Premises Conditions

Tick to confirm that you have established a GM safety committee to advise on risk assessments of contained use activities

Give brief details of the genetic modification safety committee

The Trust genetic modification safety committee has been formed as part of the process of initiating the first clinical trial of cancer gene therapy at James Cook University Hospital. The inaugural meeting was held on June 5th 2007, when Terms of Reference were agreed. The remit of the committee is to carry out a risk assessment of all newly emerging therapeutics involving genetically modified organisms within the Trust. A minimum of two committee meetings are to be held, (or more frequently if required) and reporting arrangements are to the Research Governance Committee, with copy to Organisational Safety/Risk Committee for information. Membership of the committee, which is chaired by the Trust's Medical Director, includes the following; Chair of Risk Committee, Chair of Clinical Effectiveness Sub-committee, Clinical Director - Oncology, Chief of Service - Pathology, R&D Director, Research Network representative, Non-executive Director, Patient & Public Representatives, Infection control, Representative from facilities. Staff side representation, Pharmacy representation.

For activities involving GMMs, describe the waste management measures which will apply to the activity

Contaminated materials including syringes, vials, swabs and materials used for cleaning will be placed in sharps bins and disposed of by incineration.

Tick to confirm that you are attaching a summary of the risk assessment

Tick if you are claiming exemption from disclosure for sections of the risk assessment

Please enter comments of the GM safety committee on the risk assessment

It was agreed that procedures within the Trust would ensure that containment at the required level would be provided. The first version of the risk assessment had stipulated that clinical waste be double bagged, sealed with a red identification tie and identified as GMO waste by indelible pen, however, it was agreed by the committee that waste would instead be discarded into burn bins and sent for incineration as per normal hospital procedures. This was supported by guidance obtained by the representatives from Facilities and Risk Management. The risk assessment was therefore amended to reflect this change.

Project Ref 1/01.1

Date Ackn'd 31/01/2001 02/03/2022
CU2 Project Title FOR INVESTIGATIONS OF MOLECULAR MECHANISMS IN TUMOURIGENESIS
Class 2 1-50 litres
**Project Additional Information**

**Purposes of the contained use**

For investigations of molecular mechanisms in tumourigenesis

**Recipient or parental organism**

The E coli host will be E coli K12 derivatives - HB101, XL1B, DH5α, Y1088, 1089, 1090, C600 and the non-K 12 strain, BLR (rec derivative of BL21)

The source of insect cells will be the SF9 cell line. Mammalian cell lines will include a number of well characterised (immortalised) cell lines of human or murine origin (see appendix in attached risk assessment). For some experiments, primary embryo fibroblasts (rat and mouse) will also be used.

**Host/vector system**

The plasmid backbones are all pUC based and are non-mobilisable. They include: for bacteria; pUC 12, 18, 19, pSP65, pBSBluescript, pCR..., pTOPO-PCR; for mammalian cells; pA64, pT109, pSt5, pCITE, pGY25, pLk-neo, pBABE, pcDNA3; for insect SF9 cells; pVLH6.

Transduction of mammalian and insect cells will be accomplished by DNA-mediated transfection. None of the mammalian vector systems will be used to generate replication defective (or competent) viruses.

**Origin & function**

The inserted sequences (see appendix in attached risk assessment) comprise a number of genes encoding mammalian proteins with either known or strongly suspected oncogenic potential. The perceived hazard arises from manipulation of naked (oncogenic) DNA.

**Evaluation of foreseeable effects**

The oncogenic sequences (see appendix in attached risk assessment) are capable of encoding biologically active proteins which are potentially pathogenic to humans. Some of the prokaryotic and eukaryotic vector systems are optimised for high level expression of protein. The oncogenic sequences are highly unlikely to alter the pathogenicity or properties of the bacterial host cell. Enforced expression of such sequences in mammalian cells will, in some instances, affect the malignant properties of the cells. Sequences encoding biologically active oncogenic proteins are classified as carcinogens for which containment level 2 is appropriate. Neither the DNA, encoded protein, bacterial or mammalian transfectants are likely to have any deleterious effect on the environment. The GM microorganisms are incapable of surviving outside of the laboratory environment. All laboratory procedures will follow good microbiological practice. GM microorganisms will be manipulated in a Class II Microbiological safety cabinet. Written records of staff training will be obtained and checked before commencement of work by individuals. Handling and manipulation of naked DNA will require the wearing of disposable gloves. Mammalian cell cultures for DNA transfection procedures will be handled in a Class 2 cabinet. Where possible, sharps will be avoided in

02/03/2022
all operations. Disposable plasticware (pipettes especially) will be used for mammalian cell culture.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

For preparation of plasmic DNA/protein, bacteria will be collected by centrifugation and lysed. Liquid waste material will be rendered non-viable by decontamination overnight with Virkon (1%) and autoclaving prior to sink disposal. Any contaminated solid waste (e.g. contaminated disposable plasticware, agar plates, DNA) will be bagged and autoclaved prior to disposal as normal solid waste in accordance with laboratory practice in the laboratory. Disposal and decontamination of materials used in mammalian cell culture will be done essentially as described above for bacteriological work. The efficacy of autoclaving procedure will be validated as follows:

a) From electronic printout schedule of autoclave cycle parameters to ensure successfully completed autoclave cycle on each occasion.

b) From visual monitoring of internal control "Browne Sterilizer Control Tubes" (Albert Browne Ltd UK) on each occasion.

c) From quarterly monitoring of bacteriocidal performance following a standardised protocol in which a 100ml flask of L-broth innoculated with 10 to the power 7 E coli HB101 (or similar K12 derivative strain) is subjected to a single autoclave cycle. Maintaining sterility of the culture, the flask is then incubated at 37°C on an orbital shaker for 4 days. Under sterile conditions, 0.5ml aliquots of the culture are then plated out in triplicate onto standard L-broth agar plates which are monitored for evidence of bacterial growth after overnight incubation at 37°C.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Copies of the Professor@'s GM project and risk assessment were circulated to members of the University of Essex Genetic Modification Committee for consideration prior to a meeting on the 19th of January 2001. The project was subsequently approved by the committee and signed by the Chair.

Previous studies, such as microarrays, have identified a number of candidate genes that may be critical regulators of normal haematopoietic cells development. This project seeks to evaluate the role of these genes in murine model systems using genetic knockdown of forced expression experiments. Briefly, murine cell populations will be transduced using lentiviral vector, retroviral vectors or transfected with normal plasmids containing shRNAs or the cDNA of the gene of interest. The cells will then be functionally evaluated using a combination of in vitro and in vivo techniques, the latter involving transplantation of cells in to mice.

Recipient or parental organism
- Lentivirus parental organism- Human Immunodeficiency virus-1 (HIV-1) is classified as ACDP hazard group 3

Host/vector system
- Recombinatt lentiviral vectors pseudotyped with VSV-G envelopes, will be used with 293T cells
- MSCV used with Phoenix A and Phoenix GP cells

Origin & function
Candidate regulator genes for normal haematopoietic cell development will be obtained in the form of cDNA originating from murine genomic or RNA libraries.

**Evaluation of foreseeable effects**

The recombinant viral vectors are disabled vectors. They have had regulatory and accessory genes deleted, ensuring that viral particles produced in packaging cell lines are replication incompetent. Thus whilst they pose an infection risk they are unable to initiate further rounds of replication/infection cycles. The probability of seroconversion is minimal (Details of the origins and deletions within the MSCV and lentiviral constructs are given in appendix 1 of the risk assessment).

Whilst the VSV-G envelope extends the cellular tropism and confers greater stability and environmental survivability, it is thought there is NO significant increase in the likelihood of transfection via the airborne route of exposure. Control measures utilised are appropriate to guard against the associated residual risks.

The target genes do not encode viral specific protein, nor do they interfere with known activities of the virus and so are unlikely to have any effect upon the basic nature of the virus.

Whilst the VSV-G envelope confers greater stability and environmental survivability, control measures employed will minimise risks to the environment. These control measures include rendering all solid or liquid waste inactive within the building (either by autoclaving or use of Virkon); work carried out in containment 2 laboratories or home office inspected animal facilities; work within class 2 microbiological safety cabinets, routine disinfection of work surfaces; all staff are suitably trained in GM work and employing the necessary risk control measures.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Transduced cells will be transplanted in to mice by intravenous injection. This procedure will be carried out by specifically trained staff only.

The Biological Resource unit (BRU) houses all mice in sealed individually ventilated cages. All handling is within cabinets. The rooms are secured with sealed drains and close sealed doors. There are open ducts within the room. Corridors are sealed with electronically locking flush fitting doors. All corridor risers are sealed. The unit is inspected regularly by Home Office inspectors to ensure that it meets the required standards.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Solid waste materials (e.g. gloves, plastic ware, cell pellets etc) are rendered inactive by autoclaving (100% kill) in a validated machine located within the same building. Subsequently the solid waste enters the yellow bag clinical waste route and goes for incineration. The autoclave is performance validated by 12-point thermocouple tests on an annual basis. Records are kept on site.

Virkon is routinely used as per the manufacturers recommendations -

- Solid surfaces are disinfected with 1% Virkon solution.
- Plastic ware that can be effectively disinfected is treated with 1% Virkon for a minimum of 1 hour prior to incineration. Any contaminated glassware is treated with 1% Virkon solution for a minimum of 1 hour prior to cleaning.
- Liquid waste (culture and medium) is disinfected by the addition of Virkon to give a 1% final working concentration. 2% or 3% solutions of virkon are used for buffered solutions. A minimal contact time of 1 hour is allowed prior to disposal to sewers (as per manufacturer’s recommendation).

**Is an emergency plan required according to regulation 20?**

- [N] No

**If yes, tick to confirm that it is attached to this form**

- [N] No

02/03/2022
A query as to the risk to workers from any free virus whilst administering transduced cells to mice was raised. This is answered in appendix 4 of the risk assessment.

The committee agreed it was a GM Class 2 project.

### Purposes of the contained use

To understand the general process of cell motility which plays an important role during development and progression to cancer metastasis.

### Recipient or parental organism

Standard mammalian cell lines, typically HeLa, RK13 and BSC-1.

### Host/vector system

Vaccinia virus, shains Ankara, IHDJ, MVA and WR.

### Origin & function

pBS SKII containing a selectable marker replacing vaccinia gene of interest with upstream and downstream flanking regions to delete the entire gene. Additionally, point mutations, partial deletion or GFP versions of the vaccinia gene of interest will be replaced back into the original gene locus.

### Evaluation of foreseeable effects

In most cases it is likely that pathogenicism of the virus will be reduced and that it would lose the ability to replicate in some host cells. However, some modifications will be made to attempt to restore wild type function to the virus. It is unlikely that any modification made in these experiments would increase the pathogenicity or host range specificity of the GMO over wild type vaccinia virus.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be treated, for at least 12 hours with Virkon to a final concentration of at least 2%. This will then be discarded to drain. Solid waste will be autoclaved prior to leaving the building to be incinerated as per clinical waste. It is unlikely that any viable GMMs would remain after this treatment, and in any case would require specialist conditions for growth.

Is an emergency plan required according to regulation 20?

The Committee queried whether some vaccinia strains were classed at ACGM level 1. The possibility of vaccinia infection must be controlled by local rules and COSHH assessment.

The Committee confirmed the risk assessment as Containment Level 2 and HSE will need to be notified. There is a possibility of risk to human health and one member of staff with psoriasis will not be working on this project. Some large scale work might require facilities in the 2B1 suite. The risk to the environment was considered to be effectively zero. The project was classified as Class 2.

Project Additional Information

**Purposes of the contained use**

This work concerns the analysis of the entry, sorting and retrograde axonal transport of avirulent poliovirus type 1 Sabin 1 strain. This study will aim to clarify the mechanism of internalisation and retrograde transport of poliovirus and its exploitation as a vector for intracellular targeting of spinal cord neurons for gene therapy purposes.

**Recipient or parental organism**

Primary culture of mammalian spinal cord motor neurons. These cells are terminally differentiated and do not divide in culture. They are prepared from rodent (mouse or rat) embryos by isolating the spinal cord and then purifying in vitro the dissociated tissues. These cells are maintained in vitro for 1-2 weeks and are pathogen free.

**Host/vector system**

We will be using a recombinant Sabin 1 strain expressing green fluorescent protein (GFP) as a fusion capsid protein. The Sabin 1 strain has been used in the western world as a vaccine against the virulent poliovirus type 1 (which causes a paralytic poliomyelitis in humans as result from an invasion by circulating poliovirus into the central nervous system). The virus strain is not reported to contain DNA replication sequences.

**Origin & function**

This recombinant Sabin 1 strain will be produced by our collaborators. The virus will be produced in a unique strain of trans-complementing cells, purified in their laboratory and sent frozen to us. No further expansion, purification or titration of the virus will be done at the Lincoln's Inn Fields Laboratories who have a profound experience in producing and manipulating poliovirus will be a visiting Fellow at the Lincoln's Inn Fields Laboratories for all the duration of the project (expected 3 months). We will receive purified, titrated aliquots of virus, which will be stored frozen in a safety freezer in the CONTAINMENT LEVEL 2 at the Lincoln's Inn Fields Laboratories.

**Evaluation of foreseeable effects**

When needed, a virus aliquot will be incubated with living rodent spinal cord motor neurons, microinjected or not with the mammalian expression plasmid encoding the human poliovirus receptor in the CONTAINMENT LEVEL 2 facility. Upon viral entry and removal of free viral particles, uptake and retrograde transport will be monitored in real time by time-lapse fluorescent microscopy. In selected experiments, compartmented cultures of motor neurons will be used to monitor the passage of the virus particle through the cell body.

All the cultures used with the virus are primary and only short-term experiments are programmed (30 min - 6 h). Following incubation and imaging, cells will be disposed following safety rules or fixed with paraformaldehyde/glutaraldehyde and then processed for immunolocalisation studies. The fixing procedure will be different depending upon the technique used to visualise the final specimens. In case of electron microscopy, we will use 4% paraformaldehyde 2% glutaraldehyde overnight at room temperature whereas for light microscopy we will adopt 4% paraformaldehyde 30 min-1 hour at room temperature or 100% methanol at -20 degrees C for 30 min.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
The work will be carried out in compliance with Good Laboratory Practice and local safety rules for GM work in a Containment level 2 facility. Protective clothing will be worn. GMM contaminated material and liquid waste is inactivated in 1% Virkon and disposed after 24 hr, as per manufacturer's validated instructions; or autoclaved at 121 degrees C for 30 minutes prior to incineration by validated means through licensed contractor. Accidental spillages of liquid waste will be inactivated with 2% Virkon.

Project Ref 2/04.2

Date Ackn'd 25/03/2004
CU2 Project Title USING RECOMBINANT RETROVIRUSES TO EXPRESS POTENTIALLY
Class 2
CultureVolClass2 < 1 litre
CultureVolumeClass3-4
Project Additional Information

Purposes of the contained use
To examine the phenotypic effects of specific gene products in primary human cells and to generate immortalised cell strains with defined genetic alterations.

Recipient or parental organism
The intention is to introduce human cDNA sequences into cultured human cells.

Host/vector system
The cDNAs will be transferred into existing retroviral vectors (e.g. pBABE-puro) that are based on the Moloney murine leukaemia virus. The vectors lack the viral pol and env genes and the residual part of the gag gene is non-functional. They will be packaged into replication incompetent particles by transfection of the LinXA packaging cell line (a derivative of 293T). The particles will then be used to infect human fibroblast strains (e.g. W138, Hs68, IMR90) or primary cultures of human epithelial cells (e.g. prostate, mammary glad, skin keratinocytes). The infected cell will be selected in medium containing appropriate antibiotics (either puromycin, neomycin, hygromycin or blasticidin).

Origin & function
The genetic material will be cDNAs encoding a variety of cellular proteins that are already well characterised and in the public domain, including Ras, Myc, hTERT, Bmi1, Cbx7 and the E6 and E7 proteins of human papilloma virus 16. These have the potential to promote tumour formation (i.e. oncogenes). Alternatively, we will use short hairpin sequences that can suppress the expression of tumour suppressor genes such as INK4a, ARF, p53 and pRb. Combinations of these agents should be sufficient to convert a normal cell into one that has the hallmarks of a cancer cell.

Evaluation of foreseeable effects
The expectation is that the human cells expressing appropriate combinations of cDNAs will be capable of indefinite proliferation in culture, and will acquire an ability to form anchorage independent colonies in semi-solid medium. However, they are not expected to represent a hazard to human health as none of the cells used are capable of colonising a healthy individual and the we do not expect the manipulations to alter this. The cells will not be expected to release infectious viral particles. The retroviral vectors are incapable of replication because of removal of the viral pol and env genes and the LinxA packaging cell line has the requisite genes either integrated in the genome or expressed from BPV based episomal vectors that contain no regions of homology with the MMLV based vectors. Three independent recombination events would be required to produce a replication competent virus and the cell system has been tested exhaustively for virus production with consistently negative results.
The amphotropic virus particles are capable of infecting human cells, but will not replicate. In the extremely improbable event that the vector acquires replicative potential by recombining with endogenous retroviral sequences, this single agent is unlikely to cause deleterious consequences in the host. It is estimated that between 4 and 6 separate alterations are necessary to generate a tumorigenic cell. Retroviruses are also inherently unstable and very high titres would be required to produce a persistent infection in an immunologically competent individual. The primary dangers in working practice are expected to be the formation of aerosols and use of sharps. We propose to carry out all manipulations in a Class II microbiological safety cabinet following GLP and any additional local safety guidelines appropriate to this work. There will be no use of sharps and no sonication of solutions, which may contain virus.

None of the cell lines would be expected to be capable of remaining viable outside of the controlled culture conditions used and we do not anticipate that any of the manipulations we are proposing would alter this.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste will be deactivated in a Virkon trap (1%) and disposed after 24 hr, as per manufacturer's validated instructions. All solid waste will be autoclaved at 121.0°C for 30 minutes prior to incineration by validated means through licensed contractor. All waste form retrovirus work will be handled separately from other tissue culture waste. Accidental spillages of liquid waste will be deactivated with 2% Virkon. We do not expect the scale of low titre viral work to exceed more than 500 ml of amphotropic virus.

Is an emergency plan required according to regulation 20? [N]

02/03/2022
We will transform C. albicans strain CAI4 (uri-) with different modifications of PACT1 vector that contains the gene for uridine synthesis (uri+).

The transformants will be selected for growth in uridine deficient media and will be used for infecting mice to study both the Ovalbumin-specific immune response and to analyse the immune response against fungal infections.

Pathogenicity of wild type C. albicans: mycosis of superficial layers of skin or mucous membranes (oral thrush, vulvovaginitis, paronychia, onychomycosis, interigo); ulcers or pseudomembranes in esophagus, gastrointestinal tract or bladder; hematogenous dissemination may produce lesions in kidney, spleen, lung, liver, prosthetic cardiac valve, eye, meninges, brain. However, this microorganism is endogenous (part of the normal flora) and can be spread by contact with excretions of mouth, skin, and faeces from patients or carriers.

Origin & function
1) PACT1 - GFP, a yeast encoding yeast enhanced GFP.
2) PACT1 - OVA, the same vector but encoding for chicken ovalbumin.
3) PACT1-GFP-OVA, the same vector but encoding a fusion protein GFP-Ovalbumin.

The transformants will be selected for growth in uridine deficient media and will be used for infecting mice to study both the Ovalbumin-specific immune response and to
Analyse the immune response against fungal infections.

Chicken Ovalbumin and GFP (and other fluorescent variants) are non-pathogenic proteins. Furthermore the gene products would not be expected to cause any hazard to human health.

(Currently we plan to use GFP for tracking fungi within the mice, however, vectors using RFP, YFP or CFP may need to be generated).

**Evaluation of foreseeable effects**

The modification of the fungi by these plasmids would not be expected to change any characteristics such as host range, tropism or pathogenicity.

Non-GM work with wild-type Candida albicans is already in progress at Cancer Research UK at containment level 2. An appropriate COSHH risk assessment has been completed and this will be applicable to the modified Candida too. Please read attached COSHH assessment.

The proposed transgenic modifications will not alter the pathogenicity or otherwise of the Candida, so the fungi present no extra danger than if they were unmodified. If the latter are class 2, so are the modified fungi.

The plasmid construction is class 1 and can be undertaken at containment level 1, but any work with Candida must be undertaken at containment level 2.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

For only GMMs - application for any derogation from full containment for the class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The work will be carried out in compliance with good laboratory practice and local safety rules for GM work in a containment level 2 facility.

GMM contaminated material and all liquid waste will be deactivated in a Virkon trap (1%) and disposed after 24 hr, as per manufacturers instructions; all solid waste will be autoclaved at 121C for 30 minutes prior to incineration by validated means through licenced contractor. Accidental spillages of liquid waste will be deactivated with 2% Virkon.

Is an emergency plan required according to regulation 20? N

## Project Additional Information

### Purposes of the contained use
To protect the laboratory workers and the environment from any potential harm.

### Recipient or parental organism
Cultured mammaham cells.
These are characterised cell lines with strict growth requirements and are incapable of growth outside the culture flask.

### Host/vector system
Retroviral vectors or transfection vectors (eg pcDNA3).
The retroviral vectors are defective for replication with no gag, pol or env genes. All vectors are non-mobilisable.

### Origin & function
cDNA libraries derived from human or mouse cells. Hopefully the libraries will be representative of all human cDNAs. Our interest is in those expressing DNA repair and cell cycle checkpoint genes.

### Evaluation of foreseeable effects
The human cDNA library could potentially include harmful genes such as ancogenes. These will however represent a low percentage of the total cDNAs in the library.
The packaging line contain no helper virus and helper functions are encoded by separate segments. The vectors are non-mobilisable and defective for replications. The inserts are however under strong promoters. The insert will not change the host range of the vector.
The mammalian recipient lines have strict growth requirements and are incapable of growth outside the culture flasks.
Taken together the environmental and human risks are minimal.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

- Liquid waste will be destroyed using Virkon. Disposable plastics destroyed by autoclaving.
- See attached risk assessment for further validation.
- Virkon has been verified to be effective against retroviruses and we consider will inactivate our low litres.

**Historical Date of Additional Info**

**Significant Change ID**

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

To protect the operator from transfer of bacterial genetic material and to prevent the transfer of bacterial genetic material to other microorganisms.

**Recipient or parental organism**

Superantigen genes will be expressed in E. coli BL21 cells. These are widely used competent cells which require category I handling once transformed. Toxin genes will be under the control of an IPTG inducible promoter and will only be expressed in the presence of IPTG. IPTG inducible expression results in all metabolic activity being channelled to toxin production, resulting in a biologically unfit microorganism. The GMO would behave in the environment as a SL2I E.coli. It would have no survival advantage over other bacteria.

**Host/vector system**
Commerically available vector systems will be used. Individual risk assessments are attached detailing the particulars of each vector system. See next page for details or foreseeable risks.

**Origin & function**

Superantigens are naturally occurring exotoxins of Streptococcus pyogenes and Staphylococcus aureus. The toxins' biological functions in bacteria are unknown but toxicity in human disease is considered to be due to polyclonal T cell activation. Superantigen genes are widespread and prevalent in wild type Staphylococcus aureus and Streptococcus pyogenes, and therefore the addition of these genes into E. coli cells poses no additional risk to the environment or human health, and in fact due to the IPTG inducible expression described above, risk to human health from these toxins is diminished.

The toxin when expressed forms insoluble granules which would be biologically inert. The toxin is harvested by cell lysis under stringent denaturing conditions (6M urea) and only refolds to an active form under meticulous refolding as denaturing is reversed. Studies have shown that laboratory exposure to these superantigens poses absolutely minimal risk to human health (Rusnak, 2004 Emerging Infectious Diseases Vol10 Issue 9 p1 544-I 549).

We will use the recombinant superantigens as prototypes in experiments aimed at defining novel approaches to identification of superantigens in biological material.

**Evaluation of foreseeable effects**

Hazards associated with expression vector systems:
The plasmid contains an antibiotic (ampicillin) resistance gene. Resistance to ampicillin is already wide-spread amongst strains of E. coli causing human disease. As such, introduction of this gene into E. coli for experimental purposes poses no significant risk.

Although the risk of transfer of genetic material to other species always exists when undertaking this sort of work, risk in this case is in reality very low. The expression of superantigen is tightly controlled by the IPTG inducible promoter. Furthermore the SEK will be expressed as insoluble protein complexes and as such would be biologically inactive without purification.

To further minimise the risk of this work, it will be conducted under category 2 conditions. The sterile nature of the category 2 laboratory conditions with scrupulous disinfection and cleaning protocols will ensure that the risk of transfer of this genetic material to other bacterial species is absolutely minimal.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

n/a

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

These measures have been approved by the University of Sussex Genetic Modification Safety Committee from applications:
Expression of recombinant streptococcal superantigens in E. coli BL21 cells
Expression of recombinant streptococcal SEK in E. coli BL2I cells
Expression of recombinant streptococcal SEJ in E. coli BL2I cells
Copies of these are attached.

Once competent E. coli cells have been transformed with complete expression vectors, expression of superantigen genes can be carried out under category I conditions. This is due in part to the IPTG inducible expression of superantigen genes rendering the E. coli cells biologically unfit, as described above, and in part to the findings published by Rusnak et al (Rusnak, 2004 Emerging Infectious Diseases Vol0 Issue 9 p1544-1549) indicating that laboratory exposure to superantigens poses an absolutely minimal risk to human health, in accordance with other category 1 reagents and procedures.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Chemical disinfection of Category 2 biosafety cabinets using 70% IMS. Liquid waste will be neutralised using 10% Virkon solution before autoclaving at 121 degrees C for at least 15 minutes. Autoclave printouts will be checked following each run, and if unsatisfactory the cycle will be repeated. Following autoclaving, liquid waste will be disposed of as standard laboratory waste.

Solid waste such as agar plates will be autoclaved inside plastic bags within a metal container at 121 degrees C for at least 15 minutes. Autoclave printouts will be checked
following each run, and if unsatisfactory the cycle will be repeated. Following successful autoclaving, solid waste will be disposed of as standard laboratory waste. Attempts to grow bacteria from waste disposed of in this manner have proven unsuccessful on numerous occasions, indicating a killing efficiency of >99.999%.

Is an emergency plan required according to regulation 20?

Historical Significant Changes

Historical Date of Additional Info
This project aims to define factors that determine virulence in mycobacteria; particularly Mycobacterium tuberculosis, and Mycobacterium bevis. Systems studied include genes involved in metabolism, global gene regulation, stress responses, intracellular survival and in vivo growth. The aim is to produce strains of mycobacteria that have had genes inactivated either by removal or interruption with transposon sequences, over-expressed, or under the control of inducible promoters. The mycobacterial mutants produced will be characterised in vitro and in macrophage models of infection to learn about the biological function of the target genes. The long term aim of this research is to understand mycobacterial virulence, allowing the development of new control measures for tuberculosis, including new drugs and beller vaccines.

The Genus Mycobacteria (gram-positive, rod-shaped bacteria of the Family Actinomycete) consists of more than 40 recognised species, which can be placed into two main groups: i) fast growing non-pathogenic bacteria such as M.smegmatis (commonly used for genetic studies of mycobacteria), M. fortuitum (an environmental mycobacteria found in water sources that may occasionally cause disease in immuno-compromised people ), and M.abscessus (an environmental mycobacteria that may colonise the lungs of cystic fibrosis patients); and ii) the slow growing mycobacteria which consist of the major human pathogenic bacteria which include the TB complex that cause tuberculosis (consisting of M.tuberculosis, M.bovis, M.africanum, M.microti), M.leprae (leprosy) and the M.avium complex (opportunist infections in HIV-infected people). Mycobacteria can infect most species of animals including rodents, birds and fish. M.avium paratuberculosis is also responsible for Johne's disease in cattle and is increasingly thought to be associated with Crohn's disease (a human inflammatory bowel disease). Another slow growing mycobacteria is M.ulcerans, that causes Burul' ulcers in parts of Africa. Other human pathogenic mycobacteria include M.kansasii, M.scrofulaceum and M.gordonae. Mycobacterium tuberculosis (M.tuberculosis) is by far the most important human pathogen in the Genus Mycobacterium in terms of morbidity and mortality and sub-clinically infects a third of the world's population, killing 1.3 million people each year (WHO, Global tuberculosis report 2013). Primary tuberculosis (TB) infection occurs in the lungs resulting in a chronic granulomatous inflammation and eventually cavitating lesions that release fresh bacilli into the lung. Hemoptysis (coughing blood) can occur caused by rupture of the lung blood vessels. The space-occupying granulomatous inflammation eventually overtakes the normal lung tissue and gaseous exchange is increasingly compromised (tuberculous bronchiectasis). Inflammation of the lung parenchyma causes pleural pain. Death is often due to secondary infections and severe loss of lung function. Cough is the most common symptom alongside systemic manifestations including fever, weight loss and malaise. M.tuberculosis can infect most other parts of the body including, the bones (Pott's Disease), the lymph nodes (miliary T8 or of the neck nodes, scrofula), the gut, the skin (lupus vulgaris), genito-urinary tuberculosis, and the meninges (T8 meningitis). The clinical expression of disease is quite varied and depends on factors that include both host and microbe related characteristics. The risk of acquiring T8 in the UK is relatively small, yet possible, and varies as to socia-economic and geographic factors as well as ethnic and cultural factors. Nearly 20% of all T8 in London results from recent transmission of M.tubercuJosis to new cases; the rest is either imported from other countries or is reactivation T8 from prior exposure (often 50 years ago or more) when T8 was more prevalent in the UK. Over 95% of people exposed to M.tuberculosis do not develop
disease, but form a primary lesion in the lung (Gohn’s foci) and the infection is suppressed for years without clinical symptoms (latent tuberculosis). There is a 10% lifetime risk of reactivating this latent infection for immuno-competent people, whereas people with HIV/AIDS have a 5% per annum risk of reactivation. Other risk factors (associated with a compromised immune system) that might increase the likelihood of reactivation of TB include alcoholism, chronic renal failure, diabetes, some cancers, drug abuse, malnutrition, immuno-suppressive drugs. Active pulmonary disease has a 60% mortality over 5 years without treatment, however effective drug therapy is available. A combination of four antimicrobial drugs taken over six months is recommended as treatment, which has a 5% per annum relapse rate due normally to poor patent compliance. Multiple drug-resistant strains of M. tuberculosis have been identified that are most often resistant to two of the first line drugs (Isoniazid and Rifampicin). Treatment requires alternative antimicrobial combinations and prolonged duration (WHO, Global tuberculosis report 2013). There are >20 second line antimicrobial drugs used to treat drug-resistant TB, and a future pipeline of approximately 18 novel compounds at various stages of clinical development.

In addition to effective drug therapy, there is a vaccination against tuberculosis. Mycobacterium bovis BCG (BCG) is a heavily attenuated strain of Mycobacterium bovis, generated through repeated passage by Calmette and Guérin between 1908 and 1921. Since then this strain has been the basis of a live TB vaccine used on the human population throughout the world and has been shown to have multiple (>128) gene deletions compared with virulent M. tuberculosis (Behr, M.A et al. 1999 Science, 284: 1520-1523). There is no harm to humans except in immunocompromised states (such as HIV progression), in which case disseminated mycobacteriosis could occur. BCG is effective as a vaccine to minimise childhood disseminated tuberculosis. Its efficacy to prevent human tuberculosis varies from 0% to 85%, depending on the study and area of the world. Hypersensitivity to M. tuberculosis is usually tested by a skin test (Mantoux or Heaf test). This shows prior exposure to mycobacterial antigens, but it is impossible to distinguish BCG-vaccinated individuals from cases of sub-clinical TB infection. Acute TB often gives a powerful skin test reaction due to enhanced hypersensitivity, but results in negative tests in 25% of cases. Interferon-Gamma Release Assays (IGRA) specific for TB antigens may be used to distinguish BCG-vaccinated from TB-infected individuals and to monitor immune responses to TB antigens over time. BCG vaccination cannot be assumed to produce protective immunity to TB in adults, but because of the safety history of BCG in the past 50 years with billions of doses given without serious consequence, BCG vaccination is still offered in many countries. In some low and middle income countries, where the burden of TB is highest, and in parts of the UK, BGG is given at birth where it provides good protection against childhood disseminating TB and TB meningitis.

M.tuberculosis and M.bovis are classified by ACDP as biohazard group 3 organisms requiring level 3 containment; all work on this organism is conducted within specialised containment facilities with strict guidelines and following rigid protocols in Class I biological safety cabinets to avoid inhalation of M.tuberculosis particles. Transmission is via the respiratory route (droplet nuclei of < 5 microns) with an infectious dose of less than 3 bacteria. This low infectious dose suggests a high risk of laboratory-acquired infection via the inhalation route. M.bovis may also cause disease via the oral route of infection (historically through the ingestion of unpasteurised milk from infected cattle). Direct contact with intact skin is not considered a route of transmission for M. tuberculosis or M.bovis. Trans-cutaneous inoculation is possible but very unlikely to result in infection for M.tuberculosis. It is possible that needle stick injuries could result in disseminated TB. The route of infections for the GMM will be the same as for the parental strain. The infectious dose for M.tuberculosis via the respiratory route is less than 3 bacilli, as this represents the largest cluster of bacilli that can pass the alveoli entrance. For oral or intestinal acquisition, a theoretical infectious dose is considered to be 1 bacillus, but more likely to be thousands or more. The infectious dose for GMMs will be the same as, or greater than (i.e. requires more bacteria to infect, therefore less transmissible), the parental wild-type.

Mycobacterium tuberculosis was included on schedule 5 of the Anti-terrorism, Crimes and Security Act 2001, but removed in 2012.
Gene knockouts and knock-ins in Mycobacteria are generated in three ways: (1) by a system of self-cloning through the introduction of homologous genes with or without selectable markers, (2) using expression vectors with selectable markers which may be used to induce target gene expression, and (3) by the introduction of transposons to deactivate chromosomal genes by interrupting normal gene function.

Homologous recombination
The introduction of altered "self" genes back into the donor to create modified recipient organisms may be regarded as self-cloning. Because the pathogenic mycobacteria are classified as Hazard Group 3 organisms these procedures are included in this risk assessment. Natural genes in wild type mycobacteria will be replaced with the same gene which has been mutated or part-deleted, or a gene from a highly closely related species (i.e from M.bovis into M.tuberculosis, or vice versa) by homologous recombination, in this case DNA sequences already present in mycobacteria will simply be re-introduced. The gene function will thereby be abolished or modified and the resulting GMM will either have A) no change in properties (since the gene may not be necessary for growth in the laboratory model tested, or that the gene has several copies in the genome, or there may be other genes that compensate for the action of the lost gene); B) will have reduced ability to grow or cause disease due to the loss of gene function. In these cases (A and B) the direct hazard of the inserted gene product results in a GMM that is less than or equal to that of the parental wild-type organism. C) There are several hypothetical possibilities which may result in the phenotype of the GMM being altered in favour of increased pathogenicity: (i) By deleting a repressor gene for virulence determinants may result in genes normally only expressed during a particular phase of infection (to cause damage or immune evasion) being switched on permanently. This may at first sight imply an increased hazard, but this is unlikely as the mechanism of pathogenicity in M.tuberculosis is based on the ability to switch multiple sets of genes on and off at specific times and in specific locations. So, expression of, for example, a haemolysin gene (that is normally required for escape from the macrophage killing mechanisms), if expressed prior to arrival at an intracellular location, may make the bacteria more likely to be recognised and killed by the immune system, since such factors are likely to be highly antigenic. (ii) Deletion of a growth repressor; this is highly unlikely as the slow growth rate of mycobacteria is considered to be controlled by the law of mass action and the number of ribosomes as a ratio of the availability of tRNA species and translation initiation factors. Thus multiple genetic manipulations would be required to influence growth rate. There is also no evidence to suggest that increased growth rate would lead to an increase in TS virulence. (iii) Deletion of a dominant antigen involved in immune recognition, thereby allowing the bacteria to avoid recognition and cause more disease. This is again highly unlikely as immune recognition is a multiple-antigen-dependent event and research has shown that TS deletion mutants of dominant antigens (e.g. ESAT6) have reduced or unaltered virulence, not increased.

In consideration of all these possibilities, all M.tuberculosis (and M.bovis) mutants are treated as hazard group 3 organisms, exactly as the donor or wild-type recipient. GMM pathogenicity is unlikely to increase, and infectious route highly unlikely to change, therefore there is no increased exposure hazard risk and no increased disease risk. This is because many of these changes arise by natural mutation in the environment and many uncharacterised clinical strains of M.tuberculosis may well have such altered phenotypes.

(1). Vector systems for homologous recombination
During the cloning strategies to produce GMM by double cross-over homologous recombination, host mycobacteria are made that contain a suicide plasmid (pNIL: a simple plasmid with no mycobacterial origin of replication based on a mycobacterial plasmid pALS000, which contains genes for the maintenance of the plasmid, multiple cloning sites and selectable markers. i.e. simple, non-hazardous vectors of mycobacterial origin). These plasmids are able to replicate in laboratory strains of Escherichia coli (to allow vectors to be generated), however these plasmids cannot replicate in mycobacteria (Parish, T et al. 2003, Infect Immun; 71:1134-40). The plasmid will contain the mutated wild type gene
and will become partially integrated into the host chromosome after a single cross-over event. These single crossover GMM constructs will not have hazards greater than the wild-type. However the Single cross-over recombinants will retain the plasmid with a hygromycin resistance gene selectable marker. Hygromycin is commonly used as a selective marker in mycobacteria; it is not used as a disinfectant nor an antibiotic in clinical settings. The hygromycin resistance gene and the rest of the plasmid DNA is then lost in the second step of GMM generation as a result of counter selection (using sacB and sucrose selection). Selection for a second cross-over event removes plasmid DNA from the mycobacterial chromosome, stably inserting the mutated TB gene. The resulting GMM retains no plasmid DNA and an altered copy of a naturally-expressed TB gene.

(2). Vector systems for complementation and controlling gene expression
Complementation of the GMM will be generated using a plasmid (pAGAN, a simple, non-hazardous mycobacteria plasmid vector related to pNil and pAL5000) containing the wild-type TB gene (Parish, T et al. 2003, Infect Immun; 71:1134-40). The plasmid contains a mycobacterial origin of replication, so it can be sustained in the mycobacterial cell. The vector also has selectable antibiotic resistance marker genes for hygromycin and kanamycin. In a second strategy, plasmids that are able to integrate into the mycobacterial chromosome are used to stably insert a mycobacterial gene (Blokpoel, Me et al. 2005, Nucleic Acids Res; 33:e22). These plasmid vectors also contain inducible promoters to enable the expression of the inserted gene to be controlled or measured using antibiotic or fluorescent markers (Andreu, N et al. 2010, PloS One; 5:e10777), for example, tetracycline, which is not used to treat tuberculosis. These vectors may result in the over-expression of mycobacterial genes, however these genes are naturally expressed by mycobacteria, and since pathogenicity in TS is multifactorial these complemented mutants will have hazards the same as or less than the parent wild-type organism.

(3). Transposon mutagenesis.
A system of transposon mutagenesis will be used where a kanamycin/hygromycin resistant transposon with counterselectable markers, for example sacB (Sassetti, eM et al. 2003; Mol Microbiol; 48:77-84), will be inserted into the mycobacterial genome, inactivating gene function by interrupting the coding strand. Hygromycin is commonly used as a selective marker in mycobacteria, it is not used as a disinfectant in the laboratory or as an antibiotic in a clinical setting for mycobacterial infections. These modified mycobacteria will be treated in the same way and at the same level of containment as the recipient wild type organism.

Origin & function
The origin of genetic material (excluding vector sequences and antibiotic resistance markers discussed in the section above) will be from mycobacteria. Inserting functional or inactivated genes naturally expressed in pathogenic or nonpathogenic mycobacteria. Specific combinations are detailed below:
1. Single or multiple gene inactivation in M.tuberculosis or M.bovis (containment level three) using modified M.luberculosis (or pathogenic or non-pathogenic mycobacteria) gene sequences. GMO containment level three.
2. Single or multiple gene expression (complementation/inducible expression) in M.tuberculosis or M.bovis (containment level three) using modified M.tuberculosis (or pathogenic or non-pathogenic mycobacteria) gene sequences. GMO containment level three.
3. Single or multiple gene inactivation in M.bovis BeG or non-pathogenic mycobacteria (containment level two) using modified M.bovis BeG (or non-pathogenic mycobacteria) gene sequences. GMO containment level two.
4. Single or multiple gene expression (complementation/inducible expression) in M.bovis BeG or non-pathogenic mycobacteria (containment level two) using modified M.bovis BeG (or non-pathogenic mycobacteria) gene sequences. GMO containment level two.
5. Single or multiple gene expression (complementation/inducible expression) in M.bovis BeG or non-pathogenic mycobacteria (containment level two) using modified M.tuberculosis or pathogenic mycobacteria (containment level three) gene sequences. GMO containment level three - note change in containment level. No systematic attempt will
be made to specifically restore M.bovis BeG virulence through multiple genetic manipulations. The function of genetically-modified genes will vary. Virulence in pathogenic mycobacteria is a multifactorial process that does not depend on a single virulence factor (evidenced by greater than 100 gene deletions between the pathogenic M.tuberculosis and vaccine strain M.bovis BeG). Pathogenicity in M.tuberculosis is likely based on the ability to switch multiple sets of genes on and off at specific times and in specific locations during infection. Therefore the manipulation of a single gene is unlikely to increase mycobacterial virulence, unlike some other microbes where expression of a single toxin gene may dramatically affect pathogenicity.

**Evaluation of foreseeable effects**

**Hazards arising from the alteration of existing pathogenic traits**

**Health and Safety Executive**

The pathogenicity of mycobacteria is not fully understood but is widely shown not to be a single gene function; rather mycobacterial virulence is the result of co-ordinated expression of multiple genes. Virulence and pathogenicity of mycobacteria is determined by host-pathogen interactions, with host immunity playing a central role, which is dependent itself on human genetics, nutritional status and other factors. Thus disease, or the potential to harm, is a complex and multi-factorial process, in which single genes play synergistic roles with numerous other genes. The regulation of mycobacterial gene expression and the correct timing of switching genes on and off during infection is therefore most likely to control mycobacterial virulence. This is clearly demonstrated by M.bovis BGG, which is regarded as a regulatory mutant and the abolished virulence is due in part to the inability to regulate genes correctly. Therefore, it is unlikely that the deletion or insertion of a mycobacterial gene will increase the virulence of the recombinant mycobacteria, measured by two or more models of infection. It is remotely possible that mutants in regulatory genes may cause certain virulence genes to be permanently switched on (with the possibility of enhanced virulence in some models of infection), but the current evidence suggests that virulence requires correct temporal and spatial expression of multiple genes within the host making this scenario unlikely. There are also naturally occurring mutants of wild-type M.tuberculosis with only slight differences in virulence, therefore if all mutants are treated as wild-type, no extra hazards will arise. Others researchers have showed that cloning M.tuberculosis genes into non-pathogenic M.smegmatis did not result in a virulent phenotype as tested in mice. This experimental evidence further supports the view that pathogenicity is not a single gene function.

Accidental exposure to GM M.tuberculosis or M.bovis is unlikely to give rise to infection, with disease occurring in 5% of exposure cases (as for the wild type organism). Infection with GM bacilli will be treatable in the same way as the wild type organism with antibiotic treatment for clinical tuberculosis taking 6 months. Drug resistance can occur naturally as a result of random mutation in certain genes, e.g. rpoB, inhA (Gagneux S et al, 2007, Lancet Infect Dis; 7(5):328-37). Such point mutations that lead to drug resistance in M.tuberculosis occur at very low frequency in nature and are only selected for by exposure to antibiotics. If these resistant genes are transferred, the recipient GM bacilli will also be drug resistant and therefore more difficult to treat. Multiple drug-resistant M.tuberculosis strains remain classified as Hazard Group 3 pathogens as they are not more difficult to acquire, nor is disease any more severe. Drug-resistant M.tuberculosis simply requires different combinations of antibiotics to treat infection.

Hazard of sequences within the GMM being transferred to related micro-organisms

Horizontal (lateral) transfer of genetic material in mycobacterial populations is minimal. Mycobacterial plasmids have been identified (Le Dantec, Get al. 2001, Journal of Bacteriology; 183:2157-2164) and conjugal transfer observed in M.smegmatis (Parsons, L.M et al. 1998 Molecular Microbiology; 28:571 · 582). However, the importance of natural horizontal transfer in mycobacteria has not been established and is likely restricted to the environmental-type mycobacteria. Plasmids have not been found naturally in the human pathogenic mycobacteria, M.tuberculosis, M.bovis or M.leprae. Introducing DNA into mycobacteria is a very inefficient process in the laboratory with very low frequencies of recombination. So horizontal transfer would be a very rare event even within the Genus.
Mycobacterium. Transfer of mycobacterial genes from the GMM to other micro-organisms would be highly unlikely, firstly to occur, and secondly if it did, to alter the properties of the recipient bacteria to increase its hazard. Harbouring extra genomic material in bacteria is usually associated with decreased fitness thereby producing a counter selective effect against any recombinant (Gagneux, S et al. 2006, Science; 312:1944-6). Exchange of genes by recombination or complementation between M.tuberculosis and M.bovis is possible and may well be encountered. There are approximately 20 extra genes in M.bovis compared to the lab strain of M.tuberculosis H37Rv in addition to -68 genes that are deleted (Behr, M.A et al. 1999, Science; 284: 1520-1523). However, these genes are also present in clinical isolates of M.tuberculosis. M.bovis also has multiple point mutations compared with M.tuberculosis, as does M.bovis BGG. As M.bovis has a wider host range than M.tuberculosis, but more restricted disease in humans, gene exchange will not result in any increased virulence for either species, and both will remain as hazard group 3 organisms. However, introduction of M.tuberculosis or M.bovis genes back into M.bovis BGG may restore full virulence to BGG by replacing the deleted genes that represent the difference between M.bovis BGG and M.bovis. Such gene replacement will not however overcome the multiple point mutations in BGG that may also contribute to attenuation of BCG. Because the basis for the BeG attenuation is not fully understood, we will assume that it is possible to revert BCG back to a phenotype with increased virulence. As such, any gene introduction into M.bovis BGG from M.tuberculosis or M.bovis that includes one or more of the deleted (putatively attenuation responsible) genes, will have the potential to increase virulence and the resulting GM BGG will be classified as a potential Hazard Group 3 organisms and experiments performed under GL3 conditions (as per wild type M.tuberculosis). Re-introduction of BGG genes back into BeG will not result in any reversion of attenuation and will remain as Hazard Group 2. During laboratory manipulation of recombinant mycobacteria, any mycobacterial cultures found to be contaminated are chemically disinfected (and autoclaved in the CL3 laboratory) and the plastic/glassware autoclaved (see section 12). The risk of accidentally-transformed contaminating micro-organisms not being contained is therefore negligible.

The likelihood that the GMM could cause harm to human health

The likelihood that GM mycobacteria could cause harm to human health is high in the case of the pathogenic mycobacteria such as M.tuberculosis. The pathogenicity of numerous single gene knockouts has been shown to be only partly attenuated in animal models of infection. Complemented mutants of M.tuberculosis re-establish the normal virulence of wild-type organisms. However, gene knockout strains of M.tuberculosis are also being investigated as possible vaccine candidates (Smith, O et al. 2001, Infection and Immunity; 69: 1142-1150) and auxotrophic mutants of M.tuberculosis have been shown to be avirulent even in immuno-compromised mice. Therefore some gene knockouts will be non-pathogenic, but many will remain potential human pathogens. The chance of a knockout mutant being more virulent than the wild type is unlikely (as discussed above and in previous sections). Thus, all GMM will be treated as the parental wild-type bacteria (except in c below).

It is safe to assume that in all cases Genetically Modified mycobacteria pose ‘about the same’ or less hazard as the parental wild type strains. Because the individual effect of every gene in the genome has not been elucidated and because virulence is not the result of the acquisition of a single gene, we will assume that all mycobacterial transformants should be handled in the same way as the recipient wild-type; except in c) below:

a) The ACDP containment level of Category 1 for the non-pathogenic M.smegmatis and its transformants = Class 1 activity;

b) The ACDP Containment Level of Category 2 for M.bovis BCG (and non-pathogenic mycobacteria, such as M.abscessus) and its transformants = Class 2 Activity;

c) EXCEPT where M.bovis BCG is transformed with multiple genes that may complement the deletions responsible for the attenuation of BeG. In this case, where the deliberate attempt to restore some virulence is attempted, the ACDP Containment Level of Category 3 will apply = Class 3 activity;
d) The ACDP Containment Level of Category 3 for M. tuberculosis and M. bovis and their transformants = Class 3 Activity.

The capacity of the GMM to survive and disseminate among other organisms and the environment

The purpose of containment is to prevent exposure of the GMM to laboratory workers and the environment.

Containment Level one protocols will be followed for the non-pathogenic strain M. smegmatis. Containment Level Two protocols will be followed for the vaccine strain M. bovis BCG mutants and non-pathogenic fast growing species (such as M. abscessus). Containment Level Three protocols will be followed for GM-M. tuberculosis/M. bovis strains (and BCG transformants which complement the attenuation-related deletions).

All Containment Level 3 work will be performed in the specialised CL3 laboratories under the ACDP guidance for Hazard Group 3 micro-organisms. Namely, this will involve all work performed with live GMMs to be within a Class I microbiological safety cabinet following identical protocols as for the non-GMM wild type parental bacteria. Transport protocols out of the CL3 suite to another CL3 suite will be followed as for Group 3 organisms. All liquid waste is first chemically sterilised, then autoclaved as standard procedure for all strains in the CL3 laboratory. These methods of sterilisation have been validated and are detailed further in the CL3 code of practice and section 12 below. All waste is sterilised by autoclaving within the CL3 laboratory, followed by incineration.

Contaminated cultures are chemically sterilised and autoclaved as for wild-type M. tuberculosis. GM-M. bovis BCG/M. tuberculosis pose no more threat to the environment than wild type strains. Both wild type and GM strains are disinfected and disposed of according to Level Two Containment regulations (for M. bovis BCG) and Containment Level Three protocols (for M. tuberculosis). Thus, the risk of exposure of live GM mycobacteria to the environment or animal and plants is negligible.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All GMM in the containment level three laboratory (see above sections) will be treated as wild-type M. tuberculosis (ACDP activity class 3). Waste sterilisation and disposal procedures follow validated methods and standard operating procedures detailed in the CL3 Code of Practice. Summarised below:

The disinfectants used in the CL3 laboratory are:

1. 5% Surianios (Laboratoires Anios): N-(3-aminopropyl)-N-dodecylpropan-1,3-diamine 51mg/g, didecylmethy lammonium chloride 25mg/l. Fresh 5% Surianios solution (diluted with water) is made for each new use of the cabinet. Complete decontamination of a high titre liquid culture of M. tuberculosis with 5% Suranios requires a minimum exposure of 3 hours. Complete sterilisation of a 10ml high titre liquid culture of M. tuberculosis (4 x 10^9 colony forming units of bacteria per ml) was achieved after 3h exposure; a kill of greater than 9 logs with 5% Suranios after 3 hours. We treat overnight for simplicity and to ensure a maximal kill.

2. Amphospray 41 (Laboratoires Anios): N-(3-aminopropyl)-N-dodecylpropan-1,3-diamine, didecylmethy lammonium chloride, polyhexamethylene biguanide hydrochloride, 41% v/v ethanol. Amphospray 41 is used as a surface decontaminant (pre-prepared Surianios in 41% alcohol solution). Culture vessels and centrifuge buckets are sprayed when taking them in and out of the cabinet and for use in the cabinet as a surface disinfectant. Amphospray 41 kills M. tuberculosis within seconds; a kill of 8 10^9 units of M. tuberculosis was observed with Amphospray 41 in 5 seconds.
All waste generated in the CL3 laboratory is autoclaved at 121°C for 30 minutes before removal from the CL3 laboratory. Autoclaving at 121°C for 15 minutes is sufficient for >9 logs kill of high titre M.tuberculosis liquid culture (no colonies grew on plates from an autoclaved 7 day M.tuberculosis liquid culture of 2.7x10E9 colony forming units/ml). We have extended this autoclave time from 15 minutes to 30 minutes. Solid autoclaved waste is collected into yellow plastic bags or yellow plastic biosafe bins, sealed and removed from the CL3 laboratory immediately to prevent buildup of waste. Yellow bags and yellow sharps bins are placed into yellow palladins before removal for incineration.

Solid Waste
All solid discard (gloves, paper towels, disposable plastics) is collected into medium sized steam-permeable autoclave bags in the cabinet. Waste is double-bagged (in clear autoclave bags) before removing from the cabinet, and stored in sealable metallin before autoclaving as soon as possible. All tips and pipettes (that could potentially pierce the clinical waste bags on disposal) are placed in separate small steam-permeable autoclave bags (i.e. not with gloves, paper towels, universals etc.) inside the cabinet. This solid waste is double-bagged ‘in clear autoclave bags) before removing from the cabinet and 8uloclaved as soon as possible. After au toclaving, the autoclave bags containing solid discard (gloves, paper towels) are placed into yellow plastic bags for incineration. The autoclave bags containing sharps are disposed of into yellow plastic bins, rather than yellow plastic bags for fear of puncture.

Liquid Waste
Volumes of GMM liquid waste are expected to be small <100ml, since most culture volume is used in subsequent experimental procedures. liquid waste is sterilised chemically before removing from the safety cabinet by adding neat Surfanios to a final concentration of 5% and left overnight (following validated protocols). Reusable culture bottles are soaked in 5% Surfanios and left overnight. The following day the (diSanitised-sterilised) liquid waste is discarded into white polypropylene biosafe jars for autoclave in the CL3 laboratory. After chemical disinfection and autoclave, the liquid waste is disposed of down the sink with lots of water.

Sharps
Sharps are avoided in the CL3 laboratory where possible. All tips and pipettes are placed in a separate small steam permeable autoclave bag (not with gloves, paper towels, universals etc.) in the cabinet, double-bagged and autoclaved as detailed for solid waste above, before placing into yellow plastic sharps bins. If needles are used, they are placed into universal tubes and treated as sharps waste, autoclaving and disposing into yellow plastic bins before removal from the CL3 laboratory.

CL3 laboratory autoclave procedures
The CL3 laboratory is equipped with a L TE K150 front-loading autoclave. In addition, a L TE F150 front-loading autoclave is located in the prep room in case of a failure of the CL3 autoclave. All waste generated in the CL3 lab is autoclaved, at 121°C for 30 minutes, before leaving the laboratory. Autoclave readouts detailing run success and temperature/pressure readings are archived in the CL3 laboratory. The autoclave is connected to the protected power supply that is backed up by generators. The autoclave is serviced by a qualified technician every 6 months. In the event of an autoclave breakdown, CL3 laboratory work will be minimised to avoid generation of large volumes of waste until the CL3 autoclave fault is repaired. The Safety Officer will be informed and the autoclave engineer contacted. Excess waste will be autoclaved in the L TE Prep room autoclave (located in media prep room in the secure basement area situated on the same floor as the CL3 laboratory). Laboratory waste will already be contained in a gas-permeable autoclave bag and a translucent autoclave bag, according to normal waste disposal procedures. This double-bagged waste will be placed inside a steel box and the exterior surface disinfected. These tins will be placed into a wheeled clear plastic waste transporter located inside the CL3 laboratory. The waste transporter will be surface disinfected before transferring from the CL3 laboratory to the Prep room autoclave. After autoclaving, the waste will be disposed of as normal and the wheeled transporter returned to the CL3 laboratory. If both autoclaves breakdown, all CL3 laboratory work will be suspended until at least one of the autoclaves has been repaired. The same disinfection protocols and disinfectants will be used to chemically sterilise ADCP hazard group 1 and group 2 GM-mycobacteria working in containment level two conditions.

## Project Additional Information

### Purposes of the contained use

To screen compounds for antileishmanial activity on the promastigote and amastigote stages of the transgenic parasite using fluorescent activated cell sorting analysis.

### Recipient or parental organism

The recipient protozol parasitic strains include *L. aethiopica*, *L. major*, *L. tropica* and *L. mexicana*.

### Host/vector system

1. **Vector systems:**
   - Genomic Vector: *phGFP-S65T*;
   - Episomal vector: *pXG-GFP+

2. **Host:** DH5 alpha E.coli

### Origin & function

The original GFP integration plasmid (*pRib1.2alphaNEOalphaGFP*) intended to create stable expression of GFP in *Leishmania* species following integration into the parasite genome was developed and obtained from Dr. P (Canada). Transient and episomal expression of GFP in *Leishmania* species using vector, *pXG-GFP+*, was obtained from Dr K of the School of Medicine in Washington University in St Louis, USA. The GFP in both vector systems was originally isolated from *Aequorea victoria*. Expression of GFP in *Leishmania* species will enable identification and selection of transgenic parasites, and quantification of intracellular parasite growth following inhibitor screen.
There are no indications that the inclusion of the GFP in Leishmania spp. would increase virulence. There are no past publications revealing increased virulence in GFP transfected Leishmania parasites. These organisms are classified as a Category Level 2 pathogen and will be handled under these conditions at all times.

Evaluation of foreseeable effects

There are no indications that the inclusion of the GFP in Leishmania spp. Would increase virulence. There are no past publications revealing increased virulence in GFP transfected Leishmania parasites. These organisms are classified as a Category Level 2 pathogen and will be handled under these conditions at all times.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Transgenic parasites will always be maintained at the specified class II containment level for the purpose of culturing and drug screening experiments and therefore no derogation from full containment is necessary.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid culture waste will be treated with Virkon or 1% bleach and contained in a designated GMO waste vessel for appropriate disposal in a sink. All solid waste including disposable pipettes, pipette tips, culture flasks/vials and microscopic slides exposed to transgenic Leishmania parasites will be treated with Virkon or 1% bleach, wiped down and the contaminated tissue paper waste will be appropriately discarded as solid waste. Complete level of killing will be achieved with the above processes.

The category II laboratory will be regularly monitored by members of staff and laboratory manager to ensure good housekeeping and hygiene is regularly maintained with particular emphasis on treatment and disposal of infectious biological waste.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The risk assessment was approved by the genetic modification safety committee and no comments were made.

**Project Additional Information**

**Purposes of the contained use**

The experimental purpose of this work is to assess whether infectious clones of cassava viruses can infect the model plant species Nicotiana benthamiana, Nicotiana tabacum as well as cassava Manihot esculenta to assess the vector ability of cassava begomovirus or Ipomovirus-whitefly populations.

**Recipient or parental organism**

The bacteria Agrobacterium tumefaciens containing the full genome of cassava viruses will be used for infection of plants. Three strain are used as detailed in the risk assessment form attached: EHA105, AGL-1 and LBA1106.

**Host/vector system**

Two binary plasmid vectors are used for the transformation of Agrobacterium: pBINPLUS and pCambia0380.

**Origin & function**

Two types of plant viruses will be inserted as part or full genome inside the vector and transformed into Agrobacterium:

* Sri lanka cassava mosaic virus (SLCMV) This virus possesses a single stranded DNA bipartite genome therefore the two genomic components (DNA-A and DNA-B) have been inserted into two distinct vectors, 
The PBINPLUS DNA-A construct contains 6 overlapping open reading frames (ORFs) (2 virion sense and 4 complementary-sense) encoding the following genes:
- Coat protein (CP) determinant of vector transmission and involved in genome encapsidation
- Movement protein (MP)
- Replication associated protein (Rep)
- Transcriptional activator protein (TrAP)
- Replication enhancer protein (REn)
- Host activation protein

The pBINPLUS-DNA-B construct contains 2 non overlapping ORF encoding 2 proteins involved in the intra- and inter-cellular movement of the virions within the host:
- nuclear shuttle protein
- movement protein

* Ugandan cassava brown streak virus (UCBSV) and cassava brown streak virus are (+)ssRNA virus and their coding region translates into a large polyprotein precursor that is further processed into 10 mature proteins:
  - first protein (P1): serine proteinase
  - third protein (P3) (also encodes a second protein, P3N-PIPO, which is generated by a +2 frameshift)
  - first 6 kilodalton protein (6K1),
  - cylindrical inclusion (CI)
  - second 6 kilodaltons protein (6K2),
  - viral genome linked protein (VPg),
  - nuclear inclusion a (Nia-Pro),
  - nuclear inclusion b (Nib)
  - HAM1h
  - coat protein (CP)

**Evaluation of foreseeable effects**

Agrobacterium tumefaciens is a naturally occurring soil bacterium responsible of crown gall disease in plants. The strains used in this study are disarmed and do not have oncogenic properties however they still possess their gene transfer abilities on the T-DNA supplied by a binary plasmid. In this project on set of Agrobacteria strains were transformed to carry the DNA-a or the DNA-b of the SLCMV and another set to carry parts or the full genome of UCBSV or CBSV.

The objective of this work is to create transient expression of the plant viruses using transformed agrobacterium, not to directly genetically transform the plant. Viral cDNAs are transferred to the plants as T-DNA and the viruses transcribed multiply and spread cell to cell. Three plant species are expected to be infected Nicotiana tabacum, Nicotiana benthamiana and Manihot esculenta using a mechanical inoculation called agroinoculation.

The disarmed Agrobacteria strains are not human or animal pathogens and do not expected to pose an immediate of plant disease upon release. The introduction of the plant viruses genes in the Agrobacterium is not expected to change the virulence of the pathogenicity of the bacteria. The genomes of the viruses inserted in the Agrobacteria have not been altered and are identical to the natural strains they are derived from, therefore their transcription from the T-DNA is not expected to generate a different than from the infection by the natural virus. Due to their ability to transfer the genetic material from their T-DNA into the plant genomes and their wide host range uncontrolled release of transformed agrobacteria could have unknown but potentially adverse effects of the local ecology and plant heat and they should therefore be contained.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All disposable waste (tips, tubes spreaders, gloves and plates etc.) generated from culturing the transformed Agrobacteria will be bagged and autoclaved on a waste cycle before disposal for incineration waste.
All glasswear used for agrobacterium work will be soaked for at least 1 hour in 1 % Virkon before being autoclaved, then processed through washing up.
All working benches used for preparation of Agrobacterium propagation will be decontaminated by wiping the surface with 1 % Virkon after each use.
All plant material agroinfiltrated with the tranformed bacteria, as well as the whiteflies (Bemisia tabaci) feeding on the plants will be kept in a quarantined growth chamber under licence (Defra licence to import, move and keep prohibited invertebrates 24569/210645/9). All waste will added in two plastic bags and kept in a -20C freezer for a minimum of 24 hours (in accordance with the rules of the quarantine facilitie) before being autoclaved and disposed for incineration waste. The bags used have been previously tested as able to sustain a prolonged exposure to -20 degrees without tearing.
The autoclave is on a service contract and is inspected annually to make sure temperature and pressure reach the set parameters.
All the procedures detailed above, the use of quarantined facilities and the inactivation of the waste, will guarantee that no live agrobacteria will be released in the environment.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Project Ref  101/04.1
We already know that pathogenic E.coli K-1 and pathogenic Pseudomonads lacking active twinarginine transport (Tat) systems are attenuated. We also know that E.coli tat mutants have defects in outer membrane assembly due to problems in targeting cell-wall amidases. We wish to determine whether the lack of active Tat-dependent amidases is the predominant contributing factor which results in the avirulence of tat mutant E.coli strains.

E.coli contains three cell-wall amidases AmiA, AmiB, and AmiC. We have already constructed unmarked deletions of each in E.coli K-12 using the well-established pMAK705 system. We will use our pre-existing pMAK705-based deletion constructs to generate gene knockouts in E.coli K-1. In collaboration with Dr Christoph Tang (Centre for Molecular Microbiology and Infection, Imperial College, London) the modified E.coli K-1 strains will be tested for their ability to infect a mouse model system. (NB. No virulence testing will be done at UEA)

Host: Escherichia coli K-1 is classified as an ACDP category 2 organism. It does not express verocytotoxin. It is a common cause of neonatal meningitis and it invades the bloodstream from the nasopharynx or GI tract. Note that such invasion is rare even in neonates and healthy adults do not suffer from this condition. Mutant strains of E.coli K-1 generated by this project are most likely to have drastically reduced virulence.

Vector: the vector used is pMAK705, chloramphenicol resistant, temperature sensitive for replication) is a derivative of pBR322 and is thus mobilization defective. It is extremely unlikely that pMAK705 will be transferred to other bacteria. The antibiotic resistance gene of pMAK705 is only transiently transferred to the chromosome of the host strain in the early stages of the mutant construction protocol. None of the mutant strains constructed will be chloramphenicol resistant.

Origin & function
This project does not involve the use of 'foreign' DNA in the host organism. All GMO's will lack genes encoding native amidase enzymes.
Evaluation of foreseeable effects

Final GMO: Manipulated strains are most unlikely to be enhanced in terms of their virulence. The available literature suggests strongly that the mutant strains will be severely attenuated and thus probably non-pathogenic.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Cultures will be grown in small volumes of liquid medium (10 ml or less, generally 5 ml) and on solid medium in the form of petri-dishes. All solid media will be inactivated by extensive heat and high-pressure treatment in an autoclave. This kill method is 100% effective and will result in no viable organisms remaining. Liquid cultures can also be killed absolutely by this method. Alternatively liquid cultures will be treated with broad-spectrum disinfectants. No viable organisms will survive this treatment. Killed liquid is suitable for disposal trough the general drainage system. Killed solid waste is suitable for land-fill disposal.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

All concerns raised by Committee members have been addressed by the current version of the risk assessment.

Project Additional Information

Purposes of the contained use
RNAi knockdown and expression of protein kinases and phosphatases and associated proteins involved in intracellular signalling pathways in mammalian cells will be used to identify the roles of these proteins in relation to the signalling pathways in which they reside. This will be undertaken using retrovirus vectors.

Recipient or parental organism
Commonly used tissue culture cell lines (HEK293, HeLa, COS cells) or embryonic stem cells, hepatocytes, fibroblast and myoblast cells derived from rodents.

Host/vector system
The retroviral vectors to be used for the studies are called pHR-SIN-CSGW, pLK0.1 (Stewart et al., 2003), pMKO.1puro (Masutomi et al 2003) or pRS (commercially available origene vector). Please use full risk assessment for more information on these systems.

Origin & function
The inserts will be either RNAi constructs designed to remove intracellular mRNAs for their target genes or the cDNAs coding for the normal intracellular versions of
kinases, phosphatases, etc. All these proteins are components of signalling pathways and so could affect cell growth. However, none will be known oncogenic versions of the proteins and so should not lead to cellular transformation. It is not known whether any of the proteins are capable of altering the properties of any naturally occurring viruses in any way that would increase their pathogenicity. However, from the known properties of the proteins this would not be predicted. The transfected cultured cell lines will not survive outwith the culture medium and all liquid and solid waste will be autoclaved on site. This rules out the possibility of escape into external environment and survival, establishment or dissemination therein.

Evaluation of foreseeable effects

The RNAi constructs are designed to remove intracellular mRNAs for their target genes and so the predicted direct effect of this will be the removal of the corresponding protein from the cells infected with the virus. This is predicted to interfere with the signalling pathway and this will what will be tested. In the majority of cases it is predicted that the removal of a component from the signalling pathway will lead to the loss of ability for that signalling pathway to function. In some cases it might be that the loss of an inhibitory component could lead to an upregulation of that pathway. Both effects are likely to be deleterious to the cell in the long run and it is not predicted that cell infected with the viruses will beat a selective advantage relative to their parent cells.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Autoclaving is by validated (internal temperature probe linked to printout) autoclave, in the same building, reserved only for inactivation of waste (effective 100% kill). The autoclave undergoes annual testing to ensure correct operation. Waste will be transferred to the autoclave in covered containers.

Is an emergency plan required according to regulation 20? N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The committee had no major concerns regarding this risk assessment, which was a revised version of the first one submitted and which was revised following comments from the committee regarding the proposed possible use of primary human cells (now not proposed). The work is proposed to take place inside containment two laboratories and these laboratories also are used for work at level 1 containment. The committee did wish to make it quite clear that full level 2 containment practices would need to be employed during use of these retroviral vectors and that other staff working within the facilities must be made aware of the work.

02/03/2022
Purposes of the contained use

Reactive arthritis is a disease which has close linkage with the MHC Class 1 protein HLA-B27. The disease has been shown to occur post infection with intracellular bacteria such as Salmonella and Yersinia. This project aims to investigate the effect of salmonella infection at the cellular level in relation to the MHC Class 1 protein HLA-B27.

Recipient or parental organism

Both wild type Salmonella enteriditis and the non-virulent strain, Aro A-, will be transformed. The wild type strain is classified as a category 2 pathogen by ACDP. The non-infective strain is equivalent to ACDP category 1. Salmonellosis is a world-wide disease of humans and animals. The most common clinical manifestation of Salmonella infection is self-limiting, uncomplicated gastroenteritis. Mode of transmission is by ingestion of infected food or food contaminated by faeces from an infected animal or person and caecal-oral transmission from person to person. There is no evidence to support aerosol inhalation as a route of infection. Typically, antibiotic therapy is not administered as it appears to increase adverse effects and prolong Salmonella detection in stool.

Host/vector system

The vectors of choice are the non-mobilisable pUC derivatives; pECFP, pEGFP and pEYFP (plasmids supplied by Clontech, Basingstoke) expressing Enhanced Cyan Fluorescent Protein, Green Fluorescent Protein and Yellow Fluorescent protein respectively. The vectors also contain an ampicillin resistance gene for selection purposes.
The expressed proteins are fluorescent and possess no other known biological activity, and are therefore non-harmful.

### Origin & function

Salmonella enteriditis will be transfected with the fluorescent protein plasmids listed in the section above. These transformed bacteria will be used to infect well characterised human cell lines previously transfected with MHC Class 1 molecule proteins. Transformed S. enteriditis expressing fluorescent protein will provide a rapid means of detection in infected cells which will then be fixed and immunochemically counterstained and subjected to microscopy.

### Evaluation of foreseeable effects

Salmonella is capable of surviving for long periods in the environment, has a broad host range in humans and domestic and wild animals and has a large world-wide animal reservoir.

Conferring ampicillin resistance onto a pathogenic bacteria may be perceived to increase the hazard status relative to the host, however antibiotics are not typically used in the treatment of salmonellosis and alternative therapies are available (eg. amoxicillin and chloramphenical).

The ampicillin resistant GM S. enteriditis strain will have no environmental impact due to antibiotic resistance being already present in the wildtype population. This naturally occurring resistance is mainly due to the use of antibiotics in animal feedstuff and in the inappropriate treatment of Salmonella infections in humans. This resistance is transferred by R factors and as the plasmid used is non-mobilisable, should the GMM escape into the external environment, no transfer will occur between the GMM and wildtype Salmonella. Furthermore, when a similar GMM was created at the University of Lund (Sweden), there was a loss of plasmid from the host over time (personal communication from Dr M J Wick). This inability to persist in the genetically modified form further reduces the risk of any environmental impact.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**WASTE DISPOSAL**

Solid waste is collected in an autoclavable, lidded, biohazard labelled, metal bin. After each experiment the bin is taken directly to the autoclave facility for immediate autoclaving. After autoclaving solid waste is disposed of as normal refuse.

Liquid waste is collected in plastic tubes which are placed in an autoclavable, lidded, biohazard labelled, metal bin. After each experiment the bin is taken directly to the autoclave facility for immediate autoclaving. After autoclaving liquid waste is disposed of to drains with copious amounts of cold water.

**MONITORING**

Disinfection: The disinfectant of choice (Virkon) is used in strict accordance with the manufacturer's (Antec's) guidelines.

Autoclaving: To ensure 100% efficacy, testing of the autoclave is carried out annually, by the manufacturer, to demonstrate, using a 12 point test with independent thermocouples, that the correct temperature and pressure have been reached for the required time. On subsequent runs verification that the correct conditions were reached is obtained through use of a temperature probe in the centre of the load. Testing is arranged and test reports are kept by the Health and Safety Co-ordinator.

Inspections: Safety inspections are carried out annually to ensure Local Rules are adhered to and that risk assessments and training records are in order. Inspection reports are kept by the Health and Safety Co-ordinator.

Microbiological Safety Cabinets: Tested on a six monthly basis with annual KI test. Certificates of conformity are displayed on each cabinet and copies kept by the Health and Safety Information Officer.

Negative Pressure Suites: Tested annually by Estates and Buildings to ensure the suite is at negative pressure relevant to the immediate surroundings. Testing is arranged and test reports are kept by the Health and Safety Information Officer.
The committee agreed that the facilities and procedures are adequate to control level of risk presented to humans and the environment by these genetically modified Hazard Group 2 enteric bacteria.

**Significant Change ID**
The NF-kappaB transcription factor family consists of homo and heterodimers formed from five distinct subunits. NF-kappaB regulates many cellular genes involved in a wide variety of processes. These include immune function, inflammation, cell cycle and apoptosis. In normal cells, NF-kappaB is tightly regulated, being activated only transiently. Aberrant activation of NF-kappaB, when it becomes constitutively nuclear localised, is associated with many human diseases including inflammatory diseases (rheumatoid arthritis, asthma), cancer, atherosclerosis and alzheimer's disease.

Activation of NF-kappaB is controlled by at least three inhibitory proteins, termed IkappaB alpha, beta and epsilon. These proteins keep NF-kappaB in the cytoplasm of the cell until an appropriate signal is received. They then become phosphorylated, which targets them for ubiquitination and degradation, allowing NF-kB to translocate to the nucleus.

The purpose of this project is to assess the function of the different components of the NF-kappaB signalling pathway.

1. Vero/293 cells
These well characterised and authenticated tissue culture lines are used for the propogation of the disabled Adenovirus vector, Ad5-SVR4. In accordance with HSE guidelines this host is especially disabled and considered equivalent to ACDP Hazard Group 1.

2. Other well characterised and authenticated tissue culture cell lines (eg HeLa, U20S, THP-1, MDA-MB-231, MCF7, HT1080 and H1299) equivalent to ACDP Hazard Group 1.
These are principally to study the role of the NF-kappaB pathway in cell survival, cell growth and regulation of gene expression. Protein and RNA extracts will be made from adenivirus infected cells and analysed in various ways in the laboratory. Proliferation and apoptosis assays will also be performed. No new cell lines will be generated within the laboratory during the course of this project.

Recipient or parental organism

Attenuated Adenoviral (Ad5-SVR4) Vector System
The adenoviral vectors to be used are "attenuated" through deletion of the E1 region of the genome (containing E1A and E1B) and through insertions and deletions within the E3 gene that inactivate it. This has several affects on the virus. Firstly deletion of the E1A gene eliminates the potential for viral transformation of cells, since the E1A gene product is absolutely required for this process. It is also required for activation of all other early genes (E1B, E2, E3 and E4). The E1B gene product (also deleted) co-operates with E1A in transformation. The E2 region (E2A and E2B) contains DNA binding (E2A) and DNA polymerase (E2B) activities that are absolutely essential for viral replication. The E3 gene product helps in viral avoidance of the immune system by binding to the major histocompatability complex MHC polypeptides in the endoplasmic reticulum. However, this gene is also inactivated in this strain of adenovirus, resulting in the virus being highly susceptible to immune vurveillance. The E4 gene product is required for formation of an active complex between the E1B gene product and the E4 gene product.

The above characteristics mean that the recombinant virus is totally unable to replicate in E1A-deficient cells of any organism. Under normal circumstances no human or animal cells contain the E1A gene product, resulting in the inability of this virus to replicate in any naturally occurring organism (human or non-human mammalian). Under conditions where an organism (human or non-human mammalian) already was suffering from an adenoviral infection, it is possible that the recombinant virus could be replicated and packaged. Since this is likely to be a relatively rare event, and not one that could sustain a population of recombinant virus, the risks are extremely low. Additionally, any wild-type virus would be at a significant growth advantage with respect to the recombinant virus (for the reasons mentioned above concerning attenuation of the virus), meaning that the wild-type virus would outgrow the recombinant one very quickly.
Also, the attenuated virus cannot recombine with wild-type virus in any way that produces viable virus (Beck T. C et al Methods Cell. Biol. (1994) 43, 161-89). Recombination with a wild-type virus would, by the nature of the recombination event, remove the E1 region from the wild-type virus thereby inactivating its ability to replicate. Taken together, the above means that the recombinant virus is essentially unable to propagate in the external environment.

The wild type Adenovirus serotype 5 causes sub-clinical infections and is categorised by the ACDP as Hazard Group 2. Based on the information given above, the attenuated adenoviral (Ad5-SVR4) vector can be classified as ACDP Hazard Group 1.

Origin & function

The functions of the NF-kappaB pathway components will be elucidated by expressing dominant negative versions of different components (The NF-kappaB subunits, other transcription factors with which they interact, the IkappaBs, the IKKs and other kinases and phosphatases which control their function) in the host cells listed above. Effects on NF-kappaB regulated gene expression and NF-kappaB activation will be assessed, following cellular stimulation with, for example, lipopolysaccharide, ultra violet light or a cytokine such as TNF alpha. Furthermore, effects on cell cycle and apoptosis will be studied. Protein and RNA samples will be harvested from infected cells and analysed. These studies will be performed in a variety of cell lines, both where NF-kappaB regulation is normal and where it is aberrantly active.

Evaluation of foreseeable effects

The constructs to be used in this study, based on the NF-kappaB pathway and associated proteins have not been reported to cause immortalisation or transformation in human cells. The effects of over-expressing some of the various NF-kappaB pathway gene products have not been previously characterised in terms of immortalisation or transformation, however. It is possible, therefore, that changing the expression of genes from this pathway could be harmful. Inhibition of the NF-kappaB pathway could result in activation or inhibition of pathways that regulate the cell cycle and apoptosis, i.e., they could potentially be oncogenic. NF-kappaB also regulates inflammation and immune function. It is also possible that expression of these proteins could therefore produce adverse inflammatory effects and immune suppression. Therefore, adenoviral vectors expressing NK-kappaB pathway components and host cells transfected with these vectors, are considered equivalent to ACDP Hazard Group 2 and require Level 2 Containment.

