaneous accidental infection (stratum corneum, respiratory epithelium) are terminally differentiated cells with limited lifespan and high turnover, which greatly limits the risk of effective tumoral transformation. Nevertheless, in the context of experiments using polycistronic viral vectors for combined expression of several cDNA, tumoral transformation risk may be higher: appropriate safety measures will be undertaken to limit accidental contamination and all workers will be informed of additional risk associated with the use of such specific viral constructions.

- Environment considerations -
VSV-G pseudotyping of recombinant retroviral particles (MuLV and HIV-1 derived) would enable vectors to infect a variety of animal cell types including those of different animal species. Moreover, environmental stability tends to be increased by VSV-G pseudotyping compared to retroviruses displaying the native envelope. However, retroviral particles remain sensitive to air, temperature and pH and will have short lifespan in open environment. Importantly, recombinant retroviral vectors will be replication defective and could not produce progeny viruses able to spread to the wider human or other animal populations.

Adenoviruses are generally species specific. Indeed, serotype 5 Adenoviruses infect humans and does not naturally infect other animals. Therefore, the risk of accidental infection of other organisms is very low. Because recombinant adenoviruses will be replication incompetent, they could not spread to the wider human population from any accidentally infected individual.

*Transgene mobilization issue for retroviruses.* Recombinant viral vectors which will be used to genetically modify mammalian cells will be replication deficient and thus unable to propagate to the environment. However, a risk of recombinant vector mobilization through concomitant wild type retrovirus contamination of the targeted cell still exists. Indeed, recombinant retroviruses encompass a native encapsidation sequence which could allow production of transgene carrying viral particles if complementing viral proteins (enzymes, capsid and envelope) are provided by a compatible wild type retrovirus. The likelihood of such mobilization is still very low, even less with SIN Lentiviruses which are devoid of provirus LTR activity. Importantly, mobilized recombinant retroviruses would still be unable to replicate in other cells than those carrying the complementing wild type retrovirus. Moreover, amphotropism associated with VSV-G pseudotyping would no longer exist for viral particles encompassing mobilized recombinant retroviral genomes.

Since generation of replication competent viral particles (RCV) is associated with the highest risk factor for human health and environment, production steps will be given the highest risk factor in the whole process (i.e. production, transduction, GM cell analysis). All lentiviral productions will be carried out in strict Class2 conditions by trained and experienced workers. To decrease the likelihood of infection standard measures to decrease percutaneous as well as aerosolised transmission of viral particles will be adopted, such as no use of sharps and all work to be performed within a class II microbiological safety cabinet. Moreover, configuration of the laboratory premises will allow direct
autoclaving of all equipment in the Class 2 related lobby. All lentivirus batches will be tested for absence of RCV before use for cell transduction. In the very unlikely event of RCV generation, decontamination procedures will be carefully carried out and the event notified to the local BSO. Notably, no RCV generation involving 2nd generation SIN lentiviral vectors has ever been reported as today in the literature. MuLV derived retroviral particles and adenoviral particles will be produced by external manufacturers (Vectaly and Hybrid Systems respectively) and production batches demonstrated RCV free by internal validated methods.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For some experiments (teratoma formation, hematopoietic engraftment), genetically modified mammalian cells (human, murine) could then be transplanted by tissular or systemic injection into immunodeficient recipient mice to generate chimaeras. Importantly, protocols involved will not allow germ line transmission of the genetic modification. Since all viruses utilised to genetically manipulate the cells before transplant will have been tested for absence of RCV, there will be no risk of further infection and there will also be a minimal risk that the animals could escape from the animal facility.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

- All disposable culture/lab ware from the CL2 laboratory will be double-bagged, properly labelled as biohazard and autoclaved before leaving the building for incineration (autoclaving in adjacent lobby). [100% kill]
- All highly contaminated material, i.e. all stuff in contact with viruses (pipettes, tips, culture plates, liquid waste bottles), will be separately decontaminated (Virkon 2%/Trigene Advanced 10% for 16 hours) and liquids solidified (Vernagel) before autoclaving. [100% kill]
- Small spills will be removed after one minute surface soaking with Trigene Advanced 1% and further decontamination by 70% Ethanol. [effectively 100% kill]
- Large accidental spills will be sprinkled with Virkon powder before cleaning. [effectively 100% kill]
- Bench and cabinet surfaces will be wiped down with Trigene Advanced 1% followed by 70% Ethanol. [effectively 100% kill]
- All GM modified cell cultures will be destroyed (soaking with Trigene Advance 1% and autoclaving/incineration) [100% kill] or chemically fixed/lysed (PFA 1-4%, Guanidin, RIPA) before leaving containment [effectively 100% kill].

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
This project has been reviewed on 8th April 2009 by the West Forvie Building biological and genetic safety committee. This is satisfied that the risks have been properly addressed and that the work will be carried out under the appropriate controls and conditions. Nevertheless, the committee stressed on the need for additional risk assessment and specific information for workers undertaking experimental work with multiple insert (polycistronic) viral vector constructs which are associated with a higher risk for human health through accidental infection. Moreover, the committee emphasized that work with replication defective adenoviral vectors could be actually done at containment level 1 using MSC II.

Purposes of the contained use

Project: "Secreted membranes vesicles: role in the therapeutic plasticity of neural stem cells.
We use a bidirectional lentiviral vector (Bd.LV), as a sensitive reporter system. This vector coordinately expresses two transgenes, green fluorescent protein (GFP) and low-affinity nerve growth factor receptor (ΔNGFR), as distinct transcripts. By inserting perfectly complementary miRNA target (miT) sites into the 3' untranslated region (3' UTR) of the GFP cDNA, GFP expression is subject to miRNA-mediated regulation; ΔNGFR expression is unaffected by miRNA activity and serves as a control.
We have two kinds of LVs carrying respectively: the wild type GFP as a reporter gene or a rapid turnover or destabilized GFP as a reporter gene.

2) Project 2: Programming the oligodendroglial cell fate in neural stem/percursor cells.
We will take advantage of a lentiviral vector-based system to induce the expression (both inducible and constitutive) of either of three main transcription factors (TFs) involved in oligodendrogenesis: Olig2, Mash 1 and Sox10. In particular, we will use a first set of bidirectional lentiviral vectors (Bd.LV) that allow the coordinate constitutive expression of one of the given TFs as a reporter gene (either GFP or ΔNGFR) with the final aim of investigating the effect of the constitutive expression of each given TF on NPCs biology and differentiation potential. Subsequently, a second set of Bd.LVs (allowing the expression of a TF under the control of a Tetracycline inducible promoter (TetON) and the reverse transactivator (rTA) under the control of a constitutive promoter) will be used to achieve the temporal control of the transgene expression.

3) Project 3: transplantation of pluripotent stem cell-derived NOCs in experimental autoimmune encephalomyelitis. The transition from the neural crest to the SCP stage is marked by the appearance between others of myelin protein zero (PO) mRNA and cadherin 19. Cadherin 19 is down-regulated again as SCPs generate Schwann cells and is therefore the only well characterised marker that is restricted to the SCP stage (in vivo). Immature Schwann cells express S100β. Myelination is accompanied by equally extensive down-regulation of a set of molecules that characterise the immature Schwann cell stage such as the p75 neurotrophin receptor.
These constructs are intended to create a battery of hES cell lines expressing a fluorescent marker (GFP) under the control of promoters concerning the expression of stage-specific genes along the Schwann cell differentiation lineage. These markers will be used to selectively follow out hES cells after their differentiation towards a peripheral glial lineage.
Instead, a lentiviral vector carrying a double fusion reporter gene that stably expresses enhanced green fluorescene protein (eGFP) and firefly luciferase (fluc) reporter genes will be used to carry out an in vivo monitoring (through bioluminescence and magnetic resonance) of the presence, proliferation, migration and fate of the infected cells once transplanted into the host.

Recipient or parental organism
One Shot TOP10 Chemically Competent E. coli - disabled
Recombinant lentiviruses - HIV-1 derived, 3rd generation, replication defective, amphotrope
Mammalian cells (primary cells and cell lines) - considered as especially disabled.
- Human, murine somatic neural stem/precursor cell (NPCs);
- Human, murine somatic cell lines (HEK-293T, NIH-3T);
- Human embryonic stem cells;
- Human induced pluripotent stem cells.

Host/vector system
- TOP10 E. coli/pUC derived plasmids - no insert expression, non mobilisable
- HEK-293T/pUC derived plasmids - transient co-transfection, viral gene and insert expression (3rd generation system/4 plasmids) production of amphotrope replication deficient HIV1 derived lentiviral particles (each production batch to be tested). All transfer vectors were built from plasmid pCCL.sin.cPPT.PGK.GFP.WPRE or pRRL plasmid (see Follenzi et al., Nat Genet, 25: 217, 2000)
- Mammalian cells/ HIV-1 vectors - replication defective lentiviruses, stable genomic integration

Origin & function
Type 1 (cDNA) inserts will code for transcription factors, which are expected to play a role in cell fate decision and differentiation of neural stem/precursor cell (NPCs) or...
hES cells after their differentiation towards a central vs peripheral glial lineage, and are not expected to affect either proliferation or differentiation of targeted cells. It is difficult to predict in vivo consequences of ectopic expression of all these genes on human health. Since they are key regulator of cell identity, their overexpression could lead to pathological modifications of cell phenotype/function. However, all these transcription factors are mammalian derived, naturally occurring and does not affect cell proliferation thus suggesting the absence of major risks for human health and environment.

Type 2 (miRNA/miRNA target sequences) inserts will produce non-coding miRNA sequences targeting cell endogenous mRNA or exogenous miRNA target sequences on miRNA-regulated vectors, possibly inhibiting protein expression. As for Type 1, it is difficult to predict in vivo consequences of ectopic expression of these sequences on human health. However, since they target key regulators of cell identity, their expression could lead to pathological modifications of cell phenotype/function. Notably, several miRNA have been implied in oncogenic processes.

Type 3 (reporter genes) inserts will code for proteins with fluorescent or enzymatic properties allowing easy identification of genetically modified (GM) cells. They are thought to have no deleterious biological effect on expressing cells expected acute toxicity at very high concentration.

Type 4 (selection genes) inserts will code for enzymatic proteins able to inactivate specific antibiotic families allowing selection of GM cells. They are thought to have no pathological effect on expressing cells excepted acute toxicity at very high concentration.

Type 5 (functional non-coding sequences) inserts will act as promoters of transcription (promoters and enhancers), local chromatin structure modifiers (enhancers and insulators), RNA transcript stabilizers (WPRE) or translation regulators (IRES). They will be used (independently or in combination) into the expression cassette to achieve best control of insert expression depending on the targeted cell. No direct pathological effect is expected for these sequences. However, indirect deleterious effects should be considered for promoter and enhancer sequences through retrovirus mediated genomic integration in the host cell and potential insertional mutagenesis. Indeed, strong promoter/enhancer could lead to ectopic activation of neighbour endogene expression. Moreover, the WPRE sequence has been shown to have oncogenic properties by itself.

**Evaluation of foreseeable effects**

- **Human Health considerations**

The most obvious risk for human health is linked to accidental infection of worker by recombinant viral particles. Indeed, because only replication defective viral particles (non infectious) will be used for experimental work through this project and inserts will not produce compounds with acute toxicity (like bacteria toxins), no additional risk will be associated with the final GMO itself (mammalian cells) compared to initial organism. Importantly, primary cells coming from human samples are uncharacterised and may contain adventitious agents: they will be handled at containment Level 2 (COSHH regis).

First, risks associated with the nature and design of recombinant viral particles has to be assessed. Lentiviral recombinant particles (HIV-1 derived) will be VSV-G pseudo-typed (protein G from the Vesicular Stomatitis Virus will replace the native envelope protein). VSV-G packaging alters the tropism of the retroviral particles, requiring interaction only with phospholipids present in the plasma membrane of all cells rather than interaction with a cognate receptor as occurs with ecotropic packaging.

Thus, VSV-G pseudo-typed retroviruses acquire the ability to efficiently infect virtually all human cell types. Moreover, VSV-G pseudo-typing improves stability of the viral particle and may represent an aerosol means of transmission in addition to the expected percutaneous risk. Retroviruses stably integrate the host cell genome. This property is associated with a risk of insertional mutagenesis, i.e. ectopic activation/inhibition of host gene expression after colocalized provirus integration. Subsequent deregulation of endogene expression could theoretically lead to transduction associated detrimental effects like initiation of oncogenic processes. Moreover, the addition of the WPRE (Woodchuck Hepatitis Post transcriptional Regulatory Element) to the expression cassette in several retroviral backbones could also enhance the oncogenic potential of such vectors (SACGM, annual report 2004). Importantly, among retroviral vectors, the use of lentiviral derived backbone is thought to be safer. First, genomic integration profile of lentiviral derived vectors do not show an integration bias toward the transcriptional start site region of host cell genes like MuLV ones. Moreover, we will use exclusively SIN (Self Inactivating) vectors devoid of viral enhancer activity which reduces further the likelihood of endogen activation.

Risks associated with inserted coding sequences should also be assessed. cDNA or (shRNA/miRNA) inserts carried by viral vectors will direct ectopic expression (or inhibition) of transcription factors, signal transducers, growth factors and receptors which are expected to play a role in pluripotency, cell fate decision and differentiation from pluripotent stem cells. It is difficult to predict in vivo consequences of ectopic expression for all these genes on human health. However, since they are key regulator of cell identity, their overexpression could lead to pathological modifications of cell phenotype/function. However, malignancy is a complex multistep process which involves multiple genomic alterations and a single "hit" is unlikely to trigger alone the oncogenic process. Experiments involving co-transduction or even co-expression by the same vector of several inserts should consequently be considered at higher risk for the worker.

Above mentioned risks will be tempered by the fact we will use strictly replication defective viral vectors unable to propagate further after transduction. For all viral vector type, in the likelihood of an accidental contamination (percutaneous, aerial), amount of viral vectors able to effectively contaminate worker cells will be smaller and transduction much less efficient compared to improved in vitro transduction protocols used on cultivated cells. Importantly, VSV-G pseudotyping of retroviral particles results in complement sensitivity increasing the likelihood of immunological neutralisation in human hosts. Together, these considerations suggest that only low number of
cells may be effectively transduced through accidental contamination. Moreover, malignancy is a complex multistep process which involves multiple genomic alterations and it is unlikely that any single "hit" corresponding to an accidental infection would initiate transformation. Notably, cells exposed to non percutaneous accidental infection (stratum corneum, respiratory epithelium) are terminally differentiated cells with limited lifespan and high turnover, which greatly limits the risk of effective tumoral transformation. Nevertheless, in the context of experiments using polycistronic viral vectors for combined expression of several cDNA, tumoral transformation risk may be higher: appropriate safety measures will be undertaken to limit accidental contamination and all workers will be informed of additional risk associated with the use of such specific viral constructions.

Environmental considerations -

VSV-G pseudotyping of recombinant lentiviral particles would enable vectors to infect a variety of animal cell types including those of different animal species. Moreover, environmental stability tends to be increased by VSV-G pseudotyping compared to retroviruses displaying the native envelope. However, retroviral particles remain sensitive to air, temperature and pH and will have short lifespan in open environment. Importantly, recombinant retroviral vectors will be replication defective and could not produce progeny viruses able to spread to the wider human or other animal populations.

*Transgene mobilization issue for retroviruses.

Recombinant viral vectors which will be used to genetically modify mammalian cells will be replication deficient and thus unable to propagate to the environment. However, a risk of recombinanat vector mobilization through concomitant wild type retrovirus contamination of the targeted cell still exists. Indeed, recombainant retroviruses encompass a native encapsidation sequence which could allow production of transgene carrying viral particles if complementing viral proteins (enzymes, capsid and envelope) are provided by a compatible wild type retrovirus. The likelihood of such mobilization is still very low, even less with SIN Lentiviruses which are devoid of provirus LTR activity. Importantly, mobilized recombinant retroviruses would still be unable to replicate in other cells than those carrying the complementing wild type retrovirus. Moreover, amphotropism associated with VSV-G pseudotyping would no longer exist for viral particles encompassing mobilized recombinant retroviral genomes.

Since generation of replication competent viral particles (RCV) is associated with the highest risk factor for human helath and environment, production steps will be given the highest risk factor in the whole process (i.e. production, transduction, GM cell analysis). All lentiviral productions will be carried out in strict Class 2 conditions by trained and experienced workers. To decrease the likelihood of infection standard measures to decrease percutaneous as well as aerosolised transmission of viral particles will be adopted, such as no use of sharps and all work to be performed within a class II microbiological safety cabinet. Moreover, configuration of the laboratory premises will allow direct autoclaving of all equipment in the Class 2 related lobby. All lentivirus batches will be tested for absence of RCV before use for cell transduction. In the very unlikely event of RCV generation, decontamination procedures will be carefully carried out and the event notified to the local BSO. Notably, no RCV generation involving 3rd generation SIN lentiviral vectors has ever been reported as today in the literature.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

In the context of project 3 "transplantation of pluripotent stem cell-derived NPCs in experimental autoimmune encephalomyelitis" genetically modified mammalian cells will be transplanted by tissular or systemic injection into mice. Importantly, protocols involved will not allow germ line transmission of the genetic modification. Since all viruses used to genetically manipulate the cells before transplant are replication deficient, there will be no risk of further infection and risk of animal escape from the animal facility is minimal.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All disposable culture/lab ware from the CL2 laboratory will be double bagged, properly labelled as biohazard and autoclaved before leaving the building for incineration. (Autoclave located in lobby 218, outside CL2 room)

All highly contaminated material, ie. in contact with viruses will be decontaminated separately using 2% Virkon or 10% Trigene Advanced for 16 hours prior to autoclaving.

Small surface spills will be removed after soaking with 1% Trigene Advanced followed by wiping with 70% Ethanol

Larger surface spills will be sprinkled with Vrkon powder before cleaning as above.
Bench and safety cabinet surfaces will be wiped down with 1% Trigene Advanced followed by 1% Ethanol before and after working.

All GM modified cell cultures will be destroyed by soaking in 1% Trigene Advanced followed by autoclaving as 134 degrees C for 3 minutes and then incineration on the Addenbrooke's Hospital site or will be chemically fixed using 1-4% Paraformaldehyde solution, Guanidin, RIPA) before leaving the laboratory.

Autoclaving process is validated by the use of Browne Steriliser Tubes, type 2 for steam cycles at 134C for 3 mins. Each autoclaving cycle is monitored using an internal temperature probe properly fit into waste bags.

This project has been reviewed on 6th June 2010 by the West Forvie Biolding biological and genetic safety committee. This is satisfied that the risks have been properly addressed and that the work will be carried out under the appropriate controls and conditions.

For activities involving GMMs, describe the waste management measures which will apply to the activity

All liquid waste will be chemically inactivated using 2500 ppm available chlorine before discharge to sewers.

Solid waste will be autoclaved at 121 degrees for 15 mins using a vacumed pulse autoclave.

All these are standard approved methods of disposal. See attached Code of Practice.

**Project Additional Information**

**Purposes of the contained use**

This assessment describes the expression of a protein of interest in cell lines classified as Hazard Group 2 to facilitate relevant biological assays to demonstrate target engagement and proximal pharmacology as well as pertinent downstream effects for the purposes of drug discovery.

Work that may be carried out on these cell lines includes, but is not limited to:
- Transient transfection or baculovirus infection of primary cells or HG2 cell lines.
- Generation of stable cell lines expressing express GPCRs or their associated proteins.
- Assessing the expression of GPCRs and their associated proteins by RNA analysis or labelling by means of antibodies, fluorescent ligands nanobodies or label free methods.
- Functional characterisation of these receptors by signalling assays or other downstream assays such as cytokine or mediator release.

Future work along these lines is likely to include the use of lentiviruses to express these proteins, subject to suitable risk assessment and at the appropriate containment level.

**Recipient or parental organism**

A cell line or primary cell is classified hazard group 2 (HG2) if it is possible that it contains a biological agent that can cause human disease and may be a hazard to employees but is unlikely to spread to the community and there is usually effective prophylaxis or treatment available. These cell lines have often been immortalised using a retrovirus that may express oncogenes such as v-myc or v-raf. They are often well characterised and will be obtained from reliable sources, yet cannot be guaranteed to be virus-free, posing a small risk of infection to users.

This work may include, but is not limited to:
- Well characterised cell lines from the National Institute of Health or the American Type Culture Collection for which work is recommended to be carried out at containment level 2, eg hTERT immortalized cells, HeLa cells etc.
- Cell lines transformed/immortalised with viral agents (e.g. SV40) and/or oncogenes eg microglial cell lines such as IMG or induced pluripotent stem cells (IPSCs).
- Primary cells or cells without a well-defined history.

**Host/vector system**

Work with these cells may involve utilization of endogenously expressed receptors or signalling proteins, or these may be introduced into the cell by transient transfection, or by means of a viral vector system such as, but not limited to, baculovirus- based technologies such as BacMam.

Transfection of mammalian cell lines is achieved with plasmids, into which the cDNA encoding a wild-type or mutant G protein coupled receptor (GPCR) or accessory protein, such as a co-receptor or signalling molecule, has been ligated. In addition to the cDNA of the protein being analysed, additional coding sequence may be present. This may encode Enhanced Green Fluorescent Protein, a biotin-acceptor peptide or affinity tags such as His10, myc tag, Flag tag, hemagglutinin tag, Strep-tag or Avi-tag. A sequence corresponding to a protease cleavage site may also be present. In addition, the GPCR coding sequence may contain an insertion coding for a protein or protein fragment such as T4 lysozyme or apocytochrome b(562)RIL. The plasmid will also contain gene(s) encoding antibiotic resistance. Expression of genes may be driven by a strong promoter such as pCMV or a weaker one such as the pTK. These systems may also be used to generate a cell line stably expressing the insert protein.

The gene of interest may also be delivered into the cells using baculovirus- based technologies such as BacMam (derived from pFastBac from Life Technologies) and
derivatives thereof including pHepBacMam with a variety of tags and signal sequences, and may additionally encode genes for antibiotic resistance. While baculovirus are capable of infecting mammalian cells and the mammalian promoter they contain permit expression of the gene of interest, they are incapable of replication either within these cells or in insects; these systems in themselves are safe to use at containment level 1.

Origin & function

The inserted genes encode GPCRs or accessory proteins such as GPCR co-receptors and downstream signalling molecules. The function of GPCRs is to initiate different signalling cascades upon ligand binding. The signalling cascades result in variety of cellular responses such as transcription, proliferation, differentiation, development, inflammation, or apoptosis.

In addition to the cDNA of the protein being analysed, additional coding sequence may be present. This may encode Enhanced Green Fluorescent Protein, a biotin-acceptor peptide or affinity tags such as His10, myc tag, Flag tag, hemagglutinin tag, Strep-tag or Avi-tag. A sequence corresponding to a protease cleavage site may also be present. In addition, the GPCR coding sequence may contain an insertion, coding for a protein or protein fragment designed to aid crystallography, such as T4 lysozyme, apocytochrome b(562)RIL, flavodoxin, rubredoxin, glycogen synthase or similar fragments. These are not known to be toxic, oncogenic, or otherwise harmful.

Evaluation of foreseeable effects

Risk from host cell lines:
Primary human cells may contain adventitious agents that can cause human disease. Cell lines that have been immortalised using oncogenes or a retrovirus that may express oncogenes such as v-myc or v-raf, are often well characterised and will be obtained from reliable sources, yet cannot be guaranteed to be completely virus-free, posing a small risk of infection to users. IPSCs are also known to pose a potential risk of in vivo teratoma formation. Manipulation of these cells such as centrifugation, sonication etc may give rise to potentially infectious aerosols. Another possible route would be direct inoculation of cell material. Large volumes of culture carry greater risk of exposure and should be handled with care.

These cell lines are all adapted to growth under laboratory conditions and would not survive without specific media and atmospheric requirements, whereas primary cells are incapable of survival beyond a few passages. Therefore, they would be unable to survive outside of the laboratory and the risk of any transfer is negligible. Subsequent addition of a retroviral packaging mix to cell lines that have already been manipulated through retroviral transduction, which has the potential to mobilise the integrated genes, is also a risk to be considered.

Risk from vector/insert genes:
The genes to be expressed exogenously are not known to be toxic or oncogenic and are not expected to alter the pathogenicity of the cell lines. The vectors used do contain genes for antibiotic resistance.

The wearing of lab coat, gloves and safety goggles is required when working with HG2 material. The routes of entry for the gene product or cell derived material into the user would be via direct inoculation, or inhalation of aerosols. For this reason, work must take place in a Class II MSC and the use of sharps is prohibited. Reagents should be risk assessed prior to use on these cells to ensure absence of retroviral packaging elements. Staff will never use their own cells for work. Culture volumes may vary with the experiment being performed, but staff will strive to keep the volumes to the minimum necessary.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste generated from this contained use include cell culture supernatants as well as solid waste in the form of cell waste, plasticware etc. Liquid cultures from HG2 cell lines or GM Class 2 material will be inactivated with 1% Chemgene or similar disinfectant for at least 30 minutes prior to disposal to drain with plenty of water. The efficacy of Chemgene has been documented by the manufacturer (https://www.starlabgroup.com/Documents/eng/1167785.pdf) and is safe and effective for use as a disinfectant of CL2 waste.

All solid waste, including cell waste and plasticware will be disinfected with 1% Chemgene for 30 minutes prior to disposal in double bagged clinical waste sacks. These are collected by an external contractor for incineration.
A defined spill control procedure that takes into account the potential for class 2 GMs is in place—training has been provided to all users and the protocol has been practiced.

The GM committee was presented an overview of the planned work, including a summary of the existing facilities and working practices already in place (adequate containment facilities with access provided to trained personnel and appropriate waste disposal measures). The risk assessments for this work were then presented to the committee (also circulated before the meeting). A query was raised about the risks of teratoma to pregnant women. In reply it was pointed out that the risk was not known to be higher than for the general population, which is already significantly reduced as the cells will not be maintained in culture onsite. A member of the committee with experience of working with iPSCs confirmed all potential risks have been included in the assessment and the control measures would adequately cover these. The nature of the planned GM work was reviewed. The insert genetic material will not alter the category of risk associated with the HG2 cell line. The plasmid construction is class 1 and can be undertaken at containment level 1, but work with HG2 cell lines must be undertaken at containment level 2. The proposed modifications will not alter the tropism, pathogenicity or otherwise of the cell lines and would not increase the category of risk associated with them.

The committee also discussed safety and decontamination of instruments used in the analysis of HG2 material and reviewed cleaning protocols and user training requirements and recommended the use of secondary containment for transport, clear labelling and warning stickers. Existing cleaning protocols were found to be adequate for the level of risk posed by HG2 material. Provision of training with updated safety guidelines for all users was agreed. The disposal of GM class 2 waste was also discussed. The protocols recommended in the GM risk assessment were deemed satisfactory for the intended use. The committee also discussed storage requirements for HG2 material, and recommended that this could be safely stored in clearly labelled cryoboxes (which would constitute secondary containment) within a -150°C freezer.

The committee agreed this was a GM Class 2 project and the potential risks to users and the environment were sufficiently addressed by the risk assessments; by following the control measures indicated, these risks were considered to be effectively minimised.

Please enter comments on the GM safety committee on the risk assessment

For activities involving GMMs, describe the waste management measures which will apply to the activity

No waste material will be removed from the isolated culture suite prior to heat inactivation. - Liquid effluent (eg waste culture media buffers) will be transferred to 1 litre plastic bottles and autoclaved (123°C for 15 minutes). Autoclaved liquid waste will be placed in hermetically sealed bins supplied by an approved contractor, who disposes and incinerates the contents. No liquid effluent will be disposed of down the sink.
- Solid waste (eg plastic culture plates/flasks, plastic pipettes) will be placed in plastic biohazard bags and autoclaved (121°C for 15 minutes). Autoclaved waste will be placed in hermetically sealed bins supplied by an approved contractor, who disposes and incinerates the contents.

Testing/Monitoring: autoclave service and performance was validated by a company with UKAS certification; autoclave will be serviced regularly; computerised systems are in place to monitor temperatures during each autoclave cycle.

All activities involving modified HEK293 will be conducted under Level 2 Containment measures.

Other(s) Use of cell cultures (HEK293 Human Embryonic Kidney)

---
### Project Additional Information

#### Purposes of the contained use

Genetically modified HEK293 cells will be produced by Vectalys, France. Modified HEK293 cells will be used in diverse study protocols to determine if our compounds are substrates and/or inhibitors of the over-expressed transporters, to anticipate eventual in vivo studies in human at the clinical development stage. Studies will be carried out using cell suspensions and/or plated cells in various incubation buffers.

#### Recipient or parental organism

(Please see attached risk assessment for a more detailed explanation)

HEK293 Human Embryonic Kidney cell line immortalised with Adenovirus 5 DNA.

Due to the presence of adenoviral sequences, cells have been categorised as Class 2.

Level 2 Containment measures are in place to reduce hazards to human health and the environment.

#### Host/vector system

(Please see attached risk assessment for a more detailed explanation)

Third generation lentiviral vector (pLV) produced from a packaging line in which helper genes are provided in trans by helper constructs pENV (contains VSVG glycoprotein sequence) and pHIV-gag-pol (does not encode env, Vif, Vpr, Vpr, Vpu and Nef).

Vectors pLV and pENV are capable of infecting human cells and have been classified as Class 2. Level 2 Containment measures are in place to reduce hazards to human health and the environment.

#### Origin & function

(Please see attached risk assessment for a more detailed explanation)

Donor Organism: Immortalised epithelial colorectal adenocarcinoma cells (Caco-2) (Class 1)

Genetic inserts encode proteins of the Solute Carrier (SLC) family of transmembrane transport proteins and have been categorised as Class 1: SLC01A2 (protein OATP1A2); SLC02B1 (protein OATP2B1); SLC04C1 (protein OATP4C1); SLC10A1 (protein NTCP); SLC16A1 (protein MCT1); SLC22A1 (protein OCT1)

The SLCs contain a number of hydrophobic transmembranous alpha helixes connected via intra- and extra-cellular hydrophilic loops. Depending on the SLCs transporters are functional either monomerically or oligomerically (homo or hetero-oligomers), and are genetically localised on the external side of the plasma membrane.

The expressed sequences to do not alter the survivability/fitness of the HEK293 cell line, nor do they confer pathogenicity to the cells.
Evaluation of foreseeable effects

No genetic manipulation will be conducted at Servier Research & Development Ltd UK and the cell line will be propagated for experimental purposes only.

All work will be conducted under Level 2 Containment measures, and suitable inactivate modified cells prior to removal from the isolated cell culture suite.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

02/03/2022
The favoured method of disposal of GMO waste is through heat inactivation by autoclaving at 121°C for 15 minutes, reducing viability 100%. Plastics, agar and small volumes (30 ml universals) will be autoclaved in double lined autoclave bags. Larger volumes of liquids should be autoclaved in double lined autoclave bags. Larger volumes of liquids should be autoclaved in Pyrex containers before disposal. Autoclaved disposal bags should be clearly labelled, stating GMO waste, identifying the laboratory name and building. Autoclaved waste will be disposed of via yellow biohazard bins provided (Wastecare (GB)), these are subsequently collected and disposed of by Wastecare (GB), Laydon Road, Stevenage, Herts SG1 2BW.

Inactivation by chemical means, either a phenolic, halogenated tertiary amine or hyperchlorite solution, maybe used to the manufacturers validated specification. Plastic ware, glassware and media may be disinfected using this method. Plastic ware should then be disposed of via Wastecare (GB) in yellow biohazard bins provided, liquid waste should be disposed of via the drains whilst glassware should be washed and dried using standard good laboratory practice.

Spillages will be disinfected using aforementioned solutions and dealt with using relevant COSHH guidelines and good laboratory practice methods as required. Autoclaved waste will be disposed of via yellow biohazard bins provided (Wastecare (GB)), these are subsequently collected and disposed of by Wastecare (GB), Laydon Road, Stevenage, Herts, SG1 2BW.

The risk assessment is suitable and adequate against all foreseeable risks in accordance with Part 2 and 3 of the SACGM compendium of Guidance. As a result of the risk assessment and in conjunction with Schedule 8 Table 1a, the committee have reached a decision that this work falls under containment level 1 for laboratories working with GMMs.
Cloning and sub-cloning of Campylobacter sp. To identify the role of virulence genes in pathogenesis

Purposes of the contained use

Various cloning and sub-cloning techniques, such as directed mutagenesis or random mutagenesis, will be used to assess the role of virulence factors in the pathogenesis of Campylobacter infection.

Recipient or parental organism

The most hazardous Campylobacter strains, including Campylobacter jejuni are ACDP hazard category 2. Strains produced in this study are not likely to be more virulent than any reference strain used.

Campylobacter sp. are ubiquitous in the environment and the infection they cause is usually self-limiting.

Host/vector system

The disabled E.coli strains DH5α, TOP10, JM109 and CA434 will be used as the plasmid host and are not pathogenic. Due to the differences in codon usage between E.coli and Campylobacter, it is very unlikely that expression of Campylobacter genes will occur in E.coli. Cloning plasmids to be used, include pUC19 which does not replicate in Campylobacter and is not transmissible. These plasmids will also contain antibiotic resistance markers which are regularly used in the laboratory environment and E.coli. The plasmids are not self-transmissible.

Origin & function

Genomic DNA will be extracted from Campylobacter sp. and amplified by PCR. This DNA will then be cloned into pUC19 vectors for propagation in E. coli and transformation into Campylobacter.

The approach of creating mutants for testing, either by deletion of a gene or insertion of a transposon will make the GMM less virulent.

The majority of the genes to be expressed are innocuous bacterial enzymes used for basic metabolic functions and they are unlikely to function in isolation or in E.coli.

Evaluation of foreseeable effects

Campylobacter sp.

The duplication of metabolic genes in these studies are highly unlikely to increase virulence or survival in the environment.
The effect of gene dosage on the only known virulence determinants of Campylobacter is unknown. Expression levels of these genes may vary widely in clinical strains and the experiments here are unlikely to exceed clinical levels even in the worst case scenario. Random mutagenesis or directed gene deletion may increase or decrease virulence factor expression. None of the antibiotic markers used correspond to antibiotics that are routinely used to treat Campylobacter infection.

E.coli: 
The strains used are disabled, non-pathogenic laboratory strains which are unlikely cause disease even with the addition of fragmented DNA or genes. As such infection with recombinant E.coli or survival in the environment is deemed highly unlikely.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Waste will be autoclaved to achieve 100% kill and will then be sent to landfill after processing by approved waste disposal contractors.

**Is an emergency plan required according to regulation 20?**  N

**If yes, tick to confirm that it is attached to this form**  N

**Tick to confirm that you have attached a risk assessment to this form**  Y

**Tick if you are claiming exemption from disclosure for section of the risk assessment**  N

**Please enter comments on the GM safety committee on the risk assessment**

The GMSC has considered the proposal for work with Campylobacter, and after initial discussion to clarify the text of the risk assessment we have no concerns about the genetic modification as planned, and note that it is highly unlikely that a GMO more hazardous than the host will be generated. The main concerns expressed were regarding the safe transport, handling and disposal of the pathogenic host organism. Acceptable safe working practices have been cited in the risk assessment, and reference has been included to indicate the expertise and experience of the key post-doc who has safely and successfully worked with Campylobacter, and with other Level 2 and 3 pathogens for 13 years. One committee member has extensive experience of pathogen work including MRSA and has no problem with this straightforward application using category 2 bacteria. The GMSC has approved this proposal.

### Historical Significant Changes
- N

### Project Additional Information

#### Purposes of the contained use

Various cloning and sub-cloning techniques, such as directed mutagenesis or random mutagenesis, will be used to assess the role of virulence factors in the pathogenesis of Clostridium sp. Infection. This includes but is not limited to the species Clostridium difficile (work will not include the use of Clostridium botulinum).

#### Recipient or parental organism

- The most hazardous Clostridium sp. Strains are ACDP hazard category 2 and this includes Clostridium difficile strains. Clostridium difficile R20291 is regarded as the PCR ribotype 027 reference strain. Strains produced in this study are not likely to be more virulent than this. Clostridium difficile 630 and 630 delta erm will also be used in this study but are known to be less virulent than strain R20291.

- C. difficile only presents a hazard when the normal bacterial flora is compromised and is carried by 25% of the population with no effect to health

#### Host/vector system

- The disabled E. coli strains DH5α, TOP10, JM109 and CA434 will be used as the plasmid host and are not pathogenic. Due to the differences in codon usage between E. coli and C. difficile, it is very unlikely that expression of C. difficile genes will occur in E. coli. Also due to the random fragmentation of the genomic DNA the required elements for expression may not be cloned with the genomic DNA.
- The pMTL vectors based on the CoIE1 replicon will be used as shuttle vectors in E.coli and C.difficile. These plasmids are nic mob minus and are derived from Gram
positive and negative components, many of which (except the Gram positive replicon) do not function in clostridia. These plasmids will also contain antibiotic resistance markers which are regularly used in the laboratory environment and E.coli. The plasmids are not self-transmissable.

### Origin & function

Genomic DNA will be extracted from the Clostridium difficile sequence strains CD630 and R20291 and amplified by PCR. This DNA will then be cloned into pMTL80000 or pMTL007 series vectors for propagation in E. coli and conjugation into Clostridium difficile.

The approach of creating mutants for testing, either by deletion of a gene or insertion of a transposon will make the GMM less virulent.

The majority of the genes to be expressed are innocuous bacterial enzymes for use for basic metabolic functions and they are unlikely to function in isolation or in E coli.

### Evaluation of foreseeable effects

**C. difficile:**
- The duplication of metabolic genes in these studies are highly unlikely to increase virulence or survival in the environment.
- The effect of gene dosage on the only known virulence determinants of C. difficile. Toxins A and B is unknown. Expression levels of the genes encoding toxin A and B vary widely in clinical strains and the experiments here are unlikely to exceed clinical levels even in the worst case scenario.
- Random mutagenesis or directed gene deletion may increase or decrease virulence factor expression. None of the antibiotic markers used correspond to antibiotics that are routinely used to treat C. difficile infection.

**E. coli:**
- The strains used are disabled, non-pathogenic laboratory strains which are unlikely to cause disease even with the addition of fragmented clostridial DNA or genes. As such infection with recombinant E. coli or survival in the environment is deemed highly unlikely

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**Not Applicable**

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

**Not Applicable**

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste will be autoclaved to achieve 100% kill and will then be sent to landfill after processing by approved waste disposal contactors

Please enter comments on the GM safety committee on the risk assessment

---

02/03/2022
The GMSC has considered the proposal for work with C. difficile, and after initial discussion to clarify the text of the risk assessment we have no concerns about the genetic modification as planned, and note that it is highly unlikely that a GMO more hazardous than the host will be generated. The main concerns expressed were regarding the safe transport, handling and disposal of the pathogenic host organism. Acceptable safe working practices have been cited in the risk assessment, and reference has been included to indicate the expertise and experience of the key post-doc who has safely and successfully worked with C. difficile, and other Level 2 and 3 pathogens for 13 years. One committee member has extensive experience of pathogen work including MRSA and has no problem with this straightforward application using category 2 bacteria. The GMSC has approved this proposal.

Project Ref 3033/12.1

Date Ackn'd 12/12/2012

Date Project Ceased

CU2 Project Title Site directed mutagenesis, in Listeria spp.

Class 2

CultureVolClass2 < 1 Litre

CultureVolumeClass3-4

Non-GMM Consent Granted

Project notified under transitional arrangements

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

Project Additional Information
Purposes of the contained use

Site directed mutagenesis using plasmids such as pORI19 and pVE6007 will be used to inactivate target genes in order to assess their roles in stress response and virulence mechanisms following exposure to various antimicrobials in Listeria spp. Gene up-regulation using pIMK2 will be used to alter expression levels of target genes to assess contribution in resistance mechanisms to antimicrobials and virulence characteristics of subsequent isolates. This includes but is not limited to the species Listeria monocytogenes. No known antibiotic resistance genes will be targeted for mutagenesis.

Recipient or parental organism

The most hazardous Listeria strains, including Listeria monocytogenes are ACDP category 2. Listeria spp. are ubiquitous in the environment and the infection they cause is usually self-limiting.

Host/vector system

The disabled E. coli strains DH5α, EC101, TOP10, JM109 and CA434 will be used as the plasmid host and are not pathogenic. Due to the differences in codon usage between E. coli and Listeria spp., it is very unlikely that expression of Listeria spp. genes will occur in E. coli.

Vector systems will include, but not be limited to, the pORI19-pVE6007 gene inactivation system and the pIMK2 overexpression system. pORI19 and pIMK2 vectors will be used as shuttle vector in E. coli and Listeria spp. The pORI10 lacks RepA and therefore requires a co-plasmid pVE6007 to replicate. These plasmids contain antibiotic resistance markers which are regularly used in the laboratory environment and E. coli. pVE6007 is a temperature sensitive plasmid with a chloramphenicol resistance marker. The plasmids are not self-transmissible.

Origin & function

Genomic DNA will be extracted from the Listeria monocytogenes sequence strains EDGe and FSL R2-449 and genes of interest will be amplified by PCR/ Amplicons will then be cloned into pIMK2 or pORI19 vectors for propagation in E. coli and subsequent transformation of Listeria monocytogenes. Mutant generation through the use of pORI19-pVE6007 is likely to inactivate key resistance genes; as such it is unlikely such mutants will be more pathogenic than the wild-type strain. The pIMK2 system used to increase target gene expression. This may increase resistance to antimicrobials (non-antibiotic) but it is not envisaged that will render the organisms more pathogenic. The majority of the genes to be targeted code for innocuous bacterial enzymes used for basic metabolic functions. These proteins are unlikely to function in isolation or in E. coli.

Evaluation of foreseeable effects

Listeria spp.: The duplication of metabolic genes in these studies are highly unlikely to increase virulence or survival in the environment.

E. coli: The strains used are disabled, non-pathogenic laboratory strains which are unlikely to cause disease even with the addition of fragmented Listeria spp. DNA or genes. As such infection with recombinant E. coli or survival in the environment is deemed highly unlikely.

L. lactis: The strain used has a sole purpose in harbouring/maintaining the pVE6007 plasmid. As such no manipulations will be undertaken in L. lactis. Owing to plasmid possession strain MG1363 possesses chloramphenicol resistance.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste will be autoclaved to achieve 100% kill and liquid waste will either be autoclaved to achieve 100% kill or will be disinfected to achieve a 5 log reduction (99.999%). Solid waste will either be sent to landfill or incinerated by approved waste disposal contractors.

Project Ref 3033/19.1

Date Ackn’d 03/05/2019

CU2 Project Title Tolerance of oxidative and metal stresses in Streptococcus pneumoniae: Transcriptional responses and novel mechanisms

Class 2

Consent Granted

Date Project Ceased 02/03/2022
### Project Additional Information

#### Purposes of the contained use

The functions of genes involved in oxidative stress responses and metal homeostasis in *Streptococcus pneumoniae* (including those of transcriptional regulators) will be investigated by constructing specific deletions of the genes of interest and by integrating luciferase or ~-galactosidase genes into the genome for use as transcriptional reporters.

#### Recipient or parental organism

*S. pneumoniae* 039 is a pathogenic bacterium from a clinical isolate. It is a well-characterised and commonly-used laboratory strain of *S. pneumoniae*, in part due to its genetic tractability, and has been used in research for almost 100 years. Other *S. pneumoniae* strains that will be used as recipients include TIGR4 and the non-pathogenic 039-derived strain R6.

#### Host/vector system

Escherichia coli K12-derived, non-pathogenic strains ego DH5a, JM199, TOP10 will be used as host for vectors.

#### Origin & function

- **E. coli and click beetle/firefly** - derived genes will be obtained from plasmid DNA, Streptococcal derived-genes will be amplified by PCR from genomic DNA.
- For transcriptional reporters:
  - Firefly/ click beetle luc genes - bioluminescence, partial protein coding sequence without introns
  - E. coli LacZ' - partial protein coding sequence for ~-galactosidase enzyme
- For antibiotic resistance genes:
  - E. coli bla - ~-lactamase conferring ampicillin resistance
  - *S. pneumoniae* rpsL* - mutant form of the S12 ribosomal protein gene conferring streptomycin resistance
  - *S. pneumoniae* tetM - GTPase conferring tetracycline resistance
  - *S. pneumoniae* ada9 - adenylytransferase conferring spectinomycin resistance
  - *S. pneumoniae* emrB - methylase conferring resistance to erythromycin
  - *S. faecalis* aphlll - aminoglycoside phosphotransferase conferring kanamycin resistance

#### Evaluation of foreseeable effects

GM *S. pneumoniae* are unlikely to pose an increased risk to human health compared with the parental strain as most genetic modifications will remove or mutate genes that could contribute to pathogenicity. Erythromycin resistant
organisms are unlikely to have any increased risk to health as erythromycin is not a first-line antibiotic for treatment of S. pneumoniae infections and the ermB gene confers specific resistance to erythromycin and will not affect resistance to other clinically relevant antibiotics.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

| N/A                                                                                             |

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

| Autoclaving at 121 DC for 15 minutes with moist heat should give 100 % kill. Validation of the autoclave to effectively sterilise waste is done at least annually; where the nature or composition of the load changes further validation must be carried out. During validation, a worst case load is simulated and temperature probes are inserted - this is known as the 12 point thermocouple test. The thermocouples are connected to a recording device and readings are then taken during the autoclave cycle. The test is carried out by a competent engineer using calibrated equipment in accordance with the British Standard (BS 2646: 1993). Calibration of the autoclave is also performed to check that the control panel of the autoclave is functioning correctly and that it is regulating the decontamination process and displaying the operating parameters accurately. The Astell autoclave for autoclaving of waste creates a digital log of each run, this data is stored in the 'Technician's Folder' on the HEA drive to indicate successful decontamination of each load. Unusual loads should be monitored on a load-by-load basis. All records of performance testing are kept for a minimum of 5 years. Disinfection with Presept should give 100 % kill. Presept tablets to be used at 1,000 ppm for general laboratory disinfection. Used as per manufacturer's instructions, Presept is bactericidal for all Gram positive bacteria |

Please enter comments on the GM safety committee on the risk assessment
GMO safety committee met on 10/10/2018 to consider the risk assessment. Suggested changes were:
- Project Activity end date can be left open as not tied to a funded or time-limited project
- Review of any changes to risks after the move to new Waterside campus August 18
- Confirmation that no materials contain pathogens or toxins covered by the Anti-Terrorism Crime and Security Act
- Clarification of what is meant by sharps (scalpel blades, needles but not pipette tips)
- Method of verifying waste treatment to be added
- Confirmation that Hepatitis B immunisation is not required
- Addition of JS as a project worker
- Risk assessments were reviewed on 08/05/18 and the work approved by the committee.

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Yes

Give brief details of the genetic modification safety committee

The genetic modification Safety Committee (GMSC) is comprised of four individuals who have various roles and levels of expertise within the company.

The GMSC will meet once every two months to review ongoing experimental progress and monitoring of containment. Minutes of the GMSC meetings will be maintained and copies circulated to all members. The chair will be responsible for making the committee members aware of any intended changes to experimental plans so that updated risk assessments can be performed and reviewed in a timely manner. The chair has an extensive background in GM activities.

Microbiology Research Yes

02/03/2022
All experiments will be performed within a clean room environment. All work surfaces are easy to clean, impervious to water and resistant to acids, alkalis, solvents, disinfectants and decontamination agents. Personal protective equipment will be issued to all laboratory staff and will include disposable gloves, clean room suits and eye-protection when necessary. Personal protective clothing will not be worn out of the laboratory. All generated wastes will be treated on-site through either chemical or physical (autoclave) inactivation.

Work surfaces and small equipment items will be wiped down after use at the end of each day using a solution of 60% isopropanol. Ovens, incubators and other large pieces of equipment will be wiped down weekly with a solution of 60% isopropanol. Liquid wastes (cultures containing live cells) will be chemically inactivated by addition of bleach to a final working dilution of 2% and allowing to stand for a minimum of 15 minutes after which inactivated liquid wastes will be disposed of down the drain with plenty of water.

Solid wastes including agar culture plates containing live Ecoli or algae colonies, disposable pipettes, pipette tips, culture tubes and microcentrifuge tubes will be segregated at the point of creation and inactivated by autoclave treatment for 15-20 minutes at 121°C. Operating conditions during autoclave runs will be monitored and recorded as well as the nature of the load being treated. Chemical indicator tape will be used to indicate the effectiveness of the treatment. Degrees of kill are estimated to be in the 6 log range using these inactivation methods. Surface swabs will be taken at a minimum frequency or fortnightly from autoclaved solid waste streams and from disinfected work surfaces, and liquid samples taken from chemically-inactivated cultures. Serial plating will be performed on the appropriate growth media to assess survival of bacterial or algal GMMs. Results will be recorded and reviewed by the GMSC at each meeting.

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment
Could an alternate selectable marker, such as GFP (green fluorescent protein) be used in place of an antibiotic resistance gene to identify algal cells that have integrated the incoming DNA?

Yes, we could consider alternates, especially for longer-term developments including scale-ups, but antibiotic resistance markers will be used for initial proof of concept.

As the workspace (cleanroom) will also be used for other activities (electronics) can there be a separate set of distinguishable cleanroom suits for those staff using GMMs?

Yes this will be done. Cleanroom suits will also be laundered offsite on a twice monthly or as needed schedule.

Will there be a log of experiments with instructions in the event of employee absence due to sickness? This would include handling and/or shutdown instructions for pausing or terminating an experiment?

Yes, this will be implemented.

For activities involving GMMs, describe the waste management measures which will apply to the activity

All GMM work to be carried out in controlled areas of the lab-laminar flow cabinet and adjacent bench containing water bath and growth cabinet. GMMs are stored in a labelled and controlled area of the cold room.

Waste containers should be properly labelled.

A log book is placed in the lab to record name of user, date, bacterial line used for the experiment, method and date of killing of all material.

All material in contact with GMMs (vials, test tubes, pipettes, petri dishes, gloves, bottles) to be autoclaved at 145 degrees for 45 minutes.

A monitor strip must be inserted in the centre of the load to monitor sterilization and be kept as a record in the autoclave log book.

Autoclaved waste is transferred to a yellow plastic bag and placed in yellow bin outside for collection and incineration.

02/03/2022
No activities involving GMM will be performed in these premises. Only GM plants (first generation or further, no primary transformant) will be grown in these premises. GM plant seeds will be imported in double layered and sealed boxes. Upon reception, the seeds will be sown and boxes autoclaved. GM plants will be grown in closed growth chambers until their seeds are ready to harvest. The collected seeds will be shipped back to France in the same double layered and sealed boxes. The remaining non fertile biological material (stalk and leaves essentially) will be destroyed by heat treatment (autoclave or incineration). Depending on the waste volume, this material will be either autoclaved (low quantity) or collected in sealed container by a service provider specialised in hazardous waste management to be incinerated. The waste management procedures will destroy in any case the germination capacity of left over seeds if any.

**For activities involving GMMs, describe the waste management measures which will apply to the activity**

### Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities  

Give brief details of the genetic modification safety committee

The Genetic Modification Safety Committee within NHS Greater Glasgow & Clyde consists of Dr W C (Chairman) and D C P (Deputy Director of the MRC Virus Unit). The Committee enlist the services of any suitably qualified personnel when required. The committee generally meet on a monthly basis but do convene as required.

Committee operating procedures - The committee closely review protocols and risk assessment for each relevant trial. The committee then liaise closely with the study sponsor to resolve any outstanding queries. Once the committee are satisfied with all arrangements they will issue either a favourable or non-favourable opinion for the trial.
The investigational medicinal product (IMP) used in this study is a suspension of cells contained within a plastic screw cap vial and will only be handled openly within the operating theatre. IMP is drawn into a grafting syringe via a loading cannula, thus minimising the risk of stick injury. There is, however, a risk of aerosol generation should the grafting syringes be emptied in air. This risk will be controlled by emptying grafting syringes into a gauze as described in local rules.

Grafting syringes and canulas used in the procedure will be disposed directly into biohazard sharp bins. In addition, all other materials coming into contact with the IMP will be disposed directly into biohazard bins for incineration as clinical waste. Waste disposal contractors involved in the disposal of waste from this study hold appropriate and valid HSE and SEPA licences for the disposal of genetically modified materials, details of which can be provided on request.

Safety spill kits will be made available in all locations where IMP will be handled. Any spillage will be wiped clean with a biocidal spray and swabs disposed of as clinical waste. Within the theatre environment, all staff will wear gloves and gowns as per normal practice. All contaminated equipment will be thoroughly cleaned and all other contaminated materials will be incinerated as clinical waste.
The genetic modification safety committee were satisfied with the risk assessment.

### Project Additional Information

**Purposes of the contained use**

RP1 will be administered to subjects as an anti-tumour therapy, as part of a Phase I clinical trial to treat a wide range of solid tumour types. RP1 has a particular utility in combination with immune co-inhibitory pathway blockade. Intended indications to study include soft tissue sarcoma, breast cancer including triple negative breast cancer (TNBC), lung cancer including non-small cell lung cancer (NSCLC), melanoma, non-melanoma skin cancers, head and neck cancer, primary liver and kidney cancer and colorectal cancer. The initial clinical trial protocol intends to test RP1 in several indications as a monotherapy and in combination with anti-PD-1 therapy.

**Recipient or parental organism**

RP1 (rHSV-1 hGM-CSF/GALV-GP) is a selectively replication competent Herpes Simplex Virus-1 (HSV-1). The virus contains a codon-optimised sequence for human granulocyte macrophage colony stimulating factor (hGM-CSF) and a codon optimised sequence for the gibbon ape leukemia virus surface glycoprotein (GALV-GP) with the R- sequence deleted (R-) [GALV-GP-R-]. GALV-GP-R- expression leads to cell to cell fusion (syncytial) formation in infected tumour cells through binding to the constitutively expressed PIT-1 receptor for GALV. This results in the death of the cells by...
membrane fusion and is also intended to enhance the spread of the virus through the tumour. Since the RP1 selectively replicates in tumour cells, the expression of the GAL V-GP-R- is minimised in normal tissues. The oncolytic destruction of tumour cells leads to the release of tumour associated antigens that are intended to engender an antitumour immune response, enhanced by the local expression of GM-CSF. This is intended to be further enhanced through GALV-GP-R- mediated killing, fusion associated cell death which also results in the production of the highly immunogenic exosomes, which is expected to contribute to this immune effect. The immune response generated may then lead to immune destruction of distant, un injected tumours, and/or delay the progression of distant disease, and/or vaccinate against relapse. RP1 is intended for direct injection into solid tumours.

Host/vector system

RP1 (rHSV-1hGM-CSF/GAIV-GP) is derived from the RH018A strain of Herpes Simplex Virus-1. RP1 is produced in the Vero cell and released into the culture media during cell lysis, prior to purification.

Origin & function

RP1 was constructed using a new strain of HSV-1 (strains RH018A). Replimune obtained and compared 30 clinical strains of HSV-1 on a panel of human tumour cell lines and selected the most promising of these (strain RH018A) for further development. RP1 expresses the immune stimulatory protein GM-CSF, which augments therapeutic activity. GALV-GP-R- binds to the PiT1 receptor, which is widely expressed on mammalian cells including human tumour cells. PiT1 is also critical for cell proliferation, and its expression is therefore unlikely to be lost or down-regulated in response to cancer treatment. The truncated R- version of the protein provides constitutive fusion activity without GAL V (i.e. the virus) itself. Expressing GALV-GP-R- together with GM-CSF is expected to increase clinical activity as compared to only expressing GM-CSF. As well as causing direct tumour cell death by cell to cell fusion, cell to cell fusion followed by death is highly immunogenic and includes the release of immunogenic tumour antigen-containing exosomes. Expression of GAL V-GP-R- from an oncolytic virus is therefore expected to improve systemic, immune mediated, effects, as well as effects in the directly treated tumour thereby increasing synergy with other immunemediated approaches to cancer therapy such as immune co-inhibitory pathway blockade.

Evaluation of foreseeable effects

As described above (under Recipient or Parental Organism), the oncolytic destruction of tumour cells (upon transduction with RP 1) leads to the release of tumour associated antigens that are intended to engender an antitumour immune response, enhanced by the local expression of GM-CSF. This is intended to be further amplified through GALV-GP-R- mediated killing, fusion associated cell death which results in the production of the highly immunogenic exosomes and is expected to contribute to this immune effect. The immune response generated may then lead to immune destruction of distant, un injected tumours, and/or delay the progression of distant disease, and/or vaccinate against relapse. RP1 is intended for direct injection into solid tumours.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation is requested

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All used and unused RP1 and diluent vials used in preparation and syringes will be destroyed per institutional policy. As per the wild-type HSV-1 virus, the recombinant HSV-1 vector particles that represent RP1 are highly susceptible to dehydration, rapidly inactivated outside the host and easily inactivated (for example with 1 % Virkon solution).

Phase 1
As part of phase I of the clinical trial, biodistribution and shedding will be monitored. RP1 DNA levels in blood and urine will be determined at time-points outlined in the Schedule of Assessments of the clinical protocol, (i.e. day 1, day 2, day 3, day 15, day 16, day 17, day 29, day 30, day 31, day 43, day 57, day 71, day 85, day 99 and as part of the follow up, 30 days and 60 days after the last dose of RP1).
• Blood, saliva/oral mucosa, urine samples and injection site dressing swabs will be collected at the first, second and third RP1 injections at the following time points: pre-close, 6 (+/-2hr) hours, 21 hours (+/-3hr) and 48 hours (+/-6hr) and also immediately prior to dosing at fourth and fifth dose.
• Specimens (swabs) will be collected at any time there is a suspicion of RP1-related viral infection occur such as vesicular eruptions or other signs of herpes viral infection. Samples should be obtained as soon as possible after symptoms arise to maximize the possibility of detection of virus, optimally within 24 hours, but samples may be collected later if collection within 24hrs is not possible. Subjects will be asked to take swabs at home for the subsequent 7 days after the initial test.

Phase 2
As part of phase 2 portion of the clinical trial, biodistribution and shedding will be also monitored.
• RP1 DNA levels in Blood, Saliva/oral mucosa, urine samples and injection site dressing swabs will be collected pre-dose at the first through last RP1 injections (cycles 1 to 8). Additionally, for each of the tumour types enrolled, the first six patients the following additional time points will be required: Doses 1, 2 and 3: 6 eighth injections. Samples on injection days will be collected prior to any injections and handling of RP1. Samples will also be collected at the 30 and 60 day follow-up visits.
• Specimens (swabs) will also be collected at any time there is a suspicion of RP1-related viral infection occur such as vesicular eruptions or other signs of herpes viral infection

In phases 1 and 2 of the study, samples on injection days will be done prior to any injections and handling of RP1.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
The GMS committee reviewed the risk assessment on two occasions
Committee review on 2nd May 2018
Reviewer 1
I agree with the risk assessment, in general it is very detailed and covers all the main issues- a few minor points
below. An HSV oncolytic equivalent to this one was recently approved by the FDA for melanoma treatment so there is
a long history of assessment in humans of related HSV vectors. The novel GMO in this trial has been developed by
the same team (At Replimmue) so they have all the necessary expertise. The GMO is attenuated for tumour-selective
replication and is injected directly into the tumour.
Comments below
Section 2.2. This does not cover all the inserted genes as GMCSF is not described. In general more details are
needed in this section for all inserted genes and function.
Section 4.1 . It would be good to know the expected routes of shedding and timeframe for the GMO in comparison to
wt HSV. Appreciate that assessing shedding is part of the protocol but some indication based on previous knowledge
of Imglytic inserted here would be helpful, or any of the pre-clinical data briefly mentioned in 5.2.4k.
Section 5.1. Needs to be confirmed that the NHS contractors are licensed to transport GMO waste since it will not be
inactivated (unless there is a plan to use disinfectant before storage of waste). This isn't clear? How long before
removal and inactivation of GMO waste?
with residual virus in are not mentioned? Will sharps boxes be removed and inactivated immediately after
administration etc? Is autoclaving being used? There are no details on disinfectants etc.
Reviewer 2
With reference to Risk assessment Page 2 Notification to HSE- the sponsor has received notification to use CLASS 2
under contained Use. Does this notification include notification of GGC to Use Class 2 under contained Use or are
you using a previous notification. Each site needs to be notified The Beatson Oncology site is likely to have a
notification number. Please submit.
Section 5.1 - When the patient returns home are certain groups of people still restricted?
Who will collect the orange bags containing dressings from the homes of participants
Page 11 section 5.2.4 d and e- how will information in relation to the trial be shared with the local NHS GG&C
laboratories? e.g. information on cleaning if samples are spilled or there is a needle stick injury
Page 15 Section 6d Emergency procedures - Are there any specific safety instructions for those handling a dead
body? How will information be relayed if post mortem required?
Page 15 6e - Please discuss the trial with HAU and HDU so they are aware when the first patient is being treated and
what information will be available to be transferred with the patient in the event of an emergency e.g. Resuscitation.
Are pregnant women or immune compromised staff restricted or do they need to be made aware of any additional
risk? Please confirm this will take place and that the meeting will be documented within the local site file held by the
Page 16 section 8.- please complete
- employer details and
- other trial team members who will have contact with the patient and
- Possible interaction with HAU and HDU personnel- names may not be known but just write HAU and HDU
personnel and please discuss with leads for HAU and HDU
- Will NHS GG&C provide occupational Health support for non-NHS GGC staff? (e.g. Glasgow University staff)

When the trial is running
- Please forward any SUSARs to NHS Governance that occur with patients under the care of NHS GG&C

Page 17, Section 10- please submit the names of two reviewers for the appropriateness of this trial. In order to safe
time we would be happy for the PI to contact the reviewers and for their reviews to be sent to the GM committee.

Reviewer 3
Clarification needed on the following:
Has BWOSCC been notified to HSE as a site - the letter supplied may only cover the Sponsor.
GGCRA
- 5.2.7 doesn't cover disposal of sharps
- 5.3.1 - other than pharmacy no detail on actual routes of disposals. Need detail on any of the items
used in clinical area - giving sets etc. Looks like no specific waste handling being applied other than
for routine biological waste. Need to confirm/document this. Section 3.3.3 of Sponsor RA permits
this but suspect in pharmacy will use the rapid inactivation in the gene therapy isolator - need the
detail.
- 8.1.1 not completed - should be for domestic staff etc

Reviewer 4
I agree that more details are required as others have indicated with respect to prior data on shedding and on disposal
of dressings, sharps etc, especially once out of the hospital setting. The section on action in the event of patient death
has not been completed (it only has a "7" in the box) but I would expect this to be a potential event in this type of study
and some plan needs to be in place for this eventuality - notification to mortuary and pathology staff about any
required precautions etc.

Reviewer S
I had no fundamental safety concerns regarding the processes - there are some procedural issues around sharps
boxes etc which have been picked up by others and as long as these are addressed then that will be fine. I can't
comment on the specific GMO risks but support expert advice of reviewer.
The local investigator updated the risk assessment to take into consideration the comments of the committee above
and on the 20th February 2019 the committee requested minor updates before approving pending HSE notification
and approval.
Under local risk assessment section relating to training further confirmation was requested relating to code of practice.
- If a code of practice has not been prepared confirm in this section that appropriate training is in place to cover
risk of exposure and precautions required to hospital staff
- Please ensure that each of the local labs involved in primary, secondary or exploratory endpoints have lab
manuals according to GGC policy.
- Under emergency procedures rather than referring to a Health board policy for accidental exposure describe
how staff will be trained to deal with this event.
The study will be audited by the NHS GG&C Governance auditor to ensure patient safety after the first patient
has been recruited. The study was approved by the GMS committee pending HSE approval and local R&D
approval.

Give brief details of the genetic modification safety committee

The GM Safety Committee consists of the Director of Research, Senior Research Officer (Safety Officer) and a Research Assistant. Meetings will be held monthly. As the unit is small (5 people) any immediate issues can be addressed quickly; it is intended that (1) The Safety Officer will chair the meetings. (2) The Research Assistant will bring any concerns regarding GM and Microbiological activities to the attention of the committee. (3) The Director of Research will determine the direction of future research both in the immediate and long term. (4) As a direct consequence of which the Safety Officer will implement such measures to facilitate any modification of GM safety procedure as maybe required.

**For activities involving GMMs, describe the waste management measures which will apply to the activity**

Sterilization of all microbiological waste, GM contaminated disposable plastics (Eppendorf tubes, pipette tips and associated glassware at 121-124 C for 30 mins. By means of an autoclave within the premises (R189). Disposal of sterile waste using normal methods provided by the Leatherhead Food Institute within which the Touchlight Genetics is situated. The efficacy of sterilization procedures is to be monitored by Black Spot Brownes tubes and standard autoclave tape.

Tick to confirm that you are attaching a summary of the risk assessment **Y**

Tick if you are claiming exemption from disclosure for sections of the risk assessment ****

**Please enter comments of the GM safety committee on the risk assessment**

It is the GM committees view that the bacterial strains and vectors which Touchlight Genetics Ltd intended to use pose minimal, if any risk to laboratory personnel or the environment. It is also considered that the proposed safety measures and decontamination procedures are adequate for Class 1 organisms; a laminator flow cabinet and an autoclave are present within the laboratory. The committee recognises that all current members of the laboratory have extensive experience within the fields of microbiology and molecular biology.

Director of Research Ph.D (20 years experience at Universities of Warwick, Queen Mary College, Royal Dental School, Imperial College & the Royal Holloway.)

Senior Research Officer Ph.D (25 years at the Universities of Plymouth, Kent, Warwick and Imperial College). Research Assistant Ph.D (3 years Royal Holloway)

Research Assistant MSc (5 years at the University if Nicklaus Copernicus, 4 years as Microbiologist within Leatherhead Food International.

As senior research personnel the Director of Research and the Senior Research Officer have attended safety courses within the institutions listed above. The second research assistant has completed safety courses within the Leatherhead Food Institute.

Please enter comments of the GM safety committee on the risk assessment

In our opinion the risk assessment for the project 'Use of genetically modified human 'isogenic' cell-lines' outlines the nature of the work clearly and the characteristics of the GM organisms to be used. The hazards to human health are clearly defined and, in our opinion, we agree to the level 1 containment to be appropriate.

**Purposes of the contained use**

The purpose is to study the effect of modulating gene function in human cells in culture either by protein modification or reduction in protein levels.

**Recipient or parental organism**

The recipient organisms will comprise various characterized human cell lines maintained in tissue culture.

The human cell lines fall into 2 types:

- a) A packaging/helper cell line into which AAV DNA will be introduced and from which infectious virus will be secreted into the medium to high titre. The media from these cell lines poses a risk because of the high viral titre. As such this could provide a risk of infection to personnel working with the media.
- b) Recipient cell lines in culture. These cell will initially be exposed to a high titre of virus to permit infection (virus derived from (a) above). However the infected cell lines will be incapable of themselves producing active virus and as such are no more dangerous than the parental cell lines i.e. a negligible risk.

**Host/vector system**

The viral system which will be used is derived from the Adeno-Associated Virus (AAV) which is not categorised by ACDP.

On the other hand the virus will be packaged by transfecting transfer vector and helper vectors into specific packaging cell lines.

- This means that the viruses produced for these experiments could infect man.

However, bearing this in mind we should consider that the viruses that will be used have been modified in a number of ways which will make them safer to handle.

- The genes encoding structural and other components of the viral genome have been separated.
- The packaging cell lines allow expression of proteins required to produce progeny virus. The transfer vector is the only genetic material transferred to the target cells; consequently these cells cannot produce the proteins which are essential for viral assembly and infectivity.

**Origin & function**

The genetic material involved will be of 3 types:

1) For exon loss to knock-out gene function

- human genomic DNA surrounding the region to be targeted and a selection cassette to knock-out gene function.
2) For introduction of a SNP/small deletion/small insertion into the endogenous gene
   o human genomic DNA encompassing the region to introduce the SNP/small deletion/small insertion of interest and a selection cassette

3) For a tagged version of the endogenous gene using a reporter gene e.g. luciferase
   o human genomic DNA encompassing the region to be targeted, a reporter gene and a selection cassette.

Evaluation of foreseeable effects

Although the AAV's are not by categorized ADCP, a number of factors could increase the containment that will be required to work with them. We therefore need to consider the worst case scenarios:

The genetic material inserted into between the viral ITR's will be of 3 types:

1) For exon loss to knock-out gene function
   o genomic DNA surrounding the region to be targeted and a selection cassette to knock-out gene function

2) For introduction of a SNP/small deletion/small insertion into the endogenous gene
   o genomic DNA encompassing the region to introduce the SNP/small deletion/small insertion of interest and a selection cassette

3) For a tagged version of the endogenous gene using a reporter gene e.g. luciferase
   o genomic DNA encompassing the region to be targeted, a reporter gene and a selection cassette.

In every case, we will not be inserted a complete gene from the endogenous locus. Our technology specifically targets the endogenous gene locus and therefore we only need to target the region of interest. For example, if we want to create a point mutation in exon 1 of a gene we do not need to insert a complete cDNA with the exon 1 mutation; we just need to insert the mutated version of exon 1 with surrounding genomic DNA.

For each of the 3 types of inserted genetic material the hazards are as follows:

1) genomic DNA surrounding the region to be targeted and a selection cassette to knock-out gene function
   o This will have very few hazards associated with it as we are typically removing gene function. If the gene to be targeted is a tumour suppressor (e.g PTEN, p53) there may be an effect on cell characteristics depending on the particular gene. For example, PTEN has been shown to regulate levels of PI3K signalling and thus cell proliferation.
   o Worst case scenario: If an end-user were to infect themselves with this type of recombinant AAV vector, it is possible that the targeting construct could remove the function of the endogenous gene in the infected cells.
   o However, it would only target one allele of the gene rendering the infected cell heterozygous. For the genes which we would target (tumour suppressors) the tumorigenic effect is only seen when both alleles have been removed.
   o Also, as cancer is a multistep process removal of gene function is very unlikely to lead to complete cancer. At very worst it would make the few targeted cells one step along the path to tumorigenesis

2) genomic DNA encompassing the region to introduce the SNP/small deletion/small insertion of interest and a selection cassette
   o This is the insertion that has the most risk associated with it. For example, we may want to introduce a mutation which has been shown to be pro-oncogenic i.e. in K-Ras changing Glycine 12 to Valine. Transformation of cells has been shown to be a multi-step process requiring mutations in more than one gene. Therefore the introduction of a single mutation in the inserted genetic material provides a low risk of transforming any cell line. There is a potential for it to be oncogenic when recombined into the gene’s endogenous locus. However the expression levels of this altered version of the gene will generally be lower as it is expressed under the control of its endogenous promoter. This is in comparison to the effects on cells of the same mutation under the control of a high level exogenous (e.g. viral) promoter which has been shown to be transforming to cell lines.
   o Worst case scenario: If an end-user were to infect themselves with this type of recombinant AAV vector, it is possible that the targeting construct could change the function of the endogenous gene in the infected cells.
   o It would only target one allele of the gene rendering the infected cell heterozygous but has been shown to be associated with progression along the tumorigenesis process.
   o However, as cancer is a multistep process this gain of gene function is very unlikely to lead to complete cancer. At very worst it would make the few targeted cells one
step along the path to tumorigenesis.

- The degree of infection is likely to be small in the end-user as the targeting process is not very efficient so even if cells are infected with the recombinant AAV virus, very few of these would be correctly targeted.
- Overall, the highest level of risk does come from introducing SNP/small deletion/small insertion of interest but even if an end-user were to be infected, there is a very low risk of the infected cells being correctly targeted. If the cells are correctly targeted, these cells are very unlikely to be cancerous – at worst they will be one step along the path to cancer.

3) genomic DNA encompassing the region to be targeted, a reporter gene and a selection cassette.
- This will have very low hazards associated with it as we are not changing the endogenous expression or characteristics of the targeted gene. Reporter genes such as luciferase have no hazards associated with them.
- Worst case scenario: If an end-user were to infect themselves with this type of recombinant AAV vector, it is possible that the targeting construct could make a fusion protein with the reporter gene. However, as the reporter gene has no hazards associated with it, the only result would be that the infected cells would express the reporter gene.

There is no evidence that when the inserted genetic material recombines with the host cell lines genomic DNA that any sequences of the AAV viral genome are incorporated. In the recombinant AAV viral particles, the only AAV genomic sequences present are the ITR’s and there is no evidence that these are incorporated into the host genome during homologous recombination.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste material will be inactivated by treatment with 1% w/v Virkon solution prior to disposal. Waste material will then be placed in sealed bins and incinerated by an off-site incineration company (Vetspeed - their GM authorization is GMGM898) according to disposal notification GM105/4.1.

The disposal method is expected to achieve 100% inactivation of the GMM.

The data sheets describing inactivation by Virkon are attached

#### Project Additional Information

**Purposes of the contained use**

To study the effect on cellular function of decreasing protein levels in human cells in culture

**Recipient or parental organism**

The recipient organisms will comprise various characterised human cell lines in tissue culture. The human cell lines fall into 2 types:

- a) A packaging/helper cell line into which lentiviral transfer, packaging and envelope vectors will be introduced and from which infectious virus will be secreted into the medium at high titre. The media from these cell lines poses a risk because of the high viral titre. As such this could provide a risk of infection to personnel working with the
media.

b) Recipient cell lines in culture. These cells will initially be exposed to a high titre of virus to permit infection (virus derived from (a) above). However the infected cell lines will be incapable of themselves producing active virus and as such are no more dangerous than the parental cell lines (a negligible risk).

Host/vector system

The viral system is a third-generation lentiviral vector system, which is classified as Hazard Group Level 2.

The virus will be packaged by transflecting transfer vectors and helper vectors into specific packaging cell lines.
- This means the viruses produced could infect man.

However, the viruses being used have been modified in a number of ways to make them safe to handle.
- The genes encoding structural and other components of the viral genome have been separated so that no single vector contains the components necessary to produce replication-competent virus.
- Transfection of the three vectors into a packaging cell line allows expression of proteins required to produce progeny virus, the transfer vector is the only genetic material transferred to the target cells; consequently these cells cannot produce the proteins essential for viral assembly and infectivity.

The genetic material involved will code for small hairpin RNA (shRNA) sequences. The shRNAs will be directed against proteins that are involved in promotin cancer; therefore knockdown of the targets should no be associated with increased risks, over and above original cell lines.

Origin & function

Evaluation of foreseeable effects

In a very rare case, a user handling human cancer cell lines could be histocompatible with the original donor of the cancer cells. This poses a colonization risk if exposed to broken skin or needle stick injury. No glass or other sharps will be used and workers will be protected by a lab coat, nitrile gloves and eye protection. Skin lesions will be covered with a bandage in addition to the protective wear described above.

Possible risk of infection with virus particles. It is a possibility that the end-user could infect themselves with the virus particles. This may result in introduction of the shRNA sequence into the user's cells. We are investigating the effect of knocking down protein levels in tumour cells with the aim of impairing tumour cell growth. Knockdown of the individual target is very unlikely to have an untoward effect. No single plasmid contains all the genes necessary to produce packaged lentiviruses - resistant particles are replication-incompetent. Should the unlikely scenario of end-user infection occur, further virus production could not occur in infected cells.

Control measures employed will minimise risks to the environment. These control measures include rendering all solid or liquid waste inactive within the laboratory (either by autoclaving or use of Virkon). Work will be carried out in containment 2 laboratories in class II microbiological safety cabinets with routine disinfection of work surfaces. All staff will be suitably trained in working at containment level 2 laboratories and be aware of the necessary risk control measures.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid and solid waste is expected to be generated.
All liquid waste (including tissue culture fluids) will be inactivated by treatment with 1%w/v Virkon (or 1% Trigene) for 12 hours prior to autoclaving. Waste material will then be incinerated by an off-site incineration company (Grundon - their GM authorization is attached) according to disposal notification.

The disposal method is expected to achieve 100% inactivation of the GMM.

Datasheet information from Relyon.dupont_virkon has validated the use of this disinfectant for use with a broad range of infectious agents (including Herpes simplex virus, and retroviridae).

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The GMSC opinion is that the use of lentiviral vectors should be conducted at containment level 2. The individuals reviewing these documents are aware of the space implications for increasing the numbers of projects requiring access to category II containment facilities. For all new projects, an agreed system of work will need to be put in place, so not to compromise any other activities within the facility. This will need to be agreed prior to commencement of activities

Purposes of the contained use
To study the effect on cellular function of expression of a protein in human, and or mammalian cells in culture.

Recipient or parental organism
The recipient organisms will comprise various characterised human, and or mammalian cell lines maintained in tissue culture.
The cell lines fall into 2 types:
a) A packaging/helper cell line into which lentiviral transfer, packaging and envelope vectors will be introduced and from which infectious virus will be secreted into the medium at high titre. The media from these cell lines poses a risk because of the high viral titre. As such this could provide a risk of infection to personnel working with the media.
b) Recipient cell lines in culture. These cells will initially be exposed to a high titre of virus to permit infection (virus derived from (a) above). However the infected cell lines will be incapable of themselves producing active virus and as such are no more dangerous than the parental cell lines (a negligible risk).

Host/vector system
Packaging cells are transfected with the (replication-defective) retroviral vector and associated packaging vectors; mRNAs that are transiently transcribed from the vector are encapsidated and bud off into the cell supernatant. These supernatants, containing the retroviral particles are collected, and used to infect target cells. Upon infection of the target cell, the viral RNA molecule is reverse transcribed by RT (which is present in the virus particle), and the cDNA of the gene of interest, flanked by the LTRs, is integrated into the host DNA. Because the vector itself carries none of the viral proteins, once a target cell is infected the LTR expression cassette is incapable of proceeding through another round of virus production.

Origin & function

Evaluation of foreseeable effects
In a very rare case, a user handling human cancer cell-lines could be histocompatible with the original donor of the cancer cells. This poses a colonization risk if exposed to broken skin or needle stick injury. No glass or other sharps will be used and workers will be protected by a lab coat, nitrile gloves and eye protection. Skin lesions will be covered with a bandage in addition to the protective wear described above.
Possible risk of infection with virus particles. It is possible that the end-user could infect themselves with the virus particles. This may result in introduction of the DNA
sequence into the user’s cells. The cDNA may encode an oncogene, in which case it is possible that infection may result in a proportion of cells with tumourigenic potential. Retroviruses (distinct from lentiviruses) are only capable of infecting dividing cells; therefore exposure of any non-dividing cells is unlikely to result in infection with viral RNA. No single plasmid contains all the genes necessary to produce packaged retrovirus - therefore resultant particles are replication-incompetent. Should the unlikely scenario of end-user infection occur, further virus production could not occur in infected cells.

Control measures employed will minimise risks to the environment. These control measures include rendering all solid or liquid waste inactive within the laboratory (either by autoclaving or use of an appropriate disinfectant for example Virkon). Work will carried out in Class 2 containment laboratories in class II microbiological safety cabinets with routine disinfection of work surfaces. All staff will be suitably trained to work in Class 2 containment laboratories, in the experimental procedures undertaken for the study, and be made aware of the risk assessment and control measures being applied.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid and solid waste is expected to be generated.

All liquid waste (including tissue culture fluids) will be inactivated by treatment with 1%w/v Virkon (or 1% Chemigene) for 12 hours prior to disposal to drains.

All solid waste material will be inactivated by treatment with 1% w/v Virkon (or 1% Chemigene) solution for 12 hours prior to autoclaving. Waste material will then be incinerated by an off-site incineration company (Grundon - their GM authorization is attached) according to disposal notification.

The disposal method is expected to achieve 100% inactivation of the GMM.

Please enter comments on the GM safety committee on the risk assessment

1. The risk assessment HD_GMO_294 covers the use of the Agilent retroviral pCFB system (cat#217568 and cat#240028). Any deviation from this vector backbone will require review to insure the necessary control measures have been incorporated in the vector to limit risk of exposure and release.

2. The use of retroviral version of Agilent's Complete Control Inducible Mammalian Expression System will allow high transduction efficiencies in difficult to transfect cell lines and proviral copy number can be easily controlled to aid the application of the inducible expression system.