It should be noted that many, although not all, proteins to be used in this study have been expressed in adenoviral systems in other laboratories, with no known harmful effects on the researchers. For example, adenovirus expressing a dominant negative form of IkappaB alpha, which strongly inhibits activation of the NF-kappaB pathway, is very widely used (see for example Bondeson et al. (1999). "Defining therapeutic targets by using adenovirus: Blocking NF-kappaB inhibits both inflammatory and destructive mechanisms in rheumatoid synovium but spares anti-inflammatory mediators". Proc. Natl. Acad. Sci. USA 96, 5668-5673; Wang et al. (1999). "Control of inducible chemoresistance: Enhanced anti-tumor therapy through increased apoptosis by inhibition of NF-kappaB". Nat. Med 5, 412-417). Similarly a dominant negative form of the RelA(p65) subunit has also been expressed using adenovirus (Soares 1998). "Adenovirus-mediated expression of a dominant negative mutant of p65RelA inhibits proinflammatory gene expression in endothelial cells without sensitizing to apoptosis". J. Immunol. 161, 4572-4582).

In the very unlikely event of a release from the Level 2 Containment facility, the virus could survive in the environment for a similar period of time to the wild-type virus. If the virus were to infect a susceptible host, then expression of the recombinant genes would occur in the infected cells. Since the virus cannot propagate (except in exceptional circumstances as detailed above), expression would be limited to the cells initially infected (i.e., once the cell divides, only one daughter cell will contain the adenovirus DNA. Eventually, this would result in loss of the DNA due to natural degradation of the episomal DNA. The effect that expression of the recombinant DNA would have on the cells is unknown and one of the main reasons for undertaking the experiments described in the proposal is to have a better understanding of the functions of these proteins within cells.

It should be noted that many, although not all, proteins to be used in this study have been expressed in adenoviral systems in other laboratories, with no known harmful effects on the researchers. For example, adenovirus expressing a dominant negative form of IkappaB alpha, which strongly inhibits activation of the NF-kappaB pathway, is very widely used (see for example Bondeson et al (1999). "Defining therapeutic targets by using adenovirus: Blocking NF-kappaB inhibits both inflammatory and destructive mechanisms..."

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Committee agreed that facilities and procedures are adequate for level of risk presented by recombinant adenovirus.

Please enter comments on the GM safety committee on the risk assessment

Committee agreed that facilities and procedures are adequate for level of risk presented by recombinant adenovirus.

Project Containment
Purposes of the contained use

This assessment covers experiments using adenovirus constructs in several groups within the Division of Molecular Physiology. Research within the Division concerns the molecular mechanisms involved in the regulation of key cellular processes including energy metabolism, protein turnover, and nutrient transport. These are all important physiological processes, which are interconnected. For example, nutrient availability directly affects energy metabolism and protein synthesis and breakdown. We are investigating the common regulatory pathways that impinge on all three of these systems. Therefore, our research is underpinned by extensive common interests and involves a wide range of collaborative projects. The use of adenovirus constructs is required in several of the cell types we use, in which high level expression of signalling proteins cannot be achieved by standard transfection techniques. The interconnected physiological processes, which are currently under investigation, are described below.

Regulation of protein synthesis. This work focuses on how protein synthesis is regulated in mammalian cells. In particular, the signalling pathways and protein kinases that regulate mRNA translation in response to insulin or nutrients or in disease states such as cardiac hypertrophy. Adenoviral vectors to study signalling in cardiac hypertrophy have been used before. Recently, studies have been initiated to study the role of the AMP-activated protein kinase in the regulation of protein synthesis.

AMP-activated protein kinase. The AMP-activated protein kinase cascade is a signalling mechanism that links cellular energy status to the regulation of energy-producing and consuming processes. It serves to switch such pathways on or off in response to cellular stresses leading to ATP depletion, eg., hypoglycaemia or (in muscle) exercise.
The AMP-activated protein kinase (AMPK) is the downstream component of a protein kinase cascade that is activated by cellular stresses that deplete cellular ATP (Hardie & Hawley (2001) Bioessays 23, 1112-1119). Once activated by stress, the kinase phosphorylates numerous targets that switch on catabolic pathways that produce ATP, while switching off anabolic pathways that consume ATP. There are also recent indications that the system may also inhibit other energy-requiring processes, such as translation, protein secretion, and progress through the cell cycle. The broad aim of the project is to gain a detailed understanding of the physiological downstream targets of AMPK by utilising adenovirus vectors to express constitutively active, dominant negative or other mutated forms of AMPK in cultured mammalian cells, thus manipulating the total cellular activity (see Woods et al. (2000) Mol. Cell. Biol. 20, 6704-6711). The adenovirus vectors are particularly used for expression of these proteins in cells where the transfection efficiency is poor, or where high level or prolonged expression is required.

Control of amino acids and glucose transport. The work concerns the mechanisms by which insulin and other stimuli control the transport of glucose and amino acids into mammalian cells. The major thrust of the work is to try and understand the molecular regulation of membrane transport processes (specifically that of glucose and amino acids) in skeletal muscle and fat in response to hormonal, stress and nutrient stimuli. The main aim is defining the intracellular signalling mechanisms by which these stimuli, acutely and chronically, elicit changes in the activity of glucose and amino acid transporters. Understanding such processes is crucial if we are to gain some insight into how defects in glucose and amino acid transport and their regulation by insulin and nutrients may contribute towards the pathogenesis of conditions such as diabetes and complications that are associated with malnutrition. For example, the translocation of GLUT4 is a widely accepted paradigm of membrane trafficking in cell biology. Nevertheless, major gaps still remain in our understanding of how insulin signalling regulates this process.

Collaborative work is undertaken on mechanisms and regulation of amino acid transporters such as System A (SAT2), System N (SN1, -2) and System L (eg Ritchie et al. (2001) Cell. Physiol. Biochem 11, 259-270; Ritchie & Taylor (2001) Biochem. J 356, 719-725; Hyde et al (2001) Biochem. J. 355, 563-568. It was recently discovered that the System L transporter protein (termed IJ12/LAT1) also mediates transport of the thyroid hormones T3 and T4 across vertebrate cell membranes (Ritchie et al. (1999) J. Endocrinol. 163, R5-R9). This discovery provides a previously missing link in the chain by which thyroid hormones (TH) in the blood reach the cell nucleus, where they are generally believed to exert their major biological effects. The identification of TH transporters offers possibilities for the design and development of novel treatments for many types of thyroid disorder, based on the therapeutic regulation of thyroid hormone entry into cells and thus their actions. In order to take this work the next step towards commercial development, we aim to demonstrate that altering TH delivery to cells has significant effects on both nuclear TH appearance and TH-responsive gene transcription.

While activation or inhibition of certain protein kinases might have effects on cell division or other cellular processes that are currently hard to predict, it is important to note that we would only ever use Ad5-based vectors that have E1a and E3 deletions, which can only replicate in cells that provide the E1a function. To this end, an attenuated strain of Adenovirus (Ad5) is used as the base vector. This had had the E1region replaced by a polylinker site. Any recombination event that would restore the self-replication status of the adenovirus will only restore the construct to the wild type Ad5 with the loss of the cloned DNA insert.

The major risk to those involved in the project is in the form of aerosol inhalation during manipulation. This is minimised by the use of class 2 microbiological safety cabinets that are annually serviced and K1 tested to ensure operator protection. Also, during centrifugation steps executed outwith the cabinet, aerosol containment conisters are employed. Furthermore, the tissue culture rooms themselves are classified as Containment Level 2 areas.

Environmental risk comes from the waste produced by the work. All solid and liquid waste is inactivated by autoclaving on site.

Recipient or parental organism

1. Vero/293 cells.
   These well-characterised and authenticated tissue culture cell lines are used for the propogation of the disabled adenovirus vector.
2. We will use a variety of mammalian cell lines and primary cultures (eg muscle, fat and heart cells in primary culture). The mammalian cell-lines we propose to use include human cell lines (HepG2, BelWo, HeLa, CCL13, HEK293A, COS, U2OS) and rodent cell lines (3T3L1, L6, HiI4E, INS1, CHO). These cells have all been well characterised with a history of safe use and are equivalent to ACPD hazard group 1).
   HEK293A cells complement the E1a deletion and will be used only to culture adenoviral stocks. The other mammalian and rodent cell types for experimental studies do not complement the E1a deletion in the adenovirus vector - it remains replication defective. The viral vector does not integrate into the host cell genome, avoiding activation or
inactivation of host genes that could manifest harmful properties not apparent in the recipient. Based upon this information, the GM cells would also be assigned to hazard
group 1.

Host/vector system

Attenuated Adenoviral (Ad5-SVR4) Vector System

The adenoviral vectors to be used are "attenuated" through deletion of the E1 region of the genome (containing E1A and E1B) and through deletions within the E3 gene that
inactivate it. This has several affects on the virus. Firstly deletion of the E1A gene eliminates the potential for viral transformation of the cells, since the E1A gene product is
absolutely required for this process. It is also required for activation of all other early genes (E1B, E2, E3 and E4). The E1B gene product (also deleted) co-operated with
E1A in transformation. The E2 region (E2A and E2B) contains DNA binding (E2A) and DNA polymerase (E2B) activities that are absolutely essential for viral replication.
The E3 gene product helps in viral avoidance of the immune system by binding to the major histocompatibility complex MHC polypeptides in the endoplasmic reticulum.
However, this gene is also inactivated in this strain of adenovirus, resulting in the virus being highly susceptible to immune surveillance. The E4 gene product is required for
formation of an active complex between the E1B gene product and the E4 gene product.

The above characteristics means that the recombinant virus is totally unable to replicate in E1A-deficient cells of any organism. Under normal circumstances no human or
animal cells contain the E1A gene product, resulting in the inability of this virus to replicate in any naturally occurring organism (human or non-human mammalian). Under
conditions where an organism (human or non-human mammalian) already was suffering from an adenoviral infection, it is possible that the recombinant virus could be
replicated and packaged. Since this is likely to be a relatively rare event, and not one that could sustain a population of recombinant virus, the risks are extremely low.
Additionally, any wild-type virus would be at a significant growth advantage with respect to the recombinant virus (for the reasons mentioned above concerning attenuation
of the virus), meaning that the wild-type virus would outgrow the recombinant one very quickly).

Also the attenuated virus cannot recombine with wild-type virus in any way that produces viable virus (Becker T.C., et al Methods Cell. Biol. (1994) 43, 161-89). Recombination with a wild-type virus would, by the nature of the recombination event, remove the E1 region from the wild-type virus thereby inactivating its ability to
replicate. Taken together, the above means that the recombinant virus is essentially unable to propagate in the external environment.

The wildtype adenovirus serotype 5 causes sub-clinical infections and is categorised by the ACDP as Hazard Group 2. Based on the information given above, the
attenuated adenoviral vector can be classified as ACDP Hazard Group 1.

Origin & function

The inserted gene products are described for the three main projects separately. None of the proteins have been reported to be harmful (with the exception of PKB, which
might have oncogenic abilities).

1. Regulation of protein synthesis has been shown to play an important role in cardiac hypertrophy. To study the role of certain signalling pathways in cardiac hypertrophy
we have made use of adenoviral vectors expressing signalling components in the ras-raf-MEK-MAPK pathway (eg. constitutively active MEK (Ser218/222 to Glu), dominant
negative N17 rat (Ser17 to Asn), mouse PKC delta and a dominant negative form (lys376 to Ala), a dominant negative rat PKB (Thr308 and Ser473 to Ala) construct was
used as control) (Wang et al (2001) J. biol. Chem. 276, 32670-32677). These experiments were carried out in the class II facilities of Dr. Sutherland, under his licence. We would like to continue these studies in the facilities on the fourth floor of the MSI.

Recently, in a collaborative study, we have started to study the involvement of the AMP-activated protein kinase (AMPK) in the control of protein synthesis. The proposed
use of adenoviral vectors is described below.

2. Regulation of AMPK. Wild type or mutant (constitutively active T172D or dominant negative D139A) forms of the truncated (312 AA) rat alpha 1 subunit of AMPK.
Constructs will also contain GFP and myc epitope tags for in vitro analysis purposes.

3. Regulation of membrane transport. (The species origin of the genes is indicated between brackets. When two species are indicated this means that the genes from
these species are available).
a. proteins involved in vesicle trafficking: syntaxin 4 (human or rat), VAMP7 (human or rat), VAMP8 (human or rat), tuberin (human or rat), hamartin (human or rat) and
TUB (human or mouse). Overexpression of wild-type and cytosolic domain, binding domain and phosphorylation site mutants.
c. Signalling proteins, eg wild-type PDK1 (rat or human), PKB (rat) (wild-type, constitutively active and kinase-dead), P13KDp85 (rat or human) (dominant negative), wild-type and constitutively active GSK3 (rat), mTOR and wild-type, constitutively active and kinase dead PKC (rat) (Litherland et al (2001). Mol.Membr. Biol. 18: 195-204).

Evaluation of foreseeable effects

The resulting GM virus: Insertion of the constructs will not alter the tissue tropism, or increase the infectivity or pathogenicity of the recipient vector. Scope for recombination with wild type virus is limited and, due to the packaging limits of adenovirus, if any such recombinants did arise they would be unviable. Based upon there being no likelihood of any effect on the phenotypic characteristics of the recipient and the non-harmful nature of the insert, the resulting replication defective recombinant adenovirus/gene vector can be considered equivalent to the recipient vector in terms of hazard status ie hazard group 1. Exception to this is perhaps GM viruses expressing PKB. As mentioned above, overexpression of PKB might have harmful effects, eg promote proliferation and increased cell survival and thereby contribute to cancer progression. However, the safe use of adenoviral constructs expressing PKB has been described before (Becker, et al. (1994) Methods Cell Biol. 43, 161-189; He et al. (1998) Proc. Natl. Acad. Sci. USA 95, 2509-2514) and class 2 containment guarantees the minimised risk associated with the use of these vectors.

In the unlikely event of a release from the Level 2 Containment facility, the virus could survive in the environment for a similar period of time to the wild-type virus. If the virus were to infect a susceptible host, then expression of the recombinant genes would occur in the infected cells. Since the virus cannot propagate (except in exceptional circumstances as detailed above), expression would be limited to the cells initially infected (ie once the cell divides, only ONE daughter cell will contain the adenovirus DNA. Eventually, this would result in loss of the DNA due to natural degradation of the episomal DNA. The effect that expression of the recombinant DNA would have on the cells is unknown and one of the main reasons for undertaking the experiments described in the proposal is to have a better understanding of the functions of these proteins within cells.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste Disposal
Solid waste is collected in a lined, lidded, autoclavable, biohazard bin. Make sure no liquid waste is present in/on the solid waste items.
Single-use plastic, disposable pipettes will be used. Pipettes are fully immersed in 1% Virkon and soaked for at least 5 minutes before draining and disposing of as solid waste.
After work the lidded bin is transported, on a trolley, directly to the autoclave facility for immediate autoclaving. After autoclaving solid waste is disposed of as normal refuse.

Sharps waste are disposed of into autoclavable sharpsafe containers. The use of sharps will be avoided if possible. After work the sealed container is transported, on a trolley, directly to the autoclave facility for immediate autoclaving. After autoclaving the sharp-safe container is disposed of via the clinical waste route.

Liquid waste is collected in a sealable, robust, autoclavable container, stored within the MSC, clearly labelled as biohazard waste and containing enough Terminex to give a final concentration of 1% by volume. Chloros or Virkon are not used - they are not autoclave compatible! Aspirator set-ups will not be used.
After work the container is sealed and transported, in a plastic tub, on a trolley, directly to the autoclave facility for immediate autoclaving. After autoclaving liquid waste is disposed of to drains with copious amounts of cold water.

Monitoring
Disinfection: The disinfectant of choice (Virkon) is used in strict accordance with the manufacturer's (Antec's) guidelines. Autoclaving: To ensure 100% efficacy, testing of the autoclave is carried out annually, by the manufacturer, to demonstrate, using a 12 point test with independent thermocouples, that the correct temperature and pressure have been reached for the required time. On subsequent runs verification that the correct conditions were reached is obtained through use of a temperature probe in the centre of the load. Testing is arranged and test reports are kept by the Health and Safety Co-ordinator. Inspectors: Safety inspections are carried out annually to ensure Local Rules are adhered to and that risk assessments and training records are in order. Inspection reports are kept by the Health and Safety Co-ordinator. Microbiological Safety Cabinets: Services and K1 tested on an annual basis. Certificates of conformity are displayed on each cabinet and copies kept by the Health and Safety Information Officer. Negative Pressure Suites: Tested annually by Estates and Buildings to ensure the suite is at negative pressure relative to the immediate surrounding. Testing is arranged and test reports are kept by the Health and Safety Information Officer.

At meeting of 6 May 2002, the Committee agreed that this work could form a Class 2 connected programme.

Recent genome projects are leading to identification of the complete gene complement of different organisms. The next big challenge is to discover the functions of all these genes. We will contribute to this by focussing on vertebrate embryonic development, particularly that of the limb. We will test gene function in development of chick and fish embryos because these are good models for vertebrate development and the eggs develop outside of the mother. We will over-express genes that encode for secreted factors by implanting cells transfected with the gene into chick or fish embryos. We will over-express genes in chick embryos using RCAS (Replication Competent Avian Sarcoma virus) or attenuated AdV (Adenoviral Vector) systems. We will inhibit expression of genes in fish embryos by using morpholinos and in chick embryos by developing new antisense strategies based on viral delivery. Some of these approaches have already been used to gain insights into fundamental aspects of embryonic development. In addition, in some cases, these experiments could provide direct links to clinical medicine. Thus it is possible to study, in these model vertebrate embryos, the roles of genes known to be responsible for human congenital defects, such as Holt-Oram syndrome. Furthermore many of the genes expressed in embryos were first identified in tumours and embryos provide an invivo multicellular context in which to find out how products of these genes function. Finally these particular embryo models provide an efficient and cheap way of exploring gene function that does not require killing adult animals.

Recipient or parental organism

1. COS (African Green Monkey) cell lines. These cells will be transfected with genes that encode secreted factors and then used as grafts to deliver the factors to embryos (see below). In addition to transiently transfected cells, stably transfected cell lines will be produced and grafted.
2. QT6 cell lines. These cells will be used for the same purposes as above.
3. Chicken embryonic fibroblasts and chicken DF1 fibroblast cell lines for RCAS production. These cells will be transfected with RCAS vectors containing genes of interest (these genes may be chicken sequences or gene sequences from other vertebrates including mouse, human or fish) and used to produce genetically manipulated virus stocks that can then be used to infect susceptible chicken embryos.
4. HEK/293 cells for adenovirus production. These well-characterised and authenticated tissue culture cell lines will be used for the propagation of the disabled Adenovirus vector.
5. Chick embryos. We will test gene function with RCAS using eggs from SPAFAS (pathogen free) chickens in addition to commercially available eggs because the embryos are more susceptible to viral infection than the embryos from our usual commercial supplier in the UK. Currently we import SPAFAS eggs from Germany. We will infect chick embryos at different stage in development in 3 ways; injection of high titre virus suspensions, grafting fibroblasts producing virus, electroporating the RCAS constructs directly into chick embryos and then letting the infection spread. For the experiments with adenovirus vectors, we will use eggs from our normal supplier and use the same three strategies outlined above to infect embryos.
6. Fish embryos and fry. We will test gene function in early development using morpholinos designed to block the function of specific genes. We will inject the morpholinos into single cells at cleavage stages. We will graft cells expressing secreted factors into embryos and young fry.

Host/vector system

1. Mammalian expression vectors will be used to introduce DNA into COS cells. These vectors only enter isolated mammalian cells under special conditions such as

02/03/2022
integrates in the host genome and the episomal DNA is eventually lost through natural degradation. A virus cannot replicate under normal circumstances, expression would be limited to the infected cell and once this cell divides to one of its daughter cells. The virus never similar period of time to the wild-type virus. If the virus infected a susceptible host, then expression of the recombinant genes would occur in the infected cells. Since the reported harmful effects on researchers. In the very unlikely event of the release of virus from the Level 2 Containment facility, it could survive in the environment for a similar period of time to the wild-type virus. 3. The adenoviral vectors to be used, such as the Ad5-SVR4 system, are attenuated through deletions in both E1 and E3 regions of the genome. The net result of these alterations is that the virus is rendered replication incompetent, the potential for viral transformation is eliminated and the ability to evade the host immune system is abrogated. Unlike the retroviruses above, these viruses do not integrate in to the genome and thus cannot cause insertional mutagenesis. Under circumstances where a host mammal (human or non-human) was already suffering from an adenoviral infection, it is possible that the recombinant virus could be replicated and packaged. However the risks are extremely low because viral recombination will be a very rare event and in any case the attenuated virus cannot recombine with wild-type virus to produce a viable virus that still contains the inserted DNA (Becker et al Methods Cell Biol (1994) 43, 161-189). Harmful effects when cells are infected will depend on the gene being manipulated and the genetically modified chicken embryos will be handled as in (2) above. The wild type Adenovirus serotype 5 causes sub-clinical infections and is categorised by the ACDP as Hazard Group 2. Most human adults are immune to these serotype 5 viruses. Based on the information given above, the attenuated adenoviral (Ad5-SVR4) vector can be classified as ACDP Hazard Group 1. 4. Morpholinos act in a cell autonomous way and must be injected into individual cells. The effect wears off after about 3 days in these genetic modifications are transitory and genetically manipulated fish embryos or fry will not be allowed to reach maturity.

Origin & function

We will obtain sequence information about genes that have already been described or from EST databases that have been assembled from different organisms. We will also design antisense sequences to interfere with function of specific genes. We will test the function of genes in embryonic development by either over-expressing the genes or by trying to inhibit their function as described above. We will assess the phenotype morphologically and also use in situ hyridisation and immunohistochemistry where appropriate to monitor any molecular charges at either mRNA or protein level. The chick system allows local genetic modification and this should enable us to test the functions of genes at different stages and in different regions of developing embryos. We will use this system to examine, in particular, how limb formation is initiated and limb bud outgrowth and patterning is controlled. The experiments with fish embryos should allow rapid screening for the effects of lack of gene function in a vertebrate model system and we will focus our attention on development of paired fins. The vertebrate genes that will be investigated will include genes encoding growth factors, transcription factors, phosphatases, enzymes, receptors, and other genes of so far unknown function.

Evaluation of foreseeable effects

We will be over-expressing products of a range of different genes and these will include both transcription factors and secreted factors. Many of the molecules involved in embryonic development are also found in tumours. However in embryos, the production of these molecules is normally tightly regulated and tumours are not produced. Avian specific retroviral vectors cannot infect humans and strains of chickens differ in their susceptibility or resistance to viruses with different envelope subgroups. Most chicken strains purchased from commercial vendors are typically C/E strains and resistant to viruses with E envelope subgroup, while the viral vectors which we will be using most often will have envelope subtypes A and B (Morgan & Fekete (1996) Methods in Cell Biology 51, 185-214). In the very unlikely event of the release of virus from the Level 2 containment facility, it could survive in the environment for a similar period of time to the wild-type virus and could infect susceptible avian species if they entered the laboratory. This is impossible because the laboratory is behind a locked door. All waste is transported in sealed containers for autoclaving in the same building. Adenoviral vectors and host cells transfected with these vectors are considered equivalent to ACDP Hazard Group 2 and require Level 2 Containment because these viruses can infect humans. These adenoviral systems have been used in many other laboratories eg to over-express both normal and dominant-negative cell adhesion molecules in chicken embryos (Nakagawa & Takeichi (1998) Development 125, 2963-2971; also see Leber et al (1996) in Methods in Cell Biology, 51, 161-181) without any reported harmful effects on researchers. In the very unlikely event of the release of virus from the Level 2 Containment facility, it could survive in the environment for a similar period of time to the wild-type virus. If the virus infected a susceptible host, then expression of the recombinant genes would occur in the infected cells. Since the virus cannot replicate under normal circumstances, expression would be limited to the infected cell and once this cell divides to one of its daughter cells. The virus never integrates in the host genome and the episomal DNA is eventually lost through natural degradation.
### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The chick embryos and embryos infected with genetically modified organisms will be kept in incubators in a room behind a locked door. They will normally only be incubated for a total of 10 days, rarely beyond and will never be allowed to hatch. The fish are kept in aquaria behind a locked door system.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

#### Waste Disposal
Solid waste is collected in a lined, biohazard labelled, bin. After work the liner is sealed and transported directly to the autoclave facility, in a dedicated wheelie bin, for immediate autoclaving. After autoclaving solid waste is disposed of as normal refuse.

Liquid waste is collected in a plastic, autoclavable flask. After work the sealed flask is transported, in a plastic tub, on a trolley, directly to the autoclave facility for immediate autoclaving. After autoclaving liquid waste is disposed of to drains with copious amounts of cold water.

#### Monitoring
**Disinfection:** The disinfectant of choice (Virkon) is used in strict accordance with the manufacturer's (Antec's) guidelines.

**Autoclaving:** To ensure 100% efficacy, testing of the autoclave is carried out annually, by the manufacturer, to demonstrate, using a 12 point test with independent thermocouples, that the correct temperature and pressure have been reached for the required time. On subsequent runs verification that the correct conditions were reached is obtained through use of a temperature probe in the centre of the load. Testing is arranged and test reports are kept by the Health & Safety Co-ordinator.

**Inspections:** Safety Inspections are carried out annually to ensure Local Rules are adhered to and that risk assessments and training records are in order. Inspection reports are kept by the Health and Safety Co-ordinator.

**Microbiological Safety Cabinets:** Serviced and K1 tested on an annual basis. Certificates of conformity are displayed on each cabinet and copies kept by the Health and Safety Information Officer.

**Negative Pressure Suites:** Tested annually by Estates & Buildings to ensure the suite is at negative pressure relevant to the immediate surroundings. Testing is arranged and test reports are kept by the Health and Safety Information Officer.

Historical Significant Changes

Recipient or parental organism

1. Well characterised packaging cell lines, e.g. transformed human embryonic kidney (HEK) cell lines, that provide the genes deleted from the viral vectors in trans either by way of the cells own genome or by transfecting in complementing plasmids. These lines will be used for the propagation of the recombinant viral vectors containing the gene(s) of interest.

2. Other well characterised and authenticated tissue culture cell lines, e.g. HeLa, U2)S, MCF7, HT1080. These lines will be transfected with recombinant viruses then...
analysed in various ways in order to investigate the function of the genes/proteins of interest.

**Host/vector system**

Only well characterised, replication deficient viral vector systems with a history of safe use will be used, for example: adenoviral vector systems such as attenuated Ad5, and retroviral vector systems such as pHR-SIN-CSGW, derived from the human immunodeficiency virus 1 (HIV) genome.

Such viral vectors can only propagate in special packaging cell lines (as identified above). In cells they cannot replicate and, therefore, cannot produce a lytic infection.

**Origin & function**

The work performed in laboratories of the Division of Gene Regulation expression is concerned with different aspects of cell nucleus function. This includes chromosomal processes such as transcription and DNA replication, RNA-splicing and the function of micro RNAs (miRNAs). It also includes investigations of nuclear structure such as the nucleus and cajal bodies. The genetics material inserted into the replication deficient viral vectors will consist of cDNAs encoding for full length or mutant proteins known to regulate these processes and structures. It will also consist of sequences encoding short interfering RNAs (siRNAs), which downregulate the expression of their cellular target miRNAs amd miRNAs, which have a nuclear regulatory role. The specific genetic material to be studied includes:

1. cDNAs coding for proteins that are known or suspected to play a role in transcriptional regulation, for example the NF-kappaB subunits, hypoxia-inducible factors 1, interferon regulated factors and other transcription factors and proteins with which they interact such as the ubiquitin-like proteins, the I kappaBs, the IKKs and other kinases and phosphatases which control their function. The intention is to express these genes in mammalian cells and use various techniques to analyse their effect on gene expression, transcription factor function, the cell cycle and apoptosis. Short interfering RNAs (siRNAs) which downregulate the expression of their cellular target mRNAs will also be expressed. These siRNAs will be used to inhibit the expression of transcriptional regulators and other proteins that interact or regulate them.

2. Primary microRNAs (miRNAs), precursor miRNAs, siRNAs and cDNAs coding proteins ainvolved in mRNA driven transcriptional and translational regulation. The goal of using the retroviral system is to stably express regulatory RNAs and their target proteins in human cell cultures to investigate their role in development, tumour biogenesis and miRNA mediated gene regulation.

3. cDNAs coding for proteins that are known or suspected to play a role in DNA replication and cell cycle regulation, for example the Mcm2-7 proteins, geminin, Ctd1, Cdc6, ORC subunits, Cdc7, Cbf4, cyclins, cyclin-dependent kinases, cyclin-dependent kinase inhibitors and other kinases and phosphatases which control their function. These genes will be expressed in mammalian cells and various techniques will be used to analyse their effects on DNA replication, the cell cycle and apoptosis. Short interfering RNAs (siRNAs) which downregulate the expression of their cellular target mRNAs will also be expressed. These siRNAs will be used to inhibit the expression of DNA replication proteins and other cell cycle proteins that interact or regulate them.

4. Transcription factors, subunits or factors associated with the RNA polymerase I transcription machinery. The intention is to express these proteins in mammalian cells, to study their effect on RNA polymerase I transcription of the rRNA genes in cell growth proliferation. Short interfering RNAs which target the expression of RNA polymerase I transcription machinery components and their regulatory factors will be used to study the cellular effects of down-regulating Pol I transcription in mammalian cells.

5. cDNAs coding for proteins that are known or suspected to play a role in mitotic chromosome dynamics, for example the Aurora B kinase, INCENP, surviving, borealin, topoisomerase II, Aurora A kinase, Eg5, protein phosphatase 1, Sds22 and proteins with which they interact such as the ubiquitin-like proteins, and other kinases ans phosphatases which control their function. The intention is to express these genes in mammalian cells and use various techniques, but especially imaging based assays, often in living cells to analyse their effect on mitotic progression, mitotic chromosome dynamics, and mitotic spindle assembly and function, the cell cycle and apoptosis. Short interfering RNAs (siRNAs) which downregulate the expression of their cellular target miRNAs will also be expressed. These siRNAs will be used to inhibit the expression of the mitotic proteins listed above, and regulators of these proteins.

6. The genetic material involved will consist of cDNAs coding for mammalian nuclear proteins that are either components of the nucleolus and/or components of other classes of subnuclear bodies, including Cajal bodies, PML bodies, Speckles and Paraspeckles. In most cases these will be RNA binding proteins and related factors.
connected directly or indirectly with the biogenesis, maturation and/or transport of nuclear RNAs and RNA-protein complexes. Our intention is to express these cDNAs in mammalian cells and then to study the functions and biochemical properties or the resulting protein factors. For example, we will isolate and characterize their post-translational modifications and their interaction partners. We will also study their localization patterns in the nucleus and determine their dynamic behaviour by expressing the cDNAs as GFP-fusion proteins that can be analysed by time-lapse fluorescence microscopy. Finally, we will use siRNAs to downregulate expression of targeted nuclear proteins, such as spliceosome proteins and nucleolar factors and assess the effect of such reductions in protein levels upon pre-mRNA splicing activity, including alternative splicing patterns, and on nucleolar integrity and function.

**Evaluation of foreseeable effects**

The viral vectors used may infect a wide range of mammalian cell lines and, in the case of the retroviral vectors, they can integrate into the host cell genome and stably express the gene of interest. Some of the proteins being expressed will have the potential to interfere with normal regulation of chromosome function and associated processes such as the cell cycle and apoptosis. An infected individual could, therefore, be at risk of developing a serious disease. However, with the following key controls in place the residual risk is negligible:

1. Replication defective viral vectors are used to ensure proliferation occurs only in special packaging cell lines or in the presence of complimentary plasmids;
2. Containment Level 2 is applied in full to prevent infection of the worker or release into the external environment.

The inserted genetic material is not expected to have any positive effects on the infectivity or replication competency of the viral vectors and it is highly unlikely that there will be any effect on the host range or tropism, since the proteins of interest are not cell receptors or extracellular matrix proteins.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

**Waste Disposal**
Solid waste is collected in a lined, biohazard, autoclavable bin. After work the liner is loosely sealed and the lidded bin transported directly to the autoclave facility, on a trolley, for immediate autoclaving solid waste is disposed of as controlled waste.

Liquid waste is collected in robust, autoclavable, sealable containers containing enough disinfectant (Terminex) to give a 1% final volume. After work the sealed container is transported, in a plastic tub, on a trolley, directly to the autoclave facility for immediate autoclaving. After autoclaving liquid waste is disposed of to the drains with copious amounts of cold water.

Sharps waste is collected in a small, autoclavable sharpsafe. After work the sharpsafe is closed and transported in a plastic tub, on a trolley, directly to the autoclave facility for immediate autoclaving. After autoclaving sharpsafes are disposed of as clinical waste and sent for incineration.

**Monitoring**
- Disinfection: Virkon is used to treat spills and wipe down surfaces and equipment after work. Virkon is used in strict accordance with the manufacturer’s (Antec’s) guidelines.

- Autoclaving: During the first four years after installation an annual 12-point validation test, employing independent thermocouples, is used to demonstrate the the autoclave holds the specified temperature and pressure for the required period of time. Thereafter, autoclaves are serviced and calibrated annually, by a reputable service provider, to ensure the validation criteria are met. During normal, daily operation a temperature probe, placed at the centre of the load, is used to ensure the required conditions are achieved. Servicing and testing is arranged and test reports are kept by the SLS Health & Safety Co-ordinator.
Inspections: Safety inspections are carried out annually to ensure Local Rules are adhered to and that risk assessments and training records are in order. Inspection reports are kept by the Health & Safety Information Officer.

Committee agreed that facilities and procedures are appropriate for these activities. Committee accepted that testing for replication competent retroviruses is not routinely required given that these retroviral vectors have a history of safe use. Committee also endorsed the steps being taken within the division to allay concerns staff not directly involved in the work may have about the use of a HIV based system.

Please enter comments on the GM safety committee on the risk assessment

Historical Significant Changes

Tick if notifying a connected programme of work N
To determine the function of a range of intracellular signalling molecules, including protein and lipid kinases, lipid and protein phosphatases and associated proteins in signal transduction pathways.

Recipient or parental organism

1. Well characterised packaging cell lines (e.g. transformed human embryonic kidney (HEK) cell lines) that provide the genes deleted from the viral vectors in trans either by the way of the cells own genome or by transfecting in complimenting plasmids. These lines will be used for the propagation of the recombinant viral vectors containing the genes of interest.

2. Other well characterised and authenticated tissue culture cell lines, (e.g. HeLa, L6, 3T3-L1, U87MG, 1321N1, MCF10A and MDCK cells) and embryonic stem cells, hepatocytes, fibroblast and myoblast cells derived from rodents. These lines will be transfected with recombinant viruses then analysed in various ways in order to investigate the function of the genes/proteins of interest.

Host/vector system

Only well characterised, replication deficient viral vector systems with a history of safe use will be used, for example:

(1) pHR-SIN-CSGW is derived from human immunodeficiency virus 1 (HIV) genome but with the viral genes deleted. This vector contains the viral long terminal repeat (LTR) but with the U3 region deleted in the 3' LTR to prevent viral enhancer and promoter transfer into target cells (thus rendering it a so-called ‘self inactivated vector’). The vector also contains the Rev Response Element (RRE) to enhance expression, packaging signals, the HIV central polypurine tract (cPPT) to increase viral titre and a WPRE (Woodchuck hepatitis virus post-transcriptional regulatory element) to enhance mRNA stability. Expression of the inserted gene comes from a SFFV (spleen focus forming virus) promoter. Derivatives of this plasmid with altered restriction sites for cDNA insertion will be used. (2) pLenti6/V5-D-TOPO is a similar self inactivating Lentiviral vector for the expression of encoded proteins from a CMV promoter in infected cells. The retroviral vector is pWZL hygro, based upon Murine Moloney sarcoma virus, containing long terminal repeats, the viral gag gene and an inserted hygromycin resistance cassette, within a bacterial plasmid vector. To produce infective virus particles, the virus requires pol and env sequences provided by a packaging cell line. (4) pQCXI vectors from Clontech. These “retro-X” vectors are self-inactivating retroviral vectors designed to express a target gene alongside a selectable or fluorescent marker gene. They are based upon the Murine Maloney Leukemia Virus. These are of similar design to the pWZL vectors, except that they lack the viral gag gene, requiring this function in trans from the packaging cell line. (5) pLKO.1 is a replication incompetent self inactivating lentiviral vector for siRNA expression, encoding a puromycin resistance gene. It is available from Addgene. (6) pMKO.1puuro vector is a modification of the pQCXIN vector (Clontech) in which the puromycin resistance gene was introduced and the human U6 promoter to drive the expression of inserted cDNAs. (7) The Origene retroviral silencing plasmid pRS, contains murine retroviral long terminal repeats (LTR), puromycin resistant gene and a U6 small nuclear RNA gene promoter to effectively express the inserted hairpin DNA and to achieve RNA interference upon introduction into a mammalian cell. Such viral vectors can only propagate in special packaging cell lines (as identified above). In normal cells they cannot replicate and, therefore, cannot produce a lytic infection. Whenever possible, when experiments can be performed using rodent cells, ecotropic viruses will be produced that will not infect human cells.

Origin & function

The inserts to be used will consist of protein and lipid kinases (e.g. AMPK, PI3K, PKB, InsR), protein and lipid phosphatases (e.g. PTEN, SHiP2) and related proteins that interact or are affected by these enzymes (e.g. adaptor, scaffolding proteins, substrates, amino acid transporters). In addition viruses will be used to express short
Interfering RNAs (siRNAs) which down-regulate the expression of their cellular target mRNAs. These siRNAs will be used to target the same proteins listed above. As signalling pathways regulate cell growth and control transformation, it is possible, therefore, that changing the expression of genes from this pathway could be harmful. As signalling pathways also affect the immune system, it is also possible that expression of these proteins could therefore produce adverse inflammatory effects and immune suppression. The inserted genetic material is not expected to have any positive effects on the infectivity or replication competency of the viral vectors and it is highly unlikely that there will be any effect on the host range or tropism, since the proteins of interest are not cell receptors or extracellular matrix proteins.

**Evaluation of foreseeable effects**

It is theoretically possible that recombination between the retroviral vector and the retroviral components (transfected or stably integrated) in the packaging cell line could produce replication competent retroviruses (RCRs). However, the proposed vectors are in wide use and details of the plasmids and the demonstration that they do not give rise to replication competent viruses are available in Zufferey et al. Nat. Biotechnol. 15:871-875, 1997 and Zufferey et al, J. Virol. 72:9873-9880, 1998. There is evidence that such replication defective viruses are not pathogenic when tested in mice and a minimum of 3 recombination events are necessary to produce replication competent, recombinant virus. The effects of expression or knockdown of signalling components are unknown for many signalling molecules. It is possible that cell growth or immune function could be affected. Although retroviral particles and infected cultured cells would not survive outside culture medium, thorough measures must be taken to avoid exposure to workers. It is also possible that accidental exposure to the non-replicative virus would lead to chromosomal insertion of the virus in some cells of the worker. This apparently random insertion could inactivate or activate genes close to its point of insertion, with unknown consequences. However, the chances of such insertion occurring, and at such a pathologically significant site seem very small. Similar risks are associated with many delivery systems. The risk of replicative viral infection with these viruses seem remote. As described, this system has been developed to minimise this risk, which is also indicated by the development of these viruses for gene human therapy (see eg Braybrooke et al, 2005, Clin. Cancer Res. 11, 1512 ; Barquinero et al 2004 Gene Ther. 11 S3-9). The transfected cultured cell lines would not survive outwith the culture medium ruling out any possibility of survival, establishment or dissemination in the external environment. Also, retrovirus particles are relatively fragile, being easily inactivated by 0.1% detergent, chloroform, phenol, 1% bleach, 70% ethanol, 65oC for 30 min, pH <6.5 or >9.0, UV light, or autoclaving.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

| Waste Disposal | Solid waste is collected in a lined, biohazard labelled, autoclavable bin. After work the liner is loosely sealed and the lidded bin transported directly to the autoclave facility, on a trolley, for immediate autoclaving. After autoclaving solid waste is disposed of as controlled waste. Liquid waste is collected in robust, autoclavable, sealable containers containing enough disinfectant (Terminex) to give a 1% final volume. After work the sealed container is transported, in a plastic tub, on a trolley, directly to the autoclave facility for immediate autoclaving. After autoclaving liquid waste is disposed of to drains with copious amounts of cold water. Sharps waste is collected in a small, autoclavable sharpsafe. After work the sharpsafe is closed and transported in a plastic tub, on a trolley, directly to the autoclave facility for immediate autoclaving. After autoclaving sharpsafes are disposed of as clinical waste and sent for incineration. Monitoring | Disinfection: Virkon is used to treat spills and wipe down surfaces and equipment after work. Virkon is used in strict accordance with the manufacturer's (Antec's) guidelines. Autoclaving: During the first four years after installation an annual 12-point validation test, employing independent thermocouples, is used to demonstrate that the autoclave holds the specified temperature and pressure for the required period of time. Thereafter, autoclaves are serviced and calibrated annually, by a reputable service provider, to ensure the validation criteria are met. During normal, daily operation a temperature probe, placed at the centre of the load, is used to ensure the required conditions are achieved. Servicing and testing is arranged and test reports are kept by the College of Life Sciences Health & Safety Co-ordinator. Inspections: Safety Inspections are carried out annually to ensure Local Rules are adhered to and that risk assessments and training records are in order. Inspection reports are kept by the Health & Safety Information Officer. Microbiological Safety Cabinets: Serviced and KI tested on an annual basis. Certificates of conformity are displayed on each cabinet and copies kept by the Health & Safety Information Officer. |

### Project Additional Information

- Historical Significant Changes
- Historical Date of Additional Info
- Significant Change ID
- Date of Significant Change

Page 112 of 15326
Purposes of the contained use

To identify and investigate the role of genes/proteins involved in determining the pathogenicity and virulence of phytopathogens such as Streptomyces scabies and Pseudomonas syringae. Note: this project does not involve infection of plants - it is confined to the study of the pathogens themselves.

Recipient or parental organism

1. Plant pathogens, for example:
   - Streptomyces scabies: an opportunistic plant pathogen and causative agent of scab on root vegetables. Scab causing Streptomyces sp. are already endemic to the UK and do not cause economically significant damage on crops other than potatoes.
   - Pseudomonas syringae, pathovars maculicola and tomato: coronatine (a chlorosis-inducing phytotoxin) producing plant pathogens, endemic to the UK, causing bacterial leaf spot (or speck) on cruciferous vegetables and tomatoes respectively.

2. Commonly used, non-pathogenic, non-colonising cloning hosts, e.g. Streptomyces lividans, derivatives of E coli K12.

Host/vector system

Commercially available, widely used host/vector systems will be used for recombinant gene expression, including:

- Replication compromised shuttle vectors manipulated in lab adapted strains of E.coli. These recombinant vectors will then be transferred to the recipient via electroporation or by triparental mating via a suicide helper-plasmid.
- Lab adapted strains of E. coli and non-transmissible vectors used to construct cosmid libraries. Clones that contain the gene(s) of interest will be isolated by hybridisation and genes will be expressed in cloning hosts such as S lividans.

Origin & function

Primary focus of the work includes:

- The Tat (twin-arginine translocation) protein export system is found in the cytoplasmic membrane of most prokaryotes and is dedicated to the transport of folded proteins. The Tat system is now known to be essential for many bacterial processes including energy metabolism, cell wall biosynthesis, the nitrogen-fixing symbiosis and bacterial pathogenesis. In this project, Tat system genes in plant pathogens will be deleted/manipulated to identify and investigate the role of potential Tat-dependent pathogenicity determinants.
- Antibiotic-like gene clusters previously identified in certain plant pathogens will be assessed by phenotypic characterisation of transformed hosts. Putative functions will be confirmed by deletion of the antibiotic-like genes from the cosmid clone, and by deletion of the corresponding genes from the chromosome of the pathogen.
- Screening for additional proteins involved in virulence or multicellular behaviour of plant pathogens will be performed by transposon or targeted mutagenesis. Functions of gene products identified by mutagenesis will be ascertained by expressing them in E. coli.
- Phytopathogens may ultimately be modified by the introduction of certain avirulence genes. The purpose of these modifications is to be able to selectively elicit plant disease resistance responses.

Evaluation of foreseeable effects

Deleting/manipulating the tat system, or other genes involved in pathogenesis or secondary metabolite production, is highly unlikely to result in increased pathogenesis. The Tat system has already been deleted from a range of organisms (including plant and animal pathogens) and has universally resulted in strains less fit than the wild-type and, in the case of pathogens, lower pathogenicity than the wild-type. In the unlikely event that the organisms were to escape into the environment, they would almost certainly not persist due to their inability to compete with wild-type organisms. Introducing avirulence genes has the potential to restrict the already narrow host range of the phytopathogens that will be studied.

Therefore, no foreseeable adverse environmental effects are expected and risk to the environment is negligible.
None of the phytopathogens used in this project pose a risk to human health.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste Disposal
Solid waste is collected in a lined, biohazard labelled, autoclavable bin. After work the liner is loosely sealed and the lidded bin transported directly to the autoclave facility, on a trolley, for immediate autoclaving. After autoclaving solid waste is disposed of as controlled waste.

Liquid waste is collected in robust, autoclavable, sealable containers. After work the sealed container is transported, in a plastic tub, on a trolley, directly to the autoclave facility for immediate autoclaving. After autoclaving liquid waste is disposed of to drains with copious amounts of cold water.

Sharps waste is collected in a small, autoclavable sharpsafe. After work the sharpsafe is closed and transported in a plastic tub, on a trolley, directly to the autoclave facility for immediate autoclaving. After autoclaving sharpsafes are disposed of as clinical waste and sent for incineration.

Autoclaving: During the first four years after installation an annual 12-point validation test, employing independent thermocouples, is used to demonstrate that the autoclave holds the specified temperature and pressure for the required period of time. Thereafter, autoclaves are serviced and calibrated annually, by a reputable service provider, to ensure the validation criteria are met. During normal, daily operation a temperature probe, placed at the centre of the load, is used to ensure the required conditions are achieved. Servicing and testing is arranged and test reports are kept by the College of Life Sciences Health & Safety Co-ordinator.

Disinfection
Virkon, typically as a 1% solution, is used to treat spills and wipe down surfaces and equipment after work. Virkon is used in strict accordance with the manufacturer’s guidelines.

Monitoring
Safety Inspections are carried out annually to ensure Local Rules are adhered to and that risk assessments and training records are in order. Inspection reports are kept by the Health & Safety Information Officer.

Project Additional Information

Purposes of the contained use
To investigate cellular processes at a molecular level that may be of clinical relevance

Recipient or parental organism

Hazard Group 2 micro-organisms listed in The Approved List of Biological Agents, and Hazard Group 1 and 2 micro-organisms as categorised by ACDP guidelines.

Replication defective viruses and associated well characterised packaging cell lines as detailed in Section 2.6 to 2.12 SACGM Compendium of Guidance that can be categorised as ACDP Hazard Group 1 or 2.
Well characterised tissue culture cell lines
Primary cells.

Host/vector system
Well Characterised systems with a history of safe use will be used, for example: commercially available viral vector systems, non-mobilisable plasmid and bacteriophage vectors.

Origin & function
Wild type and mutant forms of genes and genetic material isolated from prokaryotic and eukaryotic organisms or chemically synthesised such as receptors, signalling molecules, transcription factors, enzymes, growth factors, cytokines, non-coding regulatory elements, anti-sense constructs and siRNA, reporter genes and selectable markers.

Evaluation of foreseeable effects
The genetically modified micro-organisms are likely to cause similar effects on human health and the environment as the wild type parent. Therefore, the containment measures for the parental micro-organisms (ie Containment Level 2 and additional measures required by licensing authorities) will be required to reduce the risks to research and support staff and to the broader environment to an acceptable level.

It is extremely unlikely that the genetic modification will alter significantly the fundamental properties of the parental micro-organism such as pathogenicity, infectivity, virulence, survivability, host range and/or response to prophylaxis/treatment. Therefore, additional Containment Level 3 control measures such as sealability for fumigation, HEPA filters on extract air and autoclave within laboratory suite are not merited for the level of risk i.e. not reasonably practicable.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste Disposal
Solid waste is collected in a lined, biohazard labelled, autoclavable bin. After work the liner is loosely sealed and the lidded bin transported directly to the autoclave facility, on a trolley, for immediate autoclaving. After autoclaving solid waste is disposed of as controlled waste.

Liquid waste is collected in robust, autoclavable, sealable containers. After work the sealed container is transported, in a plastic tub, on a trolley, directly to the autoclave facility for immediate autoclaving. After autoclaving liquid waste is disposed of to drains with copious amounts of cold water.

Sharps waste is collected in a small autoclavable sharpsafe. After work the sharpsafe's temporary closure is engaged and it is transported in a plastic tub, on a trolley, directly to the autoclave facility for immediate autoclaving. After autoclaving sharpsafes fully sealed then disposed of as clinical waste and collected by a specialist contractor.

Monitoring
Disinfection: Virkon is used to treat spills and wipe down surfaces and equipment after work. Virkon is used in strict accordance with the manufacturer's guidelines and efficacy data.
Autoclaving: During the first four years after installation an annual 12-point validation test, employing independent thermocouples, is used to demonstrate that the autoclave holds the specified temperature and pressure for the required period of time. Thereafter, autoclaves are serviced every 6 months by a reputable service provider and calibrated annually to ensure the validation criteria are met. During normal, daily operation indicator tape and, in the case of liquid waste a temperature probe placed at the centre of the load, are kept by the CLS Health and Safety Coordinator.

Inspections: Safety inspections are carried out regularly to ensure Local Rules are adhered to and that risk assessments and training records are in order. Inspection reports are kept by the Health and Safety Information Officer.

Please enter comments on the GM safety committee on the risk assessment

This is a broad connected programme of work supported by five risk assessments:
1. Assessment 1107 involves work with commercially available replication defective retroviral vectors that have a history of safe use to express potentially harmful genes such as those encoding proteins involved in signalling pathways.
2. Assessment 1111 involves work with a replication competent adenovirus to express genes involved in SUMO pathway - these genes could be harmful.
3. Assessment 1125 involves work with replication competent vaccinia virus. The inserted genetic material is unlikely to be harmful, and the insertion is likely to attenuate the virus.
4. Assessment 1124 involves work with Campylobacter jejuni-the most common cause of bacteria gastro-enteritis in the Western world. The genetic modification is likely to reduce its pathogenicity.
5. Assessment 1123 involves work with Salmonella typhimurium that will be modified to express siailated ligands on its surface. This modification could increase the virulence of the pathogen. However, it is unlikely that the modification will alter how these bacteria are transmitted (ie ingestion or injection) or their susceptibility to disinfectants/heat or antibiotics. Therefore, Containment Level 3 measures (ie room fumigation, HEPA extract air, sealable) are not required, nor does the laboratory need to be under negative pressure (not airbourne spread) ie implementation of these measures is not reasonably practicable since they will not significantly reduce the major risk of spread of infection by ingestion or injection.

The committee agreed that the Containment Level 2 facilities and SOP's for this programme of work are adequate for the level of risk. Special attention was given to in vivo work and it was confirmed that this work will be carried out in a dedicated laboratory, IVC and a class 2 change station or Class 2 microbiological safety cabinet will be used.

Therefore, the Committee agreed that this connected programme of work should be notified as Class 2.

**Project Ref** 6/12.1

**CU2 Project Title**
Use of genetically modified hazard group 2 viruses indigenous to the UK in molecular studies of innate and adaptive immunity

**Class** Class 2

**Culture Volume** 1-50 Litres

**Project notified under transitional arrangements** N

**Non-GMM Consent Granted**

**Historical Significant Changes**

**Historical Date of Additional Info**

**Withdrawn** N

**Tick if notifying a connected programme of work** N

**Project Additional Information**

**Purposes of the contained use**
To investigate at a molecular level the mechanisms of innate and adaptive immunity

**Recipient or parental organism**
Virus species indigenous to the UK and classified by the ACDP into Hazard Group 2, e.g. Influenza A virus, Vaccinia virus and Epstein-Barr virus. Well characterised and authenticated tissue culture cell lines will be infected for propagation of viral stocks. We may also carry out viral propagation in embryonated chicken eggs if this is the only reliable method, e.g. in the case of influenza A. Laboratory mice will be infected for in vivo studies.

**Host/vector system**
HG2 viruses will be received from collaborators ready modified or be genetically modified in-house using well established techniques, e.g. the reverse genetics system established by Enami and colleagues to rescue genes derived from cDNA into influenza A viruses.

**Origin & function**
Existing genes may be mutated or knocked down to investigate the effect this has on the immune response. Foreign sequences may also be inserted into the viral genome.
but only as markers/tags that provide a ‘read out’ and allow us to map and/or measure the immune response, e.g. a foreign epitope which can be detected with a T cell hybridoma following antigen processing.

**Evaluation of foreseeable effects**

Any viruses used in this project will be ACDP Hazard Group 2, i.e. they can cause human disease and may be a hazard to employees but are unlikely to spread to the community and there is usually effective prophylaxis or treatment available.

There is no intention to perform a knock down, mutaton or insertion that will increase the virulence of pathogenicity, or extend the host range, relative to the unmodified parent virus, i.e. any genetic modifications will invariably have a neutral or deleterious effect. As indicated above, inserted genetic material will code for peptide sequences that act as markers/tags and will not be inherently hazardous.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

- Solid waste will be autoclaved then disposed of to landfill.
- Liquid waste will be autoclaved then put to drain.
- Trace contaminated reusable labware and equipment with will be autoclaved if possible. If this is not possible, it will be disinfected with 1% Virkon overnight before being disposed of to drain.
- Any liquid waste that cannot be autoclaved (e.g. chemical or radiological contamination) will be disinfected with 1% Virkon overnight before being disposed of as special or radiological waste.
- Animal carcasses will be autoclaved then disposed of as clinical waste.

Risk assessment reviewed and approved by Committee members on 24th Jan 2012

---

**Project Containment**
We propose a systematic SILAC-based study of FMDV-induced proteome changes with subcellular resolution and to provide relative evaluations of their significance in FMDV replication and in cells supporting persistent replication. We aim to provide high-depth proteome coverage of 10,000 or more host-cell proteins. Control and FMDV replicon-transfected cells will be pooled at 2, 4, 6 and 8hrs posttransfection then extensively fractionated using ultracentrifugation methods. Fraction proteins will be isolated and further fractionated by 1D SDS-PAGE. Gel lanes will be cut into 12 slices and the proteins from each digested with trypsin, resulting in peptides eluted and analysed by high resolution mass spectrometry (MS). FMDV replicons cannot directly form infectious virus particles as capsid sequences have been deleted preventing the formation of particles to package and transmit the RNA to another susceptible cell.
**Recipient or parental organism**

FMDV replicons will be transfected into HeLa, BHK and a virus free, immortalised bovine cell line*. These host cell lines present no hazard to human health.

*Specific bovine cell line yet to be determined. As cattle is one of the hosts  

8. Containment and control measures for GMOs that are not micro-organisms (e.g. GM animals and plants)  
9. Maximum culture volumes per experiment - for GMMs only for FMDV, we want to make absolutely sure the cell line's genome does not code for FMDV capsid proteins.

**Host/vector system**

FMDV replicon RNA will be transfected directly into the host cells.

**Origin & function**

The FMDV replicon will be supplied by Prof Matrin Ryan, University of St Andrews. It includes sequences derived from foot-and-mouth disease virus genome, however, NO structural protein sequences are included. The replicon is thus is unable to generate virus particles or mediate cell-to-cell spread. It is limited to the cell into which it is introduced by transfection and maintained episomally.

**Evaluation of foreseeable effects**

The FMDV replicon is non-hazardous for the following reasons.

i) It does not encode any structural proteins and therefore lacks the ability for replicon-derived RNA to be packaged. It is therefore impossible to produce FMDV particles from this construct. Naked replicon RNA is highly unstable and cannot survive in the extracellular environment. Furthermore, it can only be transmitted to naïve cells using sophisticated laboratory-based techniques.

ii) Trans-encapsidation with structural proteins from other viruses would be extremely unlikely as this would need to have arisen from a) the presence of both the replicon and a replicating virus within the same cell and b) the ability of the coat proteins produced by the other virus to recognise and package FMDV subgenomic replicon-derived RNA. Even if both of these events were to occur, the resulting particles could not set up an infection as they would lack any genes encoding structural proteins and thus would only be able to undertake cell entry and replication of non-structural proteins. Furthermore, the absence of the structural protein coding sequences would prevent packaging and cell-cell spread.

iii) A recombination event between the replicon and another virus (termed X) could only theoretically occur if these were very closely related (e.g. another picornavirus) and if both were present in the same cell. The lack of any other picornavirus research in the laboratory, together with the containment precautions proposed for this work, mean that this event is extremely unlikely.
to occur. However, even if this highly unlikely event were to occur, recombination involving incorporation of viral structural genes into the replicon would result in the presence of structural proteins from virus X, not from FMDV. Even if the resulting construct was able to make RNA and proteins successfully, the capsid proteins of virus X are highly unlikely to be competent to package the RNA. But even if this was to occur, any particles would have the capsid of virus X (not FMDV) and therefore, due to inability to bind to appropriate receptors, would not duplicate the pathogenic profile of FMDV.

Furthermore, as picornaviruses do not replicate via a DNA intermediate and replicate entirely in the cytoplasm, there could be no host cell mediated homologous DNA recombination. Recombination between host RNA molecules is not a possible route for the provision of structural protein sequences. There is no impact on antibody testing for FMDV due to the absence of FMDV structural proteins.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

FMDV replicon work has been previously notified to HSE, initially by Prof Martin Ryan, University of St Andrews. HSE deemed that Containment Level 2 plus diligent sample and waste tracking were required. Therefore, waste disposal procedures specified in CLS SOP 48, Containment Level 2: Tissue Culture Facilities, as detailed below, will be followed.

*Waste must be disposed of correctly & all waste containers clearly labelled with your name, lab of origin, nature of the waste & the word "BIOHAZARD". Ensure no chemical waste is present in containers destined for the autoclave.*

- True sharps waste & plastic pipette tips must be disposed of into an autoclavable sharpsafe container kept within the MSC. Engage temporary closure before removal for disposal. The use of sharps must be avoided unless essential.
- Do not use large glass pipettes.
- Large plastic pipettes must be filled and drained 3 times using 1% Virkon, kept within the MSC if one is in use, before being drained completely and disposed of as solid waste.
- Solid waste must be collected in a red, lined, biohazard labelled, autoclavable bin (available from Media/Wash-Up). There must be no liquid in the solid waste. Do not use the cardboard biohazard bins.
- Liquid waste must be collected in a sealable, robust, autoclavable container. Do not use the aspirator setups.
- Blood and tissue waste (recognisable as such) must be disposed of as clinical waste (see the CLS H&S web site Waste Disposal section for further details).
- Radioactive or chemically toxic waste must not be autoclaved. Consult your Biological Safety Advisor (BSA) for advice.
At the end of the work session:
Bin liners must be loosely taped around the neck of the bag to prevent spillage during transport to the autoclave. Sharpsafes, with the temporary closure engaged, and liquid waste containers must be placed in the red biohazard bin along side the bags of solid waste and the bin removed to the anteroom. Tape the lid onto the red bin with a strip of autoclave tape and clearly write "WASTE" on the tape. Inform the Wash-Up Technician that there is CL2 waste ready for immediate uplift."
In addition to the above, to ensure a fully auditable trail, the following measures will be implemented:
- A record of all FMDV replicon waste transferred to the autoclaving facility and all autoclave runs will be kept. Note: our standard autoclaving conditions of 124 degrees C for 20 minutes will suffice.
- Once autoclaved, the FMDV replicon waste will be transferred to a large clinical waste bin.
- When full, this bin will be sealed and taken, by Safety Services personnel, the secure clinical waste freezer for final uplift and incineration by an external, specialist contractor.
Virkon, at a final concentration of 1%, will be used for surface disinfection and treatment of spills.

Please enter comments on the GM safety committee on the risk assessment
Members are reassured by the detailed phylogenetic studies carried out by St Andrews University evidencing the likelihood of generating an infectious virus harmful to the environment is extremely low. However, members noted that once inside a cell the Replicon has all the viral sequences required to replicate leading to cell death within a few hours.
Members noted there is no reliable evidence of human illness arising directly, or indirectly, from infection with FMDV-despite it being endemic in several countries and epidemic in others.
Members acknowledged the SACGM decision in 2004 to allow these studies to be carried out at Containment Level 2 with additional measures to keep materials secure at all times. In accord with this decision members agreed CLS Containment Level 2 facilities and Safe Operating Procedures are appropriate for the level of risk with the addition of streaming autoclaved waste as Clinical Waste for incineration.
Members agreed that the risk to the environment from proposed work in the future with extracts from virally infected cells provided by collaborators is not addressed by this risk assessment. This work will have to be risk assessed and approved by this Committee before it commences.

Use of genetic tools to study the basic biology/biochemistry of the Cryptosporidium parvum parasite, and to identify and validate potential drug candidates for cryptosporidiosis.

The intracellular parasite Cryptosporidium parvum will be used as a model organism due to the fact that out of 32 identified species Cryptosporidium it is one of only two species that cause disease in humans. Further, this species is amenable to genetic manipulation and is easily maintained in the laboratory. The effects of clinical infection with Cryptosporidium parvum are well known and range from asymptomatic to severe and sometimes fatal illness. However, the latter is only seen in immunocompromised individuals or those with severe underlying health issues. Most people who contract cryptosporidiosis make a full recovery without treatment.

Recipient or parental organism

The intracellular parasite Cryptosporidium parvum will be used as a model organism due to the fact that out of 32 identified species Cryptosporidium it is one of only two species that cause disease in humans. Further, this species is amenable to genetic manipulation and is easily maintained in the laboratory. The effects of clinical infection with Cryptosporidium parvum are well known and range from asymptomatic to severe and sometimes fatal illness. However, the latter is only seen in immunocompromised individuals or those with severe underlying health issues. Most people who contract cryptosporidiosis make a full recovery without treatment.

Host/vector system

The host is C. parvum Iowa II strain. This is the only strain of Cryptosporidium that will be used. To generate GMO Cryptosporidium, the organism is transfected with (1) A CRISPR/Cas9 plasmid containing a guide RNA sequence that targets the gene of interest and (2) a linear DNA fragment that contains a gene for NanoLuciferase and a selection marker. The plasmid specifically contains Streptococcus pyogenes Cas9 gene under control of Cryptosporidium regulatory elements. This plasmid also contains the Cryptosporidium U6 promoter to produce a guide RNA. The resulting RNA molecule directs the activity of Cas9 to act against a specific sequence of the
Cryptosporidium genome. Plasmids are not maintained in Cryptosporidium, therefore Cas9 and the guide RNA are only transiently expressed by Cryptosporidium and are not maintained from generation to generation. However, the linear DNA molecule containing the gene for NanoLuciferase and a selection marker (neomycin resistance gene) is incorporated into the genome at the site designated by the guide RNA. The guide RNA "guides" Cas9 to make a double stranded break in the chromosomal DNA at a specific sequence and the endogenous homologous repair machinery of Cryptosporidium repair this break by integrating the linear DNA fragment. This linear DNA fragment modifies the chromosomal DNA, for example by deleting a gene of interest, or by inserting an epitope tag at the C-terminus of the encoded protein (to allow for expression and localization studies). To encourage homologous recombination at the site designated by Cas9, the linear DNA fragment is flanked with regions homologous to the chromosomal insertion site. This integrated DNA fragment will be inherited by all progeny organisms and maintained in the chromosomal DNA.

Origin & function

The genetic material is either C. parvum genetic material being used to generate mutant strains or it is marker genes (GFP, YFP, etc) to identify expression patterns, reporter genes (luciferase, etc) to study expression levels, epitope tags (HA, GST, etc) for protein purification or the drug resistance marker (Neomycin resistance) that is needed to select for transgenic organisms. All these materials will be derived synthetically or via production of genetic material in E. coli using standard molecular biology approaches.

Evaluation of foreseeable effects

It is foreseeable that workers could become infected with C. parvum, either the parental strain (Iowa II) or any of the genetically modified strains. It is considered that none of the mutations are likely to increase pathogenicity of the organism and, indeed, many of the mutations will likely be deleterious to the organism. Neomycin Resistance (confers resistance to paromomycin) is introduced into the GM organisms in order to select for the genetic change. Paromomycin is an effective drug for treatment of cryptosporidiosis in immunocompromised mice, but not in human cryptosporidiosis and so will not affect the virulence of the organism.

The inherent homologous recombination machinery of C. parvum will be used to integrate transgenes at specific locations in the genome. All transgenes used to generate transgenic Cryptosporidium strains are chromosome borne. Currently there is only a single drug resistance marker for Cryptosporidium, therefore only a single cassette of transgenes may be introduced into a strain. Transgenic C. parvum are maintained under drug pressure, selecting for growth of only transgenic organisms. Additionally, all transgenic strains are produced from the same parental C. parvum Iowa II strain, so recombination or gene transfer from transgenics to Wild Type does not increase the genetic diversity. Cryptosporidium do not stably maintain plasmids, therefore transgenes are all chromosome borne. Transgenes expressed by Cryptosporidium parvum are not transferred from Cryptosporidium to its host (human cells in co-culture or infected animals - humans included).

Cryptosporidium are water borne, but cannot replicate in the environment. Cryptosporidium parvum can only survive and grow inside the host organism (cow, sheep, humans, immunocompromised mice).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Water bottles and used feed must be autoclaved prior to washing or disposal by placing in taped closed - autoclavable biohazard bag. Autoclave using SLS standard conditions.

Dirty bedding and isolator units must be autoclaved prior to disposal by placing in taped closed, autoclavable biohazard bag - autoclave using SLS standard conditions.

Flasks, pipettes, plates, glassware, spent media, etc will be autoclaved prior to washing or disposal by placing in taped closed, autoclavable biohazard bag - autoclave using SLS standard conditions. Spills/waste (media, feces, tissue, towels, etc) from sample collection will be placed into a biohazard bag in a biohazard bin; other surface spills will be treated with 3-6% H2O2 application for 20 minutes. Any needles/blades used for work or unintentional sharps (from broken glass/plastics) will be placed in a sharps container which is then disposed of via standard SLS clinical sharps disposal route. Biosafety cabinet/work areas - 3-6% H2O2 application for 20 minutes, or use of Diversey Oxivir Disinfectant Spray (or similar) and wipe down following handling of parasites on surfaces or nonporous materials contaminated with parasites. H2O2 made
The GM Safety Committee supported the proposed work. Discussion of the following points took place:

- **Appropriate disinfection protocols for Cryptosporidia, including alternatives to hydrogen peroxide. Neopredisan, a chlorinated phenol derivative was suggested.**
- The risk assessment notes greater risk for the young and immunocompromised. The Committee suggested that there should therefore be extra consideration given to those working with the organism who are immunocompromised or who have young children. Especially, in this regard to pregnant persons and those who have recently given birth/breast feeding. The Committee stated that the decision of how to implement this would be up to the PI, but suggested that the PI may wish to ensure that any such persons are given the option not to work with the organism. This would include anyone else who is significantly immunocompromised (noting, of course, that people must have disclosed this to the PI in order for action to be taken).

- In section 2a - hazards to human health. The Committee approved of a comment about using an attenuated strain if this becomes available. This shows the PI has considered this risk reduction principle (even though at present such a strain is not available). Likewise, the point about in vitro culture (although that is not directly related to human health).

- In section 3 – The Committee noted that the PI made a comment about Cryptosporidia not being able to be aerosolised and asked for more clarification of what is meant by this. The Committee wondered whether the PI meant that desiccation would occur and would inactivate the organism.

- In section 4a – direct effects on the environment of the host. The Committee noted that the organisms is endemic and as such no further comment is required.

- In section 4b - The genetic material. The Committee noted that the PI mentioned the antibiotic resistance cassette used being effective against an antibiotic that is relevant to treatment in immunocompromised mice. The Committee wanted to know whether this has any relevance to wild mice or other organisms in the wider environment.

- In section 5b. The PI answered no to a requirement for work to take place within a microbiological safety cabinet. The Committee wanted more clarification about the aerosol issue noted above in relation to this point.

The Committee wished for more information in relation to spill procedures and whether the PI has a special spill procedure for uncontained spills. For example, if material containing the organism were spilled on the floor of the faecal room, what would the procedure be? Would it be necessary to disinfect the floor with H2O2?

Production of pLGICs (membrane proteins) by the lentiviral transduction of mammalian cell lines

The proposed work will provide a means to study at a molecular and cellular level the functions of proteins involved in a range of fundamental cellular processes such as DNA replication, protein synthesis, inter- and intracellular signalling. This will allow us to investigate the molecular mechanisms that are important for normal cellular functioning and also the causes of a range of serious diseases such as cancer, diabetes and neurological conditions.

A range of eukaryotic cell lines will be the recipient organisms. The cells will generally be well characterised, continuous rodent, primate or human cell lines that have an established history of safe use. However, in some cases finite or less well characterised primary cell lines may be used. In such cases, care will be exercised to minimise the likelihood of adventitious agents being present. This will include careful selection of source material (utilising screening whenever possible). Note that work in E. coli required to produce the viral vectors is covered by an existing class 1 GM risk assessment and so this element of the work is not considered further in this notification.

A range of viral vector systems will be used, including lentiviral, retroviral, adeno-associated and adenoviral vectors. In line with SACGM guidance, vector/insert systems that result in essentially no risk to workers or the environment are covered under a GM class 1 assessment and are not therefore part of this notification. Such systems are:

• 2nd/3rd generation lentivirus or 3rd generation retrovirus
• Replication incompetent and self-inactivating
• Not containing X protein expressing forms of WPRE
• Insert is non-harmful
• Activity does not require sharps

and

• Disabled 2nd or 3rd generation adenovirus vectors
• Likelihood of reversion event must be low
• Stock must be demonstrably free of any replicative virus
• Insert is non-harmful
• Activity does not require sharps

This notification therefore covers vector/insert systems that fall outside of the above classification due to either the nature of the insert (e.g. biologically active, potentially harmful insert such as an active oncogene or cytokine) and/or the vector (e.g. viral vectors containing a WPRE capable of expressing any part of the X protein). Replication competent viruses of any type will NOT be used and viral packaging systems of at least second generation will be used.

Origin & function

The genetic material to be inserted into the viral vector systems will be cloned cDNA sequences derived from a variety of sources (e.g. PCR from cDNA, EST, genomic DNA, synthetic DNA produced by chemical synthesis means). In most cases, the DNA will be of eukaryotic (mainly human or rodent) origin, but some prokaryotic DNA material may be used if this is related to the ability of such organisms to cause disease (e.g. virulence factors that interfere with cellular pathways). In such cases, virulence factors would be expressed individually or, if more than one virulence factor, from separate viral vectors. Where possible, expression of virulence factors would be under inducible control to prevent unintended expression in the event of worker exposure.

Evaluation of foreseeable effects

The cell lines that will result from infection with the viruses are considered to be of low risk. As noted, most cell lines will be continuous well characterised lines, but some may be primary or less well characterised continuous cell lines and this creates a risk (through the potential for adventitious agents to be present) that warrants containment level 2, but is not related to the genetic modification element of the work. However, some elements of the genetic modification could pose a risk to human health or the wider environment. For example, expression of an oncogenic gene or biologically active molecule (such a cytokine) could make the cell line a risk to workers via internalisation (principally via injection). Whilst there will be no work with immortalised cells obtained from workers themselves, it cannot be guaranteed that an immune response would prevent harm occurring in such a situation.

Of more concern though is the potential for infection of a worker by a viral vector via injection or another route (e.g. inhalation). Whilst viral vectors will be replication incompetent, insertional mutagenesis is a risk (although very low, given that there will be no intentional infection of workers with high doses of virus, so exposure dose from an accident is likely to be low). Stable insertion of the viral DNA and expression of the associated transgene(s) is a risk should infection of a worker or someone in the wider environment occur. Expression of an oncogene could cause transformation and expression of other biologically significant proteins (e.g. signalling molecules) could elicit unpredictable responses. Some viral vectors may also contain genetic elements that are of potential concern, such as WPRE X protein sequences in some retroviral vectors, which may have oncogenic properties. Note that whenever possible, viral vectors that do not have potential to express any portion of the X protein will be used. Generally, the intention is to only use commercially available viral vector systems (whether obtained directly from the supplier or from a collaborator). Such systems would be selected on the basis of inherent safety features, one of which would be that they could not express the X protein. However, there is a possibility that a vector system capable of expressing a portion of the X protein (or where it is not clear from available information whether it could express such a portion) may be used.

Whilst the risk posed by all of these issues should be low, they are foreseeable and result in a risk that cannot be said to be insignificant. For this reason, a classification of 2 is appropriate based on these foreseeable effects.
All viral particles generated via the use of packaging helper cell lines will be replication incompetent and once initial infection of target cells has taken place, infective virus should not be present. This will be established by standard means such as PCR of cell culture supernatant.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

No GM animals with a greater potential to cause harm to human health compared to the unmodified organism will be generated and so notification is not required.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste is collected in lined autoclavable lidded boxes. Waste is either solid only or mixed solid and liquid waste. Waste is removed without delay from the site of production to a waste facility located within the same building where it is autoclaved on an appropriate cycle for the type of waste. There are:

- Liquid waste: 134 Degrees Celcius for 5 minutes
- Mixed solid and liquid waste: 121 Degrees Celcius for 20 minutes

These conditions are standard autoclave conditions known to provide 100% degree of kill. Subsequent to autoclaving, solid waste is bagged as “tiger stripe” offensive waste and sent to land fill. Liquid waste is disposed to drain. Each autoclave cycle is monitored by internal sensors and the results recorded (either via computer monitoring or paper printout) to establish that the standard conditions were met. Autoclaves are subject to service and maintenance every six months and an annual calibration, all undertaken by an external contracted service engineer appointed via a University procurement process. Autoclaves are also subject to annual insurance inspection to comply with University insurance requirements and the Pressure Systems Safety Regulations.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

Please enter comments on the GM safety committee on the risk assessment
Initial comment from University Biological Safety Advisor (UBSA):

"The risk assessment is generally well written, but more information is needed with regard to the precise nature of the vector system. Currently it states that a modified version of a cited method will be used. The inserts themselves are low risk and so the key to whether this will require notification is the vector system."

Comments from GMSC members subsequent to changes being made in light of above comment:

"VSV-G pseudotyped lentiviral vector containing full length WPRE, i.e. WPRE containing truncated X-protein, therefore Class 2."

"Looking at the list of HSE notifications, titles only, none seem relevant to this project. As previously discussed at UoD BA Committee, ideally, we need a notification to cover all replication defective viral vector work."

"I am happy with the changes made and accept this risk assessment." (UBSA)

## Project Additional Information

**Purposes of the contained use**  
Increasing basic understanding of the mechanisms underlying bacterial pathogenicity.

**Recipient or parental organism**  
Genes cloned from one pathovar of Pseudomonas syringae (parent) will be transferred into E. coli DH5α and into other pathovars of Pseudomonas syringae.

**Host/vector system**  
Vectors used will be broad host range plasmids such as pLAFR3 and ColEl replicon based pBluescript.

**Origin & function**  
Genes transfer will be used to identify genes for avirulence and virulence by function, using altered pathogenicity as the test. Following detection of activity in cosmid clones (up to 30 Kb) sub-cloning will allow functional open reading frames to be analysed. Proteins will be expressed from vector promoters.
Evaluation of foreseeable effects

The GMOs are not considered a significant risk to human health. Release of the GM Pseudomonas syringae strain with altered virulence is unlikely to result in the infection of plants. The bacteria are spread by seed and through rainsplash onto infected leaves. They are not soil-borne pathogens. Nevertheless the Pseudomonas syringae strains will not be specifically disabled.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Plants infected with GMOs will be maintained in designated growth rooms as specified in the MAFF (now DEFRA), Plant Health Licence, no PHL30A/37554/2001).

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

1. Autoclaving at 121°C for 30 mins to destroy broth and petri cultures and infected plant material (leaves and pods).
2. Soaking in a presept bath 140ppm chlorine, overnight to decontaminate glassware and plasticware.
3. Incineration of contaminated soil and pots organised by "Whiterose" No GMOs should survive.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Although the hazards posed by the work were not assessed to require greater than containment level 1 for human health, the use of plant pathogens necessitates notification of Class 2 activity.

Project Ref 275/03.1
Investigation of cellular immune responses to viruses using vaccinia virus vectors with inserts from (A) human immunodeficiency virus and (B) papilloma virus.

Recipient or parental organism
Vaccinia virus containing one of the following genes: HIV-1, gag, env, pol, nef; influenza; nucleoprotein, matrix protein, pol; papilloma virus (HPV16 and 18) E6 and E7 fusion protein -- the E6 and E7 proteins have oncogenic properties. Transformation requires E7 to bind to retinoblastoma protein. To remove oncogenic potential the E7 protein is mutated at two amino acid residues to abolish binding to retinoblastoma protein. There is no evidence in the literature that modification of the vaccinia increases its pathogenicity.

Host/vector system
Vector: vaccinia virus
Host cell: TK 143, a thymidine kinase negative cell line.

Origin & function
Inserted genes: HIV-1 gag, env, pol, nef,
    influenza matrix, nucleoprotein, pol
    Papilloma virus types 16 and 18 E6 fused to a mutated E7 protein.

The genes will be transfected into human dendritic cells to facilitate antigen presentation to stimulate virus specific cytotoxic T cells.

Evaluation of foreseeable effects
Accidental exposure to the vaccinia modified vector may result in the generation of an immune response to the product of the inserted gene. No other clinical outcome would be expected as a result of the modification.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste (plastics): 2% Virkon overnight. The manufacturer specifies that this will give 100% kill. The decontaminated waste will be then autoclaved prior to disposal via the Chelsea and Westminster Hospital waste disposal services.

Liquid waste: via autoclave, 134 degrees centigrade applied including air extraction, heating and steaming for 30 minutes. The manufacturer specifies that this will give 100% kill. Indicator strips to be used to monitor every autoclave run. Regular six monthly servicing and testing of the autoclave by the manufacturer.

The principal investigator to monitor staff to ensure correct disposal routine is followed.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

The committee agreed that a class II classification was appropriate for the work and that the safety precautions outlined were satisfactory.

Project Ref 275/04.1

Date Ackn'd 02/03/2022  CU2 Project Title  Class  CultureVolClass2  CultureVolumeClass3-4
Project Additional Information

Purposes of the contained use
To study cellular immune responses to KSHV in healthy immunocompetent individuals and in individuals infected with HIV.

Recipient or parental organism
KSHV containing a Green Fluorescence protein (GFP) insert. The modified KSHV genome contains an insert of GFP (expressed by the elongation 1-alpha promoter) and the neo gene (expressed by the RSV promoter). This construct was inserted through homologous recombination between ORF 57 and ORF 59 of the KSHV genome (Gao et al, J. Virol 2001.77: 1378-1386). The recombinant KSHV has been designated as rKSHV.152. There is no evidence that the modification of the KSHV increases virulence or pathogenicity.

Host/vector system
Vector: KSHV
Host cells: BCBL-1, a human primary effusion lymphoma cell line containing wild type KSHV.

Origin & function
Inserted gene: GFP derived from Jellyfish.
GFP will be used to detect recombinant KSHV infection in a range of mammalian cell types including endothelial cells, fibroblasts, lymphocytes and myeloid cells.
Infected cells will be used as targets for KSHV specific NK cell and T-cell responses.

Evaluation of foreseeable effects
KSHV infection does not result in pathogenic effects in healthy individuals. This virus can lead to the establishment of tumors in HIV-1 patients.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**Historical Significant Changes**

Transfered to GM8 on closure of GM309

**Historical Date of Additional Info**

**Significant Change ID**

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

Recombinant seV will be used to transfer reporter and therapeutic genes to different cell types (in vitro and in vivo) and compared to currently available gene transfer vectors.

**Recipient or parental organism**

Sendai virus (SeV) is an enveloped virus with a nonsegmented negative-strand RNA genome of 15384 nucleotides and is a member of the family Paramyxoviridae. The SeV genome contains six major genes: nucleoprotein (NP), phosphoprotein (P) and large protein (L) form a ribonucleoprotein (RPN) with the SeV genomic RNA. The matrix protein (M) engages in the assembly of viral particles. Two envelope glycoproteins, hemagglutinin-neuraminidase (HN) and fusion protein (F) mediate the attachment of virions and penetration of RNP into infected cells. SeV replication is independent of nuclear functions and does not have a DNA phase. Therefore, it does not transform cells by integrating its genetic information into the cellular genome. SeV has been reported to naturally infect rodents (causing upper respiratory tract infections) and has never been reported to infect humans.

**Host/vector system**

Transgenes are normally inserted immediately before the ORF of the viral 3'-proximan nucleocapsid (NP) protein gene in a full-length SeV CDNA copy. The inserted gene is flanked by "gene start signal" and polyadenilation/stop sequences and recognised by the viral RNA polymerase.

**Origin & function**

The Sendai genome derives from the Z-strain. The recombinant virus has been developed by a Japanese biotech company, DNAVEC. The recombinant SeV will carry different transgenes:

1. bacterial transgenes, such as beta-galactosidase or CAT;
2. Eukaryotic transgenes such as luciferase (from Photinus pyralis) and GFP (from jellyfish);

**Therapeutic genes**

**Evaluation of foreseeable effects**

1. Recombinant SeV does not have an altered tropism compared to wild type virus. However, insertion of a transgene reduces the replication speed as well as the final virus titre in a way, that is proportional to the size of the transgene, carried. In vivo a remarkable attenuated replication and pathogenicity were generally seen (Sakai et al.,

---

02/03/2022
2. Virus replication and transmission to neighbouring cells has been demonstrated in the host species (rodents). SeV has never been reported to infect humans.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Recombinant Sendai virus is stored at-80°C in 1-2 ml vials separately from the biological samples. All experiments are carried out in class II cabinets. After use, cabinets are UV irradiated for at least 30 minutes, Single-use plasticware is used. The solid waste produced is double-bagged and autoclaved (121°C/1 atm). For the liquid waste, Hypachlor for > 10 min with chlorine (2500 ppm final concentration) is used. Personnel will wear labcoats, gloves, masks and overshoes.

Please enter comments on the GM safety committee on the risk assessment

The Generic Modification Safety Committee has reviewed the application in great detail. The committee is satisfied that the virus poses no risk to humans and that adequate measures have been taken to ensure that the virus will be wholly contained within the dedicated unit set up specifically for this work.

### Project Additional Information

#### Purposes of the contained use

Chronic obstructive pulmonary disease (COPO) is an inflammatory disease that results in poorly reversible airflow limitation, with symptoms including chronic cough, shortness of breath and sputum production. Macrophages are inflammatory cells that are essential in the maintenance of lung homeostasis. These cells are highly phagocytic, and are crucial in the clearance of bacterial and cellular debris. Macrophage phagocytosis is impaired in COPO, resulting in bacterial colonisation and increased risk of infection, and there has been increasing incidences of patients with COPO being infected with Aspergillus. Aspergillus Fumigatus may affect macrophage phenotype and function, as this has also been affiliated with worsening symptoms at exacerbation. We plan to investigate uptake of Aspergillus Fumigatus by macrophages derived from human blood and lung samples.

#### Recipient or parental organism

Aspergillus Fumigatus strain ATCC46645 (ACOP classification 2).

#### Host/vector system

Aspergillus fumigatus has been modified to ubiquitously express GFP so as to be suitable for imaging purposes, FACS and phagocytosis experiments.

1. The eGFP gene (Clontech, Heidelberg, Germany) and the gpdA promoter from A fumigatus were amplified by high-fidelity PCR (Roche, Mannheim, Germany) using oligonucleotides GFP-For, GFP-Rev, gpdA-Prom-For and gpdAProm-Rev. The amplification products were cloned into the pOrive cloning vector (Qiagen, Hilden, Germany) and sequenced using external plasmid-derived primers. The fragments were subsequently cloned into the EcoRV site of pBluescript KS+ (Stratagene, Amsterdam, the Netherlands). The hygromycin resistance cassette containing the hygromycin B phosphotrans-ferase gene of E. coli under the control of the gpdA promoter was isolated from plasmid pUCGH-pyrG and inserted into the KpnI site of pBluescript KS+. Both fragments were cloned into pBluescript KS+ in opposite orientation resulting in plasmid pMAF1, that was transformed into A fumigatus protoplasts using a method described previously (Langfelder et al., 1998).

#### Origin & function

GFP label in Aspergillus is fluorescent on the FITC channel.

#### Evaluation of foreseeable effects

Aspergillus fumigatus has been modified to ubiquitously express GFP so as to be suitable for imaging purposes, FACS and phagocytosis experiments. The addition of the GFP gene allows the microbe to become fluorescent. There are no further functional changes to the microbe, and therefore it poses no greater threat to human health compared to the unmodified strain.

To create this GFP labelled strain, a hygromycin resistance cassette was inserted into the plasmid. The strain would therefore be resistant to this antibiotic. This should be noted in case of accidental infection to a human user.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
A Class II Microbiological safety cabinet (MSC) will be used when handling/processing samples. After use, the safety cabinet will be decontaminated using 2% Distel or 2% Virkon. All buckets used in centrifuges will be fitted with lids when spinning samples, and the centrifuge and buckets will be decontaminated post use using 2% Distel. In case of spillage within the centrifuge, the centrifuge lid will remain closed for 1 hour to allow any aerosol to settle. After 1 hour, the spilled material will be wiped up, area will be sprayed with 2% Distel or 2% Virkon. Distel bottle will be kept near the centrifuge.

Solid Waste: Solid waste will be collected in a biohazard bag inside the Biosafety Cabinet. Pipette tips will be collected in a small Biobin, and the bin closed and deposited into the biohazard bag (in the Biosafety Cabinet) at the end of the work session. Solid waste exposed to A Fumigatus are first disinfected with 2% virkon, prior to disposal in Biobins or biohazard bags. At the end of the work session, the biohazard bag will be closed, sprayed with 70% EtOH, and deposited into a biohazardous waste container. These will be autoclaved, and taken off-site to be incinerated.

Liquid Waste is normally aspirated into a vacuum flask containing 1/10 volume Virkon. The vacuum flask must have a final concentration of at least 10% virkon, for a minimum time of 30 minutes prior to drain disposal. Liquid waste that is not aspirated must be treated with virkon, to a final concentration of 2%, in the hood, allowing a minimum time of 30 minutes to inactivate fungus.
Many thanks for the attached and I note that all changes noted in e-mails below and in the form C have been made to the 8101. However I do have some additional comments for both the CU2 and 8i01. Hope this makes sense. Please send the completed forms back to Biosafety@imperial.ac.uk and we will fill in our bits. Many thanks

CU2 - The must read the same as the BI01 and vice versa. I have the following comments
Section 5 - This should be the Title of the activity from the BI01. - Lentiviral transfection for overexpression studies to correct defective phagocytosis in human MOM in COP. Otherwise if this title no longer fits the activity please change it in the BI01 and the Cu2
Section 6 - The highlighted text does not appear to be in the BI01. Please put this explanation in the BI01. 1.1 is probably the best place for it.
*and there has been increasing incidences of patients with COP being infected with Aspergillus. Aspergillus Fumigatus may affect macrophage phenotype and function, as this has also been affiliated with worsening symptoms at exacerbation. We plan to investigate uptake of Aspergillus Fumigatus by macrophages derived from human blood and lung samples*
Section 7 -
Recipient - This is different to the text for the recipient strain in 2.15 of the BI01. Please make it the same. Le. Aspergillus Fumigatus strain ATCC46645 (ACOP classification 2).
Vector - This is different to the text for the recipient strain in 2.16 of the BI01. Please make it the same. i.e. Aspergillus fumigatus has been modified to ubiquitously express GFP so as to be suitable for imaging purposes, FACS and phagocytosis experiments.
1. The eGFP gene (Clontech, Heidelberg, Germany) and the gpdA promoter from A. fumigatus were amplified by high fidelity PCR (Roche, Mannheim, Germany) using oligonucleotides GFP-For, GFP-Rev, gpdA-Prom-For and gpdAProm-Rev. The amplification products were cloned into the pDrive cloning vector (Qiagen, Hilden, Germany) and sequenced using external plasmid-derived primers. The fragments were subsequence cloned into the EcoRV site of pBluescript KS+ (Stratagene, Amsterdam, the Netherlands). The hygromycin resistance cassette containing the hygromycin B phosphotransferase gene of E. coli under the control of the gpdA promoter was isolated from plasmid pUCGH-pyrG and inserted into the KpnI site of pBluescript KS+. Both fragments were cloned into pBluescript KS+ in opposite orientation resulting in plasmid pMAF1, that was transformed into A. fumigatus protoplasts using a method described previously (Langfelder et al., 1998).
Origins and intended functions of the genetic material - This is different to the text for the recipient strain in 2.17 of the BI01. Please make it the same. Le. GFP labet in Aspergillus is fluorescent on the FITC channel.
7. Please add the following text which is in the CU2 to the 8i01 sections 2.18 and 4.20
*Aspergillus fumigatus has been modified to ubiquitously express GFP so as to be suitable for imaging purposes,
FACS and phagocytosis experiments. The addition of the GFP gene allows the microbe to become fluorescent. There are no further functional changes to the microbe, and therefore it poses no greater threat to human health compared to the unmodified strain.

To create this GFP labelled strain, a hygromycin resistance cassette was inserted into the plasmid. The strain would therefore be resistant to this antibiotic. This should be noted in case of accidental infection to a human user.

Section 9.1 This answer is different to the 8i01 section 4.4 please make sure that the volumes are the same.

Section 12 is different to the waste section 7 in the 8i01. Please take the text from the CU2 which is nicely detailed and add it to the 8i01. Please do not refer to an MSC as a "hood" you can use the phrase Microbiological Safety Cabinet or MSC.

Section 15 I will add this once you have modified the above.

Section 16 this is is usually the PI.

Section 18 we will complete this.

GM Safety Committee 4th Dec 2015

Dear Professor

Following the discussion of your proposal entitled "Lentiviral transfection for overexpression studies to correct defective phagocytosis in human MOM in COP0" (GMIC-4695), the committee request that the following amendments are made to the proposal prior to approval:

Reviewer 1

Section 2.15; This section asks for recipient species and strains with their ACDP classification, add Aspergillus fumigatus here.

Section 2.16 List the vector that has been used for aspergillus here, what resistance cassette is used? What type of GFP?

The added GM Aspergillus fumigatus (GFP labelled) is a class 2 GMO because the host is HG2. This project was originally a Class 1. This will mean that the project will now require notification to the HSE.

Section 2.17 GFP has a functional property, it's fluorescent ... otherwise it would be pointless expressing it

Section 4.16 GFP is not completely non-functional, you use it because it expresses fluorescent protein

Section 4.17, does the GFP vector have a selective resistance cassette? This might have an impact on treatment if somebody gets exposed to Aspergillus

Section 5.5, Who grows the Aspergillus? In which Jab? under which risk assessment? Is it just being donated or are people from RB campus going to SK campus 10 grow this up? Or just to collect?

Section 5.13 Tick the box for using FACS analysis or Sorting and mention SOP

Section 14+15 Aspergillus work is not mentioned here. GM Aspergillus fumigatus (GFP labelled) is Class 2

Reviewer 2

All looks ok in principle. I believe the room that the work will be taking place in is B148 not B146 at Guy Scadding. Also there is a discrepancy between centrifuge spillage procedures, in the form it correctly states that it will be left for 1 hour to allow aerosols to settle, but in all the SOPs it says 15mins - this is needs to be amended.

Could you please ensure that the risk assessment is revised (add GMIC number) and the amendments above addressed. I will then forward the form onto Occupational Health to complete. The completed HSE CU2 form (attached to this email), and copy of the Purchase Order (for BACs Payment) made payable to the HSE should be sent to me, I will then send it all to the HSE. Please ensure the information given in HSE Form relates to that provided in your risk assessment.

For further information, please see http://www3.imperial.ac.uk/safety/subjects/biosafety/gmprocedures

Please note that this work must be notified to the HSE and an acknowledgement receipt received prior to this work commencing.
The aims of this project are twofold. Firstly, to exploit a commercially available E.coli based protein expression system to produce proteins, or parts of proteins, of Salmonella typhimurium. The resultant products will then be used as antigens to stimulate antibody production in rabbits.

Recipient or parental organism

Salmonella typhimurium is ACDP Hazard Group 2, as it is a human and animal pathogen.

Escherichia coli BL21 is also ACDP Hazard Group 2, as it may be pathogenic and is able to colonise humans.
Host/vector system

Salmonella typhimurium is ACDP Hazard Group 2, as it is a human and animal pathogen.

Escherichia coli BL21 is also ACDP Hazard Group 2, as it may be pathogenic and is able to colonise humans.

Origin & function

Source of Host cells: E.coli BL21 commercially available (Stratagene UK), Salmonella typhimurium laboratory maintained strains.

Source of Genetic material (inserts): PCR from S.typhimurium genomic DNA template.

Evaluation of foreseeable effects

Both the GMMs are ACDP Hazard Group 2.

In the case of GM S.typhimurium; the modification takes the form of the addition of an autonomously replicating plasmid which merely serves as a marker for gene expression. The plasmid encodes the green fluorescent protein marker and also confers resistance to ampicillin. As there are a variety of alternative chemotherapeutic agents available for use; this modification is thought to pose no increase risk to human health. The environmental survivability of the GM S.typhimurium is envisaged to be similar to the parental wild type strain.

Likewise in the case of E.coli BL21, the modification takes the form of the addition of a self-replicating plasmid, upon which resides the cloned S.typhimurium gene. Expression is controlled and regulated by the addition of IPTG to growing cultures. In the absence of IPTG expression is minimal. The plasmid also confers resistance to ampicillin. As there are a wide variety of alternative therapies available, this modification is thought to pose no increased risk to human health. The environmental survivability of the GM E.coli BL21 is thought to be the same as the wild type.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Chemical Disinfection of liquid GM waste: 2% hycolin solution, as per manufacturer's recommendations, overnight exposure. 100% kill validated by periodic plating out of cultures after exposure to hycolin disinfectant.

Autoclaving of solid GM waste: Large autoclave; solid discard cycle 134 celsius for 30 minutes. 100% kill. Machine and cycle validated by thermograph and testing by manufacturer's engineer.

Autoclaving of liquid GM waste: Large autoclave; liquid discard cycle 134 celsius for 30 minutes. 100% kill. Machine and cycle validated by thermograph and testing by manufacturer's engineer.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form
The second paper entitled "Investigation of protein expression of Salmonella pathogenicity Island 2 in Salmonella typhimurium using a commercially available expression system (pET) and gene fusions to a plasmid encoded green fluorescent protein" from Professor Holden, this project was approved by the committee, with the following classifications: the Salmonella typhimurium work was classified as Class 2 Containment level 2, work involving E.Coli K12 strains were classified as Class 1, but will be carried out as Containment level 2 due to the level of facilities available, work involving B121 was classified as Class 2 Containment level 2. Again the Class 2 projects must be notified to HSE prior to any work commencing and a new GM Form A completed.

Project reference no. 01/264.
IC reference no. 00083.

Date of Significant Change

Project Additional Information

Purposes of the contained use

The aim of this project is to engineer mutants of Salmonella typhimurium by insertional mutagenesis. The genes to be mutated encode proteins involved in different aspects of Salmonella virulence. The strains will then be tested for phenotypic defects in mammalian cell lines.

Recipient or parental organism

The recipient microorganism is Salmonella typhimurium, which is a human and animal pathogen. It is placed by the ACDP in Hazard Group 2.

Host/vector system

Salmonella typhimurium (Host): pGP704; pFPV25.1; pACYC184 (Vectors).

Origin & function

Source of Host Cells: Laboratory maintained strain. Originally obtained from the PHLS, UK.

Source of Genetic material: inserts PCR from S.typhimurium genomic template.

Source of the material: vectors pACYC184 and pCR2.1 are commercially available; pGP704 and pFP25.1 are gifts from colleagues.

Evaluation of foreseeable effects

The GMM is likely to pose no increased risk to human health in comparison with the wild type parental strain. On the contrary, the GMM is likely to be attenuated in its ability to cause disease, since a putative virulence gene will have been mutated; and so in a functional sense, be disabled.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Chemical Disinfection of liquid GM waste: 2% hycolin solution, as per manufacturer's recommendations, overnight exposure. 100% kill validated by periodic plating out of cultures after exposure to hycolin disinfectant.

Autoclaving of solid GM waste: Large autoclave; solid discard cycle 134 celsius for 30 minutes. 100% kill. Machine and cycle validated by thermograph and testing by manufacturer's engineer.

Autoclaving of liquid GM waste: Large autoclave; liquid discard cycle 134 celsius for 30 minutes. 100% kill. Machine and cycle validated by thermograph and testing by manufacturer's engineer.
For the project entitled "Insertional Mutagenesis of virulence genes of Salmonella typhimurium" from Professor Holden, the project was approved by the committee with the following classifications, the Salmonella typhimurium work was classified as Class 2 containment level 2.

Project Ref 31/01.7

Date Ackn'd 12/12/2005

CU2 Project Title

IDENTIFICATION AND FUNCTIONAL CHARACTERISATION OF STREPTOCOCCUS PNEUMONIAE VIRULENCE GENES

Class 2

Consent Granted

Non-GMM Not Applicable

Project notified under transitional arrangements N

Historical Significant Changes

Transferred from GM 31 on 12/12/2005, transferred to GM553 20/09/2011
Project Additional Information

Purposes of the contained use

The aim of this project is to identify, and characterise the function of Streptococcus pneumoniae genes required for virulence. This necessitates the construction of plasmid vectors containing segments of S. pneumoniae DNA, which are used to transform wild type S. pneumoniae to make GMM strains with specific gene disruptions. The phenotype(s) of these strains will then be assessed using animal and cell culture models of disease.

Recipient or parental organism

The recipient microorganism in Streptococcus pneumoniae, which is a human pathogen. It is placed by the ACDP in Hazard Group 2.

Host/vector system

Host. Streptococcus pneumoniae.

Vectors: pJPC9111, pJPC9112, pLS1GFP, pLS70GFPcat, pucMUT, pDE1, pEVP3, pACH74, p10701

Origin & function

Source of Host Cells - Smithkline Beecham; Prof. James Paton, University of Adelaide
Source of Genetic material: inserts - PCR of Streptococcus pneumoniae DNA
Source of the material: vectors - Prof. James Paton, University of Adelaide; commercial sources.

Evaluation of foreseeable effects

The GMM is likely to pose no increased risk to human health in comparison with the wild type parental strain. On the contrary, since a putative virulence gene will have been mutated the GMM is likely to be attenuated in its ability to cause disease; and therefore be functionally disabled. The insertion mutation protocol utilised in this project renders the GMM resistant to chloramphenicol, spectinomycin, erythromycin or kanamycin. However, there are a wide variety of alternative antimicrobial agents available which are effective against S. pneumoniae infections should infection by the GMM occur. S. pneumoniae is essentially restricted to the human nasopharynx and there is no recognised environmental source. The environmental survivability of the GMM is envisaged to be the same as the wild type, with the caveat that without appropriate selection pressure reversion to the wild type is likely, and there is no increased risk to the environment posed by the GMM compared to the wild type.

All work carried out under this project will take place in appropriate Containment level 2 premises, together with appropriate waste control and management systems.

### Project Additional Information

**Purposes of the contained use**

Lentiviral, adeno-associated viral vectors (AAV) and Sendai viral vectors will be used to deliver reporter or therapeutic genes. Wild-type adenoviruses AD5 will be used for AAV titration. The above vectors, except Sendai, will be manipulated to receive the genes listed below. Viruses will be produced in cell culture under the appropriate conditions and tested for the absence of replication competence. Each gene will be tested for levels of expression and their effects on the recipient organisms. The vectors below will be used to transfer the gene(s) of interest to recipient hosts. The effects of each vector/gene insert will be screened for therapeutic effects or toxicity on the host.

**Recipient or parental organism**
SODKI and LVG-1 cells (HIV-1 based producers, 3rd generation) will be used to generate defective 3rd generation lentiviruses. (HIV-1 based producers, 3rd generation) will be used to generate defective 3rd generation Lentivirus (HIV-1 based) will be produced by transient transfection using a 4 plasmid transfection system which ensures minimal recombination likelihood. The viral genes used to produce these vectors are the gag, pol, rev and VSV-G envelope genes each on discrete plasmids. (1) pMDLg/pRRE induces the rev-dependent expression of gag and pol from the CMV promoter. (2) p tetr expresed rev under tetr control. (3)pVSV-G expresses the VSV-G envelope. (4) plasmid CLL.GFP.CLL contains the viral backbone with the gene inserts detailed below. All other wild-type viral genes have been removed. Homology has been reduced to a few tens of nucleotides. 293T cells will be used to produce these vectors.

Sendai virus will be used as a wild-type recombinant virus. Only the few genes detailed below will be used. No potentially oncogenic genes will be used. Sendai is a respiratory pathogen of rodents which may cause an inflammatory response. The Sendai to be used is derived from the Z-strain. The use of the recombinant virus has significantly less pathogenicity than the wild-type. Animal studies will be short term to determine pathogenic effects. If low pathogenicity is observed then long term studies will be performed on isolated animals. This virus is to be used as an alternative vector which infects the apical surface of lung epithelia unlike the other vectors detailed above which use the baso-lateral surface for infection.

Adeno-associated viruses will be produced from 293 cells. See ris assessment form for vector detail.

Adeno-associated virus with rep and cap genes removed encoding the above gene inserts.
Plasmid pDG will be used encoding the rep, cap and Ad genes E2A, E4 and VA for production of AAV viruses
3rd generation Lentivirus (HIV 1 based) with doxycycline repressible expression of REV/gag/pol and the VSV-G envelope protein encoding the above gene inserts.
Wild-type Sendai vectors will be used containing the inserts lac Z, GFP or CFTR only.

The following genes will be tested for therapeutic genes or as reporter genes. Gene expression will be used to correct the genetic disease associated with the gene of interest below.
Factor IX will be used to correct haemophilia B
GFP is a reporter gene for detection of gene transfer
Lac Z is a reporter gene for detection of gene transfer
HGF is a mitogen used to cause cellular proliferation to allow MLV type retroviruses to infect dividing cells.
Luciferase is a reporter gene for detection of gene transfer
LDLR will be used to lower levels of low density lipoprotein in the host
SODKI (HIV-1 based human embryonic kidney producer cells, 3rd generation) will be used to generate defective 3rd generation lentiviruses after tetracycline induction expressing GFP. This cell line has doxycycline repressible and sodium butyrate induction of expression of REV/gag/pol and the VSV-G envelope protein. LGV-1 (HIV-1 based 293 human embryonic kidney producer cells, 3rd generation) will be used to generate defective 3rd generation lentiviruses after tetracycline induction expressing GFP. This cell line has doxycycline repressible expression of REV/gag/pol and the VSV-G envelope protein. Adeno-associated virus with rep and cap genes removed encoding the gene inserts listed above. AAV will be used to infect HeLa (human fibroblasts), HT1080 (human fibroblasts), NIH3T3 (mouse fibroblasts), HEPG2 (human liver hepatocyte cells) HUH 7 (human liver hepatocyte cells), COS 7, CHO (Chinese hamster ovary cells), V79 (Chinese hamster lung cells).
A plasmid pDG will be used encoding the rep, cap and Ad genes E2A, E4 and VA for production of AAV viruses from 293 cells.
3rd generation Lentivirus (HIV 1 based) with doxycycline repressible expression of REV/gag/pol and the VSV-G envelope protein. Sendai virus will be wild type and only contain lac Z, GFP or CFTR genes to recipient organisms.

The introduction of the above genes and vectors into recipient organisms will not alter the pathogenicity of the genes used.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All materials used in this work will be disinfected using 1% Virkon and autoclaved as per manufacturer's instructions.
Waste will include solid and liquid.
Degree of kill be be expected to exceed 90%.
Sterilised materials will be tested for kill by tissue culture infectivity assays to ensure viruses are inactive.
The testing procedures will be carried out for each virus preparation and use.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

The Imperial College Safety Committee has accepted the containment levels proposed.

Project Ref 32/05.1

Date Ackn'd 13/02/2006

CU2 Project Title INVESTIGATION OF MEMBRANE TRAFFICKING AND DISEASE

Class 2

CultureVolClass2 < 1 litre

CultureVolumeClass3-4
The lentiviral vectors contain woodchuck hepatitis post-transcriptional regulatory element (WPRE) to enhance transgene expression. This element may be capable of expressing part of the X protein from WHV. A number of publications have suggested that truncated hepadna virus X-proteins may have oncogenic properties and as such WPRE are currently being investigated for oncogenic potential. Appropriate precautions in line with class 2 work therefore need to be used until this has been evaluated.

Recipient or parental organism

Plasmids will be cloned and amplified using competent E. coli cells. Bacteria containing plasmids pose no additional risk to human health.

Lentivirus, AAV and adenovirus will be produced by transient transfection using several plasmids to ensure minimal likelihood of recombination. Vectors will be monitored for replication competence. All viral vectors are designed with low homology to prevent recombination with the host. The multiplasmid transfection system ensures the likelihood/possibility of recombination is effectively zero. Genetic material needed to create a wild-type virus is not carried over with the viral particles and therefore recombination cannot take place.

The GMM cannot survive outside laboratory conditions and so hazard to the environment is minimal.

None of the genes to be inserted encode a pathogen or pathogenic determinant or are known to be oncogenic.

The lentiviral vector contains Woodchuck hepatitis post-transcriptional regulatory element (WPRE) to enhance transgene expression. This element however may be capable of expressing part of the X protein from WHV. A number of publications have suggested that truncated hepadna virus X-proteins may have oncogenic properties and as such WPRE are currently being investigated for oncogenic potential. Appropriate precautions in line with class 2 work therefore need to be used until this has been evaluated.

Adenovirus is deleted in E1 rendering it replication defective and therefore unable to cause illness.

AAV production can involve the use of a helper virus, usually wild-type adenovirus or Herpes Simplex Virus. Although both of these can infect humans, the infections are easily treatable.

The GMM cannot survive outside laboratory conditions and so hazard to the environment is minimal.

In essence no hazards arise from the alteration of existing traits of the host.
Host/vector system

Replication defective HIV-1 based lentivirus will be produced using a 3/4 plasmid transfection system.

Packaging plasmids:
- psPAX2 is a second generation packaging plasmid, deleted in viral auxiliary genes vpr, vif, vpu and nef and without env. The HIV-1 viral genes remaining are gag (virion structural proteins), pol (retrovirus specific enzymes), rev (post transcriptional regulator) and tat (regulatory gene) under a CAG promoter (consisting of a CM V enhancer, chicken b-actin promoter and chicken b-actin intron).
- pMDLg/pRRE and pRSV-Rev are third generation packaging plasmids. pMDLg/pRRE contains genes gag and pol under control of CMV promoter and gene Rev is positioned on plasmid pRSV-Rev separately.
- Envelope: pMD2.G

Expressing the VSV-G envelope using a CMV promoter.

Vectors: This is the only genetic material transferred to target cells and contains the viral backbone and transgene cassette.
- pWPXLd-GFP: a standard vector containing an EGFP reporter gene expressed from an EF-1alfa promoter.
- pWPT-GFP: a standard vector containing an EGFP reporter gene expressed from an intron-less version of EF-1alfa, EF-short.
- pWPI: a bicistronic vector allowing simultaneous expression of a transgene and EGFP marker to facilitate tracking of transduced cells using EF-1alfa promoter.
- pHRsinSFFV: Spleen focus forming virus (sFFV) promoter is driving expression of the transgene, which is fused to the EGFP reporter.

Production of replication defective adenovirus is through homologous recombination with pAd.CMV-Link.1 derived plasmids and Ad5 strain d17001. This strain is deleted in E1 and the majority of the E3 region (3.2kb). The resulting adenovirus will contain a therapeutic or reporter gene under the control of CMV promoter.

AAV vectors are based on the non-pathogenic human papovavirus and are deleted for virally alal virally encoded proteins. The vectors consist of an expression cassette and minimal cis elements necessary for replication and packaging of the recombinant genome. AAV replicative and structural (rep and c ap) genes are supplied in trans on a separate plasmid. Production of AAV is possible by transfecting these plasmids into adenovirus or HSV infected cells. It can also be achieved by co-transfecting with a "helper plasmid" containing the minimal Ad components necessary for helper-function thus avoiding use of helper virus. Replication defective adeno-associated virus of various serotypes will be produced using either a helper plasmid or virus and used to investigate and determine the optimal AAV vector/serotype for the transduction of specific cell types of interest. See ref. JP. Louboutin, L. Wang and J M Wilson J Gene Med2005; 7:442-451. Once this is determined AAV containing therapeutic genes will be produced.

Origin & function

Genes to be inserted:
- EGFP (Enhanced Green Fluorescent Protein) is a reporter gene which will aid in determining efficiency of gene transfer.
- REP-2 is a functional isoform of REP-1 and will be used as a control to demonstrate specific requirements for REP1.
- GDI extract Rabs from the membranes and can recycle them.
- Rab 27a, 27b, 38 and others participate in intracellular transport and targeting of proteins.
- Rab effectors, such as melanophilin and myRIP, determine specificity of Rab function and participate in formation of complexes with other molecules such as motors (myosin V, VII) and cytoskeletal elements (actin).

Evaluation of foreseeable effects

No hazards should arise directly from the inserted gene product or by alteration of existing traits.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Due to the presence of the WPRE in the lentiviral vectors all work involving these vectors will be carried out strictly in line with class 2 work.
Adenovirus and AAV are class 1.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste such as tissue culture supernatant will be chemically treated with 2% Virkon overnight, validation will be according to manufacturers instructions and disposal will be down the sink.

Solid waste such as pipette tips, culture plates and glass pasteur pipettes will be autoclaved for 20 mins at 120 degrees C 15lb/sw.inch. Validation will be via qualitative monitoring and chart recoder in addition to an annual service maintenance contract. It will then be incinerated and disposed of as clinical waste by an off site contractor.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Lentivirus vectors containing WPRE are potentially oncogenic. At the moment this is one of the most efficient to use, although in future a safer alternative may be found. The researches are proposing to use both lentiviral and adenoviral vectors, if can avoid lentiviral then will. Committee advised the Principal Investigator to incorporate adeno-associated vector (replication deficient Cat 1) to risk assessment. This project is notifiable to the HSE. Agreed: Class 2, containment level 2.

Adenovirus is deleted in E1 rendering it replication defective and therefore unable to cause illness.
The GMM cannot survive outside laboratory conditions and so hazard to the environment is minimal.

In essence no hazards arise from the alteration of existing traits of the host.

Host/vector system

HIV vectors
Replication deficient HIV-1 based lentivirus will be produced using a 4 plasmid transfection system to generate vectors.

Packaging plasmids: pMDLg/pRRE and pRSV-Rev are third generation packaging plasmids. pMDLg/pRRE contains genes gag and pol under control of the CMV promoter and gene Rev is positioned on plasmid pRSV-Rev.
Envelope: pMD2.G expresses the VSV-G envelope from a CMV promoter.
Vector: This is the only genetic material transferred to target cells and contains the viral backbone and transgene cassette. pWPI is a bicistronic vector allowing simultaneous expression of a transgene and EGFP from the EF-1alpha promoter. pWPXl-d-GFP: a standard vector containing an EGFP reporter gene expressed from an EF-1alpha promoter. pWPT-GFP: a standard vector containing an EGFP reporter gene expressed from an intron-less version of EF-1alpha, EF-short.

Adenovirus vectors
Production of replication deficient adenovirus is through homologous recombination between pshuttle (an expression cassette containing the gene of interest and promoter) and pAdEasy-1 (plasmid containing the adeno viral backbone deleted in E1 and E3). The resulting adenovirus will contain a gene under the control of CMV promoter.

Origin & function

Genes to be inserted:
TGFbeta (transforming growth factor) superfamily members and down stream effectors (to include TGFbeta, activin and bone morphogenic protein and the receptor serine threonine kinases (ALK1-6) and Smads). We will initially focus on the Smad proteins: The transforming growth factor-beta superfamily members transduce their signal from the membrane to the nucleus through distinct combinations of transmembrane type I and II serine threonine receptors and their downstream effectors, the Smad proteins, which play a central role in transduction of receptor signals to specific target genes in the nucleus (In the first instance Smad2 will be used).

Cyclin dependent kinase inhibitors. Progression through the cell cycle is regulated by cyclins and cyclin dependent kinases (CDK). The kinase activities of the cyclinD/CDK complexes are negatively regulated by several different molecules including the WAK1/CIP.KIP family which exercise broad acting inhibition of the CDKs and includes p21waf, p57kip2 and p27kip1 and the INK4 family, which specifically inhibit CDK4 and CDK6 and include p15, p16, p18 and p19. (In the first instance p21waf will be used).

EGF (epidermal growth factor) receptor family: The EGF family exert their biological effects by binding to and activating the EGF receptor (c-erbB1), a receptor tyrosine kinase, which occupies a prominent role as a primary regulator of epithelial cell function. (In the first instance c-erbB1 will be used).

FGF (fibroblast growth factor) receptor family: The FGF family contains 23 members in mammals and have been implicated in regulation of many key cellular processes including proliferation, differentiation, migration, apoptosis, angiogenesis and wound healing. They bind to five related, specific cell surface receptors.

Evaluation of foreseeable effects

No hazards should arise directly from the inserted gene product or by alteration of existing traits.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Due to the presence of the WPRE in the lentiviral vectors all work involving these vectors will be carried out strictly in line with class 2 work. Adenovirus are class 1.

Project Ref  543/07.1

Date Ackn'd  CU2 Project Title  Class CultureVolClass2 CultureVolumeClass3-4
**Project Additional Information**

**Purposes of the contained use**

Identification and study of the host contribution to bacterial infection and pathogenesis. This is done by infection of the fruitfly *Drosophila melanogaster* with the class 2 pathogen *Mycobacterium marinum*. Both host (*Drosophila*) and pathogen (*M. Marinum*) can be genetically modified.

**Recipient or parental organism**

- *Mycobacterium marinum*
- *Drosophila melanogaster*

**Host/vector system**

- *M. marinum* vectors: pVK173T, pFPV2, and equivalents/derivatives thereof.
- *D melanogaster*: crippled P-element-derived transposable elements (carried in vector pUAST and equivalents/derivatives thereof).

**Origin & function**

- *M. marinum*: transgenes encoding fluorescent proteins such as dsRed and GFP, from corals or jellyfish, used for tracking bacteria cells.
- *D melanogaster*: transgenes encode a variety of molecules (signal-transduction molecules, fluorescent proteins, etc.) of heterologous (human, mouse, jellyfish, coral, bacteria) or homologous origin; used to alter the course of infection and hence to be informative as to the genetic basis of susceptibility to infection or of pathogenesis.

**Evaluation of foreseeable effects**

- **Foreseeable effects**: *M. marinum*: in our hands, fluorescent derivatives typically grow more slowly and are slightly less pathogenic than wild-type strains; they will also be resistant to some aminoglycoside antibiotics (apramycin or kanamycin), the net effect should be a mild decrease in pathogenicity for these strains, since primary treatment for *M. marinum* does not typically depend on aminoglycosides.
D. melanogaster: transgenic files should exhibit reduced fitness relative to other laboratory strains; since lab strains of drosophila are already poorly-adapted for life in the environment, these flies should present no environmental risk.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

We are very careful to prevent release of any pathogen-infected Drosophila.

1. Individual infected flies are tracked.
2. In most cases flies are infected, placed in culture vials and never again removed. Once the experiment is completed, the entire vial (including contained flies) is frozen to kill flies, then autoclaved to kill bacteria, and finally incinerated.
3. In cases where an experiment requires removal of live infected flies as samples, all flies within the vial are anethetized before the vial is opened, preventing inadvertent escapes.
4. Fly-traps will be placed at frequent intervals in the fly room to attract and contain escaped flies.

Using these techniques, in the course of 6 years doing similar experiments at Stanford University, I observed fewer than 10 escapes of a total of more than 100,000 infected flies. All of these escapes were due to defective vial closures; I have now changed the type of vial-closure to one that is more secure, so fewer escapes are expected.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solids: Waste will be double-bagged and autoclaved at 124C for 15 minutes. Appropriate autoclave indicator tape will be used to monitor autoclave function. After autoclaving, waste will be incinerated by White Rose. Waste containing live flies as well as pathogens will be frozen for at least 6 hours at -20C before autoclaving.

Liquid: Addition of disinfectant (chlorine bleach to 5% or 1 haztab/litre) followed by pouring down designated sink.

Both procedures are expected to achieve 100% killing.

Monitoring will be done by attempting to culture M. marinum using standard techniques either after autoclaving or after addition of bleach, as appropriate.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

Please enter comments on the GM safety committee on the risk assessment

GMSC approved at meeting of 1 May 2007.

Project Containment
This project is directed at understanding antigenic variation in trypanosomes and how the organism evades the complement system in mammalian hosts.

i) Antigenic variation
The trypanosome wears a dense Variant Surface Glycoprotein (VSG) coat which shields invariant molecules on the trypanosome surface from the immune system. The trypanosome evades the immune system of the mammalian host, by continuously changing its VSG coat. As trypanosomes multiply in the blood of an infected mammal, eventually an antibody response is raised against a given VSG coat, killing all trypanosomes wearing this coat. However, at the population level, trypanosomes are continuously generated that have switched to a new (and temporarily unrecognisable) coat. These switch variants are not recognised by host antibodies, and can form the next wave of infection. Antigenic variation allows trypanosomes to form chronic infections in large mammals which can last for many years.

An individual trypanosome has about 1000 genes encoding different VSG coats. The active VSG gene is located in a VSG expression site, which is invariably located at a
T. brucei brucei 427 strain that we currently work with (and which is sensitive to human serum) grown very well in vitro. In contrast, T. brucei rhodesiense field isolates that are resistant to human serum do not grow in vitro. We would therefore like to create a T. brucei brucei strain that can grow well in vitro in human serum. We would like to genetically modify nonhuman infective T. brucei brucei strains, and insert virulence genes like the Serum Resistance Antigen (SRA) gene into these trypanosomes so that they become resistant to human serum. This will make T. brucei brucei comparable to the T. brucei rhodesiense that we already currently hold. However, these genetically modified trypanosomes will have the advantage of being manipulable in vitro instead of requiring expansion in laboratory rodents. In addition, the virulence genes would be regulatable, greatly increasing the safety of the experiment. We would therefore be able to study the pathogenic aspects of human infectivity in a manipulable in vitro system, and could avoid amplification in laboratory animals.

### E. coli K12 or B derivatives
- **Trypanosoma brucei brucei 427**

### Host/vector system
- **Recipient or parental organism**
  - Bacterial or parasite host with plasmid vectors

### Origin & function

**Antigenic variation**

- Single copy marker genes will be inserted into the repetitive VSG expression sites in order to follow the transcriptional behaviour of single expression sites. Constructs containing fluorescent marker genes like Green Fluorescent Protein (GFP), Yellow Fluorescent Protein (YFP) and DsRed, and drug resistance marker genes like the hygromycin, neomycin, blasticidin, and puromycin resistance genes into various regions of the T. brucei genome including the VSG expression sites. Marker genes introduced into VSG expression sites will allow monitoring of their transcriptional behaviour.

- VSG expression sites include multiple genes of unknown function, in addition to the telomeric VSG gene. RNAi (double stranded RNA inhibition) will be used to inactivate the transcripts from various Expression Site Associated Genes (ESAGs), in addition to transcripts from other candidate genes possibly playing a role in antigenic variation. This technique allows the researcher to investigate the essentiality of different gene families.

**Evasion of the complement system**

- Virulence genes like the Serum Resistance Antigen (SRA) gene will be inserted into nonhuman infective T. brucei brucei strains so that they become resistant to human...
serum. These virulence genes would be inserted behind a tetracyclin inducible promoter, allowing the researcher to turn expression on and off. This will make *T. brucei* comparable to *T. brucei rhodesiense* and facilitate study of the pathogenic aspects of human infectivity in a manipulable in vitro system avoiding amplification in laboratory animals.

**Evaluation of foreseeable effects**

i) Antigenic variation
The genes used here are completely neutral markers encoding fluorescent proteins, or are drug resistance genes for drugs that are not therapeutically relevant for African trypanosomiasis. There is therefore no biochemical mechanism that could explain how these genetic modifications could change the host range or virulence of the genetically modified trypanosome. The genetic modifications proposed would not change *T. brucei* susceptibility to the therapeutic drug suramin and there is no reason to believe that these genetic modifications would change the tissue tropism of the parasite. The double-stranded RNA inhibition (RNA) experiments resulting in the ablation of *T. brucei* RNA transcripts will incapacitate the parasites if the transcripts that are being targeted are essential. Nonessential transcripts being targeted will not result in a change to the trypanosome phenotype. The genetic modifications resulting in the introduction of marker genes into the VSG expression site could result in damage to the active VSG expression site. This would lead to reduced efficiency of antigenic variation. None of these procedures would lead to increased risk to human health and safety.

ii) Evasion of the complement system
These *T. brucei* genetic modifications could make a trypanosome strain that lyases in human serum into one that doesn't lyse in human serum, making it potentially human infective. These genetically modified strains would become similar to the human infective *T. brucei rhodesiense* strains. All published evidence indicates that the SRA gene product is a receptor that interferes with internalisation of the Trypanosome Lytic Factor (TLF) present in human serum. There is no published evidence indicating that expression of the SRA protein could affect the tissue tropism of the trypanosomes. The SRA protein is a receptor for the Trypanosome Lytic Factor, and there is no known biochemical mechanism that could mediate changed drug susceptibilities in an SRA transgenic trypanosome. There is no known biochemical pathway that would confer susceptibility to the drug suramin, currently used in treating human trypanosomiasis, to *T. brucei* SRA gene transgenics. These genetic modifications could increase risk to human health and safety and consequently additional containment and control measures have been assigned. However, even though these genetically modified organisms would be less safe than the original trypanosome, they would be much more safe to work with than human infective *T. brucei rhodesiense* as the tetracyclin inducible nature of virulence gene expression means that the researcher can restrict expression of these genes to the shortest period of time.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not Applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

These parasites do not produce spores and are fragile organisms. They are rapidly killed outside the culture vessel or blood by desiccation, osmotic shock, washing with water, detergents, and cannot penetrate unbroken skin. Tsetse flies are the vectors for *T. brucei* and these are endemic only in the disease areas (subSaharan Africa).

The naturally occurring organism does not represent any hazard of infection through aerosol transfer. Aerosols are tiny droplets of liquid. These dry out within minutes under the laboratory conditions. Once dehydrated such material would not be viable.

ACDP guidance on work with *T. brucei* sp.

The Schedule to the certificate of exemption accompanying the Approved List specifies a number of parasites, including *T. brucei* sp. for which full containment level 3 need not be used. ACDP state that work with such parasites does not generally require an inward flow of air to the laboratory or the use of a microbiological safety cabinet as none of these agents if normally infectious by the airborne route. ACDP recommends that for working with these agents in research a separate room should be used or a designated area in a larger laboratory. In ACDP's guidance list is the notation that the laboratory need not be sealable for fumigation.

In relation to the individual control measures to be omitted:
a) Isolated laboratory suite
A dedicated room will be used for working with T. brucei. The room will at all times be operated to derogated Containment Level 3 working practices and have a documented Code of Practice.

b) Laboratory not sealable for fumigation
There is no foreseeable need to fumigate the laboratory. In the event of a major spillage, the bulk of material would be soaked up on absorbent paper towels, then autoclaved, killing any parasites. The area would be wiped down with disinfectant. Any aerosols created that were not cleaned in this initial effort would dry out, killing both host cell and parasite. The area of the laboratory would be left isolated for a period to ensure effective drying. Effective parasite transmission is only possible via direct inoculation of viable parasites.

c) No negative pressure, HEPA filtered extract, microbiological safety cabinet or specified measures to control aerosol dissemination.

The organism presents no hazard of infection by the airborne route. Class II microbiological safety cabinets are in use in the dedicated laboratory, they are necessary for sterile culture of the organism; they are not required for operator safety. Activities involve small scale, standard laboratory techniques with no aerosol generating procedures.

d) Equipment not within the laboratory
Although the laboratory contains most of the necessary equipment for the work, some activities use specialist equipment that cannot reasonably be accommodated within the dedicated facility. In all cases a safe system of transport involving secondary containment is in use, any equipment used is cleaned and disinfected immediately on completion of the work and any contaminated items either returned to the dedicated laboratory or removed for disposal as waste. The following activities are undertaken outside the dedicated laboratory:

i) Storage: transfected parasite stocks are frozen and stored temporarily at -80 degrees C in the adjacent Containment Level 2 laboratory before long term storage in liquid nitrogen within the Containment Level 3 laboratory. The samples will be in Nunc ampules in closed and sealed freezing boxes that are clearly marked as biohazard. The -80 degrees C freezer will be locked during use and accessed only by authorised personnel.

ii) Autoclaving: an autoclave validated for disposal of waste is located within the same building.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Consumables (mainly plasticware eg pipettes, flasks, tubes) - autoclave using a make safe cycle as specified in BS 2646, Part 3, 1993 (121-125 degrees C for at least 15 minutes), discharge any excess liquids to drains, dispose of solids via the industrial (black bag) waste stream for landfill.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [N]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

Please enter comments on the GM safety committee on the risk assessment
The aim of this project is to 1) construct strains of these bacteria lacking specific genes, 2) establish whether gene inactivation has affected their ability to cause disease, and 3) further characterise the proteins encoded by these virulence genes.

Escherichia coli, Shigella spp., Neisseria meningitidis, Neisseria gonorrhoeae and Haemophilus influenzae are ACDP Hazard Group 2, as they are human pathogens. The organisms will have the equivalent or less potential to cause human disease as the wild-type bacterium. The insertions will interrupt gene function and are likely to attenuate the host.
Host/vector system

Neisseria meningitidis, Neisseria gonorrhoeae, Haemophilus influenzae (Hosts)/ pMID216 and derivatives (vector)

Shigella and E. coli (Host)/pCR2.1, pUC and pET derivatives, pACYC184, pSTM115, pYH204, pMID216 (vectors)

All these are plasmids which have been used previously with the corresponding microbes. They carry antibiotic resistance markers for agents not usually used to treat human infections with these bacteria.

Origin & function

Source of genetic material (inserts): transposons and antibiotic resistance markers.

Source of genetic material (vectors): pCR 2.1 topo, pACYC184, pUC and pET derivatives: commercially available
pMID216 from collaborator
pYH204, pSTM115: generated in own laboratory

Evaluation of foreseeable effects

All the GMMs are ADCP Hazard Group 2 except the disabled E. coli strain.

The modification of the host bacteria is in the form of insertions into the chromosome that inactivate gene function. The insertions carry antibiotic resistance markers that encode for resistance against antibiotics not used for treatment of infections caused by these micro-organisms. These modifications should not pose any increased risk to human health. The environmental survivability of the GMM will be similar to the parental wild-type strains.

For disabled E. coli, the modifications is in the form of a self replicating plasmid which may contain cloned genes from the pathogenic bacteria. The plasmids confer resistance to ampicillin, kanamycin, and erythromycin. There is a wide variety of alternative agents that can be used to treat successfully infections cause by E. coli. The environmental survivability of the GMM will be similar to the parental strain.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Chemical disinfection of GMM waste except N. meningitidis:
1% virkon as per manufacturers instructions, at least 1 hour exposure. Plates and plasticare sterilised by autoclaving.
Discard cycle 134 degrees C for 30 min. 100% kill. Machine and cycle validated after each cycle by thermograph; autoclaves thermocouple tested regularly (6 monthly) qualified engineer.

Autoclaving of waste contaminated by Neisseria meningitidis: Discard cycle 134 degrees C for 30 min. 100% kill. Machine and cycle validated after each cycle by thermograph; autoclaves tested regularly qualified engineer.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]
It was considered that work with disabled E. coli strains could be conducted in Containment Level 1 facilities. However, this work will be done in a Containment Level 2 laboratory along with the work on Neisseria gonorrhoeae, Haemophilus influenzae, Shigella flexneri, and E. coli K1. The importance of prompt reporting any incidents and episodes of diarrhoeal disease among researchers working with Shigella spp. was highlighted.

People working with N. meningitidis must complete a health questionnaire; any persons with suspected immunodeficiency must be seen by the Occupational Health doctor before working with the bacterium. It was recommended that work with N. meningitidis is carried out in a dedicated (Containment Level 3) room. Only individuals who have undergone a locally approved training programme would be allowed to work with live N. meningitidis. All person must be aware of the signs and symptoms of meningococcal infection, and should seek early medical advice should they become unwell, informing medical staff of their potential exposure to N. meningitidis at the work place. All accidents/spillages to be reported promptly to the Occupational Health Department and Department Safety Officer. A list of individuals allowed to work with the meningococcus, details of the clinical presentation of N. meningitidis infection, and guidelines for safe working is to be kept at the entrance to the designated facility at all times.

Page 191 of 15326
## Purposes of the contained use

Generation of replication deficient and amplification of Adenovirus 5.

## Recipient or parental organism

High efficiency transfection tool for delivering exocytosis competent and incompetent SNAP receptors. These will be capable of affecting exocytosis. The level of protein expression will be regulated either by using a tetracycline inducible promoter or by controlling the level of infection.

## Host/vector system

- E. coli K12 strains and pUC vectors (Clontech).
- Eukaryotic cells (HEK 293) Adeno-X-vectors (Clontech).

## Origin & function

Host cells are from a commercial source (e.g. Invitrogen, Stratagen and Promega).

Mammalian and bacterial plasmid are purchased from Clontech.

## Evaluation of foreseeable effects

These will be safe due to the appropriate procedures and containment. The products are expected to inhibit regulated secretion; should the particular infected cell be important for release of a hormone/transmitter, then the lack of secretion will cause symptoms. However, the use of only small quantities $1\times10^9$ infectious units for animal injection or dilute titres for cell culture experiments (up to $5 \times 10^8$ infectious units/ml) will reduce the risk of harm to health.

## Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Class II microbiological safety cabinet in a containment level 2 laboratory.

## For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None applied for

## Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Solid waste will be chemically disinfected by addition 25000 ppm chlorine (Chloros) according to the manufacturers instructions into a designated, downward sink. Excess chloros will be removed by rinsing with water and solid material autoclaved. Liquid waste will be disinfected as above, but liquid will be poured away after disinfection, with copious amount of water.

From: Minutes of Safety Committee meeting, 21st February 2001, Department of Biochemistry, Imperial College

Dolly-10: 'Infection of mammalian cells in culture and neurons in vivo with exocytosis-incompetent SNARE constructs via a recombinant replication-defective adenovirus'. Various items required clarification; the risk assessment was approved as a Class 2 activity, pending the required revision to the risk assessment. It was also stipulated that the project should be reviewed after 3 months, to check whether some of the assumptions regarding viral toxicity still held. If all was well, the usual 6-month review would be in order. In addition, the HSE would have to be notified and the fee paid.

Project Ref 8/01.14

Date Ackn'd 26/10/2001

CU2 Project Title STUDY OF INTRACELLULAR TRAFFICKING IN MAMMALIAN TISSUE CULTURE CELLS - INFECTION OF MELANOCYTES WITH GFP - CONJUGATED PROTEINS USING A BRCAS VIRUS VECTOR.

Class 2

Culture Vol Class 2 < 1 litre

Non-GMM not applicable

Consent Granted

Project notified under transitional arrangements N
Project Additional Information

Purposes of the contained use

To study protein trafficking and organelle formation in mammalian tissue culture cells by fluorescence and video microscopy. The BRCAS system is to be used to increase infection efficiencies.

Recipient or parental organism

Chick fibroblasts are infected with a disabled Rous Sarcoma Virus. Mouse melanocytes will be transfected with the RSV-A receptor and infected with a disabled Rous Sarcoma Virus. The virus cannot replicate and carries no risk to human or animal health.

Host/vector system

Chick fibroblasts are infected with a disabled Rous Sarcoma Virus. Mouse melanocytes are to be transformed with the RSV-A receptor and infected with a disabled Rous Sarcoma Virus.

Origin & function

BRCAS RNA is derived from Rous Sarcoma Virus. When incorporated into the chick genome, fluorescent proteins from sequences of human DNA are expressed. Fluorescent proteins are to be identified by microscopy.

Evaluation of foreseeable effects

Viral nucleic acid has been engineered so as to make it non-replicative. There are no hazards to human health and all risks are negligible.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Cells infected with BRCAS will be handled in sterile cell culture cabinets fitted with HEPA filters and complying with class II regulations. In the long term the cells will be maintained as frozen stocks.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be chemically disinfected using 1% Virkon for at least 1 hour to give a degree of kill of effectively 100%. The Virkon will be used according to manufacturer's instructions and recommendations, and the manufacturer's protocol will be strictly adhered to. Virkon is effective against retrovirus. Solid waste including petri dishes, plastic pipettes, disposable centrifuge tubes, gloves and paper towels will be autoclaved according to the Biochemistry Department safety instructions and as per available literature. This should give an effective degree of kill of 100% and will be monitored by performing culture tests at regular intervals. All tissue culture plastics in contact with retrovirus will be disposed of in autoclave bags in the tissue culture hood and sealed to prevent aerosol dispersal, prior to autoclaving. Clinical waste is...
removed from the laboratory via yellow bags clearly marked as clinical waste.

It was advised to classify this project as containment level 2 due to the use of a retrovirus which, although disabled, could be potentially hazardous to the environment.

02/03/2022
Botulinum neurotoxins (BoNT) act by cleaving specific proteins involved in synaptic vesicle exocytosis resulting in inhibition of neuro-transmission. In order for the various BoNT serotypes to gain access to their specific substrates they have to be taken up by the neuron. This is thought to occur by the binding of the BoNT to a specific receptor on the plasma membrane of the target cell followed by receptor mediated endocytosis of the BoNT. The specific endocytic pathways involved in this have not been defined. One of the best characterised mechanisms of receptor mediated endocytosis involves uptake via clathrin-coated pits. It has been shown that this clathrin dependent endocytosis pathway can be disrupted at a number of specific points by the expression of truncated or mutant forms of the proteins involved, specifically AP180, auxilin (Zhao et al., 2001) and clathrin heavy chain (Liu et al., 1998).

In order to use these tools to access the contribution of clathrin mediated trafficking to the action of BoNT on synaptic vesicle function and hence synaptic transmission it will be necessary to express the above dominant negative forms of the clathrin associated proteins in neuronal cell cultures. Successful high-level introduction of DNA has proved difficult in neurons. Currently the best characterised and most widely used system to introduce DNA into neurons involves the use of replication-deficient adenoviruses. In fact this system has been used successfully for the introduction of constructs expressing other proteins involved in vesicle trafficking into cerebellar granule neurons (Yang et al., 2000).

The aim of this project is to use the replication-deficient adenovirus expression system to express mutant and truncated forms of clathrin associated proteins in neuronal cells in culture, thus disrupting clathrin mediated trafficking pathways. The ability of these cells to take up and traffick BoNT will then be assessed. This will allow us to determine if the routes of entry to the cell and intracellular trafficking of the various BoNT serotypes are mediated by any of the characterised clathrin mediated pathways.

Genes for rat or bovine clathrin associated proteins will be inserted into shuttle vectors and transfected into a commercial human embryonal kidney cell line where they will be packaged into replication-incompetent adenovirus. These will be harvested and used to infect primary cultures of rodent neuronal cells.

Host/vector system

Full length cDNAs for the various clathrin associated proteins will be maintained in non-expressing bacterial vectors (e.g. Bluescript). These will be used as templates for the construction of previously defined truncations (using internal restriction enzyme sites or amplification of specific regions by (PCR) and site directed mutations (using commercial kits eg. Stratagene QuickChange kit). These constructs will be initially cloned into the multi-cloning site of the mammalian expression vector pcDNA1.1 and transfected into cell lines using standard calcium phosphate or lipofectamine reagents. Since transfection of neuronal cells is notoriously difficult with these techniques it is envisaged that in order to achieve sufficiently high transfection efficiencies to allow biochemical studies a commercial adenovirus expression system will have to be used. Therefore the constructs will also be cloned initially into the p-Shuttle vector for testing in the adenovirus expression system and for subsequent studies into the pTRE-Shuttle vector which restricts expression to cells co-transfected with Adeno-X-Tet off virus. Constructs will be amplified in the specified E. coli strains and those in shuttle vectors transfected into the human embryonal kidney 293 cell line were the replication-incompetent adenovirus will be produced and released into the medium. The harvested replication-incompetent adenovirus will be applied to mammalian (non-human) neuronal cells in culture.

Origin & function

All the DNA constructs which will be used have been originally cloned from either rodent or bovine cDNA libraries (Morris et. al 1993; Schroder et. al. 1995; Liu et. al 1995). These will be used to produce truncated and mutated forms of the clathrin associated proteins, AP180, auxilin and clathrin heavy chain. These are expected to have impaired function and to inhibit clathrin mediated endocytosis when expressed in mammalian cells in culture.

Evaluation of foreseeable effects

Truncated genes for clathrin associated proteins will be expressed in wild type (non-human) neuronal cells in culture, using a replication-incompetent adenovirus vector, thus no disabling mutations will be present in the recipient cells. Even if there was a naturally occurring mutation it is unlikely that this could be overcome by expression of proteins which will inhibit clathrin mediated vesicular trafficking pathways. Although, non-regulated expressing adenovirus will be used for pilot studies, the majority of the experiments will use regulatable viruses. This additional level of safety is in built by the necessity to add a second virus, termed the Adeno-X-Tet off expressing the Tet transactivator protein which is necessary for activation of the CMV-TRE promoter in the Adeno-X-TRE virus and allows expression of the gene product contained in the latter. Despite the fact that truncated clathrin associated proteins inhibit receptor mediated endocytosis they have not been reported to cause cell death in non-neuronal cell lines and the relatively small quantities of virus being used would preclude any hazard to the user, particularly when handled under containment. Replication-deficient adenovirus can infect human cells, however risk of infection to the experimenter will be minimised by working in a class II hood. As the adenovirus produced by the packaging cell line is replication-deficient any subsequent infection cannot lead to further propagation. No evidence suggests that the disruption of clathrin mediated trafficking pathways will be either oncogenic nor pathogenic. Transfer of the genetic material to organisms outside the laboratory is highly unlikely since this would require the occurrence of a rare recombination event with wild type adenovirus; wild type virus is not used in the lab.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste: 10000 ppm chlorine from chloros is added which will be flushed into designated, downward draw sink. This gives 100% degree of killing as stated by the manufacturer.

Solid waste in compliance with HSE and departmental guidelines complete ‘kill’ of solid GM waste is achieved first by soaking in 1% hypochlorite for at least 1 hour followed by rinsing with water and autoclaving. An automated programmable Rodwell Monach 1534 autoclave is employed and validated by biannual 12 point load tests by departmental approved engineers. The latter test is performed by placing 12 thermocouples at various locations throughout different types of loads during the autoclave cycle and the temperature reading recorded. For the sterilisation of solid GM waste including plastic ware, a program lasting 1 hr 45 mins using a chamber set point of 128 degrees centigrade is performed. To absolutely ensure an efficient autoclave cycle, an additional integral thermocouple in this device is placed in the centre of the load using a 126 degrees centigrade load temperature set point and an audible alarm indicates cycle failure. In addition, hypochlorite (1%) has been validated by others as a suitable method for complete killing of adenovirus. All chloros decontaminated-autoclaved solid waste is placed in sealed biohazard bags tagged with colour coded ‘cable ties’ and sent for incineration.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Project Ref 8/02.3

Date Ackn’d 02/03/2022
**Project Additional Information**

**Purposes of the contained use**

We wish to over-express foreign proteins of interest in order to study the properties of these proteins. None of the proteins which we would express in this system are hazardous to human health. These recombinant baculoviruses will be occlusion-positive, therefore potentially remain infective for their insect host via the normal oral route.

**Recipient or parental organism**

The parental baculoviruses have individual, narrow host ranges within insects and do not infect humans, other vertebrates, or other non-target invertebrates. Although the GMOs could, theoretically, survive in certain protected environments, the risk to the environment is negligible.

**Host/vector system**

The baculovirus used in these studies are infectious to particular species (mainly agricultural pests) within the Lepidoptera (moths and butterflies). The baculoviruses we will use are: Autographa californica Nucleopolyhedrovirus, Bombyx mori Nucleopolyhedrovirus, and Anticarsia geminitalis Nucleopolyhedrovirus. These viruses will be grown in some of the following cultured insect cells: Spodoptera frugiperda Sf9 and SF21 cells, Trichoplusia ni Tn368 cells and ‘Hi5’ cells, Mamestra brassica cells, Anticarsia geminitalis UFLAG2 cells and Helioverpa zea BCIRL-Hz-AM1 cells. Additionally, these viruses may be reared in T. ni, Spodoptera spp., H. zea and Heliothis virescens larvae.

**Origin & function**

The genes to be inserted into the baculoviruses were obtained from colleagues, commercial sources, or were cloned ourselves. Genes to be individually expressed in these baculoviruses are: UPD-glycosyltransferases from various species, Spodoptera littoralis ecdysone oxidase and 3-dehyroecdysone reductase, Cardiochiles nigriceps polydnavirus genes, Heliothis armigera Entomopoxvirus genes, GFP and derivatives, acetyl CoA synthase, adenylosuccinate synthase, influenza NP, der-PI antigen, LCMV GP, B, mori prothoracicotrophic hormone, H, virescens juvenile hormone esterase, M. sexta eclosion hormone, P. tritici tox34 insecticidal toxin, P. plagiophthalmus luciferase, E. coli beta galactosidase) from occlusion-positive recombinant baculoviruses. In general, we are expressing these proteins using baculoviruses as eukaryotic expression vectors, for the purpose of producing large enough quantities of these proteins for biological and biochemical characterisation of their function. These proteins will be expressed in an occlusion-positive virus background for either of two purposes: 1) To assess how expression of foreign insect proteins affects the oral route of infection and 2) To allow production of proteins as polyhedrin fusion proteins to produce recombinant occlusion bodies for antibody production.
Evaluation of foreseeable effects

For most of these genes, their expression within a recombinant baculovirus will not change the replication properties of the virus in cell culture or in larvae infected via the oral route. A few of the genes (e.g., those encoding products which interact with insect hormone metabolism pathways or the P. tritici tox34 insecticidal toxin) may alter the kinetics of infection within the larval host, but are not envisaged to alter the other parameters of the replication properties of the recombinant baculoviruses compared to parental 'wild' viruses. In the case of baculoviruses which are expressing foreign proteins as fusion constructs, these may decrease the infectivity of the recombinant baculoviruses to the larval host via the normal oral route of infection.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste containing GMMs will be treated with a solution of 1% Virkon with at least 1 hour contact time, as per manufacturer's instructions. The degree of kill for this method is effectively 100%. Liquid waste and solid waste containing GMMs will be autoclaved using manufacturer's recommendations. Success of each autoclave cycle will be monitored by technical staff with the aid of paper printouts which record equipment performance. Autoclaves are inspected yearly by an independent contractor. Chemically treated and autoclaved liquid waste will ultimately be disposed of down the drain. All autoclaved, solid waste is taken to a central collection point for incineration by an approved contractor. Again, degree of kill for this method is effectively 100%.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

The risk assessment proposal was considered satisfactory with no alterations required (GM activity notice dated 01-7-02). However, the work cannot commence until HSE approval has been obtained.

**Project Additional Information**

**Purposes of the contained use**
To express small amounts of wild type or mutated a-latrotoxin and a-latroinsectotoxin. Although the micro-organisms used will be unable to survive in the human body or in the environment, the introduced genes encode harmful toxins; so to limit any theoretical risk, the experiments proposed will be carried out under containment. Because the amounts of the active toxin produced will be minimal and the employed procedures will prevent any exposure of the experimenter and the environment, Containment level 2 is sufficient.

**Recipient or parental organism**
Parental organism: the black widow spider (Latrodectus sp.)
Recipient: (1) baculovirus; (2) E.coli K-12 disabled strain; (3) non-human mammalian cell lines (COS7, monkey; NB2A, mouse).

**Host/vector system**
Baculovirus carrying the toxin gene will be used to infect small-scale insect cells cultures (SF9, Hi5). Non viral plasmid vectors carrying the toxin will be introduced into E. coli bacteria and non-human cell lines for small-scale growth and protein expression.

These strains are harmless to humans and will not survive in the human body or the environment.

**Origin & function**
The genes encoding a-latrotoxin and a-latroinsectotoxin have been obtained from Prof. Eugene V Grishin of The Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry, Russian Academy of Sciences, Russia. The a-latrotoxin gene is also being used by Prof. Thomas C. Sudhof of the University of Texas SW Medical School at Dallas. The isolation and use of these genes has been published previously (Kiyatkin et al., 1993, Eur J Biochem. 213:121-127; Dulubova et al., 1996, J. Biol.Chem. 271:7535-7543;
The latrotoxin genes will be used to introduce point mutations and produce truncated and mosaic mutants of the two toxins, with the intent to express small quantities of the wild type and mutant toxins. The latter will serve as analytical tools to study the mechanisms of neurotransmission in cultured cells or extracted tissues (no in vivo experiments will be conducted).

**Evaluation of foreseeable effects**

The microorganisms used in the study are attenuated and cannot survive in the human body or penetrate into the bloodstream. Only α-latrotoxin may be harmful to humans, and only in its un-mutated form. However, if swallowed, the toxin is unstable in the stomach and intestine and cannot cause any serious damage. The only theoretical and easily avoidable risk is posed if a substantial amount of GMM carrying α-latrotoxin were to enter the bloodstream, in which case the expressed toxin could cause some poisoning. But even in this worst-case scenario, the amount of α-latrotoxin released into the bloodstream would be very small and essentially harmless.

In contrast, α-latroinsectotoxin is not dangerous to mammals but is toxic to insects. However, the GMM carrying the gene for α-latroinsectotoxin will not be released into the environment and cannot survive outside the laboratory conditions.

Importantly, the procedures used will totally nullify the risk of internal exposure or dissemination.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The solid waste produced (bacterial and cell pellets, pipettes, plates, tubes, tips) will be autoclaved and then incinerated. The liquid waste (used media and supernatants cleared of most GMMs) will be autoclaved and discarded after large-volume dilution. The degree of kill is 100% in both cases, and this will be monitored by temperature probes and control plating.

02/03/2022
We will introduce genes encoding non-toxic reporter molecules including Green Fluorescent Protein, Luciferase, Chloramphenicol acetyl transferase and beta-galactosidase into different enteric bacteria. These reporter genes will be expressed from either constitutive or regulated bacterial promoters. The aim of the work is to use the reporter gene products to (1) track bacteria to different cells or sub-cellular locations within eucaryotic hosts; (2) to detect the activity of different promoters under different conditions.

The reporter genes will be supplied from existing plasmids as cloned DNA sequences or purchased from commercial suppliers. They will be introduced into any enteric bacteria other than those classified as class III or above. Examples will be Escherichia coli (other than verotoxigenic forms), Shigella spp. Salmonella enterica (other than class III agents such as S. Typhi and S. Paratyphi), Citrobacter spp etc.

The host bacteria will be any enteric bacteria. The genes will either be introduced directly into the chromosome of the bacteria (via suicide vectors or PCR methodologies).
Alternatively the genes will be cloned onto non-transferable plasmids such as those based on ColE1 replicons or pAYC184 (pUC plasmids for example).

**Origin & function**

The genetic material involved is from a variety of sources such as jelly fish (Green Fluorescent Protein), bacteria (beta-galactosidase, luciferase, chloramphenicol acetyl transferase) but will not be cloned from these sources. We will use well-defined existing plasmids or genes from commercial sources. The DNA is simply to be used to report gene expression activity in enteric bacteria under different conditions.

**Evaluation of foreseeable effects**

The genes we have selected are all extremely well characterised and have been used without incident in thousands of research laboratories around the world. We will only use the named reporters associated with this application. If we decide to use any novel reporters we will amend the local risk assessment. To our knowledge there have been no foreseeable effects of these reporters other than high level expression could cause toxicity to the host bacteria (as with over expression of many proteins).

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All the experiments will be performed in a well maintained CL2 facility either in The Flowers Building or the CBS facility at Imperial College. A copy of the protocol for handling enteric pathogens in these facilities is enclosed for inspection and has been approved by the local safety committee. Briefly we have detailed policies for handling contaminated liquid and solid waste that involved the contained removal of materials for autoclaving. Hence, all contaminated material is autoclaved or inactivated using chemical disinfection procedures using a variety of accepted and validated disinfectants including phenolics (hycolin etc), Virkon S or chloros. All disinfectants are made up and utilised as described in the enclosed protocol. We routinely validate inactivation using a viable count method based on the killing of control cultures of bacteria within accepted ranges. All waste material is removed using clinical waste disposal methodologies in place at Imperial College.

02/03/2022
The aim of the use is to study S. Typhi using a safer attenuated derivative suitable for use at CL2. This will facilitate further examination of (a) the vaccine potential of these derivatives (b) the mechanisms of pathogenesis of S. Typhi.

Recipient or parental organism

Both S. Typhi BRD948/CVD908-htrA (aroC aroD htrA) and ZH9 (aroA aroC ssaV) or similar derivatives have been extensively studied in human volunteers and have been shown so far to be safe and highly attenuated vaccine candidates. ZH9 is through phase II clinical study and is being prepared for an efficacy study in phase III in the field./ Both BRD948 and ZH9 harbour at least three independently, non-reverting attenuating mutations. Both strains fail to colonise the human host and, as S. Typhi, are unable to colonise animals or plants. Both are based on the well characterised S. Typhi strain Ty2 which has been recently fully sequenced. Both strains harbour deletion mutations that are fully sequenced and inactivating. Both strains have been shown to be attenuated in mice as well as humans.

Project Ref 8/03.4

Date Ackn’d: 12/12/2003
CU2 Project Title: MALARIAR RESEARCH - TRANSGENIC PLASMODIUM FALCIPARUM PARASITES: ESTABLISHMENT OF AN INDUCIBLE SYSTEM TO CONDITIONALLY DISRUPT ESSENTIAL GENES AND VALIDATE NOVEL TARGETS FOR INTERVENTION

Date Project Ceased: 20/06/2016

Withdrawn: N

Tick if notifying a connected programme of work: N

Historical Significant Changes

Historical Date of Additional Info: 20/06/2016

Significant Change ID: 8/03.4a

Date of Significant Change: 07/05/2013

Project Additional Information

Purposes of the contained use

The first aim of the project is to establish an inducible gene expression system in the asexual red blood stage stages of Plasmodium falciparum. The strategy will consist in the integration of a plasmid leading to the stable expression of a tetracycline Repressor fused to an activating domain (transactivator) and to the conditional expression of a reporter gene (chloramphenicol acetyltransferase or GFP) controlled by tet-operator dependent promoter, as recently described in Meissner et al 2002, Science). The second aim is to use this inducible system to create conditional knockouts for genes that are essential for the survival of Plasmodium falciparum. The candidate genes to be disrupted include:
- proteases of the rhomboid family potentially required for host cell invasion.
- Calmodulin-dendent kinases potentially involved in a stage differentiaion and organelle secretion
- Surface antigens and secreted adhesins potentially playing a role in parasite differentiation and host cell interaction.

**Recipient or parental organism**

*Plasmodium falciparum* is the causative agent of malaria in human. Its life cycle is split between the human host and an insect vector. Transmission to human occurs via bite by the mosquito vector and only female *Anopheles* mosquitoes are involved as the males do not feed on blood.

*Falciparum* malaria symptoms include: complain of headache, fever and aches and pains all over the body, and diarrhoea and abdominal pain are sometimes present. Spleen and liver are often palpable on clinical examination. This may be misdiagnosed as influenza in non-endemic areas, and, unless treated promptly, the clinical picture can deteriorate rapidly. Can progress to cerebral malaria: confusion, delirium, loss of consciousness. Incubation period: at least 7 days.

Infection could occur through: 1/ Bite from infected mosquito. 2/ Accidental inoculation (needlestick injury) with blood used to culture parasites in the laboratory.

The strain of *P. falciparum* to be used in this study are the two isolates D10 and 3D7, and both of which are sensitive to chloroquine.

**Host/vector system**

The vectors to be employed in the proposed experiments are all derived from the commercially available bluescript from Stratagene. Most of the constructs are designed to express modified proteins or to generate knockout by homologous recombination in *P. falciparum*. These vectors are all described in the literature cited below. The selectable marker genes are the *Toxoplasma gondii* and human dihydrofolate reductase-thymidylate kinase genes. The reporter genes include chloramphenicol acetyltransferase and the green fluorescent protein. The tetracycline repressor originate from *E. coli* and is fused to an activating domain generated in *T. gondii*.

The *P. falciparum* genes to be studied include ROM1, ROM2 and ROM3 (rhomboid-like proteases involved in parasite motility and other undefined functions), cammodulin dependant kinases and surface antigens. Their cDNA will be tagged with epitopes and cloned into the Calmodilin expressing plasmids previously described (Crabb 1997).

The flanking sequences controlling expression of the transgenes are derived from the *P. faciparum* calmodulin genes.

**Origin & function**

The genetic material originates from *P. falciparum*, *T. gondii*, human and E coli.

Rhomboid proteases, kinases, surface antigens.

Gene originating for other organisms: tetracycline repressor (tetR), green fluorescent protein (GFP), chloramphenicol acetyl transferase (CAT). Dihydrofolate reductase (DHFR).
Functions: Selectable marker to integrate and/or disrupt genes by homologous recombination (TgDHFR, human DHFR), reporter genes (GFP) and Creation of chimeric fusion to follow the traffic of protein (GFP), and Creation of chimeric fusion to follow the traffic of protein (GFP), and modulation of gene expression (tetR).

Evaluation of foreseeable effects

1. The genes coding for these proteins will be disrupted in P.falciparum by homologous recombination or by conditional knockout using the inducible tetracycline based gene expression system.

We anticipate an alteration of the ability of parasites to infect cells and to progress into their life cycle.

2. These genes will be expressed as mutants: fused to an epitope tag, insertion of site specific point mutations deletions or GFP fusions of these genes will be used to generate transgenic parasites.

No change increase of virulence is expected.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Plasmodium falciparum is a micro-organism

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Plasmodium falciparum is classified as Class 3, but as the pathogen is not transmitted through the airborne route, fumigation of the lab is not required.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Propagated of the P. falciparum intraerytotic stages in human blood must take place in the CL3 unit on the 6th floor of the SAF building. The room and equipment fulfills all the safety requirements. The manipulation of live parasites will be done in a safety cabinet. Wearing gloves and laboratory coats are requested and use of no needles or sharps is not allowed. No material or equipment can leave to zone before decontamination or autoclaving.

All the solid wastes will be autoclaved in the Containment 3 zone. Autoclaving: 30 minutes at 121 degrees.C at 15p.s.i. (1.1kg/sq.cm. Monitoring: Autoclave performance is monitored continuously by means of autoclave printout, by the temperature monitoring inserted into the load, and by "thermo-stripes", and checked, serviced and monitored (including a multipoint thermocouple test) annually by an independent company. Work carried out in the Containment level 3 laboratory is autoclaved within the containment room prior to removal to the main autoclave for a second round of autoclaving. The liquid wastes will be decontaminated with 5% of chlorous.

Is an emergency plan required according to regulation 20?  
If yes, tick to confirm that it is attached to this form
Tick to confirm that you have attached a risk assessment to this form
Tick if you are claiming exemption from disclosure for section of the risk assessment

Please enter comments on the GM safety committee on the risk assessment

The genetic modification safety committee agreed that the project involving Plasmodium falciparum can be conducted in a CL3 unit and that the genetic modifications to be introduced according to the project are not anticipated to change the category of containment. In the case of a laboratory exposure to the parasite, the person infected should immediately be treated. For treatment, chloroquine sensitive malaria is controlled by intravenous chloroquine.

#### Project Additional Information

**Purposes of the contained use**

To generate transgenic Plasmodium berghei parasites and transgenic Anopheles gambiae and Anopheles stephensi mosquitoes for malaria control

**Recipient or parental organism**

The genes modified on transgenic P.berghei parasites encode for motility proteins or genes involved in a mosquito specific immune reaction. the parasites will have reduced motility and infectivity in mosquitoes.

The transgenic mosquitoes will express marker genes (e.g. luciferase or EGFP) or RNA1 genes against marker genes or mosquito specific genes. The introduction of...
marker genes will not have any effect on the phenotype of the mosquitoes, the RNAi genes against GAGs (glucosaminoglycans) are anticipated to reduce the ability of malaria parasites to invade mosquito salivary glands.

### Host/vector system

In mice and mosquitoes (the GMM hosts), the transgenic parasites are anticipated to have reduced infectivity.

### Origin & function

The genetic material (genes involved in parasite motility, mosquito immunity or marker genes) originates from lab stocks. The intended function of the genetics material is to generate transgenic parasites with knockout or replacements of parasite motility genes, or mosquitoes expressing RNAi genes or marker genes.