3. Initial an optimised protocol using 10cm dishes will be used. Once this process has been setup within Horizon it is recommended that the virus production be tested in containers with closures (T flasks) to reduce risk of spills.

Purposes of the contained use

To study the ability of recombinant oncolytic adenoviruses to kill tumour cells growing in culture.

Recipient or parental organism

The recipient organisms will comprise various characterised human cancer cell lines maintained in tissue culture. These cell lines have a long history of safe use across the research community and represent minimal risks to health or the environment.

Host/vector system

- Proprietary Oncolytic Adenovirus Species C Type 5 oncolytic viral vector. This vector is attenuated to ensure it selectively replicates in human tumour cells and not in normal cells via deletions in the regulator sequences of key genes.
genes involved in replication of the virus. In addition, several regions of the adenoviral genome have been deleted to enable insertion and expression of an exogenous transgene.

- Hazards associated with risk of infection: Adenoviruses cause generally mild respiratory tract infections which are self-limiting and generally asymptomatic. As the recombinant oncolytic adenovirus selectively replicates in tumour cells, in the event of accidental infection of a worker's normal cells, further virus production would not occur, which minimizes risks to health.
- Potential hazards to the environment: Although human Ad5 adenovirus vectors have been shown to be capable of entering some animal cells, they do not replicate efficiently. Furthermore, the virus is selective for tumour cells and not normal cells. Therefore it is unlikely that work with this vector will represent a significant risk to the environment.
- Control measures employed will minimize risks to workers and the environment. These control measures include rendering all solid or liquid waste inactive within the laboratory (either by autoclaving, incineration or use of disinfectant). Work will be carried out in containment 2 laboratories in a class II microbiological safety cabinets with routine disinfection of work surfaces. All staff will be suitably trained in working at containment 2 laboratories and be aware of the necessary risk control measures.
- Note that this type of human adenovirus serotype 5 (Ad5) vectors have been extensively used across the research community and have been approved for use in solid tumours and Ad5 has been tested in multiple forms in clinical trials.

Origin & Function

Evaluation of foreseeable effects

- After infection of human cancer cell lines in vitro, the oncolytic adenovirus replicates, which then results in lysis of the tumour cells.
- Therefore the main potential hazards to health or the environment associated with the genetically modified tumour cell lines is the release of infective adenovirus particles when the tumour cell is lysed by the virus.
- Hazards associated with risk of infection: Adenoviruses cause generally mild respiratory tract infections which are self-limiting and generally asymptomatic. As the recombinant oncolytic adenovirus selectively replicates in tumour cells, in the event of accidental infection of a worker's normal cells, further virus production would not occur, which should minimize risks to health.
- Potential hazards to the environment: Although human Ad5 adenovirus vectors have been shown to be capable of entering some animal cells, they do not replicate efficiently. Furthermore, the virus is selective for tumour cells and not normal cells. Therefore it is unlikely that work with this vector will represent a significant risk to the environment.
- Control measures employed will minimize risks to workers and the environment. These control measures include rendering all solid or liquid waste inactive within the laboratory (either by autoclaving, incineration or use of disinfectant). Work will be carried out in containment 2 laboratories in class II microbiological safety cabinets with routine disinfection of work surfaces. All staff will be suitably trained in working at containment 2 laboratories and be aware of the necessary risk control measures.
- Note that these types of adenoviruses have been used for decades in both gene therapy and oncology applications in the laboratory and the clinic. For example human adenoviruses serotype 5 (Ad5) have been approved for human use in solid tumors and Ad5 have been tested in multiple forms in clinical trials. For example Ph I - III clinical trials have been conducted with replicating Ads having deletions or specific promoter use conferring tumor replication selectivity (e.g. ONYX-015).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

To study the ability of recombinant oncolytic herpes simplex virus vectors to kill tumour cells growing in culture.

The recipient organisms will comprise various characterised human cancer cell lines maintained in tissue culture. These cell lines have a long history of safe use across the research community and represent minimal risks to health or the environment.

Host/vector system

- Proprietary oncolytic HSV-1 Herpes simplex virus vectors. These vectors contain deletions (e.g. deletion of the gamma34.5 neuropathogenesis gene) that effectively attenuates the virulence of HSV-1 to ensure it selectively replicates in tumour cells but not normal neuronal cells (i.e. neurovirulence has been eliminated).
- Typically the temporal expression of one or more viral proteins are modified so that they are expressed earlier in the viral replication cycle. This is sufficient to overcome the partial innate antiviral response that exists in tumor cells, as during tumorigenesis mutations occur in pathways that confer growth advantages to the cancer cell that render the cell incapable of mounting a complete antiviral response. However, this mutation is insufficient to overcome the full antiviral response that occurs in normal cells.
- In some cases the vector will be modified via the introduction of immunomodulatory transgenes, to help the virus evade anti-viral T-cells while promoting anti-tumour immune cell recruitment and/or stimulation of anti-tumour immune cell activity.
- These types of attenuations/modifications are the basis of Talimogene laherparepvec (T-Vec/Imlygic), the first FDA-approved oncolytic virus (Conry et al 2018. Human Vaccines and Immunotherapeutics, 14, 839-846). Therefore, the safety profile of Herpes simple viruses modified in this way are excellent.

Origin & function

- The genetic material is a proprietary modified herpes simplex virus type 1 (HSV-1) that has been modified as described above to attenuate the virulence of HSV-1 to ensure it selectively replicates in tumour cells but not normal neuronal cells (i.e. neurovirulence has been eliminated).
- In some cases the vectors will contain human immunomodulatory transgenes to help the virus evade anti-viral T-cells while promoting anti-tumour immune cell recruitment and/or stimulation of anti-tumour immune cell activity.
- After Infection of human cancer cell lines in vitro, oncolytic herpes simplex virus vectors replicate, which then results in lysis of the tumour cells.
- Therefore the main potential hazards to health or the environment associated with the genetically modified tumour cell lines is the release of infective herpes virus particles when the tumour cell is lysed by the virus.
- For recombinant oncolytic HSV1. As the recombinant oncolytic herpes virus selectively infects tumour cells, in the event of accidental infection of a workers normal cells, further virus production would not occur, which should minimizes risk to health. Furthermore, antiviral drugs are available for the treatment of infections like acyclovir, foscarnet valacyclovir, famciclovir, and penciclovir that can inhibit viral replication. However, to our knowledge there have been no reports of laboratory acquired infections resulting from work with these types of viral vector.
-For completeness the following applies to Parental or Wild-type HSV-1 the following infection risks have been identified. Hazards associated with risk of infection: Parental HSV-1 is associated mainly with "above the waist" infections involving the mouth, pharynx, face, eye, and central nervous system (CNS), but can be associated with "below the waist" infections of the genital region (although these symptoms are mainly associated with HSV-2 infection). Herpes labialis/cold sores: Caused mainly by HSV-1. Primary infections with HSV-1 are acquired usually in childhood and may be asymptomatic or subclinical. Symptomatic primary infections present mainly as gingivostomatitis, with fever, sore throat, fetor oris, anorexia, cervical adenopathy, and mucosal edema and vesicular and ulcerative painful lesions involving the buccal mucosa, tongue, gums, and pharynx. Ulcers heal without scarring within 2-3 weeks. Recurrent infections have generally milder symptoms and clinical course. Recurrent lesions due to HSV-1 occur mainly on a specific area of the lip (vermilion border of the lip), and are called "cold sores" or "fever blisters". The lesions heal in approximately 8-10 days. Herpetic whitlow: Characterized by formation of painful vesicular lesions on the nail or finger area. Infections of the eye: Characteristic dendritic ulceration occurs on conjunctiva, and cornea. HSV infection may cause other ocular diseases, including blepharitis/dermatitis, conjunctivitis, dendritic epithelial keratitis, and corneal ulceration. Encephalitis: Serious infections of the CNS, affecting both children and adolescents. It may occur due to primary or latent infection with HSV-1 virus. HSV encephalitis affects one temporal lobe, leading to focal neurologic signs and edema. Genital herpes: It is a sexually transmitted disease. Genital herpes is caused mainly by HSV-2. Primary genital herpes is characterized by formation of multiple, bilateral, painful, and extensive genital ulcers, which heal without scarring within 12 days. Patients also present with tender enlarged lymph nodes, fever, malaise, and myalgia. Rarely, the disease may also cause aseptic meningitis with neck rigidity and severe headache. Recurrent genital herpes disease is of shorter duration, is milder and does not have systemic symptoms. The main manifestation of the disease is prodromal paresthesias in the perineum, genitalia or buttocks, followed by formation of grouped lesions on the external genital area. The lesions heal without scarring in 2-5 days. Neonatal Herpes: Neonatal herpes is an extremely severe disease with a very high mortality rate. Neurological complications may occur in infants who survive the infection.
- Potential hazards to the environment: Although, non-human primates in captivity can be accidentally infected and rabbits and rodents have been infected experimentally the host range of human herpes simplex virus 1 is generally restricted to humans in the wild. Furthermore, this recombinant version of the virus has been engineered to be attenuated and selective for tumour cells and not normal cells. Therefore it is unlikely that work with this vector will represent a significant risk to the environment.
- Control measures employed will minimise risks to workers and the environment. These control measures include rendering all solid or liquid waste inactive within the laboratory (either by autoclaving, incineration or use of ). Work will carried out in containment 2 laboratories in class II microbiological safety cabinets with routine disinfection of work surfaces. All staff will be suitable trained in working at containment 2 laboratories and be aware of the necessary risk control measures.
- Note that a number of herpes simplex virus 1-based viral vectors have been evaluated and approved for human therapy e.g. Talimogene laherparepvec (T-Vec/Imlygic), which is the first FDA-approved oncolytic virus (Conny et al 2018. Human Vaccines and Immunotherapeutics, 14, 839-846). Therefore, the safety profile of Herpes simplex virus 1-based vectors are excellent.

Evaluation of foreseeable effects

- For recombinant oncolytic HSV1. As the recombinant oncolytic herpes virus selectively infects tumour cells, in the event of accidental infection of a workers normal cells, further virus production would not occur, which should minimizes risk to health. Furthermore, antiviral drugs are available for the treatment of infections like acyclovir, foscarnet valacyclovir, famciclovir, and penciclovir that can inhibit viral replication. However, to our knowledge there have been no reports of laboratory acquired infections resulting from work with these types of viral vector.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid and solid waste is expected to be generated.
All liquid waste (including tissue culture fluids) will be inactivated by treatment with 1%w/v Virkon (or 2% Chemgene) for 12 hours prior to disposal to drains.
All solid waste material will be inactivated by treatment with 1% w/v Virkon (or 2% Chemgene) solution for 12 hours prior to autoclaving. Waste material will then be
Incinerated by an off-site incineration company (Grundon - their GM authorization is attached) according to disposal notification. The disposal method is expected to achieve 100% inactivation of the GMM. Datasheet information from Relyon.dupont _virkon has validated the use of this disinfectant for use with a broad range of infectious agents.

Datasheet information from Relyon.dupont _virkon has validated the use of this disinfectant for use with a broad range of infectious agents.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The GMSC opinion is that the use of herpes simplex virus 1-based viral vectors is appropriate at containment level 2. All equipment in the process has been assessed and will be suitable for the process with the risk of aerosol production minimal. All waste routes are also effective and approved.

Y

Give brief details of the genetic modification safety committee

The committee is a sub-committee of the Biological Safety Committee and consists of a representative from all the sub sections of the company involved in GM Organism work.

The committee will meet not less than four times per year to review the use of GMOs. However, it is not anticipated that there will be any major changes in the types and varieties of GMOs in use.

The GMMs that are currently generated by Takeda Cambridge Ltd are completely destroyed by standard autoclaving. All laboratory waste (for example gloves, used plasticware, pipettes, and anything else contaminated) will be subject to autoclaving before leaving the premises. In the case of liquids, a strong disinfectant (for example Chloros) will be used to treat samples and regular testing will take place to gauge the level of killing. Bench tops are impervious to water and are resistant to moderate heat and the organic solvents, acids, alkalis, and chemicals used to decontaminate the work surfaces and equipment. For minor spillages it is anticipated that a solution of 70% Ethanol or 60% Isopropanol will be used to decontaminate – any solid waste from the decontamination process will be autoclaved before leaving the building. The laboratory is designed so that it can be easily cleaned. Carpets and rugs in laboratories are deemed inappropriate. Laboratory furniture is capable of supporting anticipated loading and uses. Spaces between benches, cabinets, and equipment are accessible for cleaning. In accordance with Good Laboratory Practice, Protective laboratory coats, gowns, smocks, or uniforms designated for lab use are worn while in the laboratory. This protective clothing is removed and left in the laboratory before leaving for non-laboratory areas (e.g., cafeteria, library, administrative offices). All protective clothing is either disposed of in the laboratory or laundered by the institution; it should never be taken home by personnel. Gloves are worn when hands may contact potentially infectious materials, contaminated surfaces or equipment. Wearing two pairs of gloves may be appropriate. Gloves are disposed of when overtly contaminated, and removed when work with infectious materials is completed or when the integrity of the glove is compromised. Disposable gloves are not washed, reused, or used for touching “clean” surfaces (keyboards, telephones, etc.), and they should not be worn outside the lab. Hands are washed following removal of gloves.

Please enter comments of the GM safety committee on the risk assessment
Takeda Cambridge Ltd (formerly Paradigm Therapeutics Ltd.) has been working under licence #GM 860 (to Paradigm Therapeutics Ltd, 418 Cambridge Science Park) with the GMMs outlined in Appendix 1. In accordance with this, the GMSC has recommended that Takeda Cambridge continue to work only with fully verified commercial sources of Host strains and vectors to maintain all work at Hazard Level 1 and Containment Level 1.

### Project Additional Information

**Purposes of the contained use**

SH-SY5Y-HTT-LC3 cells expressing fluorescently tagged huntingtin protein (HTT-GFP (green fluorescent protein)) and fluorescently tagged microtubule-associated protein 1-light chain 3 (LC3-mCherry) will be used to investigate how the cellular process of protein degradation is regulated.

All humans have the Huntingtin gene (HTT) which codes for the huntingtin protein (Htt). This gene contains a repeated section called a trinucleotide repeat. When the length of this repeated section reaches a certain threshold, it produces an altered form of the protein, mutant Htt (mHtt). The differing functions of mHtt from Htt are the cause of the pathological changes which cause the disease symptoms of Huntington's disease. The Htt protein interacts with over 100 other proteins and appears to have multiple biological functions. In this system a recombinant Htt protein that is tagged with the well-characterized fluorescent protein, GFP, will be over expressed in order to generate fluorescently-tagged protein aggregates which can be visualized. The clearance of these protein aggregates by the cellular process of autophagy can then be monitored.

Autophagy is a catabolic process involving degradation of a cells own components through the lysosomal machinery. Autophagy involves the formation of a membrane around a targeted region of the cell (generating an autophagosome) which separates the contents from the rest of the cytoplasm. This autophagosome then fuses with a
lysosome (which contains the enzymes required for degradation) and the contents are degraded. The LC3 protein is the only known mammalian protein that specifically associates with the autophagosome membrane. By tagging LC3 with mCherry, another well-characterized fluorescent protein, it can be used in the cell line detailed here as a marker to identify autophagosomes.

SH-SY5Y-HTT-LC3 cell monolayers will be cultured according to containment level II (CL2) regulations. Microscopic visualization of the fluorescent tagged Htt and LC3 proteins under a variety of conditions (e.g. alterations in nutrient supply) will enable a better understanding of the protein degradation process.

The parental cell line SH-SY5Y, is a human neuroblastoma which was derived as a subclone of the SK-N-SH cell population originating from a human bone marrow sample (ATCC #CRL-2266). The SH-SY5Y cell line displays neuronal-like properties and continuous cultures were established in vitro (Biedler et al., 1973. Cancer Res. 33, 2643-2652; Biedler et al., 1978, Cancer Res. 38, 3751-3757) without the need for immortalization using retrovirus. SH-SY5Y cells can be maintained in a containment level 1 facility (as per instructions from ATCC). SH-SY5H-HTT-LC3 cells can not survive outside the laboratory and this cell line can not produce viral particles (Section 7). The SH-SY5Y-HTT-LC3 cell line will be treated as a CL2 cell line and all material will be totally inactivated (by exposure to Trigene advance (Medichem)) at the end of each experiment. No foreseeable effects on human health and safety are expected.

The human neuroblastoma SH-SY5Y cell line is a subclone of the SK-N-SH cell population which originates from a human bone marrow sample (ATCC #CRL-2266). This cell line has neuronal-like properties and continuous cultures were established in vitro by selection for growth (Biedler et al., 1973. Cancer Res. 33, 2643-2652; Biedler et al., 1978, Cancer Res. 38, 3751-3757) without the need for immortalization. SH-SYSY-HTT-LC3 cells can not survive outside the laboratory and this cell line can not produce viral particles (detailed below). The SH-SYSY-HTT-LC3 cell line will be treated as a CL2 cell line and all material will be totally inactivated (by exposure to Trigene advance *) at the end of each experiment. All solid material that has been in contact with this cell line, following inactivation, will be autoclaved on site. Inactivated liquid waste and inactivated, autoclaved solid waste material will be collected and taken off site by Grundons and either disposed of according to liquid waste regulations or in the case of solid waste, incinerated. No foreseeable effects on human health and safety are expected.

*As per manufacturer's information (Medichem) Trigene advance formula is a nanoemulsion that enables the active molecules in the product to be carried rapidly through cell walls of micro-organisms. Rapid penetration of cell membranes by Trigene advance disinfectant constituents ensures cell death is equally rapid. Trigene advance works quicker than conventional high level disinfectants and achieves apoptosis (cell death) rather than merely suspending activity as with conventional disinfectant products.

The SH-SYSY-HTT-LC3 cell line was generated in the laboratory of a collaborator at the University of British Columbia. An overview of the process taken to generate this cell line is detailed below and full details of the vectors and delivery systems employed can be found on the Clontech website.

Proteins to be overexpressed in SH-SYSY cells:
1) HTT: All humans have the Huntingtin gene (HTT) which codes for the huntingtin protein (Htt). Part of this gene is a repeated section called a trinucleotide repeat. When the length of this repeated section reaches a certain threshold, it produces an altered form of the protein, mutant Htt (mHtt). The differing functions of mHtt are the cause of the pathological changes which cause the disease symptoms of Huntington's disease. The Htt protein interacts with over 100 other proteins and appears to have multiple biological functions. This protein will be expressed as a fusion with green fluorescent protein to allow microscopic visualisation (HTT-GFP).

2) LC3: The LC3 (microtubule-associated protein 1-light chain 3) protein is the only known mammalian protein that specifically associates with the autophagosome membrane and thus can be used as a specific marker of autophagosomes. This protein will be expressed as a fusion with the fluorescent protein mCherry to allow microscopic visualisation (LC3-mCherry).

Expression System and Delivery System
Expression of both LC3-mCherry and HTT-GFP was achieved by adaptation of the Lenti-X Tet-On Advanced system (Clontech). Detailed information about this system can
be found: http://www.clontech.com/products/detail.asp?product_id=172013&product_group_id=171916&product_family_id=1419&tabno=2 Briefly, this system is based on the generation of lentiviral expression vectors, the expression from which can be modulated by the presence of doxycycline (see below). These vectors are packaged into replicon-incompetent lentivirus using lentivirus packaging systems and the lentiviral packaging 293T cell line (Clontech). As detailed below, the system deploys a number of specific measures to ensure that viral replication can only occur in the packaging 293T cell line and can not occur in the cell line which is transduced. The replicon-incompetent lentivirus were then used to transduce the SH-SY5Y cells. The resultant SH-SY5Y-HTT-LC3 cells can not generate replicon-competent lentivirus (RCL; discussed below).

The gene expression system consists of a vector construct that stably expresses the tet-On advanced transcriptional activator (rtTA), and response elements (pLVX-Tight-Puro) into which the genes of interest are cloned (in this case, HTT-GFP and LC3-mCherry). The pLVX vector (Clontech) is an HIV-1-based lentiviral expression vector. This vector contains the viral processing elements necessary for the production of replicon-competent lentivirus. This vector does not contain the total complement of all viral packaging proteins and thus by itself lacks all of the necessary components to produce replicon-competent lentivirus. The other required components are expressed in the packaging cell line. The rtTA and IRES m-cherry fused to LC3 are driven by the CMV promoter. The HTT-GFP is driven by the pTight promoter (Tet On). The LC3-mCherry is constitutively expressed where as HTT-GFP is under rtTA control and is only expressed in the presence of doxycycline.

As indicated above, the lentiviral expression vectors and the lentivirus packaging systems and 293T cells lines that were used to generate the SH-SY5Y-HTT-LC3 cell line were obtained from Clontech. As detailed on the Clontech website: there are several measures that have been taken to ensure that viral replication is specifically restricted to specific packaging cells to minimize the possibility of generating a RCL. Clontech state that: 'the emergence of RCL is undetectable from systems using this approach'. Clontech’s lenti-X vectors contain less than one third of the wild-type HIV-1 genome. All essential replication genes have been completely removed and are instead supplied as separate DNA entities in the Lentiviral HTX packaging mix. The Lenti-X HTX packaging mix is only utilized with 293T cells. Clontech's lentiviral packaging systems utilize split-genes to provide the viral packaging elements on individual plasmids that physically separate the viral envelope, env (usually VSV-G), sequence from the gag-pro-pol sequences. As an additional safety measure, pol is also separated from gag-pro. The result is that gag, pol and env reside on three physically distinct entities. This split-gene packaging strategy reduces the risk of generating RCL because multiple recombination events are necessary to create a virus that harbours the sequences required for independent replication. Use of the system generates replicon-competent virus particles. Such virus particles were used to generate the SH-SY5Y-HTT-LC3 cell line.

Measures are in place to ensure that all matter (solid and liquid) that has been in contact with the SH-SY5Y-HTT-LC3 cell line will be disposed of so that it has no impact on human health and safety. SH-SY5H-HTT-LC3 cells can not survive outside the laboratory environment and this cell line has been created in such a manner to prevent the production of viral particles (detailed above). Due to the fact that the SH-SY5Y-HTT-LC3 cell line was generated using a lentivirus system it will be treated as a CL2 cell line and all material will be totally inactivated (by exposure to Trigene advance*) at the end of each experiment. All solid material that has been in contact with this cell line, following inactivation, will be autoclaved on site. Inactivated liquid waste and inactivated, autoclaved solid waste material will be collected and taken off site by Grundons and either disposed of according to liquid waste regulations or in the case of solid waste, incinerated. No foreseeable effects on human health and safety are expected.

*As per manufacturer's information (Medichem)Trigene advance formula is a nanoemulsion that enables the active molecules in the product to be carried rapidly through cell walls of micro-organisms. Rapid penetration of cell membranes by Trigene advance disinfectant constituents ensures cell death is equally rapid. Trigene advance works quicker than conventional high level disinfectants and achieves apotosis (cell death) rather than suspending activity as with conventional disinfectant products.

Origin & function

The vector construction, preparation of lentivirus and the generation of stable cell lines (detailed above) was carried out in the laboratory of a collaborator at the University of British Columbia.

SH-SY5Y-HTT-LC3 cells that can express fluorescently tagged huntingtin protein (HTT-GFP (green fluorescent protein)) and fluorescently tagged LC3 protein (LC3-mCherry) will be used to investigate how the cellular process of protein degradation is regulated. All humans have the Huntingtin gene (HTT) which codes for the protein huntingtin (Htt). Part of this gene is a repeated section called a trinucleotide repeat. When the length of this repeated section reaches a certain threshold, it produces an altered form of the protein, mutant Htt (mHtt). The differing functions of mHtt to Htt are the cause of the pathological changes which cause the disease symptoms of Huntington's disease. The Htt protein interacts with over 100 other proteins and appears to have multiple biological functions. In this system the Htt protein...

quicker than conventional high level disinfectants and achieves apoptosis (cell death) rather than merely suspending activity as with conventional disinfectant products.

**Evaluation of foreseeable effects**

The SH-SY5Y-HTT-LC3 cell line will be maintained in a CL2 facility and will be treated as CL2 material (see 8). The vector construction, preparation of lentivirus and the generation of the SH-SY5Y-HTT-LC3 stable cell line (detailed above) was carried out in the laboratory of a collaborator at the University of British Columbia. The parental

SH-SY5Y cell line can be maintained in CL1 facilities (in accordance with ATCC guidelines). In addition, this cell line was transformed with replicon-incompetent lentivirus (according to Clontech literature; detailed above) and does not contain the necessary virus machinery to shed replicon-competent particles. However, to ensure maximal safe practice, the SH-SY5Y-HTT-LC3 cell line will be maintained in a CL2 facility and will be treated as CL2 material.

All humans have the Huntingtin gene (HTT) which codes for the protein huntingtin (Htt). Part of this gene is a repeated section called a trinucleotide repeat. When the length of this repeated section reaches a certain threshold, it produces an altered form of the protein, mutant Htt (mHtt). The differing functions of mHtt to Htt are the cause of the pathological changes which cause the disease symptoms of Huntington's disease. The Htt protein interacts with over 100 other proteins and appears to have multiple biological functions. The LC3 protein is involved in the formation of the autophagosome during autophagy. We do not anticipate any foreseeable effects on human health and safety during and after the use of this cell line.

As previously indicated, measures are in place to ensure that all matter (solid and liquid) that has been in contact with the SH-SY5Y-HTT-LC3 cell line is inactivated and disposed of so that it has no impact on human health and safety. SH-SYSH-HTT-LC3 cells can not survive outside the laboratory and this cell line lacks the cellular machinery to produce viral particles (detailed above). The SH-SY5Y-HTT-LC3 cell line will be treated as a CL2 cell line and all material will be totally inactivated (by exposure to Trigene Advance*) at the end of each experiment. All solid material that has been in contact with this cell line, following inactivation, will be autoclaved on site. Inactivated liquid waste and inactivated, autoclaved solid waste material will be collected and taken off site by Grundons and either disposed of according to liquid waste regulations or in the case of solid waste, incinerated. No foreseeable effects on human health and safety are expected.

* As per manufacturer's information (Medichem)Trigene advance formula is a nanoemulsion that enables the active molecules in the product to be carried rapidly through

cell walls of micro-organisms. Rapid penetration of cell membranes by Trigene advance disinfectant constituents ensures cell death is equally rapid. Trigene advance works

quicker than conventional high level disinfectants and achieves apoptosis (cell death) rather than merely suspending activity as with conventional disinfectant products.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Assessment of the SH-SY5Y-HTT-LC3 line risk assessment (please see attached risk assessment number XXXX) by the internal GMO committee dictated that this cell line should be maintained as a CL2 cell line because it was generated using replicon incompetent lentivirus. The tissue culture laboratories have been set up according to the relevant regulations. The tissue culture laboratory where this work will take place has the following features:

1. Benches are impervious to water and resistant to acids, alkalis, solvents, decontamination agents and are easy to clean
2. Labs are under negative pressure
3. The maintenance of the cell line will be carried out in class II biosafety hoods which have double hepa filters and have been certified as functional to perform such work
4. All solid waste (pipettes; plastic ware etc) will be treated with a solution of Trigene to inactivate the material. The waste is then autoclaved on site prior to collection and disposal by Grundons
5. All liquid waste, any contaminated solid waste and cellular material is totally inactivated by exposure to Trigene advance (1:10 dilution; Medichem*) prior to collection and disposal by Grundons
6. All personnel using the TC facilities are made aware (by verbal means and the use of appropriate hazard stickers) as to the nature of the work being undertaken in the lab
7. All personnel using the TC facilities receive appropriate training for which there are written records
8. All personnel will wear the appropriate personal protective equipment. By adhering to the CL2 guidelines together with knowledge regarding the SH-SY5Y-HTT-LC3 cell line, no foreseeable effects on human health and safety are expected.

*As per manufacturer's information (Medichem) Trigene advance formula is a nanoemulsion that enables the active molecules in the product to be carried rapidly through cell walls of micro-organisms. Rapid penetration of cell walls by Trigene advance disinfectant constituents ensures cell death is equally rapid. Trigene advance works quicker than conventional high level disinfectants and achieves apoptosis (cell death) rather than merely suspending activity as with conventional disinfectant products.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

The SH-SY5Y-HTT-LC3 cell line can not survive outside the laboratory. This cell line does not contain the cellular machinery to shed replicon-competent viral particles (discussed above). SH-SY5Y-HTT-LC3 cultures will be treated as CL2 material and the following details our waste management measures:

1. Culture medium will be aspirated with plastic pipettes and will be collected in a suitable vessel which is appropriately labelled.
2. Media will be decontaminated and 100% inactivated by exposure to Trigene advance* (1:10 dilution; Medichem).
3. Decontaminated/inactivated media will be collected and disposed of by Grundons.
4. Plastic ware that has been in contact with the cell line (e.g. pipettes, flasks etc) will be exposed to trigene to inactivate any remaining material.
5. De-contaminated plastic ware will be stored in autoclave boxes and autoclaved on site.
6. Any solid tissue culture material (e.g. gloves, paper towels etc) will be placed in autoclave bags and autoclaved.
7. All autoclaved material will be collected and disposed of by Grundons.

* As per manufacturer's information (Medichem) Trigene advance formula is a nanoemulsion that enables the active molecules in the product to be carried rapidly through cell walls of micro-organisms. Rapid penetration of cell walls by Trigene advance disinfectant constituents ensures cell death is equally rapid. Trigene advance works quicker than conventional high level disinfectants and achieves apoptosis (cell death) rather than merely suspending activity as with conventional disinfectant products.
The Genetic Modification Safety Committee of Takeda Cambridge Ltd (Jonathan Ellery PhD, Alan Hendrick PhD, 2010) upon review of the risk assessment for the SH-SY5Y-HTT-LC3 cell line determined that:

The parental cell line SH-SY5Y requires class 1 containment and has not been immortalised deliberately with retrovirus. This cell line represents no hazard to human health.

The lentivirus systems used to introduce the HTT-GFP and LC3-mCherry genes into the SH-SY5Y cell line are designed to minimise the risk of generating a cell line that is capable of producing replicon competent virus particles.

It has been noted that there is no supporting data to show this to be the case for SH-SY5Y-HTT-LC3.

Of the two proteins to be expressed only one of these (a mutant form not being expressed) has been shown to be involved with a human pathology.

The risk from exposure to a tagged version of the protein is negligible.

It was decided to categorise this work as class 2 because the cell line was generated using a lentiviral system and that a mutant version of the Htt protein has been implicated in a human pathology.

Project Ref 3043/11.1

Date Ackn'd: 28/03/2011

CU2 Project Title: Use of BV-2 cells to investigate cellular mechanisms of neurodegeneration

Class: Class 2

CultureVolClass2: ≤ 1 Litre

Consent Granted

Non-GMM

Date Project: 02/03/2022
The BV2 cell line is an immortalized microglia cell line, which will be used to analyse mechanisms of neurodegeneration. Immortalized cell lines proliferate and therefore represent a valuable source for in vitro cell assays. This is in contrast with primary rodent microglia, which do not appear to proliferate in vitro. Furthermore, the protocol to isolate primary microglia is lengthy and requires confluent mixed glial preparations to be obtained (2 weeks in vitro) before the microglia can be isolated. Following isolation, the yield of microglia is generally very low and thus the number of experiments/glial preparation is limited.

Microglia activation has been reported in Alzheimer's disease. This results in release of cytokines and reactive oxygen species (ROS) that have neurotoxic effects. It is therefore critical to analyse microglia function and potentially the interplay between microglia and neurons in order to validate potential drug targets. BV-2 cells will be stimulated with beta-amyloid or other stimuli eg lipopolysaccharide to induce cell activation. Cytokine release and ROS production will be measured. Target expression analysis by immocytochemistry and Western blotting will be performed in microglia cell lysates and the effect of blocking the target on interest on ROS and cytokine release will be analysed. Compound treatment to inhibit the target of interest as well as RNAi experiments will be performed. For the latter, transient target knockdown studies will be performed using si-RNA transfection via lipid or defined polymers.

BV-2 cells have been generated by infecting mouse primary microglial cells with a v-raf/v-myc oncogene carrying retrovirus (J2). Since BV-2 cells retain most of the morphological, phenotypical and functional properties described for freshly isolated microglial cells, it can be concluded that J2 virus infection resulted in the immortalization of active microglial cells (Blasi E., et al J Neuroimmunology 1990).

In more detail, microglial cells were purified by shaking and subsequent selective plastic adherence of 1-week old mixed brain cultures obtained from C57BL/6 mice, as detailed in Giulian and Baker, 1986; Bocchini et al., 1988. The cultures were incubated overnight with control supernatants or J2 virus containing supernatants, fed biweekly with RPMI 1640, supplemented with 10% heat-inactivated fetal bovine serum, gentamicin and L-glutamine (4mM) (complete medium). Foci of proliferating cells (BV-2 cells) were observed in the infected cultures, whereas the uninfected cells gradually lost adherence properties and eventually died. BV-2 cell cultures appeared as a population composed of adherent, variably shaped cells. When assessed for histochemical markers, BV-2 cells exhibited a high degree of homogeneity, being >90% positive for nonspecific esterase activity. All cells lacked peroxidase activity. Upon continuous in vitro culture (>18 months), morphological, phenotypical and functional properties of BV-2 cells remained unchanged and, as assessed by Northern blot analysis, such cells constitutively expressed high levels of J2 virus mRNA. Most of the cells were similar to primary newborn microglia (Giulian and Baker, 1986), therefore indicating that J2 virus infection resulted in the immortalization of active microglial cells. Phagocytosis studies using C. Albicans microorganisms strengthen this conclusion. In fact, it is well-known that astrocytes and oligodendrocytes have phagocytic ability to some extent (Noske et al., 1982; Saito et al., 1986; Bjerkness et al., 1987); however, only microglial cells are able to ingest large-size particles such as Candida (Bocchini et al., 1988). Thus, also in this respect, BV-2 cells and primary microglial cells were indistinguishable. Upon opsonization the percentage of phagocytic cells as well as the phagocytosis index were enhanced, indicating that a functionally active Fc receptor system is expressed on BV-2 cells. Similarly to primary microglia (Giulian et al., 1986; Frei et al., 1986), BV-2 cells retain constitutive as well as inducible secretory functions. From these literature data, we have therefore decided to use this cell line for our in vitro studies involving microglia in neurodegeneration.

Recipient or parental organism

The BV-2 cell line was generated using v-raf/v-myc oncogene carrying retrovirus expressing the nuclear v-myc and the cytoplasmic v-raf oncogene products as well as the env gp70 antigen at the surface level. V-myc is the viral homolog of c-myc. The v-myc oncogene can transform several lineages of cells either alone or in co-operation with other oncogenes. V-raf is a murine leukemia viral oncogene homolog 1, also capable of transforming cells. When mutated, oncogenes have the potential to cause normal cells to become cancerous.

Importantly, the BV-2 cell line produces an enveloped recombinant ecotropic retrovirus capable of infecting murine cells only (http://bioinformatics.istge.it/cldb/cl7130.html); such virus is known for its in vitro transforming ability and in vivo tumorigenic potential. Although BV-2 cells can not survive outside the laboratory, all BV-2 biological material will be totally inactivated (by exposure to Trigene advance*) at the end of each experiment. No foreseeable effects on human health and safety are expected.

*As per manufacturer's information (Medichem) Trigene advance formula is a nanoemulsion that enables the active molecules in the product to be carried rapidly through cell walls of micro-organisms. Rapid penetration of cell membranes by Trigene advance disinfectant constituents ensures cell death is equally rapid. Trigene penetration of cell membranes by Trigene advance disinfectant constituents ensures cell death is equally rapid. Trigene advance works quicker than conventional high level disinfectant products and achieves apoptosis (cell death) rather than merely suspending activity as with conventional disinfectant products. Trigene advance has been reported to be bactericidal, fungicidal as well as virucidal and sporicidal (http://www.medi-mark.co.uk/products/categories/?trigene_advance_laboratory?). It is recommended to be used at 1:200 for general purpose and at 1:100 for high risk areas.

Evaluation of foreseeable effects

Health considerations
The use of the cell line for research purposes should not represent a risk to humans as BV-2 cells are capable of infecting murine cells only (http://bioinformatics.istge.it/cldb/cl7130.html). Although BV-2 cells can not survive outside the laboratory, all BV-2 biological material will be totally inactivated (by exposure to Trigene advance*) at the end of each experiment. No foreseeable effects on human health and safety are expected

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Care should be taken in order not to infect other murine cells present in the laboratory. Care should be taken in order not to spread the cell line in the environment as there is potential to infect murine cells. All BV-2 biological material will be totally inactivated (by exposure to Trigene advance*) at the end of each experiment. It is therefore highly unlikely that the virus could survive any unintentional discharge into a sanitary sewage system. Solid waste will be autoclaved prior to incineration offsite.

The BV-2 cell line is recognised as an important tool for the study of neurodegenerative processes of its phenotype and that it has been immortalised. The GMO committee is satisfied that because of the ectropic nature of the retrovirus generated by the cell line and that no further genetic modification has been proposed that this material can be adequately controlled within a class 2 environment. The procedures detailed in this assessment clearly demonstrate that contaminated material will be contained and inactivated before leaving the laboratory environment protecting both staff and the environment.

Project notified under transitional arrangements N
Agmatinase is an enzyme (EC3.5.3.11) that belongs to the arginase family. It hydrolyses agmatine to form putrescine and urea. Agmatine is a putative neurotransmitter acting on imidazoline, alpha-2 adrenergic and NMDA receptors. Agmatine shows neuroprotection in several in vitro models. Furthermore, agmatine improves memory in aged rats as well as after scopolamine challenge. It is of interest to determine whether downregulating agmatinase similar effects can be measured. These experiments will therefore be of importance for potential novel treatments to improve cognitive function.

Recipient or parental organism
Rodent primary neurones and in vivo Mouse/Rat

Host/vector system
The lentiviral vector expression system used as well as the transgene used have a very low risk for Human Health and safety. These 2 points are discussed below Lentiviral Expression System

Lentiviruses belong to the family Retroviridae, which forms a diverse and extensive family affecting both human and animal species. Retroviruses are characterised by a unique replication mechanism involving reverse transcription of the viral RNA genome, giving rise to a DNA provirus that contain two positive sense copies of the RNA genome, encased within a capsid that is surrounded by a host-cell derived envelope glycoprotein and cell-surface determinants. These interactions are generally specific and are believed to be the principal factor affecting cell type and species specificity. Receptor binding triggers membrane fusion mediated by the transmembrane subunit of the virion envelope glycoprotein, resulting in delivery of the virus capsid to the target cell.

The first risk to human health from the use of this expression system comes from the fact that it is based on HIV-1. However retroviruses are generally transmitted via exposure to contaminated body fluids or percutaneous inoculation and thus lentiviral vectors are not infectious via the airborne route. The main risk of infection is consequently the risk of injection but it is highly unlikely to happen as all measure to avoid have been considered (see part C for detailed measures).

Origin & function
The transgene has a very low risk because it would be highly unlikely that expression in a few cells would be sufficient to lead to a disease state. The inability of the lentiviral vector to propagate in mammalin cells also reduces the risk.

Proteins that are commonly used as reporter genes and genes used for the identification and selection of translated cells (EGFP) will be used in this system and are not known to have toxic or oncogenic effects. Genes that will be excluded from this expression system are genes encoding a) proteins of retroviral origin b) toxins c) oncogenes

Evaluation of foreseeable effects
Human health hazard
Oral ingestion will be prevented by standard laboratory working practices. Aerosol formation resulting from an accident outside of the safety cabinet and involving lentivirus particle-containing liquid may lead to transduction of a limited number of the laboratory worker's skin or mucosa' cells with modified viruses. However, these modified virus particles carry an extremely low risk for humans. Firstly, they are replication-incompetent. Secondly, these particles carry an extremely low infection risk, and transduction of
a laboratory worker's skin or mucosa is virtually impossible. In addition no genes encoding toxins, oncogenes, or pathogen-derived genes are used in our studies. In the unlikely event of accidental transduction of a laboratory worker's skin and mucosal cell layers. The most likely route of accidental infection with a lentivirus will be via inadvertent percutaneous inoculation however the control of sharps to minimise inadvertent exposure decrease considerably the chances of such accident (see Part C for procedure and control measure with sharp). Moreover use of personal protective equipment designed to prevent a mucosal exposure/splash to the face and exposure of hands (especially in persons with broken skin or open cuts). Infection of the community at large with lentiviruses particles is impossible for the above described reasons of replication incompetence.

HAZARDS TO THE ENVIRONMENT

As the viral systems used are self-inactivating and non-replicative, it is extremely unlikely that accidental release into the environment will cause any environmental damage or risk to others. The potential risks for lentiviral expression are released into a human population already infected with HIV, allowing for potential recombination events that would incorporate the inserted sequence into a viable RCL. This scenario is extremely unlikely, and would in any case be unlikely to cause any additional problem.

This lentiviral vector is designed for gene expression in mammalian cells and transduces a wide range of host human and non-human cell lines which can be dividing or non-dividing. Indeed the vector is pseudotyped with VSV-G envelope and therefore has a greater host range however it cannot survive even after infection (which is highly unlikely). Although VSVG-pseudotyped virus particles on transduce in theory all mammalian cell, transduction is also highly dependent on the concentration of the virus particles in a given medium. Once produced they are aliquoted and stored in small amounts (each tube contains at maximum 10µl) at -80C, considering infectivity of the vector drops markedly at room temperature it is hard to envisage an accidental mechanism for release that would allow survival.

Moreover lentiviral vectors are enveloped RNA viruses that are relatively unstable and highly susceptible to dehydration. Lentivirus particles have thus a short half-life and are unstable at room temperature. However, they can survive for long periods in high protein media. Retroviruses are rapidly inactivated outside the host, as illustrated by the fact that close contact is required for transmission. Furthermore, many retroviruses require high titre inoculations to establish an infection. Therefore, the survivability of retroviruses is not thought to pose a risk to the environment.

Rodents such as wild-type mice and rats, cannot support replication of infectious HIV-1 (Morrow 1987, Lewis 1995, Bieniasz 2000, Goffinet 2007). As a result, the potential for shedding of replication-competent lentiviruses (RCL) from such animals is very low (even if RCL were present in the original vector inoculum).

There are no conceivable hazards associated directly with the lentiviral vectors (containing the inserts) as they will not replicate/survive outside the laboratory and are mostly designed to be protective. EGFP will be primarily expressed in the CNS (as it uses neuron specific promoters). Similarly, shRNA and miRNA sequences will not survive as they are highly unstable and thus would disappear very quickly if accidentally spilled into the environment. Sequences within the viruses cannot be transferred to other micro-organisms without a rare recombination event as described above. Thus we see no conceivable hazard associated with transfer of the expressed sequences.

Summary

Environmental risk is very low because accidental release is very unlikely to result in production of RCL. Although the virus is capable of transducing mammalian cells it lacks the genes for replication and expression of proteins required for packaging into capsids.

The viral materials have been classified as CL2 and to minimise the risk of release to the environment from the laboratory. However, if accidental release into the environment does occur the vectors/plasmids could not survive and the risk is minimal.

References
The work outlined above has been assessed as a Class 2 activity even though the risk of pathogenicity to the end worker is very low as the virus is severely replication defective and encodes no toxic proteins. Biosafety 2 conditions will be followed as prescribed by the HSE for handing and usage of the stock vials of lentivirus and when working with primary neuronal cells. However, it is permissible to reduce the containment level at some point following vector delivery into animal brain as there is no expectation of infection, the site of inoculation has been thoroughly cleansed, and the bedding changed. Indeed for experimental animals that have been inoculated with non-replicating virus, the risk of operator exposure from the infected animals is minimal as is the potential for virus shedding. It is therefore appropriate to house these animals in a containment level 1 facility after recovery (Karlen 2007).

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

As the viral systems used are self-inactivating and non-replicative, it is extremely unlikely that accidental release into the environment will cause any environmental damage or risk to others. The potential risks for lentiviral expression are release into a human population already infected with HIV, allowing for potential recombination events that would incorporate the inserted sequence into a viable, replication competent virus. Some animals, such as wild-type mice, cannot support replication of infectious HIV-1. As a result, the potential for shedding of replication-competent lentiviruses (RCL) from such animals is very low (even if RCL were present in the original vector inoculum).

There are no conceivable hazards associated directly with the plasmids (containing the inserts) as they will not replicate/survive outside the laboratory, are mostly designed to be protective, and are primarily active in the CNS (as they use neuron specific promoters). Similarly, shRNA and miRNA sequences will not survive as they are highly unstable and this would disappear very quickly if accidentally spilled into the environment. Sequences within the viruses cannot be transferred to other micro-organisms without a rare recombination event as described above. Thus we see no conceivable hazard associated with transfer of the expressed sequences.

Waste handling

- Solid waste will then be neutralised by soaking in a validated chemical reagent prior to being bagged up in double autoclave bags, then autoclaved prior to incineration offsite.
- Liquid volumes will be disposed of into sealed biohazard containers filled with Virkon* for incineration. It is routine that all liquid waste material is neutralised before disposal to allow transportation in leak-proof containers to prevent spillage

In vivo
- Needles should be used with extreme care, only used when absolutely necessary and should never be resheathed, but disposed of directly into a suitable waste container (sharp bin). Sharps will be discarded in a yellow glass container (sharp bin) to be stored in a safe manner prior to incineration.
- Animal waste is considered non-infectious and disposed of along with the waste from non-infected animals so animal carcasses will be incinerated offsite.

It is worth highlighting that there is no aqueous disposal to sewers on site and that all waste is sent off site for incineration. If necessary any material can get autoclaved prior to being taken off site for incineration.

Following class 2 procedures for the stereotaxic injection, good laboratory practice and extreme care with sharps will be sufficient to insure that all contaminated material will be contained and inactivated before leaving the laboratory environment protecting both staff and the environment.

All workers using animals or primary cells are required to attend an in-house training prior to starting work and are then closely supervised by experienced research scientist until competent in all procedures. No worker will be precluded from the work proposed here and no vaccinations are required. We do not feel that specific health monitoring is required, although all workers will be made aware of the nature of the viruses that are being used.

Workers performing the surgical and behavioural tests are required to follow agreed procedures for the handling of animals to reduce the risk from allergens and bites… etc including the use of appropriate protective clothing and face masks, but there are no extra risks associated with the fact that the animal has undergone the procedures detailed. All in vivo work is carried out with the appropriate licenses and permissions from UK regulatory authorities.

Summary

All work with viral stocks and primary cultures will be carried out in class 2 safety cabinets. The lentivirus is unable to propagate in the primary cells so RCL will not be generated. In addition all plasticware and solutions that are used will be chemically inactivated with validated reagents before autoclaving prior to disposal for incineration. This will effectively prevent release of lentivirus to the environment and protect workers.

The maximum injection into an animal is 8µl. the Hamilton syringe is the only sharp tool in contact with the virus, it will be filled in a class 2 safety cabinet and it will be either a closed box inside a closed ice bucket or securely attached to a rig. Thus there is minimal risk of accidental puncturing of the skin with a contaminated syringe.
Once injected the viral particles cannot re-infect any other tissues as: (i) the coat protein is lost following attachment and the DNA is incorporated into the host cell replication deficient; (ii) they are replication deficient. Hence, lentiviral vectors cannot re-infect once injected into the brain.

Biological material will be totally inactivated (by exposure to Virkon* and/or DISTEL and/or Trigene advance*) at the end of each experiment. It is therefore highly unlikely that the virus could survive any unintentional discharge into a sanitary sewage system. No foreseeable effects on human health and safety are expected.

Project Additional Information

Purposes of the contained use

Aim:
HDAC2 is a histone deacetylase belonging to class I HDACs. HDACs regulate histone acetylation resulting in modulation of gene transcription. In particular, HDCA2 ablation has been shown to improve cognitive function possibly by increasing brain derived neurotrophic factor (BDNF) levels. Reduction of HDAC2 via adeno-associated viral vectors carrying shRNAs directed against HDAC2 injected into the CA1 region alleviated memory deficits in CK-p25 mice. Conversely, HDAC2 over expression in mice resulted in decreased dendritic spines and impaired memory. HDAC2 inhibition has therefore the potential of improving cognition and representing an innovative treatment for neurodegenerative diseases such as Alzheimer's.

A lentivirus delivering a shRNA and mediating gene knockdown of HDAC2 in brain cells (glial and neurons) would be a very useful tool to confirm the role of HDAC2 in regulation of BDNF levels and on cell viability/morphology. Moreover, testing the effect on HDAC2 knockdown in vivo in cognition tests would be useful to confirm literature findings. These experiments are important given the current interest in HDAC2 in the pathophysiology and therapy of neurodegenerative diseases.

Recipient or parental organism

Primary rodent neurones and Mouse/Rat

Host/vector system

The lentiviral vector expression system used as well as the transgene used have a very low risk for Human Health and safety. Theses 2 points are discussed below.

Lentiviral vector Expression System

Lentiviruses belong to the family Retroviridae, which forms a diverse and extensive family affecting both human and animal species. Retroviruses are characterised by a unique replication mechanism involving reverse transcription of the viral RNA genome, giving rise to a DNA provirus that contain two positive sense copies of the RNA genome, encased within a capsid that is surrounded by a host-cell derived envelope. Cellular entry involves interaction between the surface subunit of the virion envelope glycoprotein and cell-surface determinants. These interactions are generally specific and are believed to be the principal facotr affecting cell type and species specificity. Receptor binding triggers membrane fusion mediated by the transmembrane subunit of the virion envelope glycoprotein, resulting in delivery of the virus capsid to the target cell.

The first risk to human health from the use of this expression system comes from the fact that it is based on HIV-1. However retroviruses are generally transmitted via exposure to contaminated body fluids or percutaneous inoculation and thus lentiviral vectors are not infectious via the airborne route. The main risk of infection is consequently the risk of injection but it is highly unlikely to happen as all measure to avoid have been considered (see part C for detailed measures).
The transgene has a very low risk because it would be highly unlikely that expression in a few cells would be sufficient to lead to a disease state. The inability of the lentiviral vector to propagate in mammalian cells also reduces the risk.

Proteins that are commonly used as reporter genes and genes used for the identification and selection of transfected cells (EGFP) will be used in this system and are not known to have toxic or oncogenic effects. Genes that will be excluded from this expression system are genes encoding a) proteins of retroviral origin b) toxins c) oncogenes.

Evaluation of foreseeable effects

Human health hazard

Oral ingestion will be prevented by standard laboratory working practices. Aerosol formation resulting from an accident outside of the safety cabinet and involving lentivirus particle-containing liquid may lead to transduction of a limited number of the laboratory worker's skin or mucosa' cells with modified viruses. However, these modified virus particles carry an extremely low risk for humans. Firstly, they are replication-incompetent. Secondly, these particles carry an extremely low infection risk, and transduction of a laboratory worker's skin or mucosa is virtually impossible. In addition no genes encoding toxins, oncogenes, or pathogen-derived genes are used in our studies. In the unlikely event of accidental transduction of a laboratory worker's skin and mucosal cell layers.

The most likely route of accidental infection with a lentivirus will be via inadvertent percutaneous inoculation however the control of sharps to minimise inadvertent exposure decrease considerably the chances of such accident (see Part C for procedure and control measure with sharp). Moreover use of personal protective equipment designed to prevent a mucosal exposure/splash to the face and exposure of hands (especially in persons with broken skin or open cuts). Infection of the community at large with lentivirus particles is impossible for the above described reasons of replication incompetence.

HAZARDS TO THE ENVIRONMENT

As the viral systems used are self-inactivating and non-replicative, it is extremely unlikely that accidental release into the environment will cause any environmental damage or risk to others. The potential risks for lentiviral expression are released into a human population already infected with HIV, allowing for potential recombination events that would incorporate the inserted sequence into a viable RCL. This scenario is extremely unlikely, and would in any case be unlikely to cause any additional problem.

This lentiviral vector is designed for gene expression in mammalian cells and transduces a wide range of host human and non-human cell lines which can be dividing or non-dividing. Inded the vector is pseudotyped with VSV-G envelope and therefore has a greater host range however it cannot survive even after infection (which is highly unlikely). Although VSVG-pseudotyped virus particles can transduce in theory all mammalian cell, transduction is also highly dependent on the concentration of the virus particles in a given medium. Once produced they are aliquoted and stored in small amounts (each tube contains at maximum 10µl) at -80C, considering infectivity of the vector drops markedly at room temperature it is hard to envisage an accidental mechanism for release that would allow survival.

Moreover lentiviral vectors are enveloped RNA viruses that are relatively unstable and highly susceptible to dehydration. Lentivirus particles have thus a short half-life and are unstable at room temperature. However, they can survive for long periods in high protein media. Retroviruses are rapidly inactivated outside the host, as illustrated by the fact that close contact is required for transmission. Furthermore, many retroviruses require high titre inoculations to establish an infection. Therefore, the survivability of retroviruses is not thought to pose a risk to the environment.

Rodents such as wild-type mice and rats, cannot support replication of infectious HIV-1 (Morrow 1987, Lewis 1995, Bieniasz 2000, Goffinet 2007). As a result, the potential for shedding of replication-competent lentiviruses (RCL) from such animals is very low (even if RCL were present in the original vector inoculum).

There are no conceivable hazards associated directly with the lentiviral vectors (containing the inserts) as they will not replicate/survive outside the laboratory and are mostly designed to be protective. EGFP will be primarily expressed in the CNS (as it uses neuron specific promoters). Similarly, shRNA and miRNA sequences will not survive as they are highly unstable and thus would disappear very quickly if accidentally spilled into the environment. Sequences within the viruses cannot be transferred to other micro-organisms without a rare recombination event as described above. Thus we see no conceivable hazard associated with transfer of the expressed sequences.
Environmental risk is very low because accidental release is very unlikely to result in production of RCL. Although the virus is capable of transducing mammalian cells it lacks the genes for replication and expression of proteins required for packaging into capsids. The viral materials have been classified as CL2 and to minimise the risk of release to the environment from the laboratory. However, if accidental release into the environment does occur the vectors/plasmids could not survive and the risk is minimal.

For further information, see also the safety guidance "Biosafety Considerations for Research with Lentiviral Vectors" published by the US NIH as well as the following articles:

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The work outlined above has been assessed as a Class 2 activity even though the risk of pathogenicity to the end worker is very low as the virus is severely replication defective and encodes no toxic proteins. Biosafety 2 conditions will be followed as prescribed by the HSE for handling and usage of the stock vials of lentivirus and when working with primary neuronal cells. However, it is permissible to reduce the containment level at some point following vector delivery into animal brain as there is no expectation of infection, the site of inoculation has been thoroughly cleaned, and the bedding changed. Indeed for experimental animals that have been inoculated with non-replicating virus, the risk of operator exposure from the infected animals is minimal as is the potential for virus shedding. It is therefore appropriate to house these animals in a containment level 1 facility after recovery (Karlen 2007).

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
As the viral systems are self-inactivating and non-replicative, it is extremely unlikely that accidental release into the environment will cause any environmental damage or risk to others. The potential risks for lentiviral expression are release into a human population already infected with HIV, allowing for potential recombination events that would incorporate the inserted sequences into a viable, replication competent virus. This scenario is extremely unlikely, and would in any case be unlikely to cause any additional problem.

This virus is designed for gene expression in mammalian cells and transduces a wide range of host human and non-human cell lines which can be dividing or non-dividing. Indeed the vector is pseudotyped with VSV-G envelope and therefore has a greater host range however it cannot survive even after infection (which is highly unlikely). Although VSVG-pseudotyped virus particles can transduce, in theory all mammalian cells, transduction is also highly dependent on the concentration of the virus particles in a given medium. Once produced they are aliquoted and stored in small amounts (each tube contains at maximum 10µl) at -80C, considering infectivity of the vector drops markedly at room temperature it is hard to envisage an accidental mechanism for release that would allow survival.

Moreover lentiviral vectors are enveloped RNA viruses that are relatively unstable and highly susceptible to dehydration. Lentivirus particles have thus a short half-life and are unstable at room temperature. However, they can survive for long periods in high protein media. Retroviruses are rapidly inactivated outside the host, as illustrated by the fact that close contact is required for transmission. Furthermore, many retroviruses require high titre inoculations to establish an infection. Therefore, the survivability of retroviruses is not thought to pose a risk to the environment.

Some animals, such as wild-type mice, cannot support replication of infectious HIV-1. As a result, the potential for shedding of replication-competent lentiviruses (RCL) from such animals is very low (even if RCL were present in the original vector inoculum).

There are no conceivable hazards associated directly with the plasmids (containing the inserts) as they will not replicate/survive outside the laboratory, are mostly designed to be protective, and are primarily active in the CNS (as they use neuron specific promoters). Similarly, shRNA and miRNA sequences will not survive as they are highly unstable and thus would disappear very quickly if accidentally spilled into the environment.

Sequences within the viruses cannot be transferred to other micro-organisms without a rare recombination event as described above. Thus we see no conceivable hazard associated with transfer of the expressed sequences.

Waste handling

In vitro and in vivo
- Solid waste will be neutralised by soaking in a validated chemical reagent prior to being bagged up in double autoclave bags, then autoclaved prior to incineration offsite.
- Liquid volumes will be disposed of into sealed biohazard containers filled with Virkon* for incineration. It is routine that all liquid waste material is neutralised before disposal to allow transportation in leak-proof containers to prevent spillage

In vivo
- Needles should be used with extreme care, only used when absolutely necessary and should never be resheathed , but disposed of directly into a suitable waste container (sharp bin). Sharps will be discard in a yellow glass container (sharp bin) to be stored in a safe manner prior to incineration.
- Animal waste is considered non-infectious and disposed of along with the waste from non-infected animals so animal carcasses will be incinerated offsite. It is worth highlighting that there is no aqueous disposal to sewers on site and that all waste is sent off site for incineration. If necessary any material can get autoclaved prior to being taken off site for incineration.

Following class 2 procedures for the stereotaxic injection, good laboratory practice and extreme care with sharps will be sufficient to insure that all contaminated material will be contained and inactivated before leaving the laboratory environment protecting both staff and the environment.

All workers using animals or primary cells are required to attend an in-house training prior to starting work and are then closely supervised by experienced research scientist until competent in all procedures. No workers will be precluded from the work proposed here and no vaccinations are required. We do not feel that specific health monitoring is required, although all workers will be made of the nature of the viruses that are being used.
Workers performing the surgical and behavioural test are required to follow agreed procedures for the handling of animals to reduce risk from allergens and bites... etc including the use of appropriate protective clothing and face masks, but there are no extra risks associated with the fact that the animal has undergone the procedures detailed. All in vivo work is carried out with the appropriate licences and permissions from UK regulatory authorities.

Summary
All work with viral stocks and primary cultures will be carried out in class 2 safety cabinets. The lentivirus is unable to propagate in the primary cells so RCL will not be generated. In addition all plastic ware and solutions that are used will be chemically inactivated with validated reagents before autoclaving prior to disposal for incineration. This will effectively prevent release of lentivirus to the environment and protect workers.

The maximum injection into an animal is 8µl. The Hamilton syringe is the only sharp tool in contact with the virus, it will be filled in a class 2 safety cabinet and it will be either a closed box inside a closed ice bucket or securely attached to a rig. Thus there is minimal risk of accidental puncturing of the skin with a contaminated syringe. Once injected the viral particles cannot re-infect any other tissues as: (i) the coat protein is lost following attachment and the DNA is incorporated into the host cell replication deficient; (ii) they are replication deficient. Hence, lentiviral vectors cannot re-infect once injected into the brain.

Biological material will be totally inactivated (by exposure of Virkon* and/or DISTEL and/or Trigene advance*) at the end of each experiment. It is therefore highly unlikely that the virus could survive any unintentional discharge into a sanitary sewage system. No foreseeable effects on human health and safety are expected.

following stereotaxic injection to knockdown and study the role of D-amino-acid oxidase (DAAO)

Aim:
The flavo enzyme D-amino-acid oxidase (DAAO) metabolizes D-serine, which is the endogenous N-methyl D-aspartate receptor (NMDAR) co-agonist. As such, it has the potential to modulate the function of NMDAR and to contribute to the widely hypothesized involvement of NMDAR signalling in schizophrenia.

A lentivirus delivering a shRNA and mediating gene knockdown of the glial enzyme DAAO in specific brain structures would be a very useful tool to confirm the role of DAAO in D-serine metabolism. These issues are important given the current interest in DAAO in the pathophysiology and therapy of neuropsychiatric disorders.

Recipient or parental organism
Mouse/Rat

Host/vector system
Lentiviral Vector Expression System
Lentiviruses belong to the family Retroviridae, which forms a diverse and extensive family affecting both human and animal species. Retroviruses are characterised by a unique replication mechanism involving reverse transcription of the viral RNA genome, giving rise to a DNA provirus that contain two positive sense copies of the RNA genome, encased within a capsid that is surrounded by a host-cell derived envelope. Cellular entry involves interaction between the surface subunit of the virion envelope glycoprotein and cell-surface determinants. These interactions are generally specific and are believed to be the principal factor affecting cell type and species specificity. Receptor binding triggers membrane fusion mediated by the transmembrane subunit of the virion envelope glycoprotein, resulting in delivery of the virus capsid to the target cell.

The first risk to human health from the use of this expression system comes from the fact that it is based on HIV-1. However retroviruses are generally transmitted via exposure to contaminated body fluids or percutaneous inoculation and thus lentiviral vectors are not infectious via the airborne route. The main risk of infection is consequently the risk of injection but it is highly unlikely to happen as all measure to avoid have been considered (see part 8 and 11 for detailed measures).

Origin & function
Summary
The transgene has a very low risk because it would be highly unlikely that expression in a few cells would be sufficient to lead to a disease state. The inability of the lentiviral
vector to propagate in mammalian cells also reduces the risk. Proteins that are commonly used as reporter genes and genes used for the identification and selection of transfected cells (EGFP) will be used in this system and are not known to be toxic or oncogenic. Genes that will be excluded from this expression system are genes encoding a) proteins of retroviral origin b) toxins c) oncogenes

**Evaluation of foreseeable effects**

**HUMAN HEALTH HAZARD**
The lentiviral vector expression system used as well as the transgene used have a very low risk for human health and safety as explained in the GMO characteristics description above.

Oral ingestion will be prevented by standard laboratory working practices. Aerosol formation resulting from an accident outside of the safety cabinet and involving lentivirus particle-containing liquid may lead to transduction of a limited number of the laboratory workers' skin or mucosa' cells with modified viruses. However, these modified virus particles carry an extremely low risk for humans. Firstly, they are replication-incompetent and self inactivating (see part 7 - Host/Vector system). Secondly, these particles carry an extremely low infection risk, and transduction of a laboratory worker's skin or mucosa by lentivirus particles, this will be self-limited, due to natural shedding of superficial epithelial skin and mucosal cell layers.

The most likely route of accidental infection with a lentivirus will be via inadvertent cutaneous inoculation however the control of sharps to minimise inadvertent exposure decrease considerable the chances of such accident (see 11 for procedure and control measure with sharp). Moreover use of personal protective equipment designed to prevent a mucosal exposure/spit to the face and exposure of hands (especially in persons with broken skin or open cuts). Infection of the community at large with lentivirus particles is more than unlikely for the above described reasons of replication incompetence.

**HAZARDS TO THE ENVIRONMENT**
As the viral systems used are self-inactivating and non-replicative, it is extremely unlikely that accidental release into the environment will cause any environmental damage or risk to others. The potential risks for lentiviral expression are release into a human population already infected with HIV, allowing for potential recombination events that would incorporate the inserted sequence into a viable RCL. This scenario is extremely unlikely, and would in any case be unlikely to cause any additional problem.

This lentiviral vector is designed for gene expression in mammalian cells and transduces a wide range of host human and non-human cell lines which can be dividing or non-dividing. Indeed the vector is pseudotyped with VSV-G envelope and therefore has a greater host range however it cannot survive even after infection (which is highly unlikely). Although VSVG-pseudotyped virus particles can transduce in theory all mammalian cells, transduction is also highly dependent on the concentration of the virus particles in a given medium. Once produced they are aliquoted and stored in small amounts (each tube contains at maximum 10µl) at -80C, considering infectivity of the vector drops markedly at room temperature it is hard to envisage an accidental mechanism for release that would allow survival.

Moreover lentiviral vectors are enveloped RNA viruses that are relatively unstable and highly susceptible to dehydration. Lentivirus particles have thus a short half-life and are unstable at room temperature. However, they can survive for long periods in high protein media. Retroviruses are rapidly inactivated outside the host, as illustrated by the fact that close contact is required for transmission. Furthermore, many retroviruses require high titre inoculations to establish an infection. Therefore, the survivability of retroviruses is not thought to pose a risk to the environment.

Rodents such as wild-type mice and rats, cannot support replication of infectious HIV-1 (Morrow 1987, Lewis 1995, Bieniasz 2000, Goffnet 2007). As a result, the potential for shedding of replication-competent lentiviruses (RCL) from such animals is very low (even if RCL were present in the original vector innoculum).

There are no conceivable hazards associated directly with the lentiviral vectors (containing the inserts) as they will not replicate/ survive outside the laboratory and are mostly designed to be protective. EGFP will be primarily expressed in the CNS (as it used neuron specific promoters). Similarly, shRNA and miRNA sequences will not survive as they are highly unstable and thus would disappear very quickly if accidentally spilled into the environment. Sequences within the viruses cannot be transferred to other micro-organisms without a rare recombination event as described above. Thus we see no conceivable hazard associated with transfer of the expressed sequences.

Summary
Environmental risk is very low because accidental release is very unlikely to result in production of RCL. Although the virus is capable of transducing into mammalian cells it
lacks genes for replication and coat proteins. The viral materials have been classified as CL2 to minimise the risk of release to the environment from the laboratory. However, if accidental release into the environment does occur the vectors/plasmids could not survive and the risk is minimal. For further information, see also:
- The safety guidance "Biosafety Considerations for Research with Lentiviral Vectors" published by the US NIH.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All surgical procedures are carried out in a procedural room attached to the animal facility that was built within the last five years to a high standard. The surgery room is mechanically ventilated and an inward airflow is maintained extracting room air to atmosphere. The workplace is maintained at air pressure negative to atmosphere. In put air and extract air to the workplace is filtered using high efficiency particulate absorption (HEPA). However since these agents are not airborne pathogens, the use of a safety cabinet, negative air pressure and HEPA filtration of exhaust air would not be mandatory. Moreover the access to the laboratory is restricted to authorised persons (by using badge)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

The work outlined above has been assessed as a Class 2 activity even though the risk of pathogenicity to the end worker is very low as the virus is severely replication defective and encodes no toxic proteins. Biosafety 2 conditions should be followed as prescribed by the HSE for handling and usage. However, it is permissible to reduce the containment level at some point following vector delivery into animal brain as there is no expectation of infection, the site of inoculation has been thoroughly cleansed, and the bedding changed. Indeed for experimental animals that have been inoculated with non-replicating virus, the risk of operator exposure from the infected animals is minimal as is the potential for virus shedding. It is therefore appropriate to house these animals in a containment level 1 facility.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

- Solid waste will be neutralised by soaking into Virkon* prior to being bagged up in double autoclave bags, then autoclaved prior to incineration offsite.
- Needles should be used with extreme care, only used when absolutely necessary and should never be resheathed, but disposed of directly into a suitable waste container (sharp bin). Sharps will be discarded in a yellow glass container (sharp bin). Sharps will be discarded in a yellow glass container to be stored in a safe manner prior to incineration.
- Liquid volumes will be disposed of into sealed biohazard containers filled with Virkon* for incineration. It is routine that all liquid waste material is neutralised before disposal to allow transportation in leak-proof containers to prevent spillage.
- Animal waste is considered non-infectious and disposed of along with the waste from non-infected animals so animal carcasses will be incinerated offsite. It is worth highlighting that there is no aqueous disposal to sewers on site and that all waste is sent off site for incineration. If necessary any material can get autoclaved prior to being taken off site for incineration.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [Y]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

Please enter comments on the GM safety committee on the risk assessment
The GMO committee has deemed that the handling of the virus stock supplied by the Uney laboratory in Bristol University is a Class 2 activity. This decision has been reached that, although the virus will not be generated at Takeda Cambridge Ltd, and that the lentivirus particles have been generated using a third generation 4 plasmid expression system, the possibility of a recombination event leading to replication competent virus can never be discounted. It is also noted that the Woodchuck Post-transcriptional Regulatory Element (WPRE) has been associated with potential oncogenic effects with some viral gene delivery systems. The EGFP and the shRNA encoded by the lentivirus are not known to possess any inherent toxic or pathogenic hazard to either individuals or to the environment. The committee is satisfied that the necessary procedures have been put in place to allow the safe injection of virus into animals within the animal facility and that there is no risk to the environment due to the inherent instability of the lentiviral particles, non-replicative nature and self inactivation of the virus after insertion into the host genome.

Purposes of the contained use

Aim
The objective of the proposed studies is to investigate the role of a number of proteins of interest in the CNS, using lentiviral vectors expressing small hairpin RNAs (shRNAs), which act to downregulate the translation of specific proteins by binding and promoting the breakdown of their coding mRNA transcripts. The studies will focus on discovering the role of the proteins in both physiological (cognition and neurotransmission for instance) and pathological (in CNS disease states) processes that occur in the brain, with the overarching aim of identifying potential new drug targets for CNS diseases. The genes/proteins of interest that will be targeted by the shRNAs do not include any growth factors, confirmed oncogenes, cytotoxins, or immunomodulators, and none of them are of retroviral origin.

Methods
Target material will be transduced with replication incompetent lentiviral vectors expressing shRNA transcripts either targeting specific mRNAs/proteins of interest, or with vectors expressing scrambled shRNAs, in the case of the negative control treatment groups. The lentiviral vectors will also express enhanced green fluorescent protein (EGFP) to aid in the identification, visualisation and isolation of transduced cells. The extent of mRNA and protein knockdown that is achieved will then be assessed at different time points (e.g. 24h-48h-72h), post-transduction, using suitable in vitro assays, including, RT-PCR, Western Blotting, and immunocytochemistry. Once the conditions that lead to the optimal knockdown of the mRNAs/proteins have been determined, what effects the knockdown of the proteins have on various physiological parameters will be evaluated using standard experimetal techniques.

Description of the lentiviral vectors used for the experiment
The lentiviral vectors will be produced and supplied by James Uney’s Lab, which is based at the University of Bristol. Each aliquot of lentiviral reagent comprises of a small volume (5 to 10 μl) that contains no more than 1x10e08 viral particles which decreases the risk to the operator. The lentiviral vectors are generated with the following safety features to minimise the chance of a random recombination event occurring that leads to the generation of replication competent lentivirus (RCL).

Self inactivating (SIN) non replication-competent HIV based lentiviral vectors
The virus integrates into the target cell's genome via long terminal repeats (LTRs). These have had the U3 region of the 3' LTR deleted such that when they integrate in the genome of the target cell the same deletion is transferred to the 5' LTR and is sufficient to prevent transcription of full length vector RNA.

Segregation of the viral genes required for production of lentiviral particles
The lentiviral vectors are generated using four standard plasmid vectors that must be co-transfected into a packaging cell line for the production of lentivirus particles in trans. Three plasmids carry one of the essential genes required for viral capsid production whilst the fourth carries the transgene genetic material to be packaged into the resultant viral vector (target specific shRNA or scrambled shRNA and EGFP). By segregating each of the essential viral genes required for viral generation the chance of a multiple recombination event that generates a viral genome capable of generating RCL is minimised. Together with the SIN this makes the likelihood of generating RCL very small.

Recipient or parental organism
Mammalian Cells

Host/vector system
Lentiviruses belong to the Retroviridae virus family, a diverse and extensive family of viruses, which are capable of infecting both human and animal species. Retroviruses are characterised by a unique replication mechanism involving reverse transcription of the viral RNA genome, which gives rise to a DNA provirus that contains two positive sense copies of the viral RNA genome; and in a functional assembled virus, the viral genome is encased within a capsid that is surrounded by a host-cell derived envelope. Cellular entry of the virus involves interactions between glycoproteins contained in the virion’s envelope and extracellular plasma membrane proteins on target cells. These interactions are generally specific and are believed to be the principal factor determining which species and type of cells a specific virus is capable of infecting. The binding of a virus’s envelope glycoproteins to an appropriate receptor site on a target cell triggers the fusion of the virion’s envelope membrane with the plasma membrane of the target cell, which results in the delivery of the virus capsid to the intracellular space of the target cell.

In this proposal cells targeted for transduction by lentiviral vectors are biosafety 2 or lower and are not infected with wildtype lentivirus. The lentiviral vector system proposed for use in these studies is based on HIV-1 and therefore a theoretical risk to human health exists. Retroviruses are, however, generally transmitted via exposure to contaminated body fluids or percutaneous inoculation, and they are generally not transmitted via the airborne route. Accidental
piercing of the skin or other surface tissues with virus containing objects, therefore, represents the main potential route by which accidental infection could occur. The consequence of accidental infection can be minimised by using lentiviral vectors that are unable to replicate and hence unable to transduce further cells and to contain genetic material that is highly unlikely to have a detrimental effect on human health or the environment. It is also possible that the random integration of the viral genome into cells can lead to the trans-activation of genes downstream of the integration site.

Production of these proposed lentiviral vectors will take place in the lab of James Uney, at the University of Bristol. The lentiviral vector stock will be received from James Uney’s lab in aliquots of 5 to 10 µl containing between 1x10^8 to 1x10^10 transducing units (TU)/µl of vector in TSSM buffer (20mM Tromethamine, 100mM NaCl, 10mg/mL sucrose, 10mg/mL mannitol). The material should be essentially free of the HEK-293T helper cell line used to produce the viral titre. Each aliquot of lentiviral vector solution should contain not more than 1x10^8 viral particles.

The viral stock will consist of viral particles containing the vector genome (full capsids) and also of a variable number of empty viral capsids. Other trace components that might be present include, but are not limited to, inorganic salts, vitamins, other nutrients, human cellular proteins, carbohydrates, amino acids, and fats. The material is normally shipped frozen within manufacturer designed racks and will be stored in a designated -80°C freezer.

The Lentiviral Expression System that will be used include the following key safety features:

Self Inactivation (SIN)

All of the transgene/EGFP containing plasmid vectors that will be used contain a deletion in the 3' LTR (ΔU3) that does not affect generation and packaging of the viral genome in the HEK-293T producer cell line. After transduction of target cells the process of integration into the genome of the target cell copies the deletion to the 5' LTR preventing transcription of the integrated lentiviral genome and subsequently is no longer capable of producing packagable viral genomic material. This reduces the risk of mobilisation of the genetic material even following a superinfection with wild-type HIV. Such activity has not been observed even under permissive in vitro conditions (Bukovsky et al 1999). Moreover, deletion of enhancer and promoter elements from the 3' U3 region in the vector construct will result in a provirus that is entirely devoid of the U3 enhancer sequences, which will result in a reduction in the potential for transactivation of cellular genes due to an insertion event. Insertion can also cause loss of gene expression with harmful effects and such as event can not be ruled out with any system that integrates into the genome of a cell.

Segregation of genes required for generation of lentiviral particles

The retroviral genes required to generate viral particles has been reduced to the essential gag, pol, rev and env genes. Each gene is delivered to the packaging cell line on a separate plasmid vector. The genetic material to be packaged into the viral particle is supplied on an additional fourth bacterial plasmid. The four plasmids do not contain any regions of homology with each other to prevent undesirable recombination events that could lead to the generation of a RCL.

The HIV-1 Env gene has been replaced by the VSV-G gene from Vesicular Stomatitis Virus in the pMD2-VSVG.env plasmid. Pseudotyping HIV-1 vectors obviates safety concerns associated with the use of HIV-1 gp120, which has known pathogenic consequences. However, pseudotyping has a big impact on the biodistribution and tropism of viral vectors. In particular, HIV-1 gp120 restricts transduction of HIV-1 vectors to CD4+ cells, which limits its use to CD4+ cells, like T cells and macrophages. In contrast, heterologous envelopes, like VSV-G, typically broaden the tropism and allow gene transfer into a broad variety of cells.

The transgene/EGFP containing plasmid vectors (pRRL plasmid vectors) that will be used, only contain essential viral cis-acting sequences, including the LTRs and will be the only plasmids to include the packaging signal Ψ. Although the packaging plasmids used in these systems allows for the expression in trans of proteins required to produce viral progeny (e.g. gal, pol, rev, env) in the HEK-293T producer cell lines, none of them contain LTRs or the Ψ packaging sequence. The lentiviral accessory genes (vif, vpr, vpu and nef) that are dispensable for lentiviral vector production/transduction have been deleted from the packaging construct as they are not required for in vitro replication but the products they encode have cytotoxic activities.

Expression of the gag and pol genes from pMDLgpl-RRE has been rendered Rev-dependent by virtue of the presence of the HIV-1 Rev Responsive Element (RRE) in the gag/pol mRNA transcript. All the transgene/EGFP containing plasmid/vectors that will be used also include RRE. Addition of the RRE in these plasmids prevents gag and pol expression in the absence of Rev, which is supplied by the pRSV-REV plasmid. The viral rev protein is provided in trans to ensure efficient nuclear export of the full-length viral RNA genome through binding to the RRE by enhancing and stabilising the export of viral mRNAs from the nucleus. The HIV-1 Rev protein mediates nuclear export of both unspliced full-length and partially spliced viral RNAs by bridging an interaction between the Rev response element (RRE) in the genomic DNA and the host cell CRM1 nuclear export pathway. The Rev/RRE system is highly conserved among lentiviruses, and removal of the RRE sequence and associated splice donor/acceptor
sequences results in a loss of transduction efficiency.

The LTR used to drive expression from the pRRL plasmids has been modified so as to increase lentiviral vector production but to also allow lentiviral vector production to be independent of tat expression, which has been removed. A constitutive promoter (RSV promoter) has been placed upstream of the 5' LTR in the pRRL plasmids to offset the requirement for Tat. Tat is essential for the replication of wild-type HIV-1, as it is required for the efficient production of viral RNA. It is known that Tat-deleted mutants of wild-type HIV are not replication competent (Vendel and Lumb 2003; O'Brien et al. 1990). The deletion of Tat further decreases the risk of generating a putative RCL.

Lentiviral vectors have a very low potential to cause immunogenicity.

The pRRL vector includes the Woodchuck Post-transcriptional Regulatory Element (WPRE) to promote mRNA export and stabilise transgene mRNA levels, which should give rise to increased transgene expression. There have been concerns surrounding the potential oncogenic activity of the native WPRE, because of the expression of an oncogenic WHV-X protein from an open reading frame found within the element. The WHV-X ORF translation start site has been mutated in the WPRE used in these lentiviruses to prevent expression of WHV-X protein removing the oncogenic risk (Zanta-Boussif et al. 2009).

Transcription of the transgene/EGFP will either be under the control of the U6 and CMV promoters respectively or the Polymerase II human synapsin I (SynI) promoter. It is noted that although the LTRs have been mutated to remove U3 enhancer sequences this does not prevent trans-activation by readthrough from strong promoters such as CMV. The U6 promoter is well suited to drive the expression of shRNAs due to it possessing the following favourable characteristics: (i) it initiates from position +1 of the transcripts, and (ii) it yields transcripts that do not terminate with a poly-A tail but with a series of four to five thymidine residues, which results in a series of 3' U residues leading to a fully functional shRNA sequence. Indeed, the structure of the transcribed product closely resembles synthetic double-stranded siRNAs, except for the fact that the two strands are linked by a spacer sequence. This system has been used to successfully inhibit gene expression in mammalian cells lines, with efficiencies comparable with that of synthetic siRNA.

The hSynI promoter directs high expression specifically in neuronal cell types which negates the chance of trans-activation of genes in non-neuronal cells.