### Evaluation of foreseeable effects

The transgenic parasites will have reduced motility and infectivity in mosquitoes.

The introduction of marker genes will not have any effect on the phenotype of the mosquitoes, the RNAi genes against GAGs (glucosaminoglycans) are anticipated to reduce the ability of malaria parasites to invade mosquito salivary glands.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Mosquito cages are designed to effectively prevent escape at all stages. Cages are clearly labeled giving the species, date of collection and relevant modification. Personnel will be wearing lab coats at all times and gloves when necessary. The mosquitoes are contained within the insectary which has a specialised entry system to prevent mosquito escape.

The organisms can not survive at the embryonal or larval stage unless maintained in water, so in the event of a spillage they would not survive. Following a spillage the area will be dried and any solid waste will be autoclaved.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)  
N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Mosquitoes: autoclaved (solid cycle) by college staff after killing by starvation and exposing adult mosquitoes to freezing temperatures or by placing larvae in boiling water. The degree of kill is 100% and this practice is standard for mosquito rearing. This is monitored by an autoclave printout and by the use of a thermophile probe inserted into the load, and by thermostrips. The autoclave is serviced and monitored annually by a departmentally approved contractor.

Parasites: Plasmodium parasites are killed by high temperatures (100% effectively), achieved by the autoclave as monitored by a thermograph. This is monitored by an autoclave printout and by the use of a thermophile probe inserted into the load, and by thermostrips. The autoclave is serviced and monitored annually by a departmentally approved contractor.

**Project Additional Information**

**Purposes of the contained use**

* to map and sequence target genes in Leishmania species and Trypanosoma brucei, in relation to their chromosomal position and stability between genomes.

* to clone Leishmania and Trypanosoma brucei genes into plasmid vectors engineered for prokaryotic expression: to express and purify the target proteins for further analyses.

* to target specific genes for disruption (by homologous recombination) to generate null, loss-of-function of gain-of-function mutants for phenotypic analyses, by the introduction of antibiotic resistance genes into chromosomal sites in the genomes of non-infective Leishmania or T. brucei stages.
Recipient or parental organism

E. coli K12 strains: eg E. coli BL21 (DE3) pLysS
Leishmania major MHOM/IL/81 Friedlin
Leishmania mexicana MNYC/B762/M379
Leishmania donovani MHOM/SD/82/IS-CL2D
Leishmania infantum MCAN/es/98/LLM-724
Leishmania (Viannia) braziliensis MHOM/BR/75/M<2904
Trypanosoma brucei brucei Lister 427

Host/vector system

For E. coli host:
Plasmid vectors: pUC based such as the pBS, pSK, pGEX or pEt series
Cosmid vectors: pWE15 (Strategene) or similar

For Leishmania/T brucei host:
Plasmid shuttle vectors: pUC based such as the pBS or pSK series.

Origin & function

The sources of parasite material (both Leishmania species and Trypanosoma brucei) are collaborating reference centres, both in the UK and abroad, that supply frozen samples in sealed containers for transport into the containment laboratory. Frozen material is stored in the vapour phase of liquid nitrogen until required for in vitro culture.

The genetic material from these parasites will be used:
* in gene mapping studies
* for expression studies to generate recombinant proteins for structural and functional analysis
* to generate null, loss-of-function or gain-of-function Leishmania or T. brucei mutants for phenotypic analyses

Evaluation of foreseeable effects

Species of Leishmania are causative agents of human Leishmaniasis; the parasite species L. donovani, L. infantum, L. braziliensis are designated hazard group 3f$ (ACDP categorisation). The remaining species covered by this notification, L. major and L. mexicana, are hazard group 2 (ACDP categorisation), as is Trypanosoma brucei, which is non-infective to man. In susceptible individuals, leishmaniasis is treatable (as detailed in the Code of Practice, June 1992).

The target genes for manipulation will be wild type Leishmania or T. brucei sequences that have been fully characterised by DNA sequencing. The products of these genes are not known to have a role in the progression of human disease but this possibility cannot be discounted for those genes coding for proteins of unknown function. The GMMs are unlikely to express proteins at a level significantly higher than wild type parasites that have not been genetically-modified.

The pathogenicity of Leishmania species and the hazard this imposes to experimental work in the Department of Biological Sciences is already covered by Codes of Practice for cultivation in culture (June 1992) and in animals (January 1993). Genetically-modified Leishmania will be subject to the same safety protocols; the environmental risk is therefore no greater than with unmodified parasites. The life cycle of Leishmania involves transmission of extra-cellular parasite stages between hosts by a sandfly vector, followed by intracellular maintenance within macrophages in the mammalian host. No other organism is known to be at risk from infection. There is no sandfly colony on the South Kensington site of Imperial College, so transmission of the parasite, by inoculation of infective parasites into susceptible mammalian hosts, is impossible.

Transgenic Leishmania will be resistant to one or more antibiotics but this is irrelevant to therapy against human leishmaniasis (for which pentavalent antimonials are the current drugs of choice). Transgenic T. brucei will also be resistant to one or more antibiotics but this is irrelevant as T. brucei is non-infective to man.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Table 1a Measure 2 Laboratory: sealable for fumigation. Justification - Parasites not transmissible through the airborne route.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

GM waste is of 2 types: liquid and solid.
Liquid GMM waste: is treated by chemical disinfection, using Chloros diluted 1:10 (final concentration 10,000ppm available chlorine), with contact time > 12 hours. This gives 100% kill, as validated by testing described in the attached risk assessments.
Solid GMM waste: is autoclaved at 134 degrees C for 15 minutes at 27 psi pressure. This gives 100% kill, as validated by testing described in the attached risk assessments.

All clinical waste is sealed in bags and transported on robust trays from the containment facility to the autoclave, via the interlock hatch. This waste is handled by authorised personnel only. After autoclaving, the material is transferred to yellow bags for incineration.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The GMSC agreed with the classification and containment measures assigned to this project. Minor modifications were required to be made to the risk assessment form prior to notification to the HSE.

Project Ref 8/04.3
Genetic modification of Trypanosoma brucei

Purposes of the contained use
Basic research related to coelomate cell biology of eukaryotes and development of therapeutics for protozoan parasites using cell culture and transgenic analysis techniques.

Recipient or parental organism
Trypanosoma brucei brucei Lister 427 and derivatives expressing T7 polymerase and the tetracycline repressor. Lifecycle forms of the parasite both mammalian bloodstream and insect procyclic stages are grown in vitro. The 427 strain of T.brucei has been in vitro cultured for many years and is bloodstream monomorphic. The genetic modifications proposed for this study are on genes of the CCCH zinc finger family that have no "activity" in themselves but may act to regulate gene expression via RNA binding. It is therefore unlikely that either the parental organisms of those generated in this research are hazardous to health or the environment. Plasmids are propagated in standard non-virulent laboratory E. coli strains (E. coli K12-DH5a, XL1Blue or TOP10) and it is unlikely that they represent a hazard to health or the environment.

Host/vector system
Overview:
The aim of this GMO system/study is the expression of mutant and wild type versions of trypanosome proteins and the suppression or ablation of these proteins in trypanosome cells in order to ascertain biological function. The host strains are T. brucei brucei Lister 427 and derivatives 427/SMB, 427/29-13, 427/449. These later forms of the parental strain have been previously engineered to express T7 polymerase and tetracycline repressors (427/SMB and 427/29-13) or the tetracycline repressor alone (427/449). Plasmid vectors are pUC based pGEM or pBluescript series shuttle vectors that are non-mobilisable and contain an ampicillin resistance marker (for cloning in E. coli) and a selectable marker for transfection into T. brucei (Hygromycin, Neomycin or Phleomycin). T. brucei plasmid shuttle vectors for RNAi are p2T7i, for gene knockout are pTNP, pNP, pH and for ectopic expression are pM2C-C/N, pHD451 and pHD430 that are propagated in standard laboratory strains of non-virulent E. coli K12.

Specific notes:
Ectopic expression will be via plasmids (pM2C-C/N, pHD451 or pHD430) engineered for expression in T. brucei that integrate into the trypanosome genome at the tubulin
locus on chromosome 1 or to the rRNA locus on chromosome 9. Due to the fact that these organisms trans-splice their mRNA, and have unique promoter structures, these vectors are incapable of expression in other systems. No attempt is made to optimise expression in these system and there are no reports that expression levels would be greater than 2% of the cellular protein content.

Vector p2T7 is targetted to the ribosomal rRNA locus on chromosome 9. Selection is with phleomycin or hygromycin. This vector expresses RNA that is not capped, and cannot be translated, and hence no protein is expressed. Besides the selectable marker, no protein product is produced. Gene knockout vectors integrate into the 5' and 3' untranslated regions of the targeted gene and result in ablation of the coding sequence and insertion of a selectable marker. Consequently this results in loss of function for the targeted gene and protein product.

Growth of all GM trypanosomes is routinely 10ml in a single culture flask or for large experiments (infrequent) <100ml in a single culture flask. All vectors/GM trypanosomes will carry a selectable marker for hygromycin, phleomycin or neomycin and/or a combination of these drugs and these will be included in culture media. PHD430 and pH451 described in Biebinger S, Wirtz LE, Lorenz P and Clayton C. Vectors for inducible expression of toxic products in bloodstream and procyclic. Trypanosoma brucei. Mol. Biochem Parasitol. 1997 vol 85 p99-112. p2T7 described in LaCount DJ, Bruse S, Hill KL, Donelson JE. Double-stranded RNA interference in Trypanosoma brucei using head-to-head promoters. Mol Biochem Parasitol. 2000 vol 111 p67-76.

For E. col K12 (XL1 Blue, DH5a or TOP10) standard vectors will be used based on pGEM and pBluescript.

Origin & function

CCCH zinc finger proteins are a family of proteins implicated in post-transcriptional control of gene expression, that may be significant in regulation of the Trypanosoma brucei genome. Over the course of this research potentially all known T.brucie CCCH family members will be studied (approximately 40-50 genes). The genetic material will be each of the T.brucie genes encoding CCCH zinc finger proteins that have been amplified from genomic T.brucie DNA and subsequently cloned into T.brucie ectopic expression expression systems (those mentioned above eg: pH451) and T.brucie RNA interference vectors and vectors for gene knockout (those mentioned above eg: p2T7i) for examining the cellular consequence of over-expression from the ectopically expressed gene or gene silencing/ablation once vectors have been stably transfected into T. brucei brucei 427 derivatives (as above). Cloning into the trypanosome vectors (eg: p2T7i and pH451) is performed in E. coli and only the final construct is transfected into T.brucie. The consequences of perturbed expression for individual CCCH proteins can then be phenotypically assessed in order to dissect functionality. Therefore it will be necessary for each vector containing a CCCH insert sequence to be propagated in standard laboratory E. coli hosts (as mentioned above).

E.coli cloning vectors are commercially available and will be transformed into the commercially available XL1-Blue or DH5a host strains or similar. Trypanosoma RNAi and ectopic expression vectors (p2T7i and pH451) are freely available academically generated plasmids that have been widely used for their specific purposes. In these cases E. coli strain XL1-Blue will be used for the propagation of clones prior to transfection of T.brucie.

The CCCH functions in trypanosomes have not been studied in detail (this study addresses these questions), but the suspected mechanism by which function is mediated is through post-transcriptional control of gene expression via RNA binding and subsequent stabilisation or destabilisation. Studies of CCCH proteins in other systems suggest this mode of action. Therefore the CCCH family of proteins has no "activity" in themselves but represent a specific class of regulatory molecules.

Evaluation of foreseeable effects

The genes (and derived GMOs) used in this research are unlikely to be directly part of pathogenic systems. The propogation of T. brucie in the mammalian host is reliant on a cell surface coat comprising a variable surface glycoprotein (VSG). All evidence that is available suggests that this is the primary virulence pathway. Moreover, the parasite does not secrete factors as far as is known that have a role in virulence.

As the CCCH genes have no biological activity in themselves it seems unlikely that they would transfer harm to another organism. CCCH proteins are found in diverse organisms including humans but the specific T. brucie C CCCH genes under study have no identifiable homologues in humans and therefore no identifiable activity or harmful effects.

All experiments that have been previously conducted on T. brucie CCCH proteins report no consequences for VSG expression. All experiments in this research are aimed
at alteration of function; in essentially all cases this results in a less efficient system, and hence the modified organism is less hazardous than the parental strain. It should be noted that the strain selected for study is non-pathogenic to humans as there is a lytic factor in human serum that efficiently kills the organism. None of the intended modifications could be expected to affect this to the extent that resistance will emerge.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Liquid GMM waste will be chemically treated with either.

1. Chloros diluted 1:10 (final concentration 10,000ppm available chlorine), contact time >12 hours or
2. Cultures in flasks or centrifuge bottles, are treated by addition of Virkon powder to a final concentration of 1% or by the addition of an equal volume of a 2% solution of Virkon. Cultures are left in Virkon for a minimum of one hour.

These solutions can then be disposed of down the sink and any glassware sent for washing up. A kill efficiency of 100% is-obtained either procedure.

Viability can be monitored by motility of the organisms and by morphology for

1. Cultures of bloodstream form or procyclic form T. brucei brucei Lister 427 were grown in either HMI-9 or SDM79 media supplemented with fetal calf serum (15%). The cultures were grown to various stages of density. Immediately after the addition of Chloros diluted at 1:10, no live parasites were observed on a slide. After 16hr, >99% of the cells had totally lysed. The results were consistent for all cultures when diluted with Chloros.
2. By Defra standard efficacy suspension testing (manufacturers tests).

Solid GMM waste is collected into dedicated waste bags, sealed and autoclaved (134 degrees C, 15 minutes at 27 psi pressure). A kill efficiency of 100% is achieved by autoclaving and no intact organisms remain following autoclaving. Autoclaving is monitored by temperature indicator paper in each run and this departmental facility is monitored by departmental safety officers.

All waste will be sealed in bags and transported on robust trays from the containment facility to the autoclave. This waste will be handled by authorised personnel only. After autoclaving, the material will be transferred to yellow bags for incineration.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The GMSC agreed with the classification and containment measures assigned to the proposed project.
**Project Additional Information**

**Purposes of the contained use**

The overall purpose of the project is to evaluate these strains as potential human vaccines.

**Recipient or parental organism**

All strains are derivatives of S. typhi Ty2. All the strains contain deletion mutations in two genes. The first deletion is in the aroC gene. AroC encodes the chorismate synthase enzyme which is critical in the synthesis of aromatic amino acids. Disruption of aromatic amino acid synthesis has been extremely well characterised, and results in severe virulence attenuation in Salmonella (Tacket et al. 1992, O'Callaghan et al. 1988).
The second deletion is in ssaV. This gene encodes a component of the type III secretion system present on the Salmonella pathogenicity island 2 (SP1-2). SP1-2 mutations are severely attenuating and there is evidence that this is because they reduce systemic spread of the organism (Shea et al 1999).

All strains are equally non-hazardous. The parental strain of all the strains to be studies, S. typhi ZH9, has been studies preclinically by Khan et al. (2003) and clinically by Hindle et al (2002). In the latter study, volunteers were given the strain orally. No adverse symptoms were reported.

Host/vector system

All genes are encodes on the chromosome of S. typhi and therefore there is no plasmid vector system involved.

Origin & function

Several genes encoding non-toxic antigens are cloned within the chromosome of the attenuated S. typhi strains.

Evaluation of foreseeable effects

The strains of S. typhi used are designed as potential human vaccines. They are specifically designed to cause a self limiting infection and to induce protective immunity. The parental strain, S. typhi ZH9, has been evaluated both in preclinical and clinical trials and was found to be well tolerated and produced no unforeseen adverse effects.

The antigens to be cloned into these strains are well described in the literature and are non-toxic either by virtue of properties inherent to the molecules or by site directed mutagenesis.

We foresee no risk associated with these strains.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Cultures will inactivated by either chemically or by heat serilisation (autoclaving).

Chemical sterilisation (used of liquid cultures)
Addition of Virkon to a final concentration of 2%; leave overnight; dispose of waste down sink.
Validation - manufacturer's web site.

Autoclaving (used for solid culture waste, agar plates etc)
134 degrees C 3 minutes
Each run is monitored by Departmental staff.
Autoclave is checked periodically by use of a 12 point thermocouple test.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

02/03/2022
The Committee approved the risk assessment as Class 2. The experiments use derivatives of Salmonella typhi with two non-reverting attenuating mutations and pose little risk to the workers or to the environment. However as the wild type pathogen is a Hazard Group 3 agent, it was thought prudent to classify this project as Class 2. The control measures in place are adequate for the proposed work.

### Purposes of the contained use

The aim of this project is to define, at a molecular level, the virulence attributes of fungi, in particular *Aspergillus fumigatus*, *Aspergillus nidulans*, *Aspergillus flavus*, *Candida albicans* and *Candida glabrata*. We also intend to investigate selected attributes in the model fungus *Saccharomyces cerevisiae*.

### Recipient or parental organism

</tbody>
</table>

### Host/vector system

We will use standard *E. coli* and *S. cerevisiae* vectors e.g. pUC, pBluescript, YE, YI and YC series. We will use a series of *C. glabrata* episomal vectors (Kitada et al, Gene 175:105, 1996). Mobilisable *Aspergillus* vectors will not be used.

### Origin & function

The majority of inserted genes will be from the same species, eg used to complement a null allele to create a reconstituted strain, and therefore do not constitute the construction of a GMM.

We are investigating fungal virulence and wish to analyse all attributes associated with the ability to cause disease. Current examples of genes under investigation (and the functions that they are known, or predicted to encode) include *C. glabrata* ACE2 (transcription factor) *C. glabrata* CTS1 (endo-chitinase) and *A. fumigatus* PacC (transcription factor). We will also analyse other genes related to virulence in these species.

We will also construct *Aspergillus* and *Candida* DNA libraries in *S. cerevisiae*. We will also add selected tags eg GFP, TAP, HA, etc to selected genes.
We will use heterologous antibiotics genes er ampR, bleR, hygR as markers of transformation.

**Evaluation of foreseeable effects**

The GMM are disabled and are unlikely to be able to survive in the environment and the modifications proposed (gene inactivation) would not confer a selective advantage even if they were to be transferred to a wild type organism. The likelihood of hazard is therefore considered to be no greater than that of the parental strains.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Tick if you are claiming exemption from disclosure for section of the risk assessment**

N
Q 1.3 not really answered. If none of the proposed GMMs are likely to be any more hazardous than the host without an insert, then this should be stated, and a justification given e.g perhaps there are no known toxins in any of the fungal pathogens being used, or measures will be taken to specifically exclude any toxin genes from being expressed?

Reviewer 2:
2.2.1.1 PI needs to consider the worst case scenario for strains that do not contain auxotrophies.

Reviewer 3:
The hazards need to be identified and then explanations of how the risks are reduced by operational practices mentioned here.
1.21 Paragraph3: give some examples of genes being disrupted and/or replaced. Write explicitly the kind of phenotype assays that will be carried out to test the effects of the genetic modifications.
1.23 Give more details of the plasmids used for transformation of the fungi (Aspergillus sp and Candida sp). Specify the selectable markers used.
2.1.1.2 List the hazards to human health posed by the organisms used. Explain the diseases caused, not just the reasons to think that the risks are mitigated by the auxotrophies.
2.1.1.3 Give examples of the "majority" of genes. List some examples of the remaining "minority". Here is the first mention of complementation of the auxotrophies by the transforming plasmids. This appears to negate some of the mitigating effects described extensively in preceding sections. Therefore clear statements about this must appear in many of the introductory paragraphs.
2.3.2.1 In order to study the function of putative virulence genes, phenotypic assays including infection models require an infectious GMM: this will by definition be a hazard to humans and the environment. Hence this MUST be explicitly stated in the introductory paragraphs to all sections.

Project Additional Information

Purposes of the contained use

Envelope assembly project:
The cell wall envelope of Gram-positive pathogens has important functions as a surface organelle that allows bacteria to interact with their environment, in particular the tissues of the infected host. Major structures found within the cell wall envelope of Gram-positive bacteria include peptidoglycan, carbohydrates, proteins and other wall polymers such as teichoic acid (WTA) and lipoteichoic acid (LTA). The goal of this project is uncover genetic determinants required for the synthesis of these envelope structures, determine how their expression is regulated, biochemically and structurally characterize the function of encoded proteins and assess their contribution to pathogenesis. A more detailed knowledge of these envelope structures will help us design new strategies to prevent their synthesis or function and hence prevent infections.

The staphylococcus aureus research on gene regulation will consist of three research streams.

Stream one will focus on the pleiotropic virulence gene transcription regulator SarA (and homologues therefore) and will explore its interaction with the transcription machinery - the RNA polymerase. Of particular interest is to unravel how SarA influences transcriptional output via modulating the RNA polymerase. Stream two will investigate the genome-wide distribution of SarA during normal growth, infection and in response to antimicrobial compounds. Stream three will be centred on the mechanism of action of bacteriophage-derived small molecular weight proteins that either target or are "re-educated" to target the S. aureus RNAP.

Recipient or parental organism

Listeria strains

EGDe, EGD, 10403, Mack, CLIP11262,F6854,F2365 and derivatives thereof that have defects in cell wall envelope assembly pathways. These strains have a long history of safe use in diverse laboratories around the world.

Escherichia coli:

Wild-type K12 strains and derivatives thereof with required phenotypes for cloning and expressing staphylococcal or bacterial genes of other bacterial origin will be used in these studies. Strains commonly used in the laboratory include strain DH5alpha, XL1blue and CA800 and BL21 (DE3). These strains have a widespread and long history of safe use.

Bacillus anthracis Sterne; This strain is a veterinary vaccine strain.

Bacillus subtilis

Bacillus subtilis strain 168 and derivative thereof, which have defects in the assembly of envelope structures. These strains have a widespread and long history of safe use.

Staphylococcus strains

Newman, SA113, NCTC8325, RN4220, RN450, COL, BB270, N315, NW2, USA300, EMRSA-15, EMSRA-16 and mutants thereof with defects in cell wall envelope pathways and regulatory pathways.

Strain RN4220 and RN 450 are a commonly used laboratory strains. These strains have acquired several mutations that make them less virulent and we will use them for our experiments, whenever possible.

Lower risk strains:

Strains Newman, SA113, NCTC8325, RN4220, RN450 are all methicillin sensitive strains and have been propagated in laboratories for an extended period of time and infections can be treated very effectively with conventional beta lactame antibiotics.
Higher risk strains. Strains COL, BB270, NW2, USA300, EMSRA-15, and EMSRA-16 are higher risk strains, which are methicillin resistant and infections can only be treated with a specific set of antibiotics including vancomycin, trimethoprim-sulfamethoxazole, clindamycin, minocycline, fluoroquinolones or doxycycline and. As outlined in a separate form, additional safety measurements will be taken when working with these higher risk strains.

Host/vector system

We will use standard E.coli vectors i.e. 
- pET vectors and derivatives for protein expression in E.coli
- pGEX - vectors and derivatives for protein expression in E.coli
- pQE30 vectors and derivatives for protein expression in E.coli

We still use standard plasmid vector used in Gram-positive bacteria
- pCL55 and derivatives - single site chromosomal integration vector for S. aureus
- pPL2 and derivatives - single site chromosomal integration vector for Listeria monocytogenes

The list contains the most commonly used vectors but may not be all inclusive. We also seek permission to use additional plasmid vectors with similar characteristics. Again, only plasmid vectors will be used which confer to the target organism antibiotic resistences that naturally occur in these organisms.

Origin & function

The majority of inserted genes will be from the same species or genes from other Gram-positive bacteria that encode for proteins with similar functions.

We are investigating envelope assembly pathways and gene regulation in Gram-positive bacteria and their contribution to cause disease. Current examples of genes under investigation include

- tagO - gene required for the synthesis of the cell wall polymer wall teichoic acid
- femA, B, X - fem factors required for peptidoglycan synthesis
- ypfP - glycosyl transferase - required for glycolipid synthesis
- ItaA - possible glycolipid flipase required for glycolipid anchoring LTA
- srtA - sortase required for anchoring of cell surface proteins
- att - hydrolytic enzyme - required for cell division and part of the bacterial envelope
- sarA and homologues therefore - transcription regulators

We will also construct S. aureus and L. monocytogenes libraries in E. coli
We will also add selected tags i.e. GFP, His, HA etc to selected genes.
We will use antibiotic genes i.e. ermC, tetM, as markers of transformation.

Evaluation of foreseeable effects

The majority of inserted genes will be from the same species or genes from other Gram-positive bacteria encoding proteins with homologous functions. Therefore, the likelihood of hazard is considered to be no greater than that of the parental strains.

Project Ref 8/07.4

Date Ackn'd 30/08/2007

Date Project Ceased

CU2 Project Title Investigation of the physiological and plant pathogenic properties of Burkholderia cepacia complex organisms.

Class CultureVolClass2 CultureVolumeClass3-4

Class 2 1-50 Litres

Non-GMM Consent Granted Not Applicable

Project notified under transitional arrangements N

02/03/2022
A key research focus is aimed at understanding the virulence mechanisms employed by Burkholderia cepacia complex (Bcc) pathogens using plant model systems. A second aim of research in this area is to study aspects of primary and secondary metabolism of Bcc. Both aims will involve random and targeted mutagenesis of selected Bcc strains to identify mutants with altered phenotypes or reduced virulence on a plant host.

Burkholderia cepacia species were originally identified as plant pathogens by Burkholder in the early 1950’s. Subsequently, Bcc strains have been associated with opportunistic infections of, in particular, cystic fibrosis patients. The burkholderia species to be tested include strains of B. cepacia, B multivorans, B graminis, B hospital. All strains are part of the internationally recognized Vandamme LMG stock collection in Ghent, Belgium.

So far, the roles of only a few Bcc virulence factors have been examined in animal infection models. Studying virulence in in vivo animal models is often complex, time-consuming, and expensive. This proposal aims to use the model plants Arabidopsis and Nicotiana benthamiana as hosts for studying virulence mechanisms of selected Bcc strains.

One of the main aims of this project is to generate a collection of random mutants of selected strains of Burkholderia that have been shown to cause disease symptoms on the plant host (Arabidopsis thaliana and/or plasposon technology whereby genes in the recipient organism are randomly inactivated by the insertion of a DNA element. It is important to note at this point that in the case increased virulence mutants of Burkholderia were to be identified in this system, no further work would be carried out on this class of mutants until a new risk assessment would have been prepared and approved. Once mutants of interest have been prepared and approved. Once mutants of interest have been identified, DNA fragments flanking the insertion site will be cloned in standard disarmed E.coli K12 derivatives for sequence analysis to identify the affected gene. It is only at this stage that the identity of the affected gene will become known. The sequence will allow cloning of the wildtype gene for further functional analysis using standard molecular biology approaches (e.g mutation analysis, protein expression, protein interaction studies, etc).

Complementation studies will involve the cloning of wildtype Burkholderia genes in E.coli lab strains and transferring these constructs to the selected Burkholderia mutants to test for complementation.

Apart from the mutant screen approach described above, the following genes will be specifically targeted.

1. Genes encoding respiratory proteins, in particular terminal oxidases
2. Putative HCN biosynthesis genes
3. Two component regulatory genes and sigma factors
4. Putative quorum sensing genes.

It is expected that mutants defective in the targeted pathways be less fit and less pathogenic than the wildtype strains. These mutants will be used in basic biochemical and
regulatory studies on the metabolic pathways and the metabolome of Bcc.

Evaluation of foreseeable effects

As explained above the work described is either aimed at identifying reduced virulence mutants or is expected to result in less fit and less pathogenic mutants. However, in the case increased virulence mutants of Burkholderia were to be identified in this system, no further work would be carried out on this class of mutants until a new risk assessment would have been prepared and approved. Laboratory work with the wild type gene products identified in these screens is very unlikely to lead to increased risk above the use of the wild type organism.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

As part of the screen for reduce virulence Bcc mutants, plants will be inoculated with randomly generated Bcc mutants in the category 2 lab suite and then transferred to a controlled environment plant growth room (PGR) which is outside the category 2 lab suite, but on the same level in the building and under the same restricted card access control (not open to the public). We will put the following control measures in place:

In a large closed container to the PGRs on the same level. Inside the PGR, plants grown in plastic pots will be placed in sturdy plastic trays to avoid any runoff of water potentially containing Bcc organisms. Infected plant material that category 2 lab suite. This will ensure that all infected plant material, including compost and disposable plastic ware, will be contained and earmarked for autoclaving before leaving the PGR. Plastic trays in growth rooms used for these experiments will be wiped down with both disinfectant and 70% ethanol after each use. Plants infected with Bcc in the plant growth room will be clearly marked and segregated from other plants to avoid any cross-contamination. Only authorized personnel will be allowed to handle infected plants in the PGR and dedicated lab coats and gloves will be supplied within the PGR.

We believe that the above measures will safely contain the use of category 2 Bcc organisms in a category 1 plant growth room. We anticipate that this work will be transferred to a newly commissioned suite of category 2 plant growth rooms at the beginning of 2008.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Culture remnants and preparations originating from the live Bcc cultures will be collected and killed using a chemical disinfectant (Virkon) according to the manufacturers recommendations (essentially by addition of Virkon to a final concentration of 1%, with a minimum contact time of 24 hours) and subsequently discarded in the drain.

Disposable plastic ware that has been in contact with Bcc (including culture plates) will be placed in autoclave buns for disposal, while sharps and any broken glassware are put into autoclave cinbins for disposal as clinical waste after autoclaving. The autoclave cycle to be used is 126 degrees for 10 mins. Autoclave cycles are reported out onto a mounted printer detailing all significant stages of the cycle. The autoclave is on a quarterly preventative maintenance contract, has an annual insurance inspection and cycle 2 (Discard) validated by 12 point thermocouple testing. Equally, a validated kill cycle will be used to autoclave plant and compost waste contaminated with Bcc organisms.

Viable Bcc waste will be transported to the autoclave in sealed autoclave bags inside sturdy white plastic buckets. The material will be taken down on a dedicated metal trolley by the floor technician using the goods lift. Autoclave waste is subsequently incinerated. Chemical disinfection and autoclave treatment will result in 100% kill.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment N
Deselect containment level 21

2.3.3.1a. The committee recommend the use of plastic containers. Ensure that the risks associated with this project are clearly communicated to those other personnel sharing the laboratory, but not directly involved with this project.

2.3.6: Deselect containment level 1, ensure details provided under containment level 2 are left on form

MSC: Ensure and state that microbiological safety cabinet has the following: 6 monthly maintenance, monthly airflow checks that are recorded by user. Specify which cabinets in the lab are to be used.

3.1.1b. Solid waste – State that sharps will be autoclaved within an autoclavable in a cin bin prior to final disposal.

The committee was informed that the PI had confirmed that a microbiological safety cabinet would be used during the injection process as there is potential for aerosols to be produced.

The laboratories used are containment level 2 while the plant growth room is containment level 1, for this reason the PI has selected both on the risk assessment form. Burkholderia will be handled in containment level 2 facilities, once it is integral to the pant it will be transported to containment level 1 facilities. The plants will be correctly transported between two facilities. The plants will not be allowed to pollinate or flower. All plant waste will be autoclaved before disposal. The committee agreed on the classification, yet advised that risk assessment be sent to another researcher in the department for comment prior to submission to the HSE.

### Project Ref 8/07.5

- **Date Ackn'd**: 28/11/2007
- **CU2 Project Title**: Study of gene regulation in Pseudomonas that have an effect on infection and persistence within the host.
- **Class**: Class 2
- **Culture Vol**: 1-50 Litres
- **Consent Granted**: Not Applicable
- **Project notified under transitional arrangements**: N

Withdrawn N Tick if notifying a connected programme of work N
**Project Additional Information**

**Purposes of the contained use**

*Pseudomonas aeruginosa* is able to infect a wide variety of hosts and tissues and is an excellent model for studying infection by gram-negative bacteria. The project is the coordination of research conducted on two different axes, which are central for the establishment of infection and persistence within the host. One axis concerned the characterization of molecular actors involved in bacterial biofilm formation and dispersion, the second axis is the study of a novel secretion mechanism, called type VI. The type VI secretion system is required for pathogenicity and is proposed to deliver effectors towards the host cell, thus impacting processes such as cytotoxicity or internalization by non-phagocytic cells.

**Biofilm Dispersion.**

One strategy for fighting against a biofilm is to induce its dispersion and thus to make the released bacteria accessible to the immune system and antibiotic treatment. Whereas we have a good knowledge of the biofilm formation mechanisms we have a poor understanding of the dispersion step. This step is required to allow bacteria present into the biofilm to be released and to colonise neighbouring surfaces. The release might be induced upon sensing environmental cues. The focus of the project is to discover the major signalling pathways that result in *P. aeruginosa* biofilm dispersion. Within the signalling cascade we will study the receptors of the environmental cues (chemotactic pathway or two-component regulatory systems). We will analyze the output of the signalling cascade and the intracellular signal molecule cyclic-di-OMP, whose concentration is an important balance in the switch between biofilm and motility. Every single actor of the cascade can be considered as a target for modulating biofilm dispersion. Among the targets whose expression has been shown to be controled by c-di-GMP levels we will particularly study the fimbriae assembled by chaperone usher pathways (Cup).

**Type VI secretion.**

*P. aeruginosa* is known as an extracellular pathogen, but it is capable of transient internalization in non-phagocytic cells. The genetic and molecular basis allowing *P. aeruginosa* internalization are not well-established. Three genetic loci have been identified, that encode a novel type of secretion machinery (called type VI). We have preliminary data that indicate that some of the systems promote internalization of the bacteria whereas others induce cytotoxicity. We suggest that the type VI system transports effector proteins within the host. Some effectors have ACD domain (Actin-cross-linking domains) that may promote cytoskeleton rearrangement and internalisation. The aim will be to understand the molecular mechanisms of the type VI secretion system, to identify and characterize the proteins transported within the host cells and to understand their role in modulating host cell response.

**Recipient or parental organism**

**Escherichia coli**

*E. coli* K12 and derivatives will be used for cloning and as recipient for gene expression and purification. Most commonly used strains will be TG1, I-l.BiOl, C600, DH5alpha, OP5O, CCl8, XLlblue, TOPOF, S17.1. These strains have a widespread and long history of safe use.

**Pseudomonas aeruginosa**

Most well characterized laboratory strains used will be: PA01, PAI4, PAK, CHA, PA103, TB, 5G17.
A collection of Tn mutants (SMlopir/pCM639-ISphoA/hah insertions or SMlOpir/pIT2-ISlacZ/hah insertions) in the PAO1 strain will be used (Jacobs et al., PNAS, 2003). A collection of Tn mutants (MAR2xT7) in the PA14 strain will be used (Liberati et al., PNAS, 2006). Strains isolated from patients will be collected and used in the course of the program. Some isolates will be freshly collected, others have been collected for many years and store at -80°C without any further laboratory manipulations. Pseudomonas aeruginosa is sometimes present as part of the normal flora of humans and the prevalence of colonization of healthy individuals outside the hospital is relatively low.

Pseudomonas syringae
This is a plant-pathogenic organism we will use sequenced strains DC3 000, B728a and 1448a
This work is subject to DEFRA approval and we will not commence work with or hold stocks of this bacterium until we have received such approval
Other Pseudomonas and related species
Pseudomonas fluorescens (Pf-5, SBW25, Pto-I, CHAO), Pseudomonas putida (WCS358, KT2440), Pseudomonas alcaligenes (M-I), Pseudoalteromonas haloplanktis (TAC12S), These are clas organisms with a widespread and long history of safe use
Related Pseudomonas species (class 2)
Ralstonia solanacearum which is a phytopathogen without any known natural antibiotic resistance (Strain GMI1000, Molk2 and 1649). This pathogen is subject to DEFRA approval and we will not commence work with or hold stocks of this bacterium until such approval has been received
Burkholderia cepacia and cenopecia (strain J2315), are opportunistic pathogens which poses little medical risk to healthy people. However, people who have certain health problems like weakened immune systems or chronic lung diseases, particularly cystic fibrosis (CE), may be more susceptible to infections with these organism. Pseudomonas entomophila L48 (strain CT573326) is an entomopathogenic bacterium known to infect Drosophila melanogaster (fruitfly). This pathogen is subject to DEFRA approval and we will not commence work with or hold stock of this bacterium until such approval has been received

Host/vector system

1) We will used standard F. coli vectors:
   NB: These vectors could also be used as suicide vectors for P. aeruginosa mutagenesis.
   b) For gene tagging and expression:
      - pET22b/28c/28a and derivatives, pQE30Xa and derivatives, pEGFP and derivatives, pGEX and derivatives, PAC or PAN and derivatives, pBADmycHisA, B, C and derivatives, pYZ4 and derivatives, GATEWAY plasmids including the entry vector pDONOR and the destination vectors (pDEST derivatives)
   c) For expression of genes under strong promoters:
      - pBAD and derivatives, pT7-1 to pT7-6 and derivatives
   d) For studying protein-protein interaction:
      - pUTI18c and pKT25 and derivatives, pBS1479 and derivatives
2) We will use suicide vectors for the engineering of Pseudomonas mutants:
   - pKNG101 and derivatives, pEX 100 and derivatives
3) We will use broad host range vectors for expression in P. aeruginosa and related organisms (also replicative in E. coli):
   - pLAFR1, pLAFR3 and derivatives, pMMB66, 67, 190, 206 and derivatives, pBBRIMCS and derivatives, pMP220 and derivatives
4) We will use vectors for conjugation in Pseudomonas: pRK2013 and derivatives
5) We will use vectors for transposon mutagenesis in pseudomonas:

This list contains the most commonly used vectors but may not be all inclusive. We also seek permission to use additional plasmid vectors with similar characteristics. Again, only plasmid vectors will be used which confer to the target organism antibiotic resistances that naturally occur in these organisms.
The majority of inserted genes will be from the same species or genes from related organisms and will encode for proteins with similar functions. We are investigating the characterization of molecular actors involved in bacterial biofilm formation and dispersion and a novel secretion mechanism, called type VI. Current examples of genes under investigation include: ladS, retS, xcpA-Z, hpfB-C, vgr, hcp, hsi-I-III, gacA, gacS, psc, icmF, dotU, psi, cupA, cupB, cupC, cupD, cupE, rocA, rocR, rocS, prrA, prrB, tad, pil, lasB, aprA, exoS, exoY, exoU, exoY, etc...

We will also add selected tags i.e. GFP, His, HA etc to selected genes.

**Origin & function**

The majority of inserted genes will be from the same species or genes from related organisms encoding proteins with homologous functions. Therefore, the likelihood of hazard is considered to be no greater than that of the parental strains.

**Evaluation of foreseeable effects**

The majority of inserted genes will be from the same species or genes from related organisms encoding proteins with homologous functions. Therefore, the likelihood of hazard is considered to be no greater than that of the parental strains.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**Tick if you are claiming exemption from disclosure for section of the risk assessment** N
• 1.21: last sentence, add inactivated by Virkon.
• 2.1.12: Clarify what ‘Class C’ is.
• Pseudomonas syringae needs DEFRA approval, confirm if this host will still be included.
• Clarify where Pseudoalteromonas haloplanktis will be used.
• “the strains include - a full list of all strains would be better.
• Ensure that any transfer of genes from one organism into another is described.
• 2.3.3.4: plastic conical flasks recommended.
• 2.3.3.6: State the animal work will be covered in another Code of Practice and Risk Assessment.
• 2.3.3.7: state risk is yet to be identified, subject to relevant licensing, i.e. DEFRA licence.
• 2.3.4.2: training records will be signed off.
• 2.3.5 OH input is required prior to final approval.
• 3.1.1.a: remove reference to solid waste.
• 3.3: Clarify whether 2L clinical strains will be cultured and whether this will be in glass conical flasks. Plastic conical flasks are recommended.
• 3.5.1: list local P1 as person in control of area.

The GMSC agreed with the classification of this project as Class 2, Containment level 2.

Project Additional Information

**Purposes of the contained use**

The project aims to identify Anopheles gambiae genes that impact upon ONNV replication and dissemination. To this effect it will use ONNV Alphavirus Transducing Systems (ATS’s) for infection of cell lines and mosquitoes. To facilitate virus detection, viral clones expressing reporter genes, e.g. GFP, EGFP, RFP, EYFP and luciferase, will be used. Furthermore, genes of interest (including but not limited to Toll-9, Dicer-2, Hopskotch) will be silenced using short RNAi cassettes inserted into the ONNV ATS’s (alone or on addition to the reporter genes). Reporter genes and RNAi cassettes will be cloned into a multiple cloning site (MCS) that is under the control of a viral subgenomic promoter. ONNV ATS’s will be first subcloned into E.coli DHSalpha or XLI Blue strains. Transgenic viruses will be produced by in vitro transcription of the modified or non-modified ONNVATS’s, and subsequent transfection of the produced RNA into insect (e.g. Aedes aegypti C6136 and A. gambiae 4a3A) or mammalian (e.g. African green monkey Vero) cells, where the virus is produced and replicates. Cell culture supernatant containing virus will be used to infect further cell lines or mosquitoes.

**Recipient or parental organism**

The SG650 strain of ONNV (isolated from the 1996 outbreak in Uganda) has been used to generate the plasmid (p5'dsONNVic/FOY) containing a cDNA copy of the SG650 strain, a multiple cloning site and a second viral subgenomic promotor (Brault et al 2004). p5dsONNVic/FOY (to be obtained from Colorado State University) will be subject to further genetic modification. In addition a second plasmid (p5'dsONNVic/Foy-GFP) containing a cDNA copy of SG650 and encoding enhanced GFP (Brault et al 2004) will be subject to further genetic modification.

Infectious clones generated from plasmids have been shown to replicate and disseminate at similar, but slightly reduced rates to the SG650 strain (Brault et al 2004). Insertion of reporter genes/RNAi cassettes minimally reduces the ability of the virus to replicate due to difficulties in packaging a larger genome into virion particles.

**Host/vector system**

ONNV ATS’s will be used to infect Anopheles gambiae mosquitoes (03, L35 and Yaounde strains) as well as a variety of insect cell lines (Aedes aegypti C6136, Anopheles gambiae 4a3A, 4a3B, 4a2, SuaEI, SuaIB, Sua4.0, SuaS.1* and L35) and mammalian cell lines (African green monkey Vero’s, Baby hamster kidney BHK’s).

**Origin & function**

1. Reporter genes (e.g. GFP, EGFP, EYFP, luciferase). These are marker genes which emit either fluorescence (GFP, EGFP and EYFP) or luminescence (luciferase) and are valuable tools for tracking and quantifying the replication and dissemination of the virus in the mosquito or mosquito cell lines.

2. RNAi cassettes. These are short (300-600bp) DNA sequence fragments that correspond to genes of interest (e.g. Toll-9, Dicer-2 and Hopskotch), which when transcribed in both directions (through a plasmid vector) or inserted in the alphaviral genome can produce double stranded RNA intermediates which trigger the RNA interference pathways.
Toll-9 belongs to a family of transmembrane proteins involved in signalling during innate immune responses. In Drosophila Toll-9 has been shown to up-regulate anti-microbial peptides via signalling through the Toll pathway. Dicer-2 is an enzyme involved in the RNAi pathway. dsRNA molecules are cleaved into 20-25 nucleotide small interfering RNA’s (siRNAs) by Dicer enzymes. In Drosophila Dicer-2 is believed to be involved in cleavage of dsRNA (including viral RNA), resulting in the targeting of homologous mRNA for degradation. Hopkotch is a Janus kinase (JAK) which in Drosophila has a role in embryo segmentation, and innate immunity by signalling through the JAKISTAT pathway. Hopkotch binds to a receptor, DOME, resulting in the phosphorylation and subsequent activation of a transcription factor, STAT.

ONNV - ONNV is an alphavirus of the family Togaviridae that is transmitted by Anopheleine mosquitoes. The virus has caused several epidemics of human disease in Africa. ONNV causes febrile illness associated with severe joint pain, headache, retroorbital pain and sometime a pruritic maculopapular rash beginning on the neck and face, and spreading to the torso and arms. No deaths have been associated with ONNV infection, with all know patients making a full recovery. In the laboratory risk of infection is highest from infected mosquito bite or needle stick injury. Risk of infection from eye splashes is low. Reporter genes (eg GFP) are non-toxic and non-hazardous and as such do not pose any hazard to human health. RNAi cassettes (e.g. for Anopheles gambiae Toll-9, Dicer-2 and Hopkotch) are short sequences specific to mosquito genes and are not hazardous to human health. Alterations to the traits of the host may include increased ability to infect mosquito cells or adult mosquitoes. Alterations to the host will not result in any increased ability to infect humans and as such should not increase the pathogenicity of the virus in humans. The infectious agent is not air-borne and thus will not escape containment. There are no natural vector mosquito species of this infectious agent in the UK, thus the infectious agent is not an environmental hazard.

Evaluation of foreseeable effects

Containement and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Please enter comments on the GM safety committee on the risk assessment

02/03/2022
1.3: State that the SG650 strain will not be used as part of this project.
2.1.1.2: Add the type of rash and where the rash will occur on the individual.
2.3.1.1: Change ‘3$’ to ‘2*’ and expand ‘maximum of 400 mosquitoes’ to ‘pots of 50 mosquitoes’
2.3.2.2.a: Change ‘3$’ to ‘2*’ and the stock of mosquitoes will be stored in room 619.
2.3.2.2b: Replace ‘separate MSC and separate incubators’ with ‘dedicated’ MSCs and incubators.
2.3.3.1.a: reword sentence to specify a dedicated microbiological safety cabinet will be used.
2.3.3.1.a, 2.3.3.2.a, 2.3.3.2.b, 2.3.3.3.d, 2.3.3.4.a and 2.3.3.5: change ‘disabling’ to ‘inactivate’ Specify why 96% EtOFI is used for inactivation rather than 70%.
2.3.3.2.a: State the storage location
2.3.3.2.b: Add that the cytotubes will be quickly transferred into a lidded box following removal from liquid nitrogen, ensure that this procedure is added to the project SOP.
2.3.3.8: answer is ‘No’.
2.3.9.a: Change to State green gowns will be worn in 619 and 630 rooms.
2.3.4.2: Add Induction training will be signed off. This should be added to the project SOP.
2.3.5 01-1 input is required prior to final approval.
2.3.6 Assign the project as Containment level 2, Class 2.
3.1.1.a: Contact time will be 20-30 minutes. Route of disposal is down the drain.
3.1.1.b: Remove E.coli cultures. Route of disposal, autoclaving only.
3.2.a: Change from autoclave to down the drain.
3.2.b: State the box will be ‘leak proof’ and lidded.
3.3: Clarify the volumes of bacteria and cell cultures to be used.
3.5.1: State location of storage here.
Agreed: Class 2, Containment Level 2

02/03/2022
These experiments are aimed at learning with molecules control the formation of heart muscles cells early in life, and what prevents the formation of new heart muscle cells later in life.

The work will use bacterial plasmids and E.coli K12 to generate eDNA which will be put into lentiviral vectors to deliver genes to cells. The use of the lentiviral vector system will enable the efficient infection of cells grown in tissue culture with lentiviruses expressing genes that control cardiac cell growth, differentiation and survival.

E.coli K12 will be used and plasmids will include pQE31, pET28b, pGST. K12 is non-colonising and disabled. Lentivirus particles will be produced by transfection of the 293 human embryonic kidney cell line. Human and mouse cells grown in tissue culture including NIH 3T3, C2C12, primary mouse and rat cardiac myocytes and fibroblasts, muscle, rat and human stem cells and mouse and human ES cells will be the recipients of virus. These cells will express the transgene but will not produce or contain replication-competent virions so are non-infectious.

Recipient or parental organism

E.coli K12 will be used and plasmids will include pQE31, pET28b, pGST. K12 is non-colonising and disabled. Lentivirus particles will be produced by transfection of the 293 human embryonic kidney cell line. Human and mouse cells grown in tissue culture including NIH 3T3, C2C12, primary mouse and rat cardiac myocytes and fibroblasts, muscle, rat and human stem cells and mouse and human ES cells will be the recipients of virus. These cells will express the transgene but will not produce or contain replication-competent virions so are non-infectious.

Host/vector system

1) pLL3.7 - Lentiviral vector. 2) Packaging vector - psPAX2 - lacks both LTRs and has no viral packaging signal. rev is supplied in trans on a different vector, expresses no viral gene products. Envelope (VSV C) is expressed on 3) pMD2.G. 4) pWPI containing the WPRE element. Second generation lentiviral vectors are replication incompetent. No structural genes are present, therefore no replication-competent virions can be produced. E.coli K12 (host), pQE31, pET28b, pGST (vectors).

Origin & function

Ecoli, all strains are K12 derivatives. K-12 derivatives are recognised as non-colonising and disabled. They are not considered pathogenic to humans or animals. They are expected to have limited survivability in the environment and often have auxotrophic requirements, which are unlikely to be satisfied outside of laboratory culture. Second generation lentiviral vectors which are replication incompetent. No structural genes are present, therefore no replication-competent virions can be produced. For shKnockdowns: pLL3.1 - A Lentiviral vector that expresses shRNA under the mouse U6 promoter. A CMV-EGFP reporter cassette is included in the vector to monitor expression. Packaging vector - psPAX2 - lacks both LTRs and has no viral packaging signal. The following viral genes have been deleted from the packaging vector: env, tat, rev, vpr, vpu, vif and nef. Rev is supplied in trans on a different vector (RSV-Rev). The vector expressing the packaged viral genome has a self-inactivating LTR (TATA box deletion) and expresses no viral gene products. Envelope (VSV C) is expressed on a separate vector - pMD2.G And pWPI containing the WPRE element. For conditional shKnockdowns: This bicistronic vector allows for simultaneous expression of a transgene and EGFP marker to facilitate tracking of transduced cells. The EGFP marker cDNA has been inserted downstream of EMCV IRES. Tet-on systems will also be used. Any
modifications made to the plasmids under this system are biologically neutral and do not change the biosafety of the original second generation lentMral vectors. Clonal cell lines including 293, C2C12, 3T3. Primary cells, rat and mouse cardiac myocytes and fibroblast& Mouse, rat and human stem cells (bone marrow and cardiac). Mouse and human ES cells.

Evaluation of foreseeable effects

K12 is non-colonising and disabled, all plasmids used in K12 will not allow propagation of the strain outside of the laboratory environment Each lentiviral vector produced will be able to infect cells but will not be able to replicate and spread to new cells - The virions produced are replication-incompetent. The foreign proteins that will be expressed in the transfected cell and ultimately injected into mice will not affect the hazard group of the vector or host and will only be expressed by the infected cell. The WPRE element as present in pWPI has been shown to be potentially oncogenic, but as the virus it will be contained within is replication incompetent, an on-going infection in laboratory personnel is not possible.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Bacterial and lentiviral cuttures: Liquid culture, spi11s - For metal surfaces that may corrode - Trigene final concentration of 1 :100. For all other surfaces - Viricon final concentration of 2%. Treatment for 30 minutes at room temperature and then disposed of via the drain and paper towels etc will be placed in GM waste bins. Tissue Culture Plastics, pipettes will also be placed in GM waste bins. These will be autoclaved at 121 degrees for 20 minutes and 'disposed of by the Imperial College clinical waste route which ends in incineration off site. autoclaves are monitored by a chart recorder with temperature readout and validated by an annual 12 point thermocouple test.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  Y

Please enter comments on the GM safety committee on the risk assessment

The Committee agreed with the classification of Containment level 2, Class 2 assigned to the project, as lentiviral vectors containing WPRE are to be used and injected into animals necessitating the use of sharps. The P1 was advised to separate out the Class 1 aspects of the project, involving the use of attenuated adenoviral and retroviral vectors so that this work could start after College approvals are in place.

### Project Additional Information

**Purposes of the contained use**

At the IAVI Core Laboratory in London we have developed and optimised, together with collaborators in Boston and Los Angeles, a functional T-cell based assay to assess the efficacy of HIV vaccine candidates in inhibiting viral replication post-vaccination. As has recently been shown by the HINTNIMerck STEP trial the present methods used to assess vaccine efficacy do not necessarily correlate to in vivo protection, or to a functional in vitro effect.

Our assay is intended for use on clinical trial samples. At present the assay readout is based on the inhibition of a panel of HIV virus strains using a p24 HIV core antigen ELISA for virus detection. While this works very well it is very expensive and labour intensive. Part of our aim is to attempt to limit cost and streamline the assay format, to make it more applicable for trials and eventually for use at trial sites such as those used by IAVI (in developing countries).

We intend to use virus directly labelled with a fluorescent tag. This will enable us to assess viral load in the assay using a high throughput flow cytometer and may enable us to look at an earlier time point in the assay, significantly cutting the assay processing time and cost. This will involve labelling virus isolates for use in our assay.

Our second aim is to assess the ability of vaccinees post vaccination to inhibit viral replication in viruses that directly match the vaccine used in the trial. At present we use a panel of isolates ranging from closely matched isolates to those circulating in the region where the trial has been performed. Our collaborators will generate viruses that contain the exact sequences used within our vaccine candidates. These viruses will more closely match the vaccine insert and allow us to determine if the vaccine is capable of inhibiting the exact sequence used for the vaccine. Using a range of sequences derived from varying primary isolates, in the same backbone, we will be able to assess inhibition directly related to a gene of interest. Informing on what sequences to prioritise in vaccine design. All sequences added into the virus vector will be naturally occurring in the environment and will replace a homologous gene sequence in the vector.
All manipulation and virus generation will be performed by collaborators outside of the UK, and only functional viruses will then be cultured at our lab in London, with no further genetic manipulation.

Recipient or parental organism

All GMOs will be generated by our collaborators, or sourced from the NIH AIDS Research and Reagent program, then shipped to our lab for use. GMOs will be generated by tagging an existing isolate with either a fluorescent tag or the luciferase gene. This tagging is not intended to either increase or decrease pathogenicity, but is often inserted into a gene such as Nef, which is then disrupted and does reduce pathogenicity. The tags themselves are not known to have any pathogenic or detrimental effects. In addition to tagging viruses we will also be generating viruses that have a known backbone but contain a specific gene sequence of interest. This will allow us to directly assess the effect of sequences used in the vaccine and may help to prioritise other sequences for development as vaccine candidates. These inserted sequences will replace a homologue in the virus being used as a vector and will be naturally occurring sequences. This will not result in a virus that is intended to be any more, or less, pathogenic then the original strain. The genes selected for insertion will be based on the sequences used for vaccine trials, and sequences derived from currently circulating primary isolates.

Host/vector system

All modifications will be made to existing viral isolates (primary and lab adapted strains) being used in the Category 3 laboratory. The GMOs will be generated by collaborators and shipped to the IAVI Core Laboratory for use. GMOs will be shipped either as prepared DNA which will be transfected into 293 T-cells to generate virus stocks for experimental purposes, or as virus stocks that have been generated by the collaborator.

Origin & function

Luciferase and fluorescent tags are already at the collaborator laboratories, having been pre-synthesised for use. They are intended simply to act as markers of virus signifying how much virus is present either within the cells in culture or directly secreted into the cell culture supernatant. The various tags will be assessed directly using flow cytometry or a plate reader, while luciferase will be reacted with a substrate (available from Perkin Elmer) and read on a plate reader. Alternative sequences inserted into viral vectors that replace their homologue will either be:

i) synthesised based on vaccine inserts directed against naturally occurring sequences, or

ii) will be taken directly from other isolates. Our collaborators have several methods that allow for sequences from primary isolates to be ‘swapped’ into a known backbone, allowing for an assessment of responses against that specific sequence.

Changing the virus sequences is intended to result in a replicative virus which will allow an assessment of responses against the changed region, relative to the original isolate. This will aid in informing on the efficacy of specific vaccine inserts and help to prioritise vaccine candidates for further trials. Using sequences generated from circulating viruses will allow us to determine other sequences to carry forward into the next generation of vaccines. These changes are not intended to affect the virus pathogenecity, making it more or less harmful, and are intended to reflect naturally occurring sequences already circulating in the environment.

Evaluation of foreseeable effects

The use of a fluorescent or luciferase tag will not have a significant effect on the virus, but may act to limit pathogenecity. This modification is not necessary for the survival of the virus and is likely to be attenuated or lost over several cycles of replication; experiments by our collaborators suggest that the fluorescent tag in their system will be lost after several days in culture. Therefore these modifications are likely to have little or no effect other than making the virus detectable through a variety of assays, such as flow cytometry.

Modifying the sequences within the viral vector will act to replace a gene, or sequence of genes, with direct naturally occurring homologues. This is intended to affect the immune response to the virus in our experimental system, but is unlikely to have a significant affect on other virus strains. The genes selected for insertion into our vector virus will be available in the circulating strains in the environment, acting as a basis for their selection.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
All procedures will be performed under existing Category 3 conditions. These conditions are in place for HIV-1 and the proposed GMMs are not expected to require any additional containment.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All virus containing media (liquid) will be placed in 2% virkon for a minimum of 30 minutes. This waste will then be discarded down the laboratory sink as detailed in the Category 3 Code of Practice for the IAVI Core Laboratory. This procedure is guaranteed by the manufacturer.

Any solids that come into contact with virus will be placed in 2% virkon for a minimum of 30 minutes. The solid will then be rinsed in water and all liquid discarded down the sink. The solid will then be autoclaved under vacuum air extraction with rapid steam heating to 121C for 25 minutes. Followed by incineration through the Chelsea & Westminster Hospital trust clinical waste system.

The autoclaves are filled with a chart recorder to monitor the autoclave cycle and they undergo an annual 12 point thermocouple testing.

All procedures are performed under GCLP conditions and appropriate for disposal of Category 3 pathogens and are intended to result in 100% death of the GMM.

Is an emergency plan required according to regulation 20? [ ] Y

If yes, tick to confirm that it is attached to this form [ ] Y

Tick to confirm that you have attached a risk assessment to this form [ ] Y

Tick if you are claiming exemption from disclosure for section of the risk assessment [ ] N

Please enter comments on the GM safety committee on the risk assessment
Overall the GMSC were happy with the risk assessment and their comments were as follows:

Dear — Following the discussion of your proposals entitled “Qualification and Development of a T-cell mediated, in vitro, HIV-1 viral suppression assay” (GMIC-01756.1) at the last GM Safety Committee meeting, the committee request that the following amendments are made to the proposals prior to approval:

Comments: PB gave the committee an outline of the project PS stated that they were obtaining the GFP tagged viruses from collaborators and would not be creating them as part of this project US asked for this information to be included in the Form A to clarify that the group themselves were not creating the GMM themselves.

RW asked for further details regarding the pathogenicity of the Nef sequence. SP clarified this by stating that deleted Nef sequences in monkeys resulted in viruses being grown which were not pathogenic.

Comments email by DM: there are a few typos needing correction before it is sent off.

SH asked if the CL3 suite was suitable for this type of work. TN reported that the CL3 suite is operational for this type of work.

The following amendments are required prior to approval:

1. Clarify the work to be conducted by collaborators.
2. Typo ‘Category £’
3. Provide justification to answer
4. Include ‘refer to list...’
5. Specify the volumes of a small or large spillage and that the mom would be fumigated with formaldehyde.
6. OH input required prior to final approval
7. Solid waste, route of disposal: Incinerated
8. ‘robust leak proof container’
9. Include that it is Incinerated
10. Change secondary container to ‘robust leak proof container’
11. Specify the volume of a large spillage.
12. Remove reference to Needlestick injuries as sharps are not to be used in this project.

Agreed: Class 3, Containment Level 3. HSE notification and written consent required prior to commencement.

**Project Ref** 8/08.3

**Date Ackn’d** 02/03/2022
The overall aim of this research in this area is two fold:
Firstly to study aspects of primary and secondary metabolism of P. aeruginosa. We are interested in:
(i) Discovering global metabolic differences between strains from different sources, and with different genetic backgrounds.
(ii) Studying energy metabolism in P. aeruginosa, regulatory pathways and secondary metabolite production.

Secondly, to understand the survival mechanisms used by P. aeruginosa to survive abiotic stress, and under stationary phase and biofilm growth conditions. We are particularly interested in the roles of universal stress proteins in the survival of P. aeruginosa.

This will involve both random and targeted mutagenesis approaches to disrupt specific metabolic pathways as well as the screening of an ordered, non-redundant library of P. aeruginosa transposon insertion mutants (the PA14NR Set). It will also involve cloning genes, for example those encoding terminal oxidases of P. aeruginosa and this will also involve construction of transcriptional gene fusions of promoter regions of the various genes with lacZ and gfp. Preliminary cloning experiments will be conducted in E. coli strains such as XL1-blue. The genes and gene fusions will be expressed in P. aeruginosa wild type and mutant strains.

Pseudomonas aeruginosa is a ubiquitous environmental organism that can be found at very high population densities in certain environments e.g. in waste water pipes. P. aeruginosa has been associated with opportunistic infections and it is a particular problem in burns patients and patients with Cystic Fibrosis. We will be working with a number of P. aeruginosa strains including the protrophic PAO1, PA14 and PAK strains as well as the auxotroph PAO6049 met-9011 amiE200 strA (PAO1 derivative)

Self cloning in Pseudomonas aeruginosa and in disabled strains of E. coli.
subsequenty cloned for complementation studies. However, proteins that may be identified could include metabolic proteins, transporters and regulators.

Once mutants of interest have been identified, DNA fragments flanking the insertion site will be cloned in standard disarmed E. coli K12 derivatives as a start point to allow cloning of the wldtype gene for further functional analysis using standard molecular biology approaches (e.g. mutation analysis, protein expression, protein interaction studies, etc.).

Complementation studies will involve the cloning of wild-type P. aeruginosa genes in E. coli lab strains and transferring these constructs to the selected P. aeruginosa mutants to test for complementation.

2. For investigation of the energy metabolism of P. aeruginosa, regulatory pathways and secondary metabolite production some of the gene we envisage working with are:
   1. Genes encoding respiratory proteins, in particular terminal oxidases
   2. Putative HCN biodynthesis genes
   3. Two component regulatory genes and sigma factors
   4. Putative quorum sensing genes.
   5. Sigma factor and anti-sigma factor genes involved in the regulation of polysaccharide alginate by P. aeruginosa.

3. In studying the survival mechanisms used by P. aeruginosa to survive abiotic stress and under stationary phase and biofilm growth conditions we will be working with genes encoding universal stress proteins (USPs) of P. aeruginosa, which are thought to play a role in promoting survival under non-growing conditions. These will include the genes encoding the USPs PA3309, PA4352 and PA3017.

Evaluation of foreseeable effects

We will be working with a mutant library with the aim of identifying mutants with interesting metabolic properties, but it would seem most likely that mutants with metabolic defects would have reduced ability to survive in the environment and reduced virulence.

The cloned genes and their gene products we plan to work with specifically are unlikely to alter the pathogenicity of the cloning hosts. The vectors are mobilisable but there are no known environmental or safety concerns relating to the cloned genes.

It is most likely that mutation of the target genes will make the organism less pathogenic, and there is no reason to believe that the GM experiments would increase pathogenicity to organisms in the environment.

The GMM would not pose a risk to the environment. The mutant strains will be less fit than environmental strains; therefore, we do not anticipate an increased hazard to the environment of the mutant P. aeruginosa strains. Proper microbiological practice will minimise risk of environmental exposure but as there would be negligible consequences, even if containment were to be breached, the environmental risk can be judged as effectively zero.

Since the work will involve wildtype P. aeruginosa gene sequences, there is no anticipated hazard with a transfer to related microbes. Containment measures will be in place to avoid such consequences. It is in principle possible that transfer of certain genes, e.g. the terminal oxidase genes, to another bacterium would allow it to colonise a wider range of niche. However, the complex nature of the synthesis and assembly of the prosthetic groups for these enzymes, together with their complex regulation makes this a remote possibility.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Culture remnants and preparations originating from live P. aeruginosa cultures will be collected and killed using a chemical disinfectant (Virkon) according to manufacturer's recommendations essentially by addition of Virkon to a final concentration of 1% with a minimum contact time of 30 mins and subsequently discarded in the drain.
Disposable plastic ware that has been in contact with P. aeruginosa (including culture plates) will be placed in autoclave bins for disposal, while sharps are put into cinbins, autoclaved and then go for disposal as clinical waste. The autoclave cycle to be used is 126°C for 10 min. Autoclave cycles are reported out onto a mounted printer detailing all significant stages of the cycle. The Autoclave is on a quarterly preventative maintenance contract, has an annual insurance inspection and Cycle 2 (Discard) validated by 12 point thermocouple testing. Equally, a validated kill cycle will be used to autoclave plant and compost waste contaminated with P. aeruginosa.

Viable P. aeruginosa waste will be transported to the autoclave in sealed autoclave bags inside sturdy white plastic buckets. The material will be taken down on a dedicated metal trolley by the floor technician using the goods lift. Autoclave waste is subsequently incinerated. Chemical disinfection and autoclave treatment will result in 100% kill.

Comments: The risk assessment was originally submitted prior to 2006 as a class 1 project but not approved by the committee. It has been re-submitted with a new title, scientific changes and as Class 2. An up to date Code of Practice is required before it is sent to the HSE for approval

Agreed: Class 2, Containment Level 2. This project is notifiable to the HSE
**Project Additional Information**

**Purposes of the contained use**

The purpose of the project is to gain better understanding of the mechanism used by Legionella to disseminate and cause human disease. Better understanding is essential in order to develop accurate risk assessments and measures to reduce transmission and infection.

**Recipient or parental organism**

We will use the following lab stains:

- Legionella Pneumophila 130b - ATCC BAA-74
- Legionella Pneumophila, Philadelphia-1 - ATCC 33152
- Acanthamoeba castellanii

**Host/vector system**

- **Hosts:**
  - Legionella pneumophila (130b, ATCC BAA-74; Philadelphia-1, ATCC 33151; and derivatives), Escherichia coli (e.g. DH5alpha, BL21, XL1 blue, Top 10), Acanthamoeba castellanii, Dictyostelium discoideum (AX2), Saccharomyces cerevisiae (PJ69-4A, AH109)

- **Vectors:**
  - Commercially available yeast two and three hybrid vectors: pGAD424, pGBT9, pBridge and general cloning vectors.
  - Commercially available E. coli expression vectors including pMAL, pET28(a), pET3, pACYA184, pBR322, pGEX, pKK, pMMB207
  - Commercially available eukaryotic expression vectors including pEGFP-derived and pcDNA3-derived.

**Origin & function**

Origin of Legionella pneumophila - ATCC

Other hosts and vectors - commercial and in-house.

The aim of the project is to investigate the molecular and cellular basis of the interaction of Legionella pneumophila with its eukaryotic host cells.
In particular we will:

1. Site directed mutagenesis of effector genes and phenotypic characterization upon infection of macrophages and amoeba.
2. Cloning of effector genes (with and without tags - HA, GFP, Myc etc..) in bacterial expression vectors for mutant complementation.
3. Cloning the effector genes in eukaryotic expression vectors for transient and stable expression in eukaryotic cells.
4. Cloning the effector genes in yeast vectors for conduction of yeast two hybrid screens (to identify eukaryotic partner proteins).
5. Cloning the effector genes in bacterial expression vectors for protein purification (His, GST, MBP tagged).

**Evaluation of foreseeable effects**

**L. pneumophila** is an opportunistic human pathogen responsible for flu-like or pneumonia Legionnaire's diseases.

Acanthamoeba are free-living amebae belonging to the genus Acanthamoeba. They are the causative agents of granulomatous amebic encephalitis (GAE), a disease of the central nervous system (CNS), and amebic keratitis (AK), a painful sight-threatening disease of the eyes (Clinical Microbiology Reviews, Apr. 2003, p 273-307). Immunocompromised people are most at risk from Acanthamoeba infection.

*Legionella pneumophila* contains over 100 type IV secretion system genes, which conspire to subvert eukaryotic cell functions. In this project we will mutate effector genes (generating single or multiple mutants). The mutants will be complemented by plasmids encoding wild type genes. No foreign DNA will be introduced in *L. pneumophilia*. The effector genes will also be expressed in disabled *E. coli* and yeast hosts. The effector genes will also be expressed, transiently and stable, in eukaryotic cells (e.g. amoeba, macrophages).

The *Legionella* effectors by themselves are unlikely to be harmful (in bacterial or eukaryotic hosts), as their function relies on: 1. The presence of a type IV secretion system (missing form *E. coli*, yeast, eukaryotic cells). 2. Disease is dependent on expression of the whole effector repertoire. As such the most hazardous GMM is presented by over-expressing effector genes in mutant Legionella (for complementation) as this by nature involves somewhat higher level of expression that in theory can increase virulence potential, although we consider that the actual risk is very small (as disease relies on optimal expression levels).

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

*L. pneumophila* is acquired by inhalation of contaminated water from showers, air conditioning etc. Building services regularly test for presence of *L. pneumophilia* and take appropriate precautions to ensure water building water systems are not contaminated with *L. pneumophila*.

Everyone working in our lab has to wear a lab coat: the coats are kept at the entry to the lab. Nitrile gloves are used and they are immediately accessible within the lab areas.

We will express *Legionella* effector protein in eukaryotic cells (e.g. Acanthamoeba, epithelial cell, macrophages) ectopically. Any handling of the amoebae will be carried out under aseptic conditions. Any experimental procedure that has the potential to generate aerosols (e.g. sonication) will be carried out within a Class II Biosafety cabinet.

*Legionella* will be handled in class II MSC (e.g. plating, infection, lysis). All our MSC are serviced every 6 months, and they are tested/validated by KI disk test every year (as part of one of the services); an annual insurance inspection is also completed. If the MSC is used for class 2 pathogens or Class 2 work, the users also have to do a monthly airflow test.

02/03/2022
Sharp tweezers might be used to transfer glass coverslips of cells infected with Legionella between dishes. No suitable alternative is available but this use will be avoided as much as possible. After use, the tweezers will be decontaminated in 70% ethanol.

**WASTE MANAGEMENT WITHIN THE LABORATORY**

Within laboratory 1.30, the following procedures are to be followed:

1. **Autoclave waste.** Contaminated plastic flasks, plates, tips and tubes should be placed into sterilin bags mounted in rigid containers for disposal. Objects which are likely to puncture the sterilin bags should be avoided and should be placed in CinBins for disposal (see below). All sterilin bags should be kept close to the work area in the rigid containers provided. Avoid placing objects into the bags that could puncture the sides. Sterilin bags must be fitted to no more than three-quarters full. Prior to disposal the tops of the sterilin bags must be loosely taping to contain contents but allow free circulation of steam. Taped bags should be placed into the blue plastic collection boxes which are specifically designed to contain any spillage. The rigid sterilin containers should be disinfected with Virkon S after each change of bag. Collection bins are strategically placed on the laboratory floor, directly under a sink, in a position which avoids accidental tripping. Each blue box is fitted with a lid held in place using an identity tag that is used to identify the laboratory of origin.

2. **Glass flasks or large plastic flasks for re-use containing contaminated waste must be decontaminated by treatment with one of the approved disinfectants (see Appendix 5). Disinfected material can be dispensed down the sinks provided. Under no circumstances must live microorganisms be dispensed of in this manner.**

3. **Sharps:** all needles, microscope slides and scalpels must be placed in CinBins. These should be sealed when full and always placed in the blue collection boxes for autoclaving.

4. **Broken glass should be placed in the Red Box. If contaminated, no attempt should be made to decontaminate this and advice should be sought from a supervisor or from a Safety Officer (see Appendix 8).**

5. **Clinical waste.** All normal laboratory waste that is not known to be contaminated with biological agents should be placed in the Yellow Bags. This includes tissues, agarose and acrylamide gels, packaging etc. these bags are collected by approved staff, tagged and taken off site for incineration.

6. **Glassware and plasticware for Washing Up must be placed in the collapsible white boxes under the sink. This will not be autoclaved and must not contain contaminated materials. Any container used for hazardous chemicals (see COSHH assessments) should be rinsed with water before placing in box.**

**TRANSPORT OF WASTE TO THE AUTOCLAVE AREAS**

1. All material containing biological waste will be removed from the laboratory for autoclaving in covered blue plastic collection box. These bins will be placed in an approved closed metal trolley and transported by a designated member of staff.

2. The trolley will be taken directly to the autoclave using the service lift and a route approved by the Department. A bottle of Virkon S disinfectant should be placed on the trolley to handle spills in transit.

3. The plastic bins will be unloaded onto the benches next to the autoclave, either directly into the autoclave, or into the designated cold room for temporary storage. Only personnel trained in the use of the autoclave are permitted to load bins into the autoclave.

4. Bins will be autoclaved using the next available cycle.
5. In the unlikely event of a spillage during transport follow the procedures outlined in Section 8C. The Safety support team must be immediately informed and the spillage cleared up as outlined in the protocol for spillage control.

SPILLAGES OF CONTAMINATED MATERIAL

This protocol covers procedures for the containment of spillage of material containing viable microorganisms:

1. Wear full protecting clothing including goggles, gloves and laboratory coat when dealing with spillages. Do not tread in contaminated fluid.

2. The details of approved disinfectants are listed below.

3. Small spillages below two ml should be directly disinfected by use of the squeeze bottles of disinfectant provided. Squeeze the disinfectant solution directly onto the spill. The spillage can then be wiped up using tissue rolls located in the wall racks close to the laboratory exit.

4. Spillages should be cleaned as quickly as safety permits. If you suspect aerosol may be generated allow time for these to settle.

5. For larger spills inform the laboratory supervisor or the Safety Officer. Soak up excess liquid using tissue paper from rolls. Place the contaminated tissue directly into sterilin bags and place in the sterilin bags into the waste collection bins. Decontaminate the contaminated area using direct application of excess disinfectant and repeat the mopping up with tissues.

6. Disinfecting solutions must be available in the laboratory at all times. Prepared and active disinfecting solutions can be found next to the exits from the laboratories. In addition, each worker should maintain a squeeze bottle of 70% ethanol for routine hand disinfection and a bottle of an approved disinfectant for dealing with spillage at the bench.

7. If in doubt consult a senior laboratory member.

List of approved disinfectants

70% ethanol

Ethanol is suitable for disinfecting hands, small spillages and bench surfaces. Ethanol is volatile and, although it does not provide sustained action against microbes, it is particularly effective against enteric bacteria. It must be kept by each worker in small plastic squeezy bottles for personal hand disinfection and for regular swabbing of benches and small spills.

USE ETHANOL FOR HAND WASH AND BENCH SWABBING ONLY

Virkon S

Virkon S is an oxidising agent, which is a powerful disinfectant active against a wide range of bacteria and viruses.

Working stocks of 1% Virkon S must be prepared weekly.

Treatment of spills

The 1% working stock will be used directly to disinfect working surfaces. Spills of contaminated cultures should be mopped up with tissues and then the area treated with 1% Virkon. Larger volumes of spills should be treated directly with Virkon powder and wiped up with tissues. Tissues should be disposed of by the clinical waste route.
Decontamination of cultures

Bacterial cultures e.g. in flasks or centrifuge bottles, are treated by addition of Virkon powder to a final concentration of 1% or by the addition of an equal volume of a 2% solution of Virkon. Cultures should be left in Virkon for a minimum of one hour. The solution can then be disposed of down the sink and the glassware sent for washing up. Culture vessels must be filled to the brim with the Virkon solution.

Dear PF

Following the discussion of your proposal entitled "Host pathogen interaction: Characterisation of Legionella's virulence factors and analysis of their function during infection of eukaryotic cells", GMIC-01790.1 at the last GM Safety Committee meeting, the Committee request that the amendments are made to the proposal prior to approval.

Comments

The Committee questioned if Acanthamoeba castellanii will be genetically modified at a later date, for example, stable versus transient expression of the genes under study. This needs to be clarified at this stage and included in the form in order to prevent any delays to the work as well as further applications should DR F decide to genetically modify Acanthamoeba at a later stage.

Please enter comments on the GM safety committee on the risk assessment

Chlamydia is an obligate intracellular pathogen that has developed complex strategies to subvert numerous host cell processes, and thus ensures its survival growth and replication inside the cell. The aims of this project are to identify the molecular mechanisms of attachment, invasion, and intracellular survival, and identify any strain- or species-specific differences that may function as determinants of unique pathogenic traits.

Experiments will involve the use of multiple chamydial serovars/species (C. trachomatis serovars L2, B, D, C. pneumoniae, C. muridarum, C. caviae) and different epithelial (HeLa and Hep2) and macrophage-like cell lines (J774, THP-1). Biochemical approaches will be used to identify activation/suppression of signalling components. Confocal microscopy of live and fixed infected cells will be used to study the temporal and spatial controls of these components in the context of chlamydia infection.

The hazardous potential of the GMMs created is considered to be no greater than that of the parental BACTERIAL strain (DH5-alpha, TOP10 (F- mcrA Δ(mrr-hsdRMS-mcrBC) q80lacZΔM15 ΔlacX74 recA1 araD139 Δ(ara-leu)7697 galU jaiK rpsL (StrR) endA1 nupG)), which are auxotrophic for some essential amino acids. Genetic modification will not alter the basic genotype, including auxotrophy of the parental strain. Genetic modification of HUMAN CELL LINES (HeLa, Hep2, etc.) will exclusively involve transient transfection of the tagged versions of human genes. Chlamydial genes will also be expressed for studies of the localisation of the chlamydial proteins in transfected cells. No drug selection will be performed for stable transfectants or homologous recombinants, such as in knockouts or transgenics. The cells will either be killed by fixation prior to microscopy, or in the case of live cell imaging, experiments will not last beyond 24 hours.

Recipient or parental organism
The Mammalian and chlamydial genes to be cloned, propagated in E. coli DH5-alpha or TOP10 (see 1.22), and expressed for purification, protein analyses, and microscopy in E. coli or mammalian immortalised cell lines, such as HeLa, Hep2, Cos7, and CHO-K1. Human genes include, though not exclusive to N-WASP, WAVE2, Rac1, Nck, Arp3, Grb2, PI3-kinase, Cdc42, RhoA, Actin, EEA-1 FYVE domain, PI-PLCδ PH domain, BTK-PH domain, N-WASP, WA domain, Rab5a, Rab7, Lamp1, LC3, hGBP1, hGBP2, cPKCs, 14-3-3 isoforms. These genes are typically associated with various modes of actin remodelling relevant to the attachment and invasion portion of the project, and vesicle trafficking, which is related to chlamydia intracellular survival. Chlamydial genes include full-length, and deletion or inactivated derivatives of CT456 (TARP), CT663 (Chaperone), CT043 (Chaperone), CT667 (Chaperone), Cpn0585 (non-annotated, possible modulator of host RAB11 GTPase), CT229 (non-annotated, possible modulator...
of host Rab4 GTPase), engA (bacterial GTPase involved in the stringent response), IncG (inclusion membrane proteins with unknown function), IncA (inclusion membrane protein involved in homotypic fusion of multiple chlamydia incursions), etc. The chlamydia CT456 and chaperone genes are believed to be involved in the triggering of actin remodelling required for invasion, while the others have been implicated in either vesicular traffic or adaptation of chlamydia to different survival cues.