It is not considered that the use of these lentiviral vectors will result in a significantly increased risk of oncogenic activation compared to the risk possessed by any other viral delivery system. Moreover, the risk of transduction leading to harmful consequences following exposure is related in part to the titre of the viral vectors; and exposure of workers to quantities of virus high enough to cause such effects would be unlikely during standard laboratory-based manipulations of lentiviral vectors.

Origin & function

Transgene: proteins to be expressed:

EGFP

EGFP is a modified form of green fluorescent protein (GFP) that has enhanced spectral properties making it a superior tool as a reporter of gene expression in biological research. GFP is a 238 amino acid residue (26.9kDa) protein that exhibits bright green fluorescence when exposed to light in the blue to ultraviolet range and was first isolated from jellyfish Aequorea victoria. EGFP is not known to have any disease association and is regarded as non-toxic to living cells. The expression of EGFP will be used to identify cells that have been transduced with lentiviral vectors.

shRNAs targeting a number of different mRNAs

As shRNA tends to lead to a loss of activity it is inherently regarded as being safer than gain of function experiments provided processes that are known to be involved in

02/03/2022
cell cycle regulation, tumour suppressors and are growth factors are not affected. None of the targets proposed in this study are known to be cytotoxic, tumour suppressors, growth factors or to be involved in the control of the cell cycle. None of the sequences are of retroviral origin.

RNA interference (RNAi) is an antisense technology that exploits a normal cellular antiviral response that acts to inhibit viral protein synthesis through the production of short hairpin RNAs that bind and target viral double-stranded RNA (dsRNA) molecules for degradation. The shRNA molecules are processed by cellular enzymatic pathways to produce small inhibitory RNA (siRNA) species, and it is the latter RNA molecules that bind and target complementary RNA sequences for degradation by the RNA-induced silencing complex (RISC). With the use of shRNA-expressing viral vector systems, the expression of specific mammalian genes/proteins can be ‘knocked-down’, in order to study their functions.

The effects of the siRNA species that are generated in these experimental systems may have broader effects on the cell than just modulating the expression of a particular gene/protein. There may be sequences within a specific shRNA molecule that are homologous to other coding sequences within the mammalian genome that are not necessarily linked or closely related to the intended target. It is, therefore, theoretically possible that a specific siRNA may knock down the expression of genes other than the intended target one, and for this reason, the RNAi systems have been designed carefully to minimise the likelihood that there will be unwanted or potentially adverse effects arising from a non-target gene being inadvertently targeted. This is done by screening designed shRNA sequences against databases of known mammalian gene/mRNA sequences. Additionally, with the use of this approach, the shRNAs are also designed so as to bind complementary sequences that are present in rodents, but not in humans, which reduces potential risks to humans. The likelihood that a specific shRNA will bind to a human form of the target mRNA is extremely low, but it cannot be completely excluded.

Morever, RNAi interference may, additionally, also have deleterious effects upon cellular metabolism due to the triggering of antiviral responses. It has been shown that siRNA molecules (even if less than 30nt in length) can trigger dsRNA antiviral responses. Such responses not only lead to the degradation of dsRNA molecules, but also results in interferon production, which, in turn, leads to inflammation and the non-specific inhibition of protein synthesis.

MicroRNAs (miRNAs) are endogenously encoded 22-nt-long RNAs that are generally expressed in a highly tissue and/or developmental-stage specific fashion, and they function to post-transcriptionally regulate the expression of target genes. In certain experimental RNA interference approaches, this miRNA system can be harnessed/manipulated to study the functions of specific genes/proteins. For example, regulatable RNA polymerase II promoters can be experimentally activated so as to over-express endogenous microRNAs in cell culture systems. Alternatively, artificial microRNAs can also be engineered to match the features of existing microRNA genes, such as the gene encoding the human miR-30 microRNA. Some of the vectors that will be used in the proposed studies, contain a miR-30 cassette (see section 6). In these vectors, the expression of shRNA will be under the control of the PolymeraseII SynI promoter, and these vectors will yield single miR-30-EGFP transcripts, from which the miRNA will be excised by endogenous pathways before translation of EGFP.

Some of the viral vectors that will be used contain a sequence of interest that has been scrambled (scrambled shRNA), and which is not complementary to any known mammalian sequences. These vectors will be employed as negative controls to demonstrate that any observed effects are due to the knockdown of a specific mRNA/protein of interest, rather than being due to any non-specific effects that the delivery of the viral vectors might cause. This sequence will adopt a hairpin structure as with any shRNA, but it should not target any mRNA of mouse, rat or human origin. It will only serve as the negative control for the vector producing shRNA. Consequently, these sequences are unlikely to pose any safety risks for the environment or human health.

Evaluation of foreseeable effects

Human health hazards

There is a very low risk of human infection due to the small quantities of virus to be handled. The method by which the lentivirus vector is produced means that it is highly unlikely that RCL can be generated even if an infection occurs in a person who is HIV-1 positive. Infection can lead to a permanent transduction of cells and the possibility of a harmful event either by transactivation or disruption of gene expression can not be ruled out. For this reason the work with stock viral aliquots will be conducted as a class II activity. Oral ingestion will be prevented by standard laboratory safety practices. Aerosol formation resulting from an accident outside of the safety cabinet and involving lentivirus particle-containing liquid may lead to transduction of a limited number of the laboratory worker’s skin or mucosal cells with modified viruses. However, these modified virus particles carry an extremely low safety risk for human health, as they are replication-incompetent, and also because the particles carry an extremely low infection potential via the mucosal/skin routes, due to the inherent properties of the viral vectors. Moreover, the genes/proteins of interest that will be targeted by shRNAs do not include any growth factors, confirmed oncogenes, cytotoxins, or immunomodulators, and none of them are of retroviral origin. In the unlikely event of accidental transduction of a laboratory worker’s skin or mucosa by lentivirus particles, this will be self-limited, due to natural shedding of superficial epithelial skin and mucosal cell layers.

The most likely route of accidental infection with a lentivirus will be via inadvertent percutaneous inoculation. The likelihood of this occurring will, however, be minimised by adhering to appropriate risk management measures. Infection of the community at large with lentivirus particles is highly unlikely due to the viral vector particles being
replication incompetent and being extremely sensitive to desiccation.

B) HAZARDS TO THE ENVIRONMENT

The chance that active viral particles will be accidentally released into the environment is considered to be highly unlikely, as effective containment procedures will be adhered to. However, in the unlikely event that active viral vector particles do accidentally get released into the environment, the safety risks posed by such an event is considered to be negligible, due to the vectors being self-inactivating and non-replicative. The main potential risk in such an event would be the subsequent contamination of a human population already infected with HIV, which would potentially allow for recombination events that could incorporate the inserted sequences into a viable RCL. This scenario is, however, extremely unlikely, and even if it was to occur, it is unlikely that it would lead to any untoward effects.

The vectors have been pseudotyped with the VSV-G envelope in order to increase tropism, and they are, in theory, capable of transducing all dividing and non-dividing mammalian cell types. As emphasised before, the vectors, however, cannot self-propagate after infection, and successful transduction is also critically dependent on the presence of high enough concentrations of virus particles; and viral vector stock solutions are aliquoted and stored in small volumes (each tube contains at maximum 10μl) at -80°C so the potential for a high titre dose is reduced. The infectivity of the vectors rapidly decreases at room temperature so it is considered highly unlikely that the vectors could survive long enough in the environment to pose a risk if accidentally released. Furthermore, lentiviral vectors have a short half-life at room temperature due to their structural characteristics making them highly susceptible to dehydration, and relatively unstable. For this reason, retroviruses become rapidly inactivated outside host systems, and this is illustrated by the fact that close contact is required for transmission. They can, however, survive for long periods in high protein media.

Rodents, such as wild-type mice and rats, cannot support replication of infectious HIV-1 (Morrow 1987, Lewis 1995, Bieniasz 2000, Goffinet 2007). As a result, the potential for shedding of replication-competent lentiviruses (RCL) from such animals is very low (even if RCL were present in the original vector inoculum).

There are no conceivable hazards associated directly with the lentiviral vectors (containing the inserts) as they will not replicate/survive outside the laboratory and they have been designed to include many protective safety features. shRNA and miRNA sequences will also not survive as they are highly unstable, and they would, consequently, be rapidly inactivated/degraded if accidentally spilled into the environment. Moreover, as discussed above, there is a very low risk that the sequences contained within the viral vectors could be transferred to other organisms, as a rare recombination event would have to occur to allow this to happen.

Summary

The chance that active viral particles will be accidentally released into the environment is considered to be highly unlikely, as the viral vector studies that will undertaken have been classified as CL2, and effective containment procedures will be adhered to. However, in the unlikely event that active viral vector particles do accidentally get released into the environment, the safety risks posed by such an event is considered to be low due to the vectors being self-inactivating and non-replicative, and also due to the poor ability of the vectors to survive outside of their host systems (see above discussions).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

General waste handling procedures
Solid waste will be neutralised by soaking it in a validated disinfectant solution (Virkon or Distel), after which the material will be ‘double bagged’, autoclaved and, ultimately, incinerated offsite by a licensed contractor. Liquid waste will be disposed of into sealed biohazard containers, neutralised with Virkon* and then sent for incineration by a licensed contractor. It will be routine practice that all liquid waste material be neutralised before disposal, and for the neutralised waste to be transported in leak-proof containers to prevent spillages.

* Virkon
Rely+On™ Virkon® is a multi-purpose disinfectant. It contains oxone (potassium peroxymonosulphate), sodium dodecylbenzenesulfonate, sulphamic acid; and inorganic buffers. Virkon oxidizes key structures and compounds, such as proteins, leading to widespread, irreversible damage and subsequent deactivation/destruction of the microorganism. It is typically used for cleaning up hazardous spills, disinfecting surfaces and soaking equipment. With powerful, proven performance against over 500 strains of viruses, bacteria and fungi. Virkon offers a broad spectrum efficacious anti-microbial activity, and it is used by governments worldwide for Emergency Disease Control. Importantly, Virkon has specifically been validated for lentiviral inactivation (Antec-Biosentry). Virkon is sold as a powder which dissolves readily in water. It is intended to be mixed with water to form a 1% solution (i.e. 10g per litre) for hard surface and equipment disinfection. 1:100 is also the dilution rate advised for virucidal efficacy against HIV-1. The product has a pink colour, which is useful in that it helps to gauge the concentration of a prepared solution, and importantly, as Virkon ages, it discolours, making it obvious when it needs to be replaced. The solution is generally stable for five to seven days. Moreover, there is no evidence to suggest that bacterial disease-causing organisms develop resistance towards Virkon, as opposed to some other disinfectant products. Moreover, Virkon is not classified as R53, it is classified as readily biodegradable, and it does not persist in the environment.

* Distel (formally Trigene advance)
Distel is formulated as a nanoemulsion that enables the active molecules in the product to be carried rapidly through cell walls of micro-organisms, ensuring the rapid induction of cell death in treated micro-organisms. Distel works quicker than conventional high level disinfectants and achieves apoptosis (cell death) rather than merely suspending activity as with conventional disinfectant products. Distel has been reported to be bactericidal, fungicidal as well as virucidal and sporicidal. It is recommended to be used at a 1:200 dilution for general purposes, 1:100d for high risk areas, and 1:50 for disinfection of blood and bio-hazard spillages.

Summary
As any active viral particles on surfaces or in waste material will be completely inactivated at the end of each experiment by the highly effective cleaning/disinfection protocols outlined above, it is considered highly unlikely that active virus particles would unintentionally become discharged into a sanitary sewage system. No foreseeable adverse effects on human health and safety are expected.
The GMSC has deemed that the handling of the virus stock supplied by the Uney laboratory in Bristol University is a Class 2 activity. This decision has been reached that, although the virus will not be generated at Takeda Cambridge Ltd, and that the lentivirus particles have been generated using a third generation 4 plasmid expression system, the possibility of a recombination event leading to replication competent virus can never be discounted. It is also noted that the Woodchuck Post-transcriptional Regulatory Element (WPRE) has been associated with potential oncogenic effects with some viral gene delivery systems. The EGFP and shRNA encoded by the lentivirus are not known to posses any inherent toxic or pathogenic hazard to either individuals or to the environment. The GMSC is also satisfied that the knock down in expression of the target genes in this study do not pose any known hazard. The necessary procedures have been put in place to allow the safe use of the virus on primary neuronal cells and for the injection of virus into animals within the animal facility and that there is no risk to the environment due to the inherent instability of the lentiviral particles, non-replicative nature and self inactivation of the virus after insertion into the host genome.

**Project Additional Information**

**Purposes of the contained use**

**Aim**
The objective of the proposed studies is to investigate the role of a protein of interest in the CNS, using adenoviral vectors expressing small hairpin RNAs (shRNAs), which act to downregulate the translation of the protein of interest by binding and promoting the breakdown of its mRNA transcripts. The studies will be focused on discovering the role of the protein of interest in both physiological and pathological processes that occur in the brain, with the overarching aim of identifying potential new drug targets for CNS diseases.

The gene/protein of interest that will be targeted by the shRNA is not of adenoviral origin, and it has not been reported to have any oncogenic, tumour suppressor, immunomodulatory, or cytotoxic activities.

**Methods**
Target material will be transduced with replication incompetent adenoviral vectors expressing shRNA transcripts either targeting the mRNA/protein of interest. Or with vectors expressing scrambled shRNAs. In the case of the negative control treatment groups. The adenoviral vectors will also express enhanced green fluorescent protein (EGFP) to aid in the identificiation, visualisation and isolation of transduced cells. The extent of mRNA and protein knockdown that is achieved will then be assessed at different time points (e.g. 24h-48h-72h), post-transduction, using suitable in vitro assays, including, RT-PCR, Western Blotting, and immunocytochemistry. Once the conditions that lead to the optimal knockdown of the mRNAd/proteins have been determined, what effects the knockdown of the proteins have on various physiological parameters will be evaluated using standard experimented techniques.

**Recipient or parental organism**

Mouse/Rat

**Host/vector system**

Wild Type Adenoviruses
Adenoviruses are ubiquitous pathogens of both mammals and birds. Over 100 serotypes are known, 51 of which infect humans. The severity of adenoviral infections varies from acute respiratory diseases (ARD) in adults (Ad2, Ad7) to mild respiratory symptoms in children (Ad2; Ad5), gastroenteritis (Ad40; Ad41), conjunctivitis (Ad8; Ad19; Ad37), cystitis or subclinical infection (Ad12). Certain serotypes have also been shown to be tumorigenic in neonatal rats (Ad12; Ad7), although this has never been observed in humans.

Primary infection generally occurs in childhood via the airborne or faecal-oral routes and can be persistent with viral shedding continuing for month. Latent infection of
lymphoid tissue can also occur and reactivation in the immunocompromised can lead to serious complications. However, the precise mechanism of latency remains unknown. Immunity is thought to be lifelong and over 90% of individuals are seropositive for Ad2 and Ad5.

The adenovirus virion comprises a non-enveloped icosahedral capsid containing a 36 kb double stranded DNA genome (the general structure of adenoviruses is illustrated in figure 1 below). Adenoviruses can infect a broad variety of cell types including non-dividing cells) via interaction between the viral fibre protein and the cellular Coxsackie B Adenovirus Receptor (CAR) - a widely expressed, 48 kDa member of the immunoglobulin superfamily. Following virus absorption, RGD motifs on the penton base interact with cell surface αv integrins, stimulating an intracellular signalling cascade and clathrin-mediated endocytosis. Not all serotypes share the same affinity for CAR and some utilise alternate receptors and cell-surface integrins.

Adenoviruses replicate in the nucleus, where the viral genome is maintained epichromosomally, and viral gene expression is divided into two distinct phases - Early and Late transcription. Early transcription occurs 6 to 8 hours after infection, generating early proteins from four major regions, E1, E2, E3 and E4. The E1 promoter directs expression of the E1 proteins, E1A and E1B that subvert the cellular environment and control transcription of the other early genes. E1A disrupts cell-cycle regulation by binding to key regulators of transcription and mitosis. This results in the expression of the pro-apoptotic factors, including p53, which is bound and inactivated by an E1B protein. E2 proteins are required for genome replication and packaging. E3 proteins aid the evasion of the immune system by disrupting the processing of class 1 Major Histocompatibility Complexes and inhibition of Fas- and TNF-mediated apoptosis. One E3 protein, the so-called Adenovirus Death Protein (ADP), promotes cytolysis and 79 release of progeny virions. E4 proteins further subvert the cellular environment and modulate the activities of E1 proteins. Late transcription, directed by the Major late Promoter, occurs 4 to 6 hours after the onset of Early transcription and results in the expression of the structural proteins L1, L2, L3, L4 and L5. The lytic cycle lasts for 24-48 hours (depending on subtype and target cell) generating up to 1x105 viral particles per infected cell.

Disabled Recombinant Adenovirus Vector Systems.

To date, most genetic modification work involving adenoviruses has involved the development of transduction vectors derived from human Ad2, Ad5 and Ad12. `First Generation' vectors comprise the majority of Adenovirus vectors used to date and harbour a genomic deletion that removes the E1 expression cassette. E1A and E1B are usually supplied in trans using a complementing cell line that contains the E1 expression cassette (such as HEK293 or PerC6). Packaging sequences are retained in order to generate viable progeny. Since adenoviruses have a strict packaging limit (105% of the wild-type genome size), the E3 cassette is also commonly deleted since it is dispensable for growth in vitro. `Second Generation' vectors also have much of the E2 cassette deleted, increasing its packaging capacity and further disabling the virus by removing its capability to replicate and process viral DNA. This deletion also virtually eliminates the possibility of a recombination event that might result in Replication Competent Viruses (RCV). `Third Generation', or 'Gutless' vectors generally retain only packaging sequences and therefore have the largest capacity for inserted genetic material. The latter vectors, however, require extensive complementation in trans from a helper virus.

Adenoviruses can infect a wide variety of cell types, although individual serotypes have more restricted tropisms, and in most transduced tissues, expression form Ad vectors is transient due to clearance of the virus by the immune system, and expression lasts only one to two weeks. In some 'immune privileged' tissue expression may be longer persisting for a year or more. Integration into the host genome represents the only significant mechanism by which long-term expression can be maintained by disabled Ad vectors. This is relatively rare, occurring at a frequency of approximately 1 in 105 pfu in human primary cell cultures. Deletions in the viral vector or the genetic insert may alter the immunogenic or pathogenic nature of the virus. For example, proteins derived from the E3 cassette (which is often deleted in adenoviral vectors) are involved in immune evasion strategies in vivo. Their deletion, while facilitating the clearance of virus by the host immune system, might result in an increased inflammatory response and increased pathogenicity.

There is a possibility that recombination events could result in harmful sequences being transferred between related viruses. This could take place between a vector and a wild-type adenovirus or viral sequences present in a cell; for example. It has been shown that 20% of normal healthy adults have E1A sequences present in their respiratory epithelium. When engineering recombinant viruses, it is, therefore, common practice to locate an insert in place of the E1 cassette. This, any homologous recombination that restores E1 sequences to the vector will also delete the insert and vice-versa. Inserts cloned into other areas of the viral genome could be maintained in the event that E1 sequences are restored, resulting in a GM RCV. The probability of acquisition of sequences form a complementing cell line or helper virus can be minimised if there
are no overlapping sequences. For example, HEK293 cells carry cell line or helper virus can be minimised if there are no overlapping sequences. For example, HEK293 cells carry 11% of the adenovirus genome containing the E1 cassette; This includes at least 800 bp of sequence present within most E1-deleted adenovirus vectors, providing the potential for recombination that restores the E1 region in the virus.

In contrast, PerC6 and similar cell lines have been engineered to express the minimal E1A and E1B genes from heterologous promoters, and thus have no sequence overlap with most newer E1-deleted vectors, greatly reducing the frequency of generating replication-competent virus.

Most adenovirus vectors have been derived from human viruses, which are not thought to be able to replicate efficiently in animal cells. Therefore, it is unlikely that activities with these vectors will represent any significant risk to the environment. However, human Ad5 vectors have been shown to enter some animal cells and there may be environmental risk associated with inserted genetic material. Human Ad5 vectors have been shown to enter (but not replicate efficiently in) cells of mouse, rat and canine origin, which raises the question of whether or not recombination between human and animal adenoviruses might occur. There is, however, no evidence to suggest that this is possible.

Description of the recombinant pacAd5 adenoviral vector system to be used

pacAd5 Vectors produced using the RAPAd Production System

The adenoviral vectors that will be used are all recombinant disabled shRNA expressing pacAd5 vectors, which will be produced using the RAPAd4 Adenoviral Expression System (Anderson et al, 2000). In this system, replication-deficient adenoviral vectors are produced in HEK293 packaging cells using pacAd5 9.2-100 backbone and pacAd5 RSVK-NpA transgene-containing shuttle vectors, which undergo homologous recombination after co-transfection.

The recombinant pacAd5 vectors that are produced with the RAPAd system are rendered replication-deficient as a consequence of the pacAD5 9.2-100 backbone vector being devoid of the left-hand ITR, the packaging signal and E1 sequences (complete E1a and partial E1b deletions); and virus replication can, therefore, only take place in HEK293 packaging cells, in which the deleted E1 sequences that are essential for replication are provided in trans. The recombinant viruses do, however, still contain all of the other wild-type adenovirus sequences, including those that code for immune evasion proteins (E3), viral structural/assembly proteins (L1-L5), and proteins that are responsible for replication levels of E1a copy number by quantitative PCR.

Characteristics of the Recombinant Adenoviral Vecotr supplied by J U Lab.

The adenoviral vector will be produced and supplied by JU's Lab, which is based at the University of Bristol, and virus production will not take place at Takeda Cambridge's site. Each aliquot of adenoviral reagent will comprise of a small volume (5-20μl) containing up to ~8 x 10e12 viral particles/ml (2 x 10e10 IU/ml) dissolved in TSSM buffer (20mM Tromethamine, 100mM NaCl, 10mg/mL sucrose, 10mg/mL mannitol). The viral stock solution will consist of viral particles containing in the vector genome (full capsids) and also of a variable number of empty viral capsids, and it should be essentially free of the HEK293 helper cell line used to produce the vectors. Importantly, all virus preps are tested for replication competent adenovirus (RCA contamination by immune-staining procedures. Other trace components that might be present include, but are not limited to, inorganic salts, vitamins, other nutrients, human cellular proteins, carbohydrates, amino acids and fats. The material is normally shipped and stored frozen within manufacturer designed racks in a -80° freezer.

Post-transfection of target cells, the vectors will produce both a small hairpin RNA (shRNA) that targets the mRNA of the protein of interest (or a scrambled shRNA), and the enhanced green fluorescent protein (EGFP) reporter protein to facilitate the identification of transduced cells.

Transgenes of Interest Contained in the Vectors.

The transgene of interest that will be inserted into the vector will contain sequences that code for a shRNA molecule targeting the mRNA of the protein of interest (or a scrambled shRNA in the case of the negative control) and/or the transduction marker protein, EGFP. Control viral vectors that code for and express only EGFP and no shRNA will also be used in some experiments. The shRNA (or scrambled shRNA) sequences will be under the control of the U6 promoter, while the EGFP gene will be under the control of the Cytomegalovirus (CMV) promoter.
**U6 shRNA Promoter**

The U6 promoter used in the U6.shRNA-CMV.GFP constructs is well suited to drive the expression of shRNAs due to it possessing the following favourable characteristics:

(i) it initiates from position +1 of the transcripts, and (ii) it yields transcripts that do not terminate with a poly-A tail but with a series of four to five thymidine residues that results in a series of 3’ U residues which gives rise to a fully functional shRNA sequence. Indeed, the structure of the transcribed product closely resembles synthetic double-stranded siRNAs, except for the fact that the two strands are linked by a spacer sequence. This system has been used to successfully inhibit gene expression in mammalian cell lines, with efficiencies comparable with that of synthetic siRNA.

**EGFP CMV Promoter**

EGFP will be produced by all of the vectors, and it will be controlled by the CMV immediate-early enhancer, which directs high-level expression in most cell types, although expression levels vary between cell and tissue types.

**Origin & function**

**Transgene: proteins to be expressed:**

**EGFP**

EGFP is a modified form of green fluorescent protein (GFP) that has enhanced spectral properties making it a superior tool as a reporter of gene expression in biological research. GFP is a s38 amino acid residue (26.9kDa) protein that exhibits bright green fluorescence when exposed to light in the blue to ultraviolet range and was first isolated from jellyfish Aequorea victoris. EGFP is not known to have any disease association and is regarded as non-toxic to living cells. The expression of EGFP will be used to identify cells that have been transduced with adenoviral vectors.

**shRNAs targeting the protein of interest**

As shRNA tends to lead to a loss of activity it is inherently regarded as being safer than gain of function experiments provided that tumour suppressors, growth factors, and processes that are known to be involved in cell cycle regulation are not affected. The gene/protein of interest that will be targeted by the shRNA is not of adenoviral origin, and it has not been reported to have any cytotoxic tumour suppressor, growth stimulating, or cell cycle disrupting activities.

**RNA interference (RNAi)** is an antisense technology that exploits a normal cellular antiviral response that acts to inhibit viral protein synthesis through the production of short hairpin RNAs that bind and target viral double-stranded RNA (dsRNA) molecules for degradation. The shRNA molecules are processed by cellular enzymatic pathways to produce small inhibitory RNA (siRNA) species, and it is the latter RNA molecules that bind and target complementary RNA sequences for degradation by the RNA-induced silencing complex (RISC). With the use of shRNA-expressing viral vector systems, the expression of specific mammalian genes/proteins can be ‘knocked-down’, in order to study their functions.

The effects of the siRNA species that are generated in these experimental systems may have broader effects on the cell than just modulating the expression of a particular gene/protein. There may be sequences within a specific shRNA molecule that are homologous to other coding sequences within the mammalian genome that are not necessarily linked or closely related to the intended target. It is, therefore, theoretically possible that a specific siRNA may knock down the expression of genes other than the intended target, and for this reason, the RNAi systems have been designed carefully to minimise the likelihood that there will be unwanted or potentially adverse effects arising from a non-target gene being inadvertently targeted. This is done by screening designed shRNA sequences against databases of known mammalian gene/mRNA sequences. Additionally, with the use of this approach, the shRNAs are also designed so as to bind complementary sequences that are present in rodents, but not in humans, which reduces potential risks to humans. The likelihood that a specific shRNA will bind to a human form of the target mRNA is extremely low, but it cannot be completely excluded.

Moreover, RNAi interference may, additionally, also have deleterious effects upon cellular metabolism due to the triggering of antiviral responses. It has been shown that siRNA molecules (even if less than 30 nt in length) can trigger dsRNA antiviral responses. Such responses not only lead to the degradation of dsRNA molecules, but also results in interferon production, which, in turn, leads to the inflammation and the non-specific inhibition of protein synthesis.
Some of the viral vectors that will be used contain a sequence of interest that has been scrambled (scrambled shRNA), and which is not complimentary to any known mammalian sequences. These vectors will be employed as negative controls to demonstrate that any observed effects are due to the knockdown of a specific mRNA/protein of interest, rather than being due to any non-specific effects that the delivery of the viral vectors might cause. This sequence will adopt a hairpin structure as with any shRNA, but it should not target any mRNA of mouse, rat or human origin. It will only serve as the negative control for the vector producing shRNA., Consequently, these sequences are unlikely to pose any safety risks for the environment or human health.

**Evaluation of foreseeable effects**

As the adenovirus vector system that will be used is based on wild-type adenovirus serotype that is capable of infecting humans (Ad5), a theoretical risk to human health cannot be excluded even though recombinant replication-deficient viral preparations will be used, which have been validated to be virtually free of any wild-type virus. Moreover, the recombinant viruses do still contain the functional wild-type virus sequences that code for viral DNA replication proteins (E2 Polymerase/DNA binding proteins), which means that copies of the viral genome are likely to be generated in transfected cells. There is, therefore, a theoretical risk that replication-competent transgenic viruses could be formed from a rare recombination event if the vectors infect cells that are also infected with wild-type adenovirus. The probability of such an event occurring is, however, considered to be extremely low.

Adenoviruses are generally transmitted primarily via the airborne and/or faecal-oral routes, and inhalation of viral aerosols and/or oral ingestion of viral stock solution, therefore, represent the main potential routes by which accidental infection is likely to occur. The probability of a worker becoming accidentally infected is, however, considered to be low, as appropriate risk reduction measures will be implemented, Notably, micro-syringes will be filled with viral vectors only in a Class 2 MSC to avoid the production of aerosols, and the risk of infection occurring due to needle stick injuries will be negated by using blunt needles, in most cases, and by using suitable containment conditions. Oral ingestion will be prevented by standard laboratory safety practices.

Accidents resulting in spillage of viral solutions or the production of viral-containing aerosols outside of a safety cabinet could potentially lead to transduction of a limited number of a laboratory worker's skin or mucosal cells with recombinant virus. Such an event is, however, highly unlikely to have any negative consequences on the health of the infected worker, as the recombinant viral particles are replication-deficient, and modulation of the shRNA-targeted protein of interest has not been reported to cause any oncogenic, immunomodulatory, or cytotoxic activities. The vectors also contain no modifications that are known to cause pathogenicity to plants, vertebrate animals, or humans. Natural shedding of superficial epithelial skin and mucosal cell layers and rapid phagocytosis of virus by epithelial immune cells will also act to self-limit any such infections. As adenoviral vectors are generally maintained epichromosomally after transfection, there is a minimal risk of the vectors causing undesirable effects as a result of insertion events disrupting host genome functioning.

Moreover, the risk of infection leading to tumourigenesis or other untoward effects is related in part to the titre of the viral vectors; and exposure of workers to quantitites of virus high enough to cause such effects would be unlikely during standard laboratory-based manipulations of adenoviral vectors (viruses will be handled as aliquots no larger than 20ul). Importantly, as mentioned earlier, the production of the adenoviral vectors will only take place in the lab of J U which is based at the University of Bristol, and it will, in no instance, take place at Takeda Cambridge's site. This means that large volumes of viruses will not be generated on-site, which consequently decreases the risk of infection.

Infection of the community at large is highly unlikely due to the recombinant vectors being replication deficient.

**B) HAZARDS TO THE ENVIRONMENT**

Adenoviruses infect most mammalian and bird cell types (both replicative and non-replicant), and they are able to survive for prolonged periods of time outside of their host systems due to them being highly stable even in favourable conditions. The recombinant viral vectors could, therefore, potentially infect susceptible organisms if accidentally released into the environment. The chance that active viral particles will be accidentally released into the environment is, however, considered to be highly unlikely, as effective containment procedures will be strictly adhered to. Furthermore, in the unlikely event that active viral particles do accidentally get released into the environment, the safety risks posed by such an event is considered to be negligible, due to the vectors being replication-deficient. Moreover, effective infection of organisms is critically dependent on the presence of high enough concentrations of viral particles; and viral vector stock solutions will be manages so as to prevent contaminations with relatively high viral titres (after production, the vectors are stored/handled in small aliquots not bigger than 20ul).
As mentioned above, the recombinant viruses do still contain the functional wild-type virus sequences that code for viral DNA replication proteins (E2 Polymerase/DNA binding proteins), which means that copies of the viral genome are likely to be generated in transfected cells. There is, therefore, a theoretical risk that replication-competent transgenic viruses could be formed from a rare recombination event if the vectors infect cells of an organism that are also infected with wild-type adenovirus. The probability of such an event occurring is, however, considered to be extremely low.

Accidental environmental contamination with any shRNA molecules is also considered to pose negligible environmental safety risks, as they are highly unstable, and they would, consequently, be rapidly inactivated/degraded if released into the environment. There is also a very low risk that the sequences contained within the viral vectors could be transferred to other organisms, as a rare recombination event would have to occur to allow this to happen.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

General waste handling procedures
Solid waste will be neutralised by soaking it in a validated disinfectant solution (Virkon or Distel) for a minimum period of 24 hours, after which the material will be 'double bagged', autoclaved and, ultimately, incinerated offsite by a licensed contractor. Liquid waste will be disposed of into sealed biohazard containers, neutralised with Virkon* for a minimum of 24 hours, and then sent for incineration by a licensed contractor. It will be routine practice that all liquid waste material be neutralised before disposal, and for the neutralised waste to be transported in leak-proof containers to prevent spillages.

*Virkon
Rely+On™ Virkon® is a multi-purpose disinfectant. It contains oxone(potassium peroxymonosulphate), sodium dodecylbenzenesulfonate, sulphamic acid; and inorganic buffers. Virkon oxidizes key structures and compounds, such as proteins, leading to widespread, irreversible damage and subsequent deactivation/ destruction of the microorganism. It is typically used for cleaning up hazardous spills, disinfecting surfaces and soaking equipment. With powerful, proven performance agains over 500 strains of viruses, bacteria and fungi. Virkon offers a broad spectrum efficacious anti-microbial activity, and it is used by governments worldwide for Emergency Disease Control. Importantly Virkon is sold as a powder which dissolves readily in water to form a 1% solution (i.e. 10g per litre) for hard surfaces and equipment disinfection. 1:100 is also the dilution rate advised for virucidal The product has a pink colour, which is useful in that it helps to gauge the concentration of a prepared solution, and importantly, as Virkon ages, it discoulors, making it obvious when it needs to be replaced. The solution is generally stable for five to seven days. Moreover, there is no evidence to suggest that bacterial disease-causing organisms develop resistance towards Virkon, as opposed to some other disinfectant products. Moreover, Virkon is not classified as R53, it is classified as readily biodegradable, and it does not persist in the environment.

Distel (formerly Trigene advance)
Distel is formulated as a nanoemulsion that enables the active molecules in the product to be carried rapidly through cell walls of micro-organisms, ensuring the rapid induction of cell death in treated micro-organisms. Distel works quicker than conventional high level disinfectants and achieves apoptosis (cell death) rather than merely suspending activity as with conventional disinfectant products. Distel has been reported to be bactericidal, fungicidal as well as virucidal and sporicial. It is recommended to be used at a 1:2000 dilution for general purposes, 1:100d for high risk areas, and 1:50 for disinfection of blood and bio-hazard spillages.

Summary
As any active viral particles on surfaces or in waste material will be completely inactivated at the end of each experiment by the highly effective cleaning/disinfection protocols outlined above, it is considered highly unlikely that active virus particles would unintentionally become discharged into a sanitary sewage system. No foreseeable adverse effects on human health and safety are expected.
The GMSC has deemed that the handling of the adenovirus virus stock supplied by the Uney laboratory in Bristol University is a Class 2 activity. This decision has been reached that although the virus will not be generated at Takeda Cambridge Ltd, and that the adenovirus particles have been generated using an expression system that should render the virus non-replicative, the possibility of a recombination event or infection into cells containing wild-type adenovirus leading to replication competent virus can never be discounted. The EGFP and shRNA encoded by the adenovirus are not known to possess any inherent toxic or pathogenic hazard to either individuals or to the environment. The GMSC is also satisfied that the knock down in expression of the target gene in this study does not pose any known hazard. The necessary procedures have been put in place to allow the safe use of the virus.

Please enter comments on the GM safety committee on the risk assessment

Historical Significant Changes transferred to GM3344 02/12/2016
The purpose of this project is to validate positive and negative modulators of cellular processes that might be useful drug targets that work to delay or halt Neurodegeneration, the process that underlines a number of diseases including dementia. These positive and negative modulators will be identified through a druggable RNAi high content screen in a human non-neuronal cell line that is currently being performed by an outside academic collaborator. Selected targets will be further assessed by looking at their effects in neuronal and non-neuronal cells. To ensure that the targets affect specific cellular processes each of the selected RNAi targets will also be coexpressed with a fluorescent protein (FP) reporter that is directed to a specific organelle. It is expected that depletion will not necessarily cause any major alterations in unstressed neurons. Target dependent depletion through RNAi will have to be performed in a disease relevant model. For this, a lentiviral construct containing a FP tagged or untagged human Neuro degeneration relevant disease mutation or Neurodegeneration disease relevant RNAi will be combined with the RNAi dependent depletion of the relevant positive/negative regulator. Through this strategy, it is hoped that the identity and validity of one or more targets that may be useful targets for the treatment of Neurodegeneration can be determined. This work will involve the use of particles of lentiviral origin and so require containment to minimise the risk of exposure to both humans and the environment. It should be noted that we will be using third generation lentiviral self-inactivating replication defective (SIN-RD) lentiviral particles. The fact that four different plasmids are required to generate these SIN-RD lentiviral particles reduces the risk even further. Nevertheless according to current statutes and as a precautionary measure, all generation and application of virus will be done under Level 2 containment.
Origin & function

The SIN-RD lentiviral particles will contain the following sequences:

1. shRNA/miRNA directed towards the knock down of the expression of a particular endogenous mammalian target (Mouse, Rat, Human). These de novo derived sequences are not derived from an organism and will be designed to only target an individual species. In addition the sequences chosen will not target known oncogenes, tumour suppressors, cell cycle regulators, Immunomodulators and will not be of retroviral origin. Resources that will be used to assess these criteria will include the interrogation of genome wide RNA screens to assess Mitosis and cell death (www.mitochek.org).

The particles will deliver shRNA/miRNA constructs that will either target one or two genes. For shRNA constructs transcription will be driven by a constitutively active Polymerase III U6 promoter. For some targets shRNA may not represent an effective methodology for knock-down of expression so miRNA constructs prove more effective. This methodology utilises an endogenous cellular mechanism for post-transcriptionnally regulation of target genes. Artificial miRNA sequences are generated using the human miR-30 microRNA cassette under the control of a polymerase II miRNA sequences or an additional protein. The miRNA sequences will be excised by the endogenous cellular machinery before expression of the protein.

2. Fluorescent protein (FP markers which have been identified from a range of different organism; are known to be benign in terms of their effects when expressed in mammalian cells but are essential for visualisation of these cells. When these in addition are fused to a subcellular marker gene, that is expressed only in a particular sub-cellular structure within a cell, will enable the visualisation of a particular process and any changes that occur in response to the knockdown of the expression of a particular gene. Expression of the FP will be either under the control of a CMV promoter which is constitutively active and commonly used in biological research or a promoter that only allows expression in neuronal cells.

3. Human disease relevant mutated gene expression which is intended to recreate a certain aspect of disease pathology. It is expected that its expression will be cytotoxic but will not be a growth factor (which does not include trophic factors), confirmed oncogene, tumour suppressor gene (TSG), cell cycle regulator or immunomodulator, and none of them will be of retroviral orgin. Expression of the mutant proteins will be either under the control of a polymerase II promoter that is either constitutively active or only active in neuronal cells.

Lentiviral production - on site B60CRP or 430CSP

Where lentivirus is not available from the collaborator; lentiviral production will be carried out on-site. Lentiviral production will only be carried on HEK293T cells and will be carried out in a class 2 microbiological safety cabinet within a Biosafety level 2 laboratory. The HEK293T cells used for lentiviral production will be seeded in filter containing screw cap culture flasks in order to minimize the risk of spills and/or aerosol mediated viral spread. The modified PRL plasmid containing the necessary shRNA/miRNA & protein encoding sequences together with the chemical or lipid based transfection reagent (e.g. Polyethylenimine (PEI), Lipopectamine) into the HEK293T packaging cell line. After 6-12 hours, the medium is replaced with fresh serum-free medium. (e.g. Neurobasal medium with 2% B-27 supplement and 1X Pen/Strep) and grown for an additional 72-96 hours. After 24-48 hours, so as to ensure the viability of the transfected HEK293T cells, medium from the cells is collected into screw cap tube and stored at 4°C and fresh serum-free medium is added to the cells. The cells are grown for an additional 24-48 hours before the second medium solution is added to the first harvest tube. All plastic ware and solutions will be treated as if contaminated.

Still within a Biosafety level 2 microbiological safety cabinet in a Biosafety level 2 laboratory, the harvested supernatants will be filtered using a 0.45 um filter before either being dispensed as aliquots or further purified by chromatography and/or concentrated by centrifugation. For certain application the lentiviral particles will need to be a concentrated. The lentiviral particles may need to be purified to be either chromatography (e.g. ViraBind™) and eluted in a high salt solution (50mM Tris, pH 7.5,5 mM MgC12, 2 M NaCl) and/or concentrated by ultrafiltration (e.g. LentiSelect™). For certain application where a highly concentrated, highly purified virus may be required, the traditional method of sucrose cushion based centrifugation may be necessary. To minimise the possible risk of accidental viral contamination and spread due to the need for an ultracentrifuge, all loading and unloading will be done in the Biosafety level 2 cabinet. Once the sucrose cushions have been added to the centrifuge tubes, they will be transferred into the Biosafety level 2 Safety Cabinet. The unpurified or chromatography purified lentiviral particles will then be added to the sucrose cushion. The tubes will then be transferred to their respective bucket holders and the bucket sealed using their respective screw caps and marked as containing virus. The bucket will be transferred to a weighing scale and a counterpart bucket and centrifuge with water (and without lentivirus) will be prepared that is weight matched. The balanced buckets will then be transferred to the rotor before being placed within the centrifuge chamber. The ultracentrifuge will be run at 70000g for 2 hours at 20°C. Upon return of the bucket to the Biosafety level 2 cabinet, the supernatant will be removed from the tubes before transfer of the resuspended virus pellet into individual screw cap croyvials. As
the greatest risk for contamination occurs within the centrifugation buckets themselves during transport to and from the weigh scales and ultracentrifuge, not only will the centrifuge tubes also be decontaminated with DISTEL 10% and 70% isopropanol before removal from the Biosafety level 2 laboratory. In any case, at no point will concentrated virus stock be exposed to outside of the Biosafety level 2 hood environment.

The lentiviral titre will be determined in terms of the number of viral particles (VP) or Transduction units (TU) per ml. Assessing the number of VP can be assessed relatively quickly and does not involve cell infection. In this case, a bead based enrichment assay (e.g. QuickTitre™ Quantification Kit) or a p24 ELISA assay (e.g.QuickTitre™ Lentivirus Titre Kit).will be chosen. The VP quantification methods tends to overestimate the TU by 10-1000 fold. Thus, the TU/ml will in certain instances also be determined. For this, a titration range of lentiviruses expressing a fluorescent tag, serial dilution will be prepared and added to a 24 well cluster plate of T25 TC-flasks containing HEK293T for 48 hours. The percentage of fluorescent positive cells will be quantified manually under a fluorescent microscope or ideally using FACS analyser. The biological titre (TU/ml) according to the following formula: 

$$\text{TU}/\mu l = \frac{(P \times N/100 \times V) \times 1/DF}{V}$$

where P= % GFP+ cells, N= number of cells at time of transduction = 105, V= volume of dilution added to each well and DF=dilution factor.

Aliquots with not more than 1x10^8 viral per viral are subsequently stored at -80°C in individual screw capped cryotubes. The viral stock will consist of viral particles containing the vector genome (full capsids) and also of a variable number of empty viral capsids. Other trace components that might be present include, but are not limited to inorganic salts, vitamins, other nutrients, human cellular proteins, carbohydrates, amino acids, and fats.

Assessment of effects

Assessing whether the knock down has worked in neurons can be challenging. Consequently, initially the RNAi depletion of the target gene (using the FP tagged version followed by the RNAi sequence) will be assessed in immortalised cell lines (mouse NIH/3T3 and human HEK293T and human HEK293T). This work will be done initially at Biosafety level 2. In order to determine whether the knock-down has worked; the levels of mRNA and protein will be assessed post-transduction, using suitable in vitro assays, including for example, RT-PCR, Western Blotting, and immunocytochemistry. These results will subsequently be confirmed on neurons such as those derived from human induced Pluripotent stem cells (iPSCs) using immunocytochemistry.

The correct distribution and perturbed cellular functions of the relevant human Neurodegeneration relevant disease mutations will also be assessed by subsequent immunocytochemistry and Bioenergetic analysis (using Seahorse™). Other physiological parameters, including, for example, the release of specific neurotransmitters from neurons or the expression of related proteins will be measured using suitable in vitro assays, including, for example, ELISA, PCR, neurite outgrowth, electrophysiology, and neuroprotection assays. In some instances, the vectors might need to be studied in rodent neuron-glia co-cultures in order to investigate the interaction between these two cell types.

Evaluation of foreseeable effects

Human health hazards

The method by which the lentivirus vector is produced means that it is highly unlikely that RCL can be generated even if an infection occurs in a person who is HIV-2 positive. Infection can lead to a permanent transduction of cells and the possibility of a harmful event either by transactivation or disruption of gene expression cannot be ruled out. For this reason the work with stock viral aliquots will be conducted as a class ll activity. Oral ingestion will be prevented by involving lentivirus particle-containing liquid may lead to transduction of a limited number of the laboratory worker's skin or mucosal cells with modified viruses. However, these modified virus particles carry an extremely low safety risk for human health, as they are replication -incompetent, and also because the particles carry an extremely low infection potential via the mucosal/skin routes, due to the inherent properties of the viral vectors. Moreover, the genes/proteins of interest that will be targeted by shRNAs do not include any growth factors, confirmed oncogenes, cytotoxins, or immunomodulators, and none of them are of retroviral origin. The mutant genes express proteins known to be cytotoxic to neurons but it is highly unlikely such cells would be transduced via the mucosal or skin routes. In the unlikely event of accidental transduction of a laboratory worker's skin or mucosa by lentivirus, this will be self-limited due to natural shedding of superficial epithelial skin and mucosal cell layers.

The most likely route of accidental infection with a lentivirus will be via inadvertent percutaneous inoculation. The likelihood of this occurring will, however, be minimised by adhering to appropriate risk management measures. Infection of the community at large with lentivirus particles is highly unlikely due to the viral vector particles being replication incompetent and being extremely sensitive to desiccation.

Hazard to the Environment
The chance that active viral particles will be accidentally released into the environment is considered to be highly unlikely, as effective containment procedures will be adhered to. However, in the unlikely event that active viral vector particles do accidentally get released into the environment, the safety risks posed by such an event is considered to be negligible, due to the vectors being self-inactivating and non-replicative. The main potential risk in such an event would be the subsequent contamination of a human population already infected with HIV, which would potentially allow for recombination events that could incorporate the inserted sequences into a viable RCL. This scenario is, however, extremely unlikely, and even if it was to occur, it is unlikely that the vectors could survive long enough in the environment to pose a risk if accidentally released.

Furthermore, lentiviral vectors have a short half-life at room temperature due to their structural characteristics making them highly susceptible to dehydration, and relatively unstable. For this reason, retroviruses become rapidly inactivated outside host systems, and this is illustrated by the fact that close contact is required for transmission. They can, however, survive for long periods in high protein media.

There are no conceivable hazards associated directly with the lentiviral vectors (containing the inserts) as they will not replicate/survive outside the laboratory and they have been designed to include many protective safety features. shRNA and miRNA sequences will also not survive as they are highly unstable, and they would, consequently, be rapidly inactivated/degraded if accidentally spilled into the environment. Moreover, as discussed above, there is a very low risk that the sequences contained within the viral vectors could be transferred to other organisms, as a rare recombination event would have to occur to allow this to happen.

Summary
The chance that active viral particles will be accidentally released into the environment is considered to be highly unlikely, as the viral vector studies that will be undertaken have been classified as Biosafety level 2, and effective containment procedures will be adhered to (see section C for details). However, in the unlikely event that active viral vector particles do accidentally get released into the environment, the safety risks posed by such an event is considered to be low due to the vectors being self-inactivating and non-replicative, and also due to the poor ability of the vectors to survive outside of their host systems (see above discussions).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Following transduction of cell lines that are designated as requiring Biosafety Containment Level 1 with lentivirus we wish to be able to use these cells at BioSafety Containment Level 1. This can be justified by the following procedure: under Biosafety Containment Level 2 media containing virus will be removed, the transduced cells will be extensively washed to remove any remaining virus. This liquid waste will be neutralised for at least 24 hours before disposal. The washed cells will then be cultured for a further 24 hours before being tested for the absence of infectious virus before being allowed to be treated as only requiring Biosafety Containment Level 1.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

General waste handling procedures:
Solid waste will be neutralised by soaking it in a validated disinfectant solution (Virkon* or Distel) for at least 24 hours, after which the material will be 'double bagged', autoclaved and, ultimately, incinerated offsite.
At B60CRP, liquid waste will be disposed of into sealed biohazard containers filled with Virkon* for incineration. It will be routine practice that all liquid waste material be neutralised for at least 24 hours before disposal, and for the neutralised waste to be transported in leak-proof containers to prevent spillages. At 430CSP, liquid waste will be inactivated by Virkon* for 24 hours prior to drain disposal via a designated sink.

*Virkon
Rely+On™Virkon® is a multi-purpose disinfectant. It contains oxone (potassium peroxymonosulphate), sodium dodecylbenzenesulfonate, sulphamic acid; and inorganic buffers. Virkon oxidizes key structures and compounds such as proteins, leading to widespread, irreversible damage and subsequent deactivation/destruction of the microorganism. It is typically used for cleaning up hazardous spills, disinfecting surfaces and soaking equipment. With powerful, proven performance against over 500...
strains of viruses, bacteria and fungi. Virkon offers a broad spectrum efficacious anti-microbial activity, and it is used by governments worldwide for Emergency Disease Control. Importantly, Virkon is sold as a powder which dissolves readily in water. It is intended to be mixed with water to form a 1% solution (i.e. 10g per litre) for hard surface and equipment disinfection. 1:100 is also the dilution rate advised for virucidal efficacy against HIV-1.

The product has a pink colour, which is useful in that it helps to gauge the concentration of a prepared solution, and importantly, as Virkon ages, it discours, making it obvious when it needs to be replaced. The solution is generally stable for five to seven days. Moreover, there is no evidence to suggest that bacterial disease-causing organisms develop resistance towards Virkon, as opposed to some other disinfectant products. Moreover, Virkon is not classified as R53, it is classified as readily biodegradable, and it does not persist in the environment.

*Distel (formally Trigene advance)*
Distel is formulated as a nanoemulsion that enables the active molecules in the product to be carried rapidly through cell walls of micro-organisms, ensuring the rapid induction of cell death in treated micro-organisms. Distel works quicker than concentrated high level disinfectants and achieves apoptosis (cell death) rather than merely suspending activity as with conventional disinfectant products. Distel has been reported to be bactericidal, fungicidal as well as virucidal and sporicidal. It is recommended to be used at a 1:200 dilution for general purposes, 1:100d for high risk areas, and 1:50 for disinfection of blood and bio-hazard spillages.

Summary
As any active viral particles on surfaces or in waste material will be completely inactivated at the end of each experiment by the highly effective cleaning/disinfection protocols outlined above, it is considered highly unlikely that active virus particles would unintentionally become discharged into a sanitary sewage system. No foreseeable adverse effects on human health and safety are expected.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment Y

The GMSC has agreed that the production and handling of virus stocks is a Class 2 activity. This decision has been reached because although the lentivirus will be generated using a third generation, self-inactivating, 4 plasmid expression system, the possibility of a recombination event occurring that leads to replication competent virus can never be discounted with this type of virus. The potential oncogenic effects of the Woodchuck Post-transcriptional Regulatory Element have been negated by the use of the mutant form that prevents expression of the X protein. The production of large amounts of virus represents the most hazardous aspect of the proposal and the GMSC is satisfied that the necessary precautions have been put in place to ensure containment is maintained. Some of the proposed nervous system. The procedures put in place to ensure containment is maintained. Some of the proposed lentivirus will encode for proteins that are known to have neurotoxic effects and cause diseases of the human central nervous system. The procedures put in place will effectively prevent any chance of virus being delivered to the necessary tissues within a human in sufficient quantities to represent a hazard to human health. The FP and shRNA/miRNA encoded by the other lentivirus are not known to pose any inherent risk to human health or the environment. The proposed targets to be knocked down in this study also pose no known risk. The request to derogate the Biosafety Containment Level from 2 to 1 post transduction has been deemed acceptable given that the transduced cells will be washed extensively to remove any remaining viral particles and will be tested for the absence of transducing virus. It has been made clear that human iPSC cell lines that have been generated using lenti- or retrovirus methods tested negative for the absence of virus at least. These cells will always be tested for the absence of infectious particles before they can be used as if they only required Biosafety Containment Level 1.

Aim

The lentiviral siRNA knockdown studies that will be carried out as part of this body of work will be focused on discovering the role of specific proteins in both physiological and pathological eNS processes, with the overarching aim of identifying and validating potential new drug targets for psychiatric and/or neurodegenerative diseases. The proteins that will be selectively knocked down by lentiviralUy expressed siRNA will include those that have been either directly or indirectly linked to relevant eNS disease states; and, in most cases, the targeted proteins will play a role in well characterised relevant disease-related biologicaVpathological processes. Relevant neurodegeneration

02/03/2022

Page 12655 of 15326
related processes, for example, are likely to include, bioenergetics, oxidative stress, neutre-inflammation, protein
misfolding, excitotoxicity, and autophagy. Psychiatric disease related protein targets, on the other hand, are likely to
play a role in neurogenesis, neural plasticity, or the functioning of one or more disease-linked neurotransmitter
systems.

Importantly, the genes/proteins of interest that will be targeted by siRNAs do not include any growth factors,
confirmed oncogenes, tumour suppressors, cell cycle regulators, cytotoxins, or immunomodulators, and none of
them are of retroviral origin. All selected targets will be presented to the GMSC for approval.

Methods

The approach to be taken will be the application of lentiviral vectors to cell lines that are deemed biosafety level 2
or lower, including well characterised immortalised cell lines that are known not to contain lentiviral genetic
material, and human induced Pluripotent stem cells (iPSCs). The lentiviral vectors will either express siRNA
transcripts targeting specific mRNAs/proteins of interest, or with vectors expressing scrambled siRNAs, in the case
of the negative control treatment groups. The extent of mRNA and protein knockdown that is achieved will then be
assessed at different time points (e.g. 24h-48h-72h), post-transduction, using suitable in vitro assays, including for
example, RT-PCR, Western Blotting, and immunocytochemistry. Once the conditions that lead to the optimal
knockdown of the mRNAs/proteins have been determined, it will be evaluated what effects the knockdown of the
proteins have on various physiological parameters, including, for example, the release of specific neurotransmitters
from neurons or the expression of related proteins. These siRNA-induced alterations will be measured using
suitable in vitro assays, including, for example, ELISA, PCR, neurite outgrowth, electrophysiology, and
neuroprotection assays. In some instances, the vectors might need to be studied in neuron-glia co-cultures in order
to investigate the interaction between these two cell types.

Description of the lentiviral vectors used for the experiment

Third generation HIV based shRNNmiRNA expressing lentiviral vectors will be produced either internally or
sourced from external suppliers, which will include reputable commercial suppliers, and an academic group at the
University of Bristol headed by Prof. James Uney. Each aliquot of lentiviral reagent will comprise of a small volume
(5 to 30μl) that contains no more than 1x10^8 viral particles. Post-transduction of target cells, the vectors will
produce both a shRNNmiRNA targeting the mRNAs of a protein of interest, and a reporter protein to facilitate the
identification of transduced cells.

Recipient or parental organism

Mammalian Cells

Host/vector system

Vector system = self inactivating (SIN) non replication-competent HIV based lentiviral vectors

Health and Safety

Executive

The viral vectors that will be used in the proposed studies are third generation self-inactivating (SIN) non
replication-competent HIV based lentiviral vector systems, which have been designed to produce stable gene
expression in mammalian cells; and they are generated by co-transfecting a suitable immortalized packaging cell
line (e.g. HEK 293T cells) with four separate plasmids. Each of the plasmids used (described below) expresses a
different set of genes, and all of the genes from the different vectors, when combined (following co-transfection),
provide the smallest possible set of essential viral genes that is still compatible with virus production. Moreover, the
resultant vectors are all vesicular stomatitis virus (VSV-G) pseudotyped lentiviral vectors, which are self-inactivating
and highly unlikely to undergo recombination. Importantly, the viral vector system is inherently incapable of
replication in mammalian cells. Only in a patient with HIV could any form of recombination occur, i.e. the probability
of the production of replication competent lentiviral vectors (RCL) is very small.

The plasmids

The sequences that are required to generate the viral vectors are sub-cloned into 4 standard bacterial plasmid vectors. The transgene expression plasmid will contain the transgene that codes for a relevant siRNA sequence and/or a transduction marker protein (e.g. GFP), while the other 3 packaging plasmids will contain 3 different sets of sequences that code for different viral packaging proteins. A brief overview of the 4 different plasmids is provided below:

Plasmids containing the transgene of interest

The transgene expression plasmid will contain the sequences that code for the siRNA transcript that will target a specific mRNA protein of interest (or a scrambled siRNA in the case of the negative control), and also for a transduction marker protein. Control viral vectors that express only a marker protein and no siRNA will also be used in some experiments, and the corresponding plasmids for these vectors will only contain the sequence coding for the marker protein. Depending on the knockdown strategy taken, either shRNA or miRNA based constructs will be used to express the artificial siRNA sequences. In some of the constructs used, siRNA and marker protein sequences will be expressed as two separate transcripts under the control of two separate promoter elements. In other instances, siRNA and marker protein expression will be under the control of a single promoter system. The promoter elements used to control transgene expression will vary depending on the specific plasmid that is employed. Only well characterized promoter systems will, however, be used to drive transgene expression. These will include the H1, U6 small nuclear, cytomegalovirus (CMV), elongation factor 1 alpha (EF1α), phosphoglycerate kinase (PGK), ubiquitin C (UbC), and murine stem cell virus (MSCV) promoters; or in instances where siRNA expression in a specific cell subtype is desired, polymerase III promoters such as the synapsin I (SynI), neuron specific enolase (NSE), tyrosine hydroxylase (TH), calcium/calmodulin-dependent protein kinase II (CamKII), or glial fibrillary acidic protein (GFAP) promoters.

Additionally, all of the transgene constructs will contain the WPRE, cPPT, RRE, and 41 sequences, as well as the modified LTR, and these sequences are the only other coding sequences (apart from the siRNA and transduction marker proteins) that will be present in the viral vectors. The latter elements are important for the expression of the shRNA in targeted cells, and they will all be stably expressed in infected cells.

Plasmids containing the packaging related sequences

The three other plasmids that make up the 4 plasmid system will each contain a different set of sequences that code for proteins that are required for production and packaging of the viral vectors. Gag-pol will be expressed by one of the plasmids, rev by a second, and VSV-G by a third, and the latter proteins will only be provided in trans during the production phase. The specific packaging plasmids that will be used will vary depending on the packaging system that is employed. Only well characterized packaging plasmids will, however, be used in all cases. For example, in one system, gag-pol, rev and VSV-G will be expressed separately by pMDLgp-RRE, pRSVREV, and pMD2-VSVG.env packaging plasmids, respectively, whereas, in a second, they will be expressed by pPACKH1-GAG, pPACKH1-REV, and pVSV-G, respectively. Importantly, all of the above genes, that are essential for production of full length viral particles, have been removed from the expression plasmids containing the transgenes of interest. The 4 plasmids used in the system have also been engineered so as to have no common sequences, which greatly reduces the risk of a recombination event that would result in the insertion of production/packaging genes into the transgene expression plasmid.

The expression systems and the transgenes that comprise the lentiviral vectors that will be used have a very low risk for human health and safety, and the reasons for this are discussed below.

Lentiviral Vector Expression System
Lentiviruses belong to the Retroviridae virus family, a diverse and extensive family of viruses, which are capable of infecting both human and animal species. Retroviruses are characterised by a unique replication mechanism involving reverse transcription of the viral RNA genome, which gives rise to a DNA provirus that contains two positive sense copies of the viral RNA genome; and in a functional assembled virus, the viral genome is encased within a capsid that is surrounded by a host-cell derived envelope. Cellular entry of the virus involves interactions between glycoproteins contained in the virion's envelope and extracellular plasma membrane proteins on target cells. These interactions are generally specific and are believed to be the principal factor determining which species and type of cells a specific virus is capable of infecting. The binding of a virus's envelope glycoproteins to an appropriate receptor site on a target cell triggers the fusion of the virion's envelope membrane with the plasma membrane of the target cell, which results in the delivery of the virus capsid to the intracellular space of the target cell.

As the lentiviral vector system that will be used in these studies is based on HIV-1, a theoretical risk to human health exists. Retroviruses are, however, generally transmitted via exposure to contaminated body fluids or percutaneous inoculation and, they are, generally, not transmitted via the airborne route. Accidental piercing of the skin or other surface tissues with virus containing objects, therefore, represent the main potential route by which accidental infection could occur. Appropriate risk reduction measures will, however, be implemented to reduce the likelihood of this occurring.

In all of the transgene expression plasmids, the genes of interest are flanked by non-coding retroviral TRs, and no retroviral genes are encoded on the transgene plasmids. Therefore, no retroviral genes will be transferred into generated viral particles. The transgene construct is packaged into particles using an immortalised cell based packaging system, which requires the co-transfection of packaging cells (e.g. HEK293 cells) with three additional separate packaging plasmids (pMDLgp-RRE, pRSV-REV and PMD2-VSVG.env, for example). The latter 3 plasmids express the envelope protein from VSVg and the non-structural proteins of the virion, and, importantly, none of these genes will be transferred into the assembled viral vectors, since they lack the packaging signal (+), which is only present on the transgene containing plasmids.

The lentiviral Expression System that will be used include the following key safety features:

All of the lentiviruses will be generated using a 4 plasmid/3 retroviral gene (gag, pol, rev) system, which yields replication-incompetent vectors that are devoid of all viral sequences, apart from essential cis-acting sequences, including the L TRs and the packaging signal '+', and only the transgene plasmids will contain +1. This system allows for the expression in trans of proteins required to produce viral progeny (e.g. gal, pOl, rev, env) in producer cell lines, which do not contain L TRs or the'+ packaging sequence. None of the retrovirus structural genes will, therefore, actually be present in the packaged viral genome, which means that no new replication-competent lentivirus (RCL) can be produced.

Importantly, following infection of a target cell, lentiviral vectors are self-inactivating on integration into the host genome. This is achieved because the process of reverse transcription uses the 3' long terminal repeat (3' TR) as a template to produce the 5'TR. In the transgene expression plasmids that will be used, the U3 region of the 3'TR has been deleted, resulting in deletions in both 3' and 5' L TRs on integration into the host genome. The deletion in the 3'TR (uU3) does not affect generation of the viral genome in the producer cell line, but results in "self-inactivation" (SIN) of the vector after transduction of target cells, which ensures that the viral genome cannot be released from the host genome.

Moreover, deletion of enhancer and promoter elements from the 3' U3 region in the vector constructs will result in a provirus that is entirely devoid of the U3 enhancer sequences, which will result in a reduction in the potential for transactivation of cellular genes due to an insertion event. Self-inactivating vectors are also less likely to be
mobilized following a superinfection with wild-type virus (HIV), and the VSV-G gene from Vesicular Stomatitis Virus is used in place of the HIV-1 or other retroviral envelope genes, obviating safety concerns associated with the use of HIV-1 gp120, which has known pathogenic consequences. Importantly, all of the 4 plasmids used in the system have been engineered not to contain any regions of homology with each other so as to prevent undesirable recombination events that could lead to the generation of a (RCI).

Lentiviral production - on site B60CRP or 430CSP

Lentiviral production will also be carried out on-site. Lentiviral production will only be carried on HEK293T cells and will be carried out in a class 2 microbiological safety cabinet (MSC) within a dedicated Level 2 laboratory. The HEK293T cells used for lentiviral production will be seeded in filter containing screw cap culture flasks in order to minimize the risk of spills and/or aerosol mediated viral spread. For this, a modified pRRL transgene expression plasmid together with three additional separate packaging plasmids (pMDLgp-RRE, pRSV-REV and PMD2-VSVG.env) will be transfected using a transfection reagent (e.g. Polyethylenimine (PEI), Lipofectamine) into HEK293T cells. After 6-12 hours, the medium is replaced with fresh serum-free medium (Neurobasal medium with 2% B-27 supplement and 1X Pen/Strep) and grown for an additional 72-96 hours. After 24-48 hours, so as to ensure the viability of the transfected HEK293T cells, medium from the cells is collected into screw cap tube and stored at 4°C and fresh serum-free medium is added to the cells. The cells are grown for an additional 24-48 hours before the second medium solution is added to the first harvest tube. After lentivirus collection has been completed, the cells in the flask will be treated with a validated anti-microbial agent (e.g. DISTEL 10% or another equivalent product) for at least 24 hours prior to autoclaving on site. Autoclaved material will then subsequently be incinerated. Still within a Class 2 MSC in a Level 2 Biosafety laboratory, the harvested supernatants will be filtered using a 0.45 micron filter before either aliquoted or further purified by chromatography and/or concentrated by centrifugation. For certain applications, the lentiviral particles will need to be concentrated. The lentiviral particles may need to be purified by either chromatography (e.g. ViraBindTM) and eluted in a high salt solution (50mM Tris, pH 7.5, 5mM MgCl2, 2M NaCl) and/or concentrated by ultrafiltration (e.g. LentiSelectTM). For certain applications where highly concentrated, highly purified virus may be required, the traditional method of sucrose cushion based centrifugation may be necessary. To minimise the possible risk of accidental viral contamination and spread due to the need for an ultracentrifuge, all loading and unloading will be done in a class 2 MSC. Once the sucrose cushions have been added to the centrifuge tubes, they will be transferred into a class 2 MSC. The unpurified or chromatography purified lentiviral particles will then be added to the sucrose cushion. The tubes will then be transferred to their respective bucket holders and the bucket sealed using their respective screw caps and marked as containing virus. The bucket will be transferred to a weighing scale and a counterpart bucket and centrifuge with water (and without lentivirus) will be prepared that is weight matched. The balanced buckets will then be transferred to the rotor before being placed within the centrifuge chamber. The ultracentrifuge will be run at 70000g for 2 hours at 20°C. Upon return of the buckets to the class 2 MSC, the supernatant will be removed from the tubes before transfer of the resuspended virus pellet into screw cap cryovials. As the greatest risk for contamination occurs within the centrifugation buckets themselves during transport to and from the weigh scales and ultracentrifuge, not only will the centrifuge tubes but also the buckets decontaminated with DISTEL 10% and 70% isopropanol before removal from the level 2 laboratory. In any case, at no point will concentrated virus stock be exposed to outside of the class 2 MSC environment.

The lentiviral titre will be determined in terms of the number of viral particles (VP) or Transduction units (TU) per mL. Assessing the number of VP can be assessed relatively quickly and does not involve cell infection. In this case, a bead based enrichment assay (e.g. QuickTitre™ Quantification Kit) or a p24 ELISA assay (e.g. QuickTitre™ Lentivirus Titre kit) will be chosen. The VP quantification methods tend to overestimate the TU by 10-1000 fold.
Thus, the TU I ml will in certain instances also be determined. For this, a titration range of lentiviruses expressing a fluorescent tag, serial dilution will be prepared and added to a 24 well cluster plate or T25 TC-flasks containing HEK293T for 48 hours. The percentage of fluorescent positive cells will be quantified manually under a fluorescent microscope or ideally using FACs analyser.

Aliquots with not more than 1x10^8 virus per vial are subsequently stored at -80°C in screw capped cryotubes. The viral stock will consist of viral particles containing the vector genome (full capsids) and also of a variable number of empty viral capsids. Other trace components that might be present include, but are not limited to, inorganic salts, vitamins, other nutrients, human cellular proteins, carbohydrates, amino acids, and fats.

**Origin & function**

Transgene: proteins to be expressed

Health and Safety

Executive Additional hazards that also arise from the properties of the genetic material that will be inserted into the viral vectors and expressed in transfected cells.

A. Transduction Marker Proteins

Only well characterised transduction marker proteins that are not associated with any cytotoxic, immunogenic or oncogenic responses will be employed, including, for example, Fluorescent proteins such as GFP, GFPem, YFP, OsRed, mCherry, CFP.

B. shRNNmiRNA: Endogenous proteins to be depleted

The proteins that will be selectively knocked down by lentivirally expressed siRNA will include proteins that have been either directly or indirectly linked to psychiatric and/or neurodegenerative disease states; and, in most cases, the targeted proteins will play a role in well characterised relevant disease-related biological/pathological processes. Relevant neurodegeneration related processes, for example, are likely to include, bioenergetics, oxidative stress, neuro-inflammation, protein misfolding, excitotoxicity, and autophagy. Psychiatric disease related targets, on the other, are likely to play a role in neurogenesis, neural plasticity, or the functioning of one or more disease-linked neurotransmitter systems.

Importantly, the genes/proteins of interest that will be targeted by siRNAs do not include any growth factors, confirmed oncogenes, tumour suppressors, cell cycle regulators, cytokotoxins, or immunomodulators, and none of them are of retroviral origin. Depending on project objectives and human vs. rodent mRNA sequence homology, siRNA sequences will be designed either to specifically target only the human or mouse/rat mRNA sequence of a target protein, or both the human and mouse/rat sequences.

RNA interference (RNAi)

RNA interference (RNAi) is an antisense technology that exploits a normal cellular antiviral response that acts to inhibit viral protein synthesis through the production of short hairpin RNAs (shRNAs) that bind and target viral double-stranded RNA (dsRNA) molecules for degradation. The shRNA molecules are processed by cellular enzymatic pathways to produce small inhibitory RNA (siRNA) species, and it is the latter RNA molecules that bind and target complementary RNA sequences for degradation by the RNA-induced silencing complex (RISC). With the use of shRNA-expressing viral vector systems, the expression of specific mammalian genes/proteins can be 'knocked-down', in order to study their functions.

Potential deleterious effects such off-target and immunomodulatory responses can be minimised through screening designed siRNA sequences against databases of known mammalian gene/mRNA sequences during the design stage.

MicroRNAs (miRNAs) are endogenously encoded 22-nl-long RNAs that are generally expressed in a highly tissue and/or developmental-stage specific fashion, and they function to post-transcriptionally regulate the expression of
target genes. In certain experimental RNA interference approaches, this miRNA system can be
harnessed/manipulated to study the functions of specific genes/proteins. The additional benefit is that one can
place these miRNA sequences under the control of a Polymerase II promoter in which the miRNA or multiples
thereof are co-transcribed with a coding sequence. For example, RNA polymerase II promoters can be
experimentally activated so as to over-express endogenous microRNAs in cell culture systems. Alternatively,
artificial microRNAs can also be engineered to match the features of existing microRNA genes, such as the gene
encoding the human miR-30 microRNA. In an analogous method, the BLOCK-iTTM Pol II miR RNAi expression
vectors from life Technologies allow for selected miRNA sequences that are flanked on both ends with flanking
sequences that allows for their successful transcription under a Polymerase II promoter. Additional coding
sequences containing a fluorescent protein tag are placed 5’ to the miRNA.

Some of the viral vectors that will be used contain a sequence of interest that has been scrambled (scrambled
shRNAlmiRNA), and which is not complementary to any known mammalian sequences. These vectors will be
employed as negative controls to demonstrate that any observed effects are due to the knockdown of a specific
mRNA/protein of interest, rather than being due to any non-specific effects that the delivery of the viral vectors
might cause. This sequence will adopt a hairpin structure as with any shRNA/miRNA, but it should not target any
mRNA of mouse, rat or human origin. It will only serve as the negative control for the vector producing
shRNA/miRNA. Consequently, these sequences are unlikely to pose any safety risks for the environment or human
health.

Summary
The transgenes that will be expressed by the viral vectors have a very low safety risk to human health. This is
because accidental contamination with a vector would lead to only a small number of cells becoming infected, and
it would be highly unlikely that expression in only a few cells would be sufficient to lead to a disease state. The
inability of the lentiviral vectors to propagate in mammalian cells also reduces the risk.
The transduction marker proteins that will be employed are not known to cause any relevant toxicities, and the the
genes/proteins of interest that will be targeted by siRNAs do not include any growth factors, confirmed oncogenes,
cytotoxins, tumour suppressors or immunomodulalors, and none of them are of retroviral origin.

Evaluation of foreseeable effects

Human health hazards
Although the lentiviral vectors that will be used are replication incompetent and contain only -20% of the original
HIV-1 genome, there is a small risk that subsequent infection of cells already infected with the lentiviral genome by
HIV-, could lead to a rare recombination event in which the transgene is transferred to a replication-competent
virus. Thus, the sequences in the vector that will be expressed could potentially be transferred to surrounding cells.
This event is, however, extremely unlikely to occur, and it has been shown that, even under permissive in vitro
conditions, wild-type HIV-1 cannot rescue a self-inactivating HIV-1 based lentivirus once integrated into the host
genome (Bukovsky et al 1999).
Additionally, there is a theoretical risk that an infection event with the vectors could lead to the infected cells
becoming cancerous, as lentiviral integration into a host genome could potentially lead to the activation of an
endogenous oncogene. All transcriptionally active long-terminal repeats (LTRs) have, however, been removed from
the viruses as well as all promoter-like elements other than that required to drive expression of the transgene.
which should prevent unforeseen activation of such genes. The deletion of the retroviral enhancer in self-inactivating
systems reduces the risk of activation but not of disruption and therefore, retroviral infection might still
have permanent effects upon a cell (including oncogenic effects).
Importantly, the likelihood of a worker becoming accidently infected is, however, considered to be low, as
appropriate risk reduction measures will be implemented. Notably, micro-syringes will be filled with viral vectors
only in a class 2 MSC to avoid the production of aerosols. The most likely route of accidental infection with a
fentivirus will be via inadvertent percutaneous inoculation. The likelyhood of this occurring will be minimised by following the correct procedures. Oral ingestion will be prevented by standard laboratory safety practices. Moreover, the genes/proteins of interest that will be targeted by shRNAs do not include any growth factors, confirmed oncogenes, tumour suppressors, cytotoxins, or immunomodulators, and none of them are of retroviral origin. In the unlikely event of accidental transduction of a laboratory worker's skin or mucosa by lentivirus particles, this will be self-limited, due to natural shedding of superficial epithelial skin and mucosal cell layers.

HAZARDS TO THE ENVIRONMENT
The chance that active viral particles will be accidentally released into the environment is considered to be highly unlikely, as effective containment procedures will be adhered to. However, in the unlikely event that active viral vector particles do accidently get released into the environment, the safety risks posed by such an event is considered to be negligible, due to the vectors being self-inactivating and non-replicative. The main potential risk in such an event would be the subsequent contamination of a human population already infected with HIV, which would potentially allow for recombination events that could incorporate the inserted sequences into a viable RCL. This scenario is, however, extremely unlikely, and even if it was to occur, it is unlikely that it would lead to any untoward effects.

The vectors have been pseudolyped with the VSV-G envelope in order to increase tropism, and they are, in theory, capable of transducing all dividing and non-dividing mammalian cell types. As emphasised before, the vectors, however, cannot self-propagate after infection, and successful transduction is also critically dependent on the presence of high enough concentrations of virus particles; and viral vector stock solutions will be managed in a way that will prevent contaminations with relatively high viral titres. After production, the vectors are aliquoted and stored in small volumes (each tube contains at maximum 30μl) at -80°C, and when taking into account that the infectivity of the vectors rapidly decrease at room temperature, it is considered highly unlikely that the vectors could survive in the long term after being accidentally released into the environment.

There are no conceivable hazards associated directly with the lentiviral vectors (containing the inserts) as they will not replicate/survive outside the laboratory and they have been designed to include many protective safety features. shRNA and miRNA sequences will also not survive as they are highly unstable, and they would, consequently, be rapidly inactivated/degraded if accidentally spilled into the environment. Moreover, as discussed above, there is a very low risk that the sequences contained within the viral vectors could be transferred to other organisms, as a rare recombination event would have to occur to allow this to happen.

Summary
The chance that active viral particles will be accidentally released into the environment is considered to be highly unlikely, as the viral vector studies that will undertaken have been classified as CL2, and effective containment procedures will be adhered to. However, in the unlikely event that active viral vector particles do accidently get released into the environment, the safety risks posed by such an event is considered to be low due to the vectors being self-inactivating and non-replicative, and also due to the poor ability of the vectors to survive outside of their host systems (see above discussions).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Following transduction of eel lines that are designated as requiring Biosafety Containment level1 with lentivirus, we wish to be able to subsequently use these cells at Biosafety Containment level1. This can be justified by the following procedure: under Biosafety Containment Level 2 media containing virus will be removed, the transduced cells will be extensively washed to remove any remaining virus. This liquid waste will be neutralised for at least 24
hours before disposal. The washed cells will then be cultured for a further 24 hours before being tested for the absence of infectious virus before being allowed to be treated as only requiring Biosafety Containment Level 1. Sources of iPSC cells that have been shown to lack viral integration and test negative for infectious virus can be regarded as requiring biosafety level 1 containment. Such iPSC cells can also be derogated to biosafety level 1 containment once tested for the absence of infectious virus.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

General waste handling procedures:
SoUt waste will be neutralised by soaking it in a validated disinfectant solution for 24 hours, after which the material will be 'double bagged', autoclaved and, ultimately, incinerated offsite. At B60CRP, liquid waste will be disposed of into sealed biohazard containers filled with Virkon® for incineration. It will be routine practice that all liquid waste material be neutralised before disposal, and for the neutralised waste to be transported in leak-proof containers to prevent spillages. At 430CSP, liquid waste will be inactivated by Virkon® for 24 hours prior to drain disposal.

• Virkon

Virkon® is a multi-purpose disinfectant. It contains oxone (potassium peroxymonosulphate), sodium dodecylbenzenesulfonate, sulphamic acid; and inorganic buffers. Virkon oxidizes key structures and compounds, such as proteins, leading to widespread, irreversible damage and subsequent deactivation/destruction of the microorganism. It is typically used for cleaning up hazardous spills, disinfecting surfaces and soaking equipment. With powerful, proven performance against over 500 strains of viruses, bacteria and fungi, Virkon offers a broad spectrum efficacious anti-microbial activity, and it is used by governments worldwide for Emergency Disease Control. Importantly, Virkon has specifically been validated for lentiviral inactivation (Antec-Biosentry); Virkon is sold as a powder which dissolves readily in water. It is intended to be mixed with water to form a 1% solution (i.e. 10.9 per litre) for hard surface and equipment disinfection. 1:100 is also the dilution rate advised for virucidal efficacy against HIV-1.

The product has a pink colour, which is useful in that it helps 10 gauge the concentration of a prepared solution, and importantly, as Virkon ages, it discoulers, making it obvious when it needs to be replaced. The solution is generally stable for five to seven days. Moreover, there is no evidence to suggest that bacterial disease-causing organisms develop resistance towards Virkon, as opposed to some other disinfectant products. Moreover, Virkon is not classified as R53, it is classified as readily biodegradable, and it does not persist in the environment.

• Distel

Distel is formulated as a nanoemulsion that enables the active molecules in the product to be carried rapidly through cell walls of micro-organisms, ensuring the rapid induction of cell death in treated micro-organisms. Distel works quicker than conventional high level disinfectants and achieves apoptosis (cell death) rather than merely suspending activity as with conventional disinfectant products. Distel has been reported to be bactericidal, fungicidal as well as virucidal and sporicidal. It is recommended to be used at a 1:200 dilution for general purposes, 1:100 for high risk areas, and 1:50 for disinfection of blood and bio-hazard spillages.

Summary

As any active viral particles on surfaces or in waste material will be completely inactivated at the end of each experiment by the highly effective cleaning/disinfection protocols outlined above, it is considered highly unlikely that active virus particles would unintentionally become discharged into a sanitary sewage system. No foreseeable adverse effects on human health and safety are expected.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N
The GMSC has agreed that the production, handling and use of lentivirat siRNA stocks is a Class 2 activity. This decision has been reached because although the lentivirus will be generated using a third generation, self-inactivating, 4 plasmid expression system, the possibility of a recombination event occurring that leads to replication competent virus can never be discounted with this type of virus. The potential oncogenic effects of the Woodchuck Post-translational Regulatory Element have been negated by the use of the mutant form that prevents expression of the X protein. The proposal includes the potential to produce large amounts of virus. This represents the most hazardous aspect of the proposal and the GMSC is satisfied that the necessary precautions have been put in place to ensure containment is maintained. Some of the proposed lentivirus may encode for proteins that are known to have neurotoxic effects and are associated with diseases of the human central nervous system. The procedures put in place will effectively prevent any chance of virus being delivered to the necessary tissues within a human in sufficient quantities to represent a hazard to human health. The FP and shRNmiRNA encoded by the other lentivirus are not known to pose any inherent risk to human health or the environment. The proposed targets to be knocked down in this study also pose no known risk. The request to derogate the Biosafety Containment level from 2 to 1 post transduction has been deemed acceptable given that the transduced cells will be washed extensively to remove any remaining viral particles and will be tested for the absence of transducing virus. It has been made clear that human iPSC cell lines that have been generated using lenti- or retrovirus methods tested negative for the absence of virus at least. These cells will always be tested for the absence of infectious particles before being can be used as if they only required Biosafety Containment level 1.

Project Ref 3043/15.1

Date Ackn'd | CU2 Project Title | Class | CultureVolClass2 | CultureVolumeClass3-4 |
------------|-------------------|-------|------------------|-----------------------|
26/02/2015  | Generation, production and utilisation of lentiviral particles for delivery of | Class 2 | < 1 Litre |
The purpose of this project is to use lentivirus to deliver programmable nucleases, specifically zinc finger nucleases and Cas9/CRISPR, to disrupt gene function in mammalian cultured cells. The primary aim is to use gene targeting to validate novel targets for drug discovery and to set up disease relevant model systems in vitro.

Recipient or parental organism

Rodent Origin: Immortalised cell lines.
Human Origin: HEK293T, immortalised cell lines and induced pluripotent stem cells

Host/vector system

Lentivirus vectors: The four plasmids that will be used will be a modified version of pRRL, pMDLgp-RRE, pRSV-REV and PMD2-VSVG.env. The latter three are required for the production of the SIN replication defective lentiviral particles in HEK293T cells. The target shRNA/miRNA or gene will be inserted into the modified pRRL vector. This modified vector will have the following safety features: a deletion in the 3’LTR making it SIN in the infected cells, the packaging sequence is only found in the pRRL with the packaging constructs being provided by the remaining non-LTR containing plasmids. Lentivirus vectors: pMDLgp-RRE, pRSV-REV and PMD2-VSVG.env. The Tat promoter has been replaced by Polymerase Type 2 promoter, making them replication incompetent. The inclusion of these features ensures that the production of these SIN replication defective lentiviral particles only occurs in the transfected HEK293T. Outside of this setting, viral replication cannot take place and so pose a minimal risk to both humans and the environment.

Origin & function

The proposal involves the use of existing lentiviral constructs purchased commercially and the generation of new constructs on site. These constructs will contain a combination of programmable nuclease plus accessory sequences and a fluorescent protein as lineage marker. In some cases constructs will contain a combination of programmable nuclease plus accessory sequences and a selectable marker giving rise to a selectable trait in transduced cell lines. Programmable nucleases function by binding to, and cleaving, user-defined target DNA sequences. This in turn instigates a robust DNA repair response which ultimately leads to disruption of the target sequence by deletion at the cleavage site or by recombination with user-supplied synthetic vector containing sequences complementary to the target gene. Insertion of the sequences into the third generation lentiviral vector on site will be achieved by either conventional cloning or Recombineering. Lentiviral particles will either be purchased ready for use or produced in-house using the third generation system described below. Nuclease encoding lentivirus may be used in isolation or co-transduced with lentivirus encoding a targeting construct designed to recombine and insert defined sequences into the target gene.
The SIN-RD (Self-Inactivating-Replication Deficient) lentiviral particles will contain a combination of the following sequences:

1. Programmable nucleases (Zinc fingers and Cas9/CRISPR) designed to cause double stranded breaks in particular endogenous mammalian targets (Mouse, Rat, Human).

2. Fluorescent protein markers that are known to be benign in terms of their effects when expressed in mammalian cells but are essential for visualisation of these cells. When these in addition are fused to a subcellular marker gene, subcellular visualisation of a particular process can be visualised.

3. Selectable marker for conferring a selectable trait to mammalian cells in vitro. Exposure to the relevant compound will result in survival of cells containing the viral vector (positive selection) or elimination of cells containing the viral vector (negative selection).

A. Programmable nucleases: zinc finger nucleases and Cas9/CRISPR

Zinc finger nucleases and Cas9/CRISPR are both programmable nucleases systems that are designed to cause cleavage of a pre-determined DNA sequence. Zinc fingers are proteins of mammalian origin comprising a DNA binding domain which confers sequence specificity and a nuclease domain which cleaves the target sequence subsequent to precise binding. Cas9/CRISPR is a bacterial protein/RNA complex that contains a nuclease domain and an RNA-binding domain; the sequence specificity of Cas9 is determined by the sequence of the RNA (referred to as the guide RNA) with which it is complexed. To effect cleavage the guide RNA has to be supplied by co-expression with Cas9.

Zinc fingers or Cas9 protein will be directed against genes of therapeutic interest identified by literature reports or by in-house screens. Since the purpose of programmable nucleases is to cause mutations in defined DNA sequences the primary hazard is that such a mutation would lead to deleterious cellular effects. The genes/proteins of interest that will be targeted do not and will not include any growth factors (which does not include trophic factors), confirmed oncogenes, tumour suppressors or immunomodulators. In isolation these sequences are unlikely to pose any safety risks for the environment or human health.

B. Fluorescent protein tag proteins:

Genetically encoded Fluorescent proteins, such as green fluorescent protein (GFP), have been widely used as a reporter for biological research over the past decades. Their exogenous expression is not associated with any cytotoxic, immunogenic or oncogenic response. A large selection of different FP constructs have been and continue to be generated, which differ in their optical and stability properties. A current non-exhaustive list of such FPs that will be used include, GFP, GFPem, YFP, DsRed, mCherry, CFP. Further variants that may be used can be found here (http://www.einstein.yu.edu/research/facilities/fluorescent/)

C. Selectable markers

Genes that confer resistance or sensitivity to antibiotic compounds are routinely used in mammalian cell culture. Examples include Neo (G418 resistance), Puro (puromycin resistance), Bsd (blasticidin resistance), Hyg (hygromycin resistance), Zeo (zeocin resistance), and HSVTK (gancyclovir sensitivity). All of these genes have been used extensively in mammalian cell genetics with no reported adverse effects in humans or animals.

Evaluation of foreseeable effects

Procedures

During all procedures that involve the handling/use of the viral vectors, all workers (incl. those that are not working directly with the vectors) that are present within a lab where the work is undertaken are required to wear personal protective equipment (incl. both appropriate clothing and gloves) at all times. The use of two pairs of gloves is advised so the external pair can be disposed in an autoclave bag and replaced whenever necessary (e.g. in the case of contact with the viral reagent). Face masks are also available for use, where appropriate. In addition, all workers are made aware of the nature of the viral work that is going on within the laboratory, and they have to follow appropriate procedures to ensure that there is no cross-contamination into non-viral working areas. All the workers using the viral delivery systems are experienced research scientists, and junior scientists will be closely supervised until they are competent in the handling of the viruses.

In vitro assessment

Assessing whether the genome manipulation has worked will be carried out by a combination of PCR and sequencing, and will normally take place initially in biosafety level 1 immortalised cell lines that are known not to contain lentiviral genetic material. Application of lentiviral particles will be done at Biosafety level 2. After at least 24 hour incubation and extensive washing, the cells will be treated as Biosafety level 1 (see below the justification for derogation of cells post-infection to Biosafety level 1). Once validated the same procedure will be carried out in the target cell line which will be immortalised biosafety level 1 cell lines or human induced Pluripotent stem cells (iPSCs).
In the latter case these will subsequently be differentiated into defined lineages for phenotypic analysis by manipulating the culture conditions. Where viral transduction is undertaken on a class 2 cell line the resultant material will remain under biosafety level 2 conditions. In all cases phenotypic analysis will be performed using suitable in vitro assays, including for example, RT-PCR, Western Blotting, immunocytochemistry and imaging.

Human health hazards
The methods by which the lentivirus vector is produced means that it is highly unlikely that replication competent lentivirus (RCL) can be generated even if an infection occurs in a person who is HIV-1 positive. Infection can lead to a permanent transduction of cells and the possibility of a harmful event either by transactivation or disruption of gene expression cannot be ruled out. For this reason the work with stock viral aliquots will be conducted as a class II activity. Oral ingestion will be prevented by standard laboratory safety practices. Aerosol formation resulting from an accident outside of the safety cabinet and involving lentivirus particle-containing liquid may lead to transduction of a limited number of the laboratory worker's skin or mucosal cells with modified viruses, due to the inherent properties of the viral vectors. Moreover, the genes/proteins of interest that will be targeted by shRNAs do not include any growth factors, confirmed oncogenes, cytotoxins, or immunomodulators, and none of them are of retroviral origin. In the unlikely event of accidental transduction of a laboratory worker's skin or mucosa by lentivirus particles, this will be self-limited, due to natural shedding of superficial epithelial skin and mucosal cell layers.

The most likely route of accidental infection with a lentivirus will be via inadvertent percutaneous inoculation. The likelihood of this occurring will, however, be minimised by adherence to appropriate risk management measures. Infection of the community at large with lentivirus particles is highly unlikely due to the viral vector particles being replication incompetent and being extremely sensitive to dessication.

Hazard to the Environment
The probability that active viral particles will be accidentally released into the environment is considered to be extremely low, as effective containment procedures will be adhered to. However, in the unlikely event that active vector particles do accidentally get released into the environment, the safety risk posed by such an event is considered to be negligible, due to the vectors being self-inactivating and non-replicative. The main potential risk in such an event would be the subsequent contamination of a human population already infected with HIV, which would potentially allow for recombination events that could incorporate the inserted sequences into a viable RCL. This scenario is, however, extremely unlikely, and even if it was to occur, it is unlikely that it would lead to any untoward effects.

The vectors have been pseudotyped with the VSV-G envelope in order to increase tropism, and they are, in theory, capable of transducing all dividing and non-dividing mammalian cell types. As emphasised before, the vectors cannot self-propagate after infection, and successful transduction is also critically dependent on the presence of high enough concentrations of virus particles; also viral vector stock solutions are aliquoted and stored in small volume (each tube contains at maximum 10µl at 80° so the potential for a high titre dose is reduced. The infectivity of the vectors rapidly decreases at room temperature so it is considered highly unlikely that the vectors could survive long enough in the environment to pose a risk if accidentally released.

Furthermore, lentiviral vectors have a short half-life at room temperature as their structural characteristics make them highly susceptible to dehydration, and relatively unstable. For this reason, retroviruses become rapidly inactivated outside host systems, and this is illustrated by the fact that close contact is required for transmission. They can, however, survive for long periods in high protein media.

There are no conceivable hazards associated directly with the lentiviral vectors (containing the inserts) as they will not replicate/survive outside the laboratory and they have been designed to include many protective safety features. shRNA and miRNA sequences will also not survive as they are highly unstable, and they would, consequently, be rapidly inactivated/degraded if accidentally spilled into the environment. Moreover, as discussed above, there is a very low risk that the sequences contained within the viral vectors could be transferred to other organisms, as a rare recombination event would have to occur to allow this to happen.

Summary
The chance that active viral particles will be accidentally released into the environment is considered to be highly unlikely, as the viral vector studies that will be undertaken have been classified as Biosafety level 2, and effective containment procedures will be adhered to (see section C for details). However, in the unlikely event that active viral vector particles do accidentally get released into the environment, the safety risks posed by such an event is considered to be low due to the vectors being self-inactivating and non-replicative, and also due to the poor ability of the vectors to survive outside of their host systems (see above discussions).
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Following transduction of cell lines that are designated as requiring Biosafety Containment Level 1 with lentivirus, we wish to be able to subsequently use these cells at Biosafety Containment Level 1. This can be justified by the following procedure: under Biosafety Containment Level 2 media containing virus will be removed, the transduced cells will be extensively washed to remove any remaining virus. This liquid waste will be neutralised for at least 24 hours before disposal. The washed cells will then be cultured for a further 24 hours before being tested for the absence of infectious virus before being allowed to be treated as only requiring Biosafety Containment Level 1. Sources of IPSC cells that have been shown to lack viral integration and test negative for infectious virus can be regarded as requiring biosafety level 1 containment. Such IPSC cells can also be derogate to biosafety level 1 containment once tested for the absence of infectious virus.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

General cleaning procedures
Surfaces will be thoroughly cleaned with Virkon* Or Distel 10% (or an equivalent product) at the end of each experiment or after the occurrence of an accidental spillage of infectious material. Application of these anti-microbial agents will totally inactivate any viral vectors that might be present. According to the biosafety literature, all of the viruses to be used are susceptible to these disinfectants. Anything that might have potentially come into contact with the virus will be treated with Virkon* or Distel 10% before being autoclaved/incinerated.

Waste handling procedures
Solid waste will be inactivated by soaking it in a validated disinfectant solution for 24 hours, after which the material will be ‘double bagged’, autoclaved and, ultimately, incinerated offsite.

Liquid waste will be disposed of into sealed biohazard containers filled with Virkon* for incineration. It will be routine practice that all liquid waste material be neutralised before disposal, and for the neutralised waste to be transported in leak-proof containers to prevent spillages. Neutralised liquid waste will be securely sealed for collection and off-site disposal by an approved agent (B60CRP) or discarded down an approved sink (430CSP).

Summary
As any active viral particles on surfaces or in waste material will be completely inactivated at the end of each experiment by the highly effective cleaning/disinfection protocols outlined above, it is considered very unlikely that active virus particles would unintentionally become discharged into a sanitary sewage system. No foreseeable adverse effects on human health and safety are expected.

*Virkon
Rely+On™ ® is a multi-purpose disinfectant. It contains oxone (potassium peroxymonosulphate), sodium dodecylbenzenesulfonate, sulphamic acid; and inorganic buffers. Virkon oxidizes key structures and compounds, such as proteins, leading to widespread, irreversible damage and subsequent deactivation/destruction of the microorganism. It is typically used for cleaning up hazardous spills, disinfecting surfaces and soaking equipment. With powerful, proven performance against over 500 strains of viruses, bacteria and fungi. Virkon offers a broad spectrum efficacious anti-microbial activity, and it is used by governments worldwide for Emergency Disease Control. Importantly, Virkon has specifically been validated for lentiviral inactivation (Antec-Biosentry).

Virkon is sold as a powder which dissolves readily in water. It is intended to be mixed with water to form a 1% solution (i.e. 10g per litre) for hard surface and equipment disinfection. 1:100 is also dilution rate advised for virucidal efficacy against HIV-1.

*DISTEL (formerly known as Trigene advance)
DISTEL is formulated as a nonmulsion that enables the active molecules in the product to be carried rapidly through cell walls of micro-organisms, ensuring the rapid induction of cell death in treated micro-organisms. DISTEL works quicker than conventional disinfectants and achieves apoptosis (cell death) rather than merely
suspended activity as with conventional disinfectant products. DISTEL has been reported to be bactericidal, fungicidal as well as virucidal and sporicidal
(http://tristel.com/products/healthcare/laboratories/distel-high-level-laboratory-disinfectant/). It is recommended to be used at a 1:100 dilution for general purposes, 1:10
dilution for high risk disinfection

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The GMSC has agreed that the production, handling and use of the lentiviral siRNA stocks is a Class 2 activity. This decision has been reached because although the
lentivirus will be generated using a third generation, self-inactivating, 4 plasmid expression system, the possibility of a recombination event occurring that leads to
replication competent virus can never be discounted with this type of virus. The potential oncogenic effects of the Woodchuck Post-translational Regulatory Element have
been negated by the use of the mutant form that prevents expression of the X protein. The proposal includes the potential to produce large amounts of virus. This
represents the most hazardous aspect of the proposal and the GMSC is satisfied that the necessary precautions have been put in place to ensure containment is
maintained. The encoded Cas9 protein and guide RNA to be delivered by lentivirus in this proposal is now an established and widely used technique. Cas9 itself is not
known to have any detrimental effects on human health or the wider environment. The proteins targeted by the guide RNAs will be assessed on a case by case basis to
ensure their potential risk is minimal. The request to derogate the Biosafety Containment Level 2 from 2 to 1 post transduction has been deemed acceptable given that the
transduced cells will be washed extensively to remove any remaining viral particles and will be tested for the absence of transducing virus. It has been made clear that
human iPSC cell lines that have been generated using lentiv- or retrovirus methods must be negative for the absence of virus at least. These cells will always be tested for
the absence of infectious particles before they can be used as if they only require Biosafety Containment Level 1

Project Ref 3043/15.2

Date Ackn'd: 26/02/2015
CU2 Project Title: Generation and production of lentiviral particles for delivery of modifiers and gene
Class: 2
CultureVolClass2: < 1 Litre
This work will involve the use of particles of lentiviral origin to deliver modifiers of gene expression to mammalian cells. The aim is to dysregulate key disease-related pathways and then assess the effect of such manipulations on gene expression with a view to identifying novel disease-modifying targets.

Recipient or parental organism

Rodent Origin: Mouse cell lines
Human Origin: immortalised cell lines and induced pluripotent stem cells

Host/vector system

lentivirus vectors: The four plasmids that will be used will be modified versions of pRRI, pMDLgp-RRE, pRSV-REV and PMD2-VSVG.env. The latter three are required for the production of the SIN replication defective lentiviral particles in HEK293T cells. The target shRNNmiRNA or gene will be inserted into the modified pRRL vector. This modified vector will have the following safety features: a deletion in the 3'LTR making it SIN in the infected cells, the packaging sequence is only found in the pRRL vector. This modified vector will have the following safety features: a deletion in the 3'LTR making it SIN in the infected cells, the packaging sequence is only found in the pRRL vector. The Tat promoter has been replaced by Polymerase Type 2 promoter, making them replication incompetent. The inclusion of these features ensures that that the production of these SIN replication defective lentiviral particles only occurs in the transfected HEK293T. Outside of this setting, viral replication cannot take place and so pose a minimal risk to both humans and the environment.

Origin & function

The SIN-RD lentiviral particles will contain the following sequences:

Health and Safety Executive
1. shRNNmiRNA directed towards the knock down of the expression of a particular endogenous mammalian target (Mouse, Rat, Human). These de novo derived sequences are not derived from an organism.
2. Fluorescent protein marker which are known to be benign in terms of their effects when expressed in mammalian cells but are essential for visualization of these cells. When these in addition are fused to a subcellular marker gene, subcellular visualization of a particular process can be visualized.

3. Cre recombinase which catalyzes excision of sequences flanked by its recognition site, loxP.

4. Fluorescent marker protein fused to a ribosomal subunit to enable visualization of cells where vitally delivered gene expression is taking place and immunoprecipitation of ribosomes from such cells.

Methods

This proposal involves the use of existing lentiviral constructs purchased commercially and the generation of new constructs on site. These constructs will contain a combination of shRNAmiRNA and a fluorescent protein as lineage marker. In some cases constructs will contain a combination of shRNAmiRNA and Cre recombinase giving rise to a pre-determined deletion event in transduced cell lines. Insertion of the sequences into the third generation lentiviral vector on site will be achieved by either conventional cloning or Recombineering. Lentiviral particles will either be purchased ready for use or produced in-house using the third generation system described below.

Lentiviral production - Uney laboratory

Some of the lentiviral vectors will be produced on site whilst others will be obtained from the Uney laboratory, which is based at the University of Bristol. The lentiviral vectors provided by the Uney laboratory will be stock solution containing up to 1x10^10 transducing units (TU) l ml of vector in TSSM buffer (20 mM TRIS, 100 mM NaCl, 10 mg/mL sucrose, 10 mg/ml mannitol), and will be essentially free of the HEK293T helper cell line used to expand the viral titre. Each purified and concentrated aliquot of lentiviral vector solution will comprise of small volumes (up to 10 1-11) containing not more than 1x10^8 viral particles. The material is normally shipped frozen and stored within manufacturer designed racks in a _80°C freezer.

Lentiviral production - on site 860CRP or 430CSP

Lentiviral production will also be carried out on-site using HEK293T cells and will be carried out in a class 2 microbiology safety cabinet within a dedicated Biosafety level 2 laboratory. The HEK293T cells used for lentiviral production will be seeded in filter containing screw cap culture flasks in order to minimize the risk of spills and aerosol mediated viral spread. For this the modified pRRI plasmids together with three additional separate plasmids (pMDLgp-RRE, pRSV-REV and PMD2-VSVG.env) will be transfected using a transfection reagent (e.g. Polyethylenimine (PEI), lipofectamine) into HEK293T packaging line. After 6-12 hours, the medium is replaced with fresh serum-free medium (e.g. Neurobasal medium with 2% B-27 supplement and 1X PeniStrep) and grown for an additional 72-96 hours. After 24-48 hours, so as 10 ensure the viability of the transfected HEK293T cells, medium from the cells is collected into screw cap tubes and stored at 40C and fresh serum-free medium is added to the cells. The cells are grown for an additional 24-48 hours before the second medium solution is added to the first harvest tube. After lentivirus collection has been completed, the cells in the flasks will be treated with a validated anti-microbial agent (e.g. DISTEL 10% or another equivalent product) for at least 24 hours. liquid waste will be disposed off-site via an approved waste disposal agent (B60CRP) or via a designated sink (430CSP) after at least 24 hours neutralisation with 10% DISTEL or equivalent. Solid material will be autoclaved on-site and then collected for incineration by an approved waste disposal agent.

Still within a Class 2 microbiology safety cabinet in a Biosafety level 2 laboratory, the harvested supernatants will be filtered using a 0.45um filter before being either aliquoted or further purified by chromatography and or concentrated by centrifugation. The lentiviral particles may need to be purified by either chromatography (e.g. ViraBindTlo1) and eluted in a high salt solution (50 mM Tris, pH 7.5, 5 mM MgCl2, 2 M NaCl) and or concentrated by ultrafiltration (e.g. lentiSelect™). For certain application where highly concentrated, highly purified virus may be required, the traditional method of sucrose cushion based centrifugation may be necessary. To minimise the possible risk of accidental viral
contamination and spread due to the need for an ultracentrifuge, all loading and unloading will be done in the Class 2 microbiology safety cabinet. Once the sucrose cushions have been added to the centrifuge tubes, they will be transferred into the Class 2 microbiology safety cabinet. The unpurified or chromatography purified lentiviral particles will then be added to the sucrose cushion. The individually capped tubes will then be transferred to their respective bucket holders and the bucket sealed using their respective screw caps and marked as containing virus. The bucket will be transferred to a weighing scale and a counterpart bucket and tubes with water (and without lentivirus) will be prepared that is weight matched. The balanced buckets will then be transferred to the rotor before being placed within the centrifuge chamber. The ultracentrifuge will be run at 70000g for 2 hours at 20°C. Upon return of the buckets to the Class 2 microbiology safety cabinet, the supernatant will be removed from the tubes before transfer of the resuspended virus pellet into individual screw cap cryovials. As the greatest risk for contamination occurs within the centrifugation buckets themselves during transport to and from the weigh scales and during ultracentrifuge, not only will the centrifuge tubes but also the rotor be decontaminated with DISTEL 10% before removal from the Level 2 laboratory. Optionally the centrifuge rotor can be autoclaved at 121°C. In any case, at no point will concentrated virus stock be exposed to outside of the class 2 hood environment. All supernatants will be treated as above. The lentiviral titre will be determined in terms of the number of viral particles (VP) or Transduction units (TU) per ml. The number of VP can be assessed relatively quickly and does not involve cell infection. In this case, a bead based enrichment assay (e.g. QuickTitre™ Quantification Kit) or a p24 ELISA assay (e.g. QuickTitreTN Lentivirus Titre kit) will be chosen. The VP quantification methods tend to overestimate the TU by 10-1000 fold. Thus, the TU 1 ml will in certain instances also be determined. For this, a titration range of lentiviruses expressing a fluorescent tag, serial dilution will be prepared and added to a 24 well cluster plate or T25 Te-flasks containing HEK293T for 48 hours. The percentage of fluorescent positive cells will be quantified manually under a fluorescent microscope or ideally using FACS analyser. The biological titre (TU/ml) according to the following formula: TUIIJI = (P x N x 1100 x V) x 1/DF, where? = % GFP+ cells, N = number of cells at time of transduction = 10[5], V = volume of dilution added to each well and DF = dilution factor = 1 (undiluted), 10-1 (diluted 1/10), 10-2 (diluted 1/100), and so on. Aliquots with not more than 1x10B viral per vial are subsequently stored at -80°C in individual screw capped cryovials. The viral stock will consist of viral particles containing the vector genome (full capsids) and also of a variable number of empty viral capsids. Other trace components that might be present include, but are not limited to, inorganic salts, vitamins, other nutrients, human cellular proteins, carbohydrates, amino acids, and fats.

Transgene: proteins to be overexpressed

Additional hazards could also arise from the properties of the genetic material that will be inserted into the viral vectors and expressed in transfected cells.

A. Fluorescent protein tag proteins:

The green fluorescent protein (GFP) is a protein composed of 238 amino acid residues (26.9 kDa) that exhibits bright green fluorescence when exposed to light in the blue to ultraviolet range. GFP traditionally refers to the protein first isolated from the jellyfish Aequorea victoria, which has a major excitation peak at a wavelength of 395 nm and a minor one at 480 nm. Its emission peak is at 509 nm, which is in the lower green portion of the visible spectrum. EGFP is a variant of GFP containing two point mutations; S65T and F64L. These mutations dramatically improve the spectral characteristics of GFP, resulting in increased fluorescence, photostability, and a shift of the major excitation peak to 488 nm, with the peak emission kept at 509 nm. This matches the spectral characteristics of commonly available FITC filter sets and also improves folding efficiency at 37 °C thereby allowing practical use in mammalian cells. Genetically encoded fluorescent proteins such as green fluorescent protein have been widely used as a reporter for biological research over the past decades. Their exogenous expression is not associated with any cytotoxic, immunogenic or oncogenic response.
B. ere recombinase

Gre Recombinase is a tyrosine recombinase enzyme derived from the P1 Bacteriophage. The enzyme uses a topoisomerase I like mechanism to carry out site specific recombination events. The enzyme (3SkOa) is a member of the Integrase family of site specific recombinase and it is known to catalyse the site specific recombination event between two DNA recognition sites (loxP sites). This 34 base pair (bp) 10xP recognition site consists of two 13bp palindromic sequences which flank an 8bp spacer region. Two separate DNA species both containing lox? sites can undergo fusion as the result of Gre mediated recombination. DNA sequences found between two 10xP sites are said to be "10xed". The enzyme plays important roles in the life cycle of the P1 Bacteriophage such as cyclization of the linear genome and resolution of ~imeric chromosomes that form after DNA replication.

ere recombinase is a widely used tool in the field of molecular biology. The enzyme's unique and specific recombination system is exploited to manipulate genes and chromosomes in a huge range of research, such as gene knock out or knock in studies. The enzyme's ability to operate efficiently in a wide range of cellular environments (including mammals, plants, bacteria, and yeast) enables the ere-Lox recombination system to be used in a vast number of organisms, making it a particularly useful tool in scientific research.

The simplicity and robustness of the Gre-loxP systems has enabled scientists to exploit the Gre enzyme in order to manipulate DNA both in vivo and ex vitro. As the enzyme has a specific 34bp DNA substrate the genome of the organism would have to be 1018bp in length for there to be a likely occurrence of a loxP site. As mammalian genomes are on average in the region of 3x10e9 bp there is a very low chance of finding an endogenous 10xP site. For ere to be functional in a foreign host, exogenous loxP sites must be engineered. This allows precise control over the activity of the ere enzyme in test organisms.

ere recombinase is not known to cause any diseases in humans or animals.

C. shRNA: endogenous proteins to be depleted

RNA interference (siRNA)

RNA interference (siRNA) is an antisense technology that exploits a normal cellular antiviral response that acts to inhibit viral protein synthesis through the production of short hairpin RNAs that bind and target viral double-stranded RNA (dsRNA) molecules for degradation. The shRNA molecules are processed by cellular enzymatic pathways to produce small inhibitory RNA (siRNA) species, and it is the latter RNA molecules that bind and target complementary RNA sequences for degradation by the RNA-induced silencing complex (RISC). With the use of shRNA-expressing viral vector systems, the expression of specific mammalian genes/proteins can be 'knocked-down', in order to study their functions.

The effects of the siRNA species that are generated in these experimental systems may have broader effects on the cell than just modulating the expression of a particular gene/protein. There may be sequences within a specific siRNA molecule that are homologous to other coding sequences within the mammalian genome that are not necessarily linked or closely related to the intended target it is, therefore, theoretically possible that a specific siRNA may knock down the expression of genes other than the intended target one, and for this reason, the siRNA systems have be designed carefully to minimise the likelihood that there will be unwanted or potentially adverse effects arising from a non-target gene being inadvertently targeted. This is done by screening designed siRNA sequences against databases of known mammalian gene/JmRNA sequences.

RNA interference may also have deleterious effects upon cellular metabolism due to the triggering of antiviral responses. It has been shown that siRNA molecules (even if less than 30nJ in length) can trigger dsRNA antiviral responses. Such responses not only lead to the degradation of dsRNA molecules, but also results in interferon production, which, in turn, leads to inflammation and the non-specific inhibition of protein synthesis.

In some of the lentiviral vectors that will be used in the proposed studies the eukaryotic U6 Polymerase III promoter
will be used to drive the expression of specific shRNAs of interest. The U6 promoter is well suited to drive the expression of shRNAs as it possesses the following favourable characteristics: (i) it initiates from position +1 of the transcripts, and (ii) it yields transcripts that do not terminate with a poly-A tail but with a series of four to five thymidine residues, which results in a series of 3' U residues leading to a fully functional shRNA sequence. Indeed, the structure of the transcribed product closely resembles synthetic double-stranded siRNAs, except for the fact that the two strands are linked by a spacer sequence. This system has been used to successfully inhibit gene expression in mammalian cell lines, with efficiencies comparable with that of synthetic siRNA.

Some of the viral vectors that will be used contain a sequence of interest that has been scrambled (scrambled shRNA), and which is not complementary to any known mammalian sequences. These vectors will be employed as negative controls to demonstrate that any observed effects are due to the knockdown of a specific mRNA protein of interest, rather than being due to any non-specific effects that the delivery of the viral vectors might cause. This sequence will adopt a hairpin structure as with any shRNA, but it should not target any mRNA of mouse, rat or human origin. It will only serve as the negative control for the vector producing shRNA. Consequently, these sequences are unlikely to pose any safety risks for the environment or human health.

**Evaluation of foreseeable effects**

**Procedures**

During all procedures that involve the handling/use of the viral vectors, all workers (including those that are not working directly with the vectors) that are present within a lab where the work is undertaken are required to wear personal protective equipment (including both appropriate clothing and gloves) at all times. The use of two pairs of gloves is advised so the external pair may be disposed in an autoclave bag and replaced whenever necessary (e.g. in the case of contact with the viral reagent). Face masks are also available for use, where appropriate. In addition, all workers are made aware of the nature of the viral work that is going on within the laboratory, and they have to follow appropriate procedures to ensure that there is no cross-contamination into non-viral working areas. All the workers using the viral delivery systems are experienced research scientists, and junior scientists will be closely supervised until they are competent in the handling of the viruses.

**In vitro assessment**

Assessing whether the gene modulation has worked will be carried out by a combination of PCR and fluorescence microscopy, and will normally take place initially in biosafety level 1 immortalised cell lines that are known not to contain lentiviral genetic material. Application of lentiviral particles will be done at Biosafety level 2. After at least 24 hour incubation and extensive washing, the cells will be treated as Biosafety level 1 (see below the justification for removal of cells post-infection to Biosafety Level 1). Once validated the same procedure will be carried out in the target cells. Where viral transduction is undertaken on a class 2 cell line the resultant material will remain under biosafety level 2 conditions. In all cases phenotypic analysis will be performed using suitable in vitro assays, including for example, RT-PCR, Western Blotting, immunocytochemistry and imaging.

**In vitro studies**

Transduction of cells (e.g. human derived iPSC neurons, mouse and human immortalised cell lines) with the lentiviral vectors will be carried out in a Class 2 microbiology safety cabinet within a dedicated Biosafety level 2 laboratory. In the in vitro studies, the TUs, and consequently volumes added, will be dependent on the number of cells in the tissue culture dish/flask to be infected. However, as the maximum number of cells to be handled per experiment is around 1 x 10^8, not more than 1 x 10^8 viral particles per experiment will be used. None of these cells will be cultivated in the filter screw cap flasks used for HEK293T mediated lentiviral production. This is to ensure that, in particular, the HEK293T cells used for lentiviral production are not inadvertently used for lentiviral assessment! Any plastic ware or solutions that are used to handle the transduced cells will be chemically inactivated in the Biosafety level 2 laboratory with a validated anti-microbial agent (e.g. DISTEL 10% or another equivalent product) for at least 24 hours. Liquid waste will be disposed of off-site via an approved waste disposal agent (B60CRP) or via a designated sink (430eSP).
Solid material will be autoclaved on-site and then collected for incineration by an approved waste disposal agent. Once the medium containing the lentiviral particles has been removed and the cells (e.g. mouse NIH/3T3, human HEK293T) have been extensively washed, which all is done in a Class 2 microbiology safety cabinet, the cells can be used following Biosafety level 1 guidelines, as no virus will be present and the latent virus in the transduced cells is replication incompetent, unless the cell line was Originally classified as biosafety level 2 in which case the material will continue to be treated as such. A viral titre determination assay may on occasion be used to verify the absence of virus in the medium from transduced cell lines. This will be performed by PCR using oligonucleotides specific to the conserved regions within the viral genome.

An additional level of safety and screening procedure for the handling human iPSC cells will be applied for the following reason. The procedure for the generation of iPSC neurons was originally developed in 2006 by Yamanaka allows for the reprogramming of adult differentiated cells into stem cells through the introduction of four transcription factors using replication incompetent retrovirus. Since then the biosafety level of the retroviral constructs has been improved, such that both retroviral and non-viral methods of reprogramming have been reported. Even assuming that the source of our human iPSC cells resulted from work using first or second generation replication incompetent lentiviral particles, the risk of producing active lentivirus from the additional exposure to a third generation replication incompetent virus is considered negligible. Nevertheless, a number of precautionary measures will be implemented for use of these cells. Any new human iPSC line that is brought onto our site and was generated using SIN-RD lentiviruses or retroviruses (preference will be given to those lines for which there is documentation from the provider that no viral particles are being made and released) will be initially cultured at Biosafety Level 2 and tested by titre assessment to confirm that no virus is being generated. Further, after the removal of our SIN-RD lentivirus and extensive washing, the cells will be incubated in fresh medium and will be maintained at Biosafety Level 2 safety for at least 24 hours. These cells can then only be treated as Biosafely Level 1, once a virus titre assay has confirmed that no virus is being released into the medium.

Human health hazards

The method by which the lentivirus vector is produced means that it is highly unlikely that replication competent lentivirus (RCL) can be generated even if an infection occurs in a person who is HIV-1 positive. Infection can lead to a permanent transduction of cells and the possibility of a harmful event either by transactivation or disruption of gene expression cannot be ruled out. For this reason the work with stock viral aliquots will be conducted as a class II activity. Oral ingestion will be prevented by standard laboratory safely practices. Aerosol formation resulting from an accident outside of the safety cabinet and involving lentivirus particle-containing liquid may lead to transduction of a limited number of the laboratory worker's skin or mucosal cells with modified viruses. However, these modified virus particles carry an extremely low safety risk for human health, as they are replication-incompetent, and also because the particles carry an extremely low infection potential via the mucosal/skin routes, due to the inherent properties of the viral vectors. Moreover, the genes/proteins of interest that will be targeted by shRNAs do not include any growth factors, confirmed oncogenes, cytotoxins, or immunomodulators, and none of them are of retroviral origin. In the unlikely event of accidental transduction of a laboratory worker's skin or mucosa by lentivirus particles, this will be self-limited, due to natural shedding of superficial epithelial skin and mucosal cell layers.

The most likely route of accidental infection with a lentivirus will be via inadvertent percutaneous inoculation. The likelihood of this occurring will, however, be minimised by adhering to appropriate risk management measures. Infection of the community at large with lentivirus particles is highly unlikely due to the viral vector particles being replication incompetent and being extremely sensitive to desiccation.

Hazard to the Environment

The probability that active viral particles will be accidentally released into the environment is considered to be extremely low, as effective containment procedures will be adhered to. However, in the unlikely event that active viral
vector particles do accidentally get released into the environment. The safety risk posed by such an event is considered to be negligible, due to the vectors being self-inactivating and non-replicative. The main potential risk in such an event would be the subsequent contamination of a human population already infected with HIV, which would potentially allow for recombination events that could incorporate the inserted sequences into a viable RCL. This scenario is, however, extremely unlikely, and even if it were to occur, it is unlikely that it would lead to any untoward effects. The vectors have been pseudotyped with the VSV-G envelope in order to increase tropism, and they are, in theory, capable of transducing all dividing and non-dividing mammalian cell types. As emphasised before, the vectors cannot self-propagate after infection, and successful transduction is also critically dependent on the presence of high enough concentrations of virus particles; also viral vector stock solutions are aliquoted and stored in small volumes (each tube contains at maximum 10^11) at -80°C so the potential for a high titre dose is reduced. The infectivity of the vectors rapidly decreases at room temperature so it is considered highly unlikely that the vectors could survive long enough in the environment to pose a risk if accidentally released. Furthermore, lentiviral vectors have a short half-life at room temperature as their structural characteristics make them highly susceptible to dehydration, and relatively unstable. For this reason, retroviruses become rapidly inactivated outside host systems, and this is illustrated by the fact that close contact is required for transmission. They can, however, survive for long periods in high protein media. There are no conceivable hazards associated directly with the lentiviral vectors (containing the inserts) as they will not replicate/survive outside the laboratory and they have been designed to include many protective safety features. siRNA and miRNA sequences will also not survive as they are highly unstable, and they would, consequently, be rapidly inactivated/degraded if accidentally spilled into the environment. Moreover, as discussed above, there is a very low risk that the sequences contained within the viral vectors could be transferred to other organisms, as a rare recombination event would have to occur to allow this to happen. Summary

The chance that active viral particles will be accidentally released into the environment is considered to be highly unlikely, as the viral vector studies that will be undertaken have been classified as biosafety level 2, and effective containment procedures will be adhered to (see section C for details). However, in the unlikely event that active viral vector particles do accidentally get released into the environment, the safety risks posed by such an event is considered to be low due to the vectors being self-inactivating and non-replicative, and also due to the poor ability of the vectors to survive outside of their host systems (see above discussions).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Following transduction of cell lines that are designated as requiring Biosafety Containment level 1 with lentivirus, we wish to be able to subsequently use these cells at Biosafety Containment level 1. This can be justified by the following procedure: under Biosafety Containment Level 2 media containing virus will be removed, the transduced cells will be extensively washed to remove any remaining virus. This liquid waste will be neutralised for at least 24 hours before disposal. The washed cells will then be cultured for a further 24 hours before being tested for the absence of infectious virus before being allowed to be treated as only requiring Biosafety Containment Level 1. Sources of iPSC cells that have been shown to lack viral integration and test negative for infectious virus can be regarded as requiring biosafety level 1 containment. Such iPSC cells can also be derogated to biosafety level 1 containment once tested for the absence of infectious virus.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
General cleaning procedures
Surfaces will be thoroughly cleaned with Virkon® or Distel 10%* (or an equivalent product) at the end of each experiment or after the occurrence of an accidental spillage of infectious material. Application of these anti-microbial agents will totally inactivate any viral vectors that might be present. According to the biosafety literature, all of the viruses to be used are susceptible to these disinfectants. Anything that might have potentially come into contact with the virus will be treated with Virkon® or Distel 10% before being autoclaved/incinerated.

Waste handling procedures
Solid waste will be neutralised by soaking it in a validated disinfectant solution, after which the material will be 'double bagged', autoclaved and, ultimately, incinerated. Liquid waste will be disposed of into sealed biohazard containers filled with Virkon® for incineration. It will be routine practice that all liquid waste material be neutralised before disposal, and for the neutralised waste to be transported in leak-proof containers to prevent spillages. Neutralised liquid waste will be securely sealed for collection and off-site disposal by an approved agent (B60CRP) or discarded down an approved sink (430eSP).

Summary
As any active viral particles on surfaces or in waste material will be completely inactivated at the end of each experiment by the highly effective cleaning/disinfection protocols outlined above, it is considered very unlikely that active virus particles would unintentionally become discharged into a sanitary sewage system. No foreseeable adverse effects on human health and safety are expected.

*Virkon
Rely+OnTM Virkon® is a multi-purpose disinfectant. It contains oxone (potassium peroxymonosulphate), sodium dodecylbenzenesulfonate, sulphamic acid; and inorganic buffers. Virkon oxidizes key structures and compounds, such as proteins, leading to widespread, irreversible damage and subsequent deactivation/destruction of the microorganism. It is typically used for cleaning up hazardous spills, disinfecting surfaces and soaking equipment. With powerful, proven performance against over 500 strains of viruses, bacteria and fungi, Virkon offers a broad spectrum efficacious anti-microbial activity, and it is used by governments worldwide for Emergency Disease Control. Importantly, Virkon has specifically been validated for lentiviral inactivation (Antec-Biosentry).

Virkon is sold as a powder which dissolves readily in water. It is intended to be mixed with water to form a 1% solution (i.e. 10 g per litre) for hard surface and equipment disinfection. 1:100 is also the dilution rate advised for virucidal efficacy against HIV-1.

DISTEL (formerly known as Trigene advance)
DISTEL is formulated as a nanoemulsion that enables the active molecules in the product to be carried rapidly through cell walls of micro-organisms, ensuring the rapid induction of cell death in treated micro-organisms. DISTEL works quicker than conventional high level disinfectants and achieves apoptosis (cell death) rather than merely suspending activity as with conventional disinfectant products. DISTEL has been reported to be bactericidal, fungicidal as well as virucidal and sporicidal (http://www.tristel.com/products/healthcarelaboratories/Distel-high-levellaboratory-disinfectantU). It is recommended to be used at a 1:100 dilution for general purposes, 1:10 dilution for high risk disinfection.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N
Tick to confirm that you have attached a risk assessment to this form Y
Tick if you are claiming exemption from disclosure for section of the risk assessment Y
The GMSC has agreed that the production, handling and use of the lentiviral siRNA slacks is a Class 2 activity. This decision has been reached because although the lentivirus will be generated using a third generation, self-inactivating, 4 plasmid expression system, the possibility of a recombination event occurring that leads to replication competent virus can never be discounted with this type of virus. The potential oncogenic effects of the Woodchuck Post-translational Regulatory Element have been negated by the use of the mutant form that prevents expression of the X protein. The proposal includes the potential to produce large amounts of virus. This represents the most hazardous aspect of the proposal and the GMSC is satisfied that the necessary precautions have been put in place to ensure containment is maintained. The encoded fusion-protein to be delivered by lentivirus in this proposal has been used extensively in the literature and is not known to have any detrimental effects on human health or the wider environment. The request to derogate the Biosafety Containment Level from 2 to 1 post transduction has been deemed acceptable given that the transduced cells will be washed extensively to remove any remaining viral particles and will be tested for the absence of transducing virus. It has been made clear that human iPSe cell lines that have been generated using lentiviral methods must be negative for the absence of virus at least. These cells will always be tested for the absence of infectious particles before being can be used as if they only required Biosafety Containment Level 1.

Dysregulation of podocyte function and loss of kidney podocytes contributes to the progression of human kidney disease. An immortalised human podocyte cell line generated at Bristol University will be used to investigate the cellular pathways involved in the development of human renal disease. To better understand these cellular pathways, the expression or the activity of the gene of interest will be modulated by several methods:

1. The utilisation of tool compounds
2. The knock-down of the gene of interest by shRNA
3. The generation of knockout somatic cells using programmable nucleases (CRISPR or Zinc finger nucleases)
4. The generation of reporter gene cell lines expressing a reporter gene (e.g.: fluorescence protein or enzyme) under the promoter of a gene of interest

The experiments involving the transfection of vectors such as shRNA, programmable nucleases or reporter genes will be performed by the lentivirus.

The effect of modulating the expression or the activity of a target gene of interest will be determined by the expression level of proteins, mRNA or mediators involved in the target signalling pathway.

The generation of immortalised human podocyte cell line has been performed in Doctor Richard Coward's laboratory at Bristol University. Primary human podocytes that tested negative for HIV and Hepatitis B have been immortalised by the insertion of SV40 large tumour antigen and the hTERT into the genome. These immortalised human podocytes have been genetically modified to allow the cells to proliferate at the permissive temperature of 33°C and to enter growth arrest and express markers of differentiated in vivo podocytes at the temperature of 37°C. While SV40 T antigen can transform cells and is oncogenic, the U19tsA58 variant used here is unstable at 37°C minimising the risk involved with its use.

The immortal podocyte cell line has been generated by retroviral delivery of the pZip-Neo SV(X)I shuttle vector containing SV-40 large tumour antigen and the hTERT sequences. The generation of the immortal podocytes is briefly described below:

a. Generation of the pZip-Neo SV(X)I shuttle vector
   As described by Cepko et al (1), the pZip-Neo SV(X)I shuttle vector is composed of:
   - Moloney murine leukaemia virus (M-MuLV) transcriptional unit including the long terminal repeats (L TRs) necessary
for the initiation of viral transcription and the polyadenylation of viral transcripts, as well as for integration; sequences necessary for the reverse transcription of the viral genome; sequences for the encapsidation of viral RNA; and 5' and 3' splicing signals involved in the generation of the subgenomic viral env RNA.

- DNA sequences derived from the transposon Tn5 for G418 and kanamycin resistance
- Sequence coding for simian virus 40 large tumour antigen, strain U19tsA58; The tsA58 SV40 mutation (A438V) encodes a thermolabile large tumour (T) antigen (TAG) capable of immortalization only at the permissive temperature of 33°C, becoming unstable and inactive at 37°C
- Sequence coding for hTERT, the essential catalytic subunit of the human telomerase gene. Overexpression of hTERT into the cells stabilises telomere length and therefore prevents cellular senescence.

b. Generation of retroviral particle containing the pZIP-Neo SV(X)I vector
To generate the retroviral particle containing the pZIP-Neo SV(X)I vector, the pZIP-Neo SV(X)I vector has been transfected into the packaging cell line, TEFL Y-A cell line. This cell line stably expresses M-MuLV gag-pol and env genes. The TEFLY-A packaging cell line does not produce replication-competent retroviruses (1). This cell line allows the production of retrovirus containing the pZIP-Neo SV(X)I vector but the retroviruses produced are replication-defective (replication-incompetent). The structure of the SVX genome that is transferred to recipient cells via virus infection was characterized in a random G418 resistant cell line. Southern blot analysis confirmed that these retroviruses transfer a single proviral genome of the expected structure into the infected cells genome. Supernatants from the TEFL Y-A cells containing replication-defective retroviruses were used to infect the primary human glomerular epithelial cultures.

c. Generation of immortal human podocyte cell line
The donor of the human kidney nephrectomy sample has been tested negative for HIV and Hepatitis B. Primary human kidney glomeruli were isolated by differential sieving of the tissue and cultured until epithelial outgrowths (podocytes) reached confluence. At this stage the cells were passaged and supernatants from the TEFL Y-A cells containing recombinant retroviruses were used to transduce the primary human glomerular epithelial cultures. The transduced podocyte cells contain the sequence of SV40 Large tumour antigen and the sequence of hTERT. The tsA58 SV40 mutation (A438V) encodes a thermolabile large tumour (T) antigen (TAG) capable of immortalization only at the permissive temperatures. Cells are proliferative at the permissive temperature of 33°C. Transfer to the nonpermissive temperature of 37°C results in the inactivation and degradation of large T antigen. The transgene will inactivate fully at 39.5°C but normally complete quiescence occurs at 37°C after 1-3 days. The retrovirus also conferred G418 resistance. Once these cultures reached confluence, genomic integration of the transgene was selected using G418 and a switch to 33°C culture, a permissive temperature for SV40T expression. Subcloning of these cultures produced the clonal cell population used here (the host cells). Following establishment of quiescence at 3rC, the cells then enter growth arrest and express markers of differentiated in vivo podocytes.

Bibliography

Host/vector system
To study the function of podocytes in human disease, the expression of a target of interest may be decreased in the immortalised human podocyte cell line by the transduction with shRNA or programmable nuclease sequences (CRISPR or Zinc-finger nucleases) by lentivirus. The modulation of a particular cellular pathway may be studied with the use of a reporter gene assay. In this case, the vector containing the reporter gene under the regulating sequence from the promoter of a gene of interest will be introduced by lentivirus into the immortalised human podocytes. This proposal involves both the use of existing lentiviral constructs purchased commercially and the generation of new constructs on site. Lentiviral particles will either be purchased ready for use or produced in-house using the third generation system described below. Insertion of the shRNA, programmable nuclease sequences or the luciferase
genes under the promoter of the gene of interest into the third generation lentiviral vector system will be achieved on site by either conventional cloning or recombination-mediated genetic engineering. Both commercially acquired and in-house lentivirus will use the same vector backbones containing identical promoters. Target genes will be selected based on the needs of drug discovery projects; programmable nucleases and shRNA will not be produced against any growth factors, tropic factors, quiescence factors, confirmed oncogenes, tumour suppressors or immunomodulators. The production of lentivirus containing the vectors of interest are described below:

1. Generation of lentivirus

Lentiviral vectors will be purchased commercially or produced in-house using the third generation system described below. Each purified and concentrated aliquot of lentiviral reagent comprises of a small volume (5 to 101FL) that contains no more than 1x10^8 viral particles.

Vector System = self-inactivating (SIN) non replication-competent HIV based lentiviral vectors

The viral vectors that will be used in the proposed studies are self-inactivating (SIN) non replication-competent HIV based lentiviral vector systems, which have been designated to produce stable gene expression in mammalian cells; and they are generated by co-transfecting HEK 293T cells with four separate plasmids. It is worth noting that HEK293T express the SV40 T antigen but the genetic material encoding for this protein is non-mobile and will therefore not become incorporated into lentivirus. Each of the plasmids used expresses a different set of genes which, when combined following co-transfection, provide the smallest possible set of essential viral genes that is still compatible with virus production. Moreover, the vectors are all vesicular stomatitis virus (VSV-G) pseudotyped lentiviral vectors, which are self-inactivating and highly unlikely to undergo recombination. Importantly, the viral vector system is inherently incapable of replication in mammalian cells. Only in a patient with HIV could any form of recombination occur, i.e. the probability of the production of replication competent lentiviral vectors (RCL) is very small.

The plasmids

Health and Safety

The sequences that will be included in the viral vectors are sub-cloned into 4 standard bacterial plasmid vectors. One of the plasmids, pRRL, will contain the transgene that codes for a programmable nuclease and accessory, or shRNA, or the reporter protein under the promoter of the gene of interest.

Plasmids containing the packaging related sequences

The three other plasmids (pMDLgp-RRE, pRSV-REV and pMD2-VSVG.env), that make up the 4 plasmid system, each contain a different set of sequences that code for proteins that are responsible for packaging the viral vectors. All the genes (gag-pol, rev and env) required for production and packaging of the full length viable viral RNA particles have been removed from the pRRL lenti-plasmids containing the transgenes of interest. The absence of the majority of the viral structural genes renders the lentiviral vectors replication-defective. The replication and capsid genes are provided in trans during the production phase: gag-pol and rev are expressed separately (pMDLgp-RRE and pRSVREV respectively), as is the VSV-G coat protein (pMD2-VSVG.env), and it is, therefore, theoretically impossible for a purified recombinant lentiviral vector to replicate. The plasmids have been engineered so as to have no common sequences that would promote recombination, and, hence, plasmid genes do not become inserted into the pRRL plasmid. There are no known cases of recombination occurring with third generation lentiviral systems. This allows for a viral particle to be produced that can enter any cell, but, once inside, it does not have the relevant genes necessary to either re-package itself or to re-generate full length viral RNA following genomic integration.

Following infection of a target cell, lentiviral vectors are self-inactivating on integration into the host genome. This is achieved because the process of reverse transcription uses the 3' long terminal repeat (3'L TR) as a template to
produce the 5’ L TR. In the pRRL lenti-plasmids, the U3 region of the 3’L TR has been deleted, resulting in deletions in both 3’ and 5’ L TRs on integration into the host genome. These deletions are designed to ensure that the viral genome cannot be released from the host genome. This system, therefore, allows for the long term expression of the gene of interest with little risk of the production of further viral particles.

Plasmids containing the transgene of interest

One of the 4 plasmids, pRRL, will contain the sequences that code for shRNA, or programmable nuclease sequence, or reporter gene sequence under the promoter of the gene of interest.

a. Vector containing shRNA

As mentioned above, pRRL plasmid will contain the sequences that code for one shRNA transcript that will target one mRNAs/protein of interest (or a scrambled shRNA in the case of negative control). The shRNA or scrambled shRNA sequences will be under the control of the Polymerase III U6 promoter. The shRNA sequences will be chosen to target a single human gene. Target genes of the shRNA will not be produced against any growth factors, tropic factors, quiescence factors, confirmed oncogenes, tumour suppressors or immunomodulators. Additionally, the above transgene constructs contain the WPRE, cPPT, RRE, and 4’ sequences, as well as the modified L TR (see below for a description of each of the elements), and these sequences are the only other sequences with biological activity apart from the shRNA that will be present in the viral vectors. These elements are important for the expression of the inserts in the targeted cells, and they will all be stably expressed in a majority of the infected cells.

b. Vector containing CRISPR or Zinc-finger nucleases vector

Programmable nucleases function by binding to, and cleaving, user-defined target DNA sequences. This in turn instigates a robust DNA repair response which ultimately leads to disruption of the target sequence by deletion at the cleavage site or by recombination with a user-supplied synthetic vector containing sequences complementary to the target gene.

For Cas9/CRISPR, nuclease target specificity is determined by an accessory sequence, the guide RNA, which consists of a short (18 - 20 nucleotide) sequence homologous to the target gene and an additional short sequence that forms a complex with the Cas9 enzyme. In that case, the plasmid pRRL will contain the sequences that code for a Cas9/CRISPR plus accessory sequences comprising a short guide RNA that determines target specificity.

In the case of zinc finger nucleases target specificity is dependent upon the zinc finger protein sequence. The pRRL will contain in that case the sequence of zinc finger nucleases without accessory sequences.

In addition, a fluorescent protein or enzyme under the control of the Cytomegalovirus (CMV) promoter, EF1A promoter or the promoter of a gene of interest may be included. Control viral vectors that express only the fluorescent protein/enzyme and no programmable nuclease will be used in some experiments. Programmable nuclease genes will be under the control of either the CMV promoter or the EF1A promoter. For Cas9/CRISPR based constructs, the guide RNA sequences will be under the control of the Polymerase III U6 promoter.

c. Reporter gene vector: vector containing a reporter protein under the promoter of the gene of interest

Genetic reporter systems are widely used to study eukaryotic gene expression and cellular physiology. Applications include the study of receptor activity, transcription factors, intracellular signalling, mRNA processing and protein folding. For example when a particular cellular pathway is activated, it will induce the translocation of transcription factor into the nucleus. The transcription factors will then bind the regulating elements in the promoter of a gene of interest and it will induce the transcription of this gene. The reporter gene system uses this process to measure the activation of the pathway of interest.

The pRRL vector will contain the sequence coding for a reporter protein under the control of the regulating elements of the promoter of the gene of interest or the CMV or EF1A promoter. For example this reporter protein could be a fluorescent protein, an enzyme such as firefly luciferase or β-galactosidase, or a FRET-based reporter designed to detect endogenous enzymatic activity or molecular interactions. An appropriate selection marker Le.; neomycin could also be included to allow the selection of stable immortal human podocytes containing the luciferase sequence under the control of the promoter of the gene of interest.
a. Assessing efficacy of the lentivirus into a BSL 1 cell line
Assessing whether the genome manipulation or the knock-down has worked will be carried out by a combination of PCR and sequencing, and will normally take place initially in Biosafety level 1 immortalised cell lines (human HEK293T) that are known not to contain lentiviral genetic material. Application of lentiviral particles will be done at Biosafety level 2. After at least 24 hour incubation and extensive washing, the cells will treated as Biosafety level 1 (see below the justification for removal of cells post-infection to Biosafety Level 1). In order to determine whether the knock-down or the genome manipulation has worked, the levels of mRNA and protein will be assessed posttransduction, using suitable in vitro assays, including for example, RT-PCR, Western Blotting or immunocytochemistry.

b. Transduction of the lentivirus and the generation of stable expression into the immortalised human podocytes
Once validated, the same procedure will be carried out in the immortalised human podocyte cell line. As the immortalised human podocytes are maintained in a Biosafety level 2 containment, the inoculation of lentiviral particles, the transformed cells and the phenotypic analysis will also be performed in a Biosafety level 2 containment. When a lentivirus containing a programmable nuclease or the reporter gene vector will be used, a stable cell line could be established by selecting the cells in which the genome has been modified by the programmable nucleases or the integration of the reporter gene. In all cases phenotypic analysis will be performed using suitable in vitro assays, including for example, RT-PCR, Western Blotting, immunocytochemistry and imaging, or cellular bioenergy (i.e. mitochondria respiration function or glycolysis function).

Origin & function

Evaluation of foreseeable effects

* Human Health and Safety
Health Clnd Safety
Executive
The immortal human cell that will be used has a low risk for human health. The expression systems and the transgenes that comprise the lentiviral vectors that will be used have also a very low risk for human health and safety, and the reasons for this are discussed below.
A) Lentivirus containing shRNA, or programmable nucleases sequence or reporter gene vectors
The expression systems and the transgenes that comprise the lentiviral vectors that will be used have a very low risk for human health and safety, and the reasons for this are discussed below.
Lentiviral Vector Expression System
Lentiviruses belong to the Retroviridae virus family, a diverse and extensive family of viruses, which are capable of infecting both human and animal species. Cellular entry of the virus involves interactions between glycoproteins contained in the virion's envelope and extracellular plasma membrane proteins on target cells. These interactions are generally specific and are believed to be the principal factor determining which species and type of cells a specific virus is capable of infecting. The binding of a viruses' envelope glycoproteins to an appropriate receptor site on a target cell triggers the fusion of the virion's envelope membrane with the plasma membrane of the target cell, which results in the delivery of the virus capsid to the intracellular space of the target cell.
As the lentiviral vector system that will be used in these studies is based on HIV-1, a theoretical risk to human health exists. However, retroviruses are generally transmitted via exposure to contaminated body fluids or percutaneous inoculation and generally not transmitted via the airborne route. Therefore, accidental piercing of the skin or other surface tissues with virus containing objects represents the main potential route by which accidental infection could occur. Appropriate risk reduction measures will be implemented to reduce the likelihood of this occurring (see below for detailed measures).
The lentiviral vector production process is thoroughly described in the section below to highlight the key safety
features of the lentiviral vectors. In all of the modified pRRL plasmids (containing shRNA, or programmable nucleases or reporter gene sequences), the sequences inserted are flanked by non-coding retroviral LTRs, and no retroviral genes are encoded on the modified pRRL plasmids. Therefore, no retroviral genes will be transferred into generated viral particles. This construct is packaged into particles using a HEK293T cell based packaging system, which requires the cotransfection of HEK293T cells with three additional separate plasmids (pMDLgp-RRE, pRSV-REV and pMD2-G). The latter 3 plasmids express the envelope protein from VSVg and the non-structural proteins of the virion, and, importantly, none of these genes will be transferred into the assembled viral vectors, since they lack the packaging signal (4'-), which is only present on the modified pRRL containing plasmids.

The Lentiviral Expression System that will be used include the following key safety features:

• All of the pRRL containing plasmids/vectors that will be used contain a deletion in the 3' LTR (LlU3) that does not affect generation of the viral genome in the producer cell line, but results in "self-inactivation" (SIN) of the vector after transduction of target cells. Once integrated into a transected target cell, the lentiviral genome is no longer capable of producing viral genomic material than can be packaged. Moreover, deletion of enhancer and promoter elements from the 3' U3 region in the vector construct will result in a provirus that is entirely devoid of the U3 enhancer sequences, which will result in a reduction in the potential for transactivation of cellular genes due to an insertion event. Furthermore, the development of self-inactivating vectors improves the biosafety of vectors, as they are less likely to be mobilized following a superinfection with Wild-type virus (HIV).

• The number of retroviral genes that are used in the four plasmid system has been reduced to three (i.e. gag, pol, and rev).

• The VSV-G gene from Vesicular Stomatitis Virus is used in place of the HIV-1 or other retroviral envelope genes. Pseudotyping HIV-1 vectors obviate safety concerns associated with the use of HIV-1 gp120, which has known pathogenic consequences. However, pseudotyping has a big impact on the biodistribution and tropism of viral vectors. In particular, HIV-1 gp120 restricts transduction of HIV-1 vectors to CD4+ cells, which limits its use to CD4+ cells, like T cells and macrophages. In contrast, heterologous envelopes, like VSV-G, typically broaden the tropism and allow gene transfer into a broad variety of cells: This risk will mitigated by the use of self-inactivating virus and limiting the number of viral particles that will be handled at anyone time.

• Sequences encoding the proteins required for packaging of the viral genome are separated onto three plasmids, and all of the 4 plasmids used in the system have been engineered not to contain any regions of homology with each other so as to prevent undesirable recombination events that could lead to the generation of a replication-competent lentivirus (RCL), which could potentially be harmful to humans. It is important to note that no such RCL has ever been observed despite large-scale production and testing of lentiviral vectors.

• All of the pRRL containing plasmids/vectors that will be used (see above) are devoid of all viral sequences apart from essential cis-acting sequences, including the LTRs and the packaging signal 4'. Only the pRRL plasmids will contain the packaging sequence 4'. Although the packaging plasmids used in these systems allows for the expression in trans of proteins required to produce viral progeny (e.g. gal, pol, rev, env) in the HEK293T producer cell lines, none of them contain LTRs or the 4' packaging sequence. Several of the lentiviral accessory genes (vif, vpr, vpu and net) that are dispensable for lentiviral vector production/transduction have been deleted from the packaging construct. Therefore, none of the retrovirus structural genes will actually be present in the packaged viral genome, as they will never be expressed in the transduced target cells, which means that no new RCL can be produced.

• The lentiviral particles produced in this system are replication-incompetent, only carry the sequences of interest, and no other viral species are produced.

• Expression of the gag and pol genes from pMDLgp-RRE has been rendered Rev-dependent by virtue of the HIV-1 RRE (Rev Responsive Element) in the gag/pol mRNA transcript. All the modified plasmid/vectors that will be used
also include RREs. Addition of the RRE in these plasmids prevents gag and pol expression in the absence of Rev, which is contained in the pRSV-REV plasmid only. The viral rev protein is provided in trans to ensure efficient nuclear export of the full-length viral RNA genomes through binding to the RRE. The Rev/RRE system is highly conserved among lentiviruses, and removal of the RRE sequence and associated splice donor/acceptor sequences results in a loss of transduction efficiency.

- Initially, the endogenous LTR was used to drive the pRRLs plasmid expression via transactivation by the tat protein, but LTR has been modified so as to increase lentiviral vector production, and also to allow lentiviral vector production to be independent of tat expression. A constitutive promoter (RSV promoter) has been placed upstream of the 5’ LTR in the pRRL plasmids to offset the requirement for Tat, which is essential for replication of wild-type HIV-1, as it is required for the efficient production of viral RNA. It is known that Tat-deleted mutants of wild-type HIV are not replication competent. Therefore, the deletion of Tat should decrease the risk of generating a putative RCL.

- Lentiviral vectors have a very low potential to cause immunogenicity.

To be noted:
The central poly purine tract (cPPT), from the pol ORF, is included in all of the viral vectors that will be used to improve the nuclear import of the proviral DNA and hence accelerate transduction. In the lentiviral vector system that will be used, the WPRE (Woodchuck Post-transcriptional Regulatory Element) is used to promote mRNA export and also to stabilise transgene mRNA levels, which should give rise to increased transgene expression. However, it is important that such elements and their associated functions are carefully scrutinised as, in the case of WPRE, there have been unforeseen effects. There have been concerns surrounding the potential oncogenic activity of the native WPRE, because of the expression of an oncogenic WHV-X protein from an open reading frame found within the element. However, in the only study in which increased tumourigenesis has been demonstrated, EIAV and FIV vectors were injected in utero at very high titres. HIV vectors have been shown not to mediate similar effects. The expression of the protein X was abrogated simply by mutating the WHV-X ORF translation start site, which did not affect WPRE function, thereby, removing the oncogenic safety risks.

While the lentiviral vectors that are produced using this system contain only about 20% of the original genome of HIV-1, there is a very small risk that subsequent HIV-1 infection of cells already infected with the lentiviral genome could lead to a rare recombination event in which the transgene is transferred to a replication-competent virus. Thus, the sequences in the vector that will be expressed could potentially be transferred to surrounding cells. This event is, however, extremely unlikely to occur for a number of reasons:

1. The lentiviral vector is replication-incompetent and self-inactivating. A four plasmid HIV lentiviral system minimises the amount of viral genes expressed from one plasmid even further. Consequently, the lentivirus genome lacks critical components required for packaging and proliferation. In the case of a subsequent HIV-1 infection, following lentiviral integration, it has been previously shown that, even under permissive in vitro conditions, wild-type HIV-1 cannot rescue a self-inactivating HIV-1 based lentivirus once integrated into the host genome, although non-self-inactivating vectors can be. In the case of a worker already infected with HIV-1, the HIV genome will have already integrated into the host genome of infected cells. While it is conceivable that the lentiviral genome will infect the same cells and integrate into a location that will allow for homologous recombination with the native HIV-1 genome, the probability of that occurring is extremely small.

2. In order for the spread of the gene of interest to occur following accidental infection (assuming that this has led to viral integration), a series of unlikely events would have to occur:
   a. The worker would have to become infected with HIV-1 or to be already infected with the virus.
   b. The viral and lentiviral genomes would have to integrate into the host worker's genome in the same cells and in a position where they could interact to effect homologous recombination (point 1 above)
   c. Recombination would have to occur in just the right regions to allow for transfer of the gene of interest from the
lentivirus to the HIV-1 genome, which would also involve the transfer of the HIV-1 genes to the lentiviral genome. In this case, it is conceivable that a non-self-inactivating HIV could be generated that contained the gene of interest but not the rest of the genome it requires. The other gene products could be provided in trans from the lentiviral genome that may now contain the HIV-1 genes or from other HIV-1 integrants.

d. The situation in c could conceivably lead to the production of an infectious particle containing the gene of interest, but again no genes necessary for subsequent replication. In order for another round of infection to occur, the process would have to begin again.

In these circumstances, the effects of lentiviral infection are likely to be minor in comparison to the effects of the HIV-1 infection, which would be required to affect the spread of the gene of interest. In addition, the scenario described is essentially equivalent to the rescue of the lentiviral genome from the host, which has already been shown not to occur.

3. It is extremely unlikely that any worker would infect themselves with a significant dose of lentivirus as the volumes that are used in transfection experiments are small (aliquots contain a maximum of 10 IU of vector solution).

4. Moreover, insertional mutagenesis into the host genome may be considered as an oncogenic risk. We cannot rule out the possibility that, when the lentiviral genome integrates into the host genome, it will not lead to the activation of an endogenous oncogene. However, all transcriptionally active long-terminal repeats (LTRs) have been removed as well as all promoter-like elements other than that required to drive expression of the transgene. This should prevent unforeseen activation of such genes. It is noted that deletion of the retroviral enhancer in self-inactivating systems reduces the risk of activation but not of disruption, and, therefore, retroviral infection might still have permanent effects upon a cell (including oncogenic effects).

Importantly, we do not consider that the use of these lentiviral vectors will result in a significantly increased risk of oncogenic activation compared to the risk possessed by any other viral delivery system. Moreover, the risk of transduction leading to tumourigenesis or other untoward harm following exposure is related in part to the titre of the viral vectors; and exposure of workers to quantities of virus high enough to cause such effects would be unlikely during standard laboratory-based manipulations of lentiviral vectors.

Use of lentivirus with immortalised human podocyte cells

As outlined previously, the immortalised human podocytes contain a partial viral genome from Moloney murine leukemia virus (M-MuLV). Subsequent infection of these podocytes with other viruses could permit mobilisation of the viral genome and SV40T/hTERT transgenes contained within. However, this would require a very rare recombination event following a spontaneous double strand break at the site of M-MuLV integration. Sequence alignment between M-MuLV genomes and the lentiviral vectors pMDLgp-RRE, pRSV-REV, pMD2-VSVG-env and pRRL plamids shows no significant overlap or sequence homology that could facilitate recombination following a double strand break. Therefore the probability of recombination between these viral sequences is extremely low and the risk to human health is minimal.

Transgenes:

Additional hazards could arise from the properties of the genetic material that will be inserted into the viral vectors and expressed in transfected cells.

ShRNA

RNA interference (RNAi) is an antisense technology that exploits a normal cellular antiviral response that acts to inhibit viral protein synthesis through the production of short hairpin RNAs that bind and target viral double-stranded RNA (dsRNA) molecules for degradation. The shRNA molecules are processed by cellular enzymatic pathways to produce small inhibitory RNA (siRNA) species, and it is the latter RNA molecules that bind and target complementary RNA sequences for degradation by the RNA-induced silencing complex (RISC). With the use of shRNA-expressing viral vector systems, the expression of specific mammalian genes/proteins can be 'knocked-down', in order to study
their functions. Potential deleterious effects such as off-target and immunomodulatory responses can be minimised through screening designed shRNA sequences against databases of known mammalian gene/mRNA sequences during the design stage. The genes/proteins of interest that will be targeted by shRNA do not and will not include any growth factors, tropic factors, quiescence factors, confirmed oncogenes, tumour suppressors or immunomodulators. Some of the viral vectors that will be used contain a sequence of interest that has been scrambled (scrambled shRNA), and which is not complementary to any known mammalian sequences. These vectors will be employed as negative controls to demonstrate that any observed effects are due to the knockdown of a specific mRNA/protein of interest, rather than being due to any non-specific effects that the delivery of the viral vectors might cause. This sequence will adopt a hairpin structure as with any shRNA, but it should not target any mRNA of human origin. It will only serve as the negative control for the vector producing shRNA. Consequently, these sequences are unlikely to pose any safety risks for the environment or human health.

Programmable nucleases: zinc fingers and Cas9/CRISPR
Zinc fingers or Cas9 protein will be directed against genes of therapeutic interest identified by literature reports or by in-house screens. Since the purpose of programmable nucleases is to cause mutations in defined DNA sequences the primary hazard is that such a mutation would lead to deleterious cellular effects. The genes/proteins of interest that will be targeted do not and will not include any growth, tropic factors, confirmed oncogenes, tumour suppressors or immunomodulators. In isolation these sequences are unlikely to pose any safety risks for the environment or human health.

Green and red fluorescent proteins
The green fluorescent protein (GFP) is a protein composed of 238 amino acid residues (26.9 kDa) that exhibits bright green fluorescence when exposed to light in the blue to ultraviolet range. GFP traditionally refers to the protein first isolated from the jellyfish Aequorea Victoria.
Red fluorescent protein (DsRed) and its derivatives are structurally very similar to the green fluorescent proteins but are derived from Discosoma sp. mushroom anemone.
In biological research, fluorescent proteins are frequently used as a reporter of gene expression. While most small fluorescent molecules such as FITC (fluorescein isothiocyanate) are strongly phototoxic when used in live cells, fluorescent proteins are usually much less harmful when illuminated in living cells. Fluorescent proteins are not known to cause any diseases in humans or animals and have no direct effect on cellular processes.

Enzymes
Firefly luciferase is a 61 kDa monomeric protein first isolated from Photinus pyralis. The enzyme allows the photon emission through the oxidation of the beetle luciferin in a reaction that requires ATP, Mg+ and 02. The "flash" of light from the photon emission can be measured. In biological research, the luciferase protein is frequently used as reporter of gene expression. Luciferase is not known to cause any diseases in humans or animals and has no direct effect on cellular processes. The expression of luciferase under the control of a promoter of a gene of interest is unlikely to pose any safety risks for the environment or human health.
Beta-galactosidase is a 464kDa homotetrameric protein that catalyses the hydrolysis of beta-galactosides into monosaccharides and is present in the lysosomes in mammalian cells. In biological research, this activity can be utilized as a reporter of gene expression by catalysing substrates that result in luminescent, fluorescent or coloured products. Overexpression of beta-galactosidase is associated with cellular senescence but the activity of betagalactosidase is not required for senescence and cannot initiate it. Beta-galactosidase has been safely expressed as part of a gene reporter system in transgenic rodents and is not expected to pose any safety risks for the environment or human health.

FRET-based reporters of enzymatic activity or molecular interactions
Fluorescence resonance energy transfer (FRET) functions through a proximity-based transfer of energy from one fluorophore to a closely-located second fluorophore, such that the wavelength of the emitted signal is altered. In biological research this phenomenon can be utilised to assess direct interactions of molecules such as proteins. A FRET-based system can be conceivably designed to examine activity of enzymes such as proteases or kinases based on a change in proximity of two tethered fluorophores, or protein-protein interactions using fusion proteins with fluorophores like GFP. Only benign molecules will be used in these systems to ensure that these approaches have no adverse impact on human safety or the environment.

Summary on lentivirus

The transgenes that will be expressed by the viral vectors have a low safety risk to human health. This is because accidental contamination with a vector would lead to only a small number of cells becoming infected, and it would be highly unlikely that expression in only a few cells would be sufficient to lead to a disease state. The inability of the lentiviral vectors to propagate on mammalian cells also reduces the risk.

The programmable nucleases (CRISPR or Zinc Finger) that will be employed in this viral vector system are not known to cause any relevant toxicity that might represent a safety risk to human health. The Fluorescence Proteins and the enzymes that will be employed in this viral vector system are not known to cause any relevant toxicities that might represent a safety risk to human health. For both programmable nucleases and shRNA, the genes/proteins of interest that will be targeted will not include any growth factors, tropic factors, quiescence factors, confirmed oncogenes, tumour suppressors or immunomodulators, and none of them are or will be of retroviral origin. Therefore the risk of use will be low.

B) Immortalised human podocytes and transduced immortalised human podocytes

The immortalised human podocytes cell line described in this proposal have been immortalised by the insertion of U19tsA58-SV40T and hTERT sequences into the genome of primary human podocytes isolated from a donor that tested negative for Hepatitis Band HIV. The generation of this immortalised human podocyte cell line will not take place at Takeda Cambridge. This cell line has been generated in the laboratory of Doctor Richard Coward at Bristol University, UK. Due to the presence in the genome of the sequence coding for the SV40T antigen and the hTERT, this cell line will be maintained at the Biosafety level 2 containment.

As described above, this immortalised human podocyte cell line contains retroviral-integrated U19tsA58-SV40T and hTERT along with a partial viral genome. The tsA58 SV40 mutation (A438V) encodes a thermolabile large tumour (T) antigen (Tag) capable of immortalization only at the permissive temperatures. The U19 mutation (S152N and R154K) prevents binding to the SV40 origin of replication, imparting greater transformation efficiency and additionally preventing Tag-mediated replication of viral DNA, improving safety as the partial viral genome cannot be recovered from the integration site by U19tsA58-SV40 Tag. hTERT or telomerase reverse transcriptase, is the catalytic subunit of telomerase. Its overexpression stabilises telomere length preventing replicative senescence. These 2 elements induce immortalisation of the human podocytes. However, these cells do not contain the viral genes gag-pol and env required for virus production and therefore cannot produce viruses. We will confirm lack of gag-pol and env integration by PCR and lack of virus production in the podocytes by ensuring that supernatants from podocyte cultures do not transduce HEK293T cells.

Further modification of the immortalised human podocyte cell line may enhance the risk of a recombination of a replication-competent viral genome in the cells. Application to these cells of additional retrovirus or lentivirus particles could result in liberation of replication-competent retroviruses by genetic recombination events. This risk will be minimised by confirming that the viral genes gag-pol and env are not present in the genome of the immortalised human podocytes before the application of the lentivirus on the cells. Furthermore, this risk can be minimised by ensuring that any lentivirus (subclasses of retrovirus) used in experiments with the host cells does not contain gagpol, env or any other significant retroviral genes involved in packaging and replication.
The major risk factor associated with the utilisation of this cell line or the genetically modified podocyte cells would be accidental percutaneous inoculation of a worker. As described above, the immortalised podocyte cells will have to be in an environment at 33 degree Celsius to be able to proliferate. In the case of percutaneous inoculation of a worker it is unlikely that the cells can proliferate.

The SV40 large T antigen is capable of transforcting mammalian cells. However the U19tsA58 variant used here has two important safety features - (i) the U19 mutation prevents binding to SV40 origin of replication, preventing release of the integrated viral genome in the absence of further modifications or viral infections; (ii) the tsA58 mutation renders the TAg unstable at 37OC and thus would be incapable of transforming cells following infection of a human or animal host. Due to the integration of M-MuLV long terminal repeats (LTRs) and the presence of SV40 origin of replication in these podocytes, expression of wild-type SV40 TAg would result in liberation of the integrated MuLV sequences including U19tsA58-SV40T and hTERT. This risk will be avoided by ensuring that no SV40 sequence is introduced into the immortalised podocytes.

Another risk factor associated to the accidental percutaneous inoculation of a worker with immortalised human podocytes or transduced podocytes will be the potential recombination of the retroviral genome present in the podocytes and retroviral genome present in the accidentally inoculated worker. Even in that case, a series of unlikely events would have to occur to:

a. The worker would have to become infected with HIV-1 or to be already infected with the virus.

b. The viral and retroviral genomes would have to integrate into the immortal human podocyte's genome in a position where they could interact to effect homologous recombination.

c. Recombination would have to occur in precise regions to allow for transfer of the gene of interest (hTERT, SV40T antigen, shRNA, programmable nucleases, or reporter gene sequence) from the lentivirus to the HIV-1 genome, which would also involve the transfer of the HIV-1 genes to the lentiviral genome. In this case, it is conceivable that a non-self-inactivating HIV could be generated that contained the gene of interest but not the rest of the genome it requires. The other gene products could be provided in trans from the lentiviral genome that may now contain the HIV-1 genes or from other HIV-1 integrants.

d. The situation in c could conceivably lead to the production of an infectious particle containing the gene of interest, but again no genes necessary for subsequent replication. In order for another round of infection to occur, the process would have to begin again.

Although the risk for human health is low, all measures will be in place to minimize the risk of human health to avoid any accidental inoculation of a worker (see measures below).

Even if the events are unlikely, the immortalised human podocyte cell line and the transduced podocytes will be maintained at Biosafety level 2 containment. Therefore all measures will be in place to minimize the risk to human health.

Human health hazards

Oral ingestion will be prevented by standard laboratory safety practices. Aerosol formation resulting from an accident outside of the safety cabinet and involving lentivirus particle-containing liquid may lead to transduction of a limited number of the laboratory worker's skin or mucosal cells with modified viruses. However, these modified virus particles carry an extremely low safety risk for human health, as they are replication-incompetent, and also because the particles carry an extremely low infection potential via the mucosal/skin routes, due to the inherent properties of the viral vectors. Moreover, the programmable nucleases and shRNA that will be expressed or targeted will not be designed to disrupt any growth factors, trophic factors, quiescence factors, confirmed oncogenes, tumour suppressors or immunomodulators. In the unlikely event of accidental transduction of a laboratory worker's skin or mucosa by lentivirus particles, this will be self-limited, due to natural shedding of superficial epithelial skin and mucosal cell layers.
The most likely route of accidental infection with a lentivirus or the podocyte cell line will be via inadvertent percutaneous inoculation. The likelihood of this occurring will, however, be minimised by adhering to appropriate risk management measures (for the detailed measures see Measures used in the Biosafety level 2 containment). Infection of the community at large with lentivirus particles is highly unlikely due to the viral vector particles being replication incompetent. Infection of the community at large by the immortalised podocyte cells is highly unlikely due to the impossibility of the cells to survive outside of a laboratory environment.