**Evaluation of foreseeable effects**

The hazardous potential of the GMMs created is considered to be no greater than that of the parental bacterial strain (DH5-alpha), TOP10 (F- mcrA Δ(mrr-hsdRMS-mcrBC) φ80lacZam15 ΔlacX74 recA1 araD139 Δ(ara-leu)7697 galU galK rpsL (StrR) endA1 nupG), which are auxotrophic for some essential amino acids. Genetic modification will not alter the basic genotype, including auxotrophy of the parental strain. Genetic modification of human cell lines (HeLa, Hep2, etc) will exclusively involve transient infection of the tagged versions of human genes. Chlamydia genes will also be expressed for studies of the localisation of the chlamydial proteins in transfected cells. No drug selection will be performed for stable transfectants or homologous recombinants, such as in knockouts or transgenics. The cells will either be killed by fixation prior to microscopy, or in the case of live cell imaging, experiments will not last beyond 24h.

The hazardous potential of the GMMs created is considered to be minimal as they only encode tagged derivatives of normal mammalian genes.

The hosts (E.coli or immortalised mammalian cells) are classified as Level 1 agents, and introduction of gene inserts of interest should pose minimal hazards. If required, experiments will be done within the protective confines of a biosafety cabinet. Recipients (DH5-alpha, TOP10) of inserted genes are non-infectious to humans, animals, plants, and insects. In addition, dessemination to the environment outside the lab will be minimised by restricting use of the GMMs to within the confines of the laboratory and their sterilisation prior to disposal.

Of the known inserts, none have any toxin, allergen, or growth modulatory functions. The presumed function of the CT456 gene is on actin binding. Of the gene inserts with known functions, none have the ability to modulate the expression of crucial metabolic enzymes in the recipient.

The possibility of widespread dissemination of the inserted gene would likely be minimal as GMMs will be contained and used exclusively within the laboratory. The risk is recognised and work procedures have been implemented, such as segregation of the experiments within the shared work area to minimise the risk. In addition, GMMs for disposal will first be sterilised.

Human genes being studied are unlikely to confer altered pathogenicity to the recipient. Chlamydial genes of interest, which are suspected of virulence determinants may endow the recipient E. coli with partial pathogenic traits. Work involving such GMMs will be restricted to containment level 2 within a biocontainment hood, and will use no greater than 10 ml of genetically modified E. coli culture. Handling and disposal procedures will adhere to established level 2 standards.

Dissemination to the environment outside lab will be minimised by restricting use of the GMMs to within the confines of the laboratory, and their sterilisation prior to disposal.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Incubation in a shaking incubator will be restricted to small volumes (< 10 ml) contained within Falcon tubes with secured caps. The tubes will be placed in racks that are properly secured to the shaking platform. Spillage will be documented using Virkon and wiped down thoroughly. Incubation in static shelf incubator will be only for cultures grown on solid agar plates.

Routinely, 10 ml cultures, but maximum conceivable is 250ml total.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

**Liquid Waste**
Derived from culture media; inactivation via 1% Virkon treatment for at least 30 min. From the manufacturer's guide, 30 min treatment is sufficient to kill the bacteria. Waste will be disposed of in the sink.

Solid Waste
**************
Derived from plasticware, agar plates. Inactivation via autoclave (134°C, 3 min). Treatment will be monitored using the chart recorder attached to the autoclave. Inactivated waste will be incinerated.

Is an emergency plan required according to regulation 20? N
If yes, tick to confirm that it is attached to this form N

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
COMMENTS
**************

GM work cannot be carried out on Chlamydia, therefore an expression of the Chlamydia genes in E. coli or human cells will be used. Due to unknown effect of expressing potential Chlamydia virulence genes in E. coli it is remembered that the project will be proposed as class 2.

Clarification of whether using cell lines or E-coli is relevant to the entire document and also a general classification of experimental strategy required.

THE FOLLOWING AMENDMENTS ARE REQUIRED PRIOR TO APPROVAL
************************************************************************************
Title: Explained title i.e. 'Molecular mechanisms of attachment, invasion, and intracellular survival of Chlamydia.'
BSO: Stefan Hoyle, CID: 00171599
1.21: Explain on why these genes are involved in the research; what pathways are they associated with? Also it'll be helpful to annotate some of the genes eg engA, IncG, IncA etc.
1.25: Point out the use of human cells and what work will be done with the human genes. List some of the Chlamydia genes and clarify experimental strategy. Include a brief description of methodology.
1.3: Clarify the parental strain is E. coli or other cell line.
Also sentence 'genes are inactivated' is misleading as it implies creation of knockouts.
2.1.1.2: Explain if the parental strain is E. coli or other cell line.
2.1.1.3: The second sentence needs to be moved to section one.
2.1.1.6: State that a potential risk is recognised, but this is minimised. The work area is shared, but segregated which is part of the code of practice.
2.3.3.3c: Specify that samples will be opened in a Microbiological Safety Cabinet and the classification of the cabinet.
2.3.6: Complete as Class 2, Containment Level 2.
3.1.1a: Change 30h to 30 minutes.
3.2b: Remove end bracket and the end of the paragraph.
3.32a: Change this to the maximum conceivable.
3.42: "...pathogens are NOT permitted in my group."
3.5b: Typo: 'Ocupational'
3.6.2.: State there are others working in this area, a Code of Practice is in place for this.
AGREED: Class 2, Containment Level 2, HSE notification and written consent required prior to commencement.

The role of the glycostructures on the exterior of the bacterial cell wall in the immune response to Campylobacter jejuni

**Purposes of the contained use**

Campylobacter jejuni is the causative agent of gastroenteritis worldwide. The disease is generally self-limiting, rarely requiring antimicrobial therapy. However, one in 1000 infections caused by C. jejuni may lead to the Guillain-Barre syndrome, a neurological disorder.

The pathogenicity of C. jejuni is not well understood. The aim of the project is to investigate the role the glycostructures of the exterior bacterial cell wall play in the immune response. Several single-gene knockout strains have been produced at the London School of Hygiene and Tropical Medicine which have been shown to have altered glycostructures. These strains, including the wild type strain, will be used to infect mammalian immune cells, like dendritic cells and macrophages, to assess the influence on the immune response.

**Recipient or parental organism**

Campylobacter jejuni causes gastroenteritis which is generally self-limiting and rarely requires treatment with antibiotics. Infection can occur by ingestion and inoculation. Respiratory tract infections are extremely rare.

The wildtype is a hypermotile variant that is thought to resemble the original clinical isolate closely. This strain was first isolated in 1977 and the original isolate has been shown to vary from passaged lab stocks in virulence-associated phenotypes even though no detectable genetic differences could be found.

**Host/vector system**

The GMOs to be used in this activity were constructed at the London School of Hygiene and Tropical Medicine and this activity was notified previously to HSE (HSE reference number GM654/99.2). No new mutants will be constructed in this activity, therefore no host/vector systems will be used.

**Project notified under transitional arrangements**

N

**Historical Significant Changes**

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

**Project Additional Information**
Campylobacter jejuni has four distinct glycostructures, the capsular polysaccharide, LOS (like LPS, but lacking O-antigen repeats), and 2 glycosylation systems, N- and O-linked. Genetically modified Campylobacter used in this project will include mutations in genes that are responsible in the formation of each of these structures. Examples of some of these genes are given below:

- Knockout of gene cj1439 (glf), a predicted UDP-galactopyranose mutase. This mutant has been shown to be acapsular by HR-MAS NMR. The capsule has been shown to be important for adherence, invasion and protection from phagocytosis.

- Knockout of gene cj1126 (pglB), oligosaccharyl transferase. This mutant does not produce any N-linked glycoproteins.

- Knockout of gene cj1324 (gene function unkown). This mutant lacks legionimic acid on flagella.

- Knockout of gene cj1141 (neuB1), a probable N-acetylneuraminic acid synthetase. This mutant lacks sialic acid residues on LOS.

The knockouts were created at the London School of Hygiene and Tropical Medicine (HSE reference number GM654/99.2) by insertion of a kanamycin resistance cassette derived from Campylobacter species into specific restriction sites. The inserted sequences disrupt genes involved in the formation of C. jejuni glycostructures.

In addition, complement strains may be used where the gene is reintroduced into the mutant strain, within an intergenic region, in addition to a chloramphenicol resistance cassette derived from Campylobacter coli.

### Evaluation of foreseeable effects

All GMOs used have single gene knockouts in the biochemical pathways that are important for the formation of the glycostructures in C. jejuni. The glycostructures are viewed as important for the pathogenicity of C. jejuni. Therefore the mutant strains are likely to be less hazardous than the wild type strain.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

#### Liquid waste

This will be treated with 1% Virkon for a contact time of 30 minutes, as per manufacturer’s instructions, and will then be disposed of via the drains.

#### Solid waste

This will be autoclaved and then sent for incineration with other clinical waste. Autoclave cycle time is 126 C for 10 minutes and is monitored by indicator strips; a record is kept as the chart recorder print-out. Autoclave function is tested by an annual 12-point thermocouple test for validation of treatments.

Is an emergency plan required according to regulation 20?  

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Please enter comments on the GM safety committee on the risk assessment

The following Comments were made by the GM safety committee:

Comments: AR gave a brief summary of the project. YH asked if the London School of Hygiene and Tropical Medicine (LSHTM) had included Imperial College under a connected programme of work in their HSE notification thereby circumventing a further application and hence fees to the HSE. AR clarified that the HSE had approved the LSHTM to use these strains a long time ago and it would be better and more straightforward to apply through Imperial College. IH queried what Guillain-Barre syndrome was. AR explained that it was a neurological disorder. He also asked if the dendritic cells were genetically modified and AR clarified that they were not.

The following amendments are required prior to approval:
Part 1: GM centre number: GM8
Title: Expand title, for example: Role of the glycostructures of the bacterial exterior cell wall in the immune response to Campylobacter jejuni.
1.22: Clarify which genes have been mutated in the strains from LSHTM and the biochemical pathways affected. Also state any hazards associated with 'A hypermotile variant of Campylobacter jejuni strain 11168'.
1.25: State the origins of the mammalian cell cultures; are these primary cultures or cell lines?
1.3: Typo: viewd
2.3.6: Complete section, containment and classification 2.
3.1.1.a: Change the use of Virkon from ‘overnight’ to ‘30 minutes’
3.1.1.b: Solid waste: also include that the autoclave was validated in the last four weeks.
3.2.b: Include that the container will be double contained, robust, and leak proof.

Agreed: Class 2, Containment Level 2. HSE notification and written consent required prior to commencement.

All comments have been addressed and all required changes have been incorporated into the risk assessment attached to this form.

Project Ref 8/09.2

Date Ackn’d 25/06/2009
CU2 Project Title The Genetic Basis Of Anopheles Susceptibility to Plasmodium falciparum
Class CultureVol | Class CultureVolume
Class 3 | 50 ml

02/03/2022  Page 265 of 15326
The goal of this project is to identify the genetic basis of susceptibility to Plasmodium falciparum in the malaria mosquitoes, Anopheles gambiae complex (including gambiae, arabiensis, quadriannulatus, melas and merus), Anopheles stephensi, and Anopheles funestus. The project will use both long-standing lab isolates of Plasmodium falciparum (e.g., NF54, 3D7) and new isolates recently collected in the field by collaborators from Harvard School of Public Health, Makerere University, and Institut de Recherche pour le Développement (IRD). We will investigate susceptibility in both wildtype mosquitoes and mosquitoes that have particular genes knocked down using standard dsRNA techniques. All P. falciparum isolates used will be chloroquine, artemisinin and/or malarone(atovaquone and proguanil) sensitive, and field collected isolates will be tested for this sensitivity before arriving at the lab.

We will create transgenic P. falciparum stocks that express fluorescent proteins in the mosquito stages of the parasite in order to facilitate tracking these life stages of the parasite. We will feed parasites to different colonies of mosquitoes and then compare mosquitoes that are fully resistant to infection with those that are susceptible using various genotyping technologies (e.g., SNP chips). We will also compare mosquito susceptibility in mosquitoes that have certain genes knocked down by RNAi to wild type controls.

Furthermore, we will create knock-outs of genes in the parasite that we think might be important in mosquito infectivity and carry out infections of mosquitoes to test these hypotheses. Similar work has been carried out using Plasmodium berghei but many genes shown to be involved in mosquito susceptibility to P. berghei do not appear to have an effect on P. falciparum susceptibility. Therefore it is important to carry out these experiments using P. falciparum.

Recipient or parental organism

P. falciparum strains 3D7 and NF54. Both are chloroquine sensitive and have been cultured in the lab for decades.

E.coli strains DH5-alpha, TOPTEN, PMC103 and XL10-Gold. TOPTEN, PMC103 and XL10-Gold are genetically modified to tolerate plasmid sequences that are unstable in standard strains such as DH5-alpha. These strains are required due to the high AT content in the extragenic regions of P.falciparum. These strains are available from commercial sources and are CL1.

Host/vector system

P. falciparum expression vector pHH1 with either T. gondii dhfr-ts or human dhfr mutated to encode resistance to WR99210. The plasmid would not reverse the chloroquine sensitivity of the parasite.
Two selection cassettes are mainly used for transgenic Plasmodium falciparum parasite generation. The human dhfr resistance marker is the most widely used, it confers resistance to the folate drug WR99210 (Jacobus pharmaceutical). The other marker is the blasticidin deaminase gene, which confers resistance to blasticidin. We use strains 3D7 and isolate NF54 both of which are chloroquine-sensitive and neither resistance marker confers resistance to chloroquine. However hdhfr selected parasites are resistant to pyrimethamine.

Vectors used for E. coli transformation: The vectors that will be used in bacterial transformation include (a) pLL10 (pBluescript-based plasmid containing two T7 promoters for the purpose of double-stranded RNA production in vitro) (b) pGEM-T easy (for routine AT subcloning of PCR amplicons) (c) various pETM vectors (example , pETM-11, pETM-60, pETM-80 etc.) which originate from pBR322 and are used for protein expression (d) various pGEX vectors (example pGEX-4T-2 and pGEX-4T-3 etc.) which are used to express GST fusion proteins (e) various pQE vectors (example pQE-30 etc.) for the expression of his tagged proteins.

Two types of genetically modified strains of P. falciparum will be generated: reporter strains and knock-out strains. We will create transgenic P. falciparum stocks that express fluorescent or luminescent proteins (such as YFP, GFP, RFP, eGFP, eYFP) in the mosquito stages of the parasite in order to facilitate tracking life stages or tracking proteins of interest in the parasite. We will also create knock-outs of genes in the parasite that we think might be important in mosquito infectivity. Examples include secreted or transmembrane proteins expressed at the gametocyte, gamete and ookinete stages of the parasite.

E. coli will be used as to screen plasmids and amplify them to produce quantities needed for P. falciparum transformation.

Genes of interest in Anopheles species including but not limited to members of the Leucine Rich Repeat family, thioester family, and other immune molecules will be knocked down using RNAi. Both wildtype and knockdown mosquitoes will be infected with GMM falciparum (for example, GFP falciparum to facilitate the observation of the parasite within the mosquito).

Plasmodium falciparum is an infectious parasite and hazardous. If a human becomes infected with P. falciparum, following an incubation period of ~7 days, falciparum malaria can develop. Symptoms include a systemic illness with high fever, rigors, headache, myalgia, prostration and can progress to cerebral malaria: confusion, delirium, loss of consciousness and death.

E. coli strains such as Dh5alpha do not have any significant risks associated with them. Reporter genes (fluorescent and luminescent proteins) are non-toxic and non-hazardous and as such, do not pose any hazard to human health. Knock-outs of genes thought to be important in Plasmodium infectivity to mosquitoes also have no additional hazards to human health apart from the hazards associated with working with falciparum.

Alterations to the traits of P. falciparum might include decreased or increased ability to infect mosquitoes, however they are unlikely to result in any increased ability to infect humans and as such should not increase the pathogenicity of the parasite (which will remain chloroquine sensitive). These alterations are unlikely to affect infectivity to unnatural mosquito hosts, includig those mosquito species that are native to the UK.

The room in which the culturing of Plasmodium falciparum will take place is a Category Level 3 containment facility and separated from all other work and laboratory areas by restricted access corridors. Access is restricted via proximity readers.

Access is granted by the facility manager after an appropriate induction by the Chief Services Technician. All those entering the facility must be on the health surveillance database maintained by the Occupational Health Department.

In vitro culturing of falciparum will be carried out within rooms 627, 630 or 632. All mosquitoes will be in double containment and they will be membrane fed in room 630, and
Transferred to containment room 619 via a hatchway removing the need to transport the mosquitoes in unrestricted areas. The room in which they will be kept has an additional box that allows complete shut-down of the experiment via CO2 gassing should an escape occur. 619 in the insectary is restricted access only.

All people working with P. falciparum and mosquitoes will have Biological agent screening and health surveillance via Occupational Health. When not in culture, Plasmodium falciparum stocks will be kept in liquid nitrogen dewars. These dewars are kept within the CL3 facility and locked. While in culture, the parasite will be stored in a Plasmodium-only incubator in room 627, 630, or 632.

If a release of infectious material were to occur during loading or removing a sample from storage in liquid nitrogen, the area would be wiped down with 70% ethanol. As stated above, aerosolized falciparum is not infectious. Samples will be placed in screw top cryotubes within a microbiological safety cabinet. Tubes will be wiped down with 70% ethanol disabling the parasite before transport to liquid nitrogen. Screwtop lids prevent the risk of lids opening due to sudden changes in temperature. When removing samples from LN2, labcoat, gloves and eye protection will be worn. Cryotubes will be placed immediately into secondary container (in case of ingress of LN2 into cryotube and subsequent expansion at room temperature). These tubes will be taken to MSC, removed from secondary containment within the MSC, and wiped down with disinfectant.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

The CL3 has been derogated as the facility cannot be sealed for fumigation purposes. This means the use of hazard group 3 pathogens spread via the inhalation route is prohibited.

The facility is used for working with Plasmodium falciparum (hazard group 3). This is acceptable as P.falciparum (and related organisms) is not spread directly via the inhalation route (infection would only occur via percutaneous injury or mosquito transmission).

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste such as E.coli culture waste will be disinfected using 10% Chloros solution as per manufacturer's guidance and disposed of via the sink into the drains. Other liquid waste such as from cell culture waste will be autoclaved. Autoclave cycle time is 121°C for 15 minutes which is monitored by indicator strips; records kept of the chart recorder print-outs. Autoclave function is tested by an annual 12-point thermocouple test for validation of treatments.

Solid waste is collected in dedicated autoclave bags (red colour to distinguish from other waste streams) and autoclaved within the facility. Autoclave cycle time is 126°C for 10 minutes. The autoclave is maintained quarterly, 12 point thermocouple tests and insurance inspection done annually.

Detailed information on waste procedures for the facility can be found in the CoP (page 14 - 16 and SOP 2 & 3 in the appendices) as well as part 3 of the GM risk assessments.

Is an emergency plan required according to regulation 20? N

Investigating the genetic basis of Anopheles susceptibility to the human malaria, Plasmodium falciparum. (GMIC-01870.1), Dr G Christophides, Cell and Molecular Biology, Natural Sciences, South Kensington campus.

Comments: This is a new proposal investigating the basis of genetic susceptibility of Anopheles to P. falciparum, the causal agent of malaria. The following amendments are required prior to approval:

1.24: Typo: 'resitance'
1.25: Provide a list of target genes, to make it clearer.
1.4: 'x' mark classification box
2.2.1.1: Correction: 'renders in inviable.' Remove reference to bleach.
2.2.1.4: Correction: add 'P' before falciparum.
2.3.2.2.a: Remove "At the moment" second paragraph. Typo: 'cultring'. Correction: add 'P' before falciparum.
2.3.3.1.a: Room number is incorrect, 632 or 619?
2.3.3.2.b: Clarify last sentence in this paragraph.
2.3.3.6: Typo: 'CO2' (CO2), 'wetable'
2.3.3.8.a: Correction: 'work', should be 'worn'
Part 3: Tick box needs to be ticked
3.1.1.a: Clarify statement '70% ethanol, as per manufacturer's guidance'. Please state clearly your method of disinfection. Your CoP states use of 10% Chlorus. Is this not the case?
3.1.1.b: Typo: 'centigrade'. Change 'technician' to 'Engineer'. Typo: 'clincial'
3.4.a: Clarify statement '70% ethanol, as per manufacturer's guidance'. Please state clearly your method of disinfection. Your CoP states use of 10% Chlorus. Is this not the case?
3.6.1: CID numbers missing.

In the CoP, section 11, page 16, no mention is made of emergency procedures in case of accidental spills. Please rectify.

Molecular Genetoc analysis of Neisseria meningitidis virulence

Neisseria meningitidis (the meningococcus) is a commensal of the human nasopharynx found asymptptomatically in up to 15% of the population. However, upon crossing of the nasopharyngeal mucosa, which happens rarely, N. meningitidis can cause life-threatening infections mainly in children and young adults. Our scientific goal is to understand the molecular mechanisms that underlie N. meningitidis pathogenesis. The rationale is that a better understanding of meningococcal biology in general, and virulence in particular, could have profound consequences on human health by leading to the rational design of novel therapies. To achieve this goal, we use mainly a molecular genetics approach that relies on the generation and phenotypic analysis of genetically modified N. meningitidis strains. One of the main virulence attributes of Neisseria meningitidis pathogenesis is this bacterium’s ability to adhere to human cells, which relies primarily on surface organelles known as type 4 pili (Tfp). Our primary objective is to understand how these organelles, which are found in numerous bacterial species, are assembled and how they can mediate adhesion and other key virulence functions such as bacterial aggregation, competence for DNA transformation and twitching motility.

We will almost exclusively use a highly adhesive variant of a serogroup C clinical isolate of N. meningitidis, strain 8013 (C:22:NST:L3,7,9), whose genome has been sequenced and which has been used as a lab strain by the Neisseria research community for almost 20 years. This is a variant of a clinical isolate first isolated in 1989 in France that is available from the strain collection of the Institut Pasteur in Paris. Efficient vaccines are available against serogroup C strains and all personnel will be vaccinated. If at any stage of this project the use of other meningococcal strains becomes necessary, we will use one of the other well-characterized sequenced meningococcal clinical isolates belonging to A, C, Y or W135 serogroups for which efficient vaccines exist (e.g. strains FAM18, Z2491, 053442, alpha 14 etc.). We will not use serogroup B strains for which no vaccine is available.
i) For mutagenesis studies, meningococcal genes will be engineered to contain antibiotic resistance cassettes that confer resistance to antibiotics other than those used to treat meningococcal disease:
- genetic modification will be done in E. coli by cloning or by transposition and genes will be subsequently delivered in the meningococcus on pUC- or TOPO-derived cloning vectors,
- genetic modification will be done in vitro by splicing PCR (no cloning involved).
(ii) In order to test competence for DNA transformation, meningococci will be transformed with the pSY6 plasmid which contains a naturally occurring allele of the Neisseria gyrB gene. This vector integrates into the meningococcal chromosome by allelic exchange and confers resistance to nalidixic acid.
(iii) For complementation studies, we will use the pGCC4 vector in which genes of interest can be cloned under an IPTG-inducible promoter. Upon transformation, this vector integrates into the meningococcal chromosome by allelic exchange. We might also clone the genes of interest with their own promoters in the pFP10 vector that can replicate in Neisseria.

Origin & function
To select for mutants in each of the approx. 2,000 N. meningitidis genes, we will use genes encoding resistance to antibiotics. We will use well-established cassettes in the Neisseria field expressing resistance to kanamycin, erythromycin, spectinomycin or chloramphenicol, and/or a mutant allele of Neisseria's gyrB gene conferring resistance to nalidixic acid.
For complementation studies, a key part of molecular genetics, mutants presenting interesting phenotypic defects will be complemented by reintroducing in their genome the corresponding wild-type genes (or orthologs from other species such as Pseudomonas aeruginosa and Neisseria gonorrhoeae) to determine whether this restores wild-type phenotypes. For example, the inserted genes might encode proteins that are suspected to play a role in (i) type 4 pilus biology (our main area of research) or in Neisseria pathogenesis (e.g. proteins involved in resistance to complement-mediated lysis or adhesion to human cells, transcriptional regulators etc.), (ii) which might make good vaccine candidates such as conserved surface-expressed proteins, or (iii) which may be good drug targets such as genes essential for meningococcal life.

Evaluation of foreseeable effects
The hazardous potential of the GM N. meningitidis we will generate is expected to be no greater than that of the recipient strain. Actually, due to the genetic modifications that will be introduced, these GMM will most often be less virulent or even avirulent and hence less hazardous than the recipient N. meningitidis clinical isolate. Moreover, the use of antibiotic resistance cassettes expressing resistance to kanamycin, erythromycin, spectinomycin, chloramphenicol or nalidixic acid, none of which is used to treat meningococcal disease, prevents the risk of generating strains difficult to eradicate in case of accidental infection.

8.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Liquid waste (cultures). Cultures above 50 are rendered non-viable prior autoclaving by chemical inactivation using 1%
virkon (final concentration). All liquid waste is autoclaved (128°C/60 min). Treatment is monitored by chart recorder attached to autoclave. Waste is finally disposed of by incineration.

Solid Waste (pipette tips, tubes, vials, Petri dishes, plates etc.) is autoclaved (128°C/60 min). Treatment is monitored by chart recorder attached to autoclave. Waste is finally disposed of by incineration.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
Part 1: GM Centre Number is: GM8
1.21: State what types of species.
1.22: Replace, “We will endeavour” to “we will/will not”.
   - Please be specific about what isolates you intend to use. The risk assessment will need to be amended as additional strains are added.
   - Please clarify whether clinical isolate strain 8013 is a recent isolate or has been in culture for some time. Please clarify whether this isolate has been commercially sourced or recently provided by a patient.
1.25: Include a list of inserts. Please provide some more details about the inserted genes.
   - The committee was under the impression from earlier text that the idea was to interrupt genes of interest. Will you be reinstating the genes as well? Is it likely that any of the inserts increase virulence or host range?
1.3: A sentence in this paragraph does not make much sense and appears either superfluous or there is a word or two missing. Do you mean that the inserted antibiotic genes confer resistance to antibiotics that are not used clinically to treat infection?
   - It is not anticipated that additional hazards are associated directly from the inserted gene products. Genetic modifications in N. meningitidis will most often lead to strains with reduced or even abolished virulence. The major hazard would be to generate strains resistant to antibiotics used to treat meningococcal disease (penicillin G, ceftriaxone and cefotaxime), which will be prevented by using exclusively antibiotic resistance cassettes promoting resistance to other antibiotics. Indeed, to select for transformants and mutants, we will use genes promoting resistance to antibiotics. For the meningococcal work, we will use foreign cassettes encoding resistance to antibiotics such as kanamycin, erythromycin, spectinomycin or chloramphenicol as well as a cloned mutant allele of the Neisseria gyrB gene conferring resistance to nalidixic acid.
2.3.3.1.a: Obviously not “all work” can be carried out in the MSC, there will be storage and incubation to name two work processes outside the MSC. It might be more accurate to state that “all work involving manipulation of live organisms will be carried out in an MSC”.
   - A class 1 and class 2 MSC work in very different ways and offer the operator differing levels of performance in different circumstances. Essentially the class 1 offers more robust protection against aerosols generated by the work activity but does not protect the work against contamination while the class 2 offers protection to both the worker and the subject material but is more sensitive to external air movement interfering with the protection factor. These differences must be understood by the lab worker. Please state what procedures can be carried out in a class 1 MSC and what procedures can be carried out in a class 2 MSC.
   - There is also a statement - “...prevent the potential for aerosol production.” Include a reference to the COP section that is appropriate to explain this, what procedures create an aerosol? How is production prevented and if not possible how is it controlled?
2.3.3.1.c: Remove the highlighted text, as work with live N. meningitidis is always carried out at CL3 at ICL “Not for
work at containment level two but as the work is carried out at level 3, the CL3 suite provides negative pressure”.

2.3.3.3.c: Are the MSC’s tested for KI operator protection with the microfuges in the MSC and running? If not, they should be.

2.3.3.3.d: Please add here that where a leak is suspected inside a centrifuge during operation (e.g. a severe out of balance situation develops) that the centrifuge lid is left closed, the lab evacuated and advice is then sought from the Suite manager, Safety Dept and CSM.

2.3.3.4: How are liquid cultures contained during shaking incubation?

2.3.4.1: Are MSC’s OP tested under operational conditions? i.e. with running centrifuges and other user equipment inside the MSC such as waste containers, tube racks etc? If not they should be.

2.3.5: To be completed by Occupation Health Physician.

3.31a: Provide justification for this answer.

3.5.b: Reconsider the answers to include if the strategies in 3.5.a had failed.

-Who is consulted after an incident to assess the need for fumigation of and MSC and where necessary the room?

-Re centrifuges – Please add here that where a leak is suspected inside a centrifuge during operation (e.g. a severe out of balance situation develops) that the centrifuge lid is left closed, the lab evacuated and advice is then sought from the Suite manager, Safety Dept and CSM.

Agreed: Class 2, Containment Level 2. This project is notifiable to the HSE.

Purposes of the contained use

Pseudomonas aeruginosa and Klebsiella pneumoniae are able to infect a wide variety of hosts and tissues and provide excellent models for studying by gram-negative bacteria. Both organisms can cause destructive changes to human lungs including inflammation and hemorrhage with cell death (necrosis) that sometimes produces a thick, bloody, mucoid sputum. Typically these bacteria gain access after a person aspirated colonizing or exogenous oropharyngeal microbes into the lower respiratory tract. Pseudomonas and Klebsiella infections are mostly seen in people with a weakened immune system and/or weakened respiratory host defences.

This project will assess the role of host-imposed stress upon bacterial conjugative plasmid transfer. Specifically we are interested in identifying regulators of integron-mediated acquisition of antibacterial resistance among individuals in host-colonising populations of bacteria. Conjugation consists of DNA transfer, by cell contact, from one bacterium to another. Conjugative circular plasmids have been identified as shuttles and resevoirs for adaptive genes. It is now established that such lateral gene transfer plays an essential role, especially for the antibiotic resistance development and dissemination among bacteria. Moreover, integrons, platforms of mobile gene cassettes, have been instrumental in this phenomenon, through their successful association with conjugative resistance plasmids.

Multi-resistant integrons (RI) have been isolated on mobile elements responsible for their assembly and rapid propagation of multiple antibiotic resistances in Gram-negative bacteria through association with conjugative plasmids. An integron is characterized by an intI gene, coding a site specific recombinase from the tyrosine recombinase family, and an adjacent primary recombination site attI. The intI integrase allows the integration of a circular promoterless gene-cassette carrying a recombination site, attC, by driving recombination between arf and attC. The integrated gene cassettes are expressed from the Pc promoter located upstream of the attI site in the integron platform.

The order of events is: Conjugation > integrase expression> cassette recombination.

Recently it was shown that the conjugative transfer of plasmids triggers a bacterial stress response - the SOS response - in recipient cells which in turn can impact the cassette content of integrons, SOS induction during conjugation is thus most probably able to impact a wide range of genomes. Although the phenomenon has been demonstrated to occur in vitro using laboratory-adapted isolates, it has not yet been demonstrated as a physiologically relevant process in pathogenic isolates. This project will interrogate the relevance of integron-mediated acquisition of antibiotic resistance in Pseudomonas aeruginosa dn Klebsiella pneumoniae.

Our specific objectives will be to 15:04:10

1) To establish the relevance of SOS induction as a general inducer of intI expression during conjugative plasmid transfer in Pseudomonas and Klebsiella pneumoniae.
2) To establish a model for conjugative plasmid transfer between bacterial isolates colonising murine gut and pulmonary niches.
3) To screen for regulators of integrase-mediated gene cassette excision and acquisition using libraries of Pseudomonas and Klebsiella mutants.
4) To screen for regulators of integrase expression using libraries of Pseudomonas and Klebsiella mutants.
5) To assess the epidemiology of integron-bearing plasmids and chromosomes, by PCR screening and sequencing, among local populations of nosocomial Pseudomonas aeruginosa.
Recipient or parental organism

E. coli:
E. coli K12 and derivatives will be used for cloning and as recipient for gene overexpression and purification. Most commonly used strains will be TG1, HB101, C600, DH5α, OP50, CC118, XL1blue, TOP10F, S17.1. These strains have a widespread and long history of safe use.

Pseudomonas aeruginosa (Hazard Group 2, opportunistic pathogen):
Most well characterized laboratory strains used will be: PAO1, PA14, PAK, CHA, PA103, TB, SG17 (Clone C)

Strains isolated from patients will be collected and used in the course of the program. Some isolates will be freshly collected, others have been collected for many years and stored at -80°C without any further laboratory manipulations.

Other Pseudomonas and related species:
Pseudomonas fluorescens (PF-5, SBW25, PFO-1, CHAO), Pseudomonas putida (WCS358, KT2440), Pseudomonas alcaligenes (M-1), Pseudoalteromonas haloplanktis (TAC125).

Related Pseudomonas species:
Ralstonia solanacearum which is a phytopathogen without any known natural antibiotic resistance (Strain Gmi1000, Mok2 and 1649).
Burkholderia cepacia and cenopacia (strain J2315), such as P. aeruginosa is a hazard group 2 opportunistic pathogen which is isolated from cystic fibrosis patients with a poor prognosis.

Pseudomonas entomophilia L48 (strain CT573326) is an entomopathogenic bacterium known to infect Drosophila melanogaster by oral route.

We will also use Klebsiella pneumoniae (Hazard group 2) isolates: LM21, 342 (Fouts et al, 2008, PLoS Genet 4(7) e1000141) and HTUH-K2044 (Wu et al, 2009. J. Bac. 191(14) 4492-4501)

Recipient or parental organism

A collection of Tn mutants (SM10pir/pCM639-ISphoA/hah insertions or SM10pir/pIT2-ISlacZ/hah insertions) in the PAO1 strain will be used (Jacobs et al., PNAS, 2003). A collection of Tn mutants (MAR2xT7) in the PA14 strain will be used (Liberati et al., PNAS, 2006).

Host/vector system

1) We will use standard E. coli vectors:
a) For cloning:
- pBR322 and derivatives: AmpR, TetR.
- pACYC184 and derivatives: ChlR. TetR.

NB: These vectors could also be used as suicide vectors for P. aeruginosa mutagenesis.
B) For gene tagging and expression:
- PET22b/28c/28a and derivatives: ColE1 replicon, AmpR (22) and KanR (28), tag Histidine N or C-terminal
- pQE30Xa and derivatives: Tag histidine (Qiagen), AmpR.
- pEGFP and derivatives: engineering of gfp fusion, AmpR
- pGEX and derivatives: Tag GST (Glutathion S-transferase), AmpR
- PAC or PAN an derivative: AviTag, AmpR
- pBADmycHisA, B, C and derivative: expression from an arabinose promoter, tag histidine and Myc. AmpR
- pYZ4 and derivatives: KanR, Construction of phoA fusion
- GATEWAY plasmids: InVitroGen, System including the entry vector pDONOR and the destination vectors (rpDEST derivatives) for recloning and expressing tagged genes.

c) For expression of genes under strong promoters:
- pBAD an derivatives: arabinose promoter. AmpR.
- pT7-1 to pT7-6 and derivatives: T7 promoter. AmpR. To be used together with pGP1-2 which carries the gene encoding RNA polymerase from T7 phage. KmR.

d) For studying protein-protein interaction:
- pUT18c and pKT25 and derivatives. Two hybrid system from Ladant. pUT18c (pUC19 derivatives), AmpR, contains 3' region of the gene encoding adenylate cyclase (cyaA). pKT25 (pSU40 derivative), KanR, contains 5' region of cyaA.
- pBS1479 and derivatives: AmpR. Tandem Affinity Purification (TAP). The TAP-Tag contains a domain CBP(Calmodium Binding Protein) and a domain Protein A (Affinity for IgG).

2) We will use suicide vectors for the engineering of Pseudomonas mutants:
- pKNG101 and derivatives: StrR. SucR. Only replicate in the E. coli:ambdapir strain CC118.
- pEX100 and derivatives: SucR. Only replicate in E. coli:ambdapir strain CC118.

3) We will use broad host range vectors for expression in P. aeruginosa (also replicative E. coli):
- pLAFR1, pLAFR3 and derivatives: IncP, TetR. Cosmid with low copy number.
- pMMB66, 67, 190, 206 and derivatives: AmpR but pMM206 (ChlR), tac promoter.
- pBRIMCS and derivatives: ChlR (1), TetR (3), KanR (2) AmpR (4), GentR (5).
- pUCP18/19 and derivatives: AmpR. Derivatives of pUC18/19 with a 2.1 kb stabilizing fragment allowing replication in Pseudomonas.

4) We will use vectors for conjugation in Pseudomonas:

5) We will use vectors for transposon mutagenesis in pseudomonas:
- pHP45 and derivatives: Interposons carrying résistances: KanR, TetR, HgR and ChlR.
- pSUP102 and derivatives: Tn5-B10 (KanR), -B11 (GentR), - B13 (TetR), -B20 (KanR), -B21 (TetR), -B22 (GentR), -B30 (TetR), -B40 (KanR et -B41 (TetR).
- pUT-Tn5 and derivatives: TetR.

We will use any or all of the annotated P. aeruginosa genes available from the genome sequence of the PAO1and PA14 strains (http://pseudomonas.com), or Klebsiella pneumoniae isolates: LM21, 342 (Fouts et al, 2008. PLoS Genet 4(7) e1000141) and NTUH-K2044 (Wu et al, 2009. J. Bac. 191(14) 4492-4501).

We will use artificially-constructed minimal type I integron elements designed upon the templates described among naturally-occurring isolates and as curated in the Integrall database (http://integrall.bio.ua.pt/). Genes and gene promoters required and involved in integron-mediated antibiotic resistance will be cloned and/or inactivated. These
genetic elements are required for the shuttling of promoterless antibiotic resistance cassettes between bacterial strains and species. They will include, but not be limited to integrase-type tyrosine recombinase enzymes, and dedicated intergon Pc promoters.

It is not anticipated that additional hazards arise from the alteration of existing traits of the host; only traits similar to traits which naturally exist already in the host will be introduced. Where mutational screens are concerned, we anticipate the vast majority of isolates to exhibit reduced fitness.

**Evaluation of foreseeable effects**

**Pseudomonas aeruginosa: Class 2:**

Pseudomonas aeruginosa as a wild type organism is a Gram-negative, aerobic rod belonging to the bacterial family Pseudomonadaceae. The family includes other genera, which, together with certain other organisms, constitute the bacteria informally known as pseudomonads. These bacteria are common inhabitants of soil and water. They occur regularly on the surface of plants and occasionally on the surface of animals. Pseudomonas aeruginosa and two former Pseudomonas species (now reclassified as Burkholderia) are pathogens of humans. However, Pseudomonas aeruginosa is an opportunistic pathogen, meaning that it exploits some break in the host defences to initiate an infection. It causes urinary tract infections, respiratory system infections, dermatitis, soft tissue infections, bacteremia, bone and joint infections, gastrointestinal infections and a variety of systemic infections, particularly in patients with severe burns and in cancer and AIDS patients who are immunosuppressed. Pseudomonas aeruginosa infection is a serious problem in patients hospitalized with cancer, cystic fibrosis, and burns. The case fatality rate in these patients is 50 percent. Pseudomonas aeruginosa is primarily a nosocomial pathogen. The overall incidence of P. aeruginosa infections in hospitals averages about 0.4 percent (4 per 1000 discharges), and the bacterium is the fourth most commonly-isolated nosocomial pathogen accounting for 10.1 percent of all hospital acquired infections. Pseudomonas aeruginosa is sometimes present as part of the normal flora of humans and the prevalence of colonization of healthy individuals outside the hospital is relatively low.

Infection may occur through direct and extensive contact with the organism, however no procedure in the laboratory will require direct contact. In addition, personal protective equipment (PPE) including lab coat, gloves and safety glasses will be worn when working with P. aeruginosa strains to further minimize the risk of direct contact with the organism.

We will use several laboratory P. aeruginosa strains including, PAO1, PA14, PAK, TB, CHA, PA103, SG17 (Class C). We will also work with isolates obtained directly from patients at Hammersmith Hospital and those submitting samples for microbiological testing at HCA Laboratories (Harley Street). The antibiotic susceptibility profile of collected organisms will be known.

**Klebsiella pneumoniae** is a Gram-negative, non-motile, encapsulated, lactose fermenting, facultative anaerobic, rod shaped bacterium found in the normal flora of the mouth, skin, and intestines. Klebsiella pneumoniae is resident in the intestinal tract of approximately 40% of the human population. It is considered to be an opportunistic human pathogen meaning that under certain conditions it may cause disease. For example, nosocomial infections are those that hospitalized patients pick up because they are in a weakened state. Klebsiella pneumoniae is also well known in the environment and can be cultured from soil, water and vegetables. In fact, it is likely that we have K. pneumoniae in our intestine from eating raw foods such as salads. The most common infection caused by Klebsiella bacteria outside the hospital is pneumonia. Mortality in Klebsiella pneumonia is around 50% due to the underlying disease that tends to be present in affected persons. While normal pneumonia frequently resolves without complication, Klebsiella pneumonia more frequently causes lung destruction and pockets of pus in the lung (known as abscessess). The mortality rate for untreated cases is around 90%. Klebsiella can also cause less serious respiratory infections, such as bronchitis, which is usually a hospital-acquired infection. Other common hospital-acquired infections caused by Klebsiella are urinary tract infections, surgical wound infections and infection of the blood.

The hazardous potential of the GMMs created is considered to be no greater than that of the parental strain. In many cases genes are inactivated in the GMM that are required for optimal growth and pathogenesis.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**
The disposal of bacterial cultures, culture supernatants, infected cell culture medium and buffers used to wash cells will be initiated by chemical inactivation of GMs by Virkon solution (to 1% final concentration), incubated for 30 minutes at room temperature, and disposed of via designated sinks. Data supplied by the manufacturer indicates that this will result in a validated inactivation of all organisms detailed in this proposal. Contaminated glassware (e.g. flasks) will be decontaminated by the addition of 1% Virkon solution and incubated for 30 minutes at room temperature. Solid waste, including plastics, tubes, pipettes, agar plates etc will be sterilised and disposed of via the university clinical waste service. All contaminated waste is disposed of into dedicated waste bins, which are sealed and subsequently sterilised by autoclaving at 134°C for 30 minutes. Autoclave function is assessed by a chart recorder, 3 monthly servicing and annual 12 point thermocouple validation testing.

Following the discussion of your proposal entitled "Bacterial genome plasticity", GMIC-1338 at the last GM safety Committee meeting, the Committee request that the following amendments are made to the proposal prior to approval:

2.3.3.1.a: Specify what work is performed in the Microbiological Safety Cabinet and what is performed on the work bench, for more details of this, make reference to the Standard Operating Procedures.

2.3.3.3.a: Typo: 'liter'

2.3.3.9.a: Include when Safety glasses must be worn.

2.3.3.9.c: Include when Safety glasses must be worn.

2.3.5: To be completed by Occupational Health

3.5.1: Typo 'Elaini'

Comments:

SH queried about how many other Principle Investigators would be working in the same area.

EB confirmed this would be a group of less than 20 people. There are regular floor working progress meetings to discuss any issues.

SH suggested a Local Rules be produced stating the risks shared within the group.

EB also pointed out that there was a list of equipments in the code of practise and a further list of the organism for each of these pieces of equipments.

SH advised to state the volumes you use on the equipment for clarity.

Agreed: Class 2, containment Level 2. This project is notifiable to the HSE

Agree: Yes
Staphylococcus aureus is associated with a wide range of infections, many of which can become chronic or recurring. The ability of S. aureus to persist within host tissues in spite of host immune surveillance and antimicrobial therapy is believed to be due, at least in part, to a significant shift of the S. aureus phenotype to what is known as the small-colony variant (SCV). SCVs are able to persist within host cells for significantly greater periods of time than the parental strain and do not trigger an inflammatory response. However, the basis of this enhanced survival is not known. The use of genetic techniques such as transposon mutagenesis will allow us to rapidly screen for S. aureus genes that are important for the formation of SCVs and also intracellular survival. Genes identified by the screen will be further investigated using targeted gene knock-out and complementation studies. In addition to providing important insights into the molecular mechanisms of persistence it is anticipated that this approach will identify novel targets for therapeutic intervention and reveal genes that may form useful biomarkers for the development of persistent infections.

Overview: Initial experiments will involve the creation of a transposon library in S. aureus strain SH1000 using either a bacteriophage mediated system described by Wang et al., 2011 or a plasmid-borne transposon system (Bae et al., 2004). This will result in multiple isolates containing integrated transposon elements encoding erythromycin resistance. It is also likely that targeted mutations will be made to confirm gene function. Mutations giving rise to interesting phenotypes will be complemented by placing genes back on to the chromosome. This project does not involve genetic modification of other pathogens, yeast or mammalian cells.
Recipient or parental organism

E. coli DH5α will be used as a cloning host for shuttle plasmids. Other E.coli strains (K12, M15 or Rosetta) will be used for expression of recombinant proteins. Most genetic manipulations of S. aureus will initially be performed in strain RN4220 before subcloning/transduction into other strains. This is because RN4220 has a defective restriction system allowing the uptake of DNA from E. coli and other sources. SH1000 will be the principle strain modified and used in initial experiments. It is derived from 8325.4 and is methicillin sensitive (the first choice antibiotic for S. aureus infections). Its genome has been sequenced and it is amenable to genetic manipulation.

Detailed list:
- E. coli DH5 alpha, M15, Rosetta, K12
- S. aureus:
  - RN4220 - lab strain capable of accepting DNA from E. coli.
  - 8325.4 - lab strain defective in regulator rsbu. Cured of prophages
  - SH1000 - derived from 8325.4. mutation to rsbu fixed.
  - Col - Lab strain. Isolated from a hospital-acquired infection. (MRSA)
  - USA300 lac - recovered from a patient with community-acquired skin infection. (MRSA).
  - Newman - lab strain defective for fibronectin-binding protein adhesins.
  - MRSA252 - Lab strain. Isolated from a case of hospital-acquired infection (MRSA).
  - MW2 - Lab strain. Recovered from a patient with community-acquired skin infection. (MRSA).

Host/vector system

Initial experiments will involve the creation of a transposon library in S. aureus strain SH1000 using either a bacteriophage mediated system described by Wang et al., 2011 or a plasmid-borne transposon system (Bae et al., 2004). This will result in multiple isolates containing integrated transposon elements encoding erythromycin resistance. It is also likely that targeted mutations will be made to wild-type bacteria to confirm gene function (this will involve the insertion of tetracycline or erythromycin resistance cassettes into bacterial genomes). Mutations giving rise to relevant phenotypes will be complemented by placing genes back on to the chromosome using an integrative vector. Relevant phenotypes include those with the small colony variant phenotype and those with altered adhesion to, invasion of or persistence within cultured human cells.

Relevant mutations (i.e. those that lead to the SCV phenotype or alter intracellular persistence) will be transduced into other S. aureus strains including 8325.4 (lab strain defective in regulator rsbu. Cured of prophages), Col (Lab strain. Isolated from a hospital-acquired infection. (MRSA)), USA300 lac (recovered from a patient with community-acquired skin infection. (MRSA)), Newman (lab strain defective for fibronectin-binding protein adhesins), MRSA252 (Lab strain. Isolated from a case of hospital-acquired infection (MRSA)) and MW2 (Lab strain. Recovered from a patient with community-acquired skin infection. (MRSA)).

S. aureus mutants will be screened for their ability to persist within cultured cell lines. These will not be genetically modified.

Detailed list of vectors to be used:
- pTM401-403
- pTM378
- pBursa and pFA545
- pTS2
- PII39

Controlled expression of S. aureus genes will employ plasmid pRMC2 (Corrigan et al), which confers chloramphenicol and ampicillin resistance.

We will also use standard E. coli vectors:
For cloning:
- pUC18/19-pUCBM20 and derivatives: CoIE1 replicon, AmpR (Boehringer).
- pBR322 and derivatives: AmpR. TetR.

For gene expression:
- pET22b/28c/28a and derivatives: CoIE1 replicon, AmpR (22) and KanR (28). tag Histidine N or C-terminal.
- pQE30Xa and derivatives: Tag histidine (Qiagen). AmpR.
- pEGFP and derivatives: engineering of gfp fusion. AmpR.
- pGEX and derivatives: Tag GST (Glutathion S-transferase). AmpR.

Origin & function

Phage-mediated transposon mutagenesis (doi: 10.1038/nchembio Nature Chemical Biology):
This protocol employs plasmids containing a mariner-based mini transposon system that include promoters with either high or low activity. This system results in gene expression that may be up or down regulated or completely abrogated. The strains employed include: Donor strain RN4220 ΔattBφ11::Orf5 pTM304 TetR, which allows replication of plasmids pTM401-403 (below) but represses phage 11 replication. Plasmids pTM401-403 are maintained in RN4220 ΔattBφ11::Orf5 pTM304 TetR and transduced into either RN4220 or Col containing plasmid pTM378, which encodes the transposase.

The plasmids required are as follows: pTM401-pTM403, which encode the mini-transposon cassette and promoters for capsule, penicillinase and tu respectively. This provides differing promoter strengths at different growth phases. Plasmid pTM378 encodes the transposase and can replicate in RN4220 ΔattBφ11::Orf5 pTM304 TetR but not the recipient strains. This protocol employs staphylococcal phage phi11, which is used to transduce the plasmids from donor to recipient and will also be used to transduce mutated DNA from mutant strains into other strains.

Plasmid-mediated transposon mutagenesis (Bae et al., 2004 doi: 10.1073/pnas.0404728101): This protocol involves 2 plasmids (pBursa and pFA545), which are sequentially transformed into the host strain. Temperature sensitive replication and the acquisition of erythromycin resistance are used to select for transposon mutants. This protocol results in a single integrated transposon, which may or may not disrupt gene expression. Where necessary targeted knockout mutants will be produced using the temperature-sensitive plasmid pTS2, which encodes chloramphenicol resistance (McAleese et al., 2003 doi: 10.1099/mic.0.25842-0).

Mutations will be complemented using a vector that integrates onto the S. aureus chromosome, PII39 that encodes spectinomycin and tetracycline resistance (Luong and Lee, 2007 doi: 10.1016/j.mimet.2007.04.007). Controlled expression of S. aureus genes will employ plasmid pRMC2 (Corrigan et al), which confers chloramphenicol and ampicillin resistance.

We will also use standard E. coli vectors:

For cloning:
- pUC18/19-pUCBM20 and derivatives: CoIE1 replicon, AmpR (Boehringer).
- pBR322 and derivatives: AmpR. TetR.

For gene expression:
- pET22b/28c/28a and derivatives: CoIE1 replicon, AmpR (22) and KanR (28). tag Histidine N or C-terminal.
- pQE30Xa and derivatives: Tag histidine (Qiagen). AmpR.
- pEGFP and derivatives: engineering of gfp fusion. AmpR.
- pGEX and derivatives: Tag GST (Glutathion S-transferase). AmpR.
Evaluation of foreseeable effects

Whilst all S. aureus strains should be considered infectious, SH1000 is a lab strain and is thus unlikely to be significantly more virulent than clinical strains. However, it is likely that mutations with relevant phenotypes will be transduced into other strains including: 8325-4; Newman; USA300 lac; MW2; MRSA252 and Col to assess the importance of different genetic backgrounds. It is impossible to predict the relative virulence of every transposon mutant since it is theoretically possible that disruption of e.g. a regulator gene might up-regulate expression of certain virulence factors. However, it is anticipated that the vast majority of, if not all, mutations will result in reduced or unaltered virulence. It is relevant to note that previous studies on SCVs in animal models report reduced pathogenesis compared to wild-type (although the organism is able to persist within the host). The intended work will identify mutants with enhanced ability to persist within host cells. Although this may contribute to the persistence of infection, it is associated with reduced damage to host tissues and the down-regulation of cytolytic toxin expression. As such, the screening protocols employed are unlikely to select for mutants with enhanced ability to initiate infection or cause a more severe form of infection.

8.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The disposal of bacterial cultures, culture supernatants, infected cell culture medium and buffers used to wash cells will be disposed of into Virkon solution (to 1% final concentration), incubated for 30 minutes at room temperature and disposed of via designated sinks. Validated data supplied by the manufacturer indicates that this will result in inactivation of all organisms detailed in this proposal. Contaminated glasware (e.g. flasks) will be decontaminated by the addition of 1% Virkon solution and incubated for 30 minutes at room temperature. Solid waste, including plastics, tubes, pipettes, agar plates etc will be sterilised and disposed of via the university clinical waste service. All contaminated waste is disposed of into dedicated waste bins, which are sealed and subsequently sterilised by autoclaving at 134°C for 30 minutes. Autoclave function is assessed by a chart recorder, 3 monthly servicing and annual validation of a typical waste load using 12 point thermocouple testing.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
Following the discussion of your proposal entitled "Molecular Mechanisms of Staphylococcus Persistence", GMIC - 1387 at the last GM Safety Committee meeting, the Committee request that the following amendments are made to the proposal prior to approval:

Part 1: GM Centre number: GM8
1.21: Typo: ‘complimented’ change to ‘complemented’ in first and last paragraph.
1.24: Typo: ‘enhanced’

2.3.3.1.a: Specify what work is performed in the Microbiological Safety Cabinet and what is performed on the work bench, for more details of this, make reference to the Standard Operating Procedures.

2.3.4.1: Typo: ‘Quarterly’
2.3.5: To be completed by Occupational Health

Comments:
The Committee suggested adding any further strains that may be possibly used in the research in the future now.
SH queried where the work would be taking place.
AE confirmed this would mostly be bench work and some Microbiological Safety Cabinet work.

RW asked how the agar plates would be sealed?
AE informed the Committee this would be done with a non porous adhesive tape.
IH questioned which parts of this would be done in the MSC and if this could be specified in the form.
IH also queried the volumes used in the centrifuges and how would you know if there was a spill.
RW suggested using lower volumes in the bucket than it can actually handle.
IH recommended adding the centrifuge inspection in the SOP.
RW also recommended using the click-shut eppendorfs for an extra seal.
HK questioned if there would be out of office hours.
AE explained some work may be out of hours.
SH confirmed this would be included in the Local Rules and SOP.
SH then asked about the training methods.
AE pointed out that this was done in conjunction with the Safety managers.
EB also confirmed the training would be signed off by the trainee and trainer.

Agreed: Class 2, Containment Level 2. This project is notifiable to the HSE.

Professor H's group have recently developed a powerful reporter system based on fluorescent dilution that enables direct quantification of the replication dynamics of Salmonella in murine macrophages at both the population and single cell level. Its use has provided the first direct evidence of viable non-replicating Salmonella cells in an infected host. These could represent an important reservoir of persistent bacteria. We now wish to extend the system to other pathogens to study replication dynamics in vivo, and to identify and characterize non-replicating bacteria associated with chronic infections. The group of Norrby-Teglund and others have discovered that Streptococcus pyogenes can survive and replicate in human epithelial cells and macrophages.

In this project we will introduce reporter constructs into wild-type and mutant strains of Streptococcus pyogenes and examine the dynamics of replication in a variety of human cells, including macrophages. Mutant strains will be constructed and analysed to provide insights into mechanisms of survival and growth in host cells. As a result, we expect to gain novel insights into multiplication rates within human cells and to learn more about the nature of persistence in this disease.

Site-directed and transposon mutagenesis will be carried out on recipient strains described below. These vectors will be introduced in S.pyogenes to obtain deletion mutants in conjunction with plasmid based complementation. Various major putative virulence factors will be deleted to investigate the mechanisms that confer intracellular survival in host cells. Any subsequent changes in bacterial fitness will be analysed by confocal microscopy and flow cytometry. Dual fluorescence reporter plasmids will be constructed from pre-existing plasmids obtained from various collaborators. These plasmids will act as a template for our constructs which will contain variations of green and red fluorescent proteins under inducible and/or constitutive promoters. This system will be used for investigating intracellular bacterial replication using fluorescence dilution (Helaine et al, 2010).

Recipient or parental organism

Echerichia coli: Wild type K12 strains and derivatives thereof with required phenotypes for cloning and expressing streptococcal genes or genes of other bacterial origin will be used in these studies. Strains commonly used in the laboratory include DH5alpha, TOP10. These strains have a widespread and long history of safe use.

Streptococcus pyogenes: E.coli shuttle vectors will be introduced into M1T1 5448 strain and M89 H293 strain to generate gene knockout mutants.

The aim of our genetic manipulations will be to knockout major or putative virulence genes and construct fluorescent strains for in vitro visualisation. Therefore, all genetically modified organisms constructed will be no more virulent than the wild type S.pyogenes 5448 or H293 strains to generate gene knockout mutants. The aim of our genetic manipulations will be to knockout major or putative virulence genes and construct fluorescent strains for in vitro visualisation. Therefore, all
Host/vector system

Origin & function

The vector systems mentioned above will be employed to do the following:

1. Suicide vectors for Site directed mutagenesis (pucMUT, pACH74 and pAS1TAG)
2. Transposon mutagenesis (pR412, pJRS233 and pJDM-STM)
3. Cloning of PCR products (pCEM, pCR2, 1TOPO, pLS1ROM, pOri23, pBluescript, pGEM, pPP1/2, pACYC184, pVA838)
4. GFP expressing integrative plasmids (pBaSysBioll, pBSU101, pGFP, YFP, pCFP, pLS1GFP, pMV158GFP, pLS70GFPcat, pMV158GFP)
5. pLS578, pMSP3535, PcEM, PcTet, Janus are used for tagging or replacement of S. pyogenes genes with resistance genes against tetracycline, erythromycin and Kanamycin.
6. pET is an expression vector for protein overproduction
7. pHY304 is temperature-sensitive plasmid for insertional mutagenesis.
8. pSIV and is an inducible shuttle vector system.

All the listed genetic material to carry out cloning and mutagenesis are commercially available. However, for the purpose of GFP expression in the recipient organisms these plasmids will be obtained from various collaborators.

Evaluation of foreseeable effects

The foreseeable effects include the introduction of antibiotic resistance genes which could represent a hazard if released into the environment and transferred to other organisms. All GMOs and GM material is decontaminated and sterilized before disposal and operational protocols within the lab make release unlikely. Therefore transfer of genetic material to other environmental microorganisms remains extremely unlikely.

Human health:

The introduction of additional antibiotic resistance genes into the M1T1 Streptococcus strain poses a greater risk to human health in the instance of infection. However, the organism will remain susceptible to β-lactam antibiotics.

Hazardous GMMs:

One of the major goals of the project is to render the parental strains less invasive and virulent. Thus, it is expected that the GMMs created will not show any increase in virulence or fitness.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Use of new fluorophores to study bacterial infection and heme acquisition in deep tissue

1. Pathogenic bacteria:
Plasmids and transposon systems to implement genetic modifications in pathogenic strains will be propagated in E. coli DH5alpha or JM109 cells. These vectors will then be introduced into the above mentioned pathogens to confer deletions, promoter-reporter fusions, or transposon-generated libraries for various experiments. Libraries will be screened using Fluorescence-Activated Cell Sorting (FCS) to search for iron/heme-specific acquisition determinants. These same strains, and possibly other more virulent versions (stated within this report) will subsequently be used to infect mice and imaged using fluorescent topographic imaging. In the specific case of S. aureus, we will use both plasmid- and bacteriophage-based systems to implement transposon mutagenesis.

2. E. coli:
E. coli GMM strains will also be used to express large amounts of recombinant protein for structural biology and biochemical experiments. BL21 strain derivatives are used for this and expression plasmids confer ampicillin or kanamycin resistance.

3. Yeast:
We will also be using Saccharomyces cerevisiae for yeast-2-hybrid to observe protein-protein interactions (in vivo) of signal transduction components. Vectors to be used are pGBT9 and pGAD425, both of which have ampicillin resistance for E. Coli. Foreign DNA will be introduced into pathogenic bacterial strains. These strains will be cultured and measured for fluorescence intensity. We will also infect animals and monitor fluorescence expression during the infective process with whole mount imaging.

Recipient or parental organism

1. E. coli DH5alpha, JM109, BL21 (class 1)
2. Saccharomyces Cerevisiae (class 1)
3. S pneumoniae R6, TIGR4, D39 (class 2)
4. P aeruginosa PAO1, MPAO1, IA614 (class 2)
5. S. aureus: 8325.4, SH1000, Col, MW2, MRSA252, Newman, USA300 lac, RN4220 (class 2)
6. S. gordonii DL-1 (class 2)
7. S. pyogenes (A40) (class 2)
8. S. agalactiae NEM316, COH1,515, 2603V/R (class 2)
9. M. bovis BCG (class 2)
10. M. smegmatis (class 2)

My current strain inventory only includes numbers 1-4, and number 5- USA300 strain of S. aureus (to be shipped from US)

**Host/vector system**

1. For E. coli pET21b (Novagen Inc), pBAD (Invitorgen Inc.) and pE-SUMO (Lifesensors Inc., http://www.lifesensors.com/) expression systems for protein overexpression, and pUC57 for general propagation of DNA.

3. For P. aeruginosa: a TN7 mini-Tn integration vector (Choi and Schweizer, Nat Protoc. 2006.1: 153-161) to generate deletion mutants or specific chromosome integration, replicating vectors pJN015 and pSB109 for replicating extrachromosomal expression.

4. For S. aureus: phage-assisted mariner transposon system based on doi: 10, 1038/nchembio Nature Chemical Biology). The system uses plasmids pTM401-403 in conjunction with strain RN4220 for maintenance and plasmid pTM304 is also propagated in this strain to introduce the transposase. For S. aureus plasmid-mediated mutagenesis we will use a protocol as per Bae et al., 2004 doi: 10,1073/pnas. 0404728101 that involves plasmids pBursa and pFA545. These plasmids are both transformed to allow a single chromosomal deletion/integration.

Also in S. aureus and where necessary targeted knockout mutants will be produced using the temperature-sensitive plasmid pTS2 (McAleese et al., 2003 doe: 10.1099/mic 0.25842-0). Mutations will be complemented using a vector that integrates onto the S. aureus chromosome, PIIS9 (Luong and Lee, 2007 doi: 10.1016/j.mimet.2007.04.007).

5. For yeast vectors will be transformed by standard chemically competent means.

**Origin & function**

Specific genes to be modified are as follows:

1. For S. pneumoniae: (1) RitR, a transcription factor responsible for iron and oxidative stress regulation (2) Stk, a serine-threonine kinase responsible for cell wall integrity and antibiotic resistance.

2. For P. aeruginosa: (1) HasR, HxuC, PhuR, HO (heme oxygenease) - iron regulatory proteins.

3. For S. aureus: (1) Stk, a serine-threonine kinase responsible for cell wall integrity.

In the case of transposon mutagenesis, this is a relatively ransom procedure intended to create a deletion 'library' that should theoretically cover all genes within the target organism.

4. All systems utilize antibiotic resistance markers for selection. E. coli DH5alpha and JM109 non-infectious strains will be used to propagate DNA for eventual introduction into the above mentions parental species to create GMOs for research purposes.
Evaluation of foreseeable effects

Forseeable effects:

1. Hazards to human health and environment:

General hazards to human health include the propagation of the above mentioned infectious vectors that create an environment to become exposed to levels that might initiate disease.

Hazards to the environment mainly concern the antibiotic resistance determinants in our bacterial strains, and the potential for these genes to enter the environment (e.g. by improper decontamination).

Transfer of genetic information in the form of genes that code for antibiotic resistance determinants is the major concern. The project will use many different strains, and several (previously stated) antibiotic resistance genes as markers of genetic manipulation.

2. Likelihood and consequences of modifications being transferred to other microorganisms:

It is highly unlikely, given the fact that after we propagate samples (cultures) and use them, they are killed and properly disposed of (i.e. autoclaved). In addition, and detailed below, several precautions and cleaning measures are taken to ensure these organisms will not reach area beyond their zones designated for their use.

3. Most hazardous GMMs to be created:

The majority of GMMs will render the strains less efficient at causing disease. It is not anticipated that any GMMs will show increased virulence.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid Waste:

1% final concentration virkon solution for a minimum of 1hr at RT for bacterial cultures or 1% Biocleanse for 12 hrs for tissue culture waste. These can then be dispensed down the laboratory sink. Bacterial cultures .5ml are autoclaved prior to disposal. Discard cycle 134 degrees C for 3 min. Machine cycle recorded after each cycle by thermograph; autoclaves thermocoupled validation tested regularly (annually) by a qualified engineer.

Solid Waste:

Bacterial cultures on agar plates and contaminated plasticware are autoclaved prior to disposal. Discard cycle 134 degrees C for 3 min. Machine cycle recorded after each cycle by thermograph; autoclaves thermocouple validation tested regularly (annually) by a qualified engineer.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N
Please enter comments on the GM safety committee on the risk assessment

Comments: HC gave a brief description of the work.
The following amendments are required prior to approval:
Please complete the Biopersonnel registration form.
1.1: Add all the strains in this section.
2.13: Un-hatch this box.
2.18: State the Class 2 GMO's are the most hazardous, but none are more hazardous than the wild type.
4.2: Add, 'refer to Code of Practise' or other documents.
4.15: Change the order in which this is presented, begin with ‘Mode of Transmission’
4.18: Describe the biological reasons why these vectors cannot be transferred to other organisms in the environment. e.g. Non-mobilisable or, mobilisation defective etc.
5.9: Justify use of the sharps when making blood agar and why a similar gauge blunt needle cannot be used.
5.10: Give explanation for the answer 'no' to shredding of biological agents.
5.12: Answer should be 'no'.
6.5: Make answer clear by stating this depends on the risk assessment associated with which work.
12: To be completed by Occupational Health.
Agreed: Class 2, Containment Level 2. This project is notifiable to the HSE.

---

This project involves the use of genetically modified Sendai Virus and HIV Pseudoparticles. The use of HIV pseudoparticles has been assessed by the GM8 GM safety committee as falling within the definition of a Class 1 GMO. This application refers only to the use of GM Sendai virus which was assessed as falling within the definition of a Class 2 GMO due to the potential for environmental harm. The descriptions relating to the use of Pseudoparticles are included for information only.

The Human Immunology Laboratory (HIL) based at the Chelsea and Westminster hospital, will conduct and support pre-clinical and clinical studies to assess the safety, immunogenicity and potential efficacy of HIV vaccine candidates. The aim of this project is to measure specific antibody responses against the candidate vaccine vectors and their inserts pre- and post-vaccination. We are particularly interested in the neutralizing and binding antibody responses in samples collected in clinical trials.

The neutralization potential of clinical samples against candidate vaccine vectors such as Sendai Virus (SeV) or against HIV proteins (e.g. envelope, Gag) will be determined in in-vitro cell based assays using immortalized cell lines or PBMCs isolated from human volunteers. Typically, a permissive cell line is infected in a microtiter plate with a low multiplicity of infection of the candidate viral vector or cell culture supernatant of non-replicating HIV pseudoparticles which have been modified to carry a reporter gene (fluorescent proteins, Luciferase or an enzyme). After 1 to 5 days the amount of infected cells is measured using the reporter gene and when applicable after addition of substrate. Addition of the serially diluted volunteer's samples to the virus prior to the in-vitro infection will allow measurement of the presence or absence of specific neutralizing antibodies in the volunteer's samples. Neutralization of viral infection as measured by the decrease of reporter gene activity, will be interpreted as the presence of neutralizing antibodies in the samples. A neutralizing antibody titre will be measured as a function of the sample's dilution.

The presence of binding antibodies in samples will be determined by an Enzyme linked ImmunoSorbent Assay (ELISA). Typically, a preparation of detergent solubilised vaccine vectors, or preparations of purified proteins (or fragments of) from the vectors or inserts (i.e. HIV envelop or gag proteins) is used to coat microtiter plates. After incubation of the coated plates with diluted samples, presence of specific binding antibodies is measured by colorimetry or fluorescence, after the addition of a labelled secondary anti-human antibody (labels include, but are not limited to, Horse radish peroxidase, Alkaline phosphatase or a fluorescent probe).

Recipient or parental organism

All modifications described will be made to an existing Sendai virus (SeV) viral isolate (SeV stain Z). The infectivity of the Z stain is 10,000 times reduced in mice compared to circulating SeV strain. The Z strain described here will not be generated in our laboratory but by collaborators and shipped to the IAVI Core Laboratory for use. No additional modifications will be made in our laboratory.

A replication competent Sendai virus (SeV) (Z strain) expressing a reporter gene (Fluorescence, Luminescence or an enzyme) will be used for the SeV neutralization assay. The reporter gene is located upstream of all SeV genes, and none of the SeV genes have been altered.

For the binding ELISA we will use unaltered SeV as well as SeV expressing HIV-1 proteins or partial protein sequences to coat the ELISA plates. This virus will be identical to the virus used for the immunization of trial participants, or viruses that have been extensively used in the literature, to allow comparisons with other published data. Before coating the ELISA plates the virus will be disrupted with a buffer containing a detergent such as Triton X-100. In addition SeV will be used unmodified as well as SeV expressing HIV-1 proteins or partial protein sequences. SeV will not contain full length HIV at any time. Before use the SeV will be destroyed with a buffer containing a detergent such as Triton X-100.

The pseudoparticles will be generated in our lab, but this work has been classified as containment level 1 by the Imperial College Safety committee and therefore is discussed below for information only.
To produce HIV pseudoparticles two different plasmids will be used: a plasmid expressing the viral envelope sequence of interest and the pNL4.3 Luc+ENV- plasmid which is based on the HIV NL4.3 proviral clone. In this plasmid the luciferase gene is introduced in the nef gene, making it inactive. In addition a deletion at the 5’ end of the envelope gene results in a frameshift which introduces a stop codon thereby preventing the expression of the HIV envelope protein. Transfection of pNL4.3 Luc+ENV-alone can not produce pseudoparticles, because it does not express the HIV envelope protein. To produce pseudoparticles the plasmid is co-transfected with an plasmid expressing the envelope of choice. By cotransfecting both plasmids the transfected cell will produce the pseudoparticles which are secreted into the culture supernatant. The produced particles express the envelope of choice on the outside of the particle and it contains the pNL4.3 Luc+ENV-genome. Because the produced pseudoparticles do not contain a complete genome (they contain the pNL4.3 Luc+ENV-), no new viral particles can be formed after infection of target cells.

For the production of pseudoparticles we will use plasmids expressing HIV envelopes from different clades as well as SIV, human T-lymphotropic virus (HTLV) and Vesicular stomatitis virus (VSV) as control envelopes. We will not use any replication competent constructs of these additional viruses, we will only use their envelope sequences, which are expressed in a plasmid, for the production of pseudoparticles. In addition we will not be inserting these envelope sequences into the HIV genome or the NL4.3 Luc+ENV-plasmid.

To produce HIV pseudoparticles two different plasmids will be used: a plasmid expressing the viral envelope sequence of interest and the pNL4.3 Luc+ENV- plasmid which is based on the HIV NL4.3 proviral clone. In this plasmid the luciferase gene is introduced in the nef gene, making it inactive. In addition a deletion at the 5’ end of the envelope gene results in a frameshift which introduces a stop codon thereby preventing the expression of the HIV envelope protein. Transfection of pNL4.3 Luc+ENV-alone can not produce pseudoparticles, because it does not express the HIV envelope protein. We will not use any replication competent constructs of these additional viruses, we will only use their envelope sequences, which are expressed in a plasmid, for the production of pseudoparticles. In addition we will not be inserting these envelope sequences into the HIV genome or the NL4.3 Luc+ENV-plasmid.

SeV stocks will be generated by our collaborators and sent to our laboratory to be implemented in the antibody assays.

For the ELISA, SeV is the vector system that expresses a variety of HIV-1 proteins or partial proteins. This vector will be used as a source of antigen in the assays, rather than as an expression system

HIV Pseudo particles - For information.

For the production of pseudoparticles we will use plasmids expressing HIV envelopes from different clades as well as SIV, human T-lymphotropic virus (HTLV) and Vesicular stomatitis virus (VSV) as control envelopes. We will not use any replication competent constructs of these additional viruses, we will only use their envelope sequences, which are expressed in a plasmid, for the production of pseudoparticles. In addition we will not be inserting these envelope sequences into the HIV genome or the NL4.3 Luc+ENV-plasmid.

pNL4.3 Luc+ENV- and the different viral envelope expression plasmids will be used to create the pseudoparticles. Co-transfection of both plasmids will result in the formation of non replicating pseudoparticles.

Origin & function

A replication competent Sendai virus (SeV) expressing a reporter gene encoding a fluorescent protein or the luciferase protein will be used to determine SeV antibody neutralization. The fluorescent gene originates from the jellyfish Aequorea victoria, whereas the luciferase gene is either derived from the firefly (Photinus pyralis) or the sea pansy (Renilla reniformis). The reporter gene is located upstream of all SeV genes, and none of the SeV genes have been altered. The reporter gene will be used to quantify infection.

SeV(NP) or SeV expressing HIV-1 proteins or partial protein will be used to measure binding antibodies. The HIV proteins will be derived from different circulating HIV strains. The SeV will never contain the full length HIV-1 sequence or express all HIV-1 proteins in one construct. Before use, SeV will be lysed with a buffer containing a detergent such as Triton X-100.

The use of lysed SeV will enable us to determine specific antibody responses to the proteins present in the vaccine vector. No constructs or viral stocks will be produced in the laboratory, the viral stocks will be produced by collaborators and shipped to our laboratory in accordance with shipment regulations.

The pseudoparticle system has been classified a containment level 1 by the Imperial College safety Committee. These details are included for completeness.

pNL4.3 Luc+ENV -

Nef: luciferase gene is introduced in the nef gene, preventing its expression. Nef is a viral protein that interacts with host cell signal transduction proteins to provide for long survival of infected T cells and for destruction of non-infected T cells (by inducing apoptosis).

Env: The Envelope glycoprotein (Env) is the sole viral protein present on the surface of Human Immunodeficiency Virus-1 (HIV-1) virions. The Env mediates viral entry.

Evaluation of foreseeable effects

The Sendai virus used is a replication competent virus. The insert does not alter the function of the SeV genes. The strain used for the neutralization assay is the SeV Z strain the SeV used for the ELISA is an isolate derived from SeV strain Z. The Z strain is 10e4 less infectious in mice that circulating SeV stains. The loss in infection is cause by prolonged culture of the viral isolate. (K. Kiyotani et al. Arch Virol. 2001)
SeV is a non human pathogen and does not induce disease in humans. SeV is responsible for respiratory tract infection in mice, hamsters, guinea pigs and rats, with infection passing through both air and direct contact routes (Baker, DG. 1998. Clinical Microbiology Reviews. 11:231-266).

The modifications made to the SeV do not impair or alter any of the SeV gene functions and do not increase pathogenicity.

SeV is a rodent pathogen that has never been reported to cause human disease. Symptoms in rodents vary from none at all and no obvious symptoms but lung lesions on post mortem, mild snuffles through to severe pneumonia with breathing difficulties, staring coat, lack of appetite, weight loss, decreased litter size and growth retardation in kittens.

SeV is transmitted by direct contact or by inhalation of aerosols. The virus is easily killed by drying or disinfectants/detergents.

To prevent exposure to the environment all procedures will be performed in a containment level 2 laboratory, equipped with class 2 biosafety cabinet. Sealable flasks will be used for culturing to prevent spillage; in the incubator the flasks will be stored on static shelves and on a plastic tray. Centrifuges are fitted with sealable buckets which will be opened and closed in the safety cabinet. Only trained personnel will work with the above described pathogen and all laboratories are secured by badge readers, accessible by authorized personnel only.

The pseudoparticles are non replicating particles. They are capable of cell entry, however because the pseudoparticle only contains the pNL4.3 Luc+ENV- genome, no infectious particle can be formed in the infected cells. It will produce some HIV proteins (the ones present in the pNL4.3 Luc+ENV-) in the infected cell but because no HIV envelope can be produced (due to the above described deletion) it can not form a whole virion particle. So no viral dissemination will take place.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be decontaminated with 1% Virkon (final concentration) within the microbiological safety cabinet for a minimum of 20 minutes prior to disposal through the laboratory waste sink. The treatment with Virkon completely disrupts the virus thereby eliminating virus activity.

Solid waste will be decontaminated by immersion in 2% virkon solution for at least 20 minutes. The solid waste will then be autoclaved under vacuum air extraction with rapid steam heating to 121°C for 25 minutes. Followed by disposal as clinical waste.

The autoclaves are fitted with a chart recorder to monitor the autoclave cycle and undergo 6 monthly service and an annual 12 points thermocouple test with a mock load.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
Comments:
MN gave a brief description of the work.
RW checked if they would be checking the antibody response in humans. MN confirmed this; they would be blocking and binding the antibody to check the response in humans.
SH queried if they would be developing a vaccination to then test. PB explained they would be using the sendai vector, but were unsure if the vaccination would work.
SH then asked if this would involve clinical trials. MN informed the committee that there would not be clinical trial involved in this work.
RW questioned if the sendai virus could replicate in humans. MN stated that it was a non-human pathogen and could not create a disease in humans. Mice population can get infected by the virus, but not humans.
IH queried the impact this would have on the environment, since GFP was being added to the SeV, it would be considered as a pathogen with wild mice and thus under the contained use regs a hazard to the environment. MN informed the group that the minimum Containment Level of the Laboratory was 2.
SH questioned if the pathogen was Class 2, the Containment Level became 2? IH advised if it was a risk to the environment, then yes. BR pointed out to prevent the route of escape, raises the containment level requirement and thus the class.
IH confirmed that the GM Sendai virus was class 2 on the grounds that it presented a risk to the environment.
PB also added that the trial work would be done by International Aids Vaccine Initiative (IAVI).
SH asked if there were any sharps involved in the work; that would lead to a risk of infection. MN explained that the risk of infection was minor. If so, the infected cell would not replicate. A HIV test would come back positive, but further test would confirm a negative result. PB included that all the personnel involved in the work were already working with HIV.
IH asked how the HIV Psuedoparticles were attenuated. MN stated that the HIV pseudoparticles were non replicating and lacked the mechanism for packaging. IH asked if this was a robust attenuation. MN stated that two separate plasmids were required to produce the pseudoparticles, the Nef gene was inactivated and a frame shift induced stop codon prevented expression of the HIV envelope protein. The genome is incomplete and the produced particles are not capable of replication. This is reflected in the risk assessment Activity

Purposes of the contained use

Our project is part of a joined European effort (Imaging Neuroinflammation in Neurodegenerative Diseases; INMiND) to better understand neuroinflammation, in particular microglial activation in Neurodegenerative disorders. The project will entail a full functional assessment of TSPO translator protein on microglia. To that purpose we aim to use immortalised murine and human microglial cell lines and astrocytoma cell lines. In addition snap frozen human brain tissue will be used for standard immunohistochemistry techniques.

The work will comprise of placing in culture immortalised microglial cell lines (transformed by recombinant retrovirus) and astrocytoma cell lines, remove the TSPO translocator receptor or by knock-out (siRNA Dharmacon RNAi technology -siGENOME siRNA reagents from Thermo Fisher) or by blocking or activate with agonists. Function of microglia after using various stimuli will be assessed. To that end, RNA, protein and media will be extracted and frozen for relevant molecular and proteomic analysis. Following culture experiments, relevant microglial activation pathway associated with TSPO will be validated on snap frozen brain sections prepared on a cryostat using standard immunohistochemistry techniques.

The J2 retro virus is a recombinant retro virus expressing the oncogenes v-myc and v-raf used to transform the BV2 cell line. Although the cel line is bought in from an external agency, no conclusive evidence can be brought forward to demonstrate that the BV2 cell line is virus free and remains an ectotropic virus, therefore BV-2 cell line has been risk assessed to be a class 2 GMO.

Recipient or parental organism

The BV-2 cloned cells will be purchased. These cells express the nuclear v-myc and the cytoplasmic v-raf oncogene products as well as the env gp70 antigen at the surface level. The BV-2 cell line produces an enveloped recombinant ectropic J2 retrovirus; such virus is known for its in vitro transforming ability and in vivo tumorigenic potential [J Neuroimmunol. 1990 May;27(2-3):229-37]. Similarly the human HMO6 and CHME3 microglial cell lines were infected with the retroviral vector encoding v-myc oncogene (transcribed from mouse leukemia virus LTR plus neomycin-resistant gene transcribed from a SV40 early promotor) inducing propagation of immortalised human microglial cell lines

BV2; mouse (C57BL/6) microglial cells transformed by recombinant retrovirus (v-raf/v-mic); will be purchased at IRCSS
- N9; murine microglia; will be gift from Dr David Dexter, Imperial
- HMO6; human microglia; will be gift from Seung U Kim, Vancouver, Canada
- CHME3; human microglia; will be gift from Professor M Tardieu, Paris, France
- EOC2, EOC13.31, EOC20; murine microglia will be purchased at ATCC
siRNA technology will be used (Dharmacon RNAi technology) - a non viral gene silencing method (for example siGENOME siRNA Reagents from Thermo Fisher). This part of the work does not in our opinion fall under the contained use regs.

However the following Host / vector systems do:
BV2; mouse (C57BL/6) microglial cells transformed by J2 recombinant retrovirus (v-raf/v-mic) purchased at IRCSS Instituto Di Ricovero e Cura a Carattere Scientifico (Italian Research Hospital), Genova, Italy.
Human HMO6 and CHME3 microglial cell lines infected with retroviral vector encoding v-myc oncogene (transcribed from mouse leukemia virus LTR plus neomycin-resistant gene transcribed from a SV40 early promotor) inducing propagation of immortalised human microglial cell lines.

Origin & function

A murine cell line (BV-2) has been generated by infecting primary microglial cell cultures with a v-raf/v-myc oncogene carrying retrovirus. The v-raf-leukemia viral oncogene 1 (RAF1) and v-myc are genes known to play a role in cell cycle progression, apoptosis and cellular transformation.
HMO6 and CHME3 microglial cell lines were infected with the retroviral vector encoding v-myc oncogene (transcribed from mouse leukemia virus LTR plus neomycin-resistant gene transcribed from a SV40 early promotor) inducing propagation of immortalised human microglial cell lines.

Evaluation of foreseeable effects

The cell lines have been transformed with retrovirus in order to produce "immortalised" cell lines.

Knockdown of the TSPO gene will be performed using non viral gene silencing methodologies, which do not fall under the contained use regs.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All handling of cells and media potentially contaminated with the transformed cell lines will be conducted at containment level 2. Activities involving opening of the culture vessels, transferring of cells or media and similar activities where a splash or spill is possible will be conducted in a Class II safety cabinet.

All media and material in contact with cells will be decontaminated before being disposed in designated sink. Liquid will be decontaminated with virkon at a final concentration of 1% for at least 30 minutes and solid waste by autoclaving at 121 for 15 minutes in an autoclave validated for the purpose.

The cells will be double contained for storage and placed in LN2 tank in laboratory accessible only with swipe card.

The lab is shared with other users. Safety cabinet will be decontaminated with 1% Virkon and 70% Ethanol plus with one hour UV lights before other use can use the safety cabinet.

Cell vials will be stored in double containment (cryovial and storage box) in a protected area secure by swipe card entry.

A Microcentrifuge with sealed buckets will be used to contain potential aeroso.

Any spillage will be absorbed and the area treated with 1% Virkon (min contact 15 min). Absorbent material will be disposed of as solid waste via the validated autoclave.

If in direct contact on skin wash abundantly immediately with water. If in contact with mucous membrane seek advice and anti-retroviral or anti-HepC treatment with occupational health immediately. If HO is not available attend local A&E. Include incidents to be reported onto Salus (accident reporting database). Report to Safety Officer and to occupational health immediately.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste: Decontaminate with Virkon final concentration 1% min contact time 15 min Max contact time 1 hour.

Solid waste: Decontaminated with 1% Virkon min contact time 15 min Max contact time 1 hour or will be autoclaved (121ºC, 15 min, data logger to confirm successful cycle)

Any material in contact with cells or media will be decontaminated with 1% Virkon min contact time 15 min Max contact time 1 hour or will be autoclaved (121ºC, 15 min, data logger to confirm successful cycle)

Is an emergency plan required according to regulation 20?  

Yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Agreed: Class 2, Containment Level 2.

GMIC Reference Number: GMIC-1412

The J2 retro virus is a recombinant retro virus expressing the oncogenes v-myc and v-raf used to transform the BV2 cell line. This is not work carried out by Dr and the cell line is bought in from an external agency. However it has not been conclusively demonstrated in the risk assessment that the BV2 cell line is virus free, therefore BV-2 cell line has been risk assessed to be a class 2 GMO. This was the view of the committee. They will therefore have to complete a CU2 and pay the HSE the usual admin fee
The specific aim of this work is to identify, sequence, disrupt and analyse the expression of fungal genes involved in virulence. To achieve this genes will be isolated from genomic DNA by PCR, heterologous hybridisation, mutant complementation and related techniques. This will require construction of Aspergillus and Candida libraries in Saccharomyces cerevisiae/Escherichia coli shuttle vectors e.g. YEp24. Genes of interest will be sequenced and characterised further. As part of this further analysis gene disruption and replacement experiments will be performed. In addition these lesions will be complemented using the homologous gene. This will be done by DNA mediated transformation of viable fungal cells using non-mobilisable vectors carrying appropriate nutritional (for complementation of auxotrophy) or antibiotic (eg hygromycin and phleomycin) markers.

Immuno compromised mice will be infected with GM Aspergillus and Candida spp by nasal droplet, or intravenous injection, and after sacrifice tissues excised and
analysed for fungal gene expression.

**Recipient or parental organism**

**Escherichia coli:** strains in common laboratory use eg DH5alpha, XL-10 will be used as cloning tools. These strains, which are generally derivatives of the K12 strain, have a widespread and long history of safe laboratory use. They also contain numerous mutations eg thi-1 which render the strains auxotrophic and therefore unlikely to survive outside the laboratory environment. ACDP HG1

Aspergillus nidulans: there are a huge number of classically produced mutant strains of A. nidulans. These have been constructed in many strain backgrounds and often have been crossed many, many times. These strains have a long history of safe laboratory use and usually contain auxotrophic mutations eg argB that would prevent survival outside the laboratory. ACDP HG1

Aspergillus fumigatus: AF237, D141 and ATCC46645, 293, CEA10 and auxotrophic derivatives thereof eg pyrG will be used to construct knock-out, regulatable and reconstituted strains. These backgrounds have a long and safe history of use worldwide. Additionally the pyrG auxotrophies would prevent survival outside the host. ACDP HG2

Candida albicans: SC5314, CAI4 and CAI10 and auxotrophic derivatives thereof eg his3/ his3, ura3/ura3 will be used to construct knock-out, regulatable and reconstituted strains. ACDP HG2

Candida glabrata: ATCC2001 and auxotrophic derivatives thereof eg his3, ura3, trp1 will be used to construct knock-out, regulatable and reconstituted strains. ACDP HG2

Pichia pastoris: A methylotropic yeast used as a protein expression system, commercially sourced. GS115 and SMD1163 and auxotrophic derivatives thereof eg his4 will be used to express selected fungal proteins. These strains have a long and safe history of laboratory use worldwide. ACDP HG1

Saccharomyces cerevisiae: the majority of laboratory strains are derived from three major wild type lineages S288C,

We also seek permission to use other strains of the spp described above that have essentially the same characteristics as those described.

**Host/vector system**

E. coli and S. cerevisiae vectors including pUC, pBluescript, YE, YI and YC series and similar

We will use a series of C. glabrata episomal vectors (Kitada et al, Gene 175:105, 1996)

Mobilisable Aspergillus vectors will not be used.

**Origin & function**

We will construct Aspergillus and Candida libraries in Saccharomyces cerevisiae/Escherichia coli shuttle vectors e.g. YEp24. Genes of interest will be sequenced and characterised further.

As part of this further analysis gene disruption and replacement experiments will be performed. In addition these lesions will be complemented using the homologous gene. It is not possible to list all of the genes that will be inactivated as we are attempting to characterise complex processes required to maintain fitness en vivo, e.g. nutrient sensing, adherence, metabolic plasticity etc. Disruption of these genes adheres is by definition likely to result in a reduced ability to survive in vivo and therefore to cause disease. Inserted genes will either be from the same species, eg used to complement a null allele to create a reconstituted strain, tags added to selected genes eg GFP, TAP, HA, etc. Or Heterologous antibiotic genes eg ampR, bleR, hygR as markers of transformation.

**Evaluation of foreseeable effects**

The most hazardous GMM will be a reconstituted Hazard group 2 Fungal pathogen from the list of hosts e.g. Aspergillus fumigatus. This will occur where gene disruption and replacement experiments have been performed and lesions complemented using the homologous gene and where DNA mediated transformation of non-mobilisable vectors is used carrying appropriate nutritional genes for complementation of auxotrophy.

Any antibiotic or antifungal selection markers will not be the same as those used for frontline therapy.

The worst case GMO constructed is not anticipated to be any more hazardous than the wild type organisms. It is unlikely that an accidental release would harm the environment. Although classified as Hazard group 2, GM Class 2 the Aspergillus and Candida spp used are opportunistic pathogens that cause disease principally in immuno compromised individuals.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste - Treated with virkon at a minimum of 1% concentration after dilution with the waste for a minimum of 30 minutes. Disposal after treatment will be to drains. This has been independently validated as an effective method of inactivasting of the fungal pathogens in use and Aspergillus spores
http://www.therapeuticresource.ca/sporicidal.html

Solid waste - Plastic pipette tips will be disposed of into a 1% virkon solution after use for a minimum of 30 minutes before being drained and subject to autoclave treatment detailed below.

Solid Waste - Solid waste will be placed into autoclave bags and taken in lidded containers to the autoclave for treatment at 134 degrees for up to 30 minutes holding time. This waste will then be placed in orange clinical waste bags for disposal as clinical waste by the authorised Imperial College waste contractor.

The Autoclave is serviced quarterly.

Annually a worst case scenario mock load is prepared and placed in the autoclave. An engineer using a 12pt thermocouple load temperature NAMAS test apparatus ensures that every test point within the load achieves a temperature known to be effective at inactivating pathogenic microorganisms. At the same time the autoclaves load and chamber sensors are calibrated against the test rig.

In all cases a minimum of a $10^5$ reduction in microbiological burden is expected.

Purposes of the contained use

Background and Aim:
We are studying the pathogenesis of invasive fungal and bacterial infections in solid organ and haematological transplant patients. I have established a new murine model of transplant immunosuppression in which to define the immunopathogenesis of infection in these patients. Thus far I have investigated the immune responses to Aspergillus fumigatus in these patients, and have appropriate permissions for this work and clearance for Aspergillus fumigatus wild type strains. However I now need to develop murine models of Pseudomonas aeruginosa, Candida albicans/glabrata, and Cryptococcus neoformans and define the host/pathogen-dependent components of virulence in these organisms relevant to solid organ transplantation. I have NREC ethical approval to study peripheral blood immune responses to infection in solid organ transplant patients at Hammersmith Hospital. I am now starting to investigate the immunopathogenesis of invasive fungal and bacterial infections in lung transplant patients from the Harefield Hospital. Appropriate ethical permissions have been obtained from the Royal Brompton and Harefield NHS Trust Biomedical Research Unit Biobank.

Summary of the experimental procedure:
BALB/c/C57Bl/6 or derived knockout mice will be immuno suppressed with standard transplant-relevant immunosuppressants and be infected with Aspergillus fumigatus, Candida spp., Cryptococcus neoformans or Pseudomonas aeruginosa by the intra-nasal or intravenous or oral route and immune responses assayed by organbased RTPCR, ELISA or transcriptomic methods. In addition we will develop florescent/luminescent genetically modified fungal and bacterial strains in order to enable the quantification of pathogen burden either through the use of in vivo florescence imaging or FACS analysis of cellular suspensions. In addition we will breed genetically-modified pathogen gene deletion strains in order to determine the direct effects of transplant immunosuppressants on...
virulence, as many of these drugs have direct anti-fungal or anti-bacterial effects as well as being immunosuppressants (i.e. macrolides, steroids).

We will be undertaking parallel clinical studies of immunity to infection in solid organ transplant patients. This will require the analysis of immune responses in peripheral blood by FACS, RT-PCR and ELISA and similar studies in bronchoalveolar lavage isolates from these patients. All of these patients have regular screening for blood-bourne pathogens, and patients with these blood-bourne pathogens will be excluded from the study. However as part of the study we will culture clinical isolates of Aspergillus spp., Candida spp., Cryptococcus spp., and Pseudomonas spp. for subsequent phylogenetic and virulence analysis.

For in vitro studies we will use plasmid-based siRNA and reporter plasmids in order to knock down specific innate immune effectors in human/mouse primary/cell lines and measure their expression and activation in response to specific PAMP stimulants or infection with wild type pathogens or mutants. In addition we will use specific drug inhibitors and liposomal siRNA transfection.

The primary cell lines in use in the laboratory are RAW24.7, MH-S, U937, A549, HL-60, THP-1, NKL, NK92, YTS

Overview of the GMO's:

For fungal pathogens the key focus will be to develop fluorescent strains suitable for in vivo imaging studies and in addition gene deletion/mutation strains for analysis of the role of the calcineurin pathway in fungal virulence.

For bacterial strains the key focus will be the creation of fluorescent and strains for in vivo imaging analysis. In addition targeted deletions and mutations will be undertaken depending on results of virulence studies.

For mammalian studies we will use adenoviral and lentiviral transduction to either knock down specific components of host immune responses by siRNA, and in addition to enable reporter contracts and fluorescent constructs for in vitro imaging.

For in vivo murine work we will cross CreRecombinase mice with Floxed allele mice for key innate immune components and generate cell-specific inducible gene disruptions for analysis of host immunity.

Recipient or parental organism

Peripheral blood and bronchoalveolar lavage samples and lung transbronchial biopsy samples from patients and healthy controls

Mammalian: RAW24.7, MH-S, U937, THP-1, HL-60, A549, NK92, YTS, NKL from ATCC/HPA

Aspergillus fumigatus Ku80/CEA10/AF293/ATCC46645

Cryptococcus neoformans H99

Candida albicans 5301

Candida glabrata 2001

Pseudomonas aeruginosa PAO1, PA14, PAK, CHA, PA103

E. coli DH5, K12, TG1, HB101

Escherichia coli: strains in common laboratory use eg DH5alpha, XL-10 will be used as cloning tools. These strains, which are generally derivatives of the K12 strain, have a widespread and long history of safe use. They also contain numerous mutations eg thi-1 which render the strains auxotrophic and therefore unlikely to survive outside the laboratory environment.

Aspergillus nidulans: there are a huge number of classically produced mutant strains of A. nidulans. These have been constructed in many strain backgrounds and often have been crossed many, many times. These strains have a long history of safe laboratory use and usually contain auxotrophic mutations eg argB that would prevent survival outside the laboratory.

Aspergillus fumigatus: Af237, D141 and ATCC46645, Af293 and CEA10 and auxotrophic derivatives thereof eg pyrG or antibiotic selection-mediated gene disruption derivatives thereof eg hygromycin-resistant clones, will be used to construct knock-out, regulatable and reconstituted strains. These backgrounds have a long and safe history of use.
worldwide. Additionally the pyrG auxotrophies would prevent survival outside the host.
Candida albicans: SC5314, CAI4 and CAI10 and auxotrophic derivatives thereof eg his3/his3, ura3/ura3 will be used
to construct knock-out, regulatable and reconstituted strains. These strains have a long and safe history of use
worldwide.
Candida glabrata: ATCC2001 and auxotrophic derivatives thereof eg his3, ura3, trp1 will be used to construct knockout,
regulatable and reconstituted strains. These strains have a long and safe history of use worldwide.
Pichia pastoris: GS115 and SMD1163 and auxotrophic derivatives thereof eg his4 will be used to express selected
fungal proteins. These strains have a long and safe history of use worldwide.
Saccharomyces cerevisiae: the majority of laboratory strains are derived from three major wild type lineages S288C,
could not survive outside the laboratory.
The use of Caenorhabditis elegans as a model nematode host for infection modelling. The strain used is: AU37
(genotype; glp-4(bn2) I; sek-1(km4) X. glp-4 was identified in screens for loci that when mutated result in
hermaphrodite sterility; glp-4 was originally defined by a single recessive mutation, bn2, that results in temperatuesensitive
sterility in males and hermaphrodites, with the latter also exhibiting incomplete gonadal morphogenesis;
GLP-4 activity is required during the later larval and adult stages of development, and is necessary for germ cells to
progress efficiently through mitotic prophase and thus continue to proliferate. SEK-1 has MAPKK activity and belongs
to the MAPKK family.
We also seek permission to use other strains that have essentially the same characteristics as those described.
For mammalian studies we will use adenoviral and lentiviral transduction to either knock down specific components of
host immune responses by siRNA, and in addition to enable reporter constructs and fluorescent constructs for in vitro
imaging.
For in vivo murine work we will cross CreRecombinase mice with Floxed allelle mice for key innate immune
components and generate cell-specific inducible gene disruptions for analysis of host immunity. Standard knockout
mice will also be used. GM mice have been assessed seperately.

Host/vector system

For mammalian studies we will use commercially available attenuated adenoviral and 3rd generation lentiviral vector
transduction to either knock down specific components of host immune responses by siRNA, and in addition to enable
reporter constructs and fluorescent constructs for in vitro imaging. e.g. Vira power and Adenoviral Gateway expression
kits from Invitrogen.
For in vivo murine work we will cross CreRecombinase mice with Floxed allelle mice for key innate immune
components and generate cell-specific inducible gene disruptions for analysis of host immunity.
For fungal deletions we will use the plasmids pYes2 and pUChph which are episomal plasmids with selectable
markers. We will use standard E. coli and S. cerevisiae vectors eg pUC, pBluescript, YE, YI and YC series.
We will use a series of C. glabrata episomal vectors (Kitada et al, Gene 175:105, 1996). These carry HIS3, TRP1 or
URA3 markers.
For Cryptococcus neoformans Biolistic deletion and Candida PCR-based deletion will be used.
We will use standard E. coli and S. cerevisiae vectors eg pUC, pBluescript, YE, YI and YC series.
We will use a series of C. glabrata episomal vectors (Kitada et al, Gene 175:105, 1996). These carry HIS3, TRP1 or
URA3 markers. We will also use pSKII for gene disruption in C. glabrata and pCg-ACT14 for reconstitution.
We will used standard E. coli vectors:
a) For cloning:
-pCR2.1 and derivatives: ColE1 replicon, AmpR, KanR ; vecteur TA cloning for PCR products (InVitrogen). Allows
alpha complementation and blue/white cscreening on Xgal containing plates,
- pBR322 and derivatives: AmpR, TetR.
- pACYC184 and derivatives: ChiR, TetR.

NB: These vectors could also be used as suicide vectors for P. aeruginosa mutagenesis.

b) For gene tagging and expression:
- pET22b/28c/28a and derivatives: ColE1 replicon, AmpR (22) and KanR (28). Tag Histidine N or C-terminal.
- pQE30Xa and derivatives: Tag histidine (Qiagen). AmpR.
- pEGFP and derivatives: engineering of gfp fusion. AmpR.
- pGEX and derivatives: Tag GST (Glutathion S-transferase). AmpR.
- PAC or PAN and derivatives: AviTag. AmpR.
- pBADmychHisA, B, C and derivatives: expression from an arabinose promoter, tag histidine and Myc. AmpR.
- pYZ4 and derivatives: KanR. Construction of phoA fusion.
- GATEWAY plasmids: InVitroGen. System including the entry vector pDONOR and the destination vectors (pDEST derivatives) for recloning and expressing tagged genes.

c) For expression of genes under strong promoters:
- pBAD and derivatives: arabinose promoter. AmpR.
- pT7-1 to pT7-6 and derivatives: T7 promoter. AmpR. To be used together with pGP1-2 which carries the gene encoding RNA polymerase from T7 phage. KmR.

d) For studying protein-protein interaction:
- pUT18c and pKT25 and derivatives. Two hybrid system from Ladant, pUT18c (pUC19 derivative), AmpR, contains 3’ region of the gene encoding adenylate cyclase (cyaA). pKT25 (pSU40 derivative), KanR, contains 5’ region of cyaA.
- pBS1479 and derivatives: AmpR. Tandem Affinity Purification (TAP). The TAP-Tag contains a domain CBP (Calmodulin Binding Protein) and a domain Protein A (Affinity for IgG).

2) We will use suicide vectors for the engineering of Pseudomonas mutants:
- pKNG101 and derivatives: StrR. SucR. Only replicate in the E. coli ambdapir strain CC118.
- pEX100 and derivatives: SucR. Only replicate in E. coli ambdapir strain CC118

3) We will use broad host range vectors for expression in P. aeruginosa (also replicative in E. coli):
- pLAFR1, pLAFR3 and derivatives: IncP, TetR. Cosmid with low copy number.
- pUCP18/19 and derivatives: AmpR. Drivatives of pUC18/19 with a 2.1 kb stabilizing fragment allowing replication in Pseudomonas.
- commercially available third generation adenoviral or lentiviral vector systems such as ViraPower™ Adenoviral Gateway™ Expression Kit from Invitrogen

For fungal deletions we will use the E. coli derived plasmids pYes2 and pUChph which are episomal plasmids with selectable markers. We will use standard E. coli and S. cerevisiae vectors eg pUC, pBluescript, YE, YI and YC series.

We will use a series of C. glabrata episomal vectors (Kitada et al, Gene 175:105, 1996). These carry HIS3, TRP1 or URA3 markers. These are available from the Bignell and Haynes labs.

For Cryptococcus neoformans Biolistic deletion and Candida PCR-based deletion will be used. The standard constructs are from Ken Haymes lab, Exeter.

We will use standard E. coli and S. cerevisiae vectors eg pUC, pBluescript, YE, YI and YC series.

We will use a series of C. glabrata episomal vectors (Kitada et al, Gene 175:105, 1996). These carry HIS3, TRP1 or
URA3 markers. We will also use pSKII for gene disruption in C. glabrata and pCg-ACT14 for reconstitution. These are from the Haynes lab.

We will used standard E. coli vectors from the Bignell lab, Imperial College London:

a) For cloning:
   - pBR322 and derivatives: AmpR, TetR.
   - pACYC184 and derivatives: ChlR, TetR.

b) For gene tagging and expression:
   - pET22b/28c/28a and derivatives: ColE1 replicon, AmpR (22) and KanR (28), tag Histidine N or C-terminal.
   - pQE30Xa and derivatives: Tag histidine (Qiagen). AmpR.
   - pEGFP and derivatives: engineering of gfp fusion. AmpR.
   - pGEX and derivatives: Tag GST (Glutathion S-transferase). AmpR.
   - PAC or PAN and derivatives: AviTag. AmpR.
   - pBADmycHisA, B, C and derivatives: expression from an arabinose promoter, tag histidine and Myc. AmpR.
   - pYZ4 and derivatives: KanR. Construction of phoA fusion.
   - GATEWAY plasmids: Invitrogen. System including the entry vector pDONOR and the destination vectors (pDEST derivatives) for recloning and expressing tagged genes.

b) For expression of genes under strong promoters:
   - pBAD and derivatives: arabinose promoter. AmpR.
   - pT7-1 to pT7-6 and derivatives: T7 promoter. AmpR. To be used together with pGP1-2 which carries the gene encoding RNA polymerase from T7 phage. KmR.

c) For studying protein-protein interaction:
   - pUT18c and pKT25 and derivatives. Two hybrid system from Ladant, pUT18c (pUC19 derivative), AmpR, contains 3’ region of the gene encoding adenylate cyclase (cyaA). pKT25 (pSU40 derivative), KanR, contains 5’ region of cyaA.
   - pBS1479 and derivatives: AmpR. Tandem Affinity Purification (TAP). The TAP-Tag contains a domain CBP (Calmodulin Binding Protein) and a domain Protein A (Affinity for IgG).

d) For studying protein-protein interaction:
   - pUT18c and pKT25 and derivatives. Two hybrid system from Ladant, pUT18c (pUC19 derivative), AmpR, contains 3’ region of the gene encoding adenylate cyclase (cyaA). pKT25 (pSU40 derivative), KanR, contains 5’ region of cyaA.
   - pBS1479 and derivatives: AmpR. Tandem Affinity Purification (TAP). The TAP-Tag contains a domain CBP (Calmodulin Binding Protein) and a domain Protein A (Affinity for IgG).

2) We will use suicide vectors for the engineering of Pseudomonas mutants:
   - pKNG101 and derivatives: StrR. DucR. Only replicate in the E. coli pambdapir strain CC118.
   - pEX100 and derivatives: SucR. Only replicate in E. coli pambdapir strain CC118

3) We will use broad host range vectors for expression in P. aeruginosa (also replicative in E. coli):
   - pLAFR1, pLAFR3 and derivatives: IncP, TetR. Cosmid with low copy number.
   - pUCP18/19 and derivatives: AmpR. Derivatives of pUC18/19 with a 2.1 kb stabilizing fragment allowing replication in Pseudomonas.
   - commercially available third generation adenoviral or lentiviral vector systems such as ViraPower™ Adenoviral Gateway™ Expression Kit from Invitrogen

For mammalian studies we will use adenoviral and lentiviral transduction to either knock down specific components of
host immune responses by siRNA, and in addition to enable reporter constructs and fluorescent constructs for in vitro imaging. These are commercially available.

For in vivo murine work we will cross CreRecombinase mice with Floxed allele mice for key innate immune components and generate cell-specific inducible gene disruptions for analysis of host immunity. These will be from the Crabtree lab (Stanford), the Gordon lab (Aberdeen) and the Pepy lab (Montpellier).

Calcineurin is required for fungal morphogenesis and calcium signalling. GFP is a fluorescent protein.

As the genomes for these organisms are known, we may wish to knock-out a number of different genes as the work progresses.

**Evaluation of foreseeable effects**

We will be constructing gene deletion strains in the opportunists pathogens Candida albicans, Candida glabrata, Cryptococcus neoformans and Pseudomonas aeruginosa. As we are investing virulence attenuation these strains are likely to be less virulent than wild-type. Of note, all deletions in the calcineurin pathway thus far have severely attenuated virulence. We are also likely to generate fluorescent strains, however again these are unlikely to be no more virulent than wild-type.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

All knock-out mice will be housed in secure facilities in the Imperial South Kensington CBS.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All cultures and infected liquids will be sterilised by incubation in 1% Virkon/Distel for 1 hour and disposed of through designated sinks. Validated data supplied by the manufacturer dictates that this will result in inactivation of all organisms detailed in this proposal.

Contaminated glassware will be decontaminated by the addition of 1% Virkon/Distel and incubated at room temperature for 1 hour.

Solid waste, including plastics, tubes, pipettes, agar plates etc will be sterilised and disposed of via the university clinical waste service. All contaminated waste is disposed of into dedicated waste bins, which are sealed and subsequently sterilised by autoclaving at 134°C for 1 hour. Autoclave function is assessed by a chart recorder, 3 monthly servicing and an annual validation of a typical waste load using 12 point thermocouple testing.

Is an emergency plan required according to regulation 20?  

N

If yes, tick to confirm that it is attached to this form  

N

Tick to confirm that you have attached a risk assessment to this form  

Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  

N
Dear Dr AJ,

Following the discussion of your proposal entitled "Defining the pathogenesis of opportunistic fungal and bacterial infections in transplantation", GMIC-1438 at the last GM Safety Committee meeting, the Committee request that the following amendments are made to the proposal prior to approval:

2.16: Include sentence regarding commercially available lentiviral vectors.
4.12: Please answer this question.
5.8: Please include a room number. Check with H C
7.1: Safety Department to confirm alternative to Trigene.
10.2: Explain 'lavage'.
13.1: Include location of IVIS.

Spelling errors throughout the risk assessment.

Comments: S Herbst gave a brief description of the work. IH explained that Dr AJ could not attend the meeting therefore, IH emailed him questions about the risk assessment to present to the Committee. Some of the questions have been addressed by the PI and S H:

Questions from IH:

2.16: Please identify the adeno viral vectors and the lentiviral vectors mentioned in 2.14 and describe the degree to which they are disabled.
Ans: We have a number of these from J C we would like to order, S H has details and will amend the risk assessment.

4.3: Are these T cells from characterised cell lines or from clinical isolates from patients with known histories? If yes please state this, as after 96 hours culture there is an increased risk of propagating adventitious agents and we would need additional assurances that this is unlikely.
Ans: The patients have known histories and are screened (negative) for blood-borne viruses as it standard for transplantation

5.1: You will need to be quite specific about identifying the procedures that potentially generate aerosols. I don't think that the level 5 COP does this. Are these identified in individual SOP's? If so please send them through to the Safety Dept and reference them in the risk assessment.
Ans: I have sent all SOPS as current, these should detail this although I haven't had time to check this.

5.4: Change category 2 agents to infectious substances.
Ans: Agreed, will be done

5.5: Change category 2 agents to infectious substances.
Ans: Agreed, will be done

5.5: Are any of the agents imported from outside the UK in FCS or BSA? If yes please contact the Safety Dept (M B) as you may need an import licence.
Ans: No
5.7: Are rotor buckets opened in an MSC?
Ans: Yes, we will modify this section
5.9: Is there any dissection of animals to remove organs? If so please amend this section
Ans: Agreed, will be done
5.10: Fluorescence imaging of whole animals or organs?
Ans: Both, this will be clarified in the section
5.12: Autoclaving is ok as an inactivation process so long as it is carried out in an autoclave tested and validated for this purpose. Is this the case? Has the microwave inactivation process been validated by yourselves or others and can you provide data to confirm the degree of inactivation?
Ans: The Autoclave is validated for aspergillus, candida and bacteria, crypto is new, SH can ask Jon Perfect
6.5: Please make it clear that normal spectacles do not provide sufficient protection.
Ans: Agreed, will modify this section
7.1: Please specify the final concentration of Trigene e.g. A minimum concentration of 1% after dilution with the liquidwaste.
Ans: Agreed, we will mention that it is 10% for killing fungi.
7.1: change hood to MSC
Ans: Agreed, we will modify the section
8.1: Your local safety Officer should be able to help with the details of the service provider.
Ans: Agreed SH to enquire
14: Please complete this section for the Gmo's that are going to be created.
Ans: Give me a clue about what this box is, I am not sure what project aspect for instance means?
IH: This is fairly straight forwards for example in your case One aspect of the project would be E.coli cloning using non mobilisable vectors such as pUC and pbluescript with non toxic, non pathogenic inserts. Class 1
Second aspect for example Creation of gene deletion mutants in Hazard group 2 fungal pathogens Cryptococcus neoformans, Aspergillus fumigatus in order to study the calcineurin pathway in fungal virulence. Class 2
Third example Creation of gene deletion mutants in hazard group 1 opportunistic fungal pathogens Candida albicans, Candida glabrata in order to study the calcineurin pathway in fungal virulence. Class 1
And so on. I can see two other aspects to this work, the class 2 Pseudomonas and the mammalian cell line studies using adenoviral and lentiviral transduction that need mentioning in the same way. I'm assuming that the latter will be class 1 but this will depend on the level of attenuation of the vectors.
In the Meeting:
RW asked if the animals involved were GMO's.
If there are GM mice involved, please fill in the GM Form B.
HK asked what the samples were screened for.
S Herbst answered the samples were screened for blood borne viruses, such as; Hepatitis and HIV.
HK inquired if the samples were from transplant patients.
S Herbst explained they were, such as lungs, kidneys, etc.
HK checked if this involved clinical trial patients.
S Herbst confirmed, no.
SH queried what they did with samples that came back as positive.
S Herbst explained that positive samples would be disposed of and not used.
HK pointed out that the final concentration of disinfectant after dilution with the liquid waste needed to be stated.
Also, Trigene was no longer available. The Committee discussed alternatives to Trigene and concluded that this would be confirmed once M B (Associate Biological Safety Officer) attended the meeting to discuss this.
SH questioned if the full body imaging facility would be used?
S Herbst confirmed that they would be.
RB suggested including the IVIS and its location in the risk assessment.
S H asked the Committee for advice. They did not currently know what viral vectors if they would be using, should they remove this element form the RA or keep it in?
IH suggested including adding a sentence in Section 2.16 that was broad but confirmed the limitations of what might be using for example using 3rd generation self-inactivating lentiviral vectors that are commercially available.
RW also advised stating 2 or 3 of these suppliers.
IH pointed out that Cryptococcus was coming off the Schedule 5 list soon. Until this is confirmed after the 1st of October, consent for the Cryptococcus cannot be given.
Agreed: Class 2, Containment Level 2. This project is notifiable to the HSE.
Could you please ensure that the risk assessment is revised (add GMIC number) and the amendments above addressed. I will then forward the form onto Occupational Health to complete. The completed HSE form (attached to this email), and cheque made payable to the HSE should be sent to me (@imperial.ac.uk), I will then send it all to the HSE. Please ensure the information given in HSE Form relates to that provided in your risk assessment.
For further information, please see http://www3.imperial.ac.uk/safety/subjects/biosafety/geneticmodification.
Please note that this work must be notified to the HSE and an acknowledgement receipt received prior to this work commencing.

To characterize the flagellar motor of Campylobacter jejuni. The bacterial flagellar motor is a rotary motor that spins a long tail that acts as a helical propellor, enabling the bacteria to swim. Interestingly, the Campylobacter motor, although related to the "standard" motors of Escherichia coli or Salmonella enterica, is considerably more complex. By studying the Campylobacter motor we can gain comparative insights into how the motor functions, how the motor evolved (as the added complexity of Campylobacter is a relatively recently evolutionary acquisition), and furthermore develop novel, specifically anti-Campylobacter antibiotics (disruption of the motor decreases pathogenicity).

To do this we will be growing wild type and mutants of C. jejuni and imaging them in 3-D in an electron cryo-microscope. Furthermore, the closely related Helicobacter pylori and Helicobacter hepaticus have similar flagellar motors that will also be examined.

Overview of the GMMs to be constructed: Insertion of short peptide tags into pre-existing genomically-encoded flagellar motility proteins in C. jejuni (e.g. FliG, GlgP, MotB); deletion of same genomically-encoded proteins. Use of non-pathogenic lab strains of E. coli (e.g. strain DH5α) for construction of plasmids and for conjugation-mediated plasmid transfer to C. jejuni, H. hepaticus and H. pylori for homologous recombination.

Experimental procedures will include: Genetic manipulation of Campylobacter jejuni, Helicobacter pylori, and Helicobacter hepaticus (electroporation and conjugation to insert genes on plasmids or make chromosomal deletions or insertions), culturing (on agar plates in microaerobic chamber or microaerobic jars), flash-freezing (using pneumatic or gravity-driven plunge freezers to rapidly propel <<1ul of sample on EM grid into liquid ethane/propane cryogen) with subsequent imaging in electron microscope at -180°. Electron microscopy will either in-house in the adjacent Flowers Building, or shipped under liquid nitrogen storage to an off-campus microscope in Manchester, Cambridge or Eindhoven or Leiden (Netherlands).

Recipient or parental organism
All recipient organisms involved are Hazard Group 2 pathogens, and are capable of causing disease in humans. The flagellar motor is important for pathogenesis.

C. jejuni infection causes diarrhea, which may be watery or sticky and can contain blood (usually occult) and fecal leukocytes (white cells). Other symptoms often present are fever, abdominal pain, nausea, headache and muscle pain. The illness usually occurs 2-5 days after ingestion of the contaminated foods or water. Illness generally lasts 7-10 days, but relapses are not uncommon (about 25% of cases). Most infections are self-limiting and are not treated with antibiotics. However, treatment with erythromycin does reduce the length of time that infected individuals shed the bacteria in their faeces.
Helicobacter hepaticus causes chronic hepatitis, liver cancer (hepatocarcinoma) and inflammatory bowel disease in mice. The organism is most likely transmitted by fecal-oral route however the mode of liver invasion is unknown but the production of urease and a soluble hepatotoxic factor may be involved in the pathogenesis of H. hepaticus-induced liver lesions.

The importance of H. hepaticus to humans is not yet completely known.

Over 80% if people infected with H. pylori show no symptoms. Acute H. pylori may appear as an acute gastritis with abdominal pain (stomach ache) or nausea. Where this develops into chronic gastritis, the symptoms, if present, are often those of non-ulcer dyspepsia: stomach pains, nausea, bloating, belching, and sometimes vomiting or black stool.

Host/vector system

Origin & function

Genes involved in C. jejuni flagellar motility as well as homologous genes in H. hepaticus and H. pylori. Key examples include fliG (rotor component of flagellar motor, required for motility), flgP, flgQ, pflA, cjj0413 (unknown function, required but form components of the flagellar motor and are required for motility).

This work will involve genetically modifying proteins naturally encoded by Campylobacter jejuni and related organisms with the intention of adding an additional shape onto the naturally-occurring proteins. We will then be able to directly see where this additional shape appears when we look at the Campylobacter flagellar motor using our electron microscope. This is important, because this will enable us to work out where each protein is found in the motor (not something we are able to do at the moment, as each protein looks very much alike at the resolutions of contemporary electron microscopes). The additional genetic material will derive from known proteins already structurally characterised by international scientists, and is extremely likely to somewhat impair the pathogenic potential of Campylobacter jejuni and relatives because it is likely to interfere with the function of the motor.

Evaluation of foreseeable effects

GMO bacteria will either behave as they usually do, or (more likely), their flagellar motors won't function quite as well after I've added an additional protein onto them. This is directly analogous to welding an additional piece of metal onto an arbitrary part of a motor engine (including moving parts), and expecting it to work normally. Additional proteins that I'll be fusing to existing proteins will be identified according to how well they fit criteria to be grafted onto the existing proteins from an international database (the Protein Data bank, or PDB) that contains the structures of proteins determined by scientists from around the world. If these grafted proteins have an enzymatic function, this will be removed by rational mutation before fusing to existing proteins.

In summary we anticipate that they will all be less harmful than the wild-type C. jejuni, H. pylori and H. hepaticus because some level of motility attenuation which in turn is required for pathogenesis.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be treated by chemical disinfection prior to disposal (Virkon to 1% final concentration); solid waste placed in heavy-duty plastic autoclave bags, loosely sealed with autoclave tape (to allow ingress of steam) and placed into blue boxes for transport to Biochemistry autoclaves (with affixed lid).
Autoclave is validated for a worst case scenario waste load to achieve a minimum temperature of 121 degrees for 15 minutes across multiple locations within the load itself.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Following the discussion of your proposals entitled "Structural dissection of the flagellar motor from Campylobacter jejuni and related epsilon-proteobacteria", (GMIC -2267) at the last GM Safety Committee meeting, the committee request that the following amendments are made to the proposals to approval:

Comments: MB gave a brief description of the work.
MB informed the Committee that he now has new rooms for his work.
IH pointed out that if MB planned to ship any material to another organisation that he should inform the of the type of material and how it had been treated. Based on the information he provided it would be up to their BioSafety Officer and GM committee to decide how it should be handled at their end and what risk assessments they may need to complete.
HK queried the degree of kill in the freezing experiments.
MB explained when the bacteria was frozen, they were fine, it was during the thawing process when they were killed. The blot, freeze and thaw experiment would be carried out a few times to check this.

The following amendments are required prior to approval:

2.1 and 4.1: Hatch the top box if not using tissue.
10.1: Specify the disinfectant and the concentration required to be achieved after dilution with the liquid spill. E. g. Add an equal volume of 2% virkon.
13: Specify the lab as this will need to be inspected before work can start.

Agreed: Class 2, Containment Level 2. This project is notifiable to the HSE.
Could you please ensure that the risk assessment is revised (add GMIC number) and the amendments above addressed. I will then forward the form onto Occupational Health to complete. The completed HSE form (attached to this email), and cheque made payable to the HSE should be sent to me (address given). I will then send it all to the HSE. Please ensure the information given in the HSE form relates to provided in your risk assessment.
For further information please see http://www3.imperial.ac.uk/safety/subjects/biosafety/geneticmodification.
Please note that this work must be notified to the HSE and an acknowledgement receipt received prior to this work commencing

Animal Units

Large Scale Activities

Human Clinical Applications

02/03/2022
The primary objective of the research is to examine the asexual and sexual stages of Plasmodium in vitro and in vivo towards dissecting how malaria parasites move and use this understanding to develop new tools for the efficient assessment of potential anti-malarial agents, specifically to assess their ability to impair parasite motility, growth, development and transmission through the lifecycle. This requires the development of transgenic (genetically modified, [GM]) parasites that either: i) express fluorescent proteins across different stages of the asexual or sexual stages of parasite development, allowing for easy visualisation of these lifecycle stages, ii) express heterologous proteins from other organisms that permit complex genetic reorganisation in the parasite cell (e.g. Cre or FLP recombinases) or drug resistance (e.g. dihydrofolate reductase or blasticidin resistance markers) in derived parasite lines to facilitate their selection from non-genetically engineered lines, iii) genetically engineer endogenous proteins to incorporate fluorescent, drug resistant, or antigen tags for their cellular localisation or immunoprecipitation from parasite derived lysates and, iv) have individual genes that are potentially important in motility or development partially or wholly disrupted (knockout [KO] or knockdown [KD]). By examining the derived parasite lines and their resultant phenotypes (in particular for KO or KD), we aim to yield information relating to fundamental parasite cell biology, in particular parasite cell movement and/or development towards understanding growth, development and malaria parasite transmission. Whilst the majority of studies will be entirely via in vitro culture (using human blood from the blood bank in culture dishes), provision is sought to potentially include downstream experiments to explore parasite transmission through mosquitoes (parasites being fed by membrane feeders (as per current Code of Practice [CoP]) to adult Anopheles mosquitoes) or infection models with humanised mice (to explore pre-erythrocytic stages of development).

Most work will be focussed on Plasmodium falciparum with a small comparative set of experiments focussed on another laboratory adapted human parasite species Plasmodium knowlesi. Non-transgenic (non-GM) work with the third major human species Plasmodium vivax, will be undertaken when possible from isolates either available from the malaria reference repository (MR4) or from hospital isolates.
GM mosquitoes and GM mice may be used in the project and GM mosquitoes may be generated through the project (GM mice will only be sourced and will not be directly generated). Where GM mosquito generation is desired, these will be assessed on a Imperial College GM Form B before being used, stored or generated.

Recipient or parental organism

P. falciparum strains 3D7, NF54, D10, CS2 and Dd2 will be used. All are long-standing laboratory strains maintained in continuous culture for decades. P. falciparum is classified as ACDP 3** Annex 1: Biological agents which may be used at less than the minimum containment conditions”. P. knowlesi (strain A1-H) is a widely used laboratory strain classified as human simian malaria ACDP 2.

Host/vector system

pHTK, pCC1, pCC4, pD3HA circular DNA vectors are widely used to transform Plasmodium species and carry either the resistance marker human DHFR mutated to encode resistance to WR99210 or Blasticidin S deaminase gene from Aspergillus terreus to confer resistance to Blasticidin. These do not affect resistance to anti malarials chloroquine, mefloquine, artemisinin or doxycycline which can be used (or their derivatives) to treat malarial infections.

Origin & function

Two types of GMM P. falciparum and P. knowlesi will be generated: reporter strains and knock-out strains. We will create transgenic P. falciparum or knowlesi parasites that express fluorescent or luminescent proteins (for example, but not limited to, YFP, GFP, RFP, PA-GFP) in the asexual stages of the parasite to facilitate tracking life stages, or proteins of interest in the parasite. We will also create knock-outs of genes in the parasite that we think are important in parasite cell motility. Examples include secreted or transmembrane proteins expressed at the merozoite or ookinete stages of the parasite.

Altered and or inserted genes will include:
- Fluorophores, both conventional and photoactivatable
- Epitope tags, including hexa-HIS, GST, HA epitope, FLAG epitope and CLIP epitopes, for localisation or immunoprecipitation based purification
- Plasmodium altered genes may also include those that are knocked out (removed), knocked down (where insertion of domain induces protein instability or gene instability that reduces expression) or flanked by sequences that initiate gene excision (FLP/Cre) for conditional knockout.

Origin & function

The programme of work requires the development of transgenic (genetically modified, [GM]) parasites that either; i) express fluorescent proteins across different stages of the asexual or sexual stages of parasite development, allowing for easy visualisation of these lifecycle stages, ii) express heterologous proteins from other organisms that permit complex genetic reorganisation in the parasite cell (e.g. Cre or FLP recombinases) or drug resistance (e.g. dihydrofolate folate reductase or blasticidin resistance markers) in derived parasite lines to facilitate their selection from non-genetically engineered lines, iii) genetically engineer endogenous proteins to incorporate fluorescent, drug resistant, or antigen tags for their cellular localisation or immunoprecipitation from parasite derived lysates and, iv) have individual genes that are potentially important in motility or development partially or wholly disrupted (knockout [KO] or knockdown [KD]). By examining the derived parasite lines and their resultant phenotypes (in particular for KO or KD), we aim to yield information relating to fundamental parasite cell biology, in particular parasite cell movement and/or development towards understanding growth, development and malaria parasite transmission.

All GMMs to be constructed are expected to be of equal hazard to human health and the environment as parent strains (both Plasmodium species). Insertions, deletions or disruption of genes are not expected to increase the ability of the Plasmodium parasite to infect humans, increase drug resistance (beyond an experimental setting) or pose an increased risk to the environment. At no point will parasites be engineered to increase virulence.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Plasmodium falciparum (and derivatives) is a hazard group 3 pathogen requiring CL3 containment. Derogation from full containment is sort in the form of the requirement to decontaminate the laboratory in the event of a spill by fumigation. All other precautions required for full CL3 will be applied.
P.falciparum is not airborne, nor carried by droplet formation it requires direct contact to blood stream. Culture volumes in use are relatively small at 150ml per flask, these agents are extremely easily broken down and cannot survive and/or multiply in the environment, it is not considered necessary by this risk assessment to fumigate the laboratory in the event of a spill or release.
The laboratory proposed for use by this project is currently notified to the HSE as being derogated from full CL3 for fumigation.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste - Disinfected in 10% Chloros, final concentration.

Solid waste - the CL3 facility has a dedicated autoclave that is maintained and serviced by the Department. Servicing includes an annual 12 point thermocouple test with dummy loads and regular servicing throughout the year from a competent contractor.

All solid waste is autoclaved before leaving the CL3 facility and waste cycles verified by successful completion and print out.

Details of the autoclave are included in the associated CL3 code of practice for the facility.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
Comments: The committee discussed the comments made by IH prior to the meeting. SH and IH have visited the room with the FACs machine and observed the procedure for possible spill incidents. The FACs is an enclosed system except when the sample is drawn into the machine. The lid has to be removed from the sample tube (volume approx. 1.5ML) which is affixed to the machine sample dipper. The sample is taken into the machine by applying a positive pressure to the tube. There is a risk that the tube might be dropped or dislodged from the machine. In practice this is unlikely if proper procedures are followed. Training in these procedures will be key to avoiding incidents. The high throughput sampling system works in a similar manner but uses a multi well plate instead of a single tube.

The following amendments were required prior to approval:

We are going to need specific SOP's and amendments to the existing COP to accommodate the work
1.1: How will the parasites be fed to the mosquitoes? Membrane feeders as per the COP?
1.2: Typo ‘Kensington’
1.3: Specify which Laboratories the work will be carried out in.
2.10: Edit form and add spaces between strains to match up with the names of the agents.
2.15: Remove sentence, “All of these strains are genetically modified to tolerate plasmid…”
4.7: Typo ‘phlebotomist’
4.17: Typo ‘vectorsvectori’
4.18: It is worth stating that "no work known or expected to increase the pathogenicity of the parasite will be carried out" this will help set the limits of the work.
4.21: Typo ‘innocation’
5.2: What is the route to the imaging facility? Does this involve moving parasites along the corridor? If so how are they contained?
5.3: Please describe the procedure including transport and containment. This is likely to be a case for a new SOP.
5.5: Will you import any mosquitoes?
5.9: Current COP states use of sharp needles because the diaphragm of the tipper is quite thick? It would be a great step forwards if blunt needles were used instead.
7.1: Typo "pipet"

Section 12: Should be left blank for the OH physician to complete.
Section 13.1: Please be specific about which Plasmodium species are used at CL 2 and which at CL3.
- Please be specific about which aspects of the protein, DNA work is carried out at CL3 and which at CL2.
- Please state that only fixed materials are removed to CL2. Counting of any live material must be carried out at CL3 although this may be in a derogated facility.

Agreed: Class 2, Containment Level 3. The HSE need to be notified of the significant change to containment.

02/03/2022
Here we propose to use the model apicomplexan parasites (as models for human malaria parasites): mouse malaria Plasmodium berghei and the apicomplexan parasite Toxoplasma gondii as model organisms to dissect the molecular basis of host cell interactions during apicomplexan parasite colonisation of the mosquito vector midgut or entry into host cells.

The work requires the development of transgenic (genetically modified, [GM]) parasites that either; i) express fluorescent proteins across different stages of the asexual (P. berghei or T. gondii) or sexual stages of parasite development (P. berghei only), allowing for easy visualisation of these lifecycle stages, ii) express heterologous proteins from other organisms that permit complex genetic reorganisation in the parasite cell (e.g. Cre or FLP recombinases) or drug resistance (e.g. dihydrofolate reductase or blasticidin resistance markers) in derived parasite lines to facilitate their selection from non-genetically engineered lines, iii) genetically engineer endogenous proteins to incorporate fluorescent, drug resistant, or antigen tags for their cellular localisation or immunoprecipitation from parasite derived lysates and, iv) have individual genes that are potentially important in motility or development partially or wholly disrupted (knockout [KO] or knockdown [KD]).

By examining the derived parasite lines and their resultant phenotypes (in particular for KO or KD), we aim to yield information relating to fundamental parasite cell biology, in particular parasite cell movement and/or development towards understanding their growth, development and ultimately to build complete models for extrapolating to human malaria parasite cell biology.

**Recipient or parental organism**

Plasmodium berghei ANKA strain. Toxoplasma gondii RH strain. Both are long-standing strains maintained in continuous passage or culture for decades by groups all over the world. Both are classified as ACDP 2.

**Host/vector system**

Vectors used are derived from various research groups and include: for P. berghei work the PlasmoGEM vectors (Wellcome Trust Sanger Institute) and pL series vectors (Leiden University); and for T. gondii ptet vectors (Glasgow University), pHXGPR and pCT vector series (University of Glasgow and University of Melbourne respectively).
Vectors encode the resistance marker human DHFR mutated to encode resistance to WR99210 or Pyrimethamine or (for T. gondii) the chloramphenicol acetyl transferase (CAT) selectable marker, ble selectable marker conferring phleomycin resistance, mycophenolic acid for HGXPRT.

**Origin & function**

Two types of GMM P. berghei and T. gondii will be generated: reporter strains and knock-out strains. We will create transgenic parasites that express fluorescent or luminescent proteins (for example, but not limited to, YFP, GFP, RFP, PA-GFP) or epitope tags (for example, but not limited to triple HA, 2 x cMyc or Ty tags) in the asexual/sexual stages of the parasites to facilitate tracking life stages, or proteins of interest in the parasite cell. We will also create knockouts of genes in the parasite that we think are important in parasite cell motility. Examples include secreted or transmembrane proteins expressed at the merozoite or ookinete stages of the parasite.

**Evaluation of foreseeable effects**

The programme of work requires the development of transgenic (genetically modified, [GM]) parasites that either; i) express fluorescent proteins across different stages of the asexual or sexual stages of parasite development, allowing for easy visualisation of these lifecycle stages, ii) express heterologous proteins from other organisms that permit complex genetic reorganisation in the parasite cell (e.g. Cre or FLP recombinases) or drug resistance (e.g. dihydrofolate reductase or chloramphenicol resistance markers) in derived parasite lines to facilitate their selection from non-genetically engineered lines, iii) genetically engineer endogenous proteins to incorporate fluorescent, drug resistant, or antigen tags for their cellular localisation or immunoprecipitation from parasite derived lysates and, iv) have individual genes that are potentially important in motility or development partially or wholly disrupted (knockout [KO] or knockdown [KD]). By examining the derived parasite lines and their resultant phenotypes (in particular for KO or KD), we aim to yield information relating to fundamental parasite cell biology, in particular parasite cell movement and/or development towards understanding growth, development and malaria parasite transmission. All GMMs to be constructed are expected to be of equal hazard or (the majority) lesser hazard to human health and the environment as the parent strains. Insertions, deletions or disruption of genes are not expected to increase the ability of the Plasmodium parasite ot Toxoplasma parasite to infect humans, increase drug resistance (beyond an experimental setting) or pose an increased risk to the environment. At no point will parasites be engineered to purposefully increase virulence.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Liquid waste - Disinfected in 10% Chloros or Virkon and then passed down the drain with water.
Solid waste - All solid waste is autoclaved before leaving the building. The waste cycles have been validated using 12 point thermocouple test and the autoclaves serviced and maintained as per manufacturer’s instructions. All completed sterilisation cycles are checked via a print out form the autoclave. The cycle has been validated for 126°C for at least 10 minutes.
Please enter comments on the GM safety committee on the risk assessment

Date of Significant Change
**Project Additional Information**

**Purposes of the contained use**

The main focus of the project is to understand the mechanisms of host defence against bacterial infections. Inflammasomes are signalling pathways involved in the activation of inflammatory caspases in cells. Caspases are enzymes that proteolytically process a number of substrates that have various biological functions, including antimicrobial responses. However, apart from a few substrates, most others remain unidentified. The main aim of this project is to identify and characterize novel substrates of caspases in infectious and non-infectious settings. This will involve:

1. Cloning and biochemical characterization of proteins in E. coli, Pichia pastoris and/or Sf9 insect cell lines.
2. Heterologous expression and studies of proteins in immunity against bacterial infections using various cell lines in vitro.
3. Use of fluorescence microscopy to study the cell biology of host immune factors in protecting against bacterial infections.
4. Use of wild-type and gene-knockout strains of mice to study the role of host effectors in antimicrobial defences in vivo.

Most studies will be undertaken using Salmonella and Listera as laboratory ‘work horses’ to dissect the molecular pathways involved in immune activation of caspases. However, after initial experiments are carried out, related studies with other bacteria will be undertaken to compare and contrast mechanisms of host defence against different commensals (e.g. E. coli and Citrobacter), non-pathogenic (E. coli, Bacillus) or pathogenic (as listed in 2.10) microbial agents.

**Recipient or parental organism**

Biohazard group 2:
- *Salmonella enterica* Typhimurium: The following strains will be used - SB136 (InvA::ahpC), SB2199 (delta 0PrgIJ ), SB2176 (delta ssaC), SB762 (flhD::Tn10)
- *Listeria monocytogenes*
- *Streptococcus pyogenes*
- *Streptococcus pneumoniae*
- *Staphylococcus aureus*
- *Pseudomonas aeruginosa*
- *Klebsiella pneumoniae*
- *Mycobacterium bovis* BCG
- *Mycobacterium avium* subsp. Chester
- *Vaccinia virus*
- *Sendai virus* (HG1 for humans and HG2 for environmental grounds)
- *Adenoviruses* serotype 5

**Host/vector system**

The lambda recombinase system has been used to generate deletion constructs. These include plasmids such as pKD3, pKD4, pKD13, pKD20, pKD46 and related along with helper plasmids for removal of antibiotic markers which are derived from pITNs that expresses the FRT recombinase. In some cases deletion was achieved through phage P22 transductions in Salmonella. Overexpression of proteins such as GFP/RFP use pFPV, pDiGC, pWSK, pRK5 and related plasmids.

**Origin & function**

Genetically modified microorganisms that will be used will be mostly for the generation of fluorescent strains expressing either GFP/YFP/CFP/RFP for use in fluorescence microscopy. Other GMM strains will be obtained commercially or from other scientists.

The following strains of *Salmonella enterica* Typhimurium and *Listeria monocytogenes* have been received - SB136 (InvA::ahpC), SB2199 (delta 0PrgIJ ), SB2176 (delta...
Type I and II secretion systems and flagellin genes will be targeted in Salmonella. GMM organisms of biohazard group 2 will be used for work to assess the role of the host immune response to bacterial infectious agents. This will involve work with cell lines and mice following appropriate operating protocols and rules where applicable. Targeted gene deletions will involve known classes of transcriptional units such as the type-3 secretion systems or flagellins to study their roles in the activation of innate immune signalling pathways. Adenovirus serotype 5 (attenuated, lacking early virulence genes) expressing GFP will be used.

No experiments are planned that involve intentional creation of strains more pathogenic than parental strains. All GMM involves mutation or deletion of virulence genes that should lead to loss of virulence on parental strains. Most gene deletions will be carried out in collaboration with other established laboratories in the MRC CMBI to use their expertise in microbiology and microbial genetics.

Innate immune signalling genes such as capsase-1, caspase-11 and NLR and ALR genes may be expressed in eukaryotic cells using retro or lentiviral transduction to study their role in signal transduction.

Evaluation of foreseeable effects

No experiments are planned that involve intentional creation of strains more pathogenic than parental strains. All GMM involves mutation or deletion of virulence genes that should lead to loss of virulence on parental strains. Most gene deletions will be carried out in collaboration with other established laboratories in the MRC CMBI to use their expertise in microbiology and microbial genetics.

Innate immune signalling genes such as capsase-1, caspase-11 and NLR and ALR genes may be expressed in eukaryotic cells using retro or lentiviral transduction to study their role in signal transduction.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

GM animals in use are no more hazardous to human health or the environment than wild type. When infected with Class 2 GMO's the animals will be held in IVC's within the Imperial College Animal facilities at South Kensington.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste: Treatment with minimum final concentration after dilution with the waste of 1% Virkon for 60min followed by disposal in the sink. (minimum 1% Surfanios for mycobacteria)
Solid Waste: All other hazardous solid biological waste such as tissue culture plasticware (pipettes, flasks etc) will be autoclaved prior to disposal. Petri dishes with agar will be autoclaved prior to disposal.
Animal carcasses and bedding will be disposed as per BCS guidelines, also described in local rules.

13. * Is an emergency plan required according to regulation 20? Yes No
If "Yes", please check to confirm that it is attached to this form
14. *
Bio1 Form GMIC 2483
Role of inflammasomes during bacterial infections, GMIC-2483. Dr A Shenoy, Microbiology, Department of Medicine, South Kensington Campus.

Comments: HC explained this was a new group, in a new laboratory.
The Committee discussed the difference between a droplet and aerosol and the risk inhalation or of an eye splash. HC confirmed all the tissue culture work would be done in the Microbiological Safety Cabinet.
IH recommended adding an explanation to show human health was being protected while carrying out the work.
IH advised when referencing the Local Rules in the Bio1 form; to specify what section of the local rules to refer to.
The following amendments were required prior to approval: From first committee meeting Jan 2014
2.11: This is not correct about M avium being non-pathogenic. Please remove this statement
2.17: Use of GMO's includes those that have been created elsewhere but you are using in the lab. Please make sure that all imported GMO's are listed.
2.2: Add "and similar" to the cells lines to make it more generic.
4.1:0 Please be specific about the Mycobacterium sp
4.13: What is Vesphene and is there any validation data for this disinfectant?
4.18: Where it says generated; it really means used, so please include all imported GMO's in this statement. We have amended the Bio1.
4.19: Please explain why not?
4.22: Is the 2-3L of E.coli in one flask? Please give approximate numbers and volumes of a typical culture.
For all the following sections: Please provide a more accurate reference to the Local rules to make it easier to find the relevant text.
4.21: Please be specific about the Mycobacterium sp

5.1: Is there any risk of eye splash or inhalation/ingestion during streaking out especially the airborne/inhalation infection route organisms? We have had a few eye splashes during these procedures.
Explain why is Tissue Culture conducted in the MSC and not the work with infectious microorganisms?
5.2: What is meant by a sealed container? The local rules do not specify
5.3: What is being used to double contain the material? The local rules do not specify.
5.7: 30 minutes is a bit short. HSE in the past have suggested at least an hour.
5.8: The local rules do not describe the containment of this material in the shaking incubator. Please provide a description of the sealed containers that you are using.
5.10: There are some blanks in this section that need completing. Where will the work take place? Have you checked with CBS that your training in the US is valid in the UK?
5.12: Is there any plan to run viable material through an FACS?
- Describe that as a result of using Trizol in the process, this will inactivate the materials.
5.13: Where are the protocols for working with LN2 in the local rules? Please provide an accurate reference to the page and section or attach a separate SOP
7.1: Please specify that the concentration of virkon is 1% after dilution with the waste and give the contact time. What is Vesphene and is there any validation data for its effectiveness against M. avium etc
13.4: Please clarify the sentence.
15.1: What about the gene knock outs and deletions?
Agreed: Class 2, Containment Level 2. The HSE need to be notified.

The following comments were required by committee prior to approval following the second meeting in April 2014 to discuss significant changes made to the Bio1 by the PI following the first committee

1.2: Change “tissue culture cabinet” to “microbiological Safety Cabinet”. Please also clarify the ‘fixed samples’.

2.10: The agents listed need to be in the COP also.

2.12: VSV is ordinarily a HG 3 animal pathogen. However you should state that VSV may be worked on at CL2 under the circumstances of this project as the use as part of an assay system and the small quantities proposed allow for reduced containment under a clause in the classification of animal pathogens by DEFRA
A SAPO licence will still be required.

2.15: Sendai virus although Hazard group 1 for humans will be a class 2 GMO on environmental grounds.

2.16: Do any of these plasmids contain the WPRE capable of expressing all or part of the X protein?

2.17: What are the characteristics of the “other GMM strains” obtained commercially or from colleagues? Please clarify.

4.12: Please be specific about the Mycobacterium Sp and list them.

4.13: 10% virkon will not be effective for the Mycobacterium strains listed in 4.12. The Committee recommends surfanios as an alternative.

5.1: Change “cat 2 biosafety cabinet” to Class 2 Microbiological safety cabinet”

5.9: Can you please use blunt needles for cell lysis? They are available from regular suppliers of needles.

5.10: Please complete a GM Form B and submit for approval.

5.12: We will need an SOP for this. It need only be short but this is required to ensure consistency in the process.

5.13: Is there an SOP for the FACS work? This will be needed before this work can proceed.

6.5: The work requiring eye protection needs to be more clearly identified. This can be done in an SOP. It is not clear from this risk assessment when the eye protection is required. 5.1 briefly mentions it but I doubt any member of staff reading this will be clear on exactly when to put on the eye protection. A much clearer statement such as "Eye protection will be worn at all times when working with hazard group 2 microorganisms or class 2 GMO's outside of the MSC" would be better. Even then it should be considered whether this is adequate as eye protection only protects the user not those around them. Where there is a risk of splash then use of an MSC should be given priority.

7.1: Animal carcasses and bedding?

8.1: Autoclave Load validation, and thermocouple calibration requirement is annual. The quarterly testing is for maintenance

Section 9: needs SOP references

Section 10.1: Validation data for Vesphene? Please provide a reference. Also we need SOP references. Where in local rules can this be found?

Section 11: We need the SOP? COP references.

15: Class 2 refers to a GMO, technically the expression of the inserted genes is in a Hazard group 2 organisms which can then lead it to be defined as a Class 2 GMO. This is not always the case Sendai virus is ACDP hazard group 1 but will be a class 2 GMO on environmental grounds.

Comments: : HK will revise the Code of Practice and Local Rules.

IH will confirm if a SAPO licence is required.

Subsequent to the meeting IH confirmed the following. VSV is ordinarily a SAPO HG3 organism. According to DEFRA guidance on SAPO's
Where small quantities of vesicular stomatitis virus are being handled as part of a plaque assay system for human immunodeficiency viruses, Category 2 containment is sufficient. Any procedures likely to cause aerosols must be performed in a microbiological safety cabinet, and any persons having contact with the virus must not have contact with equidae for 48 hours thereafter. In all other circumstances, Category 3 containment is required.

SH pointed out that the list of pathogens needs to be made clear. The committee requests notification of any additional pathogens introduced at a later stage of the research.

SH checked if the cells were commercially available?

IH confirmed they were.

The Committee suggests that 10% virkon will not be effective for the Mycobacterium strains listed in 4.12. BR recommends surfanios.

A GM Form B need to be completed with reference to the information provided in 5.10.

Agreed: Class 2, Containment Level 2. This project is notifiable to the HSE.

Could you please ensure that the risk assessment is revised (add GMIC number) and the amendments above addressed. I will then forward the form onto Occupational Health to complete. The completed HSE CU2 form (attached to this email), and copy of the Purchase Order (for BACs Payment) made payable to the HSE should be sent to me (s.joomun@imperial.ac.uk), I will then send it all to the HSE. Please ensure the information given in HSE Form relates to that provided in your risk assessment.

For further information, please see http://www3.imperial.ac.uk/safety/subjects/biosafety/gmprocedures

Please note that this work must be notified to the HSE and an acknowledgement receipt received prior to this work commencing.

Historical Significant Changes

02/03/2022
Project Additional Information

Purposes of the contained use

To understand how bacteria control expression of genes in vitro and in vivo and will involve using strains listed in section 2.1 to:
1. Construct recombinant versions of proteins that make up the transcription machinery
2. Isolate total cellular DNA and RNA
3. Introduce fluorescence reporters to study gene expression processes.
4. Make deletions in selected genes.
Genes of interest will be expressed in the hazard group 2 bacteria listed as hosts below and in the associated Bio1 risk assessment and the phenotype analysed via numerous methods including flow cytometry, mass spectometry, immunoblot, ELISA and several in vitro biochemical analyses etc.
Genes of interest will be deleted from bacteria by site directed mutagenesis and wild type or mutated genes reintroduced into the mutants. Random insertional mutagenesis using mini-Tn5 derivatives will also be used in an untargeted approach to identify new virulence and gene regulatory determinants.
Sorting of bacteria will be conducted using a dedicated FACS situated within a microbiological safety cabinet (to be installed in the Flowers building in May 2014). All other flow cytometry uses fixed samples.

Recipient or parental organism
Staphylococcus aureus (NCTC8325, USA300, Newman) (ACDP HG2)

Host/vector system
pET vector and derivatives, pBAD vector and derivatives

Origin & function
Origin- Genes associated with gene regulation such as genes that encode subunits of the RNA polymerase (the enzyme responsible for RNA synthesis in bacteria) and regulatory factors of the RNA polymerase (e.g. sigma factors, DNA binding transcription factors)
### Evaluation of foreseeable effects

The mutants generated will either be loss of function mutants or carry non-toxic reporter genes. It is not anticipated that bacterial strains produced in the laboratory are more virulent than strains that already exist in the environment.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

n.a

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

- Material used for imaging will be inactivated by fixation using 4% paraformaldehyde for 20min or cold (-20°C) methanol for 3min. Material for isolating RNA/DNA/proteins will be inactivated using the Trizol reagent - which will inactivate biological materials.
- Liquid waste: 1% virkon after dilution with the liquid waste(min exposure time of 30 min) or autoclaved directly.
- Solid Waste: Autoclaved : Solid waste e.g. agar plates Program 7 - Plastic discard 134°C 3 minutes
- Monitor of treatment e.g. chart recorder attached to autoclave: Load temperature probe; a print out of each cycle, retained for 6 months
- Validation of treatment: Annual 12 point thermocouple test; all cycles verified using dummy loads; records of tests kept by Biochemistry lab services
- Route of disposal: After autoclaving, transported in a closed container to the clinical waste compound at the back of the SAF building; removed from site by a specialist waste contractor

### Is an emergency plan required according to regulation 20?

N

### If yes, tick to confirm that it is attached to this form

### Tick to confirm that you have attached a risk assessment to this form

Y

### Tick if you are claiming exemption from disclosure for section of the risk assessment

N
2.10: Staph’s, are these all MRSA please make it more clear which ones are and which are not?
2.10: Xanthomonas oryzae this this may need a FERA license IH will check.
2.12: Xanthomonas oryzae?
2.14: It is not clear that knock out mutants of the pathogens are being reconstituted to full function as described in
1.2. Please make it clear what genetic work is being carried out.
2.15 and 2.16: Are any of the phages going to be used as hosts or vectors?
2.17: Please give some examples to help set the limitations of the work.
4.6 and 4.14: Briefly describe how the phage are isolated from the ultrafuge supernatant of banding. If needles are
used this will need an SOP.
4.16: If this is repeated information reference a section where this info is given, otherwise please complete.
4.21: PA can cause problems through contact with the eyes especially for contact lens wearers.
5.1: There are other organisms not mentioned in this section but listed in 4.21 where you have identified the airways
or eyes as a route of infection and yet work such as plating and streaking out is listed as being carried out on the open
bench. It has been demonstrated in previous accidents that this sort of work can generate splash and aerosol giving
rise to potential for exposure. Why is this work not conducted in an MSC? How do you propose to protect staff both
the worker and those stood next to them from exposure?
I note that ALL tissue culture will be carried out in an MSC. Why is this given priority over handling pathogens?
5.2: Will the tubes have sealed lids?
5.6: ATCSA schedule 5 and Shigella? This has not been mentioned previously. If this is an error please remove
reference to Shigella and work with material on the ATCSA schedule 5 or amend previous sections and speak to the
safety department.
5.7: Applying 70% ethanol or 1% virkon to a puddle of spilled culture is not going to be optimal. You would need to
apply a concentrated disinfectant to the spill such as 5% virkon.
5.8: Any culture of HG 2 or GM class 2 organisms must be affixed in the shaking incubator using clamps and the
culture flask must be sealed sufficiently to prevent a spill if it is dropped or knocked over. Use of sticky mats and
cotton wool or foam bungs is not a sufficiently robust procedure for HG2 and GM class 2 work.
To allow gaseous exchange during culture; screw topped culture flasks with a gas exchange filter top are available
that prevent the loss of liquids even when inverted.
5.9: How are density gradient bands from ultracentrifugation removed from the tubes?
6.5: Safety glasses are not mentioned elsewhere. Where they are used, needs to be made clearer. If necessary
refer to the precise location in the local rules where this is dealt with. Why only use with PA? Other organisms in 4.21
have been identified as infectious though contact with the eyes.
7.1: Specify that the virkon is 1% after dilution with the liquid waste and give a contact time.
10.1: Treat spills with a concentrated disinfectant such as 5% virkon. This is more likely to be effective than 70%
ethanol or 1% virkon, as the ethanol/virkon at this low concentration is diluted to less than its validated concentration by the spill.

Section 14 and 15: Use of radioisotopes was not mentioned in 1.2? Why is it mentioned twice in section 15?

Comments: SW presented an overview of his proposed work.
IH asked if SW could be more specific about the genes that were going to be inserted or altered or at least give some examples.
SW said that he planned to work on at least 250 different genes.
JP asked if the knock outs were then resurrected to full function?
SW confirmed that they were.
JP asked if any of the GMO’s would be more hazardous than the non GM organisms
SW said they were not.
IH asked SW to make it clear in 2.14 that there would be knock out and reconstitution of function associated with the work. This is not clear at the moment
SH asked if Xanthomonas oryzae required a FERA scientific license.
IH said that it was a pathogen of rice and may need a license. IH will confirm this.
SH asked if microorganisms were cultured?
SW said that they were.
IH asked if these were class 2 GMO’s?
SW confirmed that they were.
IH explained that the committee could not approve a project where Class 2 GMO’s were placed on sticky mats in a shaking incubator. They had to be secured in firmly affixed clamps and that the flasks had to be suitably sealed to prevent leakage in the event a flask fell over.
SH stated that it was the PI’s responsibility to ensure that precautions stated in the risk assessment, once approved, were adhered to.
IH reminded all present that it was a contract with ICL, the GM committee and where notifiable, the HSE as well.
SW stated that he would want to culture up to 1L of MRSA USA LAC 300
IH pointed out that the material needed to be properly contained to prevent spills or breakage if dropped, not only in the incubator but during transfer of materials to and from the incubator.
SW stated that he would specify that eye protection was worn.
IH asked SW to specify when in the risk assessment.
IH stated that as he was taking minutes he would send additional comments to the committee secretary by e-mail for consideration by TC.
Agreed: Class 2, Containment Level 2. This project is notifiable to the HSE.

### Project Additional Information

**Purposes of the contained use**

Mycoplasmas are the smallest cell wall less, free-living microorganisms. The lack of a cell wall makes them resistant to many of the common antibiotics. Every year, infections caused by Mycoplasmas in poultry, cows, and pigs, result in multimillion euros losses in the USA and Europe. Currently, there are vaccines against \( M \) hyopneumoniae in pigs and \( M \) gallisepticum and \( M \) synoviae in poultry. However, there is no vaccination against many Mycoplasma species infecting pets, humans and farm animals (i.e., Mycoplasma bovis cow infection). Mycoplasma species in many cases are difficult to grow in axenic culture and those that grow need a complex media with animal serum. In large scale production of Mycoplasma species for vaccination aside from the high cost of animal serum, more important is the high irreproducibility in the production process and the possible contamination with animal viruses. All this together highlights what European industry needs: i) a defined cheap reproducible medium that is animal serum free and ii) an universal Mycoplasma chassis that could be used in a pipeline to vaccinate against Mycoplasma species, as well as any pathogen. \( M \) pneumoniae is an ideal starting point for designing such a vaccine chassis. It has a small genome (860 kb) and it is probably the organism with the most comprehensive systems biology data acquired so far. By genome comparison, metabolic modeling and rationally engineering its genome, we will create a vaccine chassis that will be introduced into an industrial pipeline. The process will be guided by the second world largest industry on animal vaccination (MSD), as well as a SME specialized on peptide display and screening. This will ensure the exploitation and commercialization of our work contributing to maintain Europe privileged position in this field. Our ultimate goal is to meet the needs of the livestock industry, taking care of ethical issues, foreseeable risks, and prepare effective dissemination and training material for the public.
Mycoplasma pneumoniae is a human pathogen (hazard group 2) that causes a form of atypical bacterial pneumonia. Symptomatic infections tend to develop over a period of several days and manifestation of pneumonia can be confused with a number of other bacterial pathogens and conditions that cause pneumonia. Common symptoms are mild and include sore throat, wheezing and coughing, fever, headache, coryza, myalgia and feelings of unease, in which symptom intensity and duration can be limited by early treatment with antibiotics (macrolides, tetracycline, ketolides, and fluoroquinolone). 15% of cases, usually adults, remain asymptomatic (Source: http://en.wikipedia.org/wiki/Mycoplasma_pneumoniae).

Host/vector system

GM mycoplasma will be engineered from the M129 laboratory strain (J Bacteriol. 1976 Jan;125(1):332-9). Plasmid based Vector systems used in this project will be customized. Plasmids carrying modifying DNA will be prepared in non pathogenic host E. coli (Top10 strain, GM Class 1), obtained from invitrogen.

Origin & function

The GM aim is to achieve attenuation by deleting/modifying the regulation of key genes on the genome. We will make genomic modifications (deletions and putting essential genes under designed promoters) to attenuate M. pneumoniae, to restrict growth to chemically-modified medium, in vitro only. Thus we will prevent growth in vivo.

Evaluation of foreseeable effects

We will make genetically-modified attenuated M pneumoniae with auxotrophies, "kill-switches" and deleted virulence factors, to allow growth in vitro, but prevent cell division in vivo. The aim is to reduce or abolish pathogenicity, while maintaining potential immunogenicity (vaccine strain). The auxotrophies and kill-switches will be lost in the absence of selection pressure, via cell death. Hence, there will be no increased risk to humans or the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste: Disinfecting culture will be diluted in a validated disinfectant, virkon to the final concentration of 1% and incubated for at least 30 mins and then only the disinfected cultures will be disposed of correctly (via drains). Solid waste: autoclaved at a minimum of 121 degrees for minimum 15 minutes holding time and disposed of via clinical waste disposal. Autoclave is serviced and subject to a multi point calibration and load validation test annually.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form
Following the discussion of your proposal entitled “MycoSynVac (P51776): Engineering of a Mycoplasma pneumoniae attenuated strain as part of a broad-spectrum animal vaccine”, GMIC-4589, at the last GM Safety Committee meeting, the Committee request that the following amendments are made to the proposal prior to approval:

1.3: For clarity please confirm that all the Class 2 work handling and manipulating M pneumoniae is carried out in 443 (COP states that the MSC is in 433? Typing error?) , the lab with the MSC and dedicated incubator, storage is in 439? What happens in 438? General Molecular biology? Section 14 mentions lab 433, what is this lab used for or is this a typing error?

4.22: What is the largest single volume?

5.4: Please add double contained according to IATA regulations and in line with College Policy and guidance on transport of dangerous goods.