* Environment and Activity Considerations
The chance that active viral particles will be accidentally released into the environment is considered to be highly unlikely, as effective containment procedures will be adhered to (see Measures used in the Biosafety level 2 containment). However, in the unlikely event that active lentiviral vector particles do accidently get released into the environment, the safety risk posed by such an event is considered to be negligible, due to the vectors being self-inactivating and non-replicative. The main potential risk in such an event would be the subsequent contamination of a human population already infected with HIV, which would potentially allow for recombination events that could incorporate the inserted sequences into a viable replication-competent lentivirus. However, this scenario is extremely unlikely and even if it was to occur, it is unlikely that it would lead to any untoward effects. As the HIV virus is a human pathogen infection of another species would not be expected to allow any form of recombination event leading to a viable transmissible entity and so the risk from this scenario is considered to be negligible. Rodents, such as Wild-type mice and rats, cannot support replication of infectious HIV-1 (2). As a result, the potential for shedding of replication-competent lentiviruses from such animals is very low (even if they were present in the original vector inoculum).

The vectors have been pseudotyped with the VSV-G envelope in order to increase tropism, and in theory they are capable of transducing all dividing and non-dividing mammalian cell types. As emphasised before, the vectors cannot self-propagate after infection, and successful transduction is critically dependent on the presence of high enough concentrations of virus particles. Viral vector stock solutions will be managed in a way that will prevent contaminations with relatively high viral titres. After production, the vectors are aliquoted and stored in screw capped cryovials at ao° c. Taking into account that the infectivity of the vectors rapidly decreases at room temperature, it is considered highly unlikely that the vectors could survive in the long term after being accidentally released into the environment. Lentiviral vectors have a short half-life at room temperature due to their structural characteristics making them highly susceptible to dehydration, and relatively unstable. For this reason, retroviruses become rapidly inactivated outside host systems, as illustrated by the fact that close contact is required for transmission. They can, however, survive for long periods in high protein media.

There are no conceivable hazards associated directly with the lentiviral vectors (containing the inserts) as they will not replicate/survive outside the laboratory and they have been designed to include many protective safety features. shRNA sequences will also not survive as they are highly unstable, and they would, consequently, be rapidly inactivated/degraded if accidentally spilled into the environment. Moreover, as discussed above, there is a very low risk that the sequences contained within the viral vectors could be transferred to other organisms, as a rare recombination event would have to occur to allow this to happen.

The risk to the environment following accidental release of the immortalised human podocytes would be negligible since the cells are incapable of surviving outside of laboratory conditions. If live podocyte cells were to directly inoculate animals, they could theoretically survive but would be quickly cleared by the immune system, as previously mentioned would be unproliferative at 37°C body temperatures and do not produce active viruses (this will be confirmed). An additional risk is associated to the accidental inoculation of rodents already infected by the Moloney murine leukaemia virus. In that case, the recombination between the genome of the Moloney murine leukaemia virus and the genome of the immortalised human podocytes could occur leading to the production of M-MuLV viruses containing the sequences of SV40 large tumour antigen and hTERT. Even if the SV40 variant present in the
Podocytes were liberated into replication-competent M-MuLV following recombination in an already-infected rodent, the tsA58 variant is incapable of transforming cells in an infected organism due to instability at 37°C body temperatures. The likelihood of this occurring will, however, be minimised by adhering to appropriate risk management measures and ensuring that all potentially contaminated material is totally inactivated before disposal.

* Containment Measures

The work outlined above has been classified as a Biosafety level 2 activity, even though the risk of pathogenicity to the end worker is considered to be very low. In all cases, HSE prescribed Biosafety 2 conditions should be adhered to when handling the immortalised human podocyte cells, generating the viral vectors in HEK293T cells, as well as their subsequent storage at -80°C. For subsequent in vitro transduction of the cells types mentioned in this proposal (e.g. human HEK293T, immortalised human podocyte cells) this will be performed under Biosafety level 2 conditions. The human transduced HEK293T used to assess the efficacy of the vectors will only be converted to Biosafety level 1 once the medium containing the virus has been removed and the infected cells have been extensively washed. The immortalised human podocytes transduced by lentivirus will be maintained under Biosafety level 2.

Procedures

During all procedures that involve the handling/use of the viral vectors or cells, all workers (incl. those that are not working directly with the vectors) that are present within a lab where the work is undertaken are required to wear personal protective equipment (at all times. The use of two pairs of gloves is advised so the external pair can be disposed in an autoclave bag and replaced whenever necessary (e.g. in the case of contact with the viral reagent). Face masks are also available for use, where appropriate. In addition, all workers are made aware of the nature of the viral work that is going on within the laboratory, and they have to follow appropriate procedures to ensure that there is no cross-contamination into non-viral working areas. All the workers using the viral delivery systems are experienced research scientists, and junior scientists will be closely supervised until they are competent in the handling of the viruses.

Lentiviral production

Production of lentiviruses will also be carried out on-site using a modified procedure based on Bukovsky et al (3). Lentiviral production will only be carried out in HEK293T cells in a Biosafety level 2 cabinet within a dedicated Biosafety level 2 laboratory. The HEK293T cells used for lentiviral production will be seeded in filter containing screw cap culture flasks in order to minimize the risk of spills and/or aerosol mediated viral spread. For this the modified pRRL plasmids together with three additional separate plasmids (pMDLgp-RRE, pRSV-REV and pMD2-VSVG.env) will be transfected using a transfection reagent (e.g. Polyethylenimine (PEI), Lipofectamine) into HEK293T packaging line. After 6-12 hours, the medium is replaced with fresh serum-free medium and grown for an additional 72-96 hours. After 24-48 hours, so as to ensure the viability of the transfected HEK293T cells, medium from the cells is collected into screw cap tube and stored at 4°C and fresh serum-free medium is added to the cells. The cells are grown for an additional 24-48 hours before the second medium solution is added to the first harvest tube. After lentivirus collection has been completed, the cells and the flasks will be decontaminated and disposed of as detailed later (see Waste Handling).

Still within a Biosafety level 2 Safety Cabinet in a Biosafety level 2 Biosafety laboratory, the harvested supernatants will be filtered using a 0.45 μm filter before either aliquotted or further purified by chromatography and/or concentrated by centrifugation. The lentiviral particles may need to be purified by either chromatography (e.g. ViraBind™) and eluted in a high salt solution (50 mM Tris, pH 7.5, 5 mM MgCl2, 2 M NaCl) and/or concentrated by ultrafiltration (e.g. LentiSelectTM). For certain application where highly concentrated, highly purified virus may be required, the traditional method of sucrose cushion based centrifugation may be necessary. To minimise the possible risk of accidental viral contamination and spread due to the need for an ultracentrifuge, all loading and unloading will be done in the Biosafety level 2 Safety Cabinet. Once the sucrose cushions have been added to the centrifuge tubes, they will be
transferred into the Biosafety level 2 cabinet. The unpurified or chromatography purified lentiviral particles will then be
added to the sucrose cushion. The individually capped tubes will then be transferred to their respective bucket holders
and the bucket sealed using their respective screw caps and marked as containing virus. The bucket will be
transferred to a weighing scale and a counterpart bucket and tubes with water (and without lentivirus) will be prepared
that is weight matched. The balanced buckets will then be transferred to the rotor before being placed within the
centrifuge chamber. The ultracentrifuge will be run at 70000g for 2 hours at 20°C. Upon return of the buckets to the
Biosafety level 2 cabinet, the supernatant will be removed from the tubes before transfer of the resuspended virus
pellet into individual screw cap cryovials. As the greatest risk for contamination occurs within the centrifugation
buckets themselves during transport to and from the weigh scales and during ultracentrifuge, the centrifuge tubes and
also the buckets will be decontaminated with Chemgene HLD4L 5% for 24 hours before removal from the Level 2
laboratory. In any case, at no point will concentrated virus stock be exposed to the environment outside of the class 2
hood. All supernatants will be treated as above.

The lentiviral titre will be determined in terms of the number of viral particles (VP) or Transduction units (TU) per ml.
The number of VP can be assessed relatively quickly and does not involve cell infection. In this case, a bead based
enrichment assay (e.g. QuickTitre™ Quantification Kit) or a p24 ELISA assay (e.g. QuickTitre™ Lentivirus Titre kit)
will be chosen. The VP quantification methods tend to overestimate the TU by 10-1000 fold. Thus, the TU 1 ml will in
certain instances also be determined. For this, a titration range of lentiviruses expressing a fluorescent tag, serial
dilution will be prepared and added to a 24 well cluster plate or T25 TC-flasks containing HEK293T for 48 hours. The
percentage of fluorescent positive cells will be quantified manually under a fluorescent microscope or ideally using
FACS analyser. The biological titre (TU/ml) according to the following formula: $TU/ml = \left( \frac{P}{N} \times 10^10 \times V \times 10DF \right)$,
where $P =$ % GFP+ cells, $N =$ number of cells at time of transduction = 105, $V =$ volume of dilution added to each well
and $DF =$ dilution factor = 1 (undiluted), 10-1 (diluted 1/10), 10-2 (diluted 1/100), and so on.

Aliquots with not more than 1x10^18 viral per vial are subsequently stored at -80°C in individual screw capped
cryotubes. The viral stock will consist of viral particles containing the vector genome (full capsids) and also of a
variable number of empty viral capsids. Other trace components that might be present include, but are not limited to,
inorganic salts, vitamins, other nutrients, human cellular proteins, carbohydrates, amino acids, and fats.

In vitro studies

Transduction of cells (e.g. human HEK293T or immortalised human podocyte cells) with the lentiviral vectors will be
carried out in a Biosafety level 2 cabinet within a dedicated Biosafety level 2 laboratory. In the in vitro studies, the
TUs, and consequently volumes added, will be dependent on the number of cells in the tissue culture dish/flask to be
infected, up to the maximum number of viral particles to be handled per experiment (around 1 x 10^18). None of these
cells will be cultivated in the filter screw cap flasks used for HEK293T mediated lentiviral production. This is to ensure
that, in particular, the HEK293T cells used for lentiviral production are not inadvertently used for lentiviral assessment.
Any plastic ware or solutions that are used to handle the transduced cells will be decontaminated and disposed of as
detailed later (see Waste Handling). Once the medium containing the lentiviral particles has been removed and the
cells (e.g. human HEK293T or immortalised human podocyte cells) have been extensively washed, which all is done
in a Biosafety level 2 cabinet, the human HEK293T cells can be used following Biosafety level 1 guidelines, as no
virus will be present and the latent virus in the transduced cells is replication-incompetent. The immortalised human
podocytes will be used following Biosafety level 2 guidelines. A viral titre determination assay may on occasion be
used to verify the absence of virus in the medium from human HEK293T cells and immortalised human podocyte
cells.

Cleaning SOPs

General cleaning procedures

Surfaces will be thoroughly cleaned with Chemgene HLD4L 5%* (or an equivalent product) at the end of each
experiment or after the occurance of an accidental spillage of infectious material. Application of these anti-microbial agents will totally inactivate any viral vectors that might be present. According to the biosafety literature, all of the viruses to be used are susceptible to these disinfectants. Anything that might have potentially come into contact with the virus will be treated with Chemgene HLD4L* before being autoclaved/incineration.

* Chemgene HLD4L

Chemgene HLD4L is formulated as a micelle cleaning technology that enables the active molecules in the product to be carried rapidly through the cell walls of micro-organisms. Swift penetration of the cell walls ensures cell death is equally rapid. The Synergetic blend of technology and active ingredients enables Chemgene HLD4L to work quicker than conventional high level disinfectants and ensure that apoptosis (cell death) is achieved rather than merely suspending activity as with conventional products. Chemgene HLD4L has been reported to be bactericidal, fungicidal as well as virucidal (HIV, Hepatitis B, Herpex Simplex, Norovirus and Coronavirus) and sporicidal. It is recommended to be used at a 1:100 dilution (1 %) for general purposes, 1 :20d for high risk areas, and 1 :20 (5%) for disinfection of blood and bio-hazard spillages.

Cleaning SOPs
General cleaning procedures
Health and Safety
Executive
Surfaces will be thoroughly cleaned with Chemgene HLD4L 5%* (or an equivalent product) at the end of each experiment or after the occurrence of an accidental spillage of infectious material. Application of these anti-microbial agents will totally inactivate any viral vectors that might be present. According to the biosafety literature, all of the viruses to be used are susceptible to these disinfectants. Anything that might have potentially come into contact with the virus will be treated with Chemgene HLD4L* before being autoclaved/incinerated.

Waste Handling
Solid waste will be neutralised by soaking it in a validated disinfectant solution, after which the material will be ‘double bagged’, autoclaved and, ultimately, incinerated offsite. It will be routine practice that all liquid waste material be neutralised before disposal, and for the neutralised waste to be transported in leak-proof containers to prevent spillages. At 860°C, liquid waste will be inactivated by Chemgene HLD4L* for 24 hours prior to drain disposal as per 430CSP and 418CSP permit requirements.

Following all work requiring biosafety level 2 containment including work with lentiviruses and immortalised human podocytes, any solutions, plastic ware and consumables that have been used will be decontaminated with Chemgene HLD4L.
HLD4L for at least 24 hours prior to removal from the biosafety level 2 laboratory and disposal as outlined above. As any active viral particles or immortalised human podocytes cells on surfaces or in waste material will be completely inactivated at the end of each experiment by the highly effective cleaning/disinfection protocols outlined above, it is considered highly unlikely that active virus particles or immortalised human podocytes would unintentionally become discharged into a sanitary sewage system. No foreseeable adverse effects on human health and safety are expected. Chemgene HLD4L

Chemgene HLD4L is formulated as a micelle cleaning technology that enables the active molecules in the product to be carried rapidly through the cell walls of micro-organisms. Swift penetration of the cell walls ensures cell death is equally rapid. The Synergetic blend of technology and active ingredients enables Chemgene HLD4L to work quicker than conventional high level disinfectants and ensure that apoptosis (cell death) is achieved rather than merely suspending activity as with conventional products. Chemgene HLD4L has been reported to be bactericidal, fungicidal as well as virucidal (HIV, Hepatitis B, Herpes Simplex, Norovirus and Coronavirus) and sporicidal. It is recommended to be used at a 1:100 dilution (1 %) for general purposes, 1 :20d for high risk areas, and 1 :20 (5%) for disinfection of blood and bio-hazard spillages.

The GMSC has agreed that the work outlined above can be safely carried out under biosafety class 2 containment. The immortalised podocyte cell line has been generated (from an individual shown to be negative for HIV or Hep8) using a retroviral system that delivers a thermolabile SV40T antigen, a human telomerase but retains its L TR. The cell line has been shown to not generate infectious particles. Although there is a chance that the retrovirus can mobilise out of the genome the thermolability of the SV40T antigen mitigates the potential transformative and oncogenic effects of subsequent accidental infection. As the planned work calls for the use of lentivirus to deliver shRNA, targeted nucleases or reporter constructs there is an increased risk of mobilisation through recombination events. Sequence analysis has shown that there is no shared common sequence between the lentiviral vectors that will be used to deliver additional genetic material and the Moloney murine leukaemia virus system used to immortalise the human podocytes essentially minimising this risk. The lentivirus themselves are generated using a third generation system whereby the essential elements required for virus production have been separated out onto different vectors and are only delivered in a transient manner to minimise the chance of a recombination event leading to replication competent virus. Even when the immortalised podocytes are transduced with a reporter gene and either shRNA or programmable nucleases in combination the likely hood of recombination is minimal. This virus system is also self-inactivating so that once integrated into the target cell's genome it cannot mobilise. As the virus integrates into the genome of cells no tumour suppressors, oncogenes, genes involved in quiescence or immune-modulators will be targeted. As recombination and mutation events cannot be ruled out this work will be carried out under class 2 containment. Transduced cells will be tested for absence of infectious particles.
**Project Additional Information**

**Purposes of the contained use**

The human immortalised proximal tubules cells will be used to investigate the cellular pathway involved in the development of human renal disease, in particular acute kidney injury.

To better understand these cellular pathways, the expression or the activity of the gene of interest will be modulated by several methods:

1. The utilisation of tool compounds
2. The knock-down of the gene of interest by shRNA
3. The generation of knockout somatic cells using programmable nucleases (CRISPR or Zinc finger nucleases)
4. The generation of reporter gene cell line (i.e. fluorescence protein or enzyme) under the promoter of the gene of interest.
The experiments involving the transfection of vectors such as shRNA or programmable nucleases will be performed by lentivirus. The effect of modulating the expression or the activity of the target of interest will be determined by the expression level of the proteins, mRNA or mediators involved in the target signalling pathway.

Recipient or parental organism

TH1 cells are derived from primary human renal proximal tubule epithelial cells (RPETCs) immortalised by two lentiviral vectors carrying the human telomerase (hTERT) and the SV40 large and small T antigen (Tag). The generation of the TH1 cells have been described by Kowolik and al. (Kowolik et al, 2004, Oncogene). Primary human RPTECs from third and fourth passage were transduced with both HIV-7/CPNO-Tag and HIV-7/CPNO-hTERT vectors.

Description of the vectors used to immortalize primary cells: This vector pHIV7/CNPO is the “backbone” of the pHIV7/CNPO-hTERT and pHIV7/CNPO-Tag. To generate the pHIV7/CNPO, the neomycin resistance (neoR) gene and an internal ribosome entry site (IRES) flanked by two LoxP sites controlled by the immediate early (IE) gene promoter of cytomegalovirus (CMV) were inserted into the pHIV7 (Kowolik and Yee, 2002). The pHIV7/CNPO-hTERT is composed of the pHIV7/CNPO in which the cDNA for the catalytic subunit of the human telomerase (hTERT) has been inserted. The pHIV7/CNPO-Tag is composed of the pHIV7/CNPO in which the cDNA for SV40 large and small T antigen has been inserted.

The resultant cell line, TH1, contains the sequence coding for SV40 Large and Small T antigen and hTERT under the CVM IE enhancer and the promoter of the HIV 5’LTR. The cell line also contains 190bp of central polypurine tract sequence (cPPT) from HIV-1, 800bp post-transcriptional regulatory element from Woodchuck hepatitis virus (WPRE) and the U3 region of the HIV 3’LTR deleted of 400bp that completely removed the enhancer and promoter sequences in this U3 region.

The immortalised cells failed to form anchorage-independent colonies in soft agar. They also failed to form tumours in nude mice. Furthermore transient Cre expression in TH1 cells leads to efficient proviral deletion and upregulation of some renal specific activities. Removal of the genes for cell immortalisation also significantly decreases the rate of cell proliferation and ultimately leads to cell senescence, suggesting that the cell cycle control remains intact in TH1 cells despite continuous passage of these cells in culture. These results strongly suggests that the immortalised cells were not transformed.

Host/vector system

To study the function of proximal tubules cells in human disease, the expression of a target of interest may be decreased in the TH1 cell line by the transduction of shRNA or programmable nuclease by lentivirus. The modulation of a particular cellular pathway may be studied with the use of a reporter gene assay. In this case, the vector contained the reporter gene under regulating sequence from the promoter of the gene of interest will be introduced by lentivirus into these TH1 cells.

This proposal involved both the use of existing lentiviral constructs purchased commercially and the generation of new constructs on site using the third generation system. Both commercially acquired and in-house lentivirus will use the same vector backbones containing identical promoters. Target genes will be selected based on the needs of drug discovery projects; programmable nucleases and shRNA will not be produced against any growth factors, tropic factors, quiescence factors, confirmed oncogenes, tumour suppressors or immunomodulators.

The production of lentivirus containing the vectors of interest are described below:

1- Generation of lentivirus
Lentiviral vectors will be purchased commercially or produced in-house using the third generation system described below. Each purified and concentrated aliquot of lentiviral reagent comprised of a small volume (5 to 10ul) that contains no more than 1X10e8 viral particles.

Vector System = self-inactivating (SIN) non replication-competent HIV based lentiviral vectors
The viral vectors that will be used in the proposed studies are self-inactivating non replication-competent HIV based lentiviral vector systems, which have been designated to produce stable gene expression in mammalian cells; and they are generated by co-transfecting HEK 293T cells with four separate plasmids. Each of the plasmids used expressed a different set of genes which, when combined following co-transfection, provide the smallest possible set of essential viral genes that is still compatible with virus production. Moreover, the vectors are all vesicular stomatitis virus (VSV-G) pseudotyped lentiviral vectors, which are self-inactivating and highly unlikely to undergo recombination. Importantly, the viral vector system is inherently incapable of replication in mammalian cells.

The plasmids
The sequences that will be included in the viral vectors are sub-cloned into 4 standard bacterial plasmid vectors.

- Plasmids containing the packaging related sequences
Each of the three other plasmids, pMDLgp-RRE, pRSV-REV and pMD2-VSVG.env contain a different set of sequences that code for proteins that are responsible for packaging the viral vectors. All the genes (gag-pol, rev and env) required for production and packaging of the full length viable viral RNA particles have been removed from the pRRL lenti-plasmids containing the transgenes of interest.

- Plasmids containing the transgene of interest
  - Vector containing shRNA
    As mentioned above, pRRL plasmid will contain the sequences that code for one shRNA transcript that will target one mRNA/protein of interest (or a scrambled shRNA in the case of negative control). The shRNA or scrambled shRNA sequences will be under the control of polymerase III U6 promoter. The shRNA sequences will be chosen to target a single mouse or rat gene. Target genes of the shRNA will not be produced against any growth factors, tropic factors, quiescence factors, confirmed oncogenes, tumor suppressors or immunomodulators.
  - Vector containing CRISPR or Zinc-finger nucleases or Cre recombinase
    Programmable nucleases function by binding to, and cleaving, user-defined target DNA sequences. This in turn instigates a robust DNA repair response which ultimately leads to disruption of the target sequence by deletion at the cleavage site or by recombination with a user-supplied synthetic vector containing sequences complementary to the target gene.
    For Cas9/CRISPR, nuclease target specificity is determined by an accessory sequence, the guide RNA, which consists of a short (18-20 nucleotide) sequence homologous to the target gene and an additional short sequence that forms a complex with the Cas9 enzyme. In the case, the plasmid pRRL, will contain the sequences that code for a Cas9/CRISPR plus accessory sequences comprising a short guide RNA that determines target specificity. The guide RNA sequences will be under the control of the Polymerase III U6 promoter.
    In the case of Zinc finger nucleases target specificity is dependent upon the zinc finger protein sequence. The pRRL will contain in that case the sequence of zinc finger nucleases under the control of either the CMV promoter or the EF1A promoter. In addition, a fluorescent protein or enzyme under the control of cytomegalovirus (CMV) promoter, EFIA promoter or the promoter of a gene of interest may be included. Control viral vectors that express only the fluorescent protein/enzyme and no programmable nuclease will be used in some experiments.
    The pRRL vector will contain the sequence coding for the Cre recombinase under the the control of the CMV promoter to allow the removal of the SV40 T antigen sequence and the hTERT sequence from the TH1 genome.
  - Reporter gene vector
    The pRRL vector will contain the sequence coding for a reporter protein (enzyme or fluorescent protein) under the control of the regulating elements of the promoter of the gene of interest or the CMV or EF1A promoter. An appropriate selection marker i.e.; neomycin could also be included to allow the selection of stable human tubule cells containing the reporter gene sequence under the control of the promoter of the gene of interest.
    The pRRL vector will contain the sequence coding for the Cre recombinase under the the control of the CMV promoter to allow the removal of the SV40 T antigen sequence and the hTERT sequence from the TH1 genome.

**Origin & function**

- Assessing efficacy of the lentivirus into a BSL1 cell line
  Assessing whether the genome manipulation or the knock-down has worked will normally take place initially in biosafety level 1 immortalised cell line (human HEK293T) that are known not to contain lentiviral genetic material. Application of lentiviral particles will be done at biosafety level 2 confinement. After at least 24 hour incubation and extensive washing, the cells will treated as biosafety level 1 (see below the justification for removal of cells post-infection to biosafety level 1). In order to determine whether the knock-down or the genome manipulation has worked, the levels of mRNA and protein will be assessed post-transduction, using suitable in vitro assays.

- Transduction of the lentivirus and the generation of stable expression into TH1 cells
  Once validated the same procedure will be carried out in the human TH1 cells. As the human proximal tubule cells are maintained in a biosafety level 2 confinement, the inoculation of lentiviral particles, the transformed cells and the phenotypic analysis will also be performed in a biosafety level 2 containment. When a lentivirus containing a programmable nuclease or the reporter gene will be used, a stable cell line could be established by selecting the cells in which the genome has been modified. In all cases phenotypic analysis will be performed using suitable in vitro assays, including for example, RT-PCR, Western Blotting, immunocytochemistry and imaging, or cellular bioenergy (i.e.: mitochondria respiration function or glycolysis function).
Evaluation of foreseeable effects

* Human Health

The immortal human proximal tubule cell that will be used has a low risk for human health. The expression systems and the transgenes that comprise the lentiviral vectors that will be used have also a very low risk for human health and safety, and the reasons for this are discussed below.

A- Lentivirus containing shRNA, or programmable nuclease sequence or reporter gene vectors

Lentiviral Vector Expression System

Lentiviruses belong to the Retroviridae virus family which are capable of infecting both human and animal species. As the lentiviral vector system that will be used in these studies is based on HIV-1, a theoretical risk to human health exists. However, retroviruses are generally transmitted via exposure to contaminated body fluids or percutaneous inoculation and generally not transmitted via the airborne route. Therefore, accidental piercing of the skin or other surface tissues with virus containing objects represents the main potential route by which accidental infection could occur. Appropriate risk reduction measures will be implemented to reduce the likelihood of this occurring.

In all of the modified pRRL plasmids (containing shRNA, or programmable nuclease or reporter gene sequences), the sequences inserted are flanked by non-coding retroviral LTRs, and no retroviral genes are encoded on the modified pRRL plasmids. Therefore, no retroviral genes will be transferred into generated viral particles. This construct is package into particles using a HEK293T cell based packaging system, which requires the co-transfection of cells with three additional separate plasmids (pMDLgp-RRE, pRSV-REV and pMD2-VSVG.env). The latter 3 plasmids express the envelope protein from VSVg and the non-structural proteins of the virion, and, importantly, none of these genes will be transferred into the assembled viral vectors, since they lack the packaging signal, which is only present on the modified pRRL containing plasmids.

The lentiviral Expression System what will be used include the following key safety features:

* All of the pRRL contain a deletion in the 3'LTR (DeltaU3) that does not affect generation of the viral genome in the producer cell line, but results in "self-inactivation" (SIN) of the vector after transduction of target cells. Once integrated into a transfected target cell, the lentiviral genome is no longer capable of producing viral genomic material that can be packaged. Moreover, deletion of enhancer and promoter elements from the 3' U3 region in the vector construct will result in a provirus that is entirely devoid of the U3 enhancer sequences, which will result in a reduction in the potential for transactivation of cellular genes due to an insertion event. Furthermore, the development of self-inactivating vectors improves the biosafety of vectors, as they are less likely to be mobilised following a superinfection with wild-type virus (HIV).

* The VSV-G gene from Vesicular Stomatitis Virus is used in place of the HIV-1 or other retroviral envelope genes. Heterologous envelopes, like VSV-G, typically broaden the tropism and allow gene transfer into a broad variety of cells. The risk will mitigated by the use of self-inactivating virus and limiting the number of viral particles that will be handled at any one time.

* Sequences encoding the proteins required for packaging of the viral genome are separated onto three plasmids, and all of the 4 plasmids used in the system have been engineered not to contain any regions of homology with each other so as to prevent undesirable recombination events that could lead to the generation of a replication-competent lentivirus (RCL), which could potentially be harmful to humans. It is important to note that no such RCL has ever been observed despite large-scale production and testing of lentiviral vectors.

* All of the pRRL containing plasmids/vectors will be used are devoid of all viral sequences apart from essential cis-acting sequences, including the LTRs and the packaging signal. Although the packaging plasmids used in these systems allows for the expression in trans of protein required to produce viral progeny (e.g. gal, pol, rev, env) in the HEK293T producer cell lines, none of them contain LTRs or the packaging sequence. Several of the lentiviral accessory genes (vif, vpr, vpu and nef) that are dispensable for lentiviral vector production/transduction have been deleted from the packaged construct. Therefore, none of the retrovirus structural genes will actually be present in the packaged viral genome, as they will never be expressed in the transduced target cells, which means that no new RCL can be produced.

* The lentiviral particles produced in this system are replication-incompetent, only carry the sequences of interest, and no other viral species are produced.

* Expression of the gag and pol genes from pMDLgp-RRE has been rendered Rev-dependent by virtue of the HIV-1 RRE (Rev Responsive Element) in the gag/pol mRNA transcript. Addition of the RRE in these plasmids prevents gag and pol expression in the absence of rev, which is contained in the pRSV-REV plasmid only. The Rev/RRE system is highly conserved among lentiviruses, and removal of the RRE sequence and associated splice donor/acceptor sequences result in a loss of transduction efficiency.

* LTR has been modified so as to increase lentiviral vector production, and also to allow lentiviral vector production to be independent of tat expression. It is known that Tat-deleted mutants of wild-type HIV-1 are not replication competent. Therefore, the deletion of Tat should decrease the risk of generating a putative RCL.

* Lentiviral vectors have a very low potential to cause immunogenicity.
In the lentiviral vector system that will be used, the WPRE (woodchuck post-transcriptional regulatory element) has been mutated to remove the oncogenic WHV-X protein from an open reading frame found in WPRE sequence. The central poly purine tract (cPPT), from the pol ORF, is included in all of the viral vectors that will be used to improve the nuclear import of the proviral DNA and hence accelerate transduction.

While the lentiviral vectors that are produced using this system contain only about 20% of the original genome of HIV-1, there is a very small risk that subsequent infection of cells already infected with the lentiviral genome of HIV-1 could lead to a rare recombination event in which the transgene is transferred to a replication-competent virus. Thus, the sequences in the vector that will be expressed could potentially be transferred to surrounding cells. This event is, however, extremely unlikely to occur for a number of reasons:

1- The lentiviral vector is replication-incompetent and self-inactivating. In the case of a subsequent HIV-contamination, wild-type HIV-1 cannot rescue a self-inactivating HIV-1 based lentivirus once integrated into the host genome, although non-self-inactivating vectors can be.

2- In order for the spread of the gene of interest to occur following accidental infection (assuming that this has lead to viral integration), a series of unlikely events have to occur:
   a- The worker would have to become infected with HIV-1 or to be already infected with the virus.
   b- The viral and lentiviral genomes would have to integrate into the host worker's genome in the same cells and in a position where they could interact to effect homologous recombination (point 1 above)
   c- Recombination would have to occur in just the right regions to allow for transfer of the gene of interest from the lentivirus to the HIV-1 genome, which could also involve the transfer of the HIV-1 genes to the lentiviral genome. In that case, it is conceivable that a non-self-inactivating HIV could be generated that contained the gene of interest but not the rest of the genome it requires. The other gene products could be provided in trans from the lentiviral genome that may now contain the HIV-1 genes or from other HIV-1 integrants.
   d- The situation in c could conceivably lead to the production of an infectious particle containing the gene of interest, but again no genes neccessary for subsequent replication. In order for another round of infection to occur, the process would have to begin again.

These circumstances, the effects of lentiviral infection are likely to be minor in comparison to the effects of the HIV-1 infection, which would be required to affect the spread of the gene of interest. In addition, the scenario described is essentially equivalent to the rescue of the lentiviral genome from the host, which has already been shown not to occur.

3- It is extremely unlikely that any worker would infect themselves with a significant dose of lentivirus as the volumes that are used in transfection experiments are small (aliquots contain a maximum of 10μl of vector solution).

4- Moreover, insertional mutagenesis into the host genome may be considered as an oncogenic risk. We cannot rule out the possibility that, when the lentiviral genome integrates into the host genome, it will not lead to the activation of an endogeneous oncogene. However, all transcriptionally active long-terminal repeats (LTRs) have been removed as well as all promoter-like elements that required to drive expression of the transgene. This should prevent unforeseen activation of such genes. It is noted that deletion of retroviral enhancer in self-inactivating systems reduces the risk of activation but not of disruption, therefore, retroviral infection might still have permanent effects upon a cell (including oncogenic effects).

Importantly, we do not consider that the use of these lentiviral vectors will result in a significant increased risk of oncogenic activation compared to the risk possessed by any other viral delivery system. Moreover, the risk of transduction leading to tumourigenesis or other untoward harm following exposure is related in part to the titre of the viral vectors; exposure of workers to quantities of virus high enough to cause such effects would be unlikely during standard laboratory-based manipulations of lentiviral vectors.

Transgenes:
Additional hazards could arise from the properties of the genetic material that will be inserted into the viral vectors and expressed in transfected cells.
• shRNA
With the use of shRNA-expressing viral vector systems, the expression of specific mammalian genes/proteins can be knocked-down, in order to study their functions. Potential deleterious effects such as off-target and immunomodulatory responses can be minimised through screening designed shRNA sequences against databases of known mammalian/mRNA sequences during the design stage. The genes/proteins of interest that will be targeted by shRNA do not and will not include any growth factors.
tropic factors, quiescence factors, confirmed oncogenes, tumor suppressors and immunomodulators. Some of the viral vectors that will be used contain a sequence of interest that has been scrambled (scrambled shRNA), and which is not complementary to any known mammalian sequences. This sequence will adopt a hairpin structure as with any shRNA, but it should not target any mRNA of human, mouse or rat origin. Consequently, these sequences are unlikely to pose any safety risks for the environment or human health.

- Programmable nucleases: zinc fingers or Cas9/Crispr or Cre recombinase
  
  Zinc fingers or Cas9 protein will be directed against genes of therapeutic interest. Since the purpose of programmable nucleases is to cause mutations in defined DNA sequences the primary hazard is that such a mutation would lead to deleterious cellular effects. The genes/proteins that will be targeted do not and will not include any growth, trophic factors, confirmed oncogenes, tumor suppressors or immunomodulators. In isolation, these sequences are unlikely to pose any safety risks for the environment or human health.

  The Cre recombinase enzyme is not known to cause any diseases in human and animals and have direct effect on cellular processes. The application of Cre recombinase in TH1 will induce the deletion of the sequences between the 2 sequences LoxP such as the sequences for coding for neomycin, hTERT and Tag and the IRES, leaving the sequence of CMV/LTR, cPPT, CMV, WPRE and LTR in the TH1 genome. In that case, the resultant cells have been shown to down-regulate proliferation and becoming senescent after few passages (Kowolik et al. 2004).

- Reporter genes: Fluorescent protein or enzymes

  The reporter gene could be a fluorescent protein or an enzyme. Fluorescent proteins, for example GFP or dsRed, are not known to cause any diseases in human or animals and have no direct effect on cellular processes. Enzymes used frequently in reporter gene assay ie luciferase of b-galactosidase are not known to cause any diseases in humans or animals and as no direct effect on cellular processes. The expression of fluorescent protein or enzymes under the control of a promoter of a gene of interest is unlikely to pose any safety risks for the environment or human health.

**Summary on lentivirus**

The transgenes have a low safety risk to human health because accidental contamination with a vector would lead to only a small number of cells becoming infected, and it would be highly unlikely that expression in only a few cells could be sufficient to lead to a disease state. The inability of the lentiviral vectors to propagate on mammalian cells also reduces the risk. The programmable nucleases (CRISPR or Zinc finger or Cre recombinase) that will be employed in this viral vector system are not known to cause any relevant toxicity that might represent a safety risk to human health. The fluorescent proteins or the enzymes are not known to cause any relevant toxicities that might represent a safety risk to human health. For both programmable nucleases and shRNA, the genes/proteins of interest that will be targeted will not include any growth factors, tropic factors, quiescence factors, confirmed oncogenes, tumor suppressors or immunomodulators, and none of them are or will be of retroviral origin. Therefore the risk of use will be low.

**B- Immortalised human proximal tubules cells TH1 and transduced immortalised TH1 cells**

The immortalised TH1 cell line have been immortalised by the presence of the coding region for both large and small T-antigen and hTERT. This cell line will be purchased from Kerafast.

Large and Small T antigen have been described to be sufficient to transform human cells. hTERT or telomerase reverse transcriptase is the catalytic subunit of telomerase. Its overexpression stabilises telomere length preventing replicative senescence. These 2 elements induce immortalisation of the human proximal tubules cells. These cells also contain the sequences for WPRE, cPPT and deltaU3 of HIV-1 virus. However these cells do not contain the viral genes gag-pol and env required for virus production and therefore cannot produce viruses. We will confirm lack of gag-pol and env integration by PCR and lack of virus production in the TH1 by ensuring that supernatants from TH1 culture do not transduce HEK293T cells.

As mentioned above, the TH1 cells contain the sequence coding for the WPRE (woodchuck post-transcriptional regulatory element). According to Kowolik and Yee 2002, the WPRE sequence hasn’t been mutated to remove the oncogenic WHV-X protein from an open reading frame found in WPRE sequence. The WPRE sequence will be sequenced to confirm the presence of the unmutated form in TH1. One of the major risk factor associated with the utilisation of this cell line would be in that case accidental percutaneous inoculation of a worker. As described by Kowolik et al, TH1 cells failed to form anchorage-independent colonies in soft agar. They also failed to form tumours in nude mice. Furthermore, this TH1 cell line could theoretically not survive into the inoculated worker but would be quickly cleared by the human immune system.

One of the major risks would be if these constructions coding for the small T-antigen and/or Large T antigen are mobilised. This could happen if the TH1 cells are accidentally inoculated to a worker already infected by a retroviral genome. Even in that case, as series of unlikely events would have to occur to:
a. The worker would have to be already infected with the HIV-1 virus.

b. The retroviral genomes would have to integrate into the immortal mouse or rat mesangial cells genome in a position where they could interact to effect homologous recombination.

c. Recombination would have to occur in precise regions to allow for transfer of the SV40 T antigen sequences from the TH1 genome to the HIV-1 genome.

d. The situation in c could conceivably lead to the production of an infectious particle containing the gene of interest.

Although the risk for human health is low, all measures will be in place to minimize the risk of human health to avoid any accidental inoculation of a worker (see measures below).

Further modification of the TH1 cell line may enhance the risk of the mobilisation of the sequence coding for small and/or large T antigen sequences, or WPRE and the sequence of DeltaU3. Application to these cells of additional lentivirus particules could result to the mobilisation of these sequences and the liberation of replication-competent retroviruses by genetic recombination events. This risk will be minimised by confirming that the viral genes gag-pol and env are not present in the genome of the immortalised TH1 cells before the application of the lentivirus used on the cells. Furthermore, the risk can be minimised by ensuring that any lentivirus used in experiments with the host cells does not contain gag-pol, env or any other significant retroviral genes involved in packaging and replication. To ensure that any replication-competent retroviruses by genetic recombination events had occurred, the supernatant of the TH1 cells will be tested for the production of retroviruses by application on HEK293T cells. In the case of DeltaU3 in the TH1, the Delta U3 contained in the TH1 will be sequenced to ensure that the sequence contains in the TH1 can not be recombined to the sequence DeltaU3 contained in the lentivirus to generate a full 3’ LTR that can affect the production of the viral genome.

Even if the events are unlikely, the immortalised human proximal tubule cell line and the transduced TH1 cells will be maintained at biosafety level 2 containment. Therefore all measures will be in place to minimize to risk to human health.

Human health hazards

Oral ingestion will be prevented by standard laboratory safety practices. Aerosol formation resulting from an accident outside of the safety cabinet and involving lentivirus particle-containing liquid may lead to transduction of a limited number of the laboratory worker’s skin or mucosal cells with modified viruses. However, these modified virus particles carry an extremely low safety risk for human health, as they are replication-incompetent, and also because the particles carry an extremely low infection potential via the mucosal/skin routes, due to the inherent properties of the viral vectors. Moreover, the programmable nucleases and shRNA that will be expressed or targeted will not be designed to disrupt any growth factors, trophic factors, quiescence factors, confirmed oncogenes, tumour suppressors or immunomodulators. In the unlikely event of accidental transduction of a laboratory worker’s skin or mucosa by lentivirus particles, this will be self-limited, due to natural shedding of superficial epithelial skin and mucosal cell layers.

The most likely route of accidental infection with a lentivirus or with the TH1 cell line will be via inadvertent percutaneous inoculation. The likelihood of this occurring will, however, be minimised by adhering to appropriate risk management measures. Infection of the community at large with lentivirus particles is highly unlikely due to the viral vector particles being replication incompetent. Infection of the community at large by TH1 cells is highly unlikely due to the impossibility of the cells to survive outside of a laboratory environment.

* Environement considerations

The chance that active viral particles will be accidentally released into the environment is considered to be highly unlikely, as effective containment procedures will be adhered to. However, in the unlikely event that active lentiviral vector particles do accidentally get released into the environment, the safety risk posed such an event is considered to be negligible, due to the vectors being self-inactivating and non-replicative. The main potential risk in such an event would be the subsequent contamination of a human population already infected with HIV, which would potentially allow for recombination events that could incorporate the inserted sequences into a viable replication-competent lentivirus. However, this scenario is extremely unlikely and even if it was to occur, it is unlikely that it would lead to any untoward effects. As the HIV virus is a human pathogen infection of another species would not be expected to allow any form of recombination event leading to a viable transmissible entity and so the risk from this scenario is considered to be negligible. Rodents, such as wild-type mice and rats, cannot support replication of infectious HIV-1 (Goffinet et al, 2007 Retrovirology). As a result, the potential for shedding of replication-competent lentiviruses from such animals is very low (even if they were present in the original vector inoculum).

The vectors have been pseudotyped with the VSV-G envelope in order to increase tropism, and in theory they are capable of transducing all dividing and non-dividing
mammalian cell types. As emphasized before, the vectors cannot self-propagate after infection, and successful transduction is critically dependent on the presence of high enough concentrations of virus particles. Viral vector stock solutions will be managed in a way that will prevent contaminations with relatively high viral titres. After production, the vectors are aliquoted and stored in screw capped cryovials at -80°C. Taking into account that the infectivity of the vectors rapidly decreases at room temperature, it is considered highly unlikely that the vectors could survive in the long term after being accidentally released into the environment. Lentiviral vectors have a short half-life, at room temperature due to their structural characteristics making them highly susceptible to dehydration, and relatively unstable. For this reason, retroviruses become rapidly inactivated outside host systems, as illustrated by the fact that close contact is required for transmission. They can, however, survive for long periods in high protein media. There are no conceivable hazards associated directly with the lentiviral vectors (containing the inserts) as they will not replicate/survive outside the laboratory and they have been designed to include many protective safety features. shRNA sequences will also not survive as they are highly unstable, and they would, consequently, be rapidly inactivated/degraded if accidentally spilled into the environment. Moreover, as discussed above, there is a very low risk that the sequences contained within the viral vectors could be transferred to other organisms, as a rare recombination event would have to occur to allow this to happen. The risk to the environment following accidental release of the immortalised human proximal tubule cells would be negligible since the cells are incapable of surviving outside of laboratory conditions. If TH1 cells were to directly inoculate animals, they would be quickly cleared by the immune system and would not produce active viruses. The likelihood of this occurring will, however, be minimised by adhering to appropriate risk management measures and ensuring that all potentially contaminated material is totally inactivated before disposal.

Summary
The chance that active viral particles will be accidentally released into the environment is considered to be highly unlikely, as the viral vector studies that will be undertaken have been classified as biosafety level 2, and effective containment procedures will be adhered to. In the unlikely event that active viral vector particles do accidentally get released into the environment, the safety risks posed by such an event is considered to be low due to the vectors being self-inactivating and non-replicative, and also due to the poor ability of the vectors to survive outside of their host systems. It is also unlikely that the immortalised human proximal tubule cells, TH1 cells, and the transduced TH1 cells will be accidentally released into the environment, as the cells handling and studies that will be undertaken have been classified as biosafety level 2, and effective containment procedures will be adhered to.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
The work outlined above has been classified as a Biosafety level 2 activity, even though the risk of pathogenicity to the end worker is considered to be very low. In all cases, biosafety level 2 conditions must be adhered to when handling the immortalised human proximal tubule cells, generating the viral vectors in HEK293T cells, as well as their subsequent storage at -80°C. For subsequent in vitro transduction of the cells types mentioned in this proposal (e.g. human HEK293T, TH1 cells) will be performed under biosafety level 2 conditions. The human transduced HEK293T used to assay the efficacy of the vectors will be converted to biosafety level 1 once the medium containing the virus has been removed and the infected cells have been extensively washed. The TH1 cells transduced by lentivirus will be maintained under biosafety level 2.

Procedures:
During all procedures that involve the handling/use of the viral vectors or cells, all workers (incl. those that are not working directly with the vectors) that are present within a lab where the work is undertaken are required to wear personal protective equipment at all times. The use of two pairs of gloves is advised so the external pair can be disposed in an autoclave bag and replaced whenever necessary (e.g. in the case of contact with the viral reagent). Face masks are also available for use, where appropriate. In addition, all workers are made aware of the nature of the viral work that is going on within the laboratory, and they have to follow appropriate procedures to ensure that there is no cross-contamination into non-viral working area. All the workers using the viral delivery systems are experienced research scientist, and junior scientists will be closely supervised until they are competent in the handling of the viruses.

Lentiviral production
Lentiviral production will also be carried out on-site using a modified procedure based on Bukovsky et al. (Bukovsky et al, 1999, J. of virology). Lentiviral production will only be carried out in HEK293T cells in a biosafety level 2 cabinet within a culture flask with screw cap filter in order to minimize the risk of spills and/or aerosol mediated viral spread. For this the modified PRRL plasmids together with three additional separate plasmids (pMDLgp-RRE, PRSV-REV and pMD2-VSVG.env) will be transfected using a transfection reagent (e.g. Polyethylenimine (PEI), Lipofectamine) into HEK293T packaging line. After 6-12 hours, the medium is replaced with fresh serum-free medium and grown for an additional 72-96 hours. After 24-48 hours, so as to ensure the viability of the transfected HEK293T cells, medium form the cells is collected into
screw cap tube and stored at 4oC and fresh serum-free medium is added to the cells. The cells are grown for an additional 24-48 hours before the second medium solution is added to the first harvest tube. After lentivirus collection has been completed, the cells and the flasks will be decontaminated and disposed of a detailed later. Still within a biosafety level 2 safety cabinet in a biosafety level 2 laboratory, the harvested supernatants will be filtered using a 0.45um filter before either aliquoted or further purified by chromatography and/or concentrated by centrifugation. The lentiviral particles may need to be purified by either chromatography and eluted in a high salt solution and/or concentrated by ultrafiltration. For certain application where highly concentrated and purified virus may be required, the traditional method of sucrose cushion based centrifugation may be necessary. To minimize the possible risk of accidental viral contamination and spread due to the need for an ultracentrifuge, all loading and unloading will be done in the biosafety level 2 safety cabinet. Once the sucrose cushions have been added to the centrifuge tubes, the unpurified or chromatography purified lentiviral particles will be added to the sucrose cushion. The individually capped tubes will then be transferred to their respective bucket holders and the bucket sealed using their respective screw caps and marked as containing virus. The buckets containing viruses will be balanced with a buckets containing a tube with water and without lentivirus. The balanced buckets will then be transferred to the rotor before being placed within the centrifuge chamber. The ultracentrifuge will be run at 70000g for 2 hours at 20oC. Upon return of the buckets to the biosafety level 2 cabinet, the supernatant will be removed from the tubes before transfer of the resuspended virus pellet into individual screw cap cryovials. As the greatest risk for contamination occurs within the centrifugation buckets themselves during transport to and from the weight scales and during ultracentrifuge, the centrifuge tubes, the buckets and the centrifuge rotor will be decontaminated by spraying Chemgene HLD4L 5%. Optionally, the centrifuge rotors could be autoclaved at 121oC. In any case, concentrated virus stock will not be exposed to the environment outside of the biosafety level 2 cabinet. All supernatants will be treated as above.

The lentiviral titre will be determined in terms of number of viral particles (VP) or transduction units (TU) per mL. The number of VP can be assessed relatively quickly and does not involve cell infection. In this case, a bead based enrichment assay or a p24 ELISA assay will be chosen. The VP quantification methods tend to overestimate the TU by 10-1000 fold. Thus, the TU/mL will in certain instances also determined. For this, a titration range of lentiviruses expressing a fluorescent tag will be prepared and added to a 24 well cluster plate or T25 TC-flasks containing HEK293T for 48 hours. The percentage of fluorescent positive cells will be quantified manually under a fluorescent microscope or ideally using FACS analyser.

Aliquots with not more than 1x10⁸ viruses per vial are stored at -80oC in individual screw capped cryotubes. The viral stock will consist of viral particles containing the vector genome (full capsids) and also of a variable number of empty viral capsids. Other trace components that might be present include, but are not limited to, inorganic salts, vitamins, other nutrients, human cellular proteins, carbohydrates, amino acids, and fats.

Cleaning SOPs
General cleaning procedures
Surfaces will be thoroughly cleaned with Chemgene HLD4L 5%* (or an equivalent product) at the end of each experiment or after the occurrence of an accidental spillage of infectious material. Application of these anti-microbial agents will totally inactivate any viral vectors that might be present. According to the biosafety literature, all the viruses to be used are susceptible to these disinfectants. Anything that might have potentially come into contact with the virus will be treated with Chemgene HLD4L* before being autoclaved/incinerated.

* Chemgene HLD4L
Chemgene HLD4L is formulated as a micelle cleaning technology that enables the active molecules in the product to be carried rapidly through the cell walls or micro-organisms. Swift penetration of the cell walls ensures cell death is equally rapid. Chemgene HLD4L has been reported to be bactericidal, fungicidal as well as virucidal (HIV, hepatitis B, Herpex Simplex, Norovirus and Coronavirus) and sporicidal. It is recommended to be used at a 1:100 dilution (1%) for general purposes, 1:20 dilution (5%) for high risk areas, and for disinfection of blood and bio-hazard spillages.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

According to the biosafety literature, all the viruses to be used are susceptible to these disinfectants. Anything that might have potentially come into contact with the virus will be treated with Chemgene HLD4L* before being autoclaved/incinerated.
being autoclaved/incinerated.

Waste Handling
Following all work requiring biosafety level 2 containment including work with lentiviruses and immortalised mouse or rat mesangial cells, solid waste will be neutralised by soaking in a validated disinfectant solution, after which the material will be “double bagged”, autoclaved and, ultimately, incinerated offsite. It will be routine practise that all liquid waste material be neutralised before disposal, and for the neutralised waste to be transported in leak-proof containers to prevent spillages. Liquid waste will be inactivated by Chemgene HLD4L* for 24 hours prior to drain disposal as per 430CSP and 418CSP permit requirements. As any active viral particles or immortalised mouse or rat mesangial cells on surface or in waste material will be completely inactivated at the end of each experiment by the highly effective cleaning/disinfection protocols outlined above, it is considered highly unlikely that active virus particles or immortalised mouse or rat mesangial cells would unintentionally become discharged into a sanitary sewage system. No foreseeable adverse effects on human health and safety are expected.

* Chemgene HLD4L
Chemgene HLD4L is formulated as a micelle cleaning technology that enables the active molecules in the product to be carried rapidly through the cell walls or micro-organisms. Swift penetration of the cell walls ensures cell death is equally rapid. Chemgene HLD4L has been reported to be bactericidal, fungicidal as well as virucidal (HIV, hepatitis B, Herpex Simplex, Norovirus and Coronavirus) and sporicidal. It is recommended to be used at a 1:100 dilution (1%) for general purposes, 1:20 dilution (5%) for high risk areas, and for disinfection of blood and bio-hazard spillages.

The TH1 cell line has been immortalised by the use of hTERT and SV40 large & small T antigen delivered by a Self-inactivating retrovirus (SIN). Retrovirus delivery includes integration of a WPRE element, 5' LTR and a 3'LTR. There is limited information about the actual deletion in the 3'LTR or if the WPRE has been mutated to remove the WHV-X oncogene. This region of the TH1 genome will be sequenced to test for deletion in the potential risk. Knowing the sequence will allow us to confirm that the retroviral vectors that will be used to deliver genetic material will not have homologous sequences that might enable recombination and increase the risk of mobilisation (especially if Cre-recombinase is used as it releases hTERT and SV40 T-antigen genetic sequence). Lentivirus will be generated using a third generation methodology which requires 4 different plasmids, that do not share sequence homology, to be transfected into the same packaging cell. The isolation of the genes required for virus production minimises the chance of accidentally generating replication competent virus (RCV). The desired packaged genetic material also undergoes self-inactivation upon integration into a host genome after infection of target cells. As this is a permanent change it is noted that no tumour suppressors, oncogenes or immune modulators will be targeted. The host cells contain the transformative SV40 T antigens so it is important to prevent mobilisation of this genetic material. There will be no homologous sequence present between the lentivirus and the SV40 T antigen coding region. If Cre-recombinase is used the hTERT and SV40 T antigens are removed leading to senescence of the cells and a removal of potential risk. In this situation as the genetic code is released a lack of homologous sequence will ensure recombination does not occur. Combined with the minimal chance of RCV being present will effectively prevent the generation of virus containing SV40 T antigen. The lentivirus being produced, although pseudotyped to have broad tropism, poses a minimal risk to the environment as it is highly unlikely to be able to infect an animal outside of the laboratory environment in the case of accidental release and the material will also rapidly deactivate at room temperature. The GMSC has agreed that this work will be conducted at biosafety level 2 because retroviral vectors are being used to deliver genetic material to host cells that have been immortalised with SV40 T antigen and hTERT.
### Project Additional Information

**Purposes of the contained use**

The mesangial cells, SV40 MES 13 and RMC cell line, will be used to investigate the cellular pathway involved in the development of human renal disease, in particular glomerulosclerosis disease.

To better understand these cellular pathways, the expression or the activity of the gene of interest will be modulated by several methods:

1. The utilisation of tool compounds
2. The knock-down of the gene of interest by shRNA
3. The generation of knockout somatic cells using programmable nucleases (CRISPR or Zinc finger nucleases)
4. The generation of reporter gene cell line (i.e.: fluorescence protein or enzyme) under the promoter of the gene of interest.
The experiments involving the transfection of vectors such as shRNA or programmable nucleases will be performed by lentivirus. The effect of modulating the expression or the activity of the target of interest will be determined by the expression level of the proteins, mRNA or mediators involved in the target signalling pathway.

**Recipient or parental organism**

- **SV40 MES 13 cell line**
  The immortalised SV40 MES 13 cell line will be purchased from ATCC. The generation of this cell line has been described by MacKay et al (MacKay et al. Kidney Int. 1988). The transgenic mice used contain the construct SV Tag 188 composed of the coding region for both large and small T-antigen along with its 72 and 21 base-pair repeats. These mice have been described to develop glomerulosclerosis and the large T antigen has been detected by immunoprecipitation in the kidney. The mesangial cells have therefore been isolated from these mice. These cells have been described to form colonies in soft agar and are positive for SV40 large T antigen.

- **RMC cell line**
  The immortalised RMC cell line will be purchased from ATCC. Primary mesangial cells have been isolated from a 3 month old rat. The cells are maintained in culture until passage 8, then they are immortalised by the pSV3-Neo vectors and maintained in the presence of G418. The cells contain the sequences of SV40 large T-antigen and neomycin genes.

**Host/vector system**

Description of the lentivirus containing shRNA, programmable nucleases sequences or gene reporter vectors

To study the function of mesangial cells in human disease, the expression of a target of interest may be decreased in the mouse or rat mesangial cell line by the transduction of shRNA or programmable nuclease by lentivirus. The modulation of a particular cellular pathway may be studied with the use of a reporter gene assay. In this case, the vector contained the reporter gene under regulating sequence from the promoter of the gene of interest will be introduced by lentivirus into these immortalised mesangial cells.

This proposal involved both the use of existing lentiviral constructs purchased commercially and the generation of new constructs on site using the third generation system. Both commercially acquired and in-house lentivirus will use the same vector backbones containing identical promoters. Target genes will be selected based on the needs of drug discovery projects; programmable nucleases and shRNA will not be produced against any growth factors, tropic factors, quiescence factors, confirmed oncogenes, tumour suppressors or immunomodulators.

The production of lentivirus containing the vectors of interest are described below:

Lentiviral vectors will be purchased commercially or produced in-house using the third generation system described below. Each purified and concentrated aliquot of lentiviral reagent comprised of a small volume (5 to 10ul) that contains no more than 1X10e8 viral particles.

**Vector System = self-inactivating (SIN) non replication-competent HIV based lentiviral vectors:**

The viral vectors that will be used in the proposed studies are self-inactivating non replication-competent HIV based lentiviral vector systems, which have been designated to produce stable gene expression in mammalian cells; and they are generated by co-transfecting HEK 293T cells with four separate plasmids. Each of the plasmids used expressed a different set of genes which, when combined following co-transfection, provide the smallest possible set of essential viral genes that is still compatible with virus production. Moreover, the vectors are all vesicular stomatitis virus (VSV-G) pseudotyped lentiviral vectors, which are self-inactivating and highly unlikely to undergo recombination. Importantly, the viral vector system is inherently incapable of replication in mammalian cells.

The plasmids:

- The sequences that will be included in the viral vectors are sub-cloned into 4 standard bacterial plasmid vectors.
  - Plasmids containing the packaging related sequences
    Each of the three other plasmids, pMDLgp-RRE, pRSV-REV and pMD2-VSVG.env contain a different set of sequences that code for proteins that are responsible for packaging the viral vectors. All the genes (gag-pol, rev and env) required for production and packaging of the full length viable viral RNA particles have been removed from the pRRL lent-plasmids containing the transgenes of interest.
  - Plasmids containing the transgene of interest
    The fourth plasmid, pRRL, will contain the sequences that code for shRNA, or programmable nuclease sequence, or reporter gene sequence under the promoter of the gene of interest.
- **a- Vector containing shRNA**
As mentioned above, pRRL plasmid will contain the sequences that code for one shRNA transcript that will target one mRNA/protein of interest (or a scrambled shRNA in the case of negative control). The shRNA or scrambled shRNA sequences will be under the control of polymerase III U6 promoter. The shRNA sequences will be chosen to target a single mouse or rat gene. Target genes of the shRNA will not be produced against any growth factors, tropic factors, quiescence factors, confirmed oncogenes, tumor suppressors or immunomodulators.

b- Vector containing CRISPR or Zinc-finger nucleases vector
Programmable nucleases function by binding to, and cleaving, user-defined target DNA sequences. This in turn instigates a robust DNA repair response which ultimately leads to disruption of the target sequence by deletion at the cleavage site or by recombination with a user-supplied synthetic vector containing sequences complementary to the target gene.

For Cas9/CRISPR, nuclease target specificity is determined by an accessory sequence, the guide RNA, which consists of a short (18-20 nucleotide) sequence homologous to the target gene and an additional short sequence that forms a complex with the Cas9 enzyme. In the case, the plasmid pRRL, will contain the sequences that code for a Cas9/CRISPR plus accessory sequences comprising a short guide RNA that determines target specificity. The guide RNA sequences will be under the control of the Polymerase III U6 promoter.

In the case of Zinc finger nucleases target specificity is dependent upon the zinc finger protein sequence. The pRRL will contain in that case the sequence of zinc finger nucleases under the control of either the CMV promoter or the EF1A promoter. In addition, a fluorescent protein or enzyme under the control of cytomegalovirus (CMV) promoter, EFIA promoter or the promoter of a gene of interest may be included. Control viral vectors that express only the fluorescent protein/enzyme and no programmable nuclease will be used in some experiments.

c- Reporter gene vector
The pRRL vector will contain the sequence coding for a reporter protein (enzyme or fluorescent protein) under the control of the regulating elements of the promoter of the gene of interest or the CMV or EF1A promoter. An appropriate selection marker i.e.; neomycin could also be included to allow the selection of stable immortal mesangial cells containing the reporter gene sequence under the control of the promoter of the gene of interest.

Origin & function

a- Assessing efficacy of the lentivirus into a BSL1 cell line
Assessing whether the genome manipulation or the knock-down has been achieved will normally take place initially in biosafety level 1 immortalised cell line (human HEK293T) that are known not to contain lentiviral genetic material. Application of lentiviral particles will be done at biosafety level 2 confinement. After at least 24 hour incubation and extensive washing, the cells will treated as biosafety level 1 (see below the justification for removal of cells post-infection to biosafety level 1). In order to determine whether the knock-down or the genome manipulation has worked, the levels of mRNA and protein will be assessed post-transduction, using suitable in vitro assays.

b- Transduction of the lentivirus and the generation of stable expression into mesangial cells (mouse or rat)
Once validated the same procedure will be carried out in the mouse or rat mesangial cells. As the mouse/rat mesangial cells are maintained in a biosafety level 2 confinement, the inoculation of lentiviral particles, the transformed cells and the phenotypic analysis will also be performed in a biosafety level 2 containment. When a lentivirus containing a programmable nuclease or the reporter gene will be used, a stable cell line could be established by selecting the cells in which the genome has been modified. In all cases phenotypic analysis will be performed using suitable in vitro assays, including for example, RT-PCR, Western Blotting, immunocytochemistry and imaging, or cellular bioenergy (i.e.: mitochondria respiration function or glycolysis function).

Evaluation of foreseeable effects

* Human health considerations
The immortal mouse/rat mesangial cell that will be used has a low risk for human health. The expression systems and the transgenes that comprise the lentiviral vectors that will be used have also a very low risk for human health and safety, and the reasons for this are discussed below.

A- Lentivirus containing shRNA, or programmable nucleases sequence or reporter gene vectors
Lentiviral Vector Expression System
Lentiviruses belong to the Retroviridae virus family which are capable of infecting both human and animal species. As the lentiviral vector system that will be used in these studies is based on HIV-1, a theoretical risk to human health exists. However, retroviruses are generally transmitted via exposure to contaminated body fluids or
percutaneous inoculation and generally not transmitted via the aribone route. Therefore, accidental piercing of the skin or other surface tissues with virus containing objects represents the main potential route by which accidental infection could occur. Appropriate measures will be implemented to reduce the likelihood of this occurring.

In all of the modified pRRL plasmids (containing shRNA, or programmable nucleases or reporter gene sequences), the sequences inserted are flanked by non-coding retroviral LTRs, and no retroviral genes are encoded on the modified pRRL plasmids. Therefore, no retroviral genes will be transferred into generated viral particles. This is constructed is packaged into particles using a HEK293T cell based packaging system, which requires the co-transfection of HEK293T cells with three additional separate plasmids (pMDLgp-RRE, pRSV-REV and pMD2-VSVG.env). The latter 3 plasmids express the envelope protein from VSVG and the non-structural proteins of the virion, and, importantly, none of these genes will be transferred into the assembled viral vectors, since they lack the packaging signal, which is only present on the modified pRRL containing plasmids.

The lentiviral Expression System will be used include the following key safety features:
* All of the pRRL contain a deletion in the 3’LTR (deltaU3) that does not affect generation of the viral genome in the producer cell line, but results in "self-inactivation" (SIN) of the vector after transduction of target cells. Once integrated into a transfected target cell, the lentiviral genome is no longer capable of producing viral genomic material that can be packaged. Moreover, deletion of enhancer and promoter elements from the 3’ U3 region in the vector construct will result in a provirus that is entirely devoid of the U3 enhancer sequences, which will result in a reduction in the potential for transactivation of cellular genes due to an insertion event. Furthermore, the development of self-inactivating vectors improves the biosafety of vectors, as they are less likely to be mobilised following a superinfection with wild-type virus (HIV).
* The VSV-G gene from Vesicular Stomatitis Virus is used in place of the HIV-1 or other retroviral envelope genes. Heterologous envelopes, like VSV-G, typically broaden the tropism and allow gene transfer into a broad variety of cells. The risk will mitigated by the use of self-inactivating virus and limiting the number of viral particles that will be handled at any one time.

* Sequences encoding the proteins required for packaging of the viral genome are separated onto three plasmids, and all of the 4 plasmids used in the system have been engineered not to contain any regions of homology with each other so as to prevent undesirable recombination events that could lead to the generation of a replication-competent lentivirus (RCL), which could potentially be harmful to humans. It is important to note that no such RCL has ever been observed despite large-scale production and testing of lentiviral vectors.

* All of the pRRL containing plasmids/vectors will be devoid of all viral sequences apart from essential cis-acting sequences, including the LTRs and the packaging signal psi. Although the packaging plasmids used in these systems allows for the expression in trans of protein required to produce viral progeny (e.g. gag, pol, rev, env) in the HEK293T producer cell lines, none of them contain LTRs or the psi packaging sequence. Several of the lentiviral accessory genes (vif, vpr, vpu and nef) that are dispensable for lentivector production/transduction have been deleted from the packaged construct. Therefore, none of the retrovirus structural genes will actually be present in the packaged viral genome, as they will never be expressed in the transduced target cells, which means that no new RCL can be produced.

* The lentiviral particles produced in this system are replication-competent, only carry the sequences of interest, and no other viral species are produced.
* Expression of the gag and pol genes from pMDLgp-RRE has been rendered Rev-dependent by virtue of the HIV-1 RRE (Rev Responsive Element) in the gag/pol mRNA transcript. Addition of the RRE in these plasmids prevents gag and pol expression in the absence of rev, which is contained in the pRSV-REV plasmid only. The Rev/RRE system is highly conserved among lentiviruses, and removal of the RRE sequence and associated splice donor/acceptor sequences result in a loss of transduction efficiency.

* LTR has been modified so as to increase lentiviral vector production, and also to allow lentiviral vector production to be independent of tat expression. It is known that Tat-deleted mutants of wild-type HIV-1 are not replication competent. Therefore, the deletion of Tat should decrease the risk of generating a putative RCL.

* Lentiviral vectors have a very low potential to cause immunogenicity.
* In the lentiviral vector that will be used, the WPRE (woodchuck post-transcriptional regulatory element) has been mutated to remove the oncogenic WHV-X protein from an open reading frame found in WPRE sequence.

While the lentiviral vectors that are produced using this system contain only about 20% of the original genome of HIV-1, there is a very small risk that subsequent infection of cells already infected with the lentiviral genome of HIV-1 could lead to a rare recombination event in which the transgene is transferred to a replication-competent virus. Thus, the sequences in the vector that will be expressed could potentially be transferred to surrounding cells. This event is, however, extremely unlikely to occur for a number of reasons:
1. The lentiviral vector is replication-competent and self-inactivating. In the case of a subsequent HIV-contamination, wild-type HIV-1 cannot rescue a self-inactivating HIV-1 based lentivirus once integrated into the host genome, although non-self-inactivating vectors can be.
2- In order for the spread of the gene of interest to occur following accidental infection (assuming that this has lead to viral integration), a series of unlikely events have to occur:

a- The worker would have to become infected with HIV-1 or to be already infected with the virus.
b- The viral and lentiviral genomes would have to integrate into the host worker's genome in the same cells and in a position where they could interact to effect homologous recombination (point 1 above).
c- Recombination would have to occur in just the right regions to allow for transfer of the gene of interest from the lentivirus to the HIV-1 genome, which could also involve the transfer of the HIV-1 genes to the lentiviral genome. In that case, it is conceivable that a non-self-inactivating HIV could be generated that contained the gene of interest but not the rest of the genome it requires. The other gene products could be provided in trans from the lentiviral genome that may now contain the HIV-1 genes or from other HIV-1 integrants.
d- The situation in c could conceivably lead to the production of an infectious particle containing the gene of interest, but again no genes neccessary for subsequent replication. In order for another round of infection to occur, the process would have to begin again.

In these circumstances, the effects of lentiviral infection are likely to be minor in comparison to the effects of the HIV-1 infection, which would be required to affect the spread of the gene of interest. In addition, the scenario described is essentially equivalent to the rescue of the lentiviral genome from the host, which has already been shown not to occur.

3- It is extremely unlikely that any worker would infect themselves with a significant dose of lentivirus as the volumes that are used in transfection experiments are small (aliquots contain a maximum of 10μl of vector solution).

4- Moreover, insertional mutagenesis into the host genome may be considered as an oncogenic risk. We cannot rule out the possibility that, when the lentiviral genome integrates into the host genome, it will not lead to the activation of an endogeneous oncogene. However, all transcriptionally active long-terminal repeats (LTRs) have been removed as well as all promoter-like elements that required to drive expression of the transgene. This should prevent unforeseen activation of such genes. It is noted that deletion of retroviral enhancer in self-inactivating systems reduces the risk of activation but not of disruption, therefore, retroviral infection might still have permanent effects upon a cell (including oncogenic effects).

Importantly, we do not consider that the use of these lentiviral vectors will result in a significant increased risk of oncogenic activation compared to the risk possessed by any other viral delivery system. Moreover, the risk of transduction leading to tumourigenesis or other untoward harm following exposure is related in part to the titre of the viral vectors; exposure of workers to quantities of virus high enough to cause such effects would be unlikely during standard laboratory-based manipulations of lentiviral vectors.

Transgenes:
Additional hazards could arise from the properties of the genetic material that will be inserted into the viral vectors and expressed in transfected cells.
• shRNA
With the use of shRNA-expressing viral vector systems, the expression of specific mammalian genes/proteins can be knocked-down, in order to study their functions. Potential deleterious effects such as off-target and immunomodulatory responses can be minimised through screening designed shRNA sequences against databases of known mammalian/mRNA sequences during the design stage. The genes/proteins of interest that will be targeted by shRNA do not and will not include any growth factors, trophic factors, quiescence factors, confirmed oncogenes, tumor suppressors and immunomodulators. Some of the viral vectors that will be used contain a sequence of interest that has been scrambled (scrambled shRNA), and which is not complementary to any known mammalian sequences. This sequence will adopt a hairpin structure as with any shRNA, but it should not target any mRNA of human, mouse or rat origin. Consequently, these sequences are unlikely to pose any safety risks for the environment or human health.
• Programmable nucleases: zinc fingers and Cas9/CRISPR
Zinc fingers or Cas9 protein will be directed against genes of therapeutic interest. Since the purpose of programmable nucleases is to cause mutations in defined DNA sequences the primary hazard is that such a mutation would lead to deleterious cellular effects. The genes/proteins that will be targeted do not and will not include any growth, trophic factors, confirmed oncogenes, tumor suppressors or immunomodulators. In isolation, these sequences are unlikely to pose any safety risks for the environment or human health.
• Reporter genes: Fluorescent protein or enzymes
The reporter gene could be a fluorescent protein or an enzyme. Fluorescent proteins, for example GFP or dsRed, are not known to cause any diseases in human or
animals and have no direct effect on cellular processes. Enzymes used frequently in reporter gene assay ie luciferase of b-galactosidase are not known to cause any diseases in humans or animals and as no direct effect on cellular processes. The expression of fluorescense protein or enzymes under the control of a promoter of a gene of interest is unlikely to pose any safety risks for the environment or human health.

Summary on lentivirus
The transgenes have a low safety risk to human health because accidental contamination with a vector would lead to only a small number of cells becoming infected, and it would be highly unlikely that expression in only a few cells could be sufficient to lead to a disease state. The inability of the lentiviral vectors to propagate on mammalian cells also reduces the risk. The programmable nucleases (CRISPR or Zinc finger) that will be employed in this viral vector system are not known to cause any relevant toxicity that might represent a safety risk to human health. The fluorescent proteins or the enzymes are not known to cause any relevant toxicities that might represent a safety risk to human health. For both programmable nucleases and shRNA, the genes/proteins of interest that will be targeted will not include any growth factors, tropic factors, quiescence factors, confirmed oncogenes, tumor suppressors or immunomodulators, and none of them are or will be of retroviral origin. Therefore the risk of use will be low.

B- Immortalised mouse or rat mesangial cells and transduced immortalised mesangial cells

The SV40 MES 13 cell line have been immortalised by the presence of the coding region for both large and small T-antigen along with its 72 and 21 base-pair repeats in the genome.

The immortalised RMC cell line contains the sequences coding for SV40 large T-antigen and neomycin. SV40 virus is a polyomavirus that is found in both monkeys and humans. As described, both cell lines, SV40 MES 13 and RMC, are from rodent origin and contain the sequences coding for SV40 small and or large T-antigen. Large and Small T antigen have been described to be sufficient to transform human cells. One of the major risk factor associated with the utilisation of this cell line would be accidental percutaneous inoculation of a worker. These mouse and rat cell lines could theoretically not survive but would be quickly cleared by the human immune system. One of the major risks would be if these constructions coding for the small T-antigen and/or Large T antigen are mobilised. This could happens if the mesangial cells are accidentally inoculated to a worker already infected by a retroviral genome. Even in that case, as series of unlikely events would have to occur to:

a. The worker would have to be already infected with the HIV-1 virus
b. The retroviral genomes would have to integrate into the immortal mouse or rat mesangial cells genome in a position where they could interact to effect homologous recombination.
c. Recombination would have to occur in precise regions to allow for transfer of the SV40 T antigen sequences from the mesangial genome to the HIV-1 genome.
d. The situation in c could conceivably lead to the production of an infectious particle containing the gene of interest.

Although the risk for human health is low, all measures will be in place to minimize the risk of human health to avoid any accidental inoculation of a worker (see measures below).

Further modification of the immortalised mouse or rat mesangial cell lines may enhance the risk of the mobilisation of the sequence coding for small and/or large T antigen sequences.

Application to these cells of additional lentivirus particules could result to the mobilisation of the small and or large T antigen sequence and the liberation of replication-competent retroviruses by genetic recombination events. This risk will be minimised by confirming that the viral genes gag-pol and env are not present in the genome of the immortalised mouse and rat mesangial cells before the application of the lentivirus used on the cells. Furthermore, the risk can be minimised by ensuring that any lentivirus used in experiments with the host cells does not contain gag-pol, env or any other significant retroviral genes involved in packaging and replication. To ensure that any replication-competent retroviruses by genetic recombination events had occurred, the supernatant of the mesangial cells will be tested for the production of retroviruses by application on HEK293 cells. Even if the events are unlikely, the immortalised mouse and rat mesangial cell line and the transduced mesangial cells will be maintained at biosafety level 2 containment. Therefore all measures will be in place to minimize to risk to human health.

Human health hazards
Oral ingestion will be prevented by standard laboratory safety practices. Aerosol formation resulting from an accident outside of the safety cabinet and involving lentivirus particle-containing liquid may lead to transduction of a limited number of the laboratory worker's skin or mucosal cells with modified viruses. However, these modified virus
particles carry an extremely low safety risk for human health, as they are replication-incompetent, and also because the particles carry an extremely low infection potential via the mucosal/skin routes, due to the inherent properties of the viral vectors. Moreover, the programmable nucleases and shRNA that will be expressed or targeted will not be designed to disrupt any growth factors, trophic factors, quiescence factors, confirmed oncogenes, tumour suppressors or immunomodulators. In the unlikely event of accidental transduction of a laboratory worker’s skin or mucosa by lentivirus particles, this will be self-limited, due to natural shedding of superficial epithelial skin and mucosal cell layers.

The most likely route of accidental infection with a lentivirus or the mesangial cell line will be via inadvertent percutaneous inoculation. The likelihood of this occurring will, however, be minimised by adhering to appropriate risk management measures. Infection of the community at large with lentivirus particles is highly unlikely due to the viral vector particles being replication incompetent. Infection of the community at large by immortalised mouse or rat mesangial cells is highly unlikely due to the impossibility of the cells to survive outside of a laboratory environment.

* Environment considerations

The chance that active viral particles will be accidentally released into the environment is considered to be highly unlikely, as effective containment procedures will be adhered to. However, in the unlikely event that active lentiviral vector particles do accidently get released into the environment, the safety risk posed such an event is considered to be negligible, due to the vectors being self-inactivating and non-replicative. The main potential risk in such an event would be the subsequent contamination of a human population already infected with HIV, which would potentially allow for recombination events that could incorporate the inserted sequences into a viable replication-competent lentivirus. However, this scenario is extremely unlikely and even if it was to occur, it is unlikely that it would lead to any untoward effects. As the HIV virus is a human pathogen infection of another species would not be expected to allow any form of recombination event leading to a viable transmissible entity and so the risk from this scenario is considered to be negligible. Rodents, such as wild-type mice and rats, cannot support replication of infectious HIV-1 (Goffinet et al, 2007 Retrovirology). As a result, the potential for shedding of replication-competent lentiviruses from such animals is very low (even if they were present in the original vector inoculum).

The vectors have been pseudotyped with the VSV-G envelope in order to increase tropism, and in theory they are capable of transducing all dividing and non-dividing mammalian cell types. As emphasized before, the vectors cannot self-propagate after infection, and successful transduction is critically dependent on the presence of high enough concentrations of virus particles. Viral vector stock solutions will be managed in a way that will prevent contaminations with relatively high viral titres. After production, the vectors are aliquoted and stored in screw capped cryovials at -80°C. Taking into account that the infectivity of the vectors rapidly decreases at room temperature, it is considered highly unlikely that the vectors could survive in the long term after being accidentally released into the environment. Lentiviral vectors have a short half-life, at room temperature due to their structural characteristics making them highly susceptible to dehydration, and relatively unstable. For this reason, retroviruses become rapidly inactivated outside host systems, as illustrated by the fact that close contact is required for transmission. They can, however, survive for long periods in high protein media.

There are no conceivable hazards associated directly with the lentiviral vectors (containing the inserts) as they will not replicate/survive outside the laboratory and they have been designed to include many protective safety features. shRNA sequences will also not survive as they are highly unstable, and they would, consequently, be rapidly inactivated/degraded if accidentally spilled into the environment. Moreover, as discussed above, there is a very low risk that the sequences contained within the viral vectors could be transferred to other organisms, as a rare recombination event would have to occur to allow this to happen.

The risk to the environment following accidental release of the immortalised rat or mouse mesangial cells would be negligible since the cells are incapable of surviving outside of laboratory conditions. If live mouse or rat mesangial cells were to directly inoculate animals, they could theoretically survive but would be quickly cleared by the immune system and would not produce active viruses. The likelihood of this occurring will, however, be minimised by adhering to appropriate risk management measures and ensuring that all potentially contaminated material is totally inactivated before disposal.

Summary

The chance that active viral particles will be accidentally released into the environment is considered to be highly unlikely, as the viral vector studies that will be undertaken have been classified as biosafety level 2, and effective containment procedures will be adhered to. In the unlikely event that active viral vector particles do accidently get released into the environment, the safety risks posed by such an event is considered to be low due to the vectors being self-inactivating and non-replicative, and also due to the poor ability of the vectors to survive outside of their host systems. It is also unlikely that the immortalised mouse and rat mesangial cells and the transduced mesangial cells will be accidentally released into the environment, as the cells handling and studies that will be undertaken have been classified as biosafety level 2, and effective containment procedures will be adhered to.
The work outlined above has been classified as a Biosafety level 2 activity, even though the risk of pathogenicity to the end worker is considered to be very low. In all cases, HSE prescribed biosafety level 2 conditions should be adhered to when handling the immortalised mouse or rat mesangial cells, generating the viral vectors in HEK293T cells, as well as their subsequent storage at -80°C. For subsequent in vitro transduction of the cells types mentioned in this proposal (e.g. human HEK293T, immortalised mouse or rat mesangial cells) will be performed under biosafety level 2 conditions. The human transduced HEK293T used to assess the efficacy of the vectors will be converted to biosafety level 1 once the medium containing the virus has been removed and the infected cells have been extensively washed. The immortalised mouse or rat mesangial cells transduced by lentivirus will be maintained under biosafety level 2.

Procedures:
During all procedures that involve the handling/use of the viral vectors or cells, all workers (incl. those that are not working directly with the vectors) that are present within a lab where the work is undertaken are required to wear personal protective equipment at all times. The use of two pairs of gloves is advised so the external pair can be disposed in an autoclave bag and replaced whenever necessary (e.g. in the case of contact with the viral reagent). Face masks are also available for use, where appropriate. In addition, all workers are made aware of the nature of the viral work that is going on within the laboratory, and they have to follow appropriate procedures to ensure that there is no cross-contamination into non-viral working area. All the workers using the viral delivery systems are experienced research scientist, and junior scientists will be closely supervised until they are competent in the handling of the viruses.