5.7: 30 minutes is probably not enough. Please increase this to 1 hour while advice is sought form the lab manager and safety officer.

5.8: Is this a shaking incubator? How are spills from the culture vessels prevented? Are the vessels leak proof? E.g. Ventilated lids rather than cotton wool plug?

6.5: Please answer no if no other PPE used.

7.1: Presumably liquid culture is disposed of via drains, not to the orange bag?

9.0: Is any refresher training carried out for emergency procedures? This could take the form of an annual review of the lab COP with all staff and a review of the emergency procedures.

10.2: Also follow the OH guidance on Laboratory accidents

15: Please mention the organisms in use e.g. Cloning in attenuated K12 E.coli strains Top 10 etc. DNA construct amplification in Attenuated E.coli K12 derived strains

Comments: MI gave a brief description of the work.

JP asked if 1% virkon was effective against mycoplasma?

MI responded that is was susceptible.

HK checked if there were any problems with mycoplasma bacterial contamination from external sources?

MI said they had not had this problem and they strictly kept everything separate for this reason.

Agreed: Class 2, Containment Level 2. This project is notifiable to the HSE.

### Project Additional Information

**Purposes of the contained use**

Use of *M. tuberculosis* and HG2 mycobacterial strains

My laboratory explores deciphering the environmental adaptation of Mtb within the host. Mainly Metabolomics, and Transcriptomics, Proteomics, and Lipidomics are used as tools for the read-out of the first steps in this adaptation. Effectively, the success of Mtb as a pathogen partially results from its capacity to invade, survive and persist within intracellular phagosomes and extracellular sites in many host tissues. Throughout the cycle of infection, Mtb encounters and survives in a variety of harsh environments in the human body including nutrient-poor, acidic, oxidative, nitrosative and hypoxic niches. Very little is known about the molecular mechanism and kinetics of adaptation of Mtb during the first stages of infection within the host. Deciphering these mechanisms in such defined environments is crucial to understanding the physiology of Mtb within the host and can also inform on us why Mtb is such an efficient intracellular pathogen. The findings will potentially lead to the discovery of new drug targets and have a better understanding on resistant bacteria in context of the host.

**Recipient or parental organism**

*M. tuberculosis* (HG3) use in my laboratory is pathogenic and can cause Human Tuberculosis (TB). TB is a bacterial infection spread through inhaling tiny droplets from the coughs or sneezes of an infected person. It is a serious
condition, but can be cured with proper treatment. TB mainly affects the lungs. However, it can affect any part of the body, including the lymph glands, bones, and nervous system.

M. marinum (HG2) causes opportunistic infections in humans. Typically, clusters of superficial nodules are described at the extremities (hands most of the time) due to its ability to infect cooler part of human body. Its growth is inhibited at 37 degree celsius. M. marinum can causes a rare disease which typically affects individuals who work with fish and keep home aquariums.

M. bovis BCG (HG2) is a vaccine against Human Tuberculosis and is not reported to cause disease in Human as M. smegmatis mc2 155 (HG1).

Non-pathogenic mycobacterial species (M. smegmatis)

Opportunistic pathogenic M. bovis BCG, M. marinum: HG2
M. tuberculosis: HG3

Fully drug sensitive laboratory strains such as M. tuberculosis H37Rv, CDC1551
Transposon mutants of M. tuberculosis from the BEI resources
Severely attenuated mutants of M. tuberculosis for use under Containment 2
Bleupan DleuD DpanCD hygR
mc2 6020 DlysA DpanCD hygR
mc2 6030 DRD1 DpanCD hygR
mc2 7000 DRD1 DpanCD unmarked

Fully drug sensitive field isolates of M. bovis

NB: derivatives mean different background of the strains such as E. coli K12 derived non-toxigenic attenuated lab strains e.g. DH5-alpha, BL21,... for mycobacterial strains, this means generation of genes deletion mutants and complemented strains conducting to a loss or decrease in virulence and pathogenicity. No work will investigate increase in virulence and pathogenicity.

Host/vector system

Plasmids to clone and express recombinant proteins in E. coli; integrative plasmids for mycobacterial mutants and complemented strains
pSMT3 and derivatives: ColE1 and pAL500 origins of replication. Not mobilisable
pYUB854 and derivatives: OriE. non mobilisable
pMV261 and derivatives: OriE. non mobilisable
pHAE159, pHAE87 and derivatives: Derivatives of conditionally replicating mycobacteriophage PH101 (ts; Bardarov et al 97)
pKINTA and derivatives: non mobilisable integrating vectors
pET and derivatives: protein expression system, non mobilisable
pVV16 and derivatives: protein expression system, non mobilisable

Origin & function

Inserted genes may be self cloning of mycobacterial genes, either in the sense orientation to allow over-expression, or in the antisense orientation to allow down-regulation, under the control of either an inducible or constructive promoter. Mycobacteria do not express any toxins and there is little risk of altering pathogenicity by this method.Selectable markers are usually either Hygromycin (not used clinically) or kanamycin (not part of first line therapy), sometimes in combination with the sucrose and the SacB enzyme as a counterselectable marker.

Reporter genes includes a range of fluorescent reporters such as GFP or mCherry, luminescent reporters such as lux operon from Photorhabdus luminescens, or the luciferase genes from Firefly or Gaussia princeps. Reporter enzymes such as beta-galactosidase, or reporter antigens such as the OVA peptide.

Evaluation of foreseeable effects

There is no evidence that any of the recombinant mycobacteria made in this project will be any more hazardous than wild type strains. There is published evidence that...
disrupting some two-components regulators alters virulence in immunocompromised animals, but this does not alter the way in which mycobacteria are handled under containment level 3 conditions. Some samples may have drug resistance so in theory may be more hazardous than wild type that are susceptible.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

NA

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

GM Class 3 and HG 3 material in CL3 Labs
All materials used in the CL3 facility are to be regarded as potentially contaminated and disposed of accordingly. All waste liquid and solid waste must be autoclaved before leaving the laboratory and disposed of in orange clinical waste bags for clinical waste disposal. Refer to the CL3 COP for details.

Liquid waste is pre treated with Surfanios at 10% final concentration and left overnight in secure vessels.

60L and 150L autoclave. Minimum 121 degrees for 15 minutes holding time. Final disposal into orange bags for clinical waste disposal.

Autoclaves are maintained and calibrated annually and subject to an annual 12pt thermocouple waste load validation test

GM Class 2 Material & Hazard Group 2

Liquid cultures of HG2 and class 2 GM myco bacteria are treated with 10% surfanios overnight before being autoclaved and disposed of as clinical waste.

GM Class 1

Liquid GM class 1 waste is treated with 2% virkon final concentration for a minimum of 30 minutes before disposal to the drains.

All solid waste (contaminated plastics, gloves etc) from CL2 labs that has been in contact with HG 1 and 2 and GM class 1 and 2 material is autoclaved at 121 degrees for a minimum holding time of 15 minutes before final disposal into orange sacs as clinical waste.

Autoclaves are maintained and calibrated annually and subject to an annual 12pt thermocouple waste load validation test

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
Dear Dr L,

Following the discussion of your proposal entitled "Chemical biology of Tuberculosis Pathogenesis" GMIC-4885 at the last GM Safety Committee meeting, the Committee request that the following amendments are made to the proposal prior to approval:

Department: Typo 'Lifes'

Complete all the ticks.

2.2: Bran – should be Brian.

2.3: Please provide an SOP describing how the urine is inactivated and how this is validated.

2.4: Coded - Please clarify that this means the samples are anonymous.

2.10: What is meant by M tb and M marinum derivatives? Please give some examples.

2.10: ACDP classification is HG1, HG2 or HG 3. Class refers to the GM classification not the wild type. Please change class to HG

2.11: Please describe under what circumstances M. marinum can cause disease (it is a HG2 pathogen) and M.bovis BCG is described as a pathogen by the HSE and is also HG2.

2.14: E.coli and derivatives? Please be a bit more specific and give examples such as E.coli K 12 derived non toxigenic attenuated lab strains e.g. DH5Alpha

Please also describe the scope of the GM work, e.g. What sort of modifications you are making and if necessary what you will not do. E.g. Increase virulence or pathogenicity.

2.15: E.coli and derivatives? Please be a bit more specific e.g. E.coli K 12 derived non toxigenic attenuated lab strains e.g. DH5Alpha.

M Bovis BCG and M marinum are described as pathogenic by the HSE, please remove all references to being non-pathogenic.

ACDP classification is HG1, HG2 or HG 3. Class refers to the GM classification not the wild type. Please change class to HG

5.1: Where are you handling the other Mycobacterium sp? Please mention if there are any circumstances where you would handle the HG2 or Class 2 GMO's in an MSC.

In this risk assessment you will need to make it clear where the Class 2 and HG 2 organisms are handled and where the HG3 and class 3 pathogens are handled.

5.7, and 5.8: What about the HG2/class 2 material?

6.4: What about the CL2 labs?

9: Spillage response and emergency procedures. We recommend that staff have refresher training at least annually. This may take the form of a desk top exercise or discussion with staff while reviewing the COP.

10.1: Does virkon work for the M Marinum and M Bovis BCG? Why not use surfanios?

Evacuate the whole lab and seek advice before allowing re-entry. It may take several hours to clear an aerosol at CL2 depending on air changes, titre and volume of the spill.

Comments: GLM gave a brief description of the work.

IH asked if Dr Robertson's (BR) Code of Practise would be used for this work.

GLM confirmed all the techniques were the same therefore; he would be using the same COP.

IH checked if BR would be conducting the training.

GLM said yes.

SH suggested updating the Local Roles for this work.

SH asked GLM to describe the process.

GLM explained TB biomarkers can be traced in 40-60% of human urine samples. The mass spectrometry will be used to analyse it.

SH inquired if the samples from Southampton University would have been decontaminated first and therefore has no bacteria. Do they do random checks for growth?

GLM said there were checks for HIV.

SH suggested getting a protocol from the collaborators regarding decontamination of the samples.

IH suggested including the room number of the mass spectrometry.

MR asked about the use of ethanol.

GLM explained it was very effective.

MR recommended explaining when and how virkon, ethanol, surfanios, etc, was used.

Agreed: Class 3, Containment Level 3. This project is notifiable to the HSE.
In this project, we would like to investigate in detail how the replicative capacity on the transmitted founder virus influences early T cell function, and how this might be associated with disease progression. This will involve amplifying full length HIV genomes from actute HIV patients, sequencing it to identify the transmitted founder virus and creating infectious molecular clones of the founder virus for use in HIV replicative capacity assays, and for a T cell viral inhibition assay. To investigate the relative contribution of each of the HIV proteins to viral replicative capacity, and its role in the viral inhibition assay, we will generate HIV chimeras using a lab adapted HIV backbone, switching each of its genes with the patient derived HIV genes and these use chimeras for replictaive
capacity assays and viral inhibition assays.
Eventually, we hope to identify targets and mechanisms that might be important for T cell inhibition of viral replication that might inform the development of an effective HIV vaccine.

The samples that we are working with are not cultured, but as they are all from acute HIV patients, some of the viral loads are high. Our procedure is to transfer the sealed frozen vial inside a sealed container to a MSC and allow it to thaw, then immediately lyse the virus from the plasma within the MSC, rendering the virus non-infectious.

The Qiagen viral lysis buffer AVL contains 50-100% Guanidinium thiocyanate. Guanidinium thiocyanate is a well-known chaotropic agent that is commonly used to lyse virus before extraction of nucleic acids. The lysis step is described on the highlighted section on page 8 of the attached RNA extraction protocol.

1. Viral RNA extraction from HIV infected plasma, cDNA synthesis and HIV amplification by PCR will be done, and the DNA shipped to Emory university (Atlanta, USA) for full length sequencing.
2. Once the sequences have been analysed and the transmitted founder virus identified, we will generate infectious molecular clones and HIV chimeras.

This will involve:
   a) Cloning of the complete patient-derived HIV genome into a pBluescript vector
   b) Cloning of various HIV genes (Gag, Pol, Nef) onto a lab adapted HIV proviral backbone to generate chimeric HIV that only differs by the inserted gene
   c) Storing the cloned DNA from (a) and (b) above until it is eventually used to generate virus stocks.
   d) Transfecting this DNA onto 293T cells to make virus stocks of the infectious molecular clones and chimeras at the IAVI CL3 lab on the same floor that is routinely used for HIV culture work involving HIV positive sample

Recipient or parental organism

E.coli competent bacteria cells such as JM109 will be used for plasmid manipulation and amplification.
Many derivatives of the E. coli K-12 and B strains have been demonstrated to be non-pathogenic and are well understood.
The host strain bacteria are non-colonising and disabled. They are equivalent to hazard group 1, as they are not pathogenic to humans or animals. They often have auxotrophic requirements which are unlikely to be satisfied outside laboratory cultures. They have very limited survivability in the environment.
These bacteria will be manipulated in a CL2 lab.

Host/vector system

The inserts will be carried on mammalian expression vectors such as pcDNA3, pcDNA3.1, pEF6/V5-His, pENTR-TOPO, pLent6/R4R2/V5-DEST, pBluescript, pUC18, pBR322, pCR-XL-TOPO, pGRN145, pGTU-Luc, pGTU, pEZMO2, pET101, and the DNA vaccine vector pVRC. Several vectors may be tested for efficiency of cloning the HIV insert and the most efficient chosen.
These plasmids also contain bacterial origin of replication and bacterial selection genes such as those encoding Ampicillin, Kanamycin and Chloramphenical resistance. Some plasmids also contain markers of mammalian selection e.g. neomycin, puromycin, hygromycin and blasticidin resistance.
Vectors are considered to be non-mobilisable thus gene transfer is a remote possibility. Neither the vector nor the inserted genes would be expected to confer any selective advantage to the micro-organism or related microorganism. All inserts in the vector will be poorly expressed but the extra burden placed on the micro-organism or on a related micro-organism (in the unlikely event that transfer occurs) will lead to non-transfected micro-organisms having a selective advantage over the GMM.
For the construction of HIV chimeras, a lab adapted HIV proviral backbone will be used. This will be ~12kb, and will be derived from the study cohort and cloned onto pBluescript. Its functional characteristics are expected to be similar to those of HIV proviral DNA.
These vectors will all be handled in a CL2 lab.

Origin & function

We will amplify HIV from plasma obtained from acute HIV infected patients. These plasma samples are from a Kenyan cohort that is predominantly infected with HIV Subtype A, D and A/D recombinants. Once we amplify HIV from the plasma, we will clone it to generate virus stocks of infectious molecular clones and chimeras of the autologous virus.

These infectious molecular clones will be used in viral replicative capacity assays to measure virus fitness and in viral inhibition assays to measure T cell killing of HIV.

1. Full genome HIV will be cloned onto an appropriate vector from 2.16 above - This is expected to have the same characteristics as the patient virus. The purpose of the cloning is not to change any functional property, but rather to study each virus in isolation.

2. Short dsDNA fragments of HIV genome will also be cloned onto a HIV proviral backbone. These will include:
   - GAG (group specific antigen): is one of the core structural protein of HIV and comprises of p24 (makes the viral capsid), p6 & p7 (nucleocapsid) and p17 (protective matrix).
   - POL: encodes the viral enzymes such as RT, Protease and integrase. During viral replication protease cleaves off the Pol polyprotein away from gag to allow viral maturation.
   - NEF(Negative Regulatory Factor): Nef downregulates CD4 (primary viral receptor) and MHC class I molecules. It also increases viral infectivity.
   - TAT (transactivator protein): increases efficiency virus transcription
   - REV: regulates traffic of virus RNA species out of the nucleus,
   - VIF: Counteracts antiviral effect of cellular APOBEC proteins,
   - VPR: Contains nuclear localisation sequence,
   - VPU: Down-regulates CD4, transports Env proteins to cell surface, counteracts antiviral effect of cellular tetherin proteins,
   - ENV: Encodes the viral envelope proteins gp120 and gp41, these proteins mediate virus-entry into target cells.

This manipulation of DNA will all be carried out in a CL2 lab.

Evaluation of foreseeable effects

We are going generate two broad categories of GMMs:

1. E.coli carrying full length HIV genome. HIV will not replicate in E.coli as HIV requires multiple cellular genes to support its life cycle, so no live virus will be in the E.coli culture. E. coli K-12 and B strains have been demonstrated to be non-pathogenic and are well-understood and are non-colonising and disabled. They are equivalent to hazard group 1, as they are not pathogenic to humans or animals. They often have auxotrophic requirements which are unlikely to be satisfied outside laboratory cultures. They have very limited survivability in the environment.

2. HIV infectious molecular clones and chimeras - These cloned viruses are however expected to have the same hazard as the wild type patient viruses - if transmitted can cause AIDS. The purpose of the cloning is not to change any functional property, but rather to study each virus in isolation. The virus stocks will be produced and stored in a CL3 lab.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No derogation. All infectious material will be handled in a CL3 lab.
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

| Tick to confirm that you have attached a risk assessment to this form | Y |
| Tick if you are claiming exemption from disclosure for section of the risk assessment | N |
Following the discussion of your proposal entitled "Amplification and cloning of full length HIV genomes to generate patient derived HIV infectious molecular clones, and chimeras", GMIC-5248 at the last GM Safety Committee meeting, the Committee request that the following amendments are made to the proposal prior to approval:

1.1: Typo in first paragraph ‘relicating’
1.2: Typo in d) ‘riutinely’
1.3: Point 3, the use of ‘infectious’ here would make this section CL3
2.2 and 2.5: Plasma from acute HIV infected patients, with a high likelihood of infection which you have identified as high risk in 2.5. According to COSHH this material should be handled in a CL3 lab. Please amend the risk assessment accordingly.
2.17: Please provide a flowchart and plasmid map with the process of insertion of HIV into a plasmid and at what precise point in the GM process is the viral genome able to express infectious HIV clones. Please also point out at what containment level these parts of the process this will be carried out. The stage at which viral particles can be expressed must be carried out in a CL3 facility.
4.17 and 4.18: You describe transferral across the mucosa as well as by percutaneous inoculation; this differs from what you explain at the meeting. Please clarify.
5.7: The Dangerous occurrence form should be replaced with Salus.
5.8: Generation of infectious clones? Is this double contained and where is it happening?
7.3: High titre HG3 culture waste needs to be autoclaved first. Only larger volumes of low titre culture aspirate can be considered for chemical treatment alone before disposal to drains. Virkon does not sterilize waste it disinfects it, please remove the word sterilized. Disinfection does not kill all microorganisms just reduces their number and virkon is unlikely to reduce the numbers to acceptable levels from high titre culture waste.
Section 10: Change references to an accident form to Salus. Also remove reference to the BioRisk manager and replace by College BioTeam
Why is the volume for a small/large spill different inside and outside the safety cabinet?
Section 14: Handling HIV plasma, change from 2 to 3. Generation of infectious HIV clones also need to be added as a CL3 activity.
Section 15: Needs to be from the point of creation of the HIV infectious clones, not just further manipulation. This point needs some clarification.
Comments: GM gave a brief description of the work.
RW asked if the work would be conducted in new laboratories?
GM confirmed this was correct and routine molecular work would be carried out in Containment Level 2.
MB asked if the high titre serum work would be carried out in the CL3?
DK answered ‘yes’ this would be in the initial phase only, once they have lysed the plasma it will go to CL2.
MB queried at what point would the plasmids become infectious?
DK explained this would be in the end part of the work.
MB And DK had a discussion on whether certain parts needed to be conducted at CL2 and CL3. DK and GM agreed to provide a flowchart explaining the work process and at what containment level that process will take place.
MB checked if splashes were likely.
DK answered this was very unlikely.
JP also pointed out that the initial lyse would render it non-infectious.
The committee needs assurance that the lysis phase reliably and robustly inactivates the virus, reducing viable viral particle levels to an undetectable level. Please forward an SOP to the Safety Department.
Agreed: Class 3, Containment Level 3. This project is notifiable to the HSE.

Project Containment

02/03/2022
Pseudomonas aeruginosa is able to infect a wide variety of hosts and tissues and is an excellent model for studying infection and secretion by gram-negative bacteria. The project is the coordination of research conducted on two different axes, which are central for the establishment of infection and persistence within the host. One axis concerned the characterization of molecular actors involved in bacterial biofilm formation and dispersion, the second axis is the study of a novel secretion mechanism, called type VI.

The type VI secretion system is required by a variety of Gram negative organisms for pathogenicity in a number of plant and animal models. The T6SS is proposed to deliver effectors towards the host cell or bacterial cell. We suggest that this novel secretion mechanism, called type VI, is involved in bacterial competition in a range of environments including plants, plant roots and soil.

We wish to establish the role of Pseudomonas species and their expression levels in lab settings as well as in a plant model of infection. We will also compete pseudomonas species with other plant pathogens and soil organisms to test for a competitive advantage in these conditions.
Biofilm formation may also be a positive characteristic in this environment and or in competition and we wish to investigate if a role is present. We will use Arabidopsis thaliana, Brassica oleracea, Nicotiana benthamiana, Solanum tuberosum and Solanum lycopersicum as hosts. They are all widely-used plant models and none of them will be genetically modified.

We will use a variety of bacteria that are listed in the accompanying risk assessment and in this form. These bacteria are hazard group 1 or 2 organisms however several of them require a FERA licence to be obtained prior to work commencing. Pseudomonas aeruginosa and Burkholderia are potential human infectious agents via broken skin contact. Eye splash and Inhalation. The other organisms are of no concern to animals or humans. However as mentioned several are plant pathogens and good microbiological practice including sterilisation of materials that they come in contact with will be undertaken to prevent any accidental release. All material will be treated in line with ADCP level 2 and local rules.

We are primarily interested in competition between Pseudomonas aeruginosa, Pseudomonas putida, Pseudomonas syringae and Agrobacterium tumefaciens. This will be the organisms we mostly work on. Additional strains have been requested as well for infrequent use.

A recent study suggests that the model strain in our work, Pseudomonas syringae pv tomato DC3000, has been largely supplanted over the past decades in the UK and elsewhere, by 11 Pseudomonas syringae pv tomato strains (Cai et al. 2011), reducing risk to the environment.

Over view of the experimentl procedures:

We will study bacteria/host interaction by analysing the effect of P. aeruginosa and other pathogen infection in vivo using Arabidopsis. Arabidopsis will be grown in a plant incubator located in our lab (1.30).

We will study bacteria/host interaction by analysing the effect of P. aeruginosa and other pathogen infection in vivo using Arabidopsis. Arabidopsis will be grown in a plant incubator located in our lab (1.30).

Plant challenges are with Arabidopsis whole plants, and will be via vacuum infiltration. Viable counts will be made on infected leaves. Alternatively plant challenges will be via topical application or inoculation of the roots/surface. Wound models may also be used where a small cut or puncture wound is placed into the plant prior to being inoculated. Inoculations will either be monospecies or co-challenges of two bacteria. We have recently published a paper with our collaborators in Taiwan shown that the T6SS of Agrobacterium Tumefaciens allows it to out compete Pseudomonas aeruginosa but only in the host (Ma, Hachani et al. 2014). Ma, L. S., A. Hachani, J. S. Lin, A. Filloux and E. M. Lai (2014). "Agrobacterium tumefaciens deploys a superfamily of type VI secretion DNase effectors as weapons for interbacterial competition in planta." Cell Host Microbe 16(1): 94-104.

Recipient or parental organism

All plant pathogen strains requiring FERA approval will be handled at containment level 2 and good microbiological practices will be employed to prevent accidental release of these organisms. All FERA licenced strains will be disposed via the internal Biohazard system and any material that comes in contact will be decontaminated with 70% ethanol and/or Virkon (See sections 7 and 10).

Escherichia coli: Hazard Group 1/ GM Class 1

Wild-type K12 strains and derivatives thereof with required phenotypes for cloning and expressing pseudomonas genes or genes of other bacterial origin will be used in these studies. Strains commonly used in the laboratory include strain DH5alpha, XL1 Blue, TG1 TOP10F, CC118, S17.1 and BL21 (DE3). These strains have a widespread and long history of safe use. The BL21 strain carries the gene encoding the T7 ENA polymerase and is used for expressing genes cloned under a T7 promoter.

Pseudomonas aeruginosa: Hazard group 2/ GM Class 2

Pseudomonas aeruginosa is a Gram-negative, aerobic rod belonging to the bacterial family Pseudomonadaceae. The family includes other genera, which, together with certain other organisms, constitute the bacteria informally known as pseudomonads. These bacteria are common inhabitants of soil and water. They occur regularly on the surfaces of plants and occasionally on the surfaces of animals. Pseudomonas aeruginosa and two former Pseudomonas species (now reclassified as Burkholderia) are pathogens of humans. However, Pseudomonas aeruginosa is an opportunistic pathogen, meaning that it exploits some break in the host defenses to initiate an infection. It causes urinary tract infections, respiratory system infections, dermatitis, soft tissue infections, bacteremia, bone and joint infections, gastrointestinal infections and a variety of systemic infections, particularly in patients with severe burns and in cancer and AIDS patients who are immunosuppressed. Pseudomonas aeruginosa infection is a serious problem in patients hospitalized with cancer, cystic fibrosis, and burns. The case fatality rate in these patients is 50 percent. Pseudomonas aeruginosa is primarily a nosocomial pathogen. The overall incidence of P. aeruginosa infections in hospitals averages about 0.4 percent (4 per 1000 discharges), and the bacterium is the fourth most commonly-isolated nosocomial pathogen accounting for 10.1 percent of all hospital-acquired infections. Pseudomonas aeruginosa is sometimes present as part of
the normal flora of humans and the prevalence of colonization of healthy individuals outside the hospital is relatively low. Infection may occur through direct and extensive contact with the organism, however no procedure in the laboratory will require direct contact. In addition, personal protective equipment (PPE) including lab coat and gloves will be worn when working with P. aeruginosa strains to further minimize the risk of direct contact with the organism.

We will use several laboratory P. aeruginosa strains including, PAO1, PA14, PAK, TB, CHA, PA103, SG17, PA7, X13273. We will also work with large collection of isolates that have been issued directly from patients at the hospitals at different stages of their life. The clinical records of the patients are available as well as the antibiotic susceptibility of the collected strains.

Burkholderia cepacia: Hazard group 2/ GM Class 2
B. cepacia is the name for a group or “complex” of bacteria that can be found in soil and water. B. cepacia poses little medical risk to healthy people. However, people who have certain health problems like weakened immune systems or chronic lung diseases, particularly cystic fibrosis (CF), may be more susceptible to infections with B. cepacia. B cepacia is a known cause of infections in hospitalized patients. The effects of B. cepacia on people vary widely, ranging from no symptoms at all, to serious respiratory infections, especially in patients with CF.

We will periodically use several laboratory strains including the sequenced genomovar III CF strain J2315

Pseudomonas putida, Pseudomonas fluorescens and Pseudomonas alcaligenes: Hazard group 1/ GM Class 1
P. putida is a gram-negative rod-shaped saprophytic soil bacterium. It demonstrates very diverse metabolism, including the ability to degrade organic solvents such as toluene. This ability has been put to use in bioremediation, or the use of microorganisms to biodegrade oil. Use of P. putida is a safe strain of bacteria, unlike P. aeruginosa for example, which is an opportunistic human pathogen. Similarly, P. fluorescens has an extremely versatile metabolism, and can be found in the soil and in water. It is an obligate aerobe but certain strains are capable of using nitrate instead of oxygen as a final electron acceptor during cellular respiration. Some P. fluorescens strains (CHA0 or Pf-5 for example) present biocontrol properties, protecting the roots of some plant species against parasitic fungi such as Fusarium or Pythium. Finally, Pseudomonas alcaligenes is a Gram-negative aerobic bacterium used as a soil inoculant for bioremediation purposes, as it can degrade polycyclic aromatic hydrocarbons and has no known pathogenic properties.

We will periodically use mostly two strains of Pseudomonas putida, WCS358 and KT2440, knowing that KT2440 genome sequence is available. We will mostly use the P. fluorescens Pf5, SBW25 and PFO-1 strains of which the genome sequence is available, and also the CHAO strain which has commonly been used in laboratories. Finally we will periodically use the P. alcaligenes strains M-1.

Pseudomonas entomophila L48: Hazard group 1/ GM Class 1
Pseudomonas entomophila is an entomopathogenic and metabolically versatile soil bacterium that, upon ingestion, kills Drosophila melanogaster as well as insects from different orders. This strain is not hazardous to human health

We will periodically use the sequenced strain CT573326 to study homologues of the genes in Pseudomonas.

Pseudoalteromonas haloplanktis: Hazard group 1/ GM Class 1
Pseudoalteromonas haloplanktis is a psychrophilic Gram-negative bacterium collected in Antarctic seawater, which produces endoglucanases and other hydrolases. The strain has no known pathogenic properties.

We will periodically use the sequenced strain TAC125 to study homologues of the genes of Pseudomonas.

Pseudomonas syringae: Hazard group 1/ GM Class 2 (FERA approval required)
Pseudomonas syringae is a Gram negative, plant-pathogenic bacterium, strains of which are noted for their diverse and host-specific interactions with different plant species. Specific strains are assigned to one of the over 50 known pathovars based on their ability to infect different plant species. A variety of symptoms are associated with woody plants infected by P. syringae. Symptoms depend on the species of plant infected and the strain of P. syringae. Common P. syringae infection-associated symptoms are: flowers and/or flower buds turn brown to black; dead dormant buds; necrotic leaf spots; discolored and/or blackened leaf veins and petioles resulting from systemic invasion and infection: spots and blisters on fruit. This strain is not hazardous to human health

We will periodically use three strains, all of which have their genome sequenced, i.e, patovar tomato DC3000, patovar syringae B728a and patovar phaseolicola 1448A.

Pseudomonas stutzeri: Hazard group 2/ Class 2 (FERA approval required)
Pseudomonas stutzeri is a nonfluorescent denitrifying bacterium widely distributed in the environment, and it has also been isolated as an opportunistic pathogen from humans. P. stutzeri is ubiquitous in hospital environments and that this species could be considered an opportunistic but rare pathogen.

Agrobacterium tumefaciens: Hazard group 1/ GM Class 2 (FERA approval required)
Agrobacterium tumefaciens is a rod-shaped, Gram-negative soil bacterium and plant pathogen. Agrobacterium tumefaciens is the causal agent of crown gall disease in dicots. Carries the Ti plasmid. This strain is not hazardous to human health.

Agrobacterium vitis: Hazard group 1 / GM Class 2 (FERA approval required)
Agrobacterium vitis is a bacterium species in the genus Agrobacterium. It is gram negative soil bacterium and is responsible for the crown gall disease of grape (plant pathogen). This strain is not hazardous to human health.

Pectobacterium carotovorum: Hazard group 1 / GM Class 2 (FERA approval required)
Pectobacterium carotovorum is a bacterium of the family Enterobacteriaceae; it formerly was a member of the genus Erwinia. The species is a plant pathogen with a diverse host range, including many agriculturally and scientifically important plant species. Two subspecies will be used atrosepticum SCRI 1001 and carotovorum SCRI 194. This strain is not hazardous to human health.

Pectobacterium carotovorum SCRI 1001 (rev 11/08) Page 5 of 15

Ralstonia solanacearum: Hazard group 1 / GM Class 2 (FERA approval required)
Ralstonia solanacearum, previously known as Pseudomonas solanacearum, is a plant pathogenic bacterium commonly found in the soils of tropical and subtropical countries. Certain strains are adapted to milder environmental conditions and have recently been isolated in northern European countries. This organism, responsible for bacterial wilts, can infect over 200 plants species. Major hosts include tobacco, tomato, potato, eggplant, pepper and banana trees. It also causes disease on the model plant Arabidopsis thaliana. This pathogen can lie dormant in water or soil until a host plant grows, then it enters the roots and colonises water-conducting vessels, from where it spreads throughout the plant. This strain is not hazardous to human health.

We will periodically use the sequenced strains GMI1000, together with currently sequenced strains Molk2 and 1649, to study homologues of the genes of Pseudomonas.

Acinetobacter baumannii: Hazard group 1 / GM Class 2
Acinetobacter is a group of bacteria commonly found in soil and water. Outbreaks of Acinetobacter infections typically occur in intensive care units and healthcare settings housing very ill patients. While there are many types or “species” of Acinetobacter and all can cause human disease, Acinetobacter baumannii accounts for about 80% of reported infections. Acinetobacter infections rarely occur outside of healthcare settings.

Acinetobacter baumli ADP1: Hazard group 1 / GM Class 2
Acinetobacter baumli is a strictly aerobic and widely spread soil bacterium with simple growth requirements and wide substrate range. The laboratory strain ADP1 has shown potential for metabolic studies and biotechnological applications, mainly for the compact easily-transformable genome and a unique metabolic network. It is an extremely rare opportunistic human pathogen that has been described once in the literature found in immunosuppressed patients.

Xanthomonas campestris pv campestris: Hazard group 1 / GM Class 2 (FERA not required as European strains)
Xanthomonas campestris pv campestris causes black rot and is considered a important and destructive disease of crucifers, infecting all cultivated varieties of brassicas worldwide. In this project only European strains will be used negating the need for a FERA licence. This strain is not hazardous to human health.

Mesorhizobium loti: Hazard group 1 / GM Class 1
Mesorhizobium loti, formerly known as Rhizobium loti, is a Gram negative species of bacteria found in the root nodules of many plant species where fix nitrogen. M. loti fixes the nitrogen from the atmosphere into ammonium (NH4+) with the enzyme nitrogenase. This is described as a symbiotic relationship because this nitrogen is fixed to a plant usable form; in return, the plant supplies M. loti with carbohydrates, proteins, and oxygen.

Host/vector system

1) We will used standard E. coli vectors:
   a) For cloning:
      - pBR322 and derivatives: AmpR. TetR.
      - pACYC184 and derivatives: ChiR. TetR.
      NB : These vectors could also be used as suicide vectors for P. aeruginosa mutagenesis.
   b) For gene tagging and expression:
      - pET22b/28c/28a and derivatives : ColE1 replicon, AmpR (22) and KanR (28). tag Histidine N or C-terminal.
- pQE30Xa and derivatives: Tag histidine (Qiagen). AmpR.
- pEGFP and derivatives: engineering of gfp fusion. AmpR.
- pGEX and derivatives: Tag GST (Glutathion S-transferase). AmpR.
- PAC or PAN and derivatives: AviTag. AmpR.
- pBADmycHisA, B, C and derivatives: expression from an arabinose promoter, tag histidine and Myc. AmpR.
- GATEWAY plasmids: InVitroGen. System including the entry vector pDONOR and the destination vectors (pDEST derivatives) for recloning and expressing tagged genes.
- pBAD and derivatives: arabinose promoter. AmpR.
- pT7-1 to pT7-6 and derivatives: T7 promoter. AmpR. To be used together with pGP1-2 which carries the gene encoding RNA polymerase from T7 phage. KmR.
- pUT18c and pKT25 and derivatives. Two hybrid system from Ladant. pUT18c (pUC19 derivative), AmpR, contains 3’ region of the gene encoding adenylate cyclase (cyaA). pKT25 (pSU40 derivative), KanR, contains 5’ region of cyaA.
- pBS1479 and derivatives: AmpR. Tandem Affinity Purification (TAP). The TAP-Tag contains a domain CBP (Calmodulin Binding Protein) and a domain Protein A (Affinity for IgG).

2) We will use suicide vectors for the engineering of mutant strains:
- pKNG101 and derivatives: StrR. SucR. Only replicate in
- pEX100 and derivatives: SucR. Only replicate in E. coli lambdapir strain CC118.

3) We will use broad host range vectors for expression in the strains listed in section 2.1 (also replicative in E. coli):
- pLAF1, pLAFR3 and derivatives : IncP, TetR. Cosmid with low copy number.
- pBBRIMCS and derivatives : ChIIR (1), TetR (3), KanR (2) AmpR (4), GentR (5).
- pUC18/19 and derivatives : AmpR. Drivatives of pUC18/19 with a 2.1 kb stabilizing frament allowing replication in Pseudomonas.

4) We will use vectors for conjugation in strains listed in section 2.1:

5) We will use vectors for transposon mutagenesis in these strains:
- pHIP45 and derivatives : Interposons carrying resistances : KanR, TetR, HgR and ChIIR.
- pSUP102 and derivatives : Tn5 –B10 (KanR), -B11 et –B12 (GentR), -B13 (TetR), -B20 (KanR), -B21 (TetR), -B22 (GentR), -B30 (TetR), -B40 (KanR) et –B41 (TetR).
- pUT-Tn5 and derivatives: TetR.
- pBK-miniTn7 and gfp derivatives. pUC19 based vectors with various resistance for delivery of gfp on the chromosom of P. aeruginosa.
- pML1 (GmR) and pLR27 (KmR) and pALMAR3 (TnR) for Tn5 delivery on the chromosom.

6) We will use plasmids to transfect eukaryotic cells:
- pEGFP-C1 and pEGFP-N1.
- pRL-TK or pRK5 vectors and derivatives (Promega).
For Agrobacterium inframe deletions, mutations or insertions will be constructed using pJQ200KS and further cured by a sucrose counter selection procedure. To complement deletion mutants or to over express specific genes in Agrobacterium pRL662, pTrc200, pJN105 or pBBR1 will be utilised.

HOST PLANT SYSTEMS:
We will use Arabidopsis thaliana, Brassica oleracea, Nicotiana benthamiana, Solanum tuberosum and Solanum lycopersicum as hosts. They are all widely-used plant models and none of them will be genetically modified.
The genetic material involved in this project has originated from Prof. Alain Filloux's laboratory. Additional strains will be sourced from approved repositories such as ATCC etc or other scientific lab from around the world (With FERA restrictions on plant pathogens.).

Our project will cover the study of microbial secretion systems and biofilm formation and the regulatory networks govern these two main mechanisms in the listed microorganisms. However, we will primarily focus on four microorganisms: P. aeruginosa, P. syringae, A. tumefaciens and P. putida.

Among the already known genes to be studied, one could name:
- Secretion system genes: structural component of the systems (tss genes, vgrG genes, hcp genes), accessory components (tagF, tagP, ...), effector and immunity genes (tse-tsi genes, ...)
- Biofilm formation genes: lecA, psl operon, pel operon, cup fimbrial clusters, ...
- Regulatory networks: two-component systems (gacA-gacS), quorum sensing system (rel, las, pqs, ...), phosphodiesterase and diguanylate cyclase, ...

**Evaluation of foreseeable effects**

Our project will cover the study of microbial secretion systems and biofilm formation and the regulatory networks govern these two main mechanisms in the listed microorganisms. However, we will primarily focus on four microorganisms: P. aeruginosa, P. syringae, A. tumefaciens and P. putida.

Among the already known genes to be studied, one could name:
- Secretion system genes: structural component of the systems (tss genes, vgrG genes, hcp genes), accessory components (tagF, tagP, ...), effector and immunity genes (tse-tsi genes, ...)
- Biofilm formation genes: lecA, psl operon, pel operon, cup fimbrial clusters, ...
- Regulatory networks: two-component systems (gacA-gacS), quorum sensing system (rel, las, pqs, ...), phosphodiesterase and diguanylate cyclase, ...

It is not envisaged that the genetically modified organisms will be significantly more fit in the environment than the original. However GMM could alter the expression of some secretion systems and biofilm formation capabilities which may affect virulence. Our data and the literature has shown that increasing these traits tends to decrease acute virulence of strains and indeed we see this with Pseudomonas aeruginosa. GMM targeting the genes we are interested in may increase the minimum inhibitory concentration of certain classes of antibiotics but not all classes. However as most of these are laboratory strains infection in healthy individuals is not a particular concern. GMM with increase/decrease activity of secretion systems (our focus is on the Type 6 Secretion System) may increase/decrease the ability of these strains to kill other bacteria/be killed by other bacteria. Environmental release of these strains could potentially be a problem in specific situations but this is unlikely. As our goal with the plant work is to study the biocontrol properties and potentially increase these properties of several environmental strains in order to help defeat plant pathogens. Therefore the GMM of environmental strains (that don’t cause human or plant disease) is designed to promote interbacterial competition against plant pathogens.

Furthermore the level of containment and procedures should prevent release or infection of these strains. There is a very low likelihood of transfer to related microorganisms as lab benches, equipment and other surface areas used for work with cultures will be decontaminated frequently. As this is the work will be performed in a Class 2 lab this is excellent procedures in place to deal with waste. Furthermore the work will be carried out in very central London further reducing the chance of any worst case scenario release.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

There is not going to be any derogation from full containment

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Waste
- GM Material, Hazard Group 2 plant pathogens & and plants
  Contaminated plastics and other solid waste eg nutrient agar or small volumes of soil will be placed inside of a biological hazard bag. The bags need to be kept in a bin close to the work area and must be filled to no more than three-quarters full.
  Prior to disposal the tops of the bags must be loosely taped to contain contents but allow free circulation of steam. Taped bags should be placed into the blue plastic collection boxes which will then be fixed with a blue zippy tie. These blue zippy ties have a unique code assigned to our lab.
  Lab bins used to temporarily collect waste destined for autoclaving in the blue boxes are regularly disinfected with 1% Virkon S or another approved disinfectant.
The blue boxes used to transport the collected waste form the lab bins are sterilised as they go through the validated autoclave with the waste (100% kill). Minimum waste load holding temperature 121 degrees C for 15 minutes. Subject to annual calibration of sensors and validation of the waste load cycle. Waste is collected regularly by the Dept. of Life Sciences technical staff and autoclaved in the Sir Ernst Chain Building. Once autoclaved for decontamination, the waste bags are transferred to a clinical waste bag and placed with in a large bin for collection via registered companies for disposal. Liquid waste will be treated with 1% final concentration virkon for a minimum of 1 hour (Minimum viable load reduction = Log5) or small volumes (<5ml) may be autoclaved directly (100% Kill). Liquid waste will then be disposed of down the sink.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
Dear Professor Filloux,

Following the discussion of your proposal entitled "Secretion system mediated competition ex planta", GMIC-5236 at the last GM Safety Committee meeting, the Committee request that the following amendments are made to the proposal prior to approval:

1.2: 5th paragraph, 1000mL (1 litre) is not small scale, please amend.

2.11: Please can you change ‘class’ to ‘hazard group’ they are two completely different things, class refers to GMO’s only, hazard group to the non GM organisms. Can you also make sure that the hazard group in section 2.10 and 2.11 match up? Whenever you have a hazard group 2 pathogen you cannot say ‘this strain is not hazardous to human health’ if they are plant pathogens (and they have not got a hazard group), can you specify this?

2.12: What about the plant pathogen, Xanthomonas campestris pathovar campestris (Black rot)? Have you confirmed with APHA that no scientific licence is required?

2.17: This is a little vague. Are you implying that genes from any of the listed organisms could be inserted into any of the pathogens? Will any of the deletion, mutations or insertions lead to increased virulence or alterations in host range? Could the down regulation of some genes increase the expression of other genes and increase the virulence of the pathogen? If yes what are the consequences? What are the limits of the work, for example is there anything you won’t do? Please give some examples of the genes you will seek to delete, mutate and insert.

2.18: Please define this better.

4.10: Infection dose is cfu/ml?

4.14: Liquid Culture?

4.18 and 4.20: The list of inserted, deleted or mutated genes is cited in 2.17 as being the annotated genes available from the genome sequence of the PAO1 and PA14 strains (http://pseudomonas.com), as well as other genes found in newly sequenced strains. In addition the genomes of Pseudomonas putida, Agrobacterium tumefaciens, Pseudomonas syringae, Mesorhizobium loti and Acinetobacter baylyi are available. This is a vast array of genes. How can you be certain that your manipulations will not increase pathogenicity or host range? Please explain and define the limits of this work.

5.7: Why only 30 minutes? HSE have previously recommended at least an hour before opening the lid. Remove reference to ‘broken glass’, as it will be double contained.

5.8: Is there any secondary containment in the shaking incubators for the HG2 and class 2 organisms? How are flasks sealed but at the same time allowing gaseous exchange? How are flasks fixed to the shaking platform? Sticky mats are not recommended. Any spill of a class 2 GMO is likely to be reportable.

We discussed this and you need to specify when double containment would be used, especially for environmental risk (plant pathogens). Please amend the risk assessment.

7.1: Is there good efficacy data for 1% virkon against the plant pathogens?

Section 10: Replace references to the accident report form with Salus.

Section 15: The class 2 work needs to be more accurately identified and listed. You may refer to existing information earlier in the form if it clearly identifies the Class 2 work.

Comments: LA gave a brief description of the work.

RW queried if they were planning on using transgenic mutants.

LA explained the core 4 paths will be targeted knock outs and transgenic mutants also.

RW pointed out there was a potential for many of these.

LA confirmed this was correct.

MB suggested defining the limits and putting them in functional groups. Then the rest of the risk assessment could mirror the functional group.

MB asked about the virulence genes.

LA agreed to define and modify.

RB reminded LA to keep in mind what the limits of the work was when completing these sections.

MB asked about secondary containment in the shaking incubators? Possibly putting the flasks in a beaker or using plastic?

AL will put any GM pathogens that are Class 2 or an environmental hazard in secondary containment. AL will specify which pathogens/mutants have to go in secondary containment.

Agreed: Class 2, Containment Level 2. This project is notifiable to the HSE.
The primary aim of my research is to understand how bacteria indigenous to the intestine (the commensal microbiota) influence systemic host defenses to infection by pathogenic microbes. This work will be split into the following phases:

(I) Investigation of what commensal intestinal bacteria, and commensal-derived products, gain access to tissues distal to the intestine.

(II) To understand how the commensal-derived signals described in (I) influence host defenses to bacterial infection by pathogens such as S. pneumoniae and K. pneumoniae.

Phase (I) will include extraction of bacterial products from murine tissue (e.g. spleen, liver and bone marrow) and assaying their concentration and ability to stimulate pattern recognition receptors (PRRs). This will include transfection of eukaryotic cells (e.g. HEK293T cells and macrophages) with PRRs and NFkB expression constructs. Further experiments will be performed to investigate the PRR activating potential of the intestinal microbiota of mice of
different ages and having received different antibiotic treatments. Phase (II) will involve isolation of murine immune cells (eg neutrophils, macrophages and dendritic cells) after treatment of mice with antibiotics to deplete their microbiota. The functions of these cells will be assayed, including the killing of bacterial pathogens, including S. pneumoniae and K. pneumoniae.

**Recipient or parental organism**

S. pneumoniae R6, TIGR4, D39, P1121, 6A (class 2)  
H. influenziae 636 (class 2)  
Klebsiella pneumoniae KP2R1 (class 2)  
Genes will be knocked out to assess their role in the virulence of these organisms

**Host/vector system**

For S. pneumoniae, H. influenziae and K. pneumoniae, vectors will not be used, instead transposon mutagenesis will be used.

**Origin & function**

Genes involved in the biosynthesis of the Streptococcus pneumoniae, H. influenziae and Klebsiella pneumoniae cell wall (for example, but not limited to, Penicillin binding proteins) will be disrupted. This will render all the GM Class 2 organisms more susceptible to killing by immune cells and less able to survive in the environment.

**Evaluation of foreseeable effects**

**S. pneumoniae**

Hazards to human health include transmission to the nasal cavity by hand contact. However, most strains we will use are avirulent. In immunocompromised individuals there is a potential for infection. S. pneumoniae can cause the following diseases: include pneumonia, bacteremia, otitis media, meningitis, sinusitis, sepsis, peritonitis and arthritis. 

Transmission of GM DNA to environmental bacteria is almost zero. GM DNA can be transmitted within the host.

**H. influenziae**

Portal of entry is through the airways, nasal and otherwise where it becomes a commensal in the nasal cavity. This opportunistic pathogen dies rapidly on the bench without being in the host (humans only). Containment will be as above. As we will work with a non-encapsulated version of this organism it is unable to infect or successfully colonise except in cases of severe immunocompromisation (e.g. a patient with cystic fibrosis).

**K. pneumoniae**

Infection can occur with direct contact of mucosal membranes with contaminated surfaces and/or object, and inhalation of infectious airborne secretions, accidental parenteral inoculation and/or ingestion. Klebsiella spp. grow rapidly on surfaces of some vegetation (eg potatoes and lettuce) but do not survive well on the skin. 

The GMMs are disabled and are unlikely to be able to survive in the environment and any modifications proposed (gene inactivation) would not confer a selective advantage even if they were to be transferred to a wild type organism.

The likelihood of hazard is therefore considered to be no greater than that of the parental strains.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid Waste: Treatment with minimum 1% Virkon after dilution with liquid waste for 1h followed by disposal in the sink.
Solid waste: All other hazardous solid biological waste such as tissue culture plasticware (pipettes, flasks etc) will be autoclaved prior to disposal. Petri dishes with agar will be autoclaved prior to disposal.
Sharps: Yellow sharps bins > autoclave sterilisation if known or potentially infected. clinical waste disposal (incineration).
Animal body or recognisable parts: Yellow rigid one way sealed tissue bins. clinical waste disposal (incineration)
Infected or potentially infected lab wastes that have been pretreated before leaving site: Disinfection or sterilisation in the laboratory suite > orange clinical waste bags > clinical waste disposal.

Comments:
2.10: Are all of these Staph strains MRSA? Please clarify which ones are and which ones are not.
2.15 and 2.16: It is unclear as to what is happening with these hosts and inserts. What insert is going into which host? Are all of these vectors only for use in the E.coli? If so please state this more clearly.
2.17: Please list some examples of the genes that you are targeting with the transposon mutagenesis.
2.2 and 4.2: What sort of microorganisms do you expect to be able the culture? Are you interested in anything in particular? If yes these should be added to 2.10 and 4.10
4.22: Please give more details about the volumes of culture in use. E.g. Is this one 4L culture or 40 x 100ml cultures?
5.8: If the culture vessel lids are sealed how is gaseous exchange achieved, please explain?
5.10: Which Form B is this? Please provide a reference number or project title.
Why is there no shedding, please explain?
5.13: Are you Sorting live Class 2 or HG 2 paths? If so where please state this somewhere in the risk assessment?
7.1: Please include the phrase "minimum 1% virkon after dilution with the liquid waste for 1hr" ……… etc
8.1: MSC’s used for operator protection will also have to be airflow tested monthly by the users (or lab manager).
10.1: Make sure it is clear that any spill is treated with concentrated virkon e.g. 5% before removing the mopped up material from the MSC.
Agreed: Class 2, Containment Level 2. This project is notifiable to the HSE.

Project Containment

02/03/2022
Page 352 of 15326
This project aims to establish standardised conditions for reliable post-transcriptional gene silencing in a parasitic nematode by RNA interference (RNAi), and assay effects on parasite development in vivo. The species selected, Nippostrongylus brasiliensis and Heligmosomoides polygyrus, are ideal for the proposed study as they are phylogenetically closely related to a range of strongylid parasites which cause serious disease in livestock worldwide. Moreover, both species are highly amenable to manipulation in the laboratory. Lentiviral delivery systems enable the transduction of both arrested and dividing cells which allowing increased transduction and knockdown efficiencies. Accomplishing stable, selective gene knock-down could lead to major advances in our fundamental understanding of nematode infections and to radically new methods for the treatment and control of helminthiases. Various recombinant DNA constructs will be used in order to introduce a fluorescent reporter and genes of the RNAi machinery from C. elegans necessary for initial binding and systemic spread of dsRNAs. The constructs will be in the form of bacterial plasmids and will be introduced into cultured cells to generate lentiviral particles that will be in turn used to introduce the relevant transgenes and shRNAmir expression cassettes in parasitic nematodes. Mice or rats will be injected subcutaneously with transgenic parasites expressing a reporter gene and/or miRNAs.
Artificial miRNAs will be designed specifically for the relevant nematode genes and may lead to silencing of gene function which in turn may result in impaired parasite survival in the host and an altered host immune function. The notifiable aspect of the project is the transduced nematodes (H. polygyrus; N. brasiliensis) for assessment of transgene expression and target gene knockdown. They are not infectious to humans but can cause disease in rodents.

Recipient or parental organism

Bacteria: E.coli (Class 1 aspect of the work included for completeness)
E. coli bacteria will be transformed with lentiviral vector plasmids for amplification.
Mammalian cell lines: HEK293T cells, COS7 cells (Class 1 aspect of the work included for completeness)
Mammalian packaging cell line HEK293T will be transfected with lentiviral vector plasmids and several helper plasmids encoding gag-pol-env sequences necessary for production of replication-incompetent virus particles. Lentiviral vector plasmids are transfected into mammalian cell lines (e.g., HEK293T, COS7) either alone or together with plasmids (e.g., pcDNA) encoding the parasite-specific target gene cDNA allowing assessment of transgene expression and to validate different shRNAmir sequences for effective knockdown of target genes, respectively. Transduced cell lines to determine virus titres
Parasites: Heligmosomoides polygyrus, Nippostrongylus brasiliensis. (Class 2 aspect of the work)
Transduced nematodes (H. polygyrus; N. brasiliensis) for assessment of transgene expression and target gene knockdown.
None of the GMO’s will be any more hazardous to human health or the environment than the wild type organisms.

Host/vector system

Packaging vectors:
pCMV-dR8.91 + pCMV-VSVG (lentiviral genome split onto two separate plasmids)
pCMVdR8.74psPAX2 + pMD2.G (lentiviral genome split onto two separate plasmids)
TransLenti packaging mix (lentiviral genome split onto 5 separate plasmids)
Transgene vectors for viral production:
pGIPZ (commercial vector with turboGFP and self-inactivating LTR)
pGIPZ_mCherry (derived from pGIPZ replacing turboGFP with mCherry)
pGIPZ_EV (derived from pGIPZ_mCherry by deletion of IRES/puro)
pGIPZ_SmACT1.1 (derived from pGIPZ_EV replacing CMV with SmACT1.1)
pGIPZ_IPP (derived from pGIPZ_EV replacing CMV with IPP)
pGIPZ_UCOE (derived from pGIPZ_EV encoding UCOE upstream of CMV)
pGIPZ_OVA (derived from pGIPZ_EV replacing mCherry with OVA)
pGIPZ_OVA_GPI (derived from pGIPZ_OVA, GPI-anchor added)
pGIPZ_OVAopt (derived from pGIPZ_OVA replacing OVA with OVA_opt)
pGIPZ_RDE-4 (derived from pGIPZ_mCherry replacing mCherry with RDE-4)
pGIPZ_ERI-5 (derived from pGIPZ_EV replacing mCherry with ERI-5)
pGIPZ_RDE-4_RERI-5 (derived from pGIPZ_ERI-5 and pGIPZ_RDE-4 adding RDE-4/IRES upstream of ERI-5)
Mammalian expression plasmid:
pcDNA3.1 (commercially available plasmid from Invitrogen)

**Evaluation of foreseeable effects**

The most hazardous GMM produced will be lentiviruses carrying fluorescent reporters or C. elegans proteins. Lentiviruses are able to infect human cells even when non-dividing, however no harmful constructs will be cloned into such vectors. There is no chance that oncogenes will be packaged into lentiviral particles because these constructs carry packaging signals, which would not lead to enclosure into a lentiviral capsid even in the accidental event of lentiviral packaging cells being transfected with the oncogenic constructs. Lentiviral particles carry a self-inactivating LTR and are replication-incompetent. The risk posed to human health by all GMM produced will be negligible, and further minimised by reducing the use of sharps.  

All GMOs generated, including nematodes, are no more harmful to human or animal health or the environment than the wild type organisms.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Infected rodents are kept in IVCs in a purpose built animal containment unit and carcasses autoclaved and disposed of by CBS staff.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

| Liquid Waste - Final concentration of not less than 1% Virkon (10g in 1litre) for 30 min |
| Solid Waste - All lentivirus-contaminated plastic are left in contact with Virkon for 30 minutes. Pipettes are then discarded in the dedicated pipette bin to prevent waste bags being pierced. All plastics are then discarded into a transparent autoclave bag into a white bucket bin for autoclaving. |
| Needles and sharps – Placed in a yellow sharps bin for autoclaving and clinical waste disposal |
| Animal Carcasses - carcasses are autoclaved and disposed of by CBS. |

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment

Please enter comments on the GM safety committee on the risk assessment
Dear Professor Selkirk,

Following the discussion of your proposal entitled “Lentiviral delivery of artificial miRNAs to parasitic nematodes” GMIC- 5743 at the last GM Safety Committee meeting, the Committee request that the following amendments are made to the proposal prior to approval:

SOP: changing the reference from rats to mice in some of the SOPs.

1.2: How are the animals infected? SOP refers to a subcutaneous method of infection, I assume this involves use of a needle?

How are the whole viable nematodes transduced? I didn’t see this in the SOP’s

1.3: Location of the FILM unit?

2.2: Remove mention of the whole viable nematodes form here unless nematode derived cell lines are being cultured.

Remove mention of the whole live mice form this section unless mouse derived cell lines are being cultured.

2.4: Are the mammalian cell lines commercially obtained? If so what guarantees of sterility are provided?

2.13: Add CRISPR gene knock out system here. (It has been decided by the PI that this will not now be incorporated into this experiment)

2.18 and 4.20: Please include a statement about the GMO’s, including the nematodes, being no more harmful to the environment than the wild type organisms.

3.1: Please tick the no box as the GM Nematodes are Class 2 and will need to be handled at CL2

4.15: Add CRISPR gene knock out system here. (It has been decided by the PI that this will not now be incorporated into this experiment)

4.21: Add the infectious route for the nematodes in mice.

5.1: Not all work? I assume this just refers to the genetic manipulation of the lentivirus, cell lines, E.coli and nematodes?

5.3: Please give a typical example of these containers.

5.5: From where are the nematodes obtained?

5.10: I appreciate that there is no shedding of material infectious to humans but what about shedding and dispersal of material

CU 2 2000 (rev 11/08) Page 7 of 12

infectious to rodents, e.g. The nematodes. How is this prevented and controlled. The SOP does not give any more information and this is an important point as the material is GM class 2 in relation to the environment and rodents.

5.12: This section refers to inactivation for further molecular investigation not waste disposal. E.g. Lysis of virus, cells or nematodes for genetic analysis, quantitative PCR etc

7.1: Specify that GM nematode infected rodents will be autoclaved before leaving site for incineration

Section 8: MSC’s used for operator and environmental protection need to be airflow tested by an engineer every 6 months and KI operator protection tested annually. Users must also carry out air flow checks monthly using a 100mm vane anemometer and record the results

Section 9: Any refresher training especially for emergency procedures?

11.5: Please complete this section. Your rooms will have a small coloured circle on the door, probably either yellow or orange. If not please get in touch with Biosafety.

15.1: Whole viable GM virally transduced nematodes expressing molecular markers will be GM Class 2

Comments: MS gave a brief description of the work.

IH pointed out that The Class 2 aspect of this project is the genetic modification of the mouse pathogenic nematodes Heligmosomoides polygyrus, Nippostrongylus brasiliensis. Gene Silencing may not be classed as class 2 GM work if it is transient, however the genetic marker labelling of the whole viable mouse and rat nematode parasites will be GM Class 2.
MS explained that they did know how long it would last, between 10 days and 3 weeks. It was the effects over the period of time they were interested in.

IH queried if the progeny from nematode worms were genetically modified?

MS pointed out that this was difficult to know. It could be passed onto the next generation.

NF suggested adding the CRISPR stage of the project to the application now.

The committee agreed this could be considered a significant change in the future. To save time and costs, it should be added to the form now.

IH asked about shedding?

MS explained there would be none if transduced.

IH wanted to know about the nematode shedding.

MS described that the eggs in the guts moved to the faeces and the bedding would be contained.

JP suggested changing the reference from rats to mice in some of the SOPs.

HK asked about what rooms were used.

MS gave the details of the rooms. The viral GM class 2 work is in the Ernst Chain Building, the transduced parasites in designated rooms, the mice parasites in the CBS (shared room).

NF enquired if the mouse handling would all be in the IVF.

MS confirmed that it was.

Agreed: Class 2, Containment Level 2. This needs to be notified to the HSE.

IC reference number: GMIC-5743

Could you please ensure that the risk assessment is revised (add GMIC number) and the amendments above addressed. I will then forward the form onto Occupational Health to complete. The completed HSE CU2 form (attached to this email), and copy of the Purchase Order (for BACs Payment) made payable to the HSE should be sent to me. I will then send it all to the HSE. Please ensure the information given in HSE Form relates to that provided in your risk assessment.

For further information, please see http://www3.imperial.ac.uk/safety/subjects/biosafety/gmprocedures

Please note that this work must be notified to the HSE and an acknowledgement receipt received prior to this work commencing.

Date Project Ceased 02/03/2022
Aim: To develop the iChip technology (Nichols et al. Applied and Environmental Biology 2010) to now facilitate in situ screening of antibiotic properties of bacteria cultivated in soil. The bacteria strains we seek permission to get registered will be developed to work as the sensors of antibiotic properties. Bioluminescent read outs should reveal whether soil bacteria cultures stress our sensor bacteria and thereby leads to a decrease in light emission. The novel screening device (here called the isCHIP or in-situ screening CHIP) will be buried in the soil outside of a laboratory environment on ICL premises at Silwood Park London. Details of the isChip can be found in the attached documents.

Initial aims are to develop a biosensor in the lab that uses GM Class 1 and 2 sensor organisms and test using soil brought into the lab. Once this phase has been established additional steps will include testing the new isCHIP in the soil in a controlled area.

In the choice of strains we have taken care in selecting strains that are clinically relevant, can survive in soil for extended periods of time, but have limited risks for the researchers and the external environment. An example is E. coli 0157:H7 which is important in several types of E coli infection making it clinically relevant. We have, however, found a strain that has been tested and found to be non-toxigenic. It should therefore not pose a threat to the researcher.

We will be testing the ability of antibiotic producers to inhibit further growth of our reporter strains.

To do this:
We will culture GM strains that have a Lux operon chromosomally integrated.
We will use Lambda red to create our own mutants with chromosomally integrated luminescens.
Finally we will attempt to create more susceptible strains by knocking out genes that protect the bacteria from exposure to antimicrobials. An example could be to knock out tolC.
All knock outs should lead to a decrease in fitness for the organism, and should therefore decrease the organism's chance of survival in the wild.

Procedures therefore include:
Genetic manipulation of a variety of bacteria i.e. electroporation and conjugation to insert genes on plasmids or make chromosomal deletions or insertions and random mutagenesis to optimise expressssson. culturing (on agar plates, some in microaerobic chamber or microaerobic jars), flash-freezing, light microscopy slide preparation with
~ 10ul of dilute cell suspension sealed between glass slides and cover glass using a solidified mixture of vaseline, paraffin wax, and lanolin, coated with a layer of nail polish. Finally cell sorting will be carried out using the ARIA designated for bacteria in the Flowers building. We will be placing the isCHIP in soil outside of a laboratory at Silwood park. The isCHIP is a contained environment that allows biochemicals to diffuse across a membrane and interact with the sensor bacteria but does not allow the escape or ingress of biological agents. Please refer to the attached detailed description of the device.

i) The site will be robustly marked in similar fashion to other projects at Silwood Park.

ii) We have designed the isCHIP to be made of 0.5mm class 2 titanium. There will be two outer layers of titanium that will protect against animals coming in contact with the enclosed bacteria. Each layer of titanium will only allow access to the inner chip through 1536 wells with a radius of 0.4mm (See attached design of prototype)

iii) The isCHIP will be contained in sealed boxes during transport. When buried, it will be buried on an area of 6 x 6 meters. We envisage <50 isCHIPs buried at a time. Each isCHIP will be marked with a flag at the surface of the burial site.

Bacillus subtilis HG1. Soil borne organism not known to cause disease in healthy human hosts

Host/vector system

TN5- Transposase (Tnp) TN5 is a member of the RNase superfamily of proteins which includes retroviral integrases. Tn5 can be found in Shewanella and Escherichia bacteria. The transposon codes for antibiotic resistance to kanamycin and therefore allows for positive selection of colonies where Tn5 has been integrated.

Lambda Red - is one of the standard methods for generating insertion, deletion, and point mutations on chromosomal targets in many gram negative bacterial species. Plasmids include PCP20, PKD46, PKD3, and PKD4.

plasmid pMV306hsp. Plasmid pMV306hsp is a modified plasmid that has been shown to have high stability and expression in mycobacteria.

Origin & function

The lux operon consist of a luxAB coding for luciferase and luxCDE coding for the fatty acid reductase complex responsible for synthesizing fatty aldehydes for the
luminescence reaction. They operon derives from V. fischeri.

Firefly luciferase is a euglobulin protein that catalyses the oxygenation of luciferin using ATP and molecular oxygen to yield oxyluciferin. It is derived from Photinus pyralis.

Kanamycin resistance gene.

**Evaluation of foreseeable effects**

Our mutagenesis strategy is to implement targeted mutagenesis. These include the insertion of a) a LuxCDABE operon and b) permutations of knockouts that increases the susceptibility of the reporter strain to antibiotics.

a) the LuxCDABE places a metabolic burden on the host, which will decrease the fitness of the GMO [1.Nunes-halldorson and Duran, 2003]. Hastings and Nealson [2. Hastings and Nealson, 1981] estimated that light emission represents an energy expenditure of approximately six ATP molecules for each photon, assuming 100% efficiency for the reaction.

The effect on fitness has been confirmed experimentally - The result suggested that the incorporation of a lux operon in an E. coli O157:H7 strain had a small negative effect on survival time in ground water (Fig 1) [Ritchie et al, 2003]. Ritchie, J.M., et al., A stable bioluminescent construct of Escherichia coli O157: H7 for hazard assessments of long-term survival in the environment. Applied and environmental microbiology, 2003. 69(6): p. 3359-3367.

b) The targeted deletions will decrease the fitness of the host organism, as the deletions are important functional proteins. An example of a knockout candidate is TolC, which plays a common role in the expulsion of diverse molecules, including protein toxins and antibacterial drugs, from the cell.

Wild type strains of all bacteria will therefore be the most hazardous strain employed; all derivative GMMs will be less pathogenic due to the lack of selective advantage of the genes in question.

We will confirm that wildtype strains have the highest fitness through survival studies before we bury the GM strains in situ.

For in situ experiments:

E. coli:

At present we are targeting three strains of E. coli (W, O1:K1:H7, and O157:H7 with no shigatoxins) for mutagenesis. Different E. coli strains have been shown to be able to survive in soil, although at low concentrations [4]. O157:H7 has specifically been shown to die out over time in soil[3]. The three strains, will, however, have mutations that reduce their fitness. No strain is pathogenic to humans. The E. coli O1:K1:H7 strain causes cystitis in chickens.

B. subtilis, P. putida, P. fluorescens, and M. smegmatis all grow naturally in soil and are non-pathogenic. We will use strains that were isolated in the UK.

These are the only strains we plan to culture for our in situ experiments.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

none.

Please enter comments on the GM safety committee on the risk assessment
Additional note post committee from the BSO
“There might be a problem using the family farm for this work as we might have to register it as a GM centre. I thought you were using Silwood Park? This would be easier as it is already notified to the HSE as a GM centre”.

21.1 Papers for Discussion

21.11 Bio1 Form
Screening for novel antibiotics in soil CL2. Dr H Low, Life Sciences, South Kensington Campus.
Comments: In the absence of the PI and Researcher, SH gave a brief description of the work.
Both IH and SH had discussed prior to the GMSC meeting if this experiment came under the GM Contained Use Regulations or the deliberate release regulations. The structure and robustness of the cell and the environmental locations (a farm as well as the Silwood Park location) were considered. It was decided to put it forwards as a contained use application.

RW asked if small samples of soil were to be bought into the lab environment, would this degrade the sample and alter the experimental outcome?
SH explained that pilot experiments would involve bringing soil into the lab but that the samples were substantial amount e.g. bucket fulls, but that this was just a proof of concept and the main experiments would have to involve environmental sampling.

RW also asked that it was likely that the isChip needed to be grown in a natural environment, so that the soil remained in its natural location with all the external influences that implies e.g. the fall in night temperature, sunlight, pH stability, exposure to rainfall etc to improve the chances of the soil organisms surviving and producing the antibiotics that were being looked for.

RW asked how long the isChip would be incubated in the soil?
SH answered, up to 30 days.
RW wanted to know if the isChip would be buried in the ground.
SH confirmed they would be, however, the depth they were buried at was not clear and this should be stated in the risk assessment and SOP.
SH also added that tests will be conducted in the labs to see if the bacteria would ingress into or leak from the isChip. The paper they cite, shows no ingress or leak.

HK asked what would happen if the isChip was lost or damaged, e.g. by an animal or farm machinery?
SH explained that the Silwood Park grounds and the grounds on the Farm were both controlled areas and the sites would be clearly marked and separated from other activities. This will should be explained in the risk assessment and SOP

RW asked how many devices were they planning on burying?
The Committee agreed this needed to be answered in the risk assessment and SOP

The following amendments were required prior to approval:
SOP: Explain how many isChips were being used, the amount of land to be used, how deep the chips will be buried, and how the chips will be secured to prevent them from going missing or being damaged. A precise location will have to be given for each site. A grid reference should be provided using a GPS device.
Bio1 Form: Typos throughout the whole form, please revise.
1.3: List locations of Silwood Park and external Farm, the field sites should include a GPS location to 8 or 10 figures. The OS app on smart phones can do this.
2.16: Add the functional properties of vectors.
2.17: ‘aldehyde’ should be ‘luciferin’
3.20: Remove ‘melis’. What will be used for decontamination?
4.7: Remove comma, answer ‘yes’
Agreed: Class 2, Containment Level 2. This needs to be notified to the HSE.
IC reference number: GMIC-6023

<tr>
<td>22/07/2016</td>
<td>Discovering the mechanisms of microbial accommodation inside plant cells</td>
</tr>
</tbody>
</table>

#### Purposes of the contained use

The aim of our work is to dissect the resistance mechanisms in Solanaceous plants (tomato, potato, and Nicotiana spp.) and understanding the molecular mechanisms underlying plant-microbe interactions. Specific focus will be on perturbations caused by microbial pathogens in the host cell endomembrane transport processes. Mainly, eukaryotic plant pathogens such as the oomycetes Phytophthora infestans and/or Phytophthora capsici, Phytophthora palmivora, Peronospora tabacina will be used to study plant immune responses and processes altered during microbial attack. Plant pathogens target secreted proteins such as cytoplasmic effectors inside host cells where they directly modify or perturb host cellular processes. These pathogens use specialised secretion systems and targeting signals to translocate effector proteins inside host cells. In filamentous pathogenic eukaryotes (fungi and oomycetes) both the nature of the recognition sequences and the focus of any effector’s localisation are largely unknown. In addition, we will also modify plants. Plants attract many parasitic and symbiotic organisms. Some of these parasites and symbionts are accommodated inside invaded plant cells in specialized compartments that are typically separated by host-derived membranes from the plant cytoplasm. This interface is critical in the regulation and development of parasitic infection or symbiotic host colonization for instance by enabling efficient macromolecule exchange. However,
the mechanisms underlining the biogenesis and functions of this intimate host-microbe interface are poorly understood. Specifically, we know little about the reprogramming of cellular and biochemical events that take place inside plant cells that are invaded by microbes. The proposed research aims to characterize the host processes required for accommodation of filamentous plant pathogens inside the plant cells with a specific focus on illustrating the role of plant endomembrane system. To this end we will investigate the mechanisms and perturbations in the plant endomembrane system during accommodation of oomycete pathogens such as Phytophthora infestans (P. infestans) within the host plants. An improved understanding of the molecular basis of the role of host endomembrane system during plant-microbe interactions will provide novel insights in plant pathology and cell biology and improved opportunities for engineering disease resistance in crop plants.

Plants are generated using agrobactrium mediated transformation. Foreign DNA transfer in plants is a mechanism occurring in the wild known as Crown-gall disease and is caused by Agrobacterium tumefaciens (gram negative bacteria). Agrobacterium tumefaciens infects the plant through its tumour inducing (Ti) plasmid which integrates a segment of its DNA (T-DNA) into the chromosomal DNA of its host plant cells. Disarmed Agrobacterium tumefaciens strains, carrying a Ti plasmid lacking tumour genes, are routinely used to insert prokaryotic or eukaryotic DNA fragments into plants of the Solanaceae and many other plants.

Plant DNA fragments are isolated as genomic DNA or cDNA and propagated in plasmids or viral vectors in E.coli. i. Cloned into a range of lambda vectors (eg lambda Flx-II, pRK290 cosmid vectors) and used in disabled E.coli strains (eg P2392, LE392, C600). ii. Cloned into non-mobilisable vectors (eg PUC19) and used in disabled E.coli strains (MC1022, DH5α). iii. Cloned into IncP transferable binary vectors and used in disabled Agrobacterium strains for transient expression in plant tissues and/or in planta as well as stable plant transformation. These clones were used as a source of DNA for manipulation of plant genomes.

The GM plants generated pose no more risk to the environment than the wild type and the bacteria are all GM class 1 and are not part of this notification.

The genetically modified variants of the DEFRA/FERA licensed pathogens (P. infestans, P. capsici, P. palmivora) will be handled under the same conditions as the non modified parental strains. The work will take place in closed containers. contained in small transparent plastic boxes/containers on wet paper towels. Infections will be performed by droplets of zoospore solutions with a pippete (10 ul droplets on the leaf surface). In some cases tissue will be frozen and ground in liquid nitrogen. Phytophthora cultures will be also stored in liquid cultures. Infected leaf samples will be taken to imaging facilities in containers mentioned above.

The eukaryotic plant pathogen; P. infestans is present in the local environment, unmodified recipient strains may be imported from outside of the UK and held under licence from DEFRA.

The premises have been inspected by APHA and the latest scientific license is attached with this notification. A full explanation of the work including the use of class 1 GMO's and GM modified plants not requiring notification can be read in the attached Bio1 risk assessment and Form D.

Recipient or parental organism

Phytophthora infestans
Phytophthora capsici
Phytophthora palmivora

Host/vector system

pTOR (6531 bp) vector with ham34 promoter and terminator from phytophthora infestans will be used. Vector is designed for expression in Phytophthora infestans.

Origin & function
Red Fluorescent Protein (RFP), Green Fluorescent protein and Yellow Fluorescent Protein will be used to achieve fluorescence labeling of Phytophthora species. Depending on the course of the research it is possible that some of the RXLR effectors (Virulence factors induced during infection) could be also mutated/knock out or overexpressed in Phytophthora.

It has been established, for example, that most natural isolates of P. infestans carry a gene for effectors, such as inf1 and Avr3a. It is likely therefore that these genes are required for full virulence and that any suppression of their expression either directly through silencing or indirectly by the expression of other effector genes will lead to loss of virulence.

Fusions to reporter genes (e.g. GFP, GUS) will be made to study the expression and localization of effector genes. All genetically modified strains of eukaryotic plant pathogens so generated will also carry antibiotic resistance genes such as hph encoding hygromycin resistance or nptII encoding G418 resistance in order to select for stably transformed clones.

Evaluation of foreseeable effects

The genetically modified strains of plant pathogens described in this risk assessment will differ from natural isolates in that the expression of effector genes is altered or that they express reporter genes. Any consequent loss of avirulence is unlikely to have an environmental effect in the UK and would not differ from naturally occurring isolates. The available information gives no indication that alteration of the expression of effector genes is likely to have other environmental effects. It has been established, for example, that most natural isolates of P. infestans carry a gene for effectors, such as inf1 and Avr3a. It is likely therefore that these genes are required for full virulence and that any suppression of their expression either directly through silencing or indirectly by the expression of other effector genes will lead to loss of virulence. Taking these factors into account we consider that the risk of harm is effectively low/zero. Therefore, transfer of modifications to related microorganisms in the environment is not likely to occur. The GM plant pathogens created are not predicted to pose any greater risk of harm to human health or the environment than the wild type.

The proposed genetic modifications are predicted to not alter the host range or virulence of the recipient strains which will not be significantly different in their pathogenicity to naturally occurring isolates and are therefore unlikely to pose more of an environmental hazard than wild type strains.

In theory the over-expression of virulence factors might be expected to enhance virulence, however there is no report so far showing this is the case. This is probably because these virulence factors are already expressed highly during infection and efforts of over-expression does not necessarily influence the virulence. Also, there are around 500 different virulence factors that coordinate virulence and changing the expression level of one gene is not likely to have a big difference in virulence.

In addition, sporangiospores and zoospores, the main stages manipulated in the laboratory that could be accidentally released lack vigour and cannot survive for extensive periods as airborne spores in the absence of suitable host plants.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid cultures are chemically inactivated using 5% sodium hypochlorite final concentration for 30 minutes, and
autoclaved prior to disposal. Laboratory disposables are autoclaved prior to disposal, sharps are sterilized in sodium hypochlorite before disposal. This waste will then be further autoclaved.

Is an emergency plan required according to regulation 20?

If yes, tick to confirm that it is attached to this form  

N  

Tick to confirm that you have attached a risk assessment to this form  

Y  

Tick if you are claiming exemption from disclosure for section of the risk assessment  

N  

Please enter comments on the GM safety committee on the risk assessment

Comments from the BSO

Section 2.17 You need to be quite specific about the genes you are altering, knocking out or introducing and what the effects will be on the host organism. There still appears to be genes mentioned in section 1.2 which do not appear in the GM section of the Bio1. See highlighted sections below. I am happy to come across to you and go through the form and the CU2 if it would help. I am free most of tomorrow morning from about 10 – Hope this helps - Ian

"In addition, fusions to reporter genes (e.g. GFP, GUS) will be made to study the expression and localization of effector genes. All genetically modified strains of eukaryotic plant pathogens so generated will also carry antibiotic resistance genes such as hph encoding hygromycin resistance or nptII encoding G418 resistance in order to select for stably transformed clones. Furthermore, eukaryotic plant pathogens will be genetically modified to express reporter genes (e.g. GFP, DsRed) to enable studies of the organisms development in planta.

Comments from GM committee

Dear Dr Bozkurt,

Following the discussion of your proposal entitled “Discovering the mechanisms of microbial accommodation inside plant cells”, GMIC-2549 at the last GM Safety Committee meeting, the Committee request that the following amendments are made to the proposal prior to approval:

2.11: A tumefaciens. Please confirm that the strains you have named are all disarmed strains well characterised with a safe history of use.

2.15: Where did you get the DEFRA containment levels from?

Section 5 and all other sections onwards from here Please reference the appropriate section of the COP where requested.

7.1: Liquid waste – Time waste is treated for?

Solid waste – Can the autoclave sterilise this amount of soil? Or is soil placed in sealable tissue bins for incineration?

7.4: Please tick the potentially or known infected lab wastes that have been pre treated box.