Lentiviral production
Lentiviral production will also be carried out on-site using a modified procedure based on Bukovsky et al. (Bukovsky et al, 1999, J. of virology). Lentiviral production will only be carried out in HEK293T cells in a biosafety level 2 cabinet within a culture flask with screw cap filter in order to minimize the risk of spills and/or aerosol mediated viral spread. For this the modified PRRL plasmids together with three additional separate plasmids (pMDLgp-RRE, pRSV-REV and pMD2-VSVG.env) will be transfected using a transfection reagent (e.g. Polyethylenimine (PEI), Lipofectamine) into HEK293T packaging line. After 6-12 hours, the medium is replaced with fresh serum-free medium and grown for an additional 72-96 hours. After 24-48 hours, so as to ensure the viability of the transducted HEK293T cells, medium form the cells is collected into screw cap tube and stored at 4°C and fresh serum-free medium is added to the cells. The cells are grown for an additional 24-48 hours before the second medium solution is added to the harvest tube. After lentivirus collection has been completed, the cells and the flask will be decontaminated and disposed of a detailed later. Still within a biosafety level 2 safety cabinet, the harvested supernatants will be filtered using a 0.45um filter before either aliquotted or further purified by chromatography and/or concentrated by centrifugation. The lentiviral particles may need to be purified by either chromatography and eluted in a high salt solution and/or concentrated by ultrafiltration. For certain application where highly concentrated and purified virus may be required, the traditional method of sucrose cushion based centrifugation may be necessary. To minimize the possible risk of accidental viral contamination and spread due to the need for an ultracentrifuge, all loading and unloading will be done in the biosafety level 2 safety cabinet. Once the sucrose cushions have been added to the centrifuge tubes, the unpurified or chromatography purified lentiviral particles will be added to the sucrose cushion. The individually capped tubes will then be transferred to their respective bucket holders and the bucket sealed using their respective screw cap marks and marked as containing virus. The buckets containing viruses will be balanced with a buckets containing a tube with water and without lentivirus. The balanced buckets will then be transferred to the rotor before being placed within the centrifuge chamber. The ultracentrifuge will be run at 70000g for 2 hours at 20°C. Upon return of the buckets to the biosafety level 2 cabinet, the supernatant will be removed from the tubes before transfer of the resuspended virus pellet into individual screw cap cryovials. As the greatest risk for contamination occurs within the centrifugation buckets themselves during transport to and from the weight scales and during ultracentrifuge, the centrifuge tubes and the buckets and the rotor will be decontaminated with spraying Chengene HLD4L 5%. Optionally, the centrifuge rotor can be autoclaved at 121°C. In any case, concentrated virus stock will not be exposed to the environment outside of the biosafety level 2 cabinet. All supernatants will be treated as above.

The lentiviral titre will be determined in terms of number of viral particles (VP) or transduction units (TU) per mL. The number of VP can be assessed relatively quickly and does not involve cell infection. In this case, a bead based enrichment assay or a p24 ELISA assay will be chosen. The VP quantification methods tend to overestimate the TU by 10-1000 fold. Thus, the TU/mL will in certain instances also determined. For this, a titration range of lentiviruses expressing a fluorescent tag will be prepared and added to a 24 well cluster plate or T25 TC-flasks containing HEK293T for 48 hours. The percentage of fluorescent positive cells will be quantified manually under a fluorescent microscope or ideally using FACS analyser.

Aliquots with not more than 1x10^6 viruses per vial are stored at -80°C in individual screw capped cryotubes. The viral stock will consist of viral particles containing the vector genome (full capsids) and also of a variable number of empty viral capsids. Other trace components that might be present include, but are not limited to, inorganic
In vitro studies
Transduction of cells (e.g., human HEK293T, mouse or rat mesangial cells) with the lentiviral vectors will be carried out in a Biosafety level 2 cabinet within a dedicated Biosafety level 2 laboratory. In the in vitro studies, the TUs, and consequently volumes added, will be dependent on the number of cells in the tissue culture dish/flask to be infected, up to the maximum number of viral particles to be handled per experiment (around 1 x 10^8). None of these cells will be cultivated in the filter screw cap flasks used for HEK293T mediated lentiviral production. This is to ensure that, in particular, the HEK293T cells used for lentiviral production are not inadvertently used for lentiviral assessment. Any plastic ware or solutions that are used to handle the transduced cells will be decontaminated and disposed of as detailed later (see Waste Handling). Once the medium containing the lentiviral particles has been removed and the cells (e.g., human HEK293T, mouse or rat mesangial cells) have been extensively washed, which all is done in a Biosafety level 2 cabinet, the human HEK293T cells can be used following Biosafety level 1 guidelines, as no virus will be present and the latent virus in the transduced cells is replication-incompetent. The immortalised human podocytes will be used following Biosafety level 2 guidelines. A viral titre determination assay may on occasion be used to verify the absence of virus in the medium from human HEK293T cells and immortalised human podocyte cells.

Cleaning SOPs

General cleaning procedures
Surfaces will be thoroughly cleaned with Chemgene HLD4L 5%* (or an equivalent product) at the end of each experiment or after the occurrence of an accidental spillage of infectious material. Application of these anti-microbial agents will totally inactivate any viral vectors that might be present. According to the biosafety literature, all of the viruses to be used are susceptible to these disinfectants. Anything that might have potentially come into contact with the virus will be treated with Chemgene HLD4L* before being autoclaved/incinerated.

* Chemgene HLD4L
Chemgene HLD4L is formulated as a micelle cleaning technology that enables the active molecules in the product to be carried rapidly through the cell walls of micro-organisms. Chemgene HLD4L has been reported to be bactericidal, fungicidal as well as virucidal (HIV, Hepatitis B, Herpex Simplex, Norovirus and Coronavirus) and sporicidal. It is recommended to be used at a 1:100 dilution (1%) for general purposes, 1:20d for high risk areas, and 1:20 (5%) for disinfection of blood and bio-hazard spillages.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

General cleaning procedures
Surfaces will be thoroughly cleaned with Chemgene HLD4L 5%* (or an equivalent product) at the end of each experiment or after the occurrence of an accidental spillage of infectious material. Application of these anti-microbial agents will totally inactivate any viral vectors that might be present. According to the biosafety literature, all the viruses to be used are susceptible to these disinfectants. Anything that might have potentially come into contact with the virus will be treated with Chemgene HLD4L* before being autoclaved/incinerated.

Waste Handling
Following all work requiring biosafety level 2 containment including work with lentiviruses and immortalised mouse or rat mesangial cells, solid waste will be neutralised by soaking in a validated disinfectant solution, after which the material will be “double bagged”, autoclaved and, ultimately, incinerated offsite. It will be routine practise that all liquid waste material be neutralised before disposal, and for the neutralised waste to be transported in leak-proof containers to prevent spillages. Liquid waste will be inactivated by Chemgene HLD4L* for 24 hours prior to drain disposal as per 430CSP and 418CSP permit requirements.

As any active viral particles or immortalised mouse or rat mesangial cells on surface or in waste material will be completely inactivated at the end of each experiment by the highly effective cleaning/disinfection protocols outlined above, it is considered highly unlikely that active virus particles or immortalised mouse or rat mesangial cells would unintentionally become discharged into a sanitary sewage system. No foreseeable adverse effects on human health and safety are expected.
Chemgene HLD4L is formulated as a micelle cleaning technology that enables the active molecules in the product to be carried rapidly through the cell walls or micro-organisms. Swift penetration of the cell walls ensures cell death is equally rapid. Chemgene HLD4L has been reported to be bactericidal, fungicidal as well as virucidal (HIV, hepatitis B, Herpex Simplex, Norovirus and Coronavirus) and sporicidal. It is recommended to be used at a 1:100 dilution (1%) for general purposes, 1:20 dilution (5%) for high risk areas, and for disinfection of blood and bio-hazard spillages.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

The host cell lines have been immortalised using genetic material encoding SV40 T antigens which are capable of immortalising human cells. This coding sequence cannot be mobilised. In the event of accidental injection into a healthy worker the immune system would rapidly destroy any cells so negating any risk. The proposed work involves the use of lentivirus to deliver various constructs into the aforementioned cells. The lentivirus will be generated using a third generation methodology which requires 4 different plasmids, that do not share sequence homology, to be transfected into the same packaging cell. The isolation of the genes required for virus production minimises the chance of accidentally generating replication competent virus (RCV). The desired packaged genetic material also undergoes self-inactivation upon integration into a host genome after infection of target cells. As this is a permanent change it is noted that no tumour suppressors, oncogenes or immune modulators will be targeted. The host cells contain the transformative SV40 T antigens so it is important to prevent mobilisation of this genetic material. There will be no homologous sequence present between the lentivirus and the SV40 T antigen coding region. Combined with the minimal chance of RCV being present will effectively prevent the generation of virus containing SV40 T antigen. The lentivirus being produced, although pseudotyped to have broad tropism, poses a minimal risk to the environment as it is highly unlikely to be able to infect an animal outside of the laboratory environment in the case of accidental release and the material will also rapidly deactivate at room temperature.

Although the risks presented here are minimal the GMSC agrees that this work will be conducted at biosafety level 2 to ensure containment is maintained because the material is being delivered into cells using lentiviruses and those cells contain genetic material encoding SV40 T antigens.

Use of the Expi293 MembranePro Expression technology system (Life Technologies) for the expression and display of mammalian cell surface membrane proteins including G-protein coupled receptors (GPCR), ion channels transporter and other membrane bound molecules in an aqueous-compatible format.

Expi293F cells are based on the HEK293 (primary human embryonic kidney cells) immortalised cell line. The Expi293F will be used to generate the VLPs, these cells have been adapted from HEK293 cells to grow in high density suspension culture. The HEK293 cell line is a permanent line established from primary embryonic human kidney cells transformed with sheared human adenovirus type 5 DNA. The E1A adenovirus gene expressed in HEK293 cells participates in the transactivation of some viral promoters, allowing these cells to produce very high levels of protein. This enables the efficient generation of viral capsids when these genes are introduced transiently into the the cell. The adenovirus genetic sequence present in HEK293 cells has been found to be non mobilisable and as such is not packaged into viral particles. This means that the cells themselves are essentially non-hazardous. These properties have meant that many virus packaging cell lines have been derived from the HEK293 cell line.

Recipient or parental organism
Expi293F cells are based on the HEK293 (primary human embryonic kidney cells) immortalised cell line. The Expi293F will be used to generate the VLPs, these cells have been adapted from HEK293 cells to grow in high density suspension culture. The HEK293 cell line is a permanent line established from primary embryonic human kidney cells transformed with sheared human adenovirus type 5 DNA. The E1A adenovirus gene expressed in HEK293 cells participates in the transactivation of some viral promoters, allowing these cells to produce very high levels of protein. This enables the efficient generation of viral capsids when these genes are introduced transiently into the the cell. The adenovirus genetic sequence present in HEK293 cells has been found to be non mobilisable and as such is not packaged into viral particles. This means that the cells themselves are essentially non-hazardous. These properties have meant that many virus packaging cell lines have been derived from the HEK293 cell line.

Host/vector system
The system uses pEF-V5-His TOPO to express the gene of interest. This plasmid does not contain any lentiviral
genes and therefore poses no risk. The lentiviral gag gene or protein (packaging mix) is provided in enhancer solutions provided with the Expi293 Membrane Pro Expression Technology system kit which will be used in the production of the VLPs. The exact nature of this enhancer material is propriety to Life Technologies but as it contains the ability to supply the gag gene or protein it will be managed as needing to be treated as a class 2 material. This system lacks any other lentiviral genes and as such does not produce or encapsulate viral DNA. Once the VLPs have been generated and purified the enhancer solution will have been removed.

Origin & function

The system relies upon the presence of the lentiviral gag core structural protein to drive the self assembly of sub viral particles that should not encapsulate DNA. These VLPs bud off from the cell surface taking membrane proteins with them. As such they will contain the proteins of either GPCR, ion channel, enzymes, transporters or other cell surface membrane proteins that are expressed in the cell.

Targets of interest that will be over-expressed for incorporation into VLPs will not be known to have cytotoxic, oncogenic or immunomodulatory effects. The purified VLPs can then be used in a variety of vitro assays to assess small molecule, peptide and protein interactions with the protein of interest present in the VLP membrane.

Evaluation of foreseeable effects

Human Health Hazard
The production method for VLPs means that it is highly unlikely that infectious virus can ever be generated. The only lentiviral gene present in the production of the VLPs is the gag gene. As the system lacks the env and pol genes infectious virus particles can not be generated and there is no viral genome to be packaged. The vectors used to express the genes of interest do not contain packaging sequences and will not therefore be packaged into the VLPs. These vectors will essentially be absent once the VLPs have been purified. There is a small chance that the gag gene and/or the vector encoding the gene of interest introduced in trans may become trapped with a VLP as it forms. As such there is a theoretical risk that if fusogenic particlles do come in to contact with cells it may introduce DNA and lead to a permanent genetic change in the cell. This risk is minimal because the number of VLPs containing any DNA will be minimal, they will be dilute and as they lack the env protein they are highly unlikely to be able to infect cells. To ensure that the other lentiviral genes are not introduced into the system VLPs will not be used with other cell cultures and production will be kept separate from cells being used for the production of lentiviral vectors. As the system does utilise a lentiviral gene during the generation of the VLPs this work will be carried out at biosafety level 2. The generation of VLPs will therefore be treated as a class II activity. Standard health and safety procedures of working will be followed throughout to eliminate any risk of infection.

Hazard to the environment
The chance that infectious lentivirus is released into the environment is considered to be negligible. The VLPs that are generated are designed to only contain the gag protein of the lentiviruses and not the gag gene. Infectious VLP generation would have to involve the gag gene encountering the remaining pol or env genes and infecting cells in the environment, the risk of this is negligible given that the VLPs lack the product of the env gene and are highly unlikely to be able to infect cells. In the event of release of the VLPs into the environment, they are labile outside of the laboratory environment being sensitive to temperature and will rapidly degrade at room temperature.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
The production of the VLPs is the point at which large volumes of concentrated material will be generated in a system.
that has had the gene encoding gag present. The purification process will essentially remove genetic material. Once aliquots of this final material has been dispensed there should be essentially no genetic material present. Subsequent experiments will not involve the use of cells and limited amounts of material will be diluted and it is thought appropriate to handle this material with good laboratory practice.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste, including pipette tips and tissue culture flasks will be neutralised by soaking in a validated disinfection solution (5% HLD4L solution, Chemgene) for 24 hours, after which the material will be double bagged, autoclaved and taken off site for incineration. Liquid waste will be chemically deactivated with 5% HLD4L solution, Chemgene for a minimum of 24 hours prior to drain disposal via a designated sink.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Project Ref 3043/16.1
The human immortalised neural progenitor cells will be used as a tool cell line in Neurodegeneration to investigate cellular pathways involved in the development of neurodegenerative disorders, in particular Huntington's.

To better understand these cellular pathways, the expression or the activity of the gene of interest will be modulated by several methods:

1. The utilisation of tool compounds
2. The knock-down of the gene of interest by shRNA
3. The generation of modified somatic cells using programmable nucleases (CRISPR or Zinc finger nucleases)
4. The generation of reporter gene cell line (e.g., fluorescence protein or enzyme) under the promoter of the gene of interest.

The experiments involving the transfection of vectors such as shRNA or programmable nucleases may be performed by lentivirus. The effect of modulating the expression or the activity of the target of interest will be determined by the expression level of the proteins, mRNA or mediators involved in the target signalling pathway.

Recipient or parental organism

1. The human immortalised neural progenitor cells, ReNcell 197VM
   - ReNcell VM is an immortalized human neural progenitor cell line with the ability to readily differentiate into neurons and glial cells.
   - ReNcell 197VM was derived from the ventral mesencephalon region of a human fetal brain tissue. Immortalized by retroviral transduction, using replication incompetent retrovirus, with the avian v-myc myelocytomatosis viral oncogene.
   - These immortalised human neural progenitor cells, ReNcell 197VM, will be purchased from Millipore. Millipore have tested the cell line and shown that it does not produce infectious virus particles.
2. Human immortalised neural progenitor cells, ReNcell mHTT Exon1 197VM
• ReNcell 197VM cells were transduced with lentiviral virus particles containing varying length HTT exon 1, eGFP, cPPT, WPRE, LTR U3 del (pHRsincpptUCOE+htt exon1 IRES eGFP 29CAG/71CAG/129 CAG WPRE).
These immortalised human neural progenitor cells, ReNcell mHTT Exon1 197VM, will be provided by UCL. This cell line contains the v-myc oncogene, a WPRE element that may contain the WHV-X oncogene ORF and therefore will be maintained in a biosafety level 2 confinement.

Description of the lentivirus containing shRNA, programmable nucleases sequences or gene reporter vectors
To utilise the neural progenitor cells to study neurodegeneration, the expression of a target of interest may be decreased in the ReNcell line by the transduction of shRNA or programmable nuclease by lentivirus.

The modulation of a particular cellular pathway may be studied with the use of a reporter gene assay. In this case, the vector containing the reporter gene under the regulation of the promoter of the gene of interest may be introduced by lentivirus into the ReNcells. In addition other exogenous genes may also be introduced using lentiviral vectors.

This proposal may involve both the use of existing lentiviral constructs purchased commercially and the generation of new constructs on site using the third or fourth generation system. Both commercially acquired and in-house lentivirus will use the same transfer vector plasmid. Target genes will be selected based on the needs of drug discovery projects; programmable nucleases and shRNA will not be produced against any growth factors, tropic factors, quiescence factors, confirmed oncogenes, tumour suppressors or immunomodulators (these targets will be presented to the GMSC for approval prior to any work taking place).

The production of lentivirus containing the vectors of interest are described below:
1- Generation of lentivirus

Executive

Lentiviral vectors will be purchased commercially or produced in-house using the third or fourth generation system described below. Each purified and concentrated aliquot of lentiviral reagent comprised of a small volume (5 to 10ul) that contains no more than 1 X 10^8 viral particles.

Vector System = self-inactivating (SIN) non replication-competent HIV based lentiviral vectors

The viral vectors that will be used in the proposed studies are self-inactivating non replication-competent HIV based lentiviral vector systems, which have been deSignated to produce stable gene expression in mammalian cells; and they are generated by co-transfecting HEK 293T cells with four to six separate plasm ids. Each of the plasm ids used expresses a different set of genes which, when combined following co-transfection, provide the smallest possible set of essential viral genes that is still compatible with virus production. Moreover, the vectors are all vesicular stomatitis virus (VSV-G) pseudotyped lentiviral vectors, which are self-inactivating and highly unlikely to undergo recombination. Importantly, the viral vector is inherently incapable of replication in mammalian cells.

The plasm ids

Third Generation

The sequences that will be included in the viral vectors are sub-cloned into 4 standard bacterial plasmid vectors.

• Plasm ids containing the packaging related sequences

Each of the three other plasm ids, pCgpV, pRSV-Rev and pCMV-VSVG contain a different set of sequences that code for proteins that are responsible for packaging the viral vectors. All the genes (gag-pol, rev and env) required for production and packaging of the full length viable viral RNA particles have been removed from the pSMPUW lentiplasm ids containing the transgenes of interest.

Fourth Generation

The sequences that will be included in the viral vectors are sub-cloned into 6 standard bacterial plasmid vectors

• Plasm ids containing the packaging related sequences
Each of the other plasmids, pTRE-gag-pro, LTRHIV2-vpr-pol, penvVSV-G, pTet-Off and ptat-IRES-rev contain a different set of sequences that code for proteins that are responsible for packaging the viral vectors. All the genes (gag-pol, rev and env) required for production and packaging of the full length viable viral RNA particles have been removed from the pSMPUW lenti-plasmids containing the transgenes of interest. An integrase deficient version of the fourth generation packaging mix is available which contains a mutation in the sequence encoding the viral integrase. The resulting integrase-deficient lentivirus (IDLV) generates circular vector episomes in transduced target cells that are gradually lost by dilution in dividing cells (transient expression), but are stable in quiescent cells.

### Plasmids containing the transgene of interest

The fourth plasmid, pSMPUW, will contain the sequences that code for shRNA, or programmable nuclease sequence, or reporter gene sequence under the promoter of the gene of interest.

**a- Vector containing shRNA**

As mentioned above, pSMPUW plasmid will contain the sequences that code for one shRNA transcript that will target one mRNA/protein of interest (or a scrambled shRNA in the case of negative control). The shRNA or scrambled shRNA sequences will be under the control of polymerase II or III promoter. The shRNA sequences will be chosen to target a single gene. The shRNA will not be produced against any growth factors, tropic factors, quiescence factors, confirmed oncogenes, tumor suppressors or immunomodulators.

**b- Vector containing CRISPR or Zinc-finger nucleases**

Programmable nucleases function by binding to, and cleaving, user-defined target DNA sequences. This in turn instigates a robust DNA repair response which ultimately leads to disruption of the target sequence by deletion at the cleavage site or by recombination with a user-supplied synthetic vector containing sequences complementary to the target gene allowing insertion of exogenous genetic sequence. For Cas9/CRISPR, nuclease target specificity is determined by an accessory sequence, the guide RNA, which consists of a short (18-20 nucleotide) sequence homologous to the target gene and an additional short sequence that forms a complex with the Cas9 enzyme. In this case, the plasmid pSMPUW, will contain the sequences that code for a Cas9/CRISPR plus accessory sequences comprising a short guide RNA that determines target specificity. The guide RNA sequences will be under the control of a Polymerase III promoter.

### Health and Safety Executive

In the case of Zinc finger nucleases target specificity is dependent upon the zinc finger protein sequence. The pSMPUW will contain in that case the sequence of zinc finger nucleases under the control of either a polymerase II promoter. In addition, a fluorescent protein or enzyme under the control of a polymerase II promoter or the promoter of a gene of interest may be included. Control viral vectors that express only the fluorescent protein/enzyme and no programmable nucleases will be used in some experiments.

The Cas9/CRISPR, if introduced into any cell line by lentivirus, will use the integrase deficient version of fourth generation packaging mix.

**c- Reporter gene vector**

The pSMPUW vector will contain the sequence coding for a reporter protein (enzyme or fluorescent protein) under the control of the regulating elements of the promoter of the gene of interest or the a polymerase II promoter. An appropriate selection marker i.e.; neomycin could also be included to allow the selection of stable human neural progenitor cells containing the reporter gene sequence under the control of the promoter of the gene of interest. Target genes will be selected based on the needs of drug discovery projects; programmable nucleases, shRNA or exogenous genetic material will not be produced against any growth factors, tropic factors, quiescence factors, confirmed oncogenes, tumour suppressors or immunomodulators (proposed targets will require approval internally by
Procedures:

During all procedures that involve the handling/use of the viral vectors or cells, all workers (incl. those that are not working directly with the vectors) that are present within a lab where the work is undertaken are required to wear personal protective equipment at all times. The use of two pairs of gloves is advised so the external pair can be disposed in an autoclave bag and replaced whenever necessary (e.g. in the case of contact with the viral reagent). In addition, all workers are made aware of the nature of the viral work that is going on within the laboratory, and they have to follow appropriate procedures to ensure that there is no cross-contamination into non-viral working area. All the workers using the viral delivery systems are experienced research scientist, and junior scientists will be closely supervised until they are competent in the handling of the viruses.

Lentiviral production

Lentiviral production will also be carried out on-site using a modified procedure based on Bukosvsky et al. (Bukosvsky et al, 1999, J. virology). Lentiviral production will only be carried out in HEK293T cells in a biosafety level 2 cabinet within a culture flask with screw cap filter in order to minimize the risk of spills and/or aerosol mediated viral spread. For this the modified pSMPUW plasmids together with three to five additional separate plasmids (pCgpV, pRSV-Rev and pCMV-VSVG or pTRE-gag-pro, L TRHIV2-vpr-pol, penv(VSV-G), pTet-Off and p tat-IRES-rev) will be transfected, using a standard chemical transfection method, into HEK293T packaging line. After 6-12 hours, the medium is replaced with fresh serum-free medium and grown for an additional 72-96 hours. After 24-48 hours, so as to ensure the viability of the transfected HEK293T cells, medium from the cells is collected into screw cap tube and stored at 40°C and fresh serum-free medium is added to the cells. The cells are grown for an additional 24-48 hours before the second medium solution is added to the first harvest tube. After lentivirus collection has been completed, the cells and the flasks will be decontaminated and disposed of (detailed later). Still within a biosafety level 2 safety cabinet in a biosafety level 2 laboratory, the harvested supernatants will be filtered using a 0.45um filter before either aliquoted or further purified by chromatography and/or concentrated by centrifugation. The lentiviral particles may need to be purified by either chromatography and eluted in a high salt solution and/or concentrated by ultrafiltration. For certain applications, where highly concentrated and purified virus may be required, the traditional method of sucrose cushion based centrifugation may be necessary. To minimize the possible risk of accidental viral contamination and spread due to the need for an ultracentrifuge, all loading and unloading will be done in the biosafety level 2 safety cabinet. Once the sucrose cushions have been added to the centrifuge tubes, the unpurified or chromatography purified lentiviral particles will be added to the sucrose cushion. The individually capped tubes will then be transferred to their respective bucket holders and the bucket sealed using their respective screw caps and marked as containing virus. The buckets containing viruses will be balanced with buckets containing a tube with water and without lentivirus. The balanced buckets will then be transferred to the rotor before being placed within the centrifuge chamber. The ultracentrifuge will run at 70000g for 2 hours at 200°C. Upon return of the buckets to the biosafety level 2 cabinet, the supernatant will be removed from the tubes before transfer of the resuspended virus pellet into individual screw cap cryovials. As the greatest risk for contamination occurs within the centrifugation buckets themselves during transport to and from the weight scales and during ultracentrifuge, the centrifuge tubes, the buckets and the centrifuge rotor will be decontaminated by spraying Chemgene HLD4L 5%. Optionally, the centrifuge rotors could be autoclaved at 1210°C. In any case, concentrated virus stock will not be exposed to the environment outside of the biosafety level 2 cabinet. All supernatants will be treated as above.

The lentiviral titre will be determined in terms of number of viral particles (VP) or transduction units (TU) per mL. The number of VP can be assessed relatively quickly and does not involve cell infection. In this case, a bead based enrichment assay or a p24 ELISA assay will be chosen. The VP quantification methods tend to overestimate the TU
by 10-1000 fold. Thus, the TU/mL will in certain instances also be determined. For this, a titration range of lentiviruses expressing a fluorescent tag will be prepared and added to a 24 well cluster plate or T25 TC-flasks containing HEK293T for 48 hours. The percentage of fluorescent positive cells will be quantified manually under a fluorescent microscope or ideally using FACS analyser/Bioanalyser. The biological titre (TU/mL) according to the following formula: 

\[
\text{TU/ul} = (P \times N \times 100 \times V) \times 1/10D, \quad \text{where } P = \% \text{ GFP+ cells}, \quad N = \text{number of cells at time of transduction} = 10^5, \\
V = \text{volume of dilution added to each well and } OF = \text{dilution factor} = 1 \text{ (undiluted), 10-1 (diluted 1/10), 10-2 (diluted 1/100), and so on.}
\]

Aliquots with not more than 1x10^8 viruses per vial are stored at -80°C in individual screw capped cryotubes. The viral stock will consist of viral particles containing the vector genome (full capsids) and also of a variable number of empty viral capsids. Other trace components that might be present include, but are not limited to, inorganic salts, vitamins, other nutrients, human cellular proteins, carbohydrates, amino acids, and fats.

a- Assessing efficacy of the lentivirus into a BSL 1 cell line

Assessing whether the genome manipulation or the knock-down has worked will normally take place initially in biosafety level 1 immortalised cell line that are known not to contain lentiviral genetic material. Application of lentiviral particles will be done at biosafety level 2 confinement. After at least 24 hour incubation and extensive washing, the cells will treated as biosafety level 1 (see below the justification for removal of cells post-infection to biosafety level 1).

In order to determine whether the knock-down or the genome manipulation has worked, the levels of mRNA and protein of the gene of interest will be assessed post-transduction.

b- Transduction of the lentivirus and the generation of stable expression into ReNcell VM neural progenitor cells

Once validated the same procedure will be carried out in the ReNcell VM neural progenitor cells. As these cells are maintained in a biosafety level 2 confinement, the inoculation of lentiviral particles, the transformed cells and the phenotypic analysis will also be performed in a biosafety level 2 containment. When a lentivirus containing a programmable nuclease or the reporter gene will be used, a stable cell line could be established by selecting the cells in which the genome has been modified. In all cases phenotypic analysis will be performed using suitable in vitro assays, including for example, RT-PCR, Western Blotting, immunocytochemistry and imaging, or cellular bioenergy (Le.: mitochondria respiration function or glycolysis function).

**Evaluation of foreseeable effects**

* Human Health

The immortal human ReNcell VM neural progenitor cell that will be used has a low risk to human health. The expression systems and the transgenes that comprise the lentiviral vectors that will be used have also a very low risk for human health and safety, and the reasons for this are discussed below.

A- Lentivirus containing shRNA, or programmable nucleases sequence or reporter gene vectors

**Lentiviral Vector Expression System**

Lentiviruses belong to the Retroviridae virus family which are capable of infecting both human and animal species. As the lentiviral vector system that will be used in these studies is based on HIV-1, a theoretical risk to human health exists. However, retroviruses are generally transmitted via exposure to contaminated body fluids or percutaneous inoculation and generally not transmitted via the airbone route. Therefore, accidental piercing of the skin or other surface tissues with virus containing objects represents the main potential route by which accidental infection could occur. Appropriate risk reduction measures will be implemented to reduce the likelihood of this occurring.

In all of the modified pSMPUW plasmids (containing shRNA, or programmable nucleases or reporter gene sequences), the sequences inserted are flanked by non-coding retroviral L TRs, and no retroviral genes are encoded on the modified pSMPUW plasmid ids. Therefore, no retroviral genes will be transferred into generated viral particles. This construct is packaged into particles using a HEK293T cell based packaging system, which requires the cotransfection of these cells with three to five additional separate plasmid ids (as detailed above). The additional plasmid ids express the envelope protein from VSVg and the non-structural proteins of the virion, and, importantly, none of these
genes will be transferred into the assembled viral vectors, since they lack the packaging signal (psi), which is only present on the modified pSMPUW plasmids. The lentiviral Expression System what will be used include the following key safety features:
* All of the pSMPUW contain a hybrid 3'LTR that does not affect generation of the viral genome in the producer cell line, but results in "self-inactivation" (SIN) of the vector after transduction of target cells. Once integrated into a transfected target cell, the lentiviral genome is no longer capable of producing viral genomic material that can be packaged. Moreover, presence of an SV40 polyA after the hybrid 3'L TR in the vector construct will result in a provirus which should reduce the potential for transactivation of cellular genes due to an insertion event. Furthermore, the development of self-inactivating vectors improves the biosafety of vectors, as they are less likely to be mobilised following a superinfection with wild-type virus (HIV).
* The VSV-G gene from Vesicular Stomatitis Virus is used in place of the HIV-1 or other retroviral envelope genes. Heterologous envelopes, like VSV-G, typically broaden the tropism and allow gene transfer into a broad variety of cells. The risk will mitigated by the use of self-inactivating virus and limiting the number of viral particles that will be handled at anyone time.
* Sequences encoding the proteins required for packaging of the viral genome are separated onto three to five plasmids, and all of the 4-6 plasmids used in the system have been engineered not to contain any regions of homology with each other so as to prevent undesirable recombination events that could lead to the generation of a replication-competent lentivirus (RCL), which could potentially be harmful to humans. It is important to note that no such RCL has ever been observed despite large-scale production and testing of lentiviral vectors.
* All of the pSMPUW containing plasmids/vectors will be used are devoid of all viral sequences apart from essential cis-acting sequences, including the L TRs and the packaging signal psi. Although the packaging plasmids used in these systems allows for the expression in trans of protein required to produce viral progeny (e.g. gal, pol, rev, env) in the HEK293T producer cell lines, none of them contain L TRs or the psi packaging sequence. Several of the lentiviral accessory genes (vif, vpr, vpu and nef) that are dispensable for lentiviral vector production/transduction have been deleted from the packaged construct. Therefore, none of the retrovirus structural genes will actually be present in the packaged viral genome, and they will never be expressed in the transduced target cells, which means that no new RCL can be produced.
* The lentiviral particles produced in this system are replication-incompetent, only carry the sequences of interest, and no other viral species are produced.
* Expression of the gag and pol genes from pgag-pol-RRE has been rendered Rev-dependent by virtue of the HIV-1 RRE (Rev Responsive Element) in the gag/pol mRNA transcript. Addition of the RRE in these plasmids prevents gag and pol expression in the absence of rev, which is contained in the pRSV-REV plasmid only. The Rev/RRE system is highly conserved among lentiviruses, and removal of the RRE sequence and associated splice donor/acceptor sequences result in a loss of transduction efficiency.
* L TR has been modified so as to increase lentiviral vector production, and also to allow lentiviral vector production to be independent of tat expression. It is known that Tat-deleted mutants of wild-type HIV-1 are not replication competent. Therefore, the deletion of Tat should decrease the risk of generating a putative RCL.
* Lentiviral vectors have a very low potential to cause immunogenicity.
* The central poly purine tract (cPPT), from the pol ORF, is included in all of the viral vectors that will be used to improve the nuclear import of the proviral DNA and hence accelerate transduction.

Health and Safety

Executive

While the lentiviral vectors that are produced using this system contain only about 20% of the original genome of HIV-1, there is a very small risk that subsequent infection of cells already infected with the lentiviral genome of HIV-1 could
lead to a rare recombination event in which the transgene is transferred to a replication-competent virus. Thus, the sequences in the vector that will be expressed could potentially be transferred to surrounding cells. This event is, however, extremely unlikely to occur for a number of reasons:

1- The lentiviral vector is replication-incompetent and self-inactivating. In the case of a subsequent HIV-contamination, wild-type HIV-1 cannot rescue a self-inactivating HIV-1 based lentivirus once integrated into the host genome, although non-self-inactivating vectors can be.

2- In order for the spread of the gene of interest to occur following accidental infection (assuming that this has lead to viral integration), a series of unlikely events have to occur:
   a- The worker would have to become infected with HIV-1 or to be already infected with the virus.
   b- The viral and lentiviral genomes would have to integrate into the host worker's genome in the same cells and in a position where they could interact to effect homologous recombination (point 1 above)
   c- Recombination would have to occur in just the right regions to allow for transfer of the gene of interest from the lentivirus to the HIV-1 genome, which could also involve the transfer of the HIV-1 genes to the lentiviral genome. In that case, it is conceivable that a non-self-inactivating HIV could be generated that contained the gene of interest but not the rest of the genome it requires. The other gene products could be provided in trans from the lentiviral genome that may now contain the HIV-1 genes or from other HIV-1 integrants.
   d- The situation in c could conceivably lead to the production of an infectious particle containing the gene of interest, but again no genes neccessary for subsequent replication. In order for another round of infection to occur, the process would have to begin again.

In these circumstances, the effects of lentiviral infection are likely to be minor in comparison to the effects of the HIV-1 infection, which would be required to affect the spread of the gene of interest. In addition, the scenario described is essentially equivalent to the rescue of the lentiviral genome from the host, which has already been shown not to occur.

3- It is extremely unlikely that any worker would infect themselves with a significant dose of lentivirus as the volumes that are used in transfection experiments are small (aliquots contain a maximum of 10IJL of vector solution).

4- Moreover, insertional mutagenesis into the host genome may be considered as an oncogenic risk. We cannot rule out the possibility that, when the lentiviral genome integrates into the host genome, it will not lead to the activation of an endogeneous oncogene. However, all transcriptionally active long-terminal repeats (LTRs) have been removed as well as all promoter-like elements that required to drive expression of the transgene. This should prevent unforeseen activation of such genes. It is noted that deletion of retroviral enhancer in self-inactivating systems reduces the risk of activation but not of disruption, therefore, retroviral infection might still have permanent effects upon a cell (including oncogenic effects).

Importantly, we do not consider that the use of these lentiviral vectors will result in a significant increased risk of oncogenic activation compared to the risk possessed by any other viral delivery system. Moreover, the risk of transduction leading to tumourigenesis or other untoward harm following exposure is related in part to the titre of the viral vectors; exposure of workers to quantities of virus high enough to cause such effects would be unlikely during standard laboratory-based manipulations of lentiviral vectors.

Transgenes:
Additional hazards could arise from the properties of the genetic material that will be inserted into the viral vectors and expressed in transfected cells.

shRNA
With the use of shRNA-expressing viral vector systems, the expression of specific mammalian genes/proteins can be knocked-down, in order to study their functions. Potential deleterious effects such as off-target and immunomodulatory responses can be minimised through screening designed shRNA sequences against databases of
known mammalian/mRNA sequences during the design stage. The genes/proteins of interest that will be targeted by
shRNA do not and will not include any growth factors, tropic factors, quiescence factors, confirmed oncogenes, tumor
suppressors and immunomodulators. Some of the viral vectors that will be used contain a sequence of interest that
has been scrambled (scrambled shRNA), and which is not complementary to any known mammalian sequences. This
sequence will adopt a hairpin structure as with any shRNA, but it should not target any mRNA of human, mouse or rat
origin. Consequently, these sequences are unlikely to pose any safety risks for the environment or human health (this
will be approved by the GMSC).

Programmable nucleases: zinc fingers or Cas9/CRISPR
Zinc fingers or Cas9 protein will be directed against genes of therapeutic interest. Since the purpose of
programmable nucleases is to cause mutations in defined DNA sequences the primary hazard is that such a mutation
would lead to deleterious cellular effects. The genes/proteins that will be targeted do not and will not include any
growth, tropic factors, confirmed oncogenes, tumor suppressors or immunomodulators. In isolation, these sequences
are unlikely to pose any safety risks for the environment or human health.

Reporter genes: Fluorescent protein or enzymes
The reporter gene could be a fluorescent protein or an enzyme. Fluorescent proteins, for example GFP or dsRed,
are not known to cause any diseases in human or animals and have no direct effect on cellular processes. Enzymes
used frequently in reporter gene assay ie luciferase or b-galactosidase are not known to cause any diseases in
humans or animals and as no direct effect on cellular processes. The expression of fluorescent protein or enzymes
under the control of a promoter of a gene of interest is unlikely to pose any safety risks for the environment or human
health.

Summary on lentivirus
The transgenes have a low safety risk to human health because accidental contamination with a vector would lead to
only a small number of cells becoming infected, and it would be highly unlikely that expression in only a few cells
could be sufficient to lead to a disease state. The inability of the lentiviral vectors to propagate on mammalian cells
also reduces the risk. The programmable nucleases (CRISPR or Zinc finger or Cre recombinase) that will be
employed in this viral vector system are not known to cause any relevant toxicity that might represent a safety risk to
human health. The fluorescent proteins or the enzymes are not known to cause any relevant toxicities that might
represent a safety risk to human health. For both programmable nucleases and shRNA, the genes/proteins of interest
that will be targeted will not include any growth factors, tropic factors, quiescence factors, confirmed oncogenes,
tumor suppressors or immunomodulators, and none of them are or will be of retroviral origin. Therefore the risk of use
will be low.

8- Immortalised human neural progenitor cells ReNcell 197VM & mHTT Exon1 197VM and transduced immortalised
ReNcell197VM & mHTT Exon1 197VM cells
Immortalised ReNcell197VM & mHTT Exon1 197VM neural progenitor cells
The immortalised ReNcell 197VM cell line has been immortalized by retroviral transduction, using replication
incompetent retrovirus, with the avian v-myc myelocytomatosis viral oncogene.
One of the major risks would be if the sequences coding for the v-myc oncogene were mobilised. This could happen if
the ReNcell 197VM or mHTT Exon1 197VM cells are accidentally inoculated to a worker already infected by a
retroviral genome. Even in that case, a series of unlikely events would have to occur to:
a. The worker would have to be already infected with the HIV-1 virus
b. The retroviral genomes would have to integrate into the immortal human neural progenitor cells genome in a
position where they could interact to effect homologous recombination.
c. Recombination would have to occur in precise regions to allow for transfer of the v-myc oncogene sequences from
the ReNcell197VM or mHTT Exon1 197VM genome to the HIV-1 genome.
d. The situation in c could conceivably lead to the production of an infectious particle containing the gene of interest. Although the risk for human health is low, all measures will be in place to minimize the risk of human health to avoid any accidental inoculation of a worker (see measures below). The ReNcell mHTT Exon1197VM cells also contain the sequences for WPRE, cPPT and deltaU3 of HIV-1 virus. However these cells should not contain the viral genes gag-pol and env required for virus production and therefore cannot produce viruses. It is not known if the WPRE sequence has been mutated to remove the oncogenic WHV-X protein from an open reading frame found in WPRE sequence. One of the major risk factors associated with the utilisation of this cell line would be in that case accidental percutaneous inoculation of a worker. This ReNcell mHTT Exon1 197VM cell line could theoretically not survive in the inoculated worker but would be quickly cleared by the human immune system. Further modification of the ReNcell197VM or mHTT Exon1197VM cell line may enhance the risk of mobilisation of the sequence coding for v-myc oncogene, or WPRE and the sequence of OU3 in the case of ReNcell mHTT Exon1 197VM. Application to these cells of additional lentivirus particles could result in the mobilisation of these sequences but should not result in the liberation of replication-competent retroviruses as the viral genes gag-pol and env should not be present in the genome of the immortalised ReNcell mHTT Exon1 197VM neural progenitor cells. The deltaU3 region contained in the ReNcell197VM mHTT Exon1 cells contains a deletion within the 3’L TR region rendering it self-inactivating and the 3’L TR contained in any virus generated in house, using pSMPUW, contains a hybrid enhanced polyA in the U3 region. If further modification is performed using lentivirus in the ReNcell 197VM mHTT Exon1 cells, the L TR regions will be sequenced to check for lack of homology. The ReNcell 197VM cells are likely to contain retroviral L TR sequences, with the v-myc oncogene. These L TR sequences would be derived from MMLV and L TRs present in any lentivirus generated in house using pSMPUW lentivirus backbone would derive from HIV-1. There should not be sequence homology between these regions. If further modifications are performed using lentivirus, these regions will be sequenced to check. Furthermore, the risk can be minimised by ensuring that any lentivirus used in experiments with the host cells does not contain gag-pol, env or any other significant retroviral genes involved in packaging and replication. The ReNcell mHTT Exon1 197VM cells contain a mutant form of Huntingtin Exon 1. Data indicate that exon 1 proteins are highly neurotoxic (Landles et al., 2010; Barbaro et al., 2015), and models that express either mutant full length HTT or mutant exon 1 of HTT can be used effectively to study HD. Exon-1 expressing models demonstrate disease phenotypes such as aggregate formation (Landles et al., 2010). One of the major risks would be if the sequence coding for the mHTT Exon1 were mobilised. This could happen if the mHTT Exon1 197VM cells are accidentally inoculated to a worker already infected by a retroviral genome. Even in that case, a series of unlikely events would have to occur to (as described above for v-myc mobilisation). Even if the events are unlikely, the immortalised human neural progenitor cell line and the transduced ReNcell 197VM & mHTT Exon1 197VM cells will be maintained at biosafety level 2 containment. Therefore all measures will be in place to minimize the risk to human health.

Human health hazards

Oral ingestion will be prevented by standard laboratory safety practices. Aerosol formation resulting from an accident outside of the safety cabinet and involving lentivirus particle-containing liquid may lead to transduction of a limited number of the laboratory worker’s skin or mucosal cells with modified viruses. However, these modified virus particles carry an extremely low safety risk for human health, as they are replication-incompetent, and also because the particles carry an extremely low infection potential via the mucosal/skin routes, due to the inherent properties of the viral vectors. Moreover, the programmable nucleases and shRNA that will be expressed or targeted will not be designed to disrupt any growth factors, trophic factors, quiescence factors, confirmed oncogenes, tumour suppressors or immunomodulators. In the unlikely event of accidental transduction of a laboratory worker’s skin or mucosa by lentivirus particles, this will be self-limited, due to natural shedding of superficial epithelial skin and mucosal cell
layers. The most likely route of accidental infection with a lentivirus or with the ReNcell 197VM & mHTT Exon1 197VM cell line will be via inadvertent percutaneous inoculation. The likelihood of this occurring will, however, be minimised by adhering to appropriate risk management measures. Infection of the community at large with lentivirus particles is highly unlikely due to the viral vector particles being replication incompetent. Infection of the community at large by ReNcell 197VM or mHTT Exon1 197VM cells is highly unlikely due to the impossibility of the cells to survive outside of a laboratory environment.

* Environment Considerations

The chance that active viral particles will be accidentally released into the environment is considered to be highly unlikely, as effective containment procedures will be adhered to. However, in the unlikely event that active lentiviral vector particles do accidently get released into the environment, the safety risk posed in such an event is considered to be negligible, due to the vectors being self-inactivating and non-replicative. The main potential risk in such an event would be the subsequent contamination of a human population already infected with HIV, which would potentially allow for recombination events that could incorporate the inserted sequences into a viable replication-competent lentivirus. However, this scenario is extremely unlikely and even if it was to occur, it is unlikely that it would lead to any untoward effects. As the HIV virus is a human pathogen, infection of another species would not be expected to allow any form of recombination event leading to a viable transmissible entity and so the risk from this scenario is considered to be negligible. Rodents, such as wild-type mice and rats, cannot support replication of infectious HIV-1 (Goffinet et ai, 2007 Retrovirology). As a result, the potential for shedding of replication-competent lentiviruses from such animals is very low (even if they were present in the original vector inoculum).

The vectors have been pseudotyped with the VSV-G envelope in order to increase tropism, and in theory they are capable of transducing all dividing and non-dividing mammalian cell types. As emphasized before, the vectors cannot self-propagate after infection, and successful transduction is critically dependent on the presence of high enough concentrations of virus particles. Viral vector stock solutions will be managed in a way that will prevent contaminations with relatively high viral titres. After production, the vectors are aliquoted and stored in screw capped cryovials at -80°C. Taking into account that the infectivity of the vectors rapidly decreases at room temperature, it is considered highly unlikely that the vectors could survive in the long term after being accidentally released into the environment. Lentiviral vectors have a short half-life, at room temperature due to their structural characteristics making them highly susceptible to dehydration, and relatively unstable. For this reason, retroviruses become rapidly inactivated outside host systems, as illustrated by the fact that close contact is required for transmission. They can, however, survive for long periods in high protein media.

There are no conceivable hazards associated directly with the lentiviral vectors (containing the inserts) as they will not replicate/survive outside the laboratory and they have been designed to include many protective safety features. shRNA sequences will also not survive as they are highly unstable, and they would, consequently, be rapidly inactivated/degraded if accidentally spilled into the environment. Moreover, as discussed above, there is a very low risk that the sequences contained within the viral vectors could be transferred to other organisms, as a rare recombination event would have to occur to allow this to happen.

The risk to the environment following accidental release of the immortalised human neural progenitor cells would be negligible since the cells are incapable of surviving outside of laboratory conditions. If ReNcell 197VM cells or mHTT Exon1 197VM cells were to directly inoculate animals, they would be quickly cleared by the immune system and would not produce active viruses. The likelihood of this occurring will, however, be minimised by adhering to appropriate risk management measures and ensuring that all potentially contaminated material is totally inactivated before disposal.

Summary
The chance that active viral particles will be accidentally released into the environment is considered to be highly unlikely, as the viral vector studies that will be undertaken have been classified as biosafety level 2, and effective containment procedures will be adhered to. In the unlikely event that active viral vector particles do accidentally get released into the environment, the safety risks posed by such an event is considered to be low due to the vectors being self-inactivating and non-replicative, and also due to the poor ability of the vectors to survive outside of their host systems. It is also unlikely that the immortalised human neural progenitor cells, ReNcell 197VM/mHTT Exon 197VM cells, and the transduced ReNcell 197VM/mHTT Exon 1 197VM cells will be accidentally released into the environment, as the cell handling and studies that will be undertaken have been classified as biosafety level 2, and effective containment procedures will be adhered to.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Following transduction of cell lines that are designated as requiring Biosafety Containment Level 1 with lentivirus, we wish to be able to subsequently use these cells at Biosafety Containment Level 1. This can be justified by the following procedure: under Biosafety Containment Level 2 media containing virus will be removed, the transduced cells will be extensively washed to remove any remaining virus. This liquid waste will be neutralised for at least 24 hours before disposal. The washed cells will then be cultured for a further 24 hours before being tested for the absence of infectious virus before being allowed to be treated as only requiring Biosafety Containment Level 1.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

General cleaning procedures
Surfaces will be thoroughly cleaned with Chemgene HLD4L 5%* (or an equivalent product) at the end of each experiment or after the occurrence of an accidental spillage of infectious material. Application of these validated chemical inactivators will totally inactivate any viral vectors that might be present. According to the biosafety literature, all the viruses to be used are susceptible to these disinfectants. Anything that might have potentially come into contact with the virus will be treated with Chemgene HLD4L* before being autoclaved/incinerated.

Waste Handling
Following all work requiring biosafety level 2 containment including work with lentiviruses and ReNcell VM cells, solid waste will be neutralised by soaking in a validated disinfectant solution for 24 hours, after which the material will be "double bagged", autoclaved and, ultimately, incinerated onsite. It will be routine practise that all liquid waste material be neutralised before disposal, and for the neutralised waste to be transported in leak-proof containers to prevent spillages. Liquid waste will be inactivated by Chemgene HLD4L * for 24 hours prior to drain disposal.
As any active viral particles or ReNcell VM cells on surface or in waste material will be completely inactivated at the end of each experiment by the highly effective cleaning/disinfection protocols outlined above, it is considered highly unlikely that active virus particles or ReNcell VM cells would unintentionally become discharged into a sanitary sewage system. No foreseeable adverse effects on human health and safety are expected.

* Chemgene HLD4L
Chemgene HLD4L is formulated as a micelle cleaning technology that enables the active molecules in the product to be carried rapidly through the cell walls or micro-organisms. Swift penetration of the cell walls ensures cell death is equally rapid. Chemgene HLD4L has been reported to be bactericidal, fungicidal as well as virucidal (HIV, hepatitis B, Herpex Simplex, Norovirus and Coronavirus) and sporicidal. It is recommended to be used at a 1 : 100 dilution (1 %) for general purposes, 1 : 20 dilution (5%) for high risk areas, and for disinfection of blood and bio-hazard spillages.
The proposal outlined above uses ReNcelis that have been immortalised by self-inactivating retroviral integration of vMyc. A derivative of this cell line has been generated by the random integration of genetic sequence predominantly to express mHTT Exon 1 to generate a useful tool cell line for the study of Huntington's disease. It is not known if the WHV-X protein ORF has been deleted from the WPRE element in the lentivirus used for the expression of the mHTT Exon 1. The proposal then covers the knock down of gene targets via either shRNA, CRISPR/Cas9 or ZFN that could be delivered using lentivirus. In addition certain genes or variants of genes involved in disease may be integrated into the cell genome again by lentiviral vectors. Although it is noted that no viral particles are reported to be shed from the ReNcelis due to the presence of oncogenes delivered via retroviral & lentiviral integration into the host genome the GMSC confirms that the cell lines must be maintained under biosafety containment level 2. The GMSC is satisfied that because of the pre-cautions put in place around the lentiviral vectors to be used and genetic sequences to be delivered that this level of containment is suitable for the subsequent use of the cell lines.

Please enter comments on the GM safety committee on the risk assessment

The proposal outlined above uses ReNcelis that have been immortalised by self-inactivating retroviral integration of vMyc. Project Ref 3043/16.2

Date Ackn'd 18/05/2016
CU2 Project Title Use of human induced pluripotent stem cells generated from primary human cells and integrating retroviral vectors
Class Class 2
CultureVolClass2 < 1 Litre
Consent Granted
To utilise human induced pluripotent stem cells (hiPSC) generated using retroviral reprogramming by third party organisations for target identification, target validation and compound/biologics testing to facilitate drug discovery. HiPSC generated from healthy control donors and patients with disease-relevant mutations, will be used to investigate genes and cellular mechanisms involved in the initiation and development of human disease, for example neurodegenerative disorders, such as Alzheimer's disease, Parkinson's disease, ALS, Huntington's disease. The hiPSC will be differentiated into a variety of both central nervous system (CNS) and non-CNS like mature cell types using non-genetic methodologies. These differentiated cells will be used in experiments including, but not limited to, cell-based assays, ELISA, western blotting, electrophysiology, immunocytochemistry/microscopy.

To expand understanding of the cellular mechanisms of a disease, or to use the cells for drug discovery-related work, the expression or the activity of genes of interest may be further modulated in the iPSC by several methods:

1. The utilisation of tool compounds
2. The over-expression of a protein of interest
3. The knock-down of the gene of interest by shRNA
4. The generation of modified somatic cells using programmable nucleases (CRISPR or Zinc finger nucleases)
5. The generation of reporter gene cell line (i.e. fluorescence protein or enzyme) under the promoter of the gene of interest.

HiPSC derived from primary human cells, most commonly fibroblasts. The hiPSC that will be used will have been generated using 3rd and or 4th generation self-inactivating (SIN) nonmobilisable integrating retroviral systems based on, but not limited to, mouse Maloney murine leukaemia virus (MMLV), Maloney murine sarcoma virus (MMSV), myeloproliferative sarcoma virus (MPSV), or human HIV. Some of the original donor material will not have been screened for human pathogens but donors will have a known medical history and will be classified as being low risk for retroviral pathogens. As such the hiPSC are highly unlikely to be producing replication competent lentivirus particles (RCLs).

Reprogramming of the hiPSC is achieved using a variety of factors, that are integrated into the cell genome by the retroviral vectors, that induce pluripotency in the donor cells. The following factors may be present in the supplied hiPSCs: SOX2: is a transcription factor that is essential for maintaining the pluripotency of undifferentiated embryonic stem cells.
KLF4: is a transcription factor that regulates proliferation, differentiation, apoptosis and somatic cell reprogramming. KLF4 may also act as a tumour suppressor gene.

OCT4: is a homeodomain transcription factor of the POU family. This protein is critically involved in the self-renewal of undifferentiated embryonic stem cells and is used as a marker for undifferentiated stem cells. It is indispensable for generating iPSC.

CMYC: is a transcription factor that plays a role in cell cycle progression, apoptosis and cellular transformation. Mutated c-Myc is found in many cancers, where it is constitutively expressed, leading to the unregulated expression of many genes, some of which are involved in cell proliferation leading to oncogenesis. This factor poses a risk if mobilised into RCL.

• NANOG: is a transcription factor critically involved with self-renewal of undifferentiated embryonic stem cells.
• LIN28: encodes a microRNA-binding protein; overexpression of which in mice can cause gigantism and a delay in puberty onset. Human GWAS studies indicates the LIN28B gene to be associated with human height and puberty timing. The biosafety risk is low for adults.
• GLI1: is a highly promiscuous transcription factor, positively or negatively regulating the expression of a number of genes.

Host/vector system

The vectors and factors used to generate any hiPSC that is supplied will be fully described prior to receipt and be reviewed by the Genetic Modification Safety Committee (GMSC) at Takeda Cambridge Ltd (TCB). Secondary transduction of the hiPSC with lentiviral vectors is planned. The hiPSC already contain integrated lentiviral sequences so subsequent lentiviral vectors will be non-homologous to mitigate the small risk of a recombination event leading to mobilisation of genetic material, such as the myc oncogene or immunomodulatory genes, that might pose a risk to human health. The integrated murine based lentivirus pose no additional risk to the environment. Secondary transduction would modify the hiPSCs to explore the underlying disease process or to generate tools for drug discovery. To this end the following could be used based upon the needs of drug discovery programs:

• Integration of shRNA constructs to 'knock down' expression of a gene of interest
• The over-expression of particular genes
• Specific modification of the host genome to using programmable nucleases:
  • Cas9/CRISPR
  • Zinc finger
• Reporter genes under the control of selected transcriptional regulatory sequences to study effects on cellular pathways

The lentivirus used will either be obtained commercially or generated de novo internally using third of fourth generation vector systems. The vector backbone and promoters used to drive vector generation in these systems will be consistent. Genes selected for study will not include growth factors, tropic factors, quiescence factors, confirmed oncogenes or tumour suppressors.

Vectors will be generated using a non replication-competent HIV based lentiviral system that upon integration into the host genome looses part of its long terminal repeat (LTR) preventing excision at a later time point. Such self-inactivating (SIN) vectors are designated to produce stable gene expression in target mammalian cells. The viral particles can only be generated upon co-transfecting a packaging cell line (HEK 293T) with at least four separate plasmids. Three of which provide the minimal set of genes required for viral production (gag-pol, rev and env). The env gene used expresses the vesicular stomatitis virus (VSV-G) to increase tropism. The final plasmid supplies the genetic material to be supplied to the target cell and as such contains packaging sequences directing it to be incorporated into nascent viral particles. Only the minimum amount of lentiviral genome is used in the system and all of the plasmids lack homologous sequences to minimise any chance of recombination. The resultant lentiviral
particles are VSV-G pseudotyped, SIN and replication incompetent in mammalian cells. Small aliquots of no more than 1 x 1 De8 viral particles in 5 to 10 microlitres will be used further reducing the risk.

Third Generation Systems use 4 standard bacterial plasmid vectors. Three plasmids encode for proteins required for production and packaging of full length viral RNA (pCgpV, pRSV-Rev and pCMV-VSVG). The gene of interest is contained in the pSMPUW plasmid. This is the only plasmid that contains the packaging sequence for incorporation into the virus particle.

Fourth Generation Systems use 6 standard bacterial plasmid vectors. The system uses tetracycline to control when viral particles are produced adding yet another level of control to production. pTRE-gag-pro, L TRHIV2-vpr-pol, penv(VSV-G), pTet-Off and plat-IRE-s-rev contain the sequences that code for proteins that are responsible for the tetracycline control and packaging the viral vectors. As above pSMPUW only contains the genetic material to be packaged into the vector and no other lentiviral gene sequence. An integrase deficient version of the fourth generation is available which contains a mutation in the sequence encoding the viral integrase.

Origin & function

The plasmid, pSMPUW, will contain the genetic sequence to be introduced. These will not include growth factors, tropic factors, quiescence factors, confirmed oncogenes or tumour suppressors. All proposed sequences to be used will require approval by the GMSC.

a-Vector containing shRNA - each vector will code for one shRNA transcript that will be designed to target one mRNA/protein of interest (or a scrambled shRNA in the case of negative control). This will be under the control of a polymerase II or III promoter.

b-Vector containing CRISPR or Zinc-finger nuclease - Programmable nucleases function by binding to, and cleaving, user-defined target DNA sequences. This instigates a robust DNA repair response which can either be used to disrupt the target sequence by deletion at the cleavage site or introduce user-supplied genetic material via recombination with a vector containing complementary sequences to the target gene.

For Cas9/CRISPR, nuclease target specificity is determined by a guide RNA, which consists of a short (18-20 nucleotide) sequence homologous to the target gene and an additional short sequence that forms a complex with the Cas9 enzyme. Vector will encode Cas9/CRISPR plus a guide RNA under the control of a Polymerase III promoter.

Zinc finger nuclease target specificity is dependent upon the zinc finger protein sequence which will be under the control of a polymerase II promoter.

A fluorescent protein or enzyme under the control of a polymerase II promoter or the promoter of a gene of interest may be included. Control vectors only expressing fluorescent protein/enzyme will also be used.

c-Reporter or overexpression gene vector - The vector will contain either sequence coding for a reporter protein, a protein to be overexpressed under the control of regulatory elements of a promoter of a gene of interest or a polymerase II promoter. An appropriate selection marker i.e.; neomycin could also be included to allow the selection of cells stably containing either the introduced genetic material.

The efficacy of lentiviral vectors will first be assessed using cell lines that routinely require biosafety level 1 containment (BSL 1). Application of lentiviral particles will be done at biosafety level 2 containment. At least 24 hours post transduction the cells will be washed to remove any residual viral particles and then treated as BSL 1 as the potential risk has been minimised. The efficacy of the genome manipulation will be assessed using in vitro assays.

hiPSC will be transduced with validated lentivirus. All procedures will be conducted at BSL2. Stable cell lines will be documented. Resultant cells will be studied to further understand disease processes or used for drug discovery efforts. This will be done by phenotypic analysis using a range of common in vitro assays, including but not limited to RT-PCR, Western Blotting, immunocytochemistry and imaging, cellular bioenergy or electrophysiology.
hiPSC are pluripotent and are capable of uncontrolled proliferation. Lentiviruses belong to the Retroviridae virus family which are capable of infecting both human and animal species. The lentiviral vector system that will be used is based on HIV-1. Retroviruses are generally transmitted via exposure to contaminated body fluids or percutaneous inoculation and generally not transmitted via the airborne route. Piercing of the skin represents the main potential route by which material could be accidentally introduced into an individual. Appropriate risk reduction measures will be implemented to reduce the likelihood of this occurring.

Accidental introduction of hiPSC into healthy individuals should not lead to the formation of teratomas because the immune system will rapidly destroy these cells. As mentioned above the pathogen status of some cells is not known. However the material is not derived from high-risk clinical patients and procedures are in place to deal with needle stick incidents. Individuals with compromised immune systems are not permitted to work with this material.

The genetic material to be incorporate into the viral particles is flanked by non-coding retroviral L TRs in the pSMPUW plasmid. No retroviral genes are encoded on this plasmid minimising the chance any will be packaged into viral particles. As the system requires the co-transfection of three to five additional separate plasmids into a permissive cell line the chance of recombination occurring that leads to the incorporation of any or all of the retroviral genes necessary for the production of a replication competent lentivirus (RCL) is very low and the risk is therefore is low. The lentiviral Expression System includes the following key safety features:

* Only pSMPUW includes L TR and packaging signal sequence required for incorporation into viral particles and integration into the genome of a transduced cell. A hybrid 3’LTR is used that does not affect generation of the viral genome in the producer cell line, but upon integration into the genome of a target cell, the 3’LTR SIN and prevents production of viral genomic material that can be packaged and reduces the chance of mobilisation due to secondary infection with lentivirus. No transcriptionally active L TRs are present in the system and an SV40 polyA is included after the hybrid 3’LTR to reduce the potential for transactivation of cellular genes due to an insertion event that might promote inappropriate gene expression leading to oncogenic effects.

* The LTR has been modified to enable lentiviral production independent of Tat expression. HIV-1 devoid of Tat is known to be replication incompetent. This decreases the risk of RCL occurring.

* The essential genes encoding the proteins required for packaging of the viral genome are separated onto three to five plasmids. These express the proteins (gag, pol, rev, env) required to generate viral particles transiently in the HEK-293T packaging cell line. Other retroviral structural genes are not present in the system. None of the plasmids have regions of homology which will prevent undesirable recombination. As multiple recombination events would be required to generate a RCL the risk of this happening is very low and has so far not been observed in large-scale production and testing of lentiviral vectors.

* Expression of the gag and pol genes has been rendered Rev-dependent by virtue of the HIV-1 RRE (Rev Responsive Element) in the gag/pol mRNA transcript. Expression requires the presence of rev, which is supplied by the pRSV-REV plasmid. The Rev/RRE system is highly conserved among lentiviruses and loss of the RRE sequence and associated splice donor/acceptor sequences results in a loss of transduction efficiency.

* Lentiviral vectors have a very low potential to cause immunogenicity.

* The central poly purine tract (cPPT), from the pol ORF, is included in all of the viral vectors that will be used to improve the nuclear import of the proviral DNA and hence accelerate transduction.

Whilst pseudotyped VSV-G is used as the envelop protein to increase the cell types that can be infected this increase in risk is mitigated by the SIN non-replication nature of the viral vectors generated. Insertional events that disrupt gene function can occur and in some instances might lead to undesirable effects and could be oncogenic. The resultant lentiviral vectors contain about 20% of the original HIV-1 genome. Recombination with wild-type HIV-1 is still potentially possible and would result in mobilisation of the transgene. This is highly unlikely because:

1. Wild-type HIV-1 is not used with in the laboratory environment.
2- hiPSC are not derived from donors either known to be HIV positive or from a high-risk population; so HIV contamination is highly unlikely.

3- Wild type HIV-1 cannot rescue a SIN HIV-1 based lentivirus once integrated into the host genome.

4- It is likely that any recombination would actually decrease the ability of HIV-1 to infect other cells or to replicate.

5- Even if a worker was already or became HIV-1 positive and was accidentally infected with lentiviral vector any recombination would require infection of the same cells. Generation of RCL would require homologous recombination to be in the right regions to enable mobilisation and incorporation to the HIV-1 genome without loss of replication ability. If such a rare event were to occur it is likely to be self limiting and the HIV-1 infection itself is of greater concern to the worker.

The use of lentiviral vectors is an efficient manner with which to deliver genetic material to numerous cell types. The design of the vectors minimises the chance for subsequent mobilisation of transgenes and inappropriate activation of endogenous oncogenes. Insertional events can lead to harmful side effects but are still very unlikely. As such the greatest risk from these vectors comes with their production where much larger volumes and numbers of vectors are being generated. The risk here is mitigated by the correct use of containment measures and the absence of sharps.

Lentiviral vectors are susceptible to dehydration and loss of viability if they are not stored in high protein conditions which reduces the risk to workers and the wider environment.

Transgenes to be delivered to target cells:
Additional hazards could arise from the properties of the genetic material that will be inserted into the viral vectors and expressed in transfected hiPSC cells.

Gene products to be overexpressed will not include any growth factors, confirmed oncogenes, or tumor suppressors. The focus of the research is on neurodegenerative diseases so with justification to and with GMSC approval immunomodulators or proteins known to be involved in neurodegeneration may be delivered by lentivirus. The 'knock-down' of specific gene expression using shRNA can lead to off-target and immunomodulatory responses in vivo. shRNA sequences wil be screened against databases of known mammalian/mRNA sequences during the design stage to avoid such complications. Genes encoding any growth factors, tropic factors, quiescence factors, confirmed oncogenes, or tumor suppressors will not be targeted. Control vectors containing a sequence of interest that has been scrambled (scrambled shRNA), and which is not complementary to and therefore do not target any known mammalian sequences. Such sequences are unlikely to pose any safety risks for the environment or human health.

Programmable nucleases: zinc fingers or Cas9/CRISPR will be directed against genes of therapeutic interest. Again genes that will be targeted will not include any growth, trophic factors, confirmed oncogenes, tumor suppressors or immunomodulators. In isolation, these sequences are unlikely to pose any safety risks for the environment or human health. Programmable nucleases may be used to generate isogenic controls lines by correcting disease causing mutations back to wild-type sequence. This is low risk because the sequence is aimed to revert back to non-disease forms of the gene.

Reporter genes: Commonly used fluorescent proteins or enzymes under the regulatory control of promoters of interest may be used to monitor effects on cellular pathways. Such proteins are not known to cause any human or animal disease and pose no-risk.

In all cases justification for any target must be submitted to the GMSC for approval prior to any work commencing.

Summary
hiPSC will be derived from low risk patient populations but may not be screened for human pathogens. The lentiviral systems are relocation incompetent and SIN minimising the potential for transgene mobilisation and propagation. The transgenes that can be used will on their own have a low risk to human health. Infection of mucosal cells may occur via aerosols but is highly unlikely due to the use of microbiological safety cabinets and secondary containment. Such
infection is self limiting due to the natural shedding of epithelial cells coupled with the replication incompetent nature of the vectors. The most likely route of accidental infection with a lentivirus or with the hiPSC line will be via inadvertent percutaneous inoculation via stick injury or open wound. The likelihood of this occurring will be minimised by following standard BSL2 containment practices. Infection of the community and environment with lentivirus particles is highly unlikely due to small quantities used, their intrinsic instability and rapid loss of viability with time. hiPSC can not survive outside of the laboratory environment so pose no wider risk. Therefore the risks towards workers, co-workers, the public and the environment associated with the use of these lentiviral vectors with hiPSC will be low and BSL2 containment is sufficient.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste Handling
Solid waste will be neutralised by soaking in a validated disinfectant solution (5% Chemgene HLD4L), after which the material will be autoclaved and then sent for incineration via a registered waste disposal company. All liquid waste will be inactivated for 24hrs prior to disposal to drains via a designated sink. Chemgene HLD4L: is formulated as a micelle cleaning technology that enables the active molecules in the product to be carried rapidly through the cell walls or micro-organisms. Swift penetration of the cell walls ensures cell death is equally rapid. Chemgene HLD4L has been reported to be bactericidal, fungicidal as well as virucidal (HIV, hepatitis B, Herpex Simplex, Norovirus and Coronavirus) and sporicidal. It is recommended to be used at a 1: 100 dilution (1 %) for general purposes, 1 :20 dilution (5%) for high risk areas, and for disinfection of blood and bio-hazard spillages. General cleaning procedures Surfaces will be thoroughly cleaned with Chemgene HLD4L 5%* (or an equivalent product) at the end of each experiment or after the occurrence of an accidental spillage of infectious material. Application of these anti-microbial agents will totally inactivate any viral vectors that might be present. According to the biosafety literature, all the viruses to be used are susceptible to these disinfectants. Anything that might have potentially come into contact with the virus will be treated with Chemgene HLD4L* before being autoclaved/incinerated.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
It is noted that the primary human cell lines used for the generation of hiPSes will be taken from patient populations with a known medical history meaning that there is a low risk of material containing harmful human pathogens. This does not rule out the presence of latent viral infection but the use of third or fourth generation integrating lentiviral systems that are self-inactivating and essentially non-mobilisable makes it highly unlikely that infective replication competent virus will be generated. Important due to the presence of the potentially oncogenic Mye sequence. Additional rounds of lentiviral transduction should not be able to mobilise any genetic elements because self-inactivating systems will be used that lack the necessary genes for viral replication and packaging. As an additional measure the GMSe will have a clear understanding of how each cell line was generated and steps will be taken to ensure overlapping and therefore potential sites for recombination are not present in lentiviral vectors. These vectors are for the introduction of further modifications. Those aimed at correcting disease mutations do not pose a risk to health. The introduction of non-disease causing genetic material for exogenous expression is not seen as a risk either. In the instance where immune-modulators may be targeted the risk although increased is well contained by the avoidance of sharps during transduction procedures. Once cells are transduced and virus removed the risk posed here is very low. Due to the use of iPSe derived from primary human cells and integrating lentiviral vectors this dictates propagation, differentiation and further transduction of cell lines at BSL2. Subsequent testing of the cells will also continue at BSL2 although the genetic modification of the cells is of very low risk.

**Project Ref** 3043/16.3

**Date Ackn'd** 18/05/2016

**CU2 Project Title** Use of human induced pluripotent stem cells generated from primary human cells by episomal methodologies

**Date Project Ceased** 02/12/2016

**Class** Class 2

**Culture Vol** < 1 Litre

**Non-GMM Consent** Consent Granted

**Historical Significant Changes** transferred to GM3344 02/12/2016
**Project Additional Information**

**Purposes of the contained use**

To utilise human induced pluripotent stem cells (hiPSC) generated using episomal reprogramming by third party organisations for target identification, target validation and compound/biologics testing to facilitate drug discovery. HiPSC generated from healthy control donors and patients with disease-relevant mutations, will be used to investigate genes and cellular mechanisms involved in the initiation and development of human disease, for example neurodegenerative disorders, such as Alzheimer's disease, Parkinson's disease, ALS, Huntington's disease.

The hiPSC will be differentiated into a variety of both central nervous system (CNS) and non-CNS like mature cell types using non-genetic methodologies. These differentiated cells will be used in experiments including, but not limited to, cell-based assays, ELISA, western blotting, electrophysiology, immunocytochemistry/microscopy.

To expand understanding of the cellular mechanisms of a disease, or to use the cells for drug discovery-related work, the expression or the activity of genes of interest may be further modulated in the iPSC by several methods:

1. The utilisation of tool compounds
2. The over-expression of a protein of interest
3. The knock-down of the gene of interest by shRNA
4. The generation of modified somatic cells using programmable nucleases (CRISPR or Zinc finger nucleases)
5. The generation of reporter gene cell line (i.e. fluorescence protein or enzyme) under the promoter of the gene of interest.

**Recipient or parental organism**

HiPSC derived from primary human cells, most commonly fibroblasts.

**Host/vector system**

The hiPSC will have been generated using an Epstein Barr Virus episomal system by a third party. By the time of transfer to Takeda Cambridge Ltd these vectors will have been lost and the cells deemed 'foot-print' free. The cells are also checked for absence of active expression of the genes present on the episomes. Although the gene expression profile has been altered they are essentially not genetically modified and the only risk is associated with any human pathogens present in culture. This risk is mitigated by donors having a known medical history and
belonging to low risk populations. Secondary transduction would modify the hiPSCs to explore the underlying disease process or to generate tools for drug discovery. To this end the following could be used based upon the needs of drug discovery programs:

- Integration of shRNA constructs to ‘knock down’ expression of a gene of interest
- The over-expression of particular genes
- Specific modification of the host genome to using programmable nucleases:
  - Cas9/CRISPR
  - Zinc finger
- Reporter genes under the control of selected transcriptional regulatory sequences to study effects on cellular pathways

The lentivirus used will either be obtained commercially or generated de novo internally using third of fourth generation vector systems. The vector backbone and promoters used to drive vector generation in these systems will be consistent. Genes selected for study will not include growth factors, tropic factors, quiescence factors, confirmed oncogenes or tumour suppressors.

Vectors will be generated using a non replication-competent HIV based lentiviral system that upon integration into the host genome looses part of its long terminal repeat (LTR) preventing excision at a later time point. Such selfinactivating (SIN) vectors are designated to produce stable gene expression in target mammalian cells. The viral particles can only be generated upon co-transfecting a packaging cell line (HEK 293T) with at least four separate plasmids. Three of which provide the minimal set of genes required for viral production (gag-pol, rev and env). The env gene used expresses the vesicular stamatitis virus (VSV-G) to increase tropism. The final plasmid supplies the genetic material to be supplied to the target cell and as such contains packaging sequences directing it to be incorporated into nascent viral particles. Only the minimum amount of lentiviral genome is used in the system and all of the plasmids lack homologous sequences to minimise any chance of recombination. The resultant lentiviral particles are VSV-G pseudotyped, SIN and replication incompetent in mammalian cells. Small aliquots of no more than 1x10e8 viral particles in 5 to 10 microlitres will be used further reducing the risk.

Third Generation Systems use 4 standard bacterial plasmid vectors. Three plasmids encode for proteins required for production and packaging of full length viral RNA (pCgpV, pRSV-Rev and pCMV-VSVG). The gene of interest is contained in the pSMPUW plasmid. This is the only plasmid that contains the packaging sequence for incorporation into the virus particle.

Fourth Generation Systems use 6 standard bacterial plasmid vectors. The system uses tetracycline to control when viral particles are produced adding yet another level of control to production. pTRE-gag-pro, LTRHIV2-vpr-pol, penV(VSV-G), pTet-Off and ptat-IRES-rev contain the sequences that code for proteins that are responsible for the tetracycline control and packaging the viral vectors. As above pSMPUW only contains the genetic material to be packaged into the vector and no other lentiviral gene sequence. An integrase deficient version of the fourth generation is available which contains a mutation in the sequence encoding the viral integrase.

### Origin & function

The plasmid, pSMPUW, will contain the genetic sequence to be introduced. These will not include growth factors, tropic factors, quiescence factors, confirmed oncogenes or tumour suppressors. All proposed sequences to be used will require approval by the GMSC.

a-Vector containing shRNA - each vector will code for one shRNA transcript that will be designed to target one mRNA of interest (or a scrambled shRNA in the case of negative control). This will be under the control of a polymerase II or III promoter.

b-Vector containing CRISPR or Zinc-finger nucleases - Programmable nucleases function by binding to, and cleaving, user-defined target DNA sequences. This instigates a robust DNA repair response which can either be used to disrupt
the target sequence by deletion at the cleavage site or to introduce user-supplied genetic material via recombination with a vector containing complementary sequences to the target gene.

For Cas9/CRISPR, nuclease target specificity is determined by a guide RNA, which consists of a short (18-20 nucleotide) sequence homologous to the target gene and an additional short sequence that forms a complex with the Cas9 enzyme. Vector will encode Cas9/CRISPR plus a guide RNA under the control of a Polymerase III promoter. Zinc finger nuclease target specificity is dependent upon the zinc finger protein sequence which will be under the control of a polymerase II promoter.

A fluorescent protein or enzyme under the control of a polymerase II promoter or the promoter of a gene of interest may be included. Control vectors only expressing fluorescent protein/enzyme will also be used.

c-Reporter or overexpression gene vector - The vector will contain either sequence coding for a reporter protein, a protein to be overexpressed under the control of regulatory elements of a promoter of a gene of interest or a polymerase II promoter. An appropriate selection marker Le.; neomycin could also be included to allow the selection of cells stably containing either the introduced genetic material.

The efficacy of lentiviral vectors will first be assessed using cell lines that routinely require biosafety level 1 containment (BSL 1). Application of lentiviral particles will be done at biosafety level 2 containment. At least 24 hours post transduction the cells will be washed to remove any residual viral particles and then treated as BSL 1 as the potential risk has been minimised. The efficacy of the genome manipulation will be assessed using in vitro assays.

hiPSC will be transduced with validated lentivirus. All procedures will be conducted at BSL2. Resultant cell lines will be documented. Resultant cells will be studied to further understand disease processes or used for drug discovery efforts. This will be done by phenotypic analysis using a range of common in vitro assays, including but not limited to RT-PCR, Western Blotting, immunocytochemistry and imaging, cellular bioenergy or electrophysiology. This activity is low risk but without data on the pathogen status of the hiPSC cell line all work will continue at BSL2.

**Evaluation of foreseeable effects**

hiPSC are pluripotent and are capable of uncontrolled proliferation. Lentiviruses belong to the Retroviridae virus family which are capable of infecting both human and animal species. The lentiviral vector system that will be used is based on HIV-1. Retroviruses are generally transmitted via exposure to contaminated body fluids or percutaneous inoculation and generally not transmitted via the airborne route. Piercing of the skin represents the main potential route by which material could be accidentally introduced into an individual. Appropriate risk reduction measures will be implemented to reduce the likelihood of this occurring.

Accidental introduction of hiPSC into healthy individuals should not lead to the formation of teratomas because the immune system will rapidly destroy these cells. As mentioned above the pathogen status of some cells is not known. However the material is not derived from high-risk clinical patients and procedures are in place to deal with needle stick incidents. Individuals with compromised immune systems are not permitted to work with this material.

The genetic material to be incorporated into the viral particles is flanked by non-coding retroviral L TRs in the pSMPUW plasmid. No retroviral genes are encoded on this plasmid minimising the chance any will be packaged into viral particles. As the system requires the co-transfection of three to five additional separate plasmids into a permissive cell line the chance of recombination occurring that leads to the incorporation of any or all of the retroviral genes necessary for the production of a replication competent lentivirus (RCL) is very low and the risk is therefore is low.

The lentiviral Expression System includes the following key safety features:

* Only pSMPUW includes L TR and packaging signal sequence required for incorporation into viral particles and integration into the genome of a transduced cell. A hybrid 3'L TR is used that does not affect generation of the viral genome in the producer cell line, but upon integration into the genome of a target cell, the 3'L TR SIN and prevents production of viral genomic material that can be packaged and reduces the chance of mobilisation due to secondary infection with lentivirus. No transcriptionally active L TRs are present in the system and an SV40 polyA is included after the hybrid 3'L TR to reduce the potential for transactivation of cellular genes due to an insertion event that might
promote inappropriate gene expression leading to oncogenic effects.

- The LTR has been modified to enable lentiviral production independent of Tat expression. HIV-1 devoid of Tat is known to be replication incompetent. This decreases the risk of RCL occurring.
- The essential genes encoding the proteins required for packaging of the viral genome are separated onto three to five plasmids. These express the proteins (gag, pol, rev, env) required to generate viral particles transiently in the HEK-293T packaging cell line. Other retroviral structural genes are not present in the system. None of the plasmid have regions of homology which will prevent undesirable recombination. As multiple recombination events would be required to generate a RCL the risk of this happening is very low and has so far not been observed in large-scale production and testing of lentiviral vectors.
- Expression of the gag and pol genes has been rendered Rev-dependent by virtue of the HIV-1 RRE (Rev Responsive Element) in the gag/pol mRNA transcript. Expression requires the presence of rev, which is supplied by the pRSV-REV plasmid. The Rev/RRE system is highly conserved among lentiviruses and loss of the RRE sequence and associated splice donor/acceptor sequences results in a loss of transduction efficiency.
- Lentiviral vectors have a very low potential to cause immunogenicity.
- The central poly purine tract (cPPT), from the pol ORF, is included in all of the viral vectors that will be used to improve the nuclear import of the proviral DNA and hence accelerate transduction.

Whilst pseudotyped VSV-G is used as the envelop protein to increase the cell types that can be infected this increase in risk is mitigated by the SIN non-replication nature of the viral vectors generated. Insertional events that disrupt gene function can occur and in some instances might lead to undesirable effects and could be oncogenic.

The resultant lentiviral vectors contain about 20% of the original HIV-1 genome. Recombination with wild-type HIV-1 is still potentially possible and would result in mobilisation of the transgene. This is highly unlikely because:

1- Wild-type HIV-1 is not used within the laboratory environment.
2- hiPSC are not derived from donors either known to be HIV positive or from a high-risk population; so HIV contamination is highly unlikely.
3- Wild type HIV-1 cannot rescue a SIN HIV-1 based lentivirus once integrated into the host genome.
4- It is likely that any recombination would actually decrease the ability of HIV-1 to infect other cells or to replicate.
5- Even if a worker was already or became HIV-1 positive and was accidentally infected with lentiviral vector any recombination would require infection of the same cells. Generation of RCL would require homologous recombination to be in the right regions to enable mobilisation and incorporation to the HIV-1 genome without loss of replication ability. If such a rare event were to occur it is likely to be self-limiting and the HIV-1 infection itself is of greater concern to the worker.

The use of lentiviral vectors is an efficient manner with which to deliver genetic material to numerous cell types. The design of the vectors minimises the chance for subsequent mobilisation of transgenes and inappropriate activation of endogenous oncogenes. Insertional events can lead to harmful side effects but are still very unlikely. As such the greatest risk from these vectors comes with their production where much larger volumes and numbers of vectors are being generated. The risk here is mitigated by the correct use of containment measures and the absence of sharps.

Lentiviral vectors themselves rapidly lose ability to transduce cells if not stored in high protein buffer and are susceptible to dehydration. This reduces the risk of accidental exposure to workers and the environment.

Transgenes to be delivered to target cells:

Additional hazards could arise from the properties of the genetic material that will be inserted into the viral vectors and expressed in transduced hiPSC cells.

Gene products to be overexpressed will not include any growth factors, confirmed oncogenes, or tumor suppressors. The focus of the research is on neurodegenerative diseases so with justification to and with GMSC approval immunomodulators or proteins known to be involved in neurodegeneration may be delivered by lentivirus.
The 'knock-down' of specific gene expression using shRNA can lead to off-target and immunomodulatory responses in vivo. shRNA sequences will be screened against databases of known mammalian/mRNA sequences during the design stage to avoid such complications. Genes encoding any growth factors, trophic factors, quiescence factors, confirmed oncogenes, or tumor suppressors will not be targeted. Control vectors containing a sequence of interest that has been scrambled (scrambled shRNA), and which is not complementary to and therefore do not target any known mammalian sequences. Such sequences are unlikely to pose any safety risks for the environment or human health.

Programmable nucleases: zinc fingers or Cas9/CasPR will be directed against genes of therapeutic interest. Again genes that will be targeted will not include any growth, trophic factors, confirmed oncogenes, tumor suppressors or immunomodulators. In isolation, these sequences are unlikely to pose any safety risks for the environment or human health. Programmable nucleases may be used to generate isogenic controls lines by correcting disease causing mutations back to wild-type sequence. This is low risk because the sequence is aimed to revert back to non-disease forms of the gene.

Reporter genes: Commonly used fluorescent proteins or enzymes under the regulatory control of promoters of interest may be used to monitor effects on cellular pathways. Such proteins are not known to cause any human or animal disease and pose no-risk.

In all cases justification for any target must be submitted to the GMSC for approval prior to any work commencing.

Summary
hiPSC will be derived from low risk patient populations but may not be screened for human pathogens. The cell supplied to Takeda Cambridge Ltd will be ‘foot-print’ free and can be regarded as not being genetically modified. Subsequent lentiviral vector systems are relitigation incompetent and SIN essentially preventing transgene mobilisation and propagation. The transgenes that can be used will on their own have a low risk to human health. Infection of mucosal cells may occur via aerosols but is highly unlikely due to the use of microbiological safety cabinets and secondary containment. Such infection is self limiting due to the natural shedding of epithelial cells coupled with the replication incompetent nature of the vectors. The most likely route of accidental infection with a lentivirus or with the hiPSC line will be via inadvertent percutaneous inoculation via stick injury or open wound. The likelihood of this occurring will be minimised by following standard BSL2 containment practices. Infection of the community and environment with lentivirus particles is highly unlikely due to small quantities used, their intrinsic instability and rapid loss of viability with time. hiPSC can not survive outside of the laboratory environment so pose no wider risk. Therefore the risks towards workers, co-workers, the public and the environment associated with the use of these lentiviral vectors with hiPSC will be low and BSL2 containment is sufficient.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste Handling
Solid waste will be neutralised by soaking in a validated disinfectant solution (5% Chemgene HLD4L), after which the material will be autoclaved and then sent for incineration via a registered waste disposal company. All liquid waste will be inactivated for 24hrs prior to disposal to drains via a designated sink.
Chemgene HLD4L: is formulated as a micelle cleaning technology that enables the active molecules in the product to be carried rapidly through the cell walls or micro-organisms. Swift penetration of the cell walls ensures cell...
death is equally rapid. Chemgene HLD4L has been reported to be bactericidal, fungicidal as well as virucidal (HIV, hepatitis B, Herpex Simplex, Norovirus and Coronavirus) and sporicidal. It is recommended to be used at a 1:100 dilution (1%) for general purposes, 1:20 dilution (5%) for high risk areas, and for disinfection of blood and bio-hazard spillages.

General cleaning procedures
Surfaces will be thoroughly cleaned with Chemgene HLD4L 5%* (or an equivalent product) at the end of each experiment or after the occurrence of an accidental spillage of infectious material. Application of these anti-microbial agents will totally inactivate any viral vectors that might be present. According to the biosafety literature, all the viruses to be used are susceptible to these disinfectants. Anything that might have potentially come into contact with the virus will be treated with Chemgene HLD4L * before being autoclaved/incinerated.

It is noted that the primary human cell lines used for the generation of hiPSCs will be taken from patient populations with a known medical history meaning that there is a low risk of material containing harmful human pathogens. This does not rule out the presence of latent viral infection but the use of third or fourth generation integrating lentiviral systems that are self-inactivating and essentially non-mobilisable makes it highly unlikely that infective replication competent virus will be generated. None of the facets used to generate the hiPSC will still be present in the cells. The lentiviral vectors described here pose a low risk because they non-mobilisable, self-inactivating and replication incompetent. In addition they lack the genetic elements necessary for viral replication and packaging. As an additional measure the GMSC will have a clear understanding of the proposed modifications. Vectors aimed at correcting disease mutations do not pose an additional risk to health. The introduction of non-disease causing genetic material for exogenous expression is not seen as a risk either. In the instance where immune-modulators may be targeted the risk although increased is well contained by the avoidance of sharps during transduction procedures. Once cells are transduced and virus removed the risk posed by the lentivirus is essentially removed. The main continuing risk is from the hiPSC and the potential presence of human pathogens. For this reason any propagation, differentiation, transduction and testing of cell lines will be carried out at BSL2.

Animal Units

Large Scale Activities

Human Clinical Applications
Human induced pluripotent stem cells (hiPSC), generated from healthy control and patients with disease-relevant mutations (specifically one healthy parental control & three offspring samples with varying CAG expansions within Huntington exon 1 coding sequence), will be used to investigate genes and cellular mechanisms involved in the initiation and development of neurodegenerative disorders, for example, Alzheimer's disease, Parkinson's disease, ALS, Huntington's disease etc.

To better understand these genes and cellular mechanisms, the expression or the activity of the gene of interest will be modulated by several methods:

1- The utilisation of tool compounds
2- The knock-down of the gene of interest by shRNA
3- The generation of modified somatic cells using programmable nucleases (CRISPR or Zinc finger nucleases)
4- The generation of reporter gene (Le. fluorescence protein or enzyme) under the control of a promoter of the gene of interest or an overexpressing cell line under the control of a promoter of the gene of interest or a ubiquitously expressing promoter

The experiments involving the transfection of vectors such as shRNA or programmable nucleases may be performed by lentivirus. The effect of modulating the expression or the activity of the target of interest will be determined by the expression level of the proteins, mRNA or mediators involved in the target signalling pathway.
Description of the human induced pluripotent stem (iPS) cells

The iPS cells are established by reprogramming human fibroblasts. These fibroblast cells have been derived from healthy and patient skin biopsies following informed consent.

Reprogramming of human fibroblast cells to iPS cells was performed at the Rockefeller University using a commercially available kit sold by Life Technologies, Cytotune - iPS 2.0 Sendai Reprogramming Kit. The reprogramming vectors include the four Yamanaka factors, Oct, Sox2, Klf4 & c-Myc, shown to be sufficient for efficient reprogramming (Takahashi et al, 2007). These are expressed from the following vectors, CytoTune 2.0 KOS, CytoTune 2.0 hc-Myc & CytoTune 2.0 hKlf4.

iPS cells have been tested with Applied Biosystems TaqMan iPSC Sendai Detection kit. This kit is used to detect the presence of and determine the levels of Sendai virus and exogenous transcription factors (cMyc, Oct3/4, Klf4, Sox2) delivered by the Sendai virus. No expression was detected in RNA from the reprogrammed iPS cells. This would indicate that there is no virus present in these iPS cells. Sendai virus is a negative sense single stranded RNA virus which must be converted to positive RNA (mRNA) before translation. The virus remains in the cytoplasm, does not enter the nucleus and does not go through a DNA intermediary, therefore the reprogramming should not result in a permanent genetic modification of these cells.

Fibroblast lines from donors have been provided as a basic research tool to investigate human disease. Consent to screen for major human pathogens is not sought at the time of donation. The donors are not known to be positive for any human pathogens. However, screening the cells for major human pathogens would have potentially significant clinical health implications for patients (e.g. HIV), for which explicit consent has not been given at the time of donation. As such, the cells and subsequent iPSC lines generated, have not and cannot be screened for human pathogens and must therefore be handled at Biological Safety Level 2.

B- Description of the lentivirus containing shRNA, programmable nucleases sequences or gene reporter vectors

To utilise the iPS cells to study neurodegeneration, the expression of a target of interest may be decreased in the iPSC line by the transduction of shRNA or programmable nuclease by lentivirus.

The modulation of a particular cellular pathway may be studied with the use of a reporter gene assay. In this case, the vector containing the reporter gene under the regulation of the promoter of the gene of interest may be introduced by standard transfection methods or lentivirus into the iPS cells.

This proposal may involve both the use of existing lentiviral constructs purchased commercially and the generation of new constructs on site using either a third or fourth generation system. Both commercially acquired and in-house lentivirus will use the same transfer vector plasmid. Target genes will be selected based on the needs of drug discovery projects; programmable nucleases and shRNA will not be produced against any growth factors, tropic factors, quiescence factors, confirmed oncogenes, tumour suppressors or immunomodulators (these targets will be approved internally by the GMSC).

The production of lentivirus containing the vectors of interest are described below:

1- Generation of lentivirus

Lentiviral vectors will be purchased commercially or produced in-house using either a third or fourth generation system described below. Each purified and concentrated aliquot of lentiviral reagent comprised of a small volume (5 to 100 l) that contains no more than 1x10^8 viral particles.

Vector System = self-inactivating (SIN) non replication-competent HIV based lentiviral vectors

The viral vectors that will be used in the proposed studies are self-inactivating non replication-competent HIV based lentiviral vector systems, which have been deSignated to produce stable gene expression in mammalian cells. They are generated by co-transfecting HEK 293T cells with four to six separate plasmids. Each of the plasmids used expresses a different set of genes which, when combined following co-transfection, provide the smallest possible set
of essential viral genes that is still compatible with virus production. Moreover, the vectors are all vesicular stomatitis
toxin virus (VSV-G) pseudotyped lentiviral vectors, which are self-inactivating and highly unlikely to undergo recombination.
Importantly, the viral vector is inherently incapable of replication in mammalian cells.

The plasmids

Third Generation

The sequences that will be included in the viral vectors are sub-cloned into 4 standard bacterial plasmid vectors.
Plasmids containing the packaging related sequences
Each of the three other plasmids, pCgpV, pRSV-Rev and pCMV-VSVG contain a different set of sequences that code
for proteins that are responsible for packaging the viral vectors. All the genes (gag-pol, rev and env) required for
production and packaging of the full length viable viral RNA particles have been removed from the pSMPUW lentiplasmids containing the transgenes of interest.

Fourth Generation

The sequences that will be included in the viral vectors are sub-cloned into 6 standard bacterial plasmid vectors
Plasmids containing the packaging related sequences
Each of the other plasmids, pTRE-gag-pro, LTRHIV2-vpr-pol, peny(VSV-G), pTet-Off and ptat-RES-rev contain a
different set of sequences that code for proteins that are responsible for packaging the viral vectors. All the genes
(gag-pol, rev and env) required for production and packaging of the full length viable viral RNA particles have been
removed from the pSMPUW lenti-plasmids containing the transgenes of interest. An integrase deficient version of the
fourth generation packaging mix is available which contains a mutation in the sequence encoding the viral integrase.
The resulting integrase-deficient lentivirus (IDLV) generates circular vector episomes in transduced target cells that
are gradually lost by dilution in dividing cells (transient expression), but are stable in quiescent cells.

Plasmids containing the transgene of interest
The plasmid, pSMPUW, will contain the genetic sequence that codes for either shRNA, programmable nuclease, a
reporter gene under the promoter of the gene of interest or protein of interest under the control of the regulating
elements of the promoter of the gene of interest or a ubiquitously expressing promoter.

a- Vector containing shRNA
As mentioned above, pSMPUW plasmid will contain the sequence that code for a selected shRNA transcript that will
target one mRNA/protein of interest (or a scrambled shRNA in the case of negative control). The shRNA or
scrambled shRNA sequences will be under the control of polymerase II or III promoter. The shRNA sequences will be
chosen to target a single gene. The shRNA will not be produced against any growth factors, tropic factors, quiescence
factors, confirmed oncogenes, tumor suppressors or immunomodulators.

b- Vector containing CRISPR or Zinc-finger nucleases
Programmable nucleases function by binding to, and cleaving, user-defined target DNA sequences. This in turn
instigates a robust DNA repair response which ultimately leads to disruption of the target sequence by deletion at the
cleavage site or by recombination with a user-supplied synthetic vector containing sequences complementary to the
target gene.

For Cas9/CRISPR, nuclease target specificity is determined by an accessory sequence, the guide RNA, which
consists of a short (18-20 nucleotide) sequence homologous to the target gene and an additional short sequence that
forms a complex with the Cas9 enzyme. In this case, the plasmid pSMPUW, will contain the sequences that code for
a Cas9/CRISPR plus accessory sequences comprisIng a short guide RNA that determines target specificity. The
guide RNA sequences will be under the control of a Polymerase III promoter.
In the case of Zinc finger nucleases target specificity is dependent upon the zinc finger protein sequence. The
pSMPUW will contain in that case the sequence of zinc finger nucleases under the control of a polymerase II
Programmable nucleases function by binding to, and cleaving, user-defined target DNA sequences. This in turn instigates a robust DNA repair response which ultimately leads to disruption of the target sequence by deletion at the cleavage site or by recombination with a user-supplied synthetic vector containing sequences complementary to the target gene.

For Cas9/CRISPR, nuclease target specificity is determined by an accessory sequence, the guide RNA, which consists of a short (18-20 nucleotide) sequence homologous to the target gene and an additional short sequence that forms a complex with the Cas9 enzyme. In this case, the plasmid pSMPUW, will contain the sequences that code for a Cas9/CRISPR plus accessory sequences containing a short guide RNA that determines target specificity. The guide RNA sequences will be under the control of a Polymerase III promoter.

In the case of Zinc finger nucleases target specificity is dependent upon the zinc finger protein sequence. The pSMPUW will contain in that case the sequence of zinc finger nucleases under the control of a polymerase II promoter. In addition, a fluorescent protein or enzyme under the control of a polymerase II promoter or the promoter of a gene of interest may be included. Control viral vectors that express only the fluorescent protein/enzyme and no programmable nuclease will be used in some experiments.

The Cas9/CRISPR, if introduced into any cell line by lentivirus, will use the integrase deficient version of fourth generation packaging mix.

c- Reporter gene/Overexpression vector

The pSMPUW vector will contain the sequence coding for a reporter protein (enzyme or fluorescent protein) or protein of interest under the control of the regulating elements of the promoter of the gene of interest or a ubiquitously expressing promoter. An appropriate selection marker i.e.; neomycin could also be included to allow the selection of stable human iPS cells containing the reporter gene sequence or gene of interest under the control of the promoter of the gene of interest or a polymerase II promoter. Any overexpression will not be of growth factors, tropic factors, quiescence factors, confirmed oncogenes, tumor suppressors or immunomodulators. Any protein to be overexpressed will be approved by GMSC beforehand.

**Origin & function**

Programmable nucleases function by binding to, and cleaving, user-defined target DNA sequences. This in turn instigates a robust DNA repair response which ultimately leads to disruption of the target sequence by deletion at the cleavage site or by recombination with a user-supplied synthetic vector containing sequences complementary to the target gene.

For Cas9/CRISPR, nuclease target specificity is determined by an accessory sequence, the guide RNA, which consists of a short (18-20 nucleotide) sequence homologous to the target gene and an additional short sequence that forms a complex with the Cas9 enzyme. In this case, the plasmid pSMPUW, will contain the sequences that code for a Cas9/CRISPR plus accessory sequences comprising a short guide RNA that determines target specificity. The guide RNA sequences will be under the control of a Polymerase III promoter.

In the case of Zinc finger nucleases target specificity is dependent upon the zinc finger protein sequence. The pSMPUW will contain in that case the sequence of zinc finger nucleases under the control of a polymerase II promoter. In addition, a fluorescent protein or enzyme under the control of a polymerase II promoter or the promoter of a gene of interest may be included. Control viral vectors that express only the fluorescent protein/enzyme and no programmable nuclease will be used in some experiments.

The Cas9/CRISPR, if introduced into any cell line by lentivirus, will use the integrase deficient version of fourth generation packaging mix.

c- Reporter gene/Overexpression vector

The pSMPUW vector will contain the sequence coding for a reporter protein (enzyme or fluorescent protein) or protein of interest under the control of the regulating elements of the promoter of the gene of interest or a ubiquitously expressing promoter. An appropriate selection marker i.e.; neomycin could also be included to allow the selection of stable human iPS cells containing the reporter gene sequence or gene of interest under the control of the promoter of the gene of interest or a polymerase II promoter. Any overexpression will not be of growth factors, tropic factors, quiescence factors, confirmed oncogenes, tumor suppressors or immunomodulators. Any protein to be overexpressed will be approved by GMSC beforehand.

**Evaluation of foreseeable effects**

- **Human Health**

  The human iPS cells that will be used have a low risk to human health. Samples are derived from patients that are not known to be infected but the disease status cannot be confirmed. Hence treated with caution at BSL2. The expression systems and the transgenes that comprise the lentiviral vectors that will be used have also a very low risk.
for human health and safety, and the reasons for this are discussed below.

A- Reprogrammed human iPS cells

The reprogrammed human iPS cells have been generated by reprogramming human skin fibroblasts using Sendai virus expressing a number of reprogramming factors. This Sendai reprogramming kit includes a number of safety features, as described below:

The host species for the Sendai virus (SeV) reported so far are mouse, rat, hamster and guinea pigs, all of which have been described to be serologically positive so should be non-pathogenic to humans. SeV is transmitted by aerosol and contact with respiratory secretions. The virus is highly contagious but the infection does not persist in immunocompetent animals.

Cytotune Sendai reprogramming vectors are based on a modified, non-transmissible form of SeV, which as a Fusion protein (F) deleted, rendering the virus incapable of producing infectious particles from infected cells. The presence of functional mutations such as temperature sensitivity in the amino acid sequence of several SeV proteins (SeVITS~F, SeVITS12~F, and SeVITS15~F) renders the vectors easily removable from transduced cells. As mentioned previously in the description of the human iPS cells, the RNA from one of the cell lines has been tested with Applied Biosystems TaqMan iPSC Sendai Detection kit. This kit is used to detect presence of and determine levels of Sendai virus and exogenous transcription factors (cMyc, Oct3/4, Klf4, Sox2) delivered by the Sendai virus. No expression was detected in RNA from the reprogrammed iPS cells. This would indicate that there is no virus present in these iPS cells.

The time needed to derive vector-free iPSCs may vary depending on culture and passage conditions. In the case of human neonatal foreskin fibroblast cells (strain BJ), it takes about 1-2 months after gene transduction to obtain vector free iPSCs. The iPS cells were cultured at the Rockefeller post transduction for at least 2 months prior to being received at UCL. All cells have been treated in the same manner and cultured for the same length of time post transduction so should be free of virus but RNA from the other 3 cell lines will be tested.

The major risks of this line is the unknown human pathogen status. Fibroblast lines from donors have been provided as a basic research tool to investigate human disease. Consent to screen for major human pathogens is not sought at the time of donation. Screening the cells for major human pathogens would have potentially significant clinical health implications for patients (e.g. HIV), for which explicit consent has not been given at the time of donation. As such, the cells and subsequent iPS lines generated, have not and cannot be screened for human pathogens and must therefore be handled at Biological Safety Level 2.

Due to the unknown pathogen status of the iPS cells, using lentivirus on these cells could pose a risk regarding potential recombination of lentivirus with retrovirus that could already be present within the cells. As consent has not been given to screen for human pathogens the supernatant from transduced cells cannot be tested for the presence of viral particles. Therefore iPS cells treated with lentivirus must be handled at Biological Safety Level 2. Therefore all measures will be in place to minimize the risk to human health.

B- Lentivirus containing shRNA, or programmable nucleases sequence or reporter gene/overexpression vectors

Lentiviral Vector Expression System

Lentiviruses belong to the Retroviridae virus family which are capable of infecting both human and animal species. As the lentiviral vector system that will be used in these studies is based on HIV-1, a theoretical risk to human health exists. However, retroviruses are generally transmitted via exposure to contaminated body fluids or percutaneous inoculation and generally not transmitted via the airborne route. Therefore, accidental piercing of the skin or other surface tissues with virus containing objects represents the main potential route by which accidental infection could occur. Appropriate risk reduction measures will be implemented to reduce the likelihood of this occurring.

In all of the modified pSMPUW plasmids (containing shRNA, programmable nucleases or reporter gene sequences),
the sequences inserted are flanked by non-coding retroviral L TRs, and no retroviral genes are encoded on the modified pSMPUW plasmids. Therefore, no retroviral genes will be transferred into generated viral particles. This construct is packaged into particles using a HEK293T cell based packaging system, which requires the cotransfection of these cells with three to five additional separate plasmids (as detailed above). The additional plasmids express the envelope protein from VSVg and the non-structural proteins of the virion, and, importantly, none of these genes will be transferred into the assembled viral vectors, since they lack the packaging signal (0), which is only present on the modified pSMPUW plasmids.

The lentiviral Expression System what will be used includes the following key safety features:
* All of the pSMPUW contain a hybrid 3’L TR that does not affect generation of the viral genome in the production cell line, but results in “self-inactivation” (SIN) of the vector after transduction of target cells. Once integrated into a transfected target cell, the lentiviral genome is no longer capable of producing viral genomic material that can be packaged. Moreover, presence of an SV40 polyA after the hybrid 3’L TR in the vector construct will result in a provirus which should reduce the potential for transactivation of cellular genes due to an insertion event. Furthermore, the development of self-inactivating vectors improves the biosafety of vectors, as they are less likely to be mobilised following a superinfection with wild-type virus (HIV).
* The VSV-G gene from Vesicular Stomatitis Virus is used in place of the HIV-1 or other retroviral envelope genes. Heterologous envelopes, like VSV-G, typically broaden the tropism and allow gene transfer into a broad variety of cells. The risk will mitigated by the use of self-inactivating virus and limiting the number of viral particles that will be handled at anyone time.
* Sequences encoding the proteins required for packaging of the viral genome are separated onto three to five plasmids, and all of the 4-6 plasmids used in the system have been engineered not to contain any regions of homology with each other so as to prevent undesirable recombination events that could lead to the generation of a replication-competent lentivirus (RCL), which could potentially be harmful to humans. It is important to note that no such RCL has ever been observed despite large-scale production and testing of lentiviral vectors.
* All of the pSMPUW containing plasmids/vectors will be used are devoid of all viral sequences apart from essential cis-acting sequences, including the LTRs and the packaging signal o. Although the packaging plasmids used in these systems allows for the expression in trans of protein required to produce viral progeny (e.g. gal, pol, rev, env) in the HEK293T producer cell lines, none of them contain L TRs or the 0 packaging sequence. Several of the lentiviral accessory genes (vif, vpr, vpu and nef) that are dispensable for lentiviral vector production/transduction have been deleted from the packaged construct. Therefore, none of the retrovirus structural genes will actually be present in the packaged viral genome, and they will never be expressed in the transduced target cells, which means that no new RCL can be produced.
* The lentiviral particles produced in this system are replication-incompetent, only carry the sequences of interest, and no other viral species are produced.
* Expression of the gag and pol genes from pCpgV has been rendered Rev-dependent by virtue of the HIV-1 RRE (Rev Responsive Element) in the gag/pol mRNA transcript. Addition of the RRE in these plasmids prevents gag and pol expression in the absence of rev, which is contained in the pRSV-REV plasmid only. The Rev/RRE system is highly conserved among lentiviruses, and removal of the RRE sequence and associated splice donor/acceptor sequences result in a loss of transduction efficiency.
* L TR has been modified so as to increase lentiviral vector production, and also to allow lentiviral vector production to be independent of tat expression. It is known that Tat-deleted mutants of wild-type HIV-1 are not replication competent. Therefore, the deletion of Tat should decrease the risk of generating a putative RCL.
* Lentiviral vectors have a very low potential to cause immunogenicity.
* The central poly purine tract (cPPT), from the pol ORF, is included in all of the viral vectors that will be used to
improve the nuclear import of the proviral DNA and hence accelerate transduction. While the lentiviral vectors that are produced using this system contain only about 20% of the original genome of HIV-1, there is a very small risk that subsequent infection of cells already infected with the lentiviral genome of HIV-1 could lead to a rare recombination event in which the transgene is transferred to a replication-competent virus. Thus, the sequences in the vector that will be expressed could potentially be transferred to surrounding cells. This event is, however, extremely unlikely to occur for a number of reasons:

1- The lentiviral vector is replication-incompetent and self-inactivating. In the case of a subsequent HIV-contamination, wild-type HIV-1 cannot rescue a self-inactivating HIV-1 based lentivirus once integrated into the host genome, although non-self-inactivating vectors can be.

2- In order for the spread of the gene of interest to occur following accidental infection (assuming that this has lead to viral integration), a series of unlikely events have to occur:
   a- The worker would have to become infected with HIV-1 or to be already infected with the virus.
   b- The viral and lentiviral genomes would have to integrate into the host worker's genome in the same cells and in a position where they could interact to effect homologous recombination (point 1 above)
   c- Recombination would have to occur in just the right regions to allow for transfer of the gene of interest from the lentivirus to the HIV-1 genome, which could also involve the transfer of the HIV-1 genes to the lentiviral genome. In that case, it is conceivable that a non-self-inactivating HIV could be generated that contained the gene of interest but not the rest of the genome it requires. The other gene products could be provided in trans from the lentiviral genome that may now contain the HIV-1 genes or from other HIV-1 integrants.
   d- The situation in c could conceivably lead to the production of an infectious particle containing the gene of interest, but again no genes necessary for subsequent replication. In order for another round of infection to occur, the process would have to begin again.
   e- It is conceivable the above could also happen if the iPS cells are already retrovirus positive.

In these circumstances, the effects of lentiviral infection are likely to be minor in comparison to the effects of the HIV-1 infection, which would be required to affect the spread of the gene of interest. In addition, the scenario described is essentially equivalent to the rescue of the lentiviral genome from the host, which has already been shown not to occur.

3- It is extremely unlikely that any worker would infect themselves with a significant dose of lentivirus as the volumes that are used in transfection experiments are small (aliquots contain a maximum of 10J.l1 of vector solution).

4- Moreover, insertional mutagenesis into the host genome may be considered as an oncogenic risk. We cannot rule out the possibility that, when the lentiviral genome integrates into the host genome, it will not lead to the activation of an endogeneous oncogene. However, all transcriptionally active long-terminal repeats (LTRs) have been removed as well as all promoter-like elements that required to drive expression of the transgene. This should prevent unforeseen activation of such genes. It is noted that deletion of retroviral enhancer in self-inactivating systems reduces the risk of activation but not of disruption, therefore, retroviral infection might still have permanent effects upon a cell (including oncogenic effects).

Importantly, we do not consider that the use of these lentiviral vectors will result in a significant increased risk of oncogenic activation compared to the risk possessed by any other viral delivery system. Moreover, the risk of transduction leading to tumourigenesis or other untoward harm following exposure is related in part to the titre of the viral vectors; exposure of workers to quantities of virus high enough to cause such effects would be unlikely during standard laboratory-based manipulations of lentiviral vectors.

Transgenes:
Additional hazards could arise from the properties of the genetic material that will be inserted into the viral vectors and expressed in transfected cells.
shRNA
With the use of shRNA-expressing viral vector systems, the expression of specific mammalian genes/proteins can be
knocked-down, in order to study their functions. Potential deleterious effects such as off-target and
immunomodulatory responses can be minimised through screening designed shRNA sequences against databases of
known mammalian/mRNA sequences during the design stage. The genes/proteins of interest that will be targeted by
shRNA do not and will not include any growth factors, tropic factors, quiescence factors, confirmed oncogenes, tumor
suppressors and immunomodulators. Some of the viral vectors that will be used contain a sequence of interest that
has been scrambled (scrambled shRNA), and which is not complementary to any known mammalian sequences. This
sequence will adopt a hairpin structure as with any shRNA, but it should not target any mRNA of human, mouse or rat
origin. Consequently, these sequences are unlikely to pose any safety risks for the environment or human health (this
will be approved by the GMSC).

Programmable nucleases: zinc fingers or Cas9/CRISPR
Zinc fingers or Cas9 protein will be directed against genes of therapeutic interest. Since the purpose of
programmable nucleases is to cause mutations in defined DNA sequences the primary hazard is that such a mutation
would lead to deleterious cellular effects. The genes/proteins that will be targeted do not and will not include any
growth, trophic factors, confirmed oncogenes, tumor suppressors or immunomodulators. In isolation, these sequences
are unlikely to pose any safety risks for the environment or human health.

Reporter genes: Fluorescent protein or enzymes/ Overexpression of proteins
The reporter gene could be a fluorescent protein or an enzyme, this reporter gene may be fused to a ribosomal
subunit (L 1 Oa). Fluorescent proteins, for example GFP or dsRed, are not known to cause any diseases in human or
animals and have no direct effect on cellular processes. Enzymes used frequently in reporter gene assay ie luciferase
or b-galactosidase are not known to cause any diseases in humans or animals and as no direct effect on cellular
processes. The expression of fluorescecent protein or enzymes under the control of a promoter of a gene of interest is
unlikely to pose any safety risks for the environment or human health.

Proteins of therapeutic interest will be targeted for potential overexpression. Genes/proteins that will be
overexpressed do not and will not include any growth factors, tropic factors, quiescence factors, confirmed
oncogenes, tumor suppressors or immunomodulators. Any protein to be overexpressed will be approved by GMSC
beforehand.

Summary on lentivirus

Health and Safety
Executive
The transgenes have a low safety risk to human health because accidental contamination with a vector would lead to
only a small number of cells becoming infected, and it would be highly unlikely that expression in only a few cells
could be sufficient to lead to a disease state. The inability of the lentiviral vectors to propagate on mammalian cells
also reduces the risk. The programmable nucleases (CRISPR or Zinc finger or Cre recombinase) that will be
employed in this viral vector system are not known to cause any relevant toxicity that might represent a safety risk to
human health. The fluorescent proteins or the enzymes are not known to cause any relevant toxicities that might
represent a safety risk to human health. For both programmable nucleases and shRNA, the genes/proteins of interest
that will be targeted will not include any growth factors, tropic factors, quiescence factors, confirmed oncogenes,
tumor suppressors or immunomodulators, and none of them are or will be of retroviral origin. Therefore the risk of use
will be low.

Human health hazards
Oral ingestion will be prevented by standard laboratory safety practices. Aerosol formation resulting from an accident
outside of the safety cabinet and involving lentivirus particle-containing liquid may lead to transduction of a limited
number of the laboratory worker's skin or mucosal cells with modified viruses. However, these modified virus particles carry an extremely low safety risk for human health, as they are replication-incompetent, and also because the particles carry an extremely low infection potential via the mucosal/skin routes, due to the inherent properties of the viral vectors. Moreover, the programmable nucleases and shRNA that will be expressed or targeted will not be designed to disrupt any growth factors, trophic factors, quiescence factors, confirmed oncogenes, tumour suppressors or immunomodulators. In the unlikely event of accidental transduction of a laboratory worker's skin or mucosa by lentivirus particles, this will be self-limited, due to natural shedding of superficial epithelial skin and mucosal cell layers.

The most likely route of accidental infection with a lentivirus or with the human iPS cell line will be via inadvertent percutaneous inoculation. The likelihood of this occurring will, however, be minimised by adhering to appropriate risk management measures. Infection of the community at large with lentivirus particles is highly unlikely due to the viral vector particles being replication incompetent. Infection of the community at large by human iPS cells is highly unlikely due to the impossibility of the cells to survive outside of a laboratory environment.

* Environmental Considerations

The chance that active viral particles will be accidentally released into the environment is considered to be highly unlikely, as effective containment procedures will be adhered to. However, in the unlikely event that active lentiviral vector particles do accidently get released into the environment, the safety risk posed in such an event is considered to be negligible, due to the vectors being self-inactivating and non-replicative. The main potential risk in such an event would be the subsequent contamination of a human population already infected with HIV, which would potentially allow for recombination events that could incorporate the inserted sequences into a viable replication-competent lentivirus. However, this scenario is extremely unlikely and even if it was to occur, it is unlikely that it would lead to any untoward effects. As the HIV virus is a human pathogen, infection of another species would not be expected to allow any form of recombination event leading to a viable transmissible entity and so the risk from this scenario is considered to be negligible. Rodents, such as wild-type mice and rats, cannot support replication of infectious HIV-1 (Goffinet et al, 2007 Retrovirology). As a result, the potential for shedding of replication-competent lentiviruses from such animals is very low (even if they were present in the original vector inoculum).

The vectors have been pseudotyped with the VSV-G envelope in order to increase tropism, and in theory they are capable of transducing all dividing and non-dividing mammalian cell types. As emphasized before, the vectors cannot self-propagate after infection, and successful transduction is critically dependent on the presence of high enough concentrations of virus particles. Viral vector stock solutions will be managed in a way that will prevent contaminations with relatively high viral titres. After production, the vectors are aliquoted and stored in screw capped cryovials at -aOOC. Taking into account that the infectivity of the vectors rapidly decreases at room temperature, it is considered highly unlikely that the vectors could survive in the long term after being accidentally released into the environment. Lentiviral vectors have a short half-life, at room temperature due to their structural characteristics making them highly susceptible to dehydration, and relatively unstable. For this reason, retroviruses become rapidly inactivated outside host systems, as illustrated by the fact that close contact is required for transmission. They can, however, survive for long periods in high protein media.

There are no conceivable hazards associated directly with the lentiviral vectors (containing the inserts) as they will not replicate/survive outside the laboratory and they have been designed to include many protective safety features. shRNA sequences will also not survive as they are highly unstable, and they would, consequently, be rapidly inactivated/degraded if accidentally spilled into the environment. Moreover, as discussed above, there is a very low risk that the sequences contained within the viral vectors could be transferred to other organisms, as a rare recombination event would have to occur to allow this to happen.

The risk to the environment following accidental release of the human iPS cells would be negligible since the cells are
incapable of surviving outside of laboratory conditions. Despite the cells being reprogrammed using Sendai virus they
do not produce virus and therefore would not be able to infect any rodent population. If human iPS cells were to
directly inoculate animals, they would be quickly cleared by the immune system and would not produce active viruses.
The likelihood of this occurring will, however, be minimised by adhering to appropriate risk management measures
and ensuring that all potentially contaminated material is totally inactivated before disposal.

Summary
The chance that active viral particles will be accidentally released into the environment is considered to be highly
unlikely, as the viral vector studies that will be undertaken have been classified as biosafety level 2, and effective
containment procedures will be adhered to. In the unlikely event that active viral vector particles do accidentally get
released into the environment, the safety risks posed by such an event is considered to be low due to the vectors
being self-inactivating and non-replicative, and also due to the poor ability of the vectors to survive outside of their
host systems. It is also unlikely that the human iPS cells will be accidentally released into the environment, as the cell
handling and studies that will be undertaken have been classified as biosafety level 2, and effective containment
procedures will be adhered to.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

General cleaning procedures
Surfaces will be thoroughly cleaned with Chemgene HLD4L 5%* (or an equivalent product) at the end of each
experiment or after the occurrence of an accidental spillage of infectious material. Application of these validated
chemical inactivators will totally inactivate any viral vectors that might be present. According to the biosafety literature,
all the viruses to be used are susceptible to these disinfectants. Anything that might have potentially come into contact
with the virus will be treated with Chemgene HLD4L * before being autoclaved/incinerated.

Waste Handling
Following all work requiring biosafety level 2 containment including work with lentiviruses and ReNcell VM cells, solid
waste will be neutralised by soaking in a validated disinfectant solution for 24 hours, after which the material will be
"double bagged", autoclaved and, ultimately, incinerated offsite. It will be routine practise that all liquid waste material
be neutralised before disposal, and for the neutralised waste to be transported in leak-proof containers to prevent
spillages. Liquid waste will be inactivated by Chemgene HLD4L * for 24 hours prior to drain disposal as per 430CSP
and 418CSP permit requirements.

As any active viral particles or ReNcell VM cells on surface or in waste material will be completely inactivated at the
end of each experiment by the highly effective cleaning/disinfection protocols outlined above, it is considered highly
unlikely that active virus particles or ReNcell VM cells would unintentionally become discharged into a sanitary
sewage system. No foreseeable adverse effects on human health and safety are expected.

* Chemgene HLD4L
Chemgene HLD4L is formulated as a micelle cleaning technology that enables the active molecules in the product to
be carried rapidly through the cell walls or micro-organisms. Swift penetration of the cell walls ensures cell death is
equally rapid. Chemgene HLD4L has been reported to be bactericidal, fungicidal as well as virucidal (HIV, hepatitis B,
Herpex Simplex, Norovirus and Coronavirus) and sporicidal. It is recommended to be used at a 1: 1 00 dilution (1 %) for
general purposes, 1 :20 dilution (5%) for high risk areas, and for disinfection of blood and bio-hazard spillages.
The GMSC has reviewed the current risk assessment and agrees with the class 2 categorisation for this work. It is noted that although the hiPSC were generated using Sendai virus that needs to be handled at BSL2 the actual cells that will be provided to TCB will be free of Sendai virus and will have lost all detectable levels of plasmid. The main risk from the hiPSCs is their unknown pathogen status but this is mitigated because all donors are of low risk clinical populations. The lentiviral systems that will be subsequently used are inherently designed to prevent inappropriate recombination and subsequent mobilisation of transgenes into replication competent viral particles. Third and fourth generation systems deliver replication incompetent, self-inactivating viral particles that lack even the minimum set of genes required for virus production. The cells themselves cannot survive outside of a lab environment and the lentiviral particles loss viability rapidly if not stored properly being susceptible to desiccation. Risk associated with these activities to humans and the environment is deemed low. The use of biosafety level 2 containment is appropriate and sufficient because of the use of lentiviral elements and the unknown pathogen status of the cells.

Project Additional Information

Purposes of the contained use

1. Measure the concentration of specific materials in samples.
2. Use extracted RNA for cDNA synthesis for expression profiling of human genes.
3. To transiently generate proteins incorporating an antibody detectable tag to confirm protein expression.

Recipient or parental organism

Adenovirus - recipient - mammalian cells grown in culture.

Host/vector system

Adenovirus
- attenuated (non-replicative) adenovirus particles supplied as a suspension
- no production of virus to be carried out

Origin & function

Adenovirus
- Originator: Invitrogen Corporation
- the virus suspension is supplied frozen by the above company
- an aliquot of supernatant is added to cultured mammalian cells and allowed to infect them
- the virus encodes a mutated tRNA that permits read through of the TAG stop codon in the gene sequence
- mRNA encoding a TAG stop codon is read through and the subsequent nucleotide sequence used to add additional amino acids to the protein being synthesised
- in recombinant cells the cDNA encoding the gene of interest contains a TAG stop codon followed by gene sequence encoding a number of amino acids that when synthesised generate an epitope that can be recognised by an antibody
- the addition of the epitope will allow confirmation of protein expression of the gene of interest in the recombinant cell line

Evaluation of foreseeable effects

The adenovirus particles can infect human cells. In the unlikely event of a user being infected the following effects are likely to happen:
1. Viral particles will infect cells
2. The tRNA will be expressed
3. There will be read through of any mRNA which has a TAG stop codon
4. It is estimated that this will be about 33% of all transcribed genes in each cell infected
5. The adenovirus does not replicate in the human cells so any effect will be transient, a maximum of 8 days
6. The resultant change in the proteins is most likely to be toxic to the cells
7. This may result in cell death of those cells infected
8. As a result of cell death in the local area of administration and an inflammatory immune response will be elicited
9. It is not anticipated that there will be any long term effects due to the attenuated nature of the adenovirus

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

ELISA and human tissue
- human sample material and plastics contaminated with material to be treated with strong disinfectant
- human samples processed for RNA will be effectively neutralised in the extraction process
- all disinfected material will then be incinerated
- for spills, solid materials will be collected and put in a container with disinfectant, liquid spills will be treated with disinfectant and then absorbed with paper towels, the area will then be further cleaned with 1% virkon solution. All collected materials will be incinerated.

Adenovirus
- all contaminated materials and plastics to be treated with strong disinfectant
- all disinfected material will then be incinerated
- for spills, solid materials will be collected and put in a container with disinfectant, liquid spills will be treated with disinfectant and then absorbed with paper towels, the area will then be further cleaned with 1% virkon solution. All collected materials will be incinerated

Please enter comments on the GM safety committee on the risk assessment

Paradigm Therapeutics Ltd has been working under license GM 860 with fully verified commercial sources of host strains and vectors at hazard level 1 and containment 1. Due to forseen expansion of experimentation, the GMSC has identified that Paradigm Therapeutics Ltd applies that the license be modified to include hazard level 2 and containment 1. All ELISA materials will be sourced commercially and have undergone routine screenings for infectious agents. The adenovirus materials will be sourced commercially from a reputable company and human tissue samples if used will be stored in appropriate containers at low temperature prior to extraction in chaotropic salts and then phenol/chloroform, which will effectively neutralise any biological hazard. The GMSC feels that these measures detailed above reduce the risk significantly.

Give brief details of the genetic modification safety committee

Our GM committee comprises of the company's CEO, one of the senior scientists and an external consultant. The committee meets twice a year to discuss safety measures in place in the laboratory and approve Genetic Modification Risk Assessments. When scientists plan to use a new genetically modified organism, the consultant advises on safety procedures.

The CEO and senior scientist make sure the suggested safety measures are incorporated into SOPs and are being followed.

Contaminated sharps are collected in closed sharp bins, tagged and are removed by clinical waste contractors for incineration.

Culture flasks, tubes and other lab consumables used in experiments are collected in a closed bin and once this is filled, are autoclaved at 134 deg C for 15 minutes for de-contamination. Then it is disposed with clinical waste for incineration.

Liquid waste (culture media etc.) in disinfected and de-contaminated using 1% solution of Virkon following manufacturers instructions. Then it is poured down the sink and flushed with copious amounts of water.

The autoclave used for de-contamination is serviced twice a year.
Comments form the GM Committee meeting on 18th March 2009.
GM Committee considered the risk assessment and approved category 1 work involving GM organisms on Plasticell premises. The following changes were suggested and carried out for the GM risk assessment forms.
HSE notification Form should include broader description of work conducted in the lab.
GM Form Part 1:
1.21. It should be prefaced with "The following cell lines will be obtained and grown".
Because GM cell lines are already constructed elsewhere, there is nothing in this RA about hosts/vectors for their construction, and so a possible comment would be as follows:
"This work involves the maintenance and growth of existing, stable GM cell lines. These are not infected with any adventitious agent, nor are they secreting the vector used for their construction. As they pose negligible risk to either workers or the environment, they are correctly classified as Class 1."
GM Part 3:
3.1.1 Disinfectants are not considered to give "100% kill rate" (only autoclaving or incineration are considered to do this). This phrase should be modified to ">10e5 kill rate".

Project Ref 3044/14.1

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

Project Additional Information

Purposes of the contained use

1. We want to validate selected targets from our small molecule screening campaigns through shRNA delivered by lentiviral particles. 2. We want to generate reporter cell lines to screen for small molecules activating the expression of this gene.
Recipient or parental organism

1. Recipient cells will be human embrionic stem cells or other types of stem cells and progenitor cells. After lentiviral transduction, the expression of one of their genes will be downregulated. Recipients cells will be characterised by qPCR and Western Blotting to assess the function of the lentiviral constructs. Cells transduced with lentiviral particles will be kept in a dedicated incubator. After processing the samples they will be conveniently inactivated and discarded. 2. Same as in 1 but upon differentiation of the stem cell in muscle they will express GFP.

Host/vector system

1. Self-inactivating replication incompetent lentivirus based on pLKO backbone and purchased from established vendors like Sigma-Aldrich. These vectors carry an shRNA used to knock-down the expression of a particular gene. 2. Self-inactivating replication incompetent lentivirus based purchased from Applied Biological Materials

Origin & function

1. shRNAs inserted in Lentiviral vector (PLKO1 backbone) with the intended function of downregulating specifically one gene. 2. Human PAX7 promoter sequence followed by GFP sDNA

Evaluation of foreseeable effects

1. The cell lines transduced with the lentiviral particles will show downregulation of a specific gene. 2. The cell lines transduced with the Pax7 reporter gene will not show any new phenotype unless PAX7 expression is stimulated by induced differentiation into muscle; in that case they will express GFP

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Disposable material exposed to lentiviral particles will be inactivated with virkon, disposed in appropriate plastic bags and autoclaved. All surfaces of the cell culture hood will be cleaned and sterilized with 70% ethanol

Yes

Give brief details of the genetic modification safety committee

Valneva SE is a European company registered in France and with operations in France, Austria, Sweden and Scotland with a corporate biological safety committee which is composed of competent members of staff with experience in aspects of biological safety from each operational site. The committee meets to review ongoing and new aspects of the companies biological safety interests in research, development and manufacturing operations. The Biological Safety committee chairperson is the EOHS Manager from the Biological production site in Livingston Scotland (Japanese Encephalitis Virus vaccine IXIARO manufacturing site). A broad range of experience of aspects of biological safety and contained use is held on site and across the organisation where commercially manufactured and CTM development products are manufactured (CAT 21 BSL2) including Japanese Encephalitis virus, Polio virus, Zika virus, recombinant Newcastle disease virus. Valneva has experience of determination and assessment of biological safety of other recombinant virus constructs and submissions to regulatory authorities. Biological safety assessment and completion of BioCOSHH and Biological Risk Assessments for viral inactive and active viral vaccine products is carried out at Valneva Scotland Ltd.

02/03/2022
Waste Control measures are in place as part of VSL procedures and as described in controlling documentation;
- LlV-SOP-0333 Waste Disposal and Spills Procedure
- Prevention of Breach of Containment of Pathogens
A range of validated disinfection agents are used to clean laboratory surfaces and equipment.
Liquid Waste from all clean rooms is disposed of via a secure drainage system. All drains feed the contained waste holding tank within the VSL facility and independent drain pipework with non-return valves are in place from the CTM facility to prevent cross contamination.
Waste is held in a 2000 L holding tank. When the level in this tank reaches 900 L, the system automatically transfers 700 L of waste to a 1000 L killing tank. Using a heated steam supply, the system heats the kill tanks to 121.50°C for 20 minutes. Using chilled water the system then cools the kill tank to 40°C. All contents are then automatically put to drain.
Solid biological waste is held on site in Yellow lidded and locked hazardous clinical waste bins provided by the licenced waste contractor. Waste bins are uplifted by the licenced waste contractor and transferred to the licenced waste contractor disposal site for incineration.
Autoclave for viral kill is available on site
In general terms measures in place to prevent a breach of containment are described specifically in all controlling documentation and SOP’s. Training in all aspects of the SOP’s is carried out and documented ensuring all requirements for control and containment are understood. Further control and prevention measures for the facility and equipment are described in the following controlling documentation;
- LlV-SOP-0333 Waste Control and Spills Procedure
- LlV-SOP-0008 Planned Preventative Maintenance
- LlV-SOP-1024 Calibration of Equipment
- LlV-SOP-0018 Plant and Equipment Monitoring Checks and Routine Inspection
- LlV-SOP-0010 Maintenance Policy
- LlV-SOP-0116 and 0060 Operation of Decontamination Autoclave
[ ] LlV-SOP-0022 Parameter Configuration of the FMS and Critical Process Parameter Recording Systems
[ ] LlV-SOP-0585 Receipt and handling of CAT 2 material in OB1 QC suite

For activities involving GMMs, describe the waste management measures which will apply to the activity

### Project Additional Information

**Purposes of the contained use**

Preparation of Clinical Trial Manufacturing lots in a CTM licensed facility for GMP manufacture at a process scale of 66 x 850cm² roller bottles producing approximately 11.5L viral harvest volume with associated downstream viral purification processing producing a Bulk Drug product of -1.1 L and required microbiological and analytical method Quality Control lot release testing.

**Recipient or parental organism**

Chickungunya wild type strain LR2006-0PY1 CHIKV

**Host/vector system**

02/03/2022
ChikV ~5nsP3 attenuated live ChikV GMO was derived from wild type strain LR2006-0PY1 CHIKV infectious clone attenuated by deleting amino acid (aa) in the hypervariable region of the nsP3 protein, residues 1656 to 1717 of the P1234 polyprotein which were substituted with a linker (aa sequence AYRAAAG).

Full detail of the attenuation process is described in the attached ChikV BioCOSHH assessment and summarised below;

**Origin & function**

Attenuated Chikungunya virus strain "~5nsP3" was obtained on Licence from the group of Peter Liljestrom at the Karolinska Institutet in Stockholm, Sweden.

Based on the virus sequence a full-length synthetic genome was produced by GeneArtTM Gene Synthesis. The virus was adapted to Vero cells by serial passaging.

A full description of the cloning strategy and the plasmid construct used to generate virus seed banks is given in the extract from the IND submission; section 3.2.S.2.3.2.2 (Attachment 1)

Successful assembly of the ChikV ~5nsP3 genome was verified by sequencing and is described in the following document;

Investigational Medicinal Product Dossier (IMPD) Chikungunya vaccine VLA1553 Verification of ChikV ~5nsP3 Sequence (Attachment 1)

Using attenuated Chikungunya virus strain "~5nsP3 " to generate ChikV live vaccine candidate for clinical evaluation. Preparation of Clinical Trial Manufacturing lots in a CTM licensed facility for GMP manufacture at a process scale of 66 x 850cm2 roller bottles producing approximately 11.5L viral harvest volume with associated downstream viral purification processing producing a Bulk Drug product of ~1.1 L and required microbiological and analytical method Quality Control lot release testing.

**Evaluation of foreseeable effects**

A full assessment of risk was carried out and documented as a BioCOSHH assessment, Attachment 2 and are summarised below;

Attenuated ChikV ~5nsP3 GMO Virus will be held at VSL as a Working Viral Seed Bank (WVSB) and used to produce GMP CTM manufacturing and development batches of vaccine. All manipulations of ChikV virus are completed within a BSL2 laboratory facility. All work is completed and controlled using standard operating procedures (SOP's) with training completed and documented for all staff. An EOHS risk assessment has been completed and protective measures and equipment have been identified, implemented with training to be carried out and documented prior to the ChikV virus being brought on site. There is no hazard or risk of infection identified following exposure to the ChikV ~5nsP3 GMO virus. However transmission by direct blood contact could act as a mode of transmission of the attenuated non-infectious strain.

The hazard and risk to the individual as an outcome of the potential mode of transmission of blood transfer is considered to be effectively zero with control measures applied offering full protection to all personnel.

This is further documented in the Environmental I occupational health and safety risk assessment to be prepared prior to the attenuated ChikV ~5nsP3 GMO being brought on site. The likelihood of any residual risk being realised is unlikely and the risk rating is identified as Effectively Zero.

The manufacturing process for Attenuated ChikV ~5nsP3 GMO viral vaccine operates within a GMP manufacturing clean room rated at BSL2 and is operated as a sterile process in closed vessels e.g. Roller Bottle cell culture and viral infection. All manual operations where live virus is manipulated in open vessels are carried out in Class II microbiological safety cabinets within the ISO 7 Classified Manufacturing Clean Rooms. Small volumes (~3mL) of live virus are sampled and used for analysis in a range of assays including; SOS PAGE analysis and safety testing.
aerosols are generated with the possible exception of a single manufacturing process step (Virus concentration using Tangential Flow Filtration) which is completed in a fully closed disposable system made of Plastics with no aerosol release into the atmosphere.

Valneva Scotland Ltd has a GMP licenced (MHRA) manufacturing facility for CTM batch manufacture and implements full control of all aspects of the manufacturing process with the live ChikV virus, implementing strict procedural, access and management control, as per the requirement of BSL2 operations including; storage and release of the virus WVSB, handling and transport of live virus samples, inactivation and control of biological waste removed from site. All testing of viral product will be outsourced to Valneva Austria or an external Contract Services Organisation (CSO).

All liquid biological waste containing attenuated ChikV ~5nsP3 GMO are treated in a steam pressurised Kill tank prior to disposal as per SEPA licence I permit.

All operational activities are controlled with Standard Operating Procedures.

Training in all aspects of the manufacturing process requirements is detailed in the controlling documentation (SOP's) with training carried out and documented in individuals training record.

All virus disinfection agents will be assessed to ensure the effectiveness of the viral kill.

VSL holds a Scottish Environment Protection Agency (SEPA) permit which documents and controls all aspects of waste disposal. SEPA conducts an annual inspection of the VSL facility and an annual report documenting waste generated including both liquid and solid biological waste is submitted.

Procedures are in place to prevent potential contact of staff operating in the ChikV manufacturing clean rooms with other members of staff during emergency procedures and evacuation of the CTM manufacturing facility. Further details of control measures are included into an Occupational Risk Assessment for ChikV operations; OHSE/001/18-01

Live WVSB is stored as frozen aliquots in a locked freezer with controlled access and requiring documented approval to release material for manufacturing and process development use.

All areas of the manufacturing and testing facility have controlled restricted access with documented training requirements and approval for access to areas required.

Based on the evaluation of risk presented in the BioCOSHH assessment the risk to the individual and the environment with all control measures in place has been determined as effectively zero.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not Applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Schedule 8 Part 2, Table 1 a, 17;

'Inactivation of GMM's in contaminated material and waste'.

Kill tank as described in section 6,

Liquid Waste from all clean rooms is disposed of via a secure drainage system. All drains feed the contained waste holding tank within the VSL facility and independent drain pipework with non-return valves are in place from the CTM facility to prevent cross contamination.

Waste is held in a 2000 L holding tank. When the level in this tank reaches 900 L, the system automatically transfer 700 L of waste to a 1000 L killing tank. Using a heated steam supply, the system heats the kill tanks to 121.50 C for 20 minutes. Using chilled water the system then cools the kill tank to 40°C. All contents are then automatically put to drain.

This is a generic method for waste disposal and not a validated method for biological pathogen 'Kill'. However for each individual pathogen the method is assessed in a Biological COSHH Risk Assessment and a justification for use is
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste Control measures are in place as part of VSL procedures and as described in controlling documentation;
LIV-SOP-0333 Waste Disposal and Spills Procedure
Prevention of Breach of Containment of Pathogens
A range of disinfection agents are used to clean laboratory surfaces and equipment including 70% Iso Propyl Alcohol (IPA) and sodium hypochlorite which have been shown to inactivate Chikungunya virus (American Association of Blood Banks FEB 2014 update to Transfusion 2009;49 (Suppl):59-61 S and Infectious Disease and Microbial Agents: Chikungunya Virus; Chandrakant Lahariya MD).

Liquid Waste from all clean rooms is disposed of via a secure drainage system. All drains feed the contained waste holding tank within the VSL facility and independent drain pipework with non-return valves are in place from the CTM facility to prevent cross contamination.

Waste is held in a 2000 L holding tank. When the level in this tank reaches 900 L, the system automatically transfer 700 L of waste to a 1000 L killing tank. Using a heated steam supply, the system heats the kill tanks to 121.50°C for 20 minutes. Using chilled water the system then cools the kill tank to 40°C. All contents are then automatically put to drain.

Complete inactivation of ChikV on incubation at a temperature of 60 degrees C for 90 minutes (2015 Science Writers Symposium Developing Tools to Keep Dengue and Chikungunya Out of Our Blood Supply; Maria Rios, Ph.D. Principal Investigator FDA Center for Biologics Evaluation and Research September 18, 2015)

Solid biological waste is held on site in Yellow lidded and locked hazardous clinical waste bins provided by the licenced waste contractor. Waste bins are uplifted by the licenced waste contractor and transferred to the licenced waste contractor disposal site for incineration. . .

Autoclave for viral kill is available on site

In general terms measures in place to prevent a breach of containment are described specifically in all controlling documentation and SOP's. Training in all aspects of the SOP's is carried out and documented ensuring all requirements for control and containment are understood. - Transgenic Fish: 
- Gene Therapy: 

02/03/2022
Autoclaving of solid and liquid waste to >121°C for 60 minutes. Temperature probe is used to monitor temperature of waste material to ensure that all areas of the material being autoclaved reach 121°C.

Used bacteria media and mammalian tissue culture media is treated with 1% Virkon overnight or Sodium hypochlorite (Chloros) at:
- 1,000 ppm for general wiping of equipment and benches
- 2,500 ppm for discard containers (if required)
- 10,000 ppm for spillages
- 20,000 ppm for work surfaces, including microbiological safety cabinets

Please enter comments of the GM safety committee on the risk assessment

The Genetic Modification Safety Committee agrees that the assessment for notifiable activity is accurate, the containment facilities are appropriate and recommends the committee and HSE be notified appropriately if Class 2 or Class 3 activity is to be carried out subsequently.

This risk assessment should be kept under review and the Biological and Genetic Modification Safety Committee should be informed if there are any significant changes in procedures, personnel or location that might affect risk of harm to humans or the environment.
This application was not progressed and the fee was refunded

Give brief details of the genetic modification safety committee

Y
A GM Safety Committee has been established and held its first meeting in January 2009. Its composition includes the University Biological Safety Officer, 2 senior scientists and 3 academic clinicians with a research or clinical interest in gene therapy, the chair UCL/UCLH research safety subcommittee, the Divisional Manager Joint UCLH/UCL biomedical research unit, a microbiologist/infectious disease clinician with experience on GM safety committees, the infection control nurse consultant and relevant pharmacy representatives will be co-opted where appropriate. The GMSC has direct accountability and reports to the joint UCL, UCLH, RFH research governance committee (cross representation by GMSC chair and 2 other GMSC members). There is also cross representation from Research Safety Sub-Committee (Chair of RSSC on GMSC). The joint unit research governance committee (cross representation by GMSC Chair and 2 other GMSC members) There is also cross representation from research safety sub-committee (Chair of RSSC on GMSC). The joint unit research governance committee will report to UCL Faculty of Faculty of Biomedical Sciences and UCLH and RFH Trust Boards via the appropriate routes within those trusts.

Remit of the Committee:
Risk Assessment (RA) of planned clinical trials involving GMO/GMMs involving UCLH, RFH and QS.
RA of planned clinical trials involving GMOs where UCL is acting as sponsor.
Provision of safety advice and recommendations specific for individual clinical trails to UCL (UCL & UCLH research governance and research safety sub-committees) and involved trusts.
Notification of high-risk trails to the HSE where indicated.
More general provision of advice.
To support/provide education to clinical staff participating in running clinical trails involving GMOs.
Generation of SOP templates.
The GMSC will meet on an ad-hoc basis and will provide a Risk Assessment for a Clinical trial involving GMMs within 28 days of its submission for consideration.

For activities involving GMMs, describe the waste management measures which will apply to the activity:

For clinical trials involving the administration of replication incompetent viral and non-viral vectors (i.e., Class 1 activities) usual existing hospital waste management procedures will be used. Contaminated material such as swabs and dressings will be placed in the yellow bag waste stream. Contaminated sharps such as needles, syringes and glass vials should be placed into sharps bins and disposed of as normal.

In the event of spillage or contamination of clinical equipment/clothes, soaking in an effective disinfectant such as virkon 1% and/or autoclaving before washing is sufficient.

Clinical staff taking blood or tissue samples from treated patients are trained to avoid exposing themselves or others to blood-borne pathogens and in the prevention and in the prevention of needle stick injuries. In the event of a needlestick injury, normal procedures should be undertaken as stipulated by the UCLH Department of Occupational Health.

Please enter comments of the GM safety committee on the risk assessment:

WT1 TCR Gene Therapy for Leukaemia: A Phase I/II Safety and Toxicity Study (WT1 TCR-001):
[Trial ID: EudraCT 2006-004950-25; MHRA CTA 20363/0253/001-0001; GTAC 128; UKCRN 5099; UCL Sponsor ID 06/154]

Summary of GMSC comments on the Risk Assessment:
The clinical trial is correctly classified as a Class 1 project and falls under the Contained Use regulations. The precautions stated in the risk assessment are commensurate with the (low) risk of the work. Transportation and spillage issues are well covered as is the risk to trial workers.

Give brief details of the genetic modification safety committee

Y
The KRL General Manager is ultimately accountable for the safety performance of KRL. The Operations Manager is responsible for ensuring safety of operations on a daily basis. The Genetic Modification Safety Committee (GMSC) provides advice to the Operations Manager for practical implementation of GM related safety, as outlined below:

- Advise on and review in detail new and amended activities involving the use of GMM
- Advise on the risk assessment and any updates to the risk assessment have been completed in accordance with the Genetically Modified Organism (Contained Use) Regulations 2000 and Advisory Committee on Genetic Modification Compendium of Guidance (ACGM)
- Advise on the bio-safety training requirements needed for personnel expected to carry out work with genetically modified micro-organisms

Composition
During the project phase, the GMSC comprises the following members:

- Biobutanol OSBL Project Manager (Chairperson)
- BP Hull Site Occupational (Health & Hygiene) Advisor
- Biobutanol Demonstration Plant Biological Safety Officer
- Biobutanol Demonstration Plant Operations Representative
- HRTC Safety Manager
- Representative of DuPont SHE Department
- BP Biofuels Technology Representative
- DuPont Technology Representative

In order for a meeting to be considered quorate, 5 of the 8 members must be present. It is the responsibility of the Chair to ensure that the attendees provide adequate expertise to make justifiable decisions and recommendations. This team will be supported by a number of consultants who can be called on to give advice as required.

Upon moving into the operations of the Biobutanol Demonstration unit and introducing GMM to the site, the GMSC composition will be revised as follows:

- KRL Operations Manager (Chairperson)
- KRL Biological Safety Officer
- BPCL HRTC HSSE Manager
- DuPont Technology Representative
- KRL Operations Team Representative
- BP Biofuels Technology Representative
- BPCL Hull Site Occupational (Health & Hygiene) Advisor

In order for a meeting to be considered quorate, 4 of the 7 members must be present. It is the responsibility of the Chair to ensure that the attendees provide adequate expertise to make justifiable decisions and recommendations. This team will be supported by a number of consultants who can be called on to give advice as required.

Meetings of the GMSC
The committee will meet on an ad hoc basis to discuss proposed modifications to the genetically modified micro-organism or the Standard operating procedures. However, scheduled meetings will be planned at least twice a year in order to review operations, near miss reports and incident reports. Dates of these meetings will be fixed in advance.

Notice of the meetings will normally be circulated one week in advance and accompanied by a meeting agenda, minutes of the last meeting and papers for discussion. The Minutes of the Committee must be issued within two weeks of the date of the meeting and will be distributed to all committee members and invited attendees. A copy will be placed in reading file stored in the facility safety corner.
Depending on the type of waste (disposables, liquids, residual GMMs on equipment, off-gas), one of the following management measures will be used for inactivation and/or removal of viable GMMs: chemical inactivation, physical inactivation by heat (off-site incineration, autoclave, steam, fermentor heaters or the process GMM inactivation system) or filtration. Any off-site disposal will be carried out using licensed waste handling contractors and registered waste disposal sites appropriate for the waste type.

The largest volumes of liquids containing GMMs will be handled via the process GMM inactivation system that consists of two heat exchangers and residence time piping to ensure GMM inactivation. Viable GMM-containing process streams from the fermenters will be pumped through an exchanger where the temperature of the process fluid is raised. Both flow rate (residence time) and temperature can be adjusted based on proven inactivation time/temperature profiles.

Each inactivation method is expected to result in a minimum log 5 reduction of GMM viability. For each inactivation method, control of the relevant parameters (such as temperature, concentration, expiry date, treatment duration) is foreseen.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment
The GMSC reviewed the risk assessment for the activity entitled “Bio-butanol Demonstration Plant” during its meeting of 9th June 2009.

Given the description of the GMMs and the activity, the GMSC agreed that the proposed containment measures are adequate. The GMSC acknowledges that in some cases the measures that will be implemented exceed the safety requirements as they are inspired by other aspects such as quality of product.

Any modifications to the process will be subject to Management of Change (MoC) which will highlight the requirement to consider whether the GMM risk assessment should be reviewed as part of any process-related modification.

Finally, the GMSC stressed that the reviewed risk assessment is accepted in connection with the specific organisms specified therein. If a new GMM is to be introduced to the process or the existing GMM further modified, then the MoC process will also highlight the requirement to review the risk assessment and amend as required to suit the specifics of the new/modified organism.

Give brief details of the genetic modification safety committee

The project has been considered by GM Safety Committee has agreed with the classification of GM1 and risk assessment for notification to the HSE.
The committee comprises the Microbiology Unit Manager, Marine Scientist, Senior Marine Chemist, Ecotoxicologist, Health and Safety Unit, Emergency Planning Advisor, Head of Marine Science and the Head of Chemistry.

OPERATING PROCEEDURES AND FREQUENCY OF MEETINGS:-
1. Chair invites members to a 6 monthly meeting to discuss H&S matters and to review either new, or current risk assessments.
2. Risk Assessments are circulated prior to the meeting.
3. During the meetings the relevant risk assessments will be discussed and any amendments required will be made by the assessment originator.
4. The amended risk assessment will then be circulated to all staff in the GMSC for further comments/suggestions.
5. Finalised risk assessments are passed to the Head of Health and Safety for approval.

The GMM proposed for use in this study is a modified strain of Saccharomyces cerevisiae (FF18984). ACDP Classification - Class 1: Gentronix Greenscreen EM™

The Ecotoxicology laboratory is a UKAS accredited facility, where the Class 1 GMM will be handled in accordance to the Standardised Working Procedure and GLP in Class 1 + containment level.

* All Solid and liquid waste is sealed in biohazard bags containing an absorbent material and inactivated in an autoclave at 134º C for 34 minutes. Inactivated waste is disposed of accordingly to local Microbiological rules with final disposal as either general laboratory waste or hazardous waste as identified appropriate.

* Contaminated glassware will be decontaminated in a final volume of 1% (w/v) Virkon solution for 24 hours prior to going through an automated glasswash cycle, followed by autoclaving as required.

* Work areas/hard surfaces will be disinfected after use using 70% Ethanol solution/Aquet 1% Solution.

---

**For activities involving GMMs, describe the waste management measures which will apply to the activity**

02/03/2022
* Hands and wrists of laboratory staff will always be washed prior to leaving the GMM area (CTR1). Furthermore, following contamination with viable yeast cells, hands and wrists will be washed immediately.

Spillage Containment -

* Liquid spills of class 1 GMMs on the bench or floor will be contained with absorbent paper tissue. The area would then be decontaminated with 1% (w/v) Virkon. Contaminated absorbent material will be put into specified biohazard waste bag/container which will be sent for autoclaving at a cycle of 134°C/34min prior to final disposal. Liquid spills will be recorded and reported to the line manager and Health and Safety.

Laboratory clothing which is contaminated/potentially contaminated with Class 1 GMMs must be sealed in large 'biohazard' bags and will be decontaminated through heat inactivation in the autoclave prior to commercial laundering.

* Contaminated broken glass will be inactivated by autoclave before appropriate disposal. The affected bench/floor area will be disinfected with 70% ethanol/water solution. Final disposal of inactivated broken glassware will be as either general laboratory waste, or hazardous waste - depending on any contamination of the glassware by hazardous chemicals.

Autoclave -
Items inactivated via autoclave are subject to a temperature of 134°C for 34 minutes. The temperature probe used in the autoclave, the autoclave cycle chart recorder and the temperature variation within the autoclave chamber are assessed and calibrated annually by a UKAS certified calibration agent. 100% degree of kill would be achieved.

Chemical agents -
Alcohols give a very rapid kill of micro-organisms, but do not provide sustained microbial action. 99.999% kill would be achieved.
Virkon is a peroxygen system that is widely used for laboratory disinfection, and is effective against bacteria, viruses and yeast. In addition, Virkon was found to be effective against 3 strains of Saccharomyces cerevisiae (the Host organism proposed for use in this study) after 5 minutes contact time at 1% using a suspension test (Alegente et al). 99.999% degree of kill is assumed after 24 hours contact with 1% Virkon solution.
And anti-fungal agent that is effective in destroying a broad spectrum of organisms including Saccharomyces spp. (Day-Impex, 2004) 99.999% kill would be achieved.

Tick to confirm that you are attaching a summary of the risk assessment  

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

SEPA's GM Safety Committee has approved the risk assessment and believes that the activities described present no risk to the environment or to human health.
The committee certifies that the laboratories in which this work will be done fully satisfy the requirements for the Advisory Committee on Genetic Modification containment level 1, with good practice being observed to containment level 2.

**Give brief details of the genetic modification safety committee**

The safety officer with overall responsibility for Hypoxium is the CEO. The safety committee consists of the safety officer and the laboratory safety officer (senior scientist). All safety procedures are overseen by an external qualified safety advisor (CFIOSH, MRSC, MISTR) with twenty years of experience. The committee meets quarterly where use is reviewed. Risk assessments are reviewed and updated annually.

Waste is inactivated using virkon, and waste removed from site by a professional specialised waste management company (Grundon) who perform high temperature incineration and dispose of the waste.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Waste is inactivated using virkon, and waste removed from site by a professional specialised waste management company (Grundon) who perform high temperature incineration and dispose of the waste.

Please enter comments of the GM safety committee on the risk assessment

This risk assessment covers the use of genetically modified cell lines supplied to Hypoxium Ltd by Horizon Discovery. All host cell lines are established lines of human origin, which are unable to survive in the outside environment. Modifications carried out do not increase the risks associated with the host cell lines, therefore for safety purposes these cells can be considered to be ‘as parental’. The committee therefore approves this risk assessment and the classification of the cell lines for use at containment level 1, and corresponding GMM Class 1.

The proposed GMMs will be GM Herpes Simplex Virus type 1 (GM-HSV1); ACDP2. Modified to incorporate polyepitopes from other human pathogens; namely, human cytomegalovirus, Epstein Barr virus or influenza virus. Others to incorporate polyepitopes derived from certain human tumours; namely, CD20 or MART1. None of these GMMs are expected to pose an increased hazard. There is no increased risk to humans nor risk to the environment (nil).

The risk assessment concludes, therefore, that precautions and procedures already in place for the production and disposal of HSV1 (ACDP2) are sufficient. All associated Standard Operating Procedures, Chemical and Biological Hazard Risk assessments pertaining to the cultivation and purification of GM-HSV1 (appended) will be complied with at all times.

Hazard Risk assessments specific to the Genetic Modification of HSV will be considered within the application for 'individual contained use activities'.

# Project Additional Information

## Purposes of the contained use

Infection of cell culture with HHV-1 results in the formation of non-infectious virus particles which lack the viral capsid and DNA. These Light (L) particles have a similar structure to infectious HHV-1 particles and have potential as vaccine candidates. The aim of this work is to create recombinant HHV-1 in which novel antigenic sequence is displayed as a fusion protein with the viral gD and vp11/12 proteins. These recombinant viruses will then be used to make L particles with the novel antigen present in the viral structural proteins.

## Recipient or parental organism

Human herpesvirus 1 strain 17. Class 2 pathogen.

## Host/vector system

- E. coli strains DH5, DH5-T1R, TOP10 dam-/dcm-

## Origin & function

Genomic DNA from HHV-1 strain 17 will be used as a template for the amplification of the viral US6 gene (gD), UL46 gene (vp11/12) and UL23.

## Evaluation of foreseeable effects

The modifications will be carried out by the insertion of novel sequence into the viral US6 gene (gD) or UL46 gene (vp11/12) as an in-fram fusion. Sequences to be inserted into these genes include (but may not necessarily be limited to) antigenic determinants for Epstein-Barr virus, Human Cytomegalovirus, Human and Canine CD20, Human Melan-A, Gallid ovalbumin and influenza A. Based on published data, insertion of sequence of sequence into these sites is not predicted to alter the pathogenicity of the virus. Recombinant viruses may be constructed using a thymidine kinase (TK) selection method. These would not be expected to have increased virulence or pathogenicity but would have resistance to 5’ bromo-deoxyctydine (B CdR) treatment.

## Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All infectious waste to be sterilised:
I. Liquid waste; hypochlorite tabs. Manufacturer's instructions followed explicitly.
II. Solid waste; Autoclave then incineration at 34 Redfern Road, Tysley, Birmingham, B11 2BH. Autoclave cycle parameters monitored and recorded electronically and verified by additional thermal indicators (tapes and tubes).

02/03/2022
The maximum amount of waste generated at one time will be 150ml of culture media/liquid waste and small quantities of solid non-sharp standard laboratory waste (for example wipes, plates).

All liquid and solid waste will be inactivated by autoclaving at 124 centigrade for 30 minutes in a dedicated autoclave giving a 100% kill effectiveness. Disposal will then be as standard laboratory waste via a commercial laboratory waste disposal company. The autoclave facility is tested for compliance by use of temperature monitoring and by use of colour change tape to confirm sterilization confirmation tests using a commercial test strip system are undertaken.

All surfaces will be regularly cleaned with a commercial bacteriocidal surface cleaner during the work and all operatives will wear PPE’s (including laboratory coats and gloves) that are decontaminated before leaving the facility.

The waste management and decontamination procedures fully comply with the guidelines contained in the SACGM compendium of guidance for handling waste.

Tick to confirm that you are attaching a summary of the risk assessment  

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

Given the use of attenuated host strains, vectors incapable of expression in mammalian cells and the low toxicity of the inserted sequences, the GMM's are appropriately classified at level 1. An accidental release would be low impact. The proposal includes working at level 2 containment despite only Level 1 GMM usage, as such all sensible precautions will be taken and the risk of release is also low. Overall the risk of the project is therefore low to negligible and the risk, management procedures are adequate.

Y

Give brief details of the genetic modification safety committee

The genetic modification safety committee (GMSC) will consist of the following members:

Chief Scientific Officer (company director), Head of Chemistry, two Pharmacologists and an external academic biological research consultant.

The GMSC will meet once yearly to review existing GMM risk assessments. Monthly meetings are held where the above gather so an agenda item to review a new GMM risk assessment can be added on an ad hoc basis.

Bacteriology  Parasitology  Transgenic Birds  Microbiology Research
GMM cell lines, cell culture media and labware used in the culture of GMM cell lines will be disposed of through the use of commercially available certified detergents (e.g. Trigene) using dilutions and disinfection times recommended by the manufacturer. Decontaminated liquid cell culture waste will be disposed of down the sink, decontaminated solid waste will be sealed in biohazard bags (or sharps containers where appropriate) and disposed of through a commercial waste disposal company.

Some GMM cell lines will be used in an assay whereby the final step requires the direct application of DMSO to the cells thus killing them. Once the cells are removed from their correct culture medium they rapidly become non-viable. Cell viability assays will be carried out to monitor the effectiveness of this method of cell kill.

Once finished with the plates are bagged, sealed in an appropriate container supplied by a commercial waste disposal company who will then dispose of them appropriately.

Screening and research into the effects of novel small molecules on established mammalian cell lines

For activities involving GMMs, describe the waste management measures which will apply to the activity

Y

Give brief details of the genetic modification safety committee

The Genetic Modification Safety Committee has the same make-up as the Biological Safety Committee is made up of Biological Safety Officer (Chair), Director of the Research School of Health and Life Sciences or his nominee, Professor of Pharmaceutical Engineering (representing the Faculty of Engineering), Head of School Sport and Exercise Science (representing the Faculty of Social Sciences, Nominees from Chemistry and Human Science (representing the Faculty of Science) and upto 4 co-opted members. The full University Biological Policy can be found at, http://www.lboro.ac.uk/admin/hse/policies/download/biological%20safety%20policy.pdf

There are two levels of Risk Assessment. If work is to be carried out with non-GM material then a Biological Risk assessment must be completed. If the work is with GM material then in addition a GM risk assessment must also be carried out with non-GM material then a Biological Risk assessment must be completed. If the work is with GM material then in addition a GM risk assessment must also be carried out (see exemplar attached). Once a GM risk assessment has been completed it is submitted to the GM safety for approval. Here it is peer reviewed by at least two members of the committee comments fed-back to the applicant(s) where necessary and revised before formal approval is given. Work cannot commence before formal approval is obtained from the GM safety committee. The GM safety committee meets formally at least once annually however the assessment and approval of GM risk assessments can be dealt with by circulation. The committee also inspects and approves new laboratories for GM and biological safety compliance before any work can be carried out. Laboratories with existing approval for GM/biological work are inspected and re-approved annually.

Level 1 (GMMs) Yes
All work will be carried out in a Biological Hazard Group II Containment laboratory.

All solid and liquid waste will be autoclaved i.e. 121 degrees C for 20 minutes prior to disposal by incineration. The autoclaves have been professionally validated against the specific types of waste we intend to use and they will be re-validated and serviced every 12 months unless a problem is identified sooner. Validation at point of use via the visual inspection of applied ‘autoclave tape’.

Liquid spills are dealt with by flushing with 1-2% v/v Virkon solution (industrial standard disinfectant for such purposes validated against a range of common cell types), the spill will then be mopped up, autoclaved (121 degrees C for 20 minutes) prior to incineration.

In all cases a 100% kill is expected prior to disposal.

Please enter comments of the GM safety committee on the risk assessment
Committee member 1.

1) Page 2: Are the same sequences being inserted into both the 51R and foetal liver cells? This is somewhat unclear. Would it be appropriate to maybe replicate the table, once for each cell line, to make this clearer?
2) Page 4: Quantity of organism - does this refer to each cell line or in total? (I would assume each based on selection B2.4.2 in risk assessment)
3) Page 5: Work likely to produce aerosols - although it is detailed in the biological risk assessment it may be worth reiterating the fact that the work is also carried out in the self-contained Class II environment of the CompacT SelecT.
4) Page 10: Room numbers are missing from the top table. For training - mention the "records of training" which are mentioned in C4.2 of the biological risk assessment.

Committee member 2

The risk assessment appears to be good so I hope this allows the project to progress.

The risk assessment appended was accepted after these had been addressed and the Risk Assessment attached is that which was accepted after modification.

02/03/2022
The principle method of inactivation of cultures of GMM's will be by treatment in an autoclave (heat inactivation) at 15 p.s.i. for 20 minutes following the manufacturer's recommendations for use.

All cultures, whether in glass or disposable containers, will be autoclaved before disposal or recovery of containers. Liquid medium from which micro-organisms have been recovered by centrifugation or filtration, and contaminated plasticware (Petri dishes, Eppendorf tubes, disposable pipettes and culture tubes etc), will also be sterilised in the autoclave prior to disposal. The autoclave will be regularly serviced and tested for effectiveness according to the manufacturer's recommendations.

Spills and leakages of contaminated liquids are to be treated with a suitable disinfectant (eg Virkon™) according to manufacturer's recommendations and in accordance with appropriate COSHH guidelines. Disposable tissues used for mopping up disinfectant-treated spills will be autoclaved prior to disposal.

Contaminated sharps will be collected in an approved designated sharps container and disposed of by incineration.

Bacteriology: Yes

Parasitology: 

Transgenic Birds: 

Microbiology Research: Yes
Inactivation of GMMs is by autoclaving and/or by chemical disinfection. Chemical disinfection is achieved by treatment with a final concentration of Virkon of a minimum of 5% for a minimum of 30 minutes. Autoclaving will be monitored daily by use of indicator tap, and the kill sufficiency measured monthly by the attempted growth of an appropriate GMM containing solution after autoclaving.

All disposable consumables that have been in contact with GMMs are autoclaved before removal from the laboratory for disposal. Autoclaving is carried out in the same laboratory as the work has been carried out. Material for autoclaving is contained using a double-bagging protocol where multiple small autoclave bags are collected in a larger autoclave bag within the microbiology safety cabinet, and then transferred to the autoclave. After autoclaving the materials are disposed of as clinical waste.

Disposable lab coats and nitrile disposable gloves are worn at all times and are not removed from the laboratory except after autoclaving for disposal.

Surfaces are cleaned daily by liberal application of 5% Virkon. Spills will be contained with disposable absorbent materials which will be treated with Virkon before autoclaving for disposal as clinical waste. The area of the spill will be treated by liberal application of 5% Virkon solution.

Tick if you are claiming exemption from disclosure for sections of the risk assessment  

Please enter comments of the GM safety committee on the risk assessment

The GMSC has read and understood the risk assessment and classifies the work as Group 1. The Academic Expert has recommended that filter tips are used on all pipetting actions involving GMOs to minimise the risk of contamination of the pipettes. This has been implemented, and added to the risk assessment accordingly.

Give brief details of the genetic modification safety committee

The CSCR GM committee reports to the Biological Safety Committee, which in turn reports to the main Centre Safety Committee. It oversees all current and potential projects within the research centre. The committee reviews current and proposed projects as a "virtual committee" and will sit formally as required e.g. to discuss a complex project proposal or significant change to an existing project. It is composed of the BSO and Deputy, Centre Safety Officer and other experienced GM users.

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The seven members of the Biological Safety Committee did not raise concerns about the project and unanimously approved the project as containment level 1 work.
Project Additional Information

Purposes of the contained use

Originating from early developing cells after fertilization, embryonic stem cells (ESC) are unique in their capacity to generate all differentiated cell types composing their original organism. The ability to cultivate ESC in vitro offers a tremendous opportunity to the scientific community to study fundamental mechanisms acting through embryonic development as well as opening exciting clinical perspectives by offering wide possibilities for in vitro pharmacological models and cell sources for regenerative medicine. Our global objective is thus to gain better knowledge in molecular factors and mechanisms controlling early ESC fate specification towards the three primitive embryonic germ layers (endoderm, mesoderm and ectoderm) and further differentiation towards mature functional cells. By bringing important insights in fundamental development processes, our project should allow us to gain in parallel a better control in ex vivo differentiation protocols from ESC and improve the production of therapeutically relevant cell types like cardiomyocytes, neurons, pancreatic cells or haematopoietic stem cells for instance.

This general perspective will develop into three leading projects implying genetic modification of various cell types:
- Project1. Factors controlling cell fate specification of pluripotent stem cells
- Project2. Transcriptional factor mediated reprogramming of somatic and embryonic stem cells
- Project3. Gene targeting in human embryonic stem cell

Since they are highly efficient vectors to genetically modify numerous cell types (notably ESC), we plan to use recombinant viral vectors derived from gamma-retroviruses, lentiviruses and adenoviruses to achieve our goal. We will use recombinant retroviral particles (MuLV derived, from the company Vectalsys, France) and recombinant lentiviral particles (HIV-1 derived, production in situ) which have amphotropic ranges of tropism (VSV-G pseudotyped). For some experiments, recombinant adenoviral particles (Ad5 derived, from the company Hybrid Systems, UK) will be also used. All recombinant viral vectors will be replication defective and each production batch properly tested for absence of infectious particles. Inserts (cDNA, shRNA) will be cloned into these vectors, alone or in combination (through the use of independent promoters, IRES or 2A sequences) with GFP, antibiotic resistance gene or another insert of interest. In situ production of lentiviral particles will be achieved by transient co-transfection of 3 plasmids (vector, helper and envelope) into 293T/17 cells. All lentiviral particles will be produced from SIN (Self Inactivating) backbones using the 2nd generation production system (Vif, Vpr, Nef and Vpu deleted helper plasmid). Work involving recombinant virus handling (production, transduction) and human primary cell culture will be performed under containment level 2 conditions in compliance with institution practice.

Recipient or parental organism

1. Escherichia coli - K12 derived strains, disabled, non colonising
2. Gamma oncoretroviruses – MuLV derived, replication defective, amphotrope
3. Lentiviruses – HIV-1 derived, replication defective, amphotrope
4. Adenoviruses – Ad5 derived, replication defective, ecotrope
5. Mammalian cells (primary cells and cell lines) – considered as especially disabled
   - Human, murine embryonic stem cell lines (H9, H1, HSF6,…)
   - Human, murine induced pluripotent stem cell lines (produced in situ)
   - Human, murine primary cells (embryonic and adult skin fibroblasts, keratinocytes, peripheral blood cells)
   - Human, murine somatic cell lines (HEK-293T, HCT-116,…)

1. E.coli K12 / pUC derived plasmids - no insert expression, plasmid non mobilisable.
2. HEK-293T / pUC derived plasmids – transient co-transfection, viral gene and insert expression, production of amphotrope replication deficient lentiviral particles (each batch to be tested).
5. Mammalian cells / Ad5 vectors – replication defective adenoviruses, transient genetic modification.

Host/vector system

1. Human, murine, xenopus cDNA (+/- TAG sequences) coding for transcription factors, signal transducers, growth factors and surface receptors. These inserts are expected to play a role in pluripotency, cell fate decision and differentiation from pluripotent stem cells (PSCs). Their expression may enhance/block commitment and differentiation of PSCs towards one of the three primitive germ layers and further differentiated progeny.
2. shRNA and miRNA sequences against cell endogenous coding sequences. These inserts are non coding RNA sequences targeting cell endogenous mRNA from above mentioned factor families (in 1) in order to inhibit protein expression by RNA interference (RNAi). Their expression may enhance/block commitment and differentiation of PSCs towards one of the three primitive germ layers and further differentiated progeny.
3. Reporter genes (GFP, LacZ, Luciferase, possibly fused to cDNA (type1 inserts)). These inserts will code for proteins with fluorescent or enzymatic properties allowing easy identification of genetically modified (GM) cells. They are thought to have no deleterious biological effect on expressing cells.
4. Selection genes (NPT, PAC). These inserts will produce enzymatic proteins able to inactivate specific antibiotic families allowing selection of GM cells. They are thought to have no deleterious biological effect on expressing cells.
5. Functional non coding sequences. These inserts will act as promoters of transcription (promoters and enhancers), local chromatin structure modifiers (enhancers and insulators), RNA transcript stabilizers (WPRE) or translation regulators (IRES). They will be used (independently or in combination) into viral expression cassettes to achieve best control of transgene expression depending on targeted cells.
6. Neutral non coding sequences (introns, isolated exons). These inserts will be used in particular for gene targeting projects to promote homologous recombination at defined genomic loci (intronic/exonic genomic sequences). They should not have biological effect by themselves.

Origin & function

Evaluation of foreseeable effects

Human Health considerations -

The most obvious risk for human health is linked to accidental infection of worker by recombinant viral particles. Indeed, because only replication defective viral particles (non infectious) will be used for experimental work through this project and inserts will not produce compounds with acute toxicity (like bacteria toxins), no additional risk will be associated with the final GMO itself (mammalian cells) compared to initial organism. Importantly, primary cells coming...
from human samples are uncharacterised and may contain adventitious agents: they will be handled at containment Level 2 (COSHH regs).

First, risks associated with the nature and design of recombinant viral particles has to be assessed. Retroviral recombinant particles (MuLV and HIV-1 derived) will be VSV-G pseudo-typed (protein G from the Vesicular Stomatitis Virus will replace the native envelope protein). VSV-G packaging alters the tropism of the retroviral particles, requiring interaction only with phospholipids present in the plasma membrane of all cells rather than interaction with a cognate receptor as occurs with ecotropic packaging. Thus, VSV-G pseudo-typed retroviruses acquire the ability to efficiently infect virtually all human cell types. Moreover, VSV-G pseudo-typing improves stability of the viral particle and may represent an aerosol means of transmission in addition to the expected percutaneous risk. Retroviruses stably integrate the host cell genome. This property is associated with a risk of insertional mutagenesis, i.e. ectopic activation/inhibition of host gene expression after colocalized provirus integration. Subsequent deregulation of endogene expression could theoretically lead to transduction associated detrimental effects like initiation of oncogenic processes. Moreover, the addition of the WPRE (Woodchuck Hepatitis Post-transcriptional Regulatory Element) to the expression cassette in several retroviral backbones could also enhance the oncogenic potential of such vectors (SACGM, annual report 2004). Importantly, among retroviral vectors, the use of lentiviral derived backbone is thought to be safer. First, genomic integration profile of lentiviral derived vectors do not show an integration bias toward the transcriptional start site region of host cell genes like MuLV ones. Moreover, we will use exclusively SIN (Self Inactivating) vectors devoid of viral enhancer activity which reduces further the likelihood of endogene activation. In contrast, recombinant adenoviral vectors are considered safer. Indeed, adenoviral genome is rarely seen to integrate into the host cell genome and transgene expression remains transient in host cells. Moreover, the disease caused by wild type adenovirus is usually just a mild and self limited common cold.

Risks associated with inserted coding sequences should also be assessed. cDNA (or shRNA/miRNA) inserts carried by viral vectors will direct ectopic expression (or inhibition) of transcription factors, signal transducers, growth factors and receptors which are expected to play a role in pluripotency, cell fate decision and differentiation from pluripotent stem cells. It is difficult to predict in vivo consequences of ectopic expression for all these genes on human health. However, since they are key regulator of cell identity, their overexpression could lead to pathological modifications of cell phenotype/function. Moreover, several of these genes have been involved in oncogenic processes and uncontrolled expression could subsequently initiate tumoral transformation. However, malignancy is a complex multistep process which involves multiple genomic alterations and a single “hit” is unlikely to trigger alone the oncogenic process. Experiments involving co-transduction or even co-expression by the same vector of several inserts should consequently be considered at higher risk for the worker. Notably, reprogramming experiments of somatic cells toward pluripotency (co-transduction with the 4 factors OCT4, SOX2, MYC, KLF4) could imply a specific risk since accidental genetic modification of worker cell could theoretically lead to teratoma formation. Above mentioned risks will be tempered by the fact we will use strictly replication defective viral vectors unable to propagate further after transduction. For all viral vector type, in the likelihood of an accidental contamination (percutaneous, aerial), amount of viral vectors able to effectively contaminate worker cells will be smaller and transduction much less efficient compared to improved in vitro transduction protocols used on cultivated cells. Of note, MuLV derived vectors are only efficient in transducing proliferating cells that limits the number of potential accidental targets. Importantly, VSV-G pseudotyping of retroviral particles results also in complement sensitivity increasing the likelihood of immunological neutralisation in human hosts. Together, these considerations suggest that only low number of cells may be effectively transduced through accidental contamination. Moreover, malignancy is a complex multistep process which involves multiple genomic alterations and it is unlikely that any single “hit” corresponding to an accidental infection would initiate transformation. Notably, cells exposed to non percutaneous accidental infection (stratum corneum, respiratory epithelium) are terminally differentiated cells with limited lifespan and high turnover,
which greatly limits the risk of effective tumoral transformation. Nevertheless, in the context of experiments using polycistronic viral vectors for combined expression of several cDNA, tumoral transformation risk may be higher: appropriate safety measures will be undertaken to limit accidental contamination and all workers will be informed of additional risk associated with the use of such specific viral constructions.

- Environment considerations -
VSV-G pseudotyping of recombinant retroviral particles (MuLV and HIV-1 derived) would enable vectors to infect a variety of animal cell types including those of different animal species. Moreover, environmental stability tends to be increased by VSV-G pseudotyping compared to retroviruses displaying the native envelope. However, retroviral particles remain sensitive to air, temperature and pH and will have short lifespan in open environment. Importantly, recombinant retroviral vectors will be replication defective and could not produce progeny viruses able to spread to the wider human or other animal populations.

Pubic Register
Health and Safety
Executive
CU 2 2000 (rev 11/08) Page 5 of 11
Adenoviruses are generally species specific. Indeed, serotype 5 Adenoviruses infect humans and does not naturally infect other animals. Therefore, the risk of accidental infection of other organisms is very low. Because recombinant adenoviruses will be replication incompetent, they could not spread to the wider human population from any accidentally infected individual.

*Transgene mobilization issue for retroviruses.
Recombinant viral vectors which will be used to genetically modify mammalian cells will be replication deficient and thus unable to propagate to the environment. However, a risk of recombinant vector mobilization through concomitant wild type retrovirus contamination of the targeted cell still exists. Indeed, recombinant retroviruses encompass a native encapsidation sequence which could allow production of transgene carrying viral particles if complementing viral proteins (enzymes, capsid and envelope) are provided by a compatible wild type retrovirus. The likelihood of such mobilization is still very low, even less with SIN Lentiviruses which are devoid of provirus LTR activity. Importantly, mobilized recombinant retroviruses would still be unable to replicate in other cells than those carrying the complementing wild type retrovirus. Moreover, amphotropism associated with VSV-G pseudotyping would no longer exist for viral particles encompassing mobilized recombinant retroviral genomes.

Since generation of replication competent viral particles (RCV) is associated with the highest risk factor for human health and environment, production steps will be given the highest risk factor in the whole process (i.e. production, transduction, GM cell analysis). All lentiviral productions will be carried out in strict Class2 conditions by trained and experienced workers. To decrease the likelihood of infection standard measures to decrease percutaneous as well as aerosolised transmission of viral particles will be adopted, such as no use of sharps and all work to be performed within a class II microbiological safety cabinet. Moreover, configuration of the laboratory premises will allow direct autoclaving of all equipment in the Class2 related lobby. All lentivirus batches will be tested for absence of RCV before use for cell transduction. In the very unlikely event of RCV generation, decontamination procedures will be carefully carried out and the event notified to the local BSO. Notably, no RCV generation involving 2nd generation SIN lentiviral vectors has ever been reported as today in the literature.

MuLV derived retroviral particles and adenoviral particles will be produced by external manufacturers (Vectalys and Hybrid Systems respectively) and production batches demonstrated RCV free by internal validated methods.

For some experiments (teratoma formation, haematopoietic engraftment), genetically modified mammalian cells (human, murine) could then be transplanted by tissular or systemic injection into immunodeficient recipient mice to
generate chimaeras. Importantly, protocols involved will not allow germ line transmission of the genetic modification. Since all viruses utilised to genetically manipulate the cells before transplant will have been tested for absence of RCV, there will be no risk of further infection and there will also be a minimal risk that the animals could escape from the animal facility.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

- All disposable culture/lab ware from the CL2 laboratory will be double-bagged, properly labelled as biohazard and autoclaved before leaving the building for incineration (autoclaving in adjacent lobby). [100% kill]
- All highly contaminated material, i.e. all stuff in contact with viruses (pipettes, tips, culture plates, liquid waste bottles), will be separately decontaminated (Virkon 2%/Trigene Advanced 10% for 16 hours) and liquids solidified (Vernagel) before autoclaving. [100% kill]
- Small spills will be removed after one minute surface soaking with Trigene Advanced 1% and further decontamination by 70% Ethanol. [effectively 100% kill]
- Large accidental spills will be sprinkled with Virkon powder before cleaning. [effectively 100% kill]
- Bench and cabinet surfaces will be wiped down with Trigene Advanced 1% followed by 70% Ethanol. [effectively 100% kill]
- All GM modified cell cultures will be destroyed (soaking with Trigene Advance 1% and autoclaving/incineration) [100% kill] or chemically fixed/lysed (PFA 1-4%, Guanidin, RIPA) before leaving containment [effectively 100% kill].

Please enter comments on the GM safety committee on the risk assessment

This project has been reviewed on 8th April 2009 by the West Forvie Building biological and genetic safety committee. This is satisfied that the risks have been properly addressed and that the work will be carried out under the appropriate controls and conditions. Nevertheless, the committee stressed on the need for additional risk assessment and specific information for workers undertaking experimental work with multiple insert (polycistronic) viral vector constructs which are associated with a higher risk for human health through accidental infection. Moreover, the committee emphasized that work with replication defective adenoviral vectors could be actually done at containment level 1 using MSC II.

Project Containment
The project is concerned with introducing genes to human somatic cell lines, embryonic stem (ES) cells or induced pluripotent stem (iPS) cells.

Recipient or parental organism

Human somatic cell lines, embryonic stem (ES) cell lines and induced pluripotent stem (iPS) cells will be co-infected with a combination of genes that have or might have oncogenic activity. The expressed genes will provide the host cell with a proliferation advantage and they will induce an undifferentiated, pluripotent state. The Sendai Virus infects human cells with high efficiency. Thus, exposure of an individual to the Sendai Virus, by possibly a break in the skin, could result in a localised transfer of the pathogenic properties of the particular gene.

Host/vector system

The target genes will be cloned into the non-transmissible sendai viral vector, SeV/deltaF, which does not encode F protein, so that this defective vector can amplify specifically in an F-expressing packaging cell line but cannot spread to F protein-nonexpressing cells. SeV vector is the cytoplasmic RNA vector that replicate in the form of negative-sense single stranded RNA in the cytoplasm of infected cells, which do not go through a DNA phase nor integrate into the host genome (Li et al. J Virol. 2000)
All DNA will be propagated in E coli (e.g. DH10B or derivatives).

Pathogenicity and transmissibility of SeV are not changed by any inserted sequences. SeV vector is the Cytoplasmic RNA vector that replicates in the form of negative-sense single stranded RNA in the cytoplasm of infected cells, which do not go through a DNA phase nor integrate into the host genome.

293T cells will be transfected with F-defective SeV vector carrying a transgene and pCAGGS-plasmids carrying the T7 RNA polymerase, NP, P, F5R, and L gene. They are cultured for 1 to 3 days to generate the seed SeV/deltaF vector. Then, these are propagated using the LLC-MK2 cells that are a monkey kidney cell line and carrying the F gene (LLC-MK2/F7). And the recovered F-defective SeV vectors are harvested.

SeV is able to infect cells from a broad host range, including humans but as this SeV is a murine parainfluenza virus, pathogenicity to humans has not been reported. As this SeV vector is a non-transmissible vector lack of F gene, transmissible virus is never produced, so that they have no possibility of horizontal transmission. This SeV vector is excluded from in vivo host within a few days to a few weeks after infection because of this vector’s immunogenicity.

None of the cell lines would be expected to remain viable outside the controlled culture conditions and infection of virus and expression of gene will be transient. We do not anticipate that any of the genetic manipulations we are proposing would alter this.

Recipient cells expressing the individual genes under study will be created which are likely to have some growth advantage or induce increased proliferation in an autocrine or paracrine manner.

Evaluation of foreseeable effects

Bacterial strain of E coli such as DH10B and its derivatives are not capable of colonizing a healthy individual.

Exposure of an individual to SeV, by possibly a break in the skin, could result in a localized transfer of the pathogenic properties of the particular gene. But no localized transfer caused by SeV has been reported.

The inserted genes are likely to have an autocrine or paracrine proliferative effect when expressed. Infection normally lasts only a few days to a few weeks. During this term, it is predicted that over-expression of pluripotent genes, oncogenes and signalling molecules could lead to an increased or decreased rate of cell division, although tumour progression and disease in the whole organism is unlikely.

The major possible source of hazard to the environment would be accidental escape of high titre virus solutions expressing cDNAs, which could then infect rodents.

SeV requires close contact for their transmission and their survival in the general environment is poor due to their fragile envelope. The vector is non-mobilisable and the successful infection of a cell would be transient without stable integration of the viral genes into host DNA.

The SeV would be able to infect a wide host range but could not be spread. There is no possibility of recombination because of RNA virus. A mutated form that is seen in flu is not produced because of a single-strand genome instead of segmented genome.

The use of sharps will be strictly controlled and avoided whenever possible. Needles and scalpels will not be permitted. Plastic Pasteur pipettes will be used for aspirating culture medium.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

No animals or plants will be used.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste will be sealed in double autoclave bags and transported to the departmental autoclave where it will be exposed to steam at 127°C for 25 minutes. Effectively 100% kill. Run information of autoclaves is stored and can be accessed or printed off at any time to ensure temperatures within the autoclave were maintained during the cycle.

All liquid waste will be inactivated by treatment with Virkon or Trigen at a final concentration of 1% for 12 hours before disposal via the drains. Effectively 100% kill as determined by manufacturer.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form  

Tick to confirm that you have attached a risk assessment to this form  

Tick if you are claiming exemption from disclosure for section of the risk assessment

Please enter comments on the GM safety committee on the risk assessment

The overall assessment for the vector itself (the Sendai Virus; HG1) would be CL1 because it is a non-integrating virus. Although the infection efficiency is very high and applies to humans and rodents, the infection would not persist and our local rules would still cover the risks under CL1.

The factor that puts this assessment on CL2 is the actual genes that are expressed. At least one of it is a known oncogene and all of them are likely to have a positive effect on cell proliferation. Furthermore, it is the aim of the project to increase proliferation and pluripotency and all genes are expressed at the same time. Taken together the hazard identification for the expressed genes and especially the fact that they are co-expressed is CL2.

The assessment was generally well written and the committee has only two comments on the form itself:
1. Define human somatic cell lines by including ‘commercially available’ otherwise refer to the Centre’s risk assessments regarding use of human cell lines.
2. Run information of autoclaves is stored and can be accessed or printed off at any time to ensure temperatures within the autoclave were maintained during the cycle.

In summary, we have to assign CL2 to the project.

Animal Units  
Large Scale Activities  
Human Clinical Applications
The purpose of this project is to study the biology of haematopoietic stem cells using the experimental approach of transgene delivery by means of retroviral vector systems. The biological questions we aim to address include the molecular controls regulating stem cell formation and stem cell plasticity as well as the molecular defects in stem cells that lead to leukaemia. The proposed work has therefore the potential to open up new areas for both fundamental and applied biomedical research with potential clinical relevance for the treatment of leukaemia.

Recipient or parental organism

E. coli transformed with pUC-based retroviral vectors will be handled at containment level 1. The retroviral work will be performed at containment level 2.

The proposed retroviral systems incorporate the following safety modifications to prevent viral replication:

1. The packaging genes are separated into two plasmids, which lack both LTRs and have no viral packaging signal.
2. The following viral genes have been deleted from the packaging vector: env, vpr, vpu, vif and nef.
3. The vectors expressing the packaged viral genome has a self-inactivating LTR (TATA box deletion) and expresses no viral gene products.
4. Envelope is expressed on a separate vector.

Host/vector system

The following host/vector system will be used:

E. coli; K12/pUC derivatives carrying the ampicillin gene driven by a bacterial promoter together with viral genes and cDNAs driven by eukaryotic promoters that do not express in bacteria.
The purpose of the project is studying both normal and malignant haemopoietic stem cell biology. All the genes we want to deliver to cells are of known function. We will use disabled retro and lenti vectors and virus pseudotypes that only infect mouse cells whenever the inserts are potential oncogenes.

Insert DNA categories:
1. Reporter genes (lacZ, GFP + variants, luciferase, PLAP) together with regulatory regions enhancers, promoters, silencers
2. Cre recombinase gene, self-exising with regulatory regions
3. SV40 large T antigen, HoxB4, Hox11, Notch1: potential oncogenic function (only to be used with ecotropic envelopes)
4. SCL, Myod, myf5, pax3, pax7, pdx1, ngn3: transcription factors (only to be used with ecotropic envelopes)

Evaluation of foreseeable effects

The risk of infection with retroviruses is through direct inoculation, which is unlikely as no needles are used for any experimental procedures involving retroviruses. Moreover, we will use virus pseudotypes that only infect mouse cells whenever the inserts are potential oncogens. The viruses used in this project are replication defective and thus not pathogenic when tested in mice.

The proposed retroviral systems incorporate the following safety modifications to prevent viral replication:
1. The packaging genes are separated into two plasmids, which lack both LTRs and have no viral packaging signal.
2. The following viral genes have been deleted from the packaging vector: env, vpr, vpu, vif and nef.
3. The vectors expressing the packaged viral genome has a self-inactivating LTR (TATA box deletion) and expresses no viral gene products.
4. Envelope is expressed on a separate vector.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

We propose to generate transgenic mice using the lentiviruses. These mice will be housed in CBS (Addenbrooke's site Cambridge) together with all our other transgenic mice. Transgenic mice will only be produced for the inserts of category 1 (ie. inert reporter genes). Due to the design of the proposed experiments (see above) and the containment procedures of CBS, the environmental risk after introduction of the transgene is negligible.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None applied for.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste is treated using 5% chloros for 24 hours prior to disposal.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

### Project Additional Information

**Purposes of the contained use**

We will produce viral particles which have both ecotropic and amphotropic ranges of tropism, using replication defective MSCV v2.1 based retroviral vectors. The gene of interest is cloned into these vectors which concomitantly either express GFP or an antibiotic resistance marker. Viral particles are produced following transient co-transfection of 293T cells with the retro/lentiviral vector and one (ecotropic) or 2 (amphotropic) packaging constructs. This will be performed under containment level 2 conditions in compliance with institute practice.

**Recipient or parental organism**

E Coli - All strains are K12 derived thus disabilingn and non-colonising. Vectors are non-mobilisable. Mammalian cells - MSCV vector is non-mobilisable.
Retrovirus - MSCV vectors are based on replication defective retroviral genomes and FUGW vectors on replication defective lentiviral genomes.

**Host/vector system**

- **Host** - 293T cells/vector - MSCV retrovirus or FUGW lentivirus
- **Host** - Mammalian cell, post infection/vector - MSCV retrovirus or FUGW lentivirus (replication incompetent).

**Origin & function**

- **Human origin**
- **cDNA** - for overexpression.
- **siRNA** - synthetically derived to be complimentary to human sequence, used to inhibit protein expression

**Evaluation of foreseeable effects**

**Risk Assessment for human health:**

The most obvious potential risk to human health is the expression of oncogenes within accidentally infected human cells. This would be impossible for exotropically packaged retrovirus or lentivirus, but is theoretically possible for amphotropically packaged retrovirus or lentivirus. Theoretically these viruses can infect human cells and lead to integration and expression of the insert in dividing cells. In turn, expression of oncogenes or potential oncogenes or of endogenous genes through insertional mutagenesis could potentially be harmful to human health. There is also the theoretical potential for propagation of the virus through recombination and the generation of replication competent retrovirus (RCR). The MSCV vector is replication defective and the production of RCR will be minimised by the use of a 3 plasmid transfection system to prevent recombination. However, testing for RCR will be performed for each batch of amphotropic virus using a marker recovery assay (each virus also expresses either a GFP marker or an antibiotic resistance marker) and only batches negative for RCR will be utilised further.

For lentiviruses, theoretically these viruses can also infect human cells and lead to integration and expression of the insert in dividing and non-dividing cells. In turn, expression of oncogenes or potential oncogenes or of endogenous genes through insertional mutagenesis could potentially be harmful to human health. There is also the theoretical potential for propagation of the virus through recombination and the generation of replication competent retrovirus (RCR). The FUGW vector is replication defective and the production of RCR will be minimised by the use of a 3 plasmid transfection system to prevent recombination. However, testing for RCR will be performed for each batch of amphotropic virus using a marker recovery assay (each virus also expresses either a GFP marker or an antibiotic resistance marker), and only batches negative for RCR will be utilised further. In addition, although the lentivirus has modifications to increase transcription and nuclear import (the WRE and HIV-1 flap element respectively) which might theoretically increase the risk of expression in infected human cells, it is replication defective and the SIN modification of the 3' LTR is duplicated in the 5'LTR upon reverse transcription.

This results in the transcriptional inactivation of the provirus and decreases the likelihood of insertional mutagenesis. These vectors also have a 5' LTR modification (U3 region replaced with CMV promoter) which along with the use of a 3 plasmid transfection system reduces the possibility of recombination and minimises the risk of production of RCR. Recently concern has been raised with regard to the WRE element, as mice transplanted with control vectors containing this element have developed tumors. Therefore, in keeping with GTAC and SACGM recommendations these vectors will be handled at containment level 2.

To decrease the likelihood of infection standard measures to decrease percutaneous as well as aerosolised transmission of the virus, such as no use of sharps ans work to be performed within a class II microbiological safety cabinet will be adopted. Aerosolised virus is theoretical risk to infect the respiratory epithelium, but its production would be minimised as above. In addition the respiratory epithelium is terminally differentiated, has a high turn-over and it is unlikely that the haematopoietic specific oncogenes involved in this proposal would have any effects on this tissue in the unlikely event of infection. Moreover, malignancy is a multistep process and it is unlikely that any single "hit" would initiate transformation and in occasional experiments where oncogenes were coexpressed this would be by cotransduction making dual infection of the same human cell highly unlikely. Also VSVg pseudotyping results in complement sensitivity increasing the likelihood of immunological neutralisation in human hosts. However, during the production and concentration of retrovirus, the transduction of cells and the subsequent analysis of these cells, CL2 conditions will be strictly adhered to.

Both viral particles are relatively unstable and standard practices will ensure adequate decontamination of facilities.
Bacterial and mammalian cells are unable to survive outside of laboratory culture conditions. See attached protocol for further details.

In summary, there is little evidence for the likelihood of hazardous long-term effects from accidental infection and overexpression of an oncogene. Adherence to the code of practice for containment 2 facilities should be adequate for prevention of inadvertent infection.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None applied for.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste will be treated with 2% Virkon overnight in labelled containers. Liquid post disinfection will be gelled with vernagel, placed in sealed containers and taken to room 1.23 for incineration. Solid waste will be placed in double autoclave bags, secured with autoclave tape and labelled with the room number and user name, followed by autoclaving and incineration. Liquid spills will be treated with 2% Virkon (non-metallic surface) or 10% trigene (metallic surfaces) and absorbed with paper towels which will then be autoclaved. Surfaces will be routinely cleaned with 10% trigene.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment Y

Please enter comments on the GM safety committee on the risk assessment

This project has been reviewed by the institute's biological and genetic safety committee. This is satisfied that the risks have been properly addressed and that the work will be carried out under the appropriate controls and conditions.

Page 12845 of 15326
The project aims to investigate strategies to modulate the differentiation of human and mouse embryonic stem cells, differentiated cells and tumour cells by introduction of genes including transcription factors and cell cycle regulators using lentiviral vectors.

Recipient or parental organism
Murine and human cells (packaging cells, primary cells, cancer cell lines and immortalized cell lines).

Host/vector system
1) E.coli, laboratory K12 derivatives/pUC based vectors;

2) Vertebrate tissue culture cells including 293 T cells, embryonic stem cells, human cancer cell lines, and cells including fibroblasts and neuroblastoma and glioblastoma cell lines derived from patient samples.

3) Lentiviral vectors

3.2) Lentiviral systems: the two types of viral system to be used employs two well characterised lentiviral vector and packaging cell lines.

3.2.1) Typa A (eg. pFUV and tet-ON derivatives thereof), 3rd generation:
. The number of genes from HIV-1 that are used in this system has been reduced to three (i.e. gag, pol, and rev).
. Genes encoding the structural and other components required for packaging the viral genome are separated onto four plasmids.
. Although the three packaging plasmids allow expression in trans of proteins required to produce viral progeny (e.g. gal, pol, rev, env) in the 293T derived producer cell
lines, none of them contain LTRs or the packaging sequence. This means that none of the HIV-1 structural and other components required for packaging the viral genome are separated onto four plasmids.

Although the three packaging plasmids allow expression in trans of proteins required to produce viral progeny (e.g. gal, pol, rev, env) in the 293T derived producer cell lines, none of them contain LTRs or the packaging sequence. This means that none of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. No new replication-competent virus can be produced.

The lentiviral particles produced are replication-incompetent and only carry the gene of interest. No other viral species are produced.

In some cases expression of our gene insert of interest will be driven expression off a tet-responsive CMV promoter, and regulated by a co-transduced lentivirus doxycyclin-responsive Tet regulator, giving an added level of safety for insert expression.

### 3.2.2. Type B (eg. Lentix0HTX from Clontech), 4th generation

The lentiviral packaging systems mentioned above are 3rd generation versions that utilize split-genes to provide the viral packaging elements on individual plasmids that physically separate the viral envelope, env (usually VSV-G), sequence from the gag-pro-pol sequences. These split-gene packaging strategies reduce the risk of generating RCL because multiple recombination events are necessary to create a virus that harbours the sequences required for independent replication. Type B (Clontech's Lenti-X HT) Packaging System also uses a split gene packaging strategy, but adds another level of safety by further uncoupling pol (RT and IN) from gag-pro. The result is that gag, pol and env reside on three physically distinct entities, rather than the standard two. This approach further reduces the possibility of creating RCL to a level below that of standard 3rd generation packaging systems, because extra recombination events are required to create such viruses. In fact, the emergence of RCL is undetectable from systems using this approach (Wu, X, et al. 2000) Mol. Ther. 2(1):47-55.) These improvements significantly increase the safety profile of our Lenti-X HTX Packaging System.

Clontech’s Lenti-X Vectors contain less than one-third of the wild-type HIV-1 genome. These wild-type sequences mainly consist of the viral LTRs and packaging signal. All essential replication genes have been completely removed and are instead supplied as separate DNA entities in the Lenti-X HT Packaging Mix (described above).

In brief, the number of genes from HIV-1 that are used in type B system has been reduced to four (i.e. gag, vpr-pol, rev and tat).

Although the four packaging plasmids allow expression in trans of proteins required to produce viral progeny (e.g. gal, pol, rev, env) in the 293 T derived producer cell lines, none of them contain HIV-1 LTRs or the packaging sequence. This means that none of the HIV-1 structural genes are actually present in the packaged viral genome, and thus, are never expressed in the transduced target cell. No new replication-competent virus can be produced.

The lentiviral particles produced are replication-incompetent and only carry the gene of interest. No other viral species are produced.

In this system, expression of tat is required in the packaging cell line, because the lentivirus vector contains an intact HIV-1 5LTR, which allows very high titers in viral preparations.

In some cases expression of our insert gene of insert of interest will be driven expression off a tet-responsive CMV promoter, and regulated by a co-transduced lentivirus doxycyclin-responsive Tet regulator, giving an added level of safety for insert expression.

After infection and selection, the manipulated cells will no longer be harbouring propagatable virus, so they will no longer represent an infection hazard.

### Origin & function

Genes and mutant derivatives thereof, usually of human, mouse or Xenopus frog origin, encoding both growth control proteins and transcription factors, along with marker genes such as GFP and antibiotic resistance genes.

### Evaluation of foreseeable effects

Some of the virus vectors will lead to growth arrest and differentiation of mammalian cells, while there is potential to promote cell proliferation. Because of the presence of the
WPRE element in the lentivirus vectors, the lentivirus constructs might transform infected mammalian cells.

The main Hazard is potential infection of persons working in the lab by the GM virus, for which a Cat II containment level is adequate.

After infection and selection, the manipulated cells will no longer be harbouring propagatable virus, so they will no longer represent an infection hazard. Work with these genetically modified cells can be undertaken at a Class I level of classification.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Only micro-organisms and tissue culture cells are involved.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Full containment level 2 will be applied.

After infection and selection, the stably manipulated cells will no longer be harbouring propagatable virus, so they will no longer represent an infection hazard. Work with these genetically modified cells can be undertaken at a Class I level of classification.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Containment level 2 waste will be autoclaved (136°C for 10 min), before subsequent discharge down the drain into the public sewer or incineration. It is expected that this will give effectively 100% killing.

Is an emergency plan required according to regulation 20? 

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

The project is concerned with understanding the mechanisms involved in lineage selection upon stem cell differentiation in the epidermis.

The work requires the use of human keratinocytes which are difficult to transfect by standard methods. Recombinant retroviral infection is therefore needed as a means of delivering the appropriate cDNA constructs into the cells. Human keratinocyte cell lines will be derived from a reliable source of normal infant skin which has been surgically removed from screened healthy individuals having a negligible risk of contamination with adventitious human pathogens.

Host/vector system

Constructs will be cloned into the non-mobilisable viral plasmid vector pBabe (puro) and derivatives based on Moloney Murine Leukaemia Virus (Morgenstern and Land 1990, Nucleic Acid Research 18 3587-3596).

RNAi constructs will be cloned into pRETRO SUPER and its commercially available derivatives.

Origin & function

All DNA will be propagated in E Coli (e.g DH10B or derivatives).

The plasmid will first be transfected into an ecotropic packaging cell line, Phoenix-eco, and the retrovirus produced will be harvested over 1-2 days.

The helper-free retrovirus producer cell line Phoenix-eco, was developed by Dr. G. Nolan at Standfors University, (http://www.standfors.edu/group/nolan/index.html) and has
been used by over 2500 labs. Phoenix-eco cells express the gag-pol and envelope genes using different non-Moloney promoters to minimize both recombination and inter-typic recombination potential. This cell line has a history of safe usage.

This ectropic retrovirus will then be used to stably infect a second packaging cell line, GP + envAm12, which produces disabled amphotropic retrovirus. The mouse cell line GP +enAm12 has been widely used for the production of amphotropic virus. Tests for the safety of the GP + envAm12 packaging line showed no evidence for the generation of wild type virus and it has a history of safe usage. Markowitz, Goff and Bank. Virology 167, 400-406 (1998). Defective amphotropic virus would then be used for the infection of human keratinocytes. Transduced cell would be selected and maintained in medium containing an appropriate antibiotic before further use in experiments.

All genes will be inserted downstream of the viral LTR with the intention of achieving a moderate level of expression in recipient cells. Infection of keratinocytes will be by transfer of supernatant culture fluids with any concentration of the virus particles. Recipient human keratinocytes expressing the individual genes under study will be created which are likely to have some growth advantage or induce proliferation in an autocrine or paracrine manner.

Evaluation of foreseeable effects

Bacterial strains of Ecoli such as DH10B and its derivatives are not capable of colonising a healthy individual.

The amphotropic retrovirus is able to infect cells from a broad host range, including humans but can not replicate unless it recombines with endogenous retrovirus. Exposure of an individual to amphotropic retrovirus, by possibly a break in the skin, could result in a localised transfer of the pathogenic properties of the particular gene. None of the cell lines would be expected to remain viable outside the controlled culture conditions and we do not anticipate that any of the genetic manipulations we are proposing would alter this.

It is predicted that over-expression of oncogenes and signalling molecules could lead to an increased rate of cell division although tumour progression and disease in the whole organism is unlikely. The major possible source of hazard to the environment would be accidental escape of high titre virus solutions expressing cDNAs, which could then infect rodents. Retroviruses require close contact for their transmission and their survival in the general environment is poor due to their fragile envelope. The vector is non-mobilisable and the successful infection of a cell would include stable integration of the viral genes into host DNA. Although the amphotropic virus would be able to infect humans it could not replicate unless it recombined with endogenous retrovirus. Even then it is unlikely that expression of a single oncogene or inactivation of a tumours, as multiple genetic alterations (between 4 and 6) are required for inducing tumours, and a safeguard mechanisms exist impeding the accumulation of these alterations in the organisms (I.e.single events like Ras or myc expression instead of unrestrained proliferation, induce growth arrest or apoptosis) (Hanahan & Weinberg, Cell 100, 57-70;2000).

The use of sharps will be strictly controlled and avoided wherever possible. Needles and scalpels will not be permitted. Plastic Pasteur pipettes will be used for aspirating culture medium.

No animals or plants will be used.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste will be sealed in double autoclave bags, and autoclaved with steam at 127°C for 25 minutes. Effectively 100% kill. Autoclaves are rountinely monitored and records are kept by the department.

All liquid waste will be inactivated by treatment with Virkon at a final concentration of 1 % for 12 hours before disposal via the drains. Effectively 100% kill as determined by
The committee noted that the consequences are unknown of infection of cells of the worker by the modified virus, and have the potential to lead to cell proliferation. However, the committee felt that the risk is extremely low, because of the method of handling the virus including the avoidance of sharps. Secondly, the rate of infection is likely to be very low as the virus has a low infectivity. This is clear since in vitro infection is increased by optimisation of conditions using eg lipophilic substances. Thirdly, the virus genome will only integrate in proliferating cells, which are relatively rare in the skin.

Please enter comments on the GM safety committee on the risk assessment

For activities involving GMMs, describe the waste management measures which will apply to the activity

Waste disposal will be carried out according to an SOP. All solid waste is to be autoclaved before being placed in plastic theatre bins and taken to incineration by a licensed outside contractor. All liquid waste is disinfected using a Virkon solution and following the manufacturers instructions for maximum kill. Non-disposable labware is disinfected prior to re-use. All spills to be cleaned using propriatory reagents e.g. spill kits. No further, monitoring is deemed necessary due to the low/zero hazard presented by the cells involved.

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The committee pointed out that correct signage on the laboratories was required and that the control of visitors would be reviewed.

A member of the committee asked if this notification covered the use of embryonic stem cells. The committee was informed that the notification covered the genetic manipulation of induced pluripotent stem cells only, and that the ethical requirements for using embryonic stem cells fell under a different set of regulations.

A member of the committee asked if we needed to name our waste provider, and was told that the waste disposal must be carried out by a contractor licensed by the Environment Agency.

All liquid and dry waste will be sent for incineration by SRCL Ltd. All material for disposal will be placed in 30 litre yellow containers which are sealed prior to removal from the room where the class one material is being used. The boxes are then labelled to clearly identify them as GM waste and placed into wheelie bins for collection. The wheelie bin containing the GM waste is clearly marked to identify from other wheelie bins for transport to the incineration depot.

Any minor liquid spillages (<20ml) will be removed by soaking up with an absorbent wipe or for larger liquid spills by the addition of absorbent granules and transfer in to a yellow container. The area will then be disinfected with either Klericide A or B (a rotational disinfectant with demonstrated virucidal activity) according to the manufacturers instructions. After inactivation, the area will be wiped and the wipe placed into the yellow container. The area is then sprayed with 70% isopropyl alcohol and the wipe placed into the yellow container. The container will be sealed and sent for incineration as above.

Overall, I think the proposal is fine aside from concerns about the way the range of transgenes are assessed in Part 2. Numerous cDNA’s have been listed and covered with the comment that they are wild type and therefore not pathogenic. I don’t think this can be assumed. A number of these cell surface proteins have essentially an unknown function and so it would ne nwise to just use this coverall phrase for all of them particularly with respect to expression of these genes in cells which wouldn't normally express the particular protein. There should be som consideration of each of the genes with respect to safety.

Newcastle University Safety Office (Head of Safety) provide health and safety assistance as a consultancy service contract to Orla Proteins Ltd. As part of this contract University GMSC will provide advice to Orla on its GM risk assessments.
All contaminated materials, including waste destined for incineration, will be inactivated by autoclaving (100% kill) prior to disposal of waste or cleaning and recycling of reusable laboratory equipment, such as glassware. Autoclaves will be validated by annual thermocouple mapping and each run will be monitored using TST (Time, Steam, and Temperature) test strips (Albert Browne Ltd. TST class 6 emulating indicator 121°C for 20 min).

Y

Give brief details of the genetic modification safety committee

The committee is represented by the Site Operations Manager, the Energy Division Operations Manager and the Compliance Officer.

A full risk assessment has been carried out which covers the containment measures for the loading procedures at Novartis through to off-loading and processing at the Granox site. The committee are responsible for ensuring that all individuals with responsibility for this procedure have been fully trained to minimise the risks to both humans and the environment. The committee will carry out routine inspections and audits to ensure that the contained use procedure is adhered to and reviewed where necessary. Records will be kept of these audits.

The waste will be chemically pretreated at the suppliers premises. The treatment will involve the use of a chemical agent which will reduce the risk associated with handling the GM virus strains.

Please enter comments of the GM safety committee on the risk assessment

The risk assessment has been carried out by the members of the GM Safety Committee and includes all the appropriate measures to ensure that the risks to humans and the environment are minimised by robust contained used procedures. Advice was sought from Specialist Inspectors from the HSE Biological Agents Unit and Novartis to ensure that all the appropriate measures are included within the risk assessment.

Historical Significant Changes
Project Additional Information

Purposes of the contained use

The purpose of the contained use is to provide a secure auditable disposal route for Level 2 GMMs produced from the manufacture of influenza vaccines at the Novartis plant. There is approximately 120 tonnes of the Level 2 GMM material produced per week which is predominantly liquid. The material will be off-loaded in the Blood plant tanks which have a capacity of 300 tonnes. From here it will be pumped to tanks 1 & 2 which have a capacity of 140 tonnes each. From here is is pumped to the fluidised bed combustion plant. The material can also be off-loaded in the Empire building and pumped directly to tanks 1 & 2 prior to incineration in the fluidised bed combustion plant.

Recipient or parental organism

Various attenuated strains of influenza virus prepared by reverse genetics and used in the manufacture of influenza vaccine e.g. AH1N1 NIBRG X 121. The materials are of relatively low pathogenicity and pose a very low risk of contracting influenza to humans and animals as the strains have been attenuated to thrive in fertilised hen eggs as host organism. There is a very remote risk of reassortment with a circulating wild virus strain.

Host/vector system

Fertilised hen eggs. Liquid egg waste. Vector could conceivably be mammalin species, human, pig, rodents and birds.

Origin & function

Lab prepared attenuated influenza virus strains used solely for the manufacture of influenza vaccines.

Evaluation of foreseeable effects

Very low probability of viral proliferation in a human/animal host, generating influenza.

Production of conventional Fluvirin (Northern Hemisphere) vaccine is considered to be safe to human health due to attenuation of human pathogenicity by egg adaptation. This is achieved through the growth of the virus through a series of passages in eggs. The new strains of A California/7/2009 x PR8 e.g. NIBRG - 121xp A/California/07/09 will also have limited pathogenicity similar to conventional Fluvirin however slightly enhanced transmissibility as a new strain, this accounts for the higher level of control applied.

There is a remote possibility of secondary reassortent with normal human/animal viruses giving rise to new strains which are replication-competent in man/animal. Note: It is generally considered to be technically difficult to produce reassortants in vitro.

When such difficulties are considered, together with the contained handling and treatment used for the waste, then the chances of an A(H1N1) attenuated virus strain...
Infecting man and producing a secondary reassortant is EXTREMELY LOW. Containment procedures from off-loading through to destruction by incineration ensure that the risk to humans and the environment is minimised.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

see attached file *Granox Ltd Novartis GMO Draft Procedures Jan 10th*

The waste is pretreated at the suppliers facility with a chemical agent that will reduce the risks associated with the virus. It will be transported in a contained manner by road tanker. On receipt at Granox it will be directed to the Blood plant connecting hose will be flushed through with Virkon prior to disconnection and the contents pumped to the storage tanks. In the unlikely event that there is insufficient storage capacity in the Blood Plant tanks, the material will be off-loaded in the Empire Building and the contents will be pumped in an enclosed system to tanks 1 & 2 prior to incineration. Both tanker offloading areas are served by sumps. In the event of a leak or spillage the split material can be recovered from the sump and pumped directly back to the Blood plant tanks or tanks 1 & 2. Spill management procedures are in place and there is a high degree of physical containment of storage tanks and associated equipment. Working losses from tanks 1 & 2 breath directly via extraction to the secondary air system of the fluidised bed combustors. The liquid material is pumped from storage to the fuel holding bin mixed with solids and pumped into the fluidised bed reactors and combusted at 850 degrees celcius, yielding complete destruction of the material. Vermin controls in place. Availability of prophylaxis in form of vaccination.

Give brief details of the genetic modification safety committee

The material is owned by our client (Domantis Ltd) and their genetic safety committee provide advice to Cryo-Store in the form of risk assessments etc. Cryo-store itself, is a ultra low temperature storage facility that will simply store the supernatant material in sealed containers in a dedicated -80 freezer unit.
All materials stored at Cryo-Store remains the research property of the client and will be returned to their premises at some time.

For activities involving GMMs, describe the waste management measures which will apply to the activity:

For activities involving GMMs, describe the waste management measures which will apply to the activity

All liquid waste, disposable labware, gloves and materials used for the treatment of spillages are treated by autoclaving on a validated sterilisation cycle of 121° C for minimum of 15 minutes. The degree of kill is expected to be 100%. Standard autoclave indicators are used to check the cycle has completed successfully.

Prior to autoclaving all re-usable laboratory glassware is also treated with 2% Hycolin solution for 24 hours.

Surfaces are routinely disinfected with commercially available surface disinfectants.

Following autoclaving all materials are removed from the premises by a licensed contractor for final disposal via incineration.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

The GM Safety Committee have reviewed the risk assessments and are satisfied that all the hazards have been identified and the associated risks reduced to their lowest level.

**Project Additional Information**

**Purposes of the contained use**
The LPS antigen is used as a positive control in a commercial ELISA kit.

**Recipient or parental organism**
Salmonella minnesota

**Host/vector system**
Plasmid pFEN207

**Origin & function**
The origin of the recombinant is unknown. The strain was inherited from a previous company involved in the culture and production of ELISA kits.
The plasmid inserted into S. minnesota results in expression of a Chlamydial epitope on the LPS of the recombinant.
The LPS antigen is used as a positive control antigen in a commercial ELISA kit.

**Evaluation of foreseeable effects**
The recombinant S. minnesota has no increased pathogenicity as a result of the transformation.
S. minnesota mutants have been frequently reported in the scientific literature.
S. minnesota can be currently found in the environment in the form of human and animal carriers and is transferred via the fecal-oral route.
Salmonellosis is a self-limiting form of gastroenteritis.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All culture work involving the live organism will be carried out in a Class II Biosafety cabinet. All disposable equipment will be initially decontaminated in 2% hycolin* (non-phenolic based) for 24 hours, then autoclaved on a validated sterilisation cycle of 121°C for 15 minutes. The degree of kill is 100%. Standard autoclave indicators are used to check the cycle has been completed successfully.

Following autoclaving all materials are removed from the premises by a licensed contractor for final disposal via incineration.

*Hycolin composition: Alkyl dimethyl benzyl ammonium chloride, fatty alcohol ethoxylate, tetrasodium EDTA)

Surfaces are routinely disinfected with commercially available surface disinfectants.

The Salmonella culture is heat killed by boiling for 15 minutes. A viability test is then performed to confirm inactivation. The viability test consists of testing a sample of the heat killed culture in both broth and agar plate mediums. The viability is checked at 24 and 48 hours after inoculation for growth.

If there is any growth present, the culture must be re-boiled for 15 minutes then retested. The process is repeated until 100% kill is confirmed.

Y

Give brief details of the genetic modification safety committee

Chair of the committee: Head of Department

Other members of the committee include the teacher supervising the project, another member of teaching staff and two biology department technicians.

Note on the qualification of committee members: The head of department has previously acted as chair of a different genetic modification safety committee when working in a government research laboratory and two other members of staff hold PhDs in aspects of molecular biology.

Agar plates and all incidental waste including gloves will be autoclaved in a benchtop autoclave used at 121°C for 20 min (the autoclave will be serviced by the manufacturer every six months). Micropipette tips will be disposed of into disinfectant (0.25% sodium hypochlorite) and left overnight before autoclaving. Following autoclave treatment the waste will be sent for incineration as clinical waste.

PCR based site directed mutagenesis of well understood genes such as those encoding lysozyme.

For activities involving GMMs, describe the waste management measures which will apply to the activity

02/03/2022
Equipment, plasticware etc will be decontaminated by soaking in Virkon®, which will be prepared as directed by the manufacturer (10g/1L). Studies have already shown that Virkon® is effective at killing the phage and at the working concentration a 10^9 fold reduction in phage titre occurs immediately. This was the limit of detection of our assay and the actual reduction is probably significantly more. This work has not been published. Decontaminated waste will either be disposed of via the sink or stored in autoclave bags and then autoclaved within the Roslin Biocentre (RBC). Published studies have shown that it takes 6 min to inactivate phage at 100°C (dry heat, Jepson and March, 2004, Vaccine 22: 2413-2419) and we anticipate it would be quicker at the higher temperature of 121°C (used in autoclaving material in the RBC) with a wet environment. The autoclave is based in the RBC is used routinely to dispose of contaminated material. After autoclaving all waste is sent for incineration.

Several disinfectants have been tested with lambda phage vaccines and under normal laboratory conditions, when used at the recommended concentrations all standard disinfectants (e.g. Virkon® http://ww2.dupont.com/Products/en_TR/Virkon.html;) will inactivate the phage.

For general work volumes are low <500ml. All procedures are carried out in dedicated laboratories. Any spillages would be mopped up with blue roll and the contaminated towel disposed of into an autoclave bag. After each experiment the area would then be treated with Virkon® prepared as directed by the manufacturer, and then mopped up again. This process would be repeated twice to ensure that any spillage is decontaminated. Waste from any spillages will be autoclaved as soon as possible in the RBC. Where larger volumes of material are present, e.g. fermentor volume 3.5L, spillages would be cleaned up initially using the spill kit provided. The area would then be treated with Virkon®, prepared as directed by the manufacturer, and mopped up again.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Please enter comments of the GM safety committee on the risk assessment

The Committee reviewed both the Risk Assessment and Notification of Intention to Use form and made some general comments, which Dr *** will incorporate. It was agreed that the five Hepatitis B variants will be included in the same Risk Assessment form. Each of the variants are very similar.

### Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Yes

Give brief details of the genetic modification safety committee

Hypha Discovery has formed a 5-person GMSC to consider and address the risks of working with genetically-modified microorganisms (GMMs) in the company. The committee is chaired by a member of the company's management team, who has previously managed research involving GMMs. The other members of the committee are the company's H&S and Biological Safety Officer, who has over 30 years' experience of microbiological R&D including working with GMMs, the key research scientist responsible for the work involving GMMs and representatives of the departments where the work involving GMMs and their products will be handled. The committee meets as needed, and GMMs are an agenda item in the company's bimonthly H&S meetings. The GMMs to be used in the current project at Hypha have been, and will be, constructed in a laboratory at the University of London and advice on the risk assessment for the GMMs has been received from the leader of the group responsible for constructing the GMMs, a highly experienced researcher in this field.

</table>
Liquid waste, unwanted cultures and contaminated non-glass items are either autoclaved (chamber temperature at 128 degrees C and probe temperature at 121 degrees C for 30 minutes, with simulated load of fresh cold water [0.8l); expected degree of kill effectively 100%) using an autoclave that is validated annually with the simulated load, pressure and temperature probes, or inactivated by adding virkon to 1% and leaving for at least 4h (expected degree of kill effectively 100%, will be validated with the GMMs).

Contaminated non-disposable glassware is immersed in 1% virkon solution and left to soak for at least 4h. The inactivated washings are disposed of via the sewer drainage system.

Degree of kill achieved by autoclaving or 1% virkon exposure will be validated for these GMMs by streaking appropriate materials onto nutrient agar plates, incubating and examining for evidence of viability.

Inactivated, post-autoclave solid waste is double-bagged for removal via the general waste collection.
The GMM risk assessment has been presented to the GMSC with the following summary findings: the environmental and health risks are low and acceptable; the GMM host strains and their engineered products are of low risk and they will be handled by trained staff using procedural and containment controls and personal protective equipment. The GMMs are constructed in Escherichia coli and Streptomyces lividans host strains to express three-gene operons encoding cytochrome P450 (CYP), ferredoxin (Fd) and ferredoxin reductase (Fdr) genes from wild-type actinomycete bacteria. These will be stored and cultured for biocatalytic purposes by Hypha Discovery using whole-cell biotransformations or the via the preparation of cell-free enzyme extracts. This risk assessment is based on the first examples of GMMs expressing 3 different CYP/Fd/Fdr systems but is intended to cover subsequent GMMs expressing similar enzyme systems sourced from environmental organisms. The donor and recipient microorganisms belong to ACDP hazard group 1 and both of the recipient microorganisms have long histories of safe laboratory use. The GMMs resulting from the insertion of the three-gene CYP-Fd-Fdr operons are considered to have a low risk for environmental harm as they are unlikely to persist in the environment and the products of the inserted genes are enzymes that already exist in the environment. These enzymes are non-hazardous and their expression does not pose a risk to human health or increase the pathogenicity of the host organisms. The containment level required for handling these GMMs is level 1.

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities: [Y]

Give brief details of the genetic modification safety committee:

GMSC is constituted as follows:

- chair by Pharmaceutic Specialist supported by;
- associate director for Specialist Operations;
- advisory function provided by the EHS Manager who will also initially act as the Biological Safety Officer with expertise in GMO work and a background in Biochemistry/Genetics;
- managers from within the user department who will oversee the work;
- biological specialists from the user department;
- Employee Safety Representative from the user department;
- Other experts seconded as required e.g. Quality

**Other(s)**

Growth of well established class 1 eukaryotic GM lines expressing human and other genes

For activities involving GMMs, describe the waste management measures which will apply to the activity

All biological waste will initially be inactivated using a disinfectant, autoclaved on site and sealed in UN approved leakproof containers for off-site incineration by Patheon's Waste Management Contractor. Cell kill will be confirmed through validated processes.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

The GMSC reviewed the information available on 13 July and classified this work as class 1. No additional measures over and above that required by risk assessment are required. Staff carrying out GMO work will have the details noted on their medical records and any required changes in health surveillance will be undertaken.

Yes

Give brief details of the genetic modification safety committee

The genetic modification safety committee includes three members. One of these is a principal investigator in the Department of Plant Sciences whose expertise is in the areas of GMOs such as arabidopsis and green algae. The others are principal investigators in the Department of Applied Mathematics and Theoretical Physics (DAMTP) who have overall responsibility for the laboratories which carry out biophysical research. One of these is both the Safety Officer and the Biological Safety Officer in DAMTP.

Tick if confidential

Yes
1) For liquid cultures:
Treat with 0.1% sodium hypochlorite for 24h. This kills any microorganisms and thus can be safely dumped down the drain. This widely-used protocol also degrades any recombinant DNA. Occasional random plating of deactivated solution will be used to verify protocol's efficacy.

2) For contaminated solid waste:
2a) For solid agar plates and serological pipettes:
Place a heavy-duty biohazard bag in designated pedal bin. When bag is full it will be collected for incineration by Vetspeed, Ltd., a University-approved commercial waste disposal company.
2b) For contaminated pipette tips, polypropylene tubes, paper towels and gloves:
Place in a yellow designated tub which is lined with clear autoclavable bag. When bag is full it will be autoclaved at 135 C on site and disposed with regular trash in black bags.
2c) For glass chambers used in microscopy and other sharps such as needles (including syringe barrels): Place in designated sharps container. When the container is full it will be collected for incineration.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

In its first meeting, the safety committee suggested several simplifications and extensions of the risk assessment which have now been incorporated. These include disposing of GM Arabidopsis prior to bolting (seed production), thus eliminating concerns about seed dispersal. This also allows all earlier growth to be conducted in dedicated growth chambers in the laboratory. All experiments in this laboratory will be done on recently-germinated plants grown in Petri dishes. When necessary, seeds from mature plants will be obtained from the Plant Sciences Department, which has state of the art facilities for contained growth of mature plants.

In addition, the committee recommended that the risk assessment include procedures for decontamination of microscopes as a matter of general usage, and also in the event of spillage (reported to the Safety Committee)

Genetic Modification Safety Committee
(Sub-Committee of School of Health and Social Sciences Health and Safety Committee)

Role of the Genetic Modification Safety Committee.
To monitor and keep under review arrangements for the control of all activities involving genetic modification (GM). To meet the statutory purpose to advise on risk assessments made in compliance with the regulations as described in the Genetically Modified Organisms (Contained Use) Regulations 2000 To provide reports, give advice and make recommendations to the HSSC Health and Safety Committee about any matter relating to the control of experimental genetic modification. To advise on safety training requirements.

Membership
The committee shall be composed of:

a. Head of Department of Natural Sciences (Chair)
b. The University Biological Safety Officer
c. Associate Dean Research, School of Health and Social Sciences
d. Professor of Cancer Biology/Person responsible for supervision and safety of GM activities on the premises
e. 2 nominees from academic staff in the department of Natural Sciences
f. Chair of the Natural Sciences Ethics Sub-committee
g. Technical Manager
h. Representative from Estates and Facilities Management Services (EFMS)
i. Elected Health and Safety Officers, UCU/UNISON

Co-opted members:
Additional members may be co-opted by the sub-committee as felt appropriate by the committee.

Quorum
A minimum of 5 members to include the Chair (or deputy), the Biological Safety Officer and the person responsible for supervision and safety of GM activities on the premises.

Frequency of meetings:
The full sub-committee shall normally meet twice per year (normally June and September). Extra meetings may be scheduled if required.

For activities involving GMMs, describe the waste management measures which will apply to the activity

- **Solid Waste** - All GM solid waste will be treated on site typically by autoclaving. Subsequent disposal by normal laboratory routes. Clinical waste and sharps bins are removed for disposal by authorised contractor and official waste disposal notes generated. There may be instances where chemical disinfection by Virkon™ (following manufacturer's defined usage) is the method of preference.

- **Sharps boxes** - All sharps boxes containing GM materials will be autoclaved on site and then disposed as per solid waste (above).

- **Liquid waste** - All GM liquid waste will be treated on site, either by autoclaving or chemical disinfection using Virkon™. Larger volumes will subsequently be discarded via drains; smaller volumes may be discarded within primary containers via solid waste route.

- **Surface disinfection** - All lab surfaces where GM activities have taken place will be disinfected after use, using Virkon™.

- **Spillages** - Any spillages involving GM materials will be disinfected using Virkon™.

- **Autoclaves** - All autoclaves are subject to annual service and calibration by competent engineer (Priorclave contract: ISO9000 certification and UKAS approval as a calibration laboratory). Each run cycle on the waste autoclave produces a printout for validation.

**Purposes of the contained use**

This project is focused on the identification of metabolic, regulatory and structural genes in Salmonella enterica serovar typhimurium that are involved in successful colonization of plants, in particularly tomatoes and lettuce. Proliferation of Salmonella within the tissue of these plants is responsible for the number and severity of produce associated gastroenteritis outbreaks increasing, so we are coming to recognize that we know little about the ecology of Salmonella and enterovirulent Escherichia coli outside of their animal hosts. It is clear that these human pathogens can contaminate roots, stems, vegetables, and/or post-harvest production stages. The goal is to define the ecology of Salmonella during colonization within fresh produce by the identification and characterization of Salmonella "plant-specific" genes and host responses. This information will help to establish which
mechanisms Salmonella needs in order to colonize fresh produce and overcome physical barriers and host restrictions on colonization. Any vegetable and fruit may be susceptible to the proliferation of Salmonella. We expect to work with tomato, lettuce, spinach, cantaloupe, onions, peppers, pears, apple and other vegetables and fruit eaten raw.

The aim of this project is to determine the role of Salmonella transcriptional regulators, capsule formation genes and other genes important during Salmonella proliferation in fresh produce. Our targets are the -4000 genes and proteins of Salmonella. In addition, we expect to modify proteins to screen possible catalytic sites or binding regions involved in Salmonella proliferation in plants.

Strong evidence exists in the literature, supported by the PI's preliminary results, which suggests that there is a key role of different regulatory and structural genes during plant infection. The basis for the proliferation in vegetables is divisible into roughly three general categories: direct acting genes, regulatory genes, and recognition genes.

Salmonella mutants will be produced and their expression will be studied during proliferation in plants. Mutants will be generated by routine mutagenesis protocols, such as the Datsenko and Wanner "One step" protocol. According with the PI's preliminary results, initial experiments will be carried out by generating mutants with deletions in rcsA and rcsB genes, two transcriptional regulator involved in capsule and biofilm formation of Salmonella in tomato. We expect to expand this research to other genes.

Gene expression will be analyzed in vivo by the recombinase-based in vivo expression technology (RIVET). The fitness of the mutants compared to the wild type will be tested in different varieties of vegetables. If we learn that a mutation shows a modified fitness, further complementation of the deleted genes will be produced to restore the phenotype and confirm the contribution of each gene during plant infection.

Recipient or parental organism

The following strains represent what we intend initially, but we may wish to take this further to other parental strains of Escherichia coli and Salmonella enterica as research proceeds.

| E. coli | DHSa F- (lacZYA-argFjU169 recA1 endA 1 hsdR17 supE44 thi-1 gyrA96 relA1. This strain is used to host plasmids for the genetic modifications. |

Example of mutants that will be generated according with the recipient strains.

Construction of versatile low- copy-number vectors for cloning, sequencing and gene expression
All the strains and plasmids that will be used in this project are tools routinely used for genetic studies in Salmonella enterica sv. Typhimurium 14028 and Escherichia coli. They are widely used by the scientific community and currently published in peer-reviewed scientific literature. The following references are included to provide detailed information on the origins and intended use of the genetic material involved.

**Bacterial mutagenesis. Plasmids pKD3, 4, 46. Gene deletion.**

Plasmid pCP20:

Salmonella enterica sv. Typhimurium 14028 and Escherichia coli DH50:

RIVET (recombinase-based in vivo expression technology) construction:

In RIVET, the promoter of interest is cloned upstream of a promoterless bicistronic InpR-lacZ operon in a genetic background that contains res-tet-res sites cloned in a neutral site of the genome. When the promoter of interest is activated, this drives expression of tnpR. TnpR acts upon "res" sites and excises the tetracycline marker cloned within them. The loss of the tetracycline resistance then creates a heritable marker of gene expression.

**Evaluation of foreseeable effects**

The bacterial strains will become kanamycin, ampicillin or chloramphenicol resistant.

**Health and Safety**

Executive

The plant tissue(s) infected with GMO Salmonella or E. coli will NOT be used to generate any GMO plants.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste containing GMO materials will be autoclaved before final disposal as clinical waste (including sharps waste). Liquid waste will either be autoclaved as above or will be chemically disinfected with 1% Virkon (final concentration). Please see Risk Assessment for more details.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The GM Safety Committee made a number of procedural recommendations, all of which have been incorporated into the final risk assessment (attached). After consideration, it was agreed was that this work fits comfortably within the definition of a class 2 activity.

Date of Significant Change
Project Additional Information

Purposes of the contained use
To study the replication and immunobiology of Hepatitis B virus in vitro by:

1. Transfecting plasmids containing HBV-DNA in to hepatoma cell lines with transient viral expression.
2. Culturing cell lines that have HBV integrated into their genome and produce full infectious virus in culture.

Recipient or parental organism
Recipient organism: The plasmid containing HBV-DNA will be transfected into 2 human hepatoma cell lines - HepG2 and HUH-7. These cells pose no risk to workers.

Parental organism: A cell line which has the HBV genome integrated into their genomic DNA - HepG2215 cells. These cells produce full infectious Hepatitis B virions in culture. The foreseeable risk in handling these cells is the innoculation of the worker with the cells or the culture supernatant and thereby infecting the worker with HBV.

The most hazardous risk to workers would be of infection by the virus therefore -

1. All workers will be vaccinated against HBV and have proven protective antibody titres prior to commencing the work.
2. All work will be carried out in our containment level 3 (CL3) facility
3. As the major risk of infection is through needle stick injury there is a NO SHARPS policy in the CL3 laboratory

If control measure failed the most severe risk would be inoculation of the worker with the virus.

Host/vector system
Hosts: Bacterial - E. coli: Disabled host
Vector: PUC 19 plasmid: non-mobilisable, BOM (-)/NIC (-), MOB (-), TRA (-) and with ampicillin resistance

There is no foreseeable effects with this host/vector system.

Origin & function
The gene sequence to be inserted into the plasmid is the full HBV-DNA extracted from human patients infected with HBV.

This sequence will be inserted into the PUC19 plasmid vector and transformed into E. coli (DH5-alpha). This DNA will then be extracted and transfected into the HepG2 and HUH-7 cell lines. These cells will be cultured and experiments to monitor viral replication will be carried out.

Evaluation of foreseeable effects
The foreseeable effect of this project, if control measures failed is the infection of the person handling the cell line with HBV.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All waste generated in the containment level 3 facility will be autoclaved in the double-ended autoclave.

1. Solid waste:
This includes laboratory plastics, laboratory overalls, gloves, paper wastes etc will be collected in double autoclave bags within a sealed container and when 3/4 full loaded into the ‘dirty’end of the autoclave which is within the CL3 laboratory. Once the cycle is complete the worker the waste is collected from the ‘clean’ end of the autoclave situated outside of the CL3 facility. The receipt from the autoclave is checked to ensure the run has passed (100% kill) and the waste is collected into yellow bags for incineration.

2. Liquid Waste
The liquid waste is decontaminated with Virkon powder - using 1g of powder per 100 ml of culture medium. This has been tested and proven to be 100% effective against Hepatitis B virus.

Project Additional Information

Purposes of the contained use

To study the interactions in-vitro between human cells of the immune response and HCV by:

1. Transforming bacteria with pJFH-1 plasmid containing full HCV sequence of a patient with fulminant hepatitis.
2. Transscribing HCV RNA from this plasmid, pJFH-1
3. Transfecting this HCV RNA, by electroporation, into a human hepatoma cell line HUH-7 to produce infectious HCV viral particles
4. Co-culturing the lymphocytes isolated (from control subjects and patients with HCV infection) with the JFH-1 transfected hepatoma cell line
5. Assessing viral kinetics and virus-specific immune responses

Recipient or parental organism

Recipient Organism 1: The plasmid pJFH-1 will be transformed into competent E.coli Bacteria DH5a which will be grown in LB medium. The amplified plasmid will be extracted from the E. coli.

Recipient organism 2: RNA transcribed from the plasmid pJFH-1 containing full length HCV cDNA will be transfected into Huh-7 human hepatoma cell line. These cells will produce full infectious HCV virions in culture. The foreseeable risk in handling these cells is the inoculation of the worker with the cells or the culture supernatant and thereby infecting the worker with HCV.

The most hazardous risk to workers would be of infection by the virus therefore:
1- All the work will be carried out in our containment level 3 (CL3) facility
2- As the major risk of infection is through needle stick injury, there is a NO SHARPS policy in the CL3 laboratory.

If control measure failed the most severe risk would be inoculation of the worker with HCV.

Host/vector system

Host 1: E. coli DH5a strain
Host 2: HUH-7 human hepatoma cell line
Vector: Full length HCV RNA
There are no foreseeable effects with this host/vector system.

**Origin & function**

HCV RNA will be transcribed and purified from the JFH-1 plasmid and used to transfect Huh-7 cells. The transfected cells will be cultured in presence or absence immune cells and experiments to monitor viral replication and host immune responses will be carried out.

**Evaluation of foreseeable effects**

The foreseeable effect if control measures failed is the infection of the worker with HCV.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the class of activity. (Measures & Justification)

None

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All the waste generated in the CL3 will be autoclaved in the double-ended autoclave.

**Solid waste:**

Include, gloves, suits, plasticware, paper waste will be decontaminated by autoclaving. Solid waste will be collected in double autoclavable bags within a sealed container. When 3/4 full, the bag will be loaded into the 'dirty' end of the autoclave which is situated within the CL3 and a 'discard' cycle (134°C for 25 min.) will be run. Once the cycle is complete, the worker will collect the autoclaved bag from the 'clean' end of the autoclave situated outside the CL3. The receipt form of the run will be checked to ensure the run has passed and the waste will be collected into yellow bags for incineration.

**Liquid waste:**

The liquid waste will be decontaminated by autoclaving. Empty containers will be half filled with the contaminated liquid waste. The containers will be disposed in 3/4 full double autoclavable bags which will be autoclaved using the 'discard' cycle (25 min at 134°C).

2. HCV is sensitive to heat treatment and temperatures from 56°C or higher can be used for complete loss of infectivity therefore the treatment of the waste load at 134°C for 25 min will completely inactivate HCV.

3. The receipt form of the run will be checked to ensure the run has passed.

4. The waste will be collected into yellow bags, closed and removed for incineration.

Contaminated laboratory surfaces and equipments are disinfected with a 40% 1-propanol solution. The surfaces will be treated with the solution for 5 min. then wiped clean.

- **Date of Significant Change**: Consented

**Project Additional Information**

**Purposes of the contained use**

MAPK and NF-κB pathways control cell survival, and this control is crucial for different biological function including apoptosis, proliferation and survival. Studies aimed at understanding the molecular mechanisms of these pathways of intracellular signalings might unveil crucial target for anti-inflammatory and anti-cancer therapies.
To perform our studies, we will generate several DNA plasmids containing Flag- or HA-tagged genes and transformed them into the E. coli bacteria in order to amplify the DNA. The purified DNA allows us to conduct transfection assay in cells. We prepared glycerol stocks of the transformed bacteria. These GMMs are essential tools to perform studies aimed at gaining better understanding of the basis for the MAPK-mediated control of cell survival.

We are planning to perform the following procedures involving GMMs:

1) Transforming the E. coli strain DH5a and other K12 E. coli strains with vectors pcDNA3.1, pSRa, pMIGR1, pSUPER, pVSV, pLentiLox 3.7, pENV, pMDL, pREV, pWPT, R8.91, MD2G, pMT2T, pRSV, pBluescript, pET, pWPI. With the aim of amplifying the DNA vectors;

2) Transfecting standard mammalian cell lines (including 293T, HeLa, NIH-3T3, HuH-7, HepG2, Hep3B, PLC5, Huh-28, Mz-ChA-1, TFK1, HF60, HuCCT-1, H69, SG231, RPMI8266, JNJ3, MM1S, ) with mammalian expression vectors (in which cells would you use the bacterial vectors?);

3 Transducing standard mammalian cell lines (such as 293T, HeLa, NIH-3T3, fibroblasts, etc) with non-replicative variants of lenti-viruses (such as pLentiLox, pWPT, pWPI, etc.) or retro-viruses (such as pMIGR1, pSUPER, etc.) The lenti-viral vectors pLentiLox and pWPT contain the woodchuck post- transcriptional regulatory element (WPRE), which has been demonstrated to have some oncogenic properties, whilst the retro-viral vectors pMIGT1 and pSUPER do not contain this element. Both lentiviruses and retro-viruses are completely unable to replicate into the transduced cells, because the packaged viruses lack Gag, Pol, and Env, which are the genes necessary for the viral replication, and the transduced mammalian cell lines do not express Gag, Pol and Env proteins.

These tools and procedures will give us the possibility to perform cellular studies aimed at gaining a better understanding of the basis for the MAPK- and NF-kB mediated control of cancer cell survival.

**Recipient or parental organism**

- E. coli strain DH5a and other K12 that present high efficiency strain for cloning and subcloning.
- Mammalian cell lines: 293T, HeLa, NIH-3T3, HuH-7, fibroblasts, and other standard mammalian cell lines.
- Fibroblasts and other primary cells (such as lymphocytes, hepatocytes, etc.) from mice, including KO and Tg mice.

**Host/vector system**

LentiLox 3.7 (PLL3.7) or other lentiviral vectors are designed for transducing cDNA or short-hairpin RNA (shRNA), which includes RNA interference in a wide range of cell types, tissues and organisms. We will use these vectors to infect and efficiently silence proteins in mammalian cells and their progeny, as described in (Rubinson and Dillon et al, Nature Genetics, 2003). These lentiviruses are pseudo-coated with VSV-G and are capable of infecting human cells, and thus present important biosafety issues. CL2 conditions should be used at all times when handling lentiviral preparations, transected cells or the combined transfection reagent.

For the purpose of using vectors in a BL2 laboratory and eliminate potential harm, the odifications described in section 1.24 have been made to prevent viral replication.

More information regarding these widely used techniques for transducing mammalian cells can be found at [http://www.sciencegateway.org/protocols/lentivirus/index.htm](http://www.sciencegateway.org/protocols/lentivirus/index.htm)

**Origin & function**

The purpose of the use of these plasmids in the host organism is to propagate and obtain recombinant proteins produced directly into the host organism.
The mammalian cells transfected and transduced with the different vectors will be expressing as well as silencing MAOK and NF-κB proteins. The lenti-viral vectors pLentiLox and pWPT used for transduction have oncogenic properties.

The following modifications have been made to prevent viral replication:

1. Packaging vector lacks both LTRs and has no viral packaging signal.
2. The following viral genes have been deleted from the packaging vector: env, tat, rev, vpr, vpu, vif and nef.
3. Rev is supplied in trans on a different vector (RSV-Rev)
4. The vector expressing the packaged viral genome has a self-inactivating LTR (TATA box deletion and expresses no viral gene products.
5. Envelope, in this case VSVG, is expressed on a separate vector.

LentiLox 3.7 (pLL3.7) or other lentiviral vectors are designed for transducing cDNA or short-hairpin RNA (shRNA), which induces RNA interference in a wide range of cell types, tissues and organisms. We will use these vectors to infect and efficiently silence proteins in mammalian cells and their progeny, as described in (Rubinson and Dillon et al, Nature Genetics, 2003). These lentiviruses are pseudo-coated with VSV-G and are capable of infecting human cells, and thus present important biosafety issues. CL2 conditions should be used at all times when handling the virus and/or the transduced cells. All decontamination steps should be performed using 2% virkon and 70% ethanol 1% SDS Gloves, lab coat should be worn at all times when handling lentiviral preparations, transfected cells or the combined transfection reagent.

For the purpose of using these vectors in a BL2 laboratory and eliminate potential harm, the modifications described in section 1.24 have been made to prevent viral replication.

More information regarding these widely used techniques for transducing mammalian cells can be found at http://www.sciencegateway.org/protocols/lentivirus/index.htm

Evaluation of foreseeable effects

N/A

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste:
Includes gloves, suits, plastic ware, paper waste will be disinfected by autoclaving. Solid waste will be collected in double autoclavable bags within a sealed container. When 3/4 full, the bag will be loaded into the autoclave and a 'discard' cycle (134° for 25 min.) will be run. Once the cycle is complete, the receipt form of the run will be checked to ensure the run has passed and the waste will be collected into yellow bags for incineration.

Liquid waste:
The liquid waste will be decontaminated by virkon (2.5g tablet/500ml infectious liquid waste) for at least 30 minutes, followed by disposal in the sink. Virkon has been tested.
by independent laboratories and been proven to be effective against a total of 20 virus families (including HIV/AIDS), 43 bacterial genera and 27 fungal genera.

Surfaces
Contaminated laboratory surfaces and equipments are disinfected with a 1% virkon solution for at least 10 min before being wiped dry. The surfaces will be further cleaned with a 70% Ethanol solution.

The Institute of Hepatology genetic modification safety committee (GMSC) has received and approved project GMOO2. The GMSC is happy for project GMOO2 to start at the Institute of Hepatology once authorized by the HSE.

Please enter comments on the GM safety committee on the risk assessment