Section 10: treating a liquid spill with 70% ethanol will not work. All liquid spills should be treated with concentrated disinfectant before being absorbed and disposed of as solid waste. Please check your COP for spills and make sure that the risk assessment and COP agree. Bleach is not a satisfactory disinfectant. You have previously specified Sodium hypochlorite. This must be purchased as a commercial product for inactivation of microorganisms, e.g. Chlorox

Comments: TB presented and overview of his proposed work.

IH asked if all of the Agrobacterium tumafaciens strains were disarmed?

PS and TB confirmed that they were.

IH pointed out that the organisms listed in 2.10 and 2.15 would need to be notified to FERA and a scientific licence obtained.

TB and PS said that they were aware of this.

IH stated that he would forward details of the FERA electronic notifications system to TB.

Agreed: Class 2, Containment Level 2. This project is notifiable to the HSE.

Project Additional Information

Purposes of the contained use

The objective of this project is to study Pseudomonas aeruginosa infection in cystic fibrosis (CF) patients and to develop a diagnosing methodology on excreted fluids. P. aeruginosa and excreted fluids isolated from CF patients will thus be analysed. Genetically modified organisms will also be studied to get a better understanding of the bacterium and the infection mechanisms. Other CF-related pathogens will be analysed in order to identify P. aeruginosa characteristic features.

To achieve our goals, we want to use rapid evaporative ionisation mass spectrometry technology (REIMS) as it has demonstrated promising results on bacteria and is quite simple to implement. During REIMS analysis, an electrical current is applied directly to biological material using forceps. The ions generated become vaporised and are passed through the forceps and channelled into the mass spectrometer.

The Royal Brompton Hospital will provide fluid samples collected from CF patients (e.g. urine, saliva, sputum, skin secretion, exhaled breath condensate) as well as bacterial strains of Pseudomonas aeruginosa and other CF related pathogens (Hazard Group 2) isolated from sputum samples. They will be provided to us as bacterial cultures on petri dishes to be incubated prior to analysis, either at RBH or lab 373C at Sir Alexander Fleming building (SAFB), South Kensington campus (SK). These will not be genetically modified (GM).

Other bacterial cultures will be provided by the microbiology laboratories of SK campus. They will also provide
GM P. aeruginosa isolates for us to analyse in order to study gene metabolic functions. The identity of each bacterial isolates will be known prior to further work and human samples will have been tested at RBH. Antibiotic susceptibilities will be known for some of them. Both samples and bacterial isolates will be transported in a designated transport carrier to SK for REIMS analysis. They will be transported following the Packing Instruction 650, detailed by Imperial College guidelines. Samples and bacterial plates will be stored in a laboratory fridge until analysis (37°C at SAFB); cryovials will be kept in the freezer (373 at SAFB). Samples and bacterial isolates will be discarded according to SOP instructions at SK (SOP Handling Waste). REIMS analysis will be performed at SAFB 373 following SOP. All steps of the procedure will be conducted in a Class II biological safety cabinet.

We will use the complete collection of P. aeruginosa genes which are annotated from the PAO1 genome sequence (http://Pseudomonas.com). This collection comprises over 5500 genes and will be completed by genes identified in newly sequenced P. aeruginosa strains (such as PA14). All the genes are cloned in the pDONOR entry vector (Gateway, invitrogen) and could be moved in the pDEST series of destination vectors that allow overexpression of the genes and production of tagged proteins. These plasmids are maintained in E. coli strains and genes will be overexpressed in E. coli for biochemical and structural applications. For studying the physiological role of the P. aeruginosa genes, the genes could be transferred from E. coli into P. aeruginosa and related strains by re-cloning in broad host range plasmids from the pMMB or pBBRMCS series and conjugated into P. aeruginosa with the help of the pRK2013 plasmid or the S17-1 E. coli strain. Whenever it is required site directed mutagenesis will be performed. The strategy will consist in interrupting the target gene by homologous recombination with an internal DNA fragment cloned into a non-replicative vector for P. aeruginosa or by creating a clean gene deletion using suicide vector which could be further cured by a sucrose selection procedure (pKNG101 or pEX series of plasmids). Moreover random transposon mutagenesis will be performed using delivery systems for Tn5 or Tn7 derivative plasmids. Some of these transposon derivatives will contain a T7 or tac promoter reading outwards for expression of downstream genes, other will carry promoterless lacZ or gfp genes to create chromosomal transcriptional fusion. The antibiotic markers carried by the plasmids and transposon used will essentially be: kanamycin, gentamycin, tetracycline, carbenicillin, ampicillin, chloramphenicol and streptomycin. For complementation studies of the obtained mutants, genes will be cloned on broad host range vectors. In all cases, the desired constructions will be introduced in P. aeruginosa by electroporation or conjugation.

Recipient or parental organism

Class 2
P. aeruginosa (HG2)

Class 1
Attenuated non toxigenis K12 derived E. coli (from standard commercially available clonin kits e.g. DHSalpha) (HG1)

Host/vector system

We will use broad host range vectors for expression in P. aeruginosa (also replicative in E. coli):
- pLAFR1, pLAFR3 and derivatives : IncP, TetR. Cosmid with low copy number.
- Mini-CTX1 and Mini-CTX2 (TetR, pMB1 origin, CTX integrase) for engineering lacZ transcripntional fusion on the chromosome.
We will use suicide vectors for the engineering of Pseudomonas mutants:
- pKNG101 and derivatives : StrR. SucR. Only replicate in the E. coli lambdapi strain CC118.
- pEX100 and derivatives: SucR. Only replicate in E. coli lambdapir strain CC118.
- pUT-Tn5 and derivatives: TetR.
- pBK-miniTn7 and gfp derivatives, pUC19 based vectors with various resistance for delivery of gfp on the chromosom of P. aeruginosa.
- pML1 (GmR) and pLR27 (KmR) and pALMAR3 (TnR) for Tn5 delivery on the chromosom.
- Mini-CTX1 and Mini-CTX2 (TetR, pMB1 origin, CTX integrase) for engineering lacZ transcriptional fusion on the chromosom.
- pFLP2 for excision of CTX backbone from the chromosom (ApR, sacB).

Origin & function

Because of the nature of this project we will use all annotated genes available from the genome sequence of the PAO1 and PA14 strains (http://Pseudomonas.com), as well as other genes which will be found in newly sequenced strains.

Evaluation of foreseeable effects

The hazardous potential of the GMMs created is considered to be no greater than that of the parental strain. In many cases genes are inactivated in the GMM that are required for optimal growth and pathogenesis.

It is not envisaged that the genetically modified organisms will be significantly more fit in the environment than the original. However GMM could alter the expression of some secretion systems and biofilm formation capabilities which may affect virulence. Our data and the literature has shown that increasing these traits tends to decrease acute virulence of strains and indeed we see this with Pseudomonas aeruginosa. GMM targeting the genes we are interested in may increase the minimum inhibitory concentration of certain classes of antibiotics but not all classes. Furthermore the chances of creating a mutant strain with increased virulence is diminishingly small as these mutants should have already arisen in the global population and be highly prevalent. In addition, as most of these are laboratory strains infection in healthy individuals is not a particular concern.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

No liquid waste will be generated in routine use as culture plates will be purchased already filled with solidified growing media. The small quantities of liquid samples will be soaked up with tissue paper to prevent spillage before disposal through the solid waste route (max 200mL/bin)

Solid waste - i.e. bacterial plates, sputum, soaked up liquids - will be sterilised in an autoclave (Waste programmes are run 121C for 20 minutes) before disposal by a specialized company for incineration.

The print outs on the bags are checked to ensure that the cycle has not failed. The autoclaves go through an annual inspection plus a 6-monthly maintenance performed by Ascot Autoclaves. The Imperial staff performs weekly checks in accordance with the manufacturer's instructions.

Is an emergency plan required according to regulation 20?

Tick if you are claiming exemption from disclosure for section of the risk assessment

N
Following the discussion of your proposal entitled "Analysis of bacteria-containing samples using Rapid Evaporative Ionization Mass Spectrophotometry (REIMS)" (GMIC-5384), the committee request that the following amendments are made to the proposal prior to approval:

Reviewer 1
1.2 This does not mention the GM work. Please include a brief description and how it fits in with the rest of the REIMS work in this overview.
2.14 Isolation of Burholderia cepacia from patients is mentioned in 1.2 Is this part of the GM process as well?
2.15 Please list all the recipient microorganisms for the GM work i.e. The host organisms. I believe from the description of your work this will include the following:
Pseudomonas aeruginosa HG2
Burkholderia cepaciae HG2
Attenuated non toxigenic K12 derived E.coli (from standard commercially available cloning kits e.g. DH5alpha, ) HG 1
7.1 ‘Liquid waste generated during disinfection’ What is this material, is it liquid culture waste? What happens to the E.coli and Pa liquid cultures? Please describe the use of any chemical disinfection e.g. "Virkon is added to the liquid culture waste to a minimum concentration of 1% for 30 minutes before disposal to the drains”
8.1 Maintenance frequency of the Autoclaves? This is likely to be annual by a qualified engineer and will include a pressure system inspection, probe calibration and waste run validation procedures. This is in addition to users checks in accordance with the manufacturer’s instructions.

Please enter comments on the GM safety committee on the risk assessment

Section 13 Lone working requires completion.
Section 14 Please be more specific about the containment level required for the various processes
The Incubation, plating and storage of Pseudomonas aeruginosa and Burkholderia cepaciae CL2
The incubation, plating and storage of attenuated E.coli CL1 1

Section 15 Please be more specific about the containment level for the various processes
The Genetic modification, incubation, plating and storage of Pseudomonas aeruginosa and Burkholderia cepaciae Class 2
The Genetic modification, incubation, plating and storage of attenuated E.coli Class 1

SOP Spillages – Need to differentiate between spills inside MSC, spills outside and MSC, spills outside a lab. The plates will be transported in double-sealed containers so there is no anticipated scenario that would lead to spillage outside the laboratory.

SOP decontamination – What about the MSC’s? cf SOP for MSC
SOP – Prep of trionic. Eye goggles? Do you mean goggles or glasses.? Goggles are usually reserved for higher risk chemicals. What is it about the chemical or the process that requires goggles? We opted for the glasses, cf SOP Preparation of Trionic Disinfectant
SOP Reims – The SOP does not look as if the forceps are in an MSC and yet the Bio1 says they should be? The picture needs to be updated, I specified in the SOP that this was a demonstration of the operation but that it has to be conducted inside the MSC. This needs to be discussed at committee. Decontamination of the forceps by forcing fluids back through them into a sink may generate infectious aerosols. Can the forceps be soaked in Trionic solution prior to flushing? That's absolutely right, I added a step consisting of sonicating the forceps in IPA before flushing.

SOP – Safety – What sort of eye protection? Goggles and glasses are available, to be chosen according to the chemical risk or as stated in SOP
SOP transport – What about transport of plates within the lab? They will be transported in racks, cf bio1 form.

What about Training and competence? We would need to see training documents detailing what the person has been trained to do with signatures form the trainee, trainer
and PI, as well as periodic refresher training. This is recorded in appendix 5.

Does the Mass Spec require service and are there any protective devices such as filters that need replacement? Is this documented? There’s no need for filter changes, the maintenance of the instruments and pumps is performed by the instrument warden. I added it in “section 8 – Maintenance” of the bio1.

Reviewer 2
4.9 Is it possible to list the organisms sp individually? Are the routes of transmission of infection are different for the different pathogens, if so this should be clearly stated for each pathogen that is being handled.

Reviewer 3
1.1: Little more detail as to why this technique is being developed. It is unclear to me why GMMs need to be created in 2.14.
2.14: What exactly are the biochemical and structural applications that the GMMs over expressing Pseudomonas genes will be used for? Not sure how this fits into the REIMS protocol at all. Relates to my comments on section 1.1
4.21: 30 plates doesn’t give much of an idea of the volume/concentration of the GMMs to be used. E.g. What size plates?

Reviewer 4
2.3: It is not clear to me which samples are being tested. It is stated that patients are regularly screened, then that sputum is not screened but other samples are, then that none of the other samples are screened. I think it should be clarified which samples are tested for what.
5.3 and 5.5: Which samples are sealed with parafilm? I presume these are culture plates or anyway containers which cannot be sealed by screw caps or equivalent.
Agreed: Class 2, Containment Level 2. This project is notifiable to the HSE.

Historical Significant Changes
Project Additional Information

The project has 4 clear goals:

1. Evaluate the H2O2-induced Invasion Phenotype (HIP). Host-cell invasion comprises motility, host-cell selection, apical organelle secretion, conoid extension, and active penetration. We will systematically evaluate each to home in on the parasite process/ies stimulated by H2O2.

   Experimental procedures: T. gondii. Continuous culture of T. gondii strains in human cell lines (Human Forskin Fibroblasts or VeroTM cell lines available commercially). Conventional light, immunofluorescence and live cell imaging for cell-based assays of invasion, motility, conoid extension. Western blot will be used as a biochemical readout of organelle exocytosis.

2. Identify molecular machinery necessary for the HIP. We will use a forward chemical genetic screen to identify effector proteins required for its manifestation. This will directly test the hypothesis that T. gondii contains genes that allow tachyzoites to detect and respond to H2O2 signals.

   Experimental procedures: As above, in addition: Chemical mutagenesis of wild-type T. gondii strains to generate mutant parasite libraries. Transfection of replicating forms with plasmid vectors or linear DNA (generated in E. coli via conventional cloning) to create GM parasites. Analysis of chemical mutant and transgenic parasite lines by western blot, southern blot (PCR), immunofluorescence and live cell imaging. Cloning via limiting dilution. Cloning by FACS cell sorting will only be attempted when provision for class II cell sorting is established at the South Kensington Campus. Any other use of FACS will always be using fixed material for counting purposes only. Deep sequencing of parasite genomic material will be undertaken at the Imperial's Genomics Facility.

3. Systematic profiling of H2O2 sensors in T. gondii. We will use a chemoproteomic mass-spectrometry approach to systematically identify cysteine thiol-based H2O2 sensors. We have demonstrated that a novel method we term oxidation-masked isotopic tandem orthogonal proteolysis activity-based protein profiling (OXisoTOP-ABPP) can identify reactive cysteines in tachyzoites, and determine which have the capacity to “sense” exogenously applied H2O2. Is this network of H2O2 sensors strain-specific (and a possible component of virulence differences between types), or hard-wired into T. gondii biology? We will expand our preliminary study of T. gondii type I tachyzoite H2O2 sensors to examine differences between the major parasite genetic backgrounds, and determine the contribution of sensors to parasite biology.

   Experimental procedures: As above, in addition: Proteomic samples will be generated from T. gondii strains and
analysed at the CISBIO Mass Spectrometry Core Facility. All work will be based within the certified laboratory areas of the Child laboratory, level 6 SAF building. T. gondii parasites are grown entirely in vitro. All experimental work which includes parasite purification for staining, imaging, developmental assays, biochemical procedures and genetic modification will be carried in a containment level 2 laboratory, room 639 Level 6 SAF. FACS-based live cell analysis of T. gondii will be performed where required on the 3 laser Fortessa II which is located in room 638 on level 6 of the Sir Alexander Fleming Building, and live sorting on the BD FACs AriaIII enclosed in a hood located in the Flowers Building, room 3.22 Imaging will be undertaken in either the Child laboratory or level 5 rooms associated with FILM. GM mice will not be used. BALB/c mice will be used for the in-house generation of antibodies. This procedure is mild in terms of its severity. This will be necessary as antibodies that recognize T. gondii proteins are not commercially available. Therefore, in order to study the biological function of the H2O2 effectors responsible for the manifestation of the invasion response, and the H2O2 sensing protein networks that this proposal will identify it will be necessary to generate antibody reagents. Before generating any antibodies, research will be done to determine if antibodies raised against proteins of interest are already available through the Toxoplasma research community. If so, we will attempt to obtain these antibodies are a shared community reagent to reduce numbers of animal used in these studies. The future down-stream assessment of the function of specific gene loci identified in goal 2 and 3 might require the assessment of gene function to parasite fitness in vivo using mouse infections. Strains of mice (such as BALB/c) and C57BL/6 will be infected IP with T. gondii parasites. The course of infection will be monitored by twice-daily recording of mouse weight. In order to provide a humane endpoint to the parasite infection model, mice will be sacrificed if they lose 20% of their starting weight. Mouse models of infection remain the only way to assess the contribution of gene function to parasite fitness and virulence in vivo.

Recipient or parental organism

Toxoplasma gondii is an obligate, intracellular, parasitic protozoan that causes the disease toxoplasmosis. Found worldwide, T. gondii is capable of infecting virtually all warm-blooded animals. While the parasite is found throughout the world, more than 50% of people have often been infected. Of those who are infected, very few have symptoms because a healthy person's immune system usually keeps the parasite from causing illness. However, pregnant women and individuals who have compromised immune systems should be cautious for them. Severe toxoplasmosis (found only in immunocompromised), causing damage to the brain, eyes, or other organs, can develop from an acute Toxoplasma infection or one that had occurred earlier in life and is now reactivated. Severe cases are more likely in individuals who have weak immune systems. Suspected infection can also be adequately treated with pyrimethamine and sulfadiazine, or azithromycin, which is given on its own. GMM T. gondii will be generated: reporter strains and knock-out strains. We will create transgenic T. gondii parasites that express fluorescent or luminescent proteins (for example, but not limited to, YFP, GFP, RFP, CFP, PA-GFP) in the asexual stages of the parasite to facilitate tracking life stages, or proteins of interest in the parasite. This will be done by either C-terminal tagging of endogenous loci by singlehomologous site-specific intergration, or using CRISPR-based integration strategies. We will also create knock-outs of genes in the parasite that we think are important in parasite response to H2O2. Examples include secreted or transmembrane proteins expressed at the different lifecycle stages of the T. gondii asexual lifecycle. Genes found to be important via KO will then be genetically complemented to rescue the KO effect. Knockout will be achieved by double homologous crossover with a drug selection cassette. CRISPR-based methods and/or conditional knockout approaches using inducible Cre recombinase activity where standard KO approaches do not work or are not suitable for the loci of interest.
Lab-adapted strains of E. coli will be used for the amplification of DNA plasmid vectors and the heterologous production of recombinant Toxoplasma proteins.

Toxoplasma Gondii strains in use: RH1, Pru, CEP, ME49, GT1. All are long standing well characterised lab strains. E.coli non toxigenic strains used for plasmid amplification will be DH5α or similar, and BL21 or similar for the production of recombinant protein.

Human Foreskin Fibroblast cell lines (HFF) or Vero cell lines (originally isolated from kidney epithelial cells extracted from an African green monkey) both available from ATCC or available commercially.

**Host/vector system**

T. gondii vectors are non-commercially available small circular plasmids. DNA vectors used will be based on those collaboratively available. All contain either: (1) chloramphenicol transferase gene (CAT) that confers resistance to chloramphenicol; (2) the DHFR selectable marker that confers parasite resistance to Pyramethimine; (3) the hypoxanthine-xanthine-guanine phosphoribosyl transferase (HXGPRT) gene that confers resistance to mycophenolic acid and xanthine. No viral vectors or any vectors with pathogenic properties would be used.

All E. coli vectors used are commercially available. Vectors will be pUC19-based for purposes of DNA amplification.

For the recombinant expression of protein, commercially available expression vector systems including pGEX-6P1, pET28a and pET-28b will be used. These vector systems include ampicillin or kanamycin resistance markers for the purposes of plasmid selection.

**Origin & function**

The list of genes that will be altered is currently unknown as it is an aim of the proposed work to discover them, but will likely include: genes encoding proteins with annotated redox functions, an association with invasion, or expression profile that matches other known invasion-associated genes, regulatory (e.g., signaling) machinery genes that mediate transduction of H2O2 signals and could include genes encoding kinases and receptors/channels (based on their predicted coding function).

None when modified would increase virulence (indeed all knockouts or other variants would be expected to be nonviable). Genes encoding fluorescent/luminescent proteins, including but not limited to YFP, GFP, RFP, CFP, luciferase and their derivatives will be introduced into T. gondii to fluorescently/luminescently-tag proteins to facilitate tracking life stages, or proteins of interest in the parasite.

Toxoplasma genes will also be modified with short epitope tags such as HA, Ty, Myc tags to enable biochemical tracking of proteins of interest.

The tagging and knocking out of specific gene loci and selection of tagged strains and KOs will involve the introduction of drug-selectable markers including either: (1) chloramphenicol transferase gene (CAT) that confers resistance to chloramphenicol; (2) the DHFR selectable marker that confers parasite resistance to Pyramethimine; (3) the hypoxanthine-xanthine-guanine phosphoribosyl transferase (HXGPRT) gene that confers resistance to mycophenolic acid and xanthine.

**Evaluation of foreseeable effects**

The knock-out process is targeted. No loci when modified would increase virulence (indeed all knockouts or other variants would be expected to be non-viable). At no stage will any GMM T. gondii line be generated that is expected to have enhanced virulence and therefore enhanced hazard to animals, the environment or human health.

No horizontal gene transfer is known to occur between Toxoplasma and other microorganisms.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

The proposed work does not include the generation of GM animals or plants.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

| None |

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

| Liquid disinfection will be done using 10% chloros or minimum 1% virkon after dilution with the waste. This will be incubated for 1 hour. This is then followed by disposal to drains. Solid waste will be autoclaved (Minimum 121 C held for 15 minutes) and then disposed of via standard waste routes. |

Chemical biology studies of Toxoplasma biology. Dr M Child, Life Sciences, South Kensington Campus.

Review by BSO:

1.3 Where is the main handling / culture / storage of the T. gondii conducted? Where are the animals infected? Please list all the labs in use here.

2.14 How is the gene knock out being achieved?

2.15 Are the T. gondii strains in use those listed in 2.10? Please list the strains. This is important in establishing the limits of the work.

2.16. Do the vectors have commercial names? If so please provide a few examples. Also which vectors are being used in the T. gondii and which are being used in the E. coli. It is not clear from the description currently given. Again this is important in establishing the limitations and boundaries of the work. The HSE will expect to see this specified.

2.17 Please list the genes that you know you will be inserting, deleting or rescuing. At the very least this would be your fluorescence or drug resistance marker genes.

2.18, 4.18 and 4.20 Is the knock out process targeted? For example there might be a concern that if genes controlling the expression of virulence markers are knocked out this might increase the likelihood of harm? Could host range be affected? The committee and HSE are likely to ask how it is known with any certainty that such a wide ranging proposal (list of genes to be altered currently unknown) is unlikely to produce any enhanced GMO’s.

4.6 Have you discussed screening and serotyping with Occupational Health?

5.1 You state that infectious aerosols might be created. You have not indicated that an MSC will be used. COSHH stipulates that at CL2 where there is a risk of exposure to a pathogen by the airborne route that an MSC must be used. Please complete the rest of this section e.g. type of MSC in use and when it will be used?

5.6 Does the LN2 SOP describe how the storage tubes that have been in LN2 liquid phase will be safely removed and thawed, bearing in mind the risk that the occasional tube will burst if defrosted too quickly and any LN2 in the tube expands faster than it can escape. This is a commonly encountered problem with liquid phase storage. Please give the room numbers.

5.7 Main lab is not listed in 1.3. Please give the lab number or location.

5.8 Please give the lab number. It is not mentioned in 1.3

5.9 Are needles or sharps used to infect or dissect animals?

5.12 What percentage paraformaldehyde and is this at room temperature or chilled?

6.5 Are these FFP3 face masks? Are all staff using them face fit tested for these? Why are face masks required? Are the allergens not controlled at source, for example in an MSC or down flow bench? TC hoods are mentioned here. By TC hood do you mean class 2 MSC? If so this was not mentioned in 5.1. Please clarify when and why MSC’s will be
used. Do you use face shields or safety glasses? I am not sure what an eye shield is?
7.1 I assume 70% ethanol is for spraying down bench surfaces after a spill has been absorbed? Please remove reference to it here. This section is for routine liquid culture waste disposal. 70% ethanol is not suitable for this purpose. Is the 10% chloros solution the strength after dilution with the liquid waste?
8.0 MSC’s are mentioned here but not in 5.1 Please add when and why MSC’s are used in 5.1.
11.2 Is the 6th floor designated lab shared with other projects not using T gondii? I thought this was also used by the insectary lab workers for animal holding?
Comments at the meeting: MC gave a brief description of the work.
NF asked what protocols were in place for possible immunocompromised researchers working on the project?
MC stated that he had a discussion with Occupational Health regarding Health Screening. If the researcher was known to be immunocompromised they would have a health screen before work begins. However OH did not routinely screen healthy individuals but would take a base line sample immediately after any potential exposure incident.
NF asked about pregnant workers?
MC would offer them the option not to work with T gondii, and to offer health screening. If immune naïve MC would recommend not working on the project.
NF pointed out the hazards can be easy to forget, what robustness would be in place?
MC explained in previous laboratories he worked in, explanations were given to groups considered at risk when they began on the project. To also operate high standards of cleanliness, label samples and ensure they are secured after use. MC also discussed with IH of possible access restrictions. The lab is on a secure floor and is already dedicated solely to the group, can be locked when not occupied, but is not independently card swipe or PIN secured. IH will look into funding for additional security.
RW checked if all the comments from the BSO had been addressed?
IH confirmed that all the comments had been addressed.
RW questioned if MC covered everything he wanted to work with on the risk assessment?
MC answered that he had also included animal work after IH suggested it.
NF wanted to know if animals could be added at this stage if the HO licence had not yet been obtained?
IH confirmed that animal work could be included with a note that this is for future work.
The following amendments were required prior to approval:
No further comments from the GMSC.
Agreed: Class 2, Containment Level 2. This needs to be notified to the HSE.
IC reference number: GMIC-6856

Legionella pneumophila uses a specialized type IV secretion system (T4SS), the Dot/Icm secretion system, to transport a large number of effector proteins into host cells. Some of the characterized translocated substrates play a role in hijacking host cellular pathways to establish the intracellular niche where the bacteria survive, replicate and ultimately cause disease. The research of my laboratory will focus on understanding the molecular mechanisms of pathogenicity by the intracellular pathogen. We will determine the molecular organization of the large double membrane-spanning Type IV Secretion System by single particle cryo-electron microscopy (cryo-EM) and establish the structural basis of substrate recruitment.

Recipient or parental organism

L. pneumophila subs. Philadelphia strain Lp02: hsdR rpsL thyA
Lp02 is a thymidine auxotroph, hence should not pose any risk to a healthy human health. The Lp02 strain was isolated in 1993 and has been studied in more than 100 publications since then.

E.coli DH5 alpha lambda pir strain. This strain will harbour the pSR47S low copy suicide plasmid. This plasmid contains lambda pir-dependent R6K replication origin; requires lambda pir-containing bacteria strain. This plasmid will carry genetic modifications which are highly specific to L. pneumophila targeted genes, and will not affect any genomic region (or properties) of L. pneumophila Lp02

Host/vector system

pSR47S – KmR; SacB, Low copy suicide plasmid, carries the kanamycin resistance cassette and a SacB (sucrose sensitivity). Contains lambda pir-dependent R6K replication origin; requires lambda pir-containing bacteria strain. Will carry genetic modifications which are highly specific to L. pneumophila targeted genes, and will not affect any genomic region (or properties) of L. pneumophila Lp02

pRK600 plasmid is a natural occurring plasmid that aids the genetic modification carried in the pSR47S plasmid to be transferred into L. pneumophila
L. pneumophila subs. Philadelphia strain (Lp02) will be used as a background strain to isolate the T4SS and will be genetically modified to incorporate different tags which will facilitate the isolation of the multiprotein complex. The introduction of the different tags in the bacterial genome, will be achieved using DNA recombination methods.

**Evaluation of foreseeable effects**

L. pneumophila Lp02 strain, is a thymidine auxotroph. In the unlikely event of the bacteria escaping its growth flask/tube, it does not pose a risk to the environment as it lacks the thymidine necessary for its survival. The strain is non virulent in several infectious models including macrophages and Galleria Mellonella larvae. In the unlikely event of aerosolization, the bacteria is not able to survive, replicate or infect humans since the lung environment lacks the thymidine quantity (100 μg/ml) necessary for its survival.

**Origin & function**

L. pneumophila Lp02 strain, is a thymidine auxotroph. In the unlikely event of the bacteria escaping its growth flask/tube, it does not pose a risk to the environment as it lacks the thymidine necessary for its survival. The strain is non virulent in several infectious models including macrophages and Galleria Mellonella larvae. Please enter comments on the GM safety committee on the risk assessment
Comments at the meeting: TDC gave a brief description of the work.
IH asked if TDC wanted to use attenuated legionella?
TDC explained they needed to use a tiny amount for growth in the agar.
IH questioned the robustness, if it were to escape would it carry growing in the environment.
BR queried what the basis of the mutation was
TDC confirmed; point mutation.
BR asked if it was not partial or complete gene deletion?
TDC explained there were several point mutations and that there were many publications that showed if it was a stable mutation with no evidence of reversion.
IH pointed out that the GM Classification level at which the work for these papers was conducted was not stated in the publication.
TDC added they could monitor for growth on Thymidine deficient media regularly.
RW advised that this may not be wise as it may select for mutants that could overcome the thymidine supplement dependency.
IH suggested if TDC could submit a paper to support multiple deletions which would reduce the risk of spontaneous reversion, this work could be done at containment level 1.
RW enquired if anyone at the College was working with this and at what containment?
IH confirmed Professor Frankel did and at containment level 2.
The Committee agreed that TDC should provide a supporting paper illustrating the extent and robustness of the attenuating mutation to do this at containment level 1.
After the meeting: TDC submitted a paper and his findings, with the following comment: The paper shows that the thymidine mutation in the LP02 strain is indeed a single point mutation in the gene (Table4). Therefore, I believe that a process for a Cat2 project might have to be initiated.
IH also agreed, class 2. The single point mutation seems to suggest that reversion is possible.
Now that this is agreed as a class 2 project the risk assessment needs more details regarding containment. Additional BSO comments are given below:
1.2: Review this wording to include a line that states something along these lines: “the LP02 strain is thymidine dependent and under normal circumstances incapable of establishing an infection or growth outside of the laboratory environment. However the attenuating mutation is only a single point mutation and reversion is not out of the question, therefore this GM work is still considered by the ICL GM committee to be Class 2”
2.14: Is GM E.coli in use? If so please list it as a recipient, and complete the rest of this section with the E.coli work details as well as the Legionella
2.18: Review this section with the finding of the GM committee in mind. See previous statement for 1.2 above.
3.1: change to no
4.16, 4.17, 4.18: Please review with the comments of the GM committee regarding the robustness of the attenuation in mind
5.1: Legionella is infectious via the airborne route. As this is a class 2 GMO activities likely to produce an aerosol will need to be conducted in an MSC. E.g. Are you...
pipetting or handling outside of any primary container liquid culture? If so I would recommend that this is handled in an MSC to control spills, splashes and aerosols generated by pipetting.

5.2: Confirm that this transport process involves double containment and that the plastic box is leak proof and drop resistant.

5.3: Are you not transporting between labs?

5.6: Please add that this material is clearly labelled and easily identifiable
Waste 7.1: Liquid waste. State that the virkon will be used at a final concentration of not less than 1% after dilution with the waste.
Solid waste. Add the words "validated autoclave" into the sentence Solid waste will be placed into an autoclavable bag for "validated autoclave sterilization.

10.1: Spills in the centrifuge should be left for one hour to settle before attempting to open the centrifuge.
A spill in the lab will result in the lab being evacuated for at least an hour to allow any aerosol to settle and be cleared by air handling

10.2: Remove affected clothing, distance yourself and others from the spill, evacuate the lab and wash any contaminated skin with soap and water as you exit.

12: Safety Department will forward this to OH for completion once the final Bio1 is received.

Section 14 and 15: Change to HG2 and class 2 respectively.

Agreed: Class 2, Containment Level 2
IC reference number: GMIC-8608
Reported: This requires HSE consent.

### Project Additional Information

#### Purposes of the contained use

The aim of this project is to understand the molecular mechanisms that regulate intracellular iron homeostasis in *Trypanosoma brucei*, a parasitic pathogen that infects humans and animals. Three subspecies are endemic in Sub-Saharan Africa: *T. brucei rhodesiense* and *T. brucei gambiense* are human infective while *T. brucei brucei* is only animal infective. All the work proposed here will be done with the non-human infective *T. brucei brucei* species - referred to as hereinafter as *T. brucei*.

The parasites live extracellularly in blood and lymphatic tissues where they interact with their host obtaining essential micronutrients such as iron for survival. Iron is a critical co-factor for numerous important reactions in both eukaryotes and prokaryotes, but in the presence of oxygen iron can be very toxic - creating the need for very tight regulation of free iron levels. In mammalian cells this regulation is achieved by iron regulatory proteins (IRP) containing iron responsive elements (IRE) that control expression of major components of the iron acquisition pathway such as the transferrin receptor (TfR). However, how this task is achieved in African trypanosomes is completely unknown.

Interestingly, African trypanosomes have a surface protein that functions as a transferrin receptor (TbTfR), and expression levels of this protein is also modulated by iron availability. However, TbTfR is structurally distinct from the mammalian TfR, and previous work indicates that *T. brucei* lacks the canonical IRP/IRE iron-based regulatory system. This research will seek to understand if trypanosomes have co-opted and co-adapted alternative eukaryotic mechanisms for iron-sensing and regulation of iron homeostasis.

#### Recipient or parental organism

Organisms and strains:
- E. Coli K12 derivatives, including DH-5 alpha, DH10B, XL-1 Blue and TOP10.
- E. coli BL21 derivative strains.
- T. brucei brucei

#### Host/vector system

Vectors:
- pBluescript, pET and pGEX expression vectors for Histag and GST fusion protein expression in bacteria. These will
be expressed in the E. Coli strains above.
p2T7 RNAi vectors. This is a Bluescript based series of plasmids which has different fragments allowing tetracycline inducible RNA interference (RNAi) inserted into them. Used in T. brucei brucei.

BES targeting vectors. These are Bluescript based plasmids containing BES fragments as target fragments allowing their insertion into T. brucei brucei VSG expression sites.

TIR expression plasmids - these are a series of vectors bearing wild type TIR genes for expression in trypanosomes.

Epitope tagged variants of these vectors will also be used as reporter constructs for iron-stravation experiments.

CRIPR-Cas9 vectors - these are pBlueSript based vectors for expression of Cas9 and sgRNA constructs in trypanosomes.

Origin & function

Selectable marker genes for bacterial plasmid vectors: Kanamycin, ampicillin, chloramphenicol

Fluorescent fusion (eGFP, mCherry, YFP) proteins for localisation studies that bear antibiotic resistance genes

hygromycin, puromycin, phleomycin and blasticidin.

T. brucei Phosphatidic acid phosphatase gene (PAP2), RNA binding protein 5 (RBP5). These proteins are hypothesized to be involved in iron uptake and usage in trypanosome cells.

T. brucei VSG expression sites associated genes (ESAGs). The VSG expression sites are the transcription units where the active VSG gene is expressed. These expression sites contain a variety of gene families (ESAGs) which are thought to be trypanosome surface receptors in addition to the telomeric VSG. These ESAGs appear to be nutrient receptors (for example transferrin receptor encoded by ESAG6 and ESAG7), and do not appear to be involved in trypanosome virulence. They are important for receptor-mediated endocytosis of iron-bound transferrin from the host.

Evaluation of foreseeable effects

E. coli strains are classed by the ACDP as Hazard group 1 and T. brucei is classed as Hazard group 2. Non of the modifications made to these cell lines will change their virulence properties. If anything, we will be making attenuated strains that will be less virulent since we will be deleting or reducing expression of genes by RNA interference.

The genes have no pathogenic determinants by themselves when transfected into host cells will not modify the cell pathogenicity. Both the E. coli and T. brucei strains used are laboratory adapted and do not establish in vivo infections in human.

The E. coli strains and T. brucei strains used are unable to survive outside defined cultured conditions hence are unlikely to pose any specific threats to the environment.

There has never been a documented case of DNA transfer from a trypanosome to another organism. T. brucei will be grown under Containment Level 2 conditions, and all trypanosomes will be destroyed with Virkon or autoclaving before trypanosome infected waste is disposed of. We don't foresee any mechanism for transferral of sequences from GM trypanosomes into the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Liquid waste: E. coli, T. brucei culturing medium.
chemical inactivation: incubation with 1% Virkon for 30 minutes before disposal down the drains and glassware will be sent for washing
Validation of treatment: all parasites have been shown to lyse in 1% Vrikon 30 seconds after treatment.
Solid waste: Contaminated culture flasks, plates, pipettes.
Treatment: Solid waste will be transferred to autoclave bags and removed for autoclaving at 126°C for 20 mins. Charts are recorded after autoclaving the waste is packed in orange bags before being disposed of via our waste contractor. Autoclaves are serviced each quarter, and validated and insurance inspected once per year in accordance with Imperial College London regulations.

Please enter comments on the GM safety committee on the risk assessment
Following the discussion of your proposal entitled “Molecular mechanisms of iron sensing in African trypanosomes” GMIC-8841 at the last GM Safety Committee meeting, the Committee request that the following amendments are made to the proposal prior to approval:

1.1: Begin with full names of the strain, Trypanosoma brucei brucei in the first instance and then shorten for clarity and keep this consistent throughout the form.
2.15: Add CRISPR Cas9 and remove reference to ‘427’ in T. brucei brucei to not restrict your strain list.
Throughout Bio1 form: Remove reference to R1, R2, R3 etc. and change to CoP page number.
Section 7 and Code of Practice: Add how the waste is dealt with. For SAPO licenced work, it has to go into the autoclave by the user.
Section 14 and Code of Practice: Add correct SAPO Licence number, SAPO/77/2017/1
Agreed: Class 2, Containment Level 2. This needs to be notified to the HSE and added to College SAPO licence
Comments:
CT gave a brief description of the work.
RW asked if this work would be based in Sir Ernst Chain Building, Containment Level 2?
CT confirmed it would be and required Access Control measures to be in place.
MB added the CL2 should already have access control in place and key locks on the doors are sufficient.
RW commented that the Bio1 risk assessment form was very complete and if the Code of Practice was based on Professor G R's CoP?
CT confirmed that it was.
RW checked if CT had included strains he thought he would be using in the future?
CT answered he would like to include CRISPR Cas9 in the future and will add this to the list of strains.
MB asked about the FACS machine in the Flowers Building and what was the procedure for disposing of the waste.
CT explained there would be no life cell sorting and the waste would be disposed of by the FACS manager or lab manager.
MB explained this could not be the case for SAPO and CT would need to consider this in his Standard Operating Procedure. Explain you will begin with an empty tank, add virkon and leave for 30 minutes.
JP suggested adding an extra 30 minutes when booking time to use the FACS machine.
MB questioned the reference made on the Bio1 form to the CoP, why R1, R2, R3 etc.
CT thought this would make referencing easier.
MB recommended changing this to referencing the CoP page number instead.
MB pointed out the SAPO licence on the SOP was incorrect and would provide CT with the corrected number.

Purposes of the contained use

*M. tuberculosis* is one of about a dozen bacterial species for which some clinical isolates are now resistant to most or all antibiotics (abx) approved for treatment of the infections they cause. Mechanisms of antimicrobial resistance (AMR) in *M. tuberculosis* deserve study for their potential relevance to AMR in other pathogens; because tuberculosis (TB) is now the leading cause of death from infectious disease; and because drug-resistant TB may be the most prevalent of all drug-resistant bacterial infections. Heritable AMR in *M. tuberculosis* emerges with interruption of treatment, and the long duration of TB treatment provides many opportunities for interruption and non-compliance. Prolonged treatment is necessary because of nonheritable resistance, also called phenotypic tolerance or persistence, defined as the transient tolerance of bacteria in an antibiotic-sensitive population to an antibiotic during exposure to an otherwise lethal concentration of that antibiotic. In contrast to “resisters”, whose AMR is genetically encoded, “persisters” are genetically sensitive bacteria whose phenotypic tolerance allows them to survive for prolonged periods during what would otherwise be rapidly curative treatment. The specific aim of this work is to identify genetic determinants that foster phenotypic tolerance in *M. tuberculosis* through the selection and analysis of high-persister (hip) mutants selected in vitro and in vivo; these strains produce a higher proportion of persister cells than a wild-type strain under the same conditions.

Definition of tolerance in this work: Phenotypic tolerance manifests as “the presence of bacteria in an antibiotic-sensitive population that are not killed by that antibiotic but, when allowed to grow in its absence, give rise to populations that can be killed by the antibiotic in the same proportion as before” [C. Nathan, Fresh approaches to anti-infective therapies. Sci Transl Med 4, 140sr142 (2012)]. Of note, in *E. coli*, persisters increase the population surviving antibiotic exposure from which mutations arise that confer heritable antimicrobial resistance (AMR), and the heritably-resistant mutants are then selected during subsequent cycles of exposure to the antibiotic. The same is likely to be the case for *M. tuberculosis*. 
The objective is to identify hip mutants in Mtb that form in vitro or in vivo during infection upon exposure to stresses imposed by a combination of host immunity and chemotherapy. The activities are divided into three parts, namely isolation of hip mutants in vitro, isolation of hip mutants in vivo and follow-up activities that pertain to mutants isolated using both methods.

Experimental procedures will include the use of routine microbiology techniques in Class I Microbiological Safety Cabinets (MSC), infection of cell lines with listed biohazard group 3 bacteria, molecular biology, mouse husbandry, mouse infections, harvesting tissues from mice, imaging of fixed cells using fluorescence microscopy, FACS analysis of fixed biological material, plasmid-based molecular cloning, and various biochemistry methodologies. All procedures are described in the Code of Practice document.

Recipient or parental organism

ACDP 3: Fully drug-sensitive laboratory strains such as M. tuberculosis H37Rv, Erdman or CDC1551 and M. bovis AF2122/97. Please note that the present work does not use M. tuberculosis clinical isolates.

Transposon libraries contructed by himar1 mutagenesis.

A strain of Mtb that bears a plasmid encoding a tetracycline-regulated (tet-on) version of beta-galactosidase. This plasmid encodes an antibiotic resistance cassette.

A strain of Mtb that will be used bears plasmids that encode a selection marker flanked by loxP sites and the Cre recombinase, respectively.

High persistence mutants selected during the research activities described here.

Host/vector system

1. Transposon libraries of Mycobacterium tuberculosis contructed by himar1 mutagenesis
2. A laboratory strain of Mycobacterium tuberculosis that bears a plasmid encoding a tetracycline-regulated (tet-on) version of a reporter such as beta-galactosidase. The plasmid is constructed using the Gateway cloning system technology.
3. A laboratory strain that bears plasmids that encode a selection marker flanked by loxP sites and the Cre recombinase. These plasmids are constructed using the Gateway cloning system technology.
4. High persistence (hip) mutants selected during the research activities. Importantly, these mutants won't be generated but rather selected from a culture of the laboratory strain of Mycobacterium tuberculosis that naturally contains mutations and is not a de facto virulent strain. None of the hip mutants selected will thus be more virulent than wild-type strains listed in 7.1.

5 and 6. Mutations will be further introduced in strains listed in 7.1 to confirm that they confer the hip phenotype. if a gene is essential for growth in vitro, knock-downs will be constructed by transforming Mtb with two plamids: pNitETSacB-kan (https://www.addgene.org/107692), which allows for the replacement of the native gene by a selection marker by recombineering, and a second plasmid that allows for the conditional expression of the gene; this plasmid will be constructed using the Gateway cloning system technology. Alternatively, knock downs will be generated using the CRISPRi technology. Briefly, a dca9 allele is under the control of a Tet-repressor-regulated promoter. Expression of Cas9 is induced in the presence of anhydrotetracycline; a cognate sgRNA (targeting the genomic region of interest) under the control of a tetR-regulated promoter; a tet repressor; a single-copy L5 integrating backbone; a pBR322-derived E. coli replication origin; a kanamycin selection marker. The current optimal backbone for M. tuberculosis is PLJR965. This backbone works as advertised in the Nature Microbiology manuscript "Programmable transcriptional repression in mycobacteria using an orthogonal CRISPR interference platform" [Rock JM et al. Nat Microbiol. 2017 Feb 6;2:16274]. If the gene is not essential, a knock out will be generated using the plasmid pNitET-SacB-kan described above.
Genes identified in the screens described above. Preliminary results in Msm hip mutants obtained in vitro using methodology 1b identified mutations in amino acid biosynthesis pathways, tRNAs and their modifiers, and transcriptional pathways. These are pathways that will be disrupted in M. tuberculosis. Importantly, these mutants won’t be generated but rather selected from a culture of the laboratory strain of Mycobacterium tuberculosis that naturally contains mutations and is not a de facto virulent strain. None of the hip mutants selected will thus be more virulent than the parental strain.

Origin & function

No experiments are planned that involve intentional creation of strains more virulent than parental strains; furthermore, all strains generated will be more tolerant but not resistant to drugs against which they have been selected. If resistance develops, which can be monitored by the presence of growth in the presence of the drug, cultures will be sterilized and discarded according to standard operating procedures so that no work will be conducted on resistant strains. Only second-line antibiotics will be used to select for hip mutants. As such, hip mutants will have increased tolerance, not increased resistance, against second-line antibiotics. Frontline antibiotics will thus remain therapeutic options in the event that an incident occurs. Knock-out or knock-down strains generated in this study using any engineering techniques described above will be as susceptible to frontline antibiotics as wild-type M. tuberculosis.

Evaluation of foreseeable effects

GM animals in use are no more hazardous to human health or the environment than wild type. When infected with Class 3 GMOs, the animals will be held in IVCs within the Imperial College Animal facilities at South Kensington.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste: Mycobacterial cultures must be disinfected by the addition of Surfanios to a minimum final concentration of 10% prior to autoclaving and further disposal down drains. Solid waste: All other hazardous solid biological waste such as tissue culture plasticware (pipettes, flasks etc) will be double-bagged and autoclaved prior to disposal via the clinical waste route. Animal carcasses and bedding will be disposed as per CBS guidelines, also described in local rules.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
Bio 1 form GMIC-8954 discussed on March 18, 2019. Feedbacks received on March 27, 2019 as follows.

Following the discussion of your proposal entitled “Isolation and study of Mycobacterium tuberculosis cells that are tolerant to antibiotics” (GMIC-8954) at the last GM Safety Committee meeting, the Committee request that the following amendments are made to the proposal prior to approval:

2.16. Some of this text looks a bit cut and paste. Please remove any unnecessary text as this will be submitted to the HSE. See example attached.

2.17 Please complete this section with a description of the genetic changes and if practical a list or indicative list of the changes being made, especially any antibiotic resistance genes. This also includes any genes disrupted by CRISPR.

2.18 Please complete this section. For example will any of the mutants show any gain of function, enhanced tolerance or resistance to antibiotics especially important are those used in frontline treatments post exposure. Is there any evidence to support reports that CRISPR might cut outside of the predicted locations and cause unpredictable consequences. Is this actually less likely to occur than risks associated with more established techniques? A quick sentence on this might be useful. If frontline treatments are affected please describe what treatments will remain.

2.19 please complete this section. If no please state no.

3.4 please tick the no box

4.12 What are the consequences of this antibiotic resistance? Will this means extra precautions are needed when selecting for antibiotic tolerant strains of this bacteria? Are other antibiotics available to treat someone in the case of accidental inoculation?

4.14 Please fill this in, possibly centrifugation causing aerosols or the use of sharps or the emergence of resistance during experiments with persisters?

4.18 First mention of disruption of 2 component regulators please give more details on this. For example is this something you intend to do or if this might occur by accident what is the likelihood that this might happen. How is virulence altered? If some of the bacteria are tolerant to antibiotics does this not make them more hazardous than wildtype? Are all of the persisters/resistors still treatable?

4.20 I don’t believe this question has been answered as this asks about the final GMM product not just the vector system. Please include changes such as Drug resistance?

5.1 You will work in room 17 so will need your own CoP (plus please note the copy you sent out of date-latest version of Robertson RA is Jan 17).

5.7 Visual inspection is fine but what if there was a spill what would you do then e.g. how long to wait to open how to clean? Is this in the SoP?

5.10 Additional training required: this does not answer the question and the information here is better suited to the
question about shedding of agents.

5.13 Please supply an SoP for FACS?

7.4. Animal Carcases? Please tick the box.

8. You should also add that equipment is maintained by users in line with the manufacturer's instructions.

10.1 What is Amphospray? Is this a validated method of inactivating Mtb complex? When is this used and when is surfanios used?

10.2 Please include that you will report on Salus as well. All unplanned events with HG3 and class 3 organisms must be reported even if there has been no exposure or no likelihood of exposure.

13.2, 13.3 and 13.4 fill in, lone working is permitted out of hours working is not.

14.1 Mention room 17

Comments:

JV Brief summary of project

Looks at development of tolerance in TB (definition of tolerance given as in Bio1: Definition of tolerance in this work: Phenotypic tolerance manifests as "the presence of bacteria in an antibiotic-sensitive population that are not killed by that antibiotic but, when allowed to grow in its absence, give rise to populations that can be killed by the antibiotic in the same proportion as before"). Persistence precedes resistance

Looking at what mutations lead to the development of persistence

Identify the pathways involved with persistence and target with drugs

Mutations will be selected and their location confirmed with sequencing.

Mutants will then be recreated using Gm to check effects

Dead Cas9 in use which transiently develops knockouts/knockdowns

The link between persisters and resistors has only been shown in ecoli. The development of resistors from persisters cannot be excluded but in ecoli they can only develop under special circumstances with a repeated exposure and growth cycle. It is believed the mutation that allows persistence allows the bacteria the time to then acquire mutations for resistance.

Asked if exposure of persisters can be treated with antibiotics.

JV yes the same as the wild type. However if they become resistors this would become more of an issue if we have been using front line antibiotics in experiments. Therapeutic options would then be limited so this should be avoided. JV suggested to wear masks to prevent exposure to any of these types of resistors. MB stated that the wearing of RPE would not be acceptable as it suggests you are not safe to work at CL3.

There was a discussion about whether the plan was to expose persisters to frontline line antibiotics in a cyclic manner (and potentially lead to resistors) in the next 5 years. Not the immediate plan but could do in the future to study the evolution to resistors. SH said that the project would likely need to return to the committee if JV wanted to extend to
Other option is to use only certain antibiotics so that there are always first line antibiotics available. There was some downside to this scientifically as you want to use clinically relevant antibiotics.

The general consensus was that if mono-exposure to an antibiotic was used this would be acceptable as therapy if usually 3 line and there was agreement to ensure there is always a therapy available.

Discussion about the Gm work: if a gene is non-essential it can be knocked out if essential knocked down. This is inducer dependent.

Gaps need to be filled about which genes are targeted etc. this is tricky as a screen will be used to identify them but some general information to best of knowledge needs to be given.

SH are strains only lab strains, JV yes. SH make sure it’s clear that only lab strains are used not clinical strains, make limitations of strain use and of the project very clear.

MB 4.18 How is virulence altered? BR says this would make it more virulent.

If you’re not aiming to do this (make it more virulent) but it might happen how can you know if it has happened? Lab strains are used often to infect mice so there is a lot of data on this to compare to. Researcher (don’t know her name sorry) they are not creating mutations they are in the starting pool so unlikely to select for increased virulence as it’s unlikely to be in the pool. A tendency for this has not been seen.

IH state in 4.18 that its historical use and an unlikely event.

SH what would you do if you saw increased virulence e.g. mortality in an experiment would you end the experiment?

MB stated a CoP for room 17 is required (RP mentioned the current version of BR CoP is Jan 17)

SH asked if the techniques/work was significantly different to that of Brian Robertson

BR confirmed that it wasn’t significantly different.

The filter technique is already an established technique for other in metabolomics (Gerald) so generic CoP for this can apply. Gerald does use vacuum filtration for metabolomics so will be the same technique.

Amphospray is also used by Gerald for metabolomics and has been validated at the crick. Link to specific protocol is required and RP stated that it should be made clear when amphospray is used and when surfanios is used.

HB made that it would be clear right away if a resister was present as it would grow in the flasks etc.

IH stated that a defined stopping point would need to be added and what action would be taken if a resister had developed so it’s clear.

Action Points:

Check for spelling errors

MB stated a CoP for room 17 is required (RP mentioned the current version of BR CoP is Jan 17)

Add SOPs to RADAR

Agreed: Class 3, Containment level 3. This is notifiable to the HSE.

Animal Units | Large Scale Activities | Human Clinical Applications
Immune responses are pivotal to immunity and inflammation. Yet, imbalanced immune responses can leave hosts susceptible to infection and/or can cause excessive inflammation and tissue damage. Modulation of immune responses is a promising therapeutic strategy to rebalance immune responses in disease situations. Such approaches could provide strategies to combat infection, including those by antimicrobial resistant (AMR) pathogens, and/or in a range of inflammatory diseases. However, the mechanisms that control the fine-tuning of immune responses are not well characterised. This limits our capacity to understand the full repertoire of mechanisms that could be targeted in immunomodulatory strategies.

The major purpose of this study is to better understand the functions of immunomodulatory immune receptors in the biology of phagocytic immune cells, and to improve our knowledge of how pathogenic microbes exploit these receptors during infection. Phagocytic immune cells express a plethora of immune receptors to recognise, respond to and kill invading microbes. They also express inhibitory immune receptors that act to ensure that phagocytes do not become activated in the wrong place and at the wrong time leading to host damage.

Some receptors belong to families containing activating and inhibitory receptors, and are considered to be immunomodulatory receptors that act to generate balanced immune responses- for example, the CEACAM & LILR families. Though there is improving knowledge of the function of these receptors on adaptive immune cells, there remains a limited understanding of their role in shaping innate immune cell responses in both the infectious and non-infectious setting. This is limited by poor knowledge of native ligands and of cross-talk between receptors. Microbial pathogens are known to directly interact with receptors belonging to these families, most likely to imbalance immune responses and to favour pathogen survival. However, the microbial ligand(s) and/or functional consequences of these host-pathogen interactions remain unidentified. Identification and development of ligands with agonistic and/or antagonistic properties is key to improving knowledge of immune responses, and to recognising mechanisms that could be targeting in future immunomodulatory therapeutics.

The main aim of this project is to identify and characterise native and microbial ligands of immunomodulatory receptors. The work in this project will involve, 1. The use of heterologous expression in cell lines and recombinant forms of receptors to identify native and/or microbial ligands of immune receptors.

---

Project Additional Information

Purposes of the contained use

Immune responses are pivotal to immunity and inflammation. Yet, imbalanced immune responses can leave hosts susceptible to infection and/or can cause excessive inflammation and tissue damage. Modulation of immune responses is a promising therapeutic strategy to rebalance immune responses in disease situations. Such approaches could provide strategies to combat infection, including those by antimicrobial resistant (AMR) pathogens, and/or in a range of inflammatory diseases. However, the mechanisms that control the fine-tuning of immune responses are not well characterised. This limits our capacity to understand the full repertoire of mechanisms that could be targeted in immunomodulatory strategies.

The major purpose of this study is to better understand the functions of immunomodulatory immune receptors in the biology of phagocytic immune cells, and to improve our knowledge of how pathogenic microbes exploit these receptors during infection. Phagocytic immune cells express a plethora of immune receptors to recognise, respond to and kill invading microbes. They also express inhibitory immune receptors that act to ensure that phagocytes do not become activated in the wrong place and at the wrong time leading to host damage.

Some receptors belong to families containing activating and inhibitory receptors, and are considered to be immunomodulatory receptors that act to generate balanced immune responses- for example, the CEACAM & LILR families. Though there is improving knowledge of the function of these receptors on adaptive immune cells, there remains a limited understanding of their role in shaping innate immune cell responses in both the infectious and non-infectious setting. This is limited by poor knowledge of native ligands and of cross-talk between receptors. Microbial pathogens are known to directly interact with receptors belonging to these families, most likely to imbalance immune responses and to favour pathogen survival. However, the microbial ligand(s) and/or functional consequences of these host-pathogen interactions remain unidentified. Identification and development of ligands with agonistic and/or antagonistic properties is key to improving knowledge of immune responses, and to recognising mechanisms that could be targeting in future immunomodulatory therapeutics.

The main aim of this project is to identify and characterise native and microbial ligands of immunomodulatory receptors. The work in this project will involve, 1. The use of heterologous expression in cell lines and recombinant forms of receptors to identify native and/or microbial ligands of immune receptors.
2. The use of biochemical and cellular based experiments to study, characterise and define receptor-ligand interactions, including native ligands as well as ligands from bacterial pathogens.

3. The use of cellular based assays to study immune receptor cross-talk, and to study the cell biology of shaping innate immune cell responses.

4. The use of wild-type, gene-knockout and transgenic mice to study the role of immune receptors in modulating immune responses in inflammatory or infectious disease settings.

Experimental procedures include routine cell culture in Class II Microbiological Safety Cabinets (MSC), microbiology, molecular biology, genetic amplification, genetic sequencing, plasmid based cloning, protein expression using routine prokaryotic (e.g. E. coli) or eukaryotic (e.g. EXPI293) expression systems, protein purification, protein biochemistry, retroviral and lentiviral transduction of cells using standard molecular biology procedures, colonisation/infection of cell lines with biohazard groups 1 and 2 bacteria. Analysis and sorting of infected and uninfected live and fixed cells or of bacterial populations by FACS and cell-sorting. Analysis of fluorescence or luminescence of uninfected live and fixed cells or bacterial populations using luminescence or fluorescence based assays. Fluorescent microscopy imaging of infected and uninfected live and fixed cells. Mouse husbandry, mouse infections, harvesting and analysis of tissues from infected and uninfected mice.

GMOs will be used for:-

1) routine cloning in E. coli. This will often involve the generation of vectors for expression of recombinant receptors or bacterial proteins (full or partial) to be expressed in prokaryotic or eukaryotic expression systems). Other work will include construction of vectors to knock-out full/parts of genes in bacterial organisms. Additionally, insertion of genes into shuttle vectors for complementation of mutations in GM bacteria or over-expression in other bacteria. Finally, vectors will be constructed to produce fluorescent bacterial strains for use in FACS or fluorescent microscopy. All of these activities involve biohazard group 1 laboratory strains of E. coli.

2) E. coli to express and purify recombinant proteins cultures using routine methodologies. This will encompass production of recombinant receptors or bacterial proteins (including full proteins, partial proteins or proteins with point or deletion mutations). Vectors in use or to be used are commerically available, or are modifications of commerically available vectors. All of these activities involve biohazard group 1 laboratory strains of E. coli.

3) GMO strains to characterise host-pathogen interactions. Bacterial strains of biohazard group 2 will be generated that have individual genes knocked out, and they will subsequently be used in functional, cellular and in vivo assays. This will include the use of libraries of bacterial mutants, as well as single mutant strains.

4) over-expression of genes in bacteria. GMMMs will be generated by introducing complementation vectors i) into knock-out mutant strains of biohazard group 2 strains, that should re-establish their previous phenotype or ii) into non-pathogenic biohazard group 1 strains, that will provide gain-of-function phenotypes in routinely used Gram positive (e.g. non-pathogenic Class I Lactococcus lactis, Streptococcus mutans) and negative (e.g. non-pathogenic Class I E. coli) species.

5) production of novel cell lines using transduction of 3rd generation lentiviral vectors. Vectors will have receptors inserted and on successful transduction will result in over expression of receptors at the cell surface. All work with lentiviral transduction will be performed in class 2 MSC cabinets.

Phage libraries will then be used to screen and select for phages that bind targets (e.g. cells or recombinant proteins), and genes identified by sequencing phagemid inserted. Currently, phage libraries for S. aureus, S. pyogenes, S. agalactiae, S. uberis, L. monocytogenes, E. coli and H. influenza are developed. Additional libraries for other CL1 and CL2 bacterial pathogens may be acquired, used or developed.

Recipient or parental organism

| Host/Vector system | Host 1: Biohazard group 1: Non-pathogenic organisms  
E. coli (BL21, Rosetta Gam, TOP10, DH5a, K12)  
Lactococcus lactis, Streptococcus mutans, Gemella hemolysans  
Host 2: Biohazard group 2: Streptococcal species  
Streptococcus pyogenes, Streptococcus agalactiae, Streptococcus dysgalactiae, Streptococcus zooepidemidis, Streptococcus oralis, Streptococcus gordonii, Streptococcus uberis, Streptococcus gallylolicus, Streptococcus sanguinis, Streptococcus aginosus  
Host 3: Biohazard group 2: Staphylococcal species  
Staphylococcus aureus, Staphylococcus epidermidis, Staphylococcus capitis, Staphylococcus canosnus, Staphylococcus hemolyticus, Staphylococcus lugdensis, Staphylococcus simulans, Staphylococcus saprophyticus  
Host 4: Biohazard group 2: Other Gram positive microbes |

Recipient or parental organism

| Host/Vector system | Host 1: Biohazard group 1: Non-pathogenic organisms  
E. coli (BL21, Rosetta Gam, TOP10, DH5a, K12)  
Lactococcus lactis, Streptococcus mutans, Gemella hemolysans  
Host 2: Biohazard group 2: Streptococcal species  
Streptococcus pyogenes, Streptococcus agalactiae, Streptococcus dysgalactiae, Streptococcus zooepidemidis, Streptococcus oralis, Streptococcus gordonii, Streptococcus uberis, Streptococcus gallylolicus, Streptococcus sanguinis, Streptococcus aginosus

Staphylococcus aureus, Staphylococcus epidermidis, Staphylococcus capitis, Staphylococcus canosnus, Staphylococcus hemolyticus, Staphylococcus lugdensis, Staphylococcus simulans, Staphylococcus saprophyticus  
Host 4: Biohazard group 2: Other Gram positive microbes |
Enterococcus faecalis, Enterococcus faecium, Gardenella vaginalis, Gemella haemolysans
Host 5: Biohazard group 2: Gram negative microbes
Escherichia coli (ExPEC), Klebsiella pneumoniae, Helicobacter pylori, Moraxella catarrhalis, Neisseria gonorrhoeae, Pseudomonas aeruginosa.

Vector 1: Routine cloning in non-pathogenic E. coli
pRSETN, pRSETC, pGEX, pET or similar systems for gene cloning and protein expression in E. coli. All are IPTG inducible and encode ampicillin resistance. pcDNA3.4 or derivatives, pEFGP, pMyc, pFlag, pHA, RP172, RP139, RP137 and similar systems for expression in EXPI293T cells for gene cloning and protein expression in eukaryotic cells. All encode ampicillin resistance. E. coli strains used for routine cloning are susceptible to other antibiotics. To be inserted into Host 1.

Vector 2: 3rd Generation Lentiviral vectors
Lentiviral plasmids being used (RP172, RP139 and RP137, and related) are 3rd generation vectors modified such that they generate replication-defective viruses. These vectors are based on the dual promoter lentiviral vector (no. 2025.pCCLsin.PPT.PA.CTE.4x-scrT.eGFPM.CMV.hPGK.NGFP.PRE) that has been modified to replace the minimal CMV promoter with the human EF1A promoter to facilitate potent expression in immune cells; replace the eGFPM with a cassette containing several unique restriction sites facilitating DNA cloning (Nhel, PacI, Pmel, Afel, SpHl, SpHl and NsiI); and replace the NGFP gene with various combinations of fluorescent proteins (mCherry, mAmetrine) and selection markers (PuroR, BlastR, ZeoR and HygroR), which were fused together by means of the ribosomal skipping peptide T2A. These vectors produce non-replicative viruses, because they lack most virulence genes of these viruses, whilst maintaining only truncated gag, rre and modified long terminal repeats that optimise plasmid packaging and allows gene expression in target cells. Only the post-transcriptional regulatory region of WPRE and not the protein X coding sequence may be present in some lentiviral plasmids.

Packaging will be carried out using separate 2 or 3-plasmid systems that supply Gag + Pol and the VSV-G pseudotyping proteins in trans, to generate viruses that transduce cell lines and lead to the expression of gene of interest. These viruses are incapable of replication within target cells and do not generate infectious ‘daughter’ viruses. To be inserted into Host 1.

Vector 3: Streptococcal / Staphylococcal cloning vectors
pLZ, pDC123, pDC, pDCerm, pMBsacB are routine E. coli/Streptococcal mutagenesis vectors. These vectors encode ampicillin, erythromycin and/or spectinomycin resistance. pCL55, pCN34 are routine E. coli/Staphylococcal mutagenesis vectors that encode chloramphenicol resistance. To be inserted into Host 1, 2, 3 or 4.

Vector 4: Gram-negative cloning vectors
The lambda recombineinase system has been used to generate deletion constructs in Gram negative bacterial organisms. These include plasmids such as pKD3, pKD4, pKD13, pKD20, pKD46 and related along with helper plasmids for removal of antibiotic markers which are derived from plTns that expresses the FRT recombinase. Similar routine cloning vectors will be used in other bacterial systems, using the expertise of other research groups in CMBI. To be inserted into Host 1 or 5.

Vector 5: Transposon mutation vectors
Vectors for construction of random transposon mutants will be used to make libraries of transposon mutants. These systems are well-established in the scientific community and are also commercially available. Vectors typically carry mini-transposons composed of a antibiotic resistance genes flanked by transposon insertion repeats, and a transposase for mobilisation of mini-transposon and insertion into host genome. Streptococcal, staphylococcal and gram-negative vectors available include pGh9:ISS1, mariner system and Tn5 system respectively. To be inserted into Host 2, 3, 4 or 5.

Vector 6: Phagemid vectors for phage display
pDJ01 phagemid vector was created by Jankovic at al. (Massey University, Palmerston North, New Zealand). The vector contains a chloramphenicol resistance cassette and a multiple cloning site and myc-tag sequence in front of the gene encoding the C-terminal domain of the minor coat protein pIII. All phage work to be performed in MSC. To be inserted into Host 1.

Origin & function

Insert1 1: Routine cloning in non-pathogenic E. coli
Genes encoding full, partial or mutated innate immune receptors, bacterial surface proteins, bacterial secreted proteins, or bacterial regulators. This work will involve the generation of various point or deletion mutations or tagging of proteins with appropriate fluorescent or affinity tags for detection. All of these activities involve biohazard group 1 laboratory strains of E. coli. To be inserted into Vector 1 or 2.

Insert 2: Transposons mutant libraries that carry antibiotic resistance cassette
To uncover the molecular basis of other interactions, we will employ a transposon mutant libraries, cell sorting and Tn-Seq. The S. pyogenes mutant libraries (strains, M3 STAB902 & M1 5448) were provided by a collaborator Kevin McIver (Baltimore, USA), and are used widely within the Streptococcal research community. The McIver lab has developed additional libraries in other S. pyogenes strains, in S. agalactiae and other streptococcal species that will be acquired and used if required. The NARSA S.
Staphylococcus aureus mutant library (strain JE2) is available and widely used within the Staphylococcal community, and other libraries have been developed and will be acquired and used if required. Similar transposon mutant libraries for other bacterial species listed in 2.14 may be acquired from commercial sources or scientific collaborations, and used similarly in cell-sorting and/or Tn-Seq experiments. To be inserted into Vector 5.

Insert 3: Targeted mutants in bacterial surface, secreted or regulator proteins

Bacteria interact with immune cells through surface or secreted proteins. Therefore, genes encoding surface proteins, structures, secreted proteins or their regulators will be targeted in Gram-positive and Gram-negative bacterial species, for example those species listed in 2.15, to characterise interactions & infection biology. The molecular basis of CEACAM interaction with S. agalactiae and S. pyogenes has been uncovered, and GMM versions are mutated in genes encoding surface proteins, structures of their regulators (bac, bca, rib, R28, M). No new GMMs will be designed with the intention of enhancing virulence. Most gene deletions will be carried out in collaboration with other established laboratories in the MRC CMBI to use their expertise in microbiology and microbial genetics. In addition, GMMs of non-pathogenic Gram-positive and Gram-negative bacteria from biohazard group I, such as Lactococcus lactis/Streptococcus mutans and non-pathogenic E. coli, respectively, will be generated which have acquired surface or secreted genes to study functions in cellular and in vivo assays. To be inserted into Vector 3 or 4.

Insert 4: Reporter genes

Mutants will be generated or acquired expressing reporter genes, for example (but not limited to) luciferase or fluorescent proteins. To be inserted into Vectors 1, 3 or 4.

Insert 5: Genes encoding innate immune receptors or regulators

Full, partial or mutated forms will be cloned into 3rd generation lentiviral vectors, and will be expressed in eukaryotic cells using lentiviral transduction to study their functions. To be inserted into Vector 2.

Insert 6: Random DNA fragments from bacterial genomes.

Purified genomic DNA is fragmented randomly by sonication, and ligated into pDJ01 phagemid vector. Vectors are electroporated into TG1 E. coli. Subsequently, E. coli are infected with VCSM13 helper phage to generated phage library. To be inserted into Vector 6.

Evaluation of foreseeable effects

No experiments are planned that involve intentional creation of strains that enhance virulence beyond the inherent virulence of parental strains. GMOs are constructed in laboratory strains or well-characterised strains (genomes sequenced) where possible. Primary assessments of virulence phenotypes will be performed compared to parental strains. If the GMO virulence capacity is not enhanced, GMOs may be constructed in clinically relevant strains with known antibiotic susceptibility profiles if required. GMOs will not be constructed in multidrug resistant clinical strains, nor in any strain resistant to last-resort antibiotics. Thus, antibiotics will remain therapeutic options in the event that an incident occurs.

Host Group 1: There is not foreseeable effect of enhanced virulence for GMMs belonging to this group.
- Cloning in E. coli is routine and does not impact virulence properties.
- Over-expression of genes in non-pathogenic organisms such as E. coli, L. lactis or S. mutans does not alter phenotypes beyond the inherent properties of the host organism.
- Insertion of phagemid vectors into E. coli does not impact virulence properties. Phagemids are not capable of infecting human or animal hosts.

Host Group 2, 3, 4 and 5:
- Construction of mutations in CL2 pathogens. Knowledge from ourselves and literature, indicates that mutation of surface proteins, secreted proteins or their regulators does not result in enhanced virulence in comparison to parental strains. Virulence phenotypes are typically multifactorial, in which multiple genes contribute. It is not expected that strains with enhanced virulence potential will be generated. These mutations will first be constructed in well-characterised strains (lab strains, genome sequenced strains or commonly used strains in academic research), prior to construction in clinical strains.
- Transposon mutant libraries of CL2 pathogens. Libraries of transposon mutants are well-characterised and commercially available. There is no evidence to suggest these libraries have enhanced virulence beyond inherent properties on the host organisms.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

GM animals to be used in this study are no more hazardous to human health or the environment than their parental wild type. When infected with CL2 GMOs, the animals will be held in IVCs within the Imperial College Animal facilities at South Kensington.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

not applicable
| Solid waste: All hazardous solid biological waste such as tissue culture plasticware (pipettes, flasks etc) will be placed in appropriate waste bins and then securely transported to be autoclaved prior to disposal by trained personnel.  
Liquid waste: Treatment with minimum 2% Virkon after dilution with liquid waste for 1h followed by disposal in the sink.  
Animal carcasses and bedding will be disposed as per CBS guidelines, also described in local rules. |
|---|

| Is an emergency plan required according to regulation 20? | N |
| If yes, tick to confirm that it is attached to this form | N |
| Tick to confirm that you have attached a risk assessment to this form | Y |
| Tick if you are claiming exemption from disclosure for section of the risk assessment | N |

Please enter comments on the GM safety committee on the risk assessment
2.14 While it's stated that no new GMMs will be designed with the intention of increasing virulence or survival vs wildtype, is this possible with any of the over expressions or re-establishment of functions inserts? If a more virulent/potent strain was created, what action would be taken?

2.16 What generation of lentiviral vectors are these?

2.18 and 4.18. How confident are you that your genetic changes will not have unintended consequences and that the consequences of the changes will have predictable results, for example altering host range?

4.8 Please provide an ethics reference

4.10 Please review the organism you have listed as infectious via the airborne route. For example, you have listed staph spp as infectious via the airborne route but this is not a usual or normal route for infection with these organisms.

4.11 When using vectors in HG2 pathogens, is 50 ml enough to make competent cells?

4.12 I would expect to see in the local rules a good system for identifying the bacterial species to ensure those which should be handled in an MSC or with other additional precautions can be clearly identified. We may need to come back to this once OH have commented on the Bio1.

4.14 This needs to be expanded on? Is this in the local rules? Good lab practice is not a control measure. For example, pipetting and manipulation of HG 2 and class 2 organisms that are infectious via the airborne route.

4.16 Ampicillin as selection for GMO, is there still treatment available when you use this antibiotics?

4.18 How would you mitigate an unexpected more hazardous mutation?

5.1 Eye protection? Is that standard in your labs? If it is and you are working in an area where those not directly involved in your research might be affected, they should also wear eye protection.

2.8 and 2.19. Have you checked with Marian in the safety Dept that none of the animal pathogens require a licence?

2.18 and 4.18. How confident are you that your genetic changes will not have unintended consequences and that the consequences of the changes will have predictable results, for example altering host range?

5.7 This should be 1 hour rather than 30 minutes to agree with 10.1

6.1 Clarification on when gloves are or are not required needs to be confirmed in the local rules

8.1 Worth stating that maintenance of equipment will be conducted according to the manufacturer’s instructions. Most of the routine maintenance can be conducted by trained lab staff.

10.1 Reference to college incident report form should be removed, all incidents should be reported via SALUS

10.5 Virkon? Is it still soluble at this concentration? You will need to add in excess of 20% of the volume of the spill if you use 5% Virkon to achieve a final concentration of 1% after dilution.

As so many bacterial species and strains are involved, it might be good to identify any which could present a risk to a healthy individual or are infectious via the aerosol route clearly.

4.12 With reference to the earlier point about identification of species involved, this would be important in the case of accidental inoculation, so the correct antibiotics were administered so a clear system of identification would be required.

Comments:

AM Role of immune receptors in neutrophils and phagocytes and impact on disease progression. Use of GM for cloning, expression of recombinant proteins, ID of bacterial ligands and use transposon libraries. Knock out genes to validate or make positive expressing strains and to complement them.

Large number of pathogens on project as screen large number then home in.
MB when will you work in an MSC and when on a bench?
AM Inoculation and overnight in a cabinet. Experiments on bench. Mutant strains all work in cabinet
Pathogens max 5-10 mls on bench usually.
Larger volumes when its E.coli
MB/IH discuss what limit to set on volumes to use on the bench and if a limit should be set for pathogens which are airborne or just a general limit as hood availability means its’s not practical to just saw an MSC is used for all work. Or even to state all via airborne route go in MSC.
Agreed its best to set a max volume on bench for all species and strains than differentiate
20mls was agreed as a reasonable limit
MB suggests a trail with water so you have an idea how far 20mls could spread.
4.21 this should be specific meningitides species in use and not spp as Neisseria is excluded.
Can the alteration of surface proteins change virulence? Proteins are related to cell attachment and effect on virulence unlikely as attachment is related to a number of different proteins so unlikely to improve it. This (changes to these proteins) would also happen in nature
IH can you make it clearer that you potentially plan to include additional similar profiles/systems/species. Line is in there but can be more apparent.
Action Points:
Lentivirus in use is 3rd gen-MB put that into Bio1
Agreed: Class 2, Containment level 2. This is notifiable to the HSE.

**Project Ref 8/21.1**

**Date Ackn'd** 16/07/2021

**CU2 Project Title**
Transfer and gene regulation of different types of mobile genetic elements in Gram-positive and Gram-negative bacteria

**Class** Class 2

**CultureVol** Class2 1 Litre

**CultureVolume** Class3-4

**Class CultureVol**

**Consent Granted**

**Non-GMM**

**Project notified under transitional arrangements** N

**Historical Significant Changes**
**Project Additional Information**

**Purposes of the contained use**

The majority of pathogenic traits in bacteria are encoded in regions of the chromosome that are able to be transferred between bacterial strains. These elements are collectively called mobile genetic elements (MGEs) and include bacteriophages, pathogenicity islands, integrative and conjugative elements (ICEs), plasmids and transposable elements. We aim to characterise these elements present in different Gram-positive and Gram-negative model bacterium organisms. We will study how these elements are transferred between bacteria and how they are regulated, characterising in molecular detail the different mechanisms they use to promote their spread. That would give us an insight as their contribution to the overall bacterial pathogenesis and allow us to design strategies to counteract bacterial infections.

**Recipient or parental organism**

Bacterial strains, either Gram-positive (S. aureus, E. faecalis, B. subtilis) and Gram-negative (E. coli, S. enterica, P. multocida) with different MGEs will be used to generate deletion mutants in the gene(s) of interest involved in the transfer and/or regulation of these elements.

**Host/vector system**

The host used in the project and the vector systems are:

S. aureus and E. faecalis:
- pMAD, pminiMAD, pBT2, pBT2-βgal (low copy number, temperature sensitive)
- pCN51 vector with a Cadmium-inducible promoter and derivatives will be used to complement mutants or overexpress genes in S. aureus
- pCN41 (promotorless) and pCN42 (under the control of a Cadmium-inducible promoter) vectors and derivatives will be used in S. aureus and other Gram-positive bacteria to measure promoter activity by generating a reporter fusion with BlaZ gene.

B. subtilis:
- pDR110 and pDR111 amyE integration vectors and derivatives that contain a multiple cloning site located downstream the IPTG-inducible Pspank promoter, will be used to overexpress genes in B. subtilis.
- pBs3Clux sacA integration vector and derivatives with a promoterless lux-reporter system will be used to measure promoter activity in B. subtilis.
- pDG1663 thrC integration vector and derivatives will be used to generate fusions with a B-galactosidase reporter and measure promoter activity in B. subtilis.
- pDR240a and DR242a vectors with antibiotic resistance cassettes (KanR and ErmR respectively) will be used for construction of single gene deletion mutants in B. subtilis.
A vector carrying the Cre recombinase will be used to promote the recombination between two lox sites. This vector is used to generate scar-deletion mutants in B. subtilis.

E. coli, S. enterica and P. multocida:
- pET-vectors (e.g. pET28a), pGEX-vectors (e.g. pGEX-4T), pProEX-Hta, pLIN, pNIC and derivatives will be used for protein expression and purification of high amounts of proteins in E. coli.
- pKT25, pKNT25, pUT18, pUT18C and derivatives will be used to perform double hybrid assays and determine protein-protein interaction in E. coli and other Gram-negative bacteria.
- pBAD18 vector and derivatives will be used to complement mutants or overexpress genes in E. coli and other Gram-negative bacteria.
- pKD46, pRWG99, pK03 Blue and pCP20 vectors will be used to generate deletion mutants in E. coli and other Gram-negative bacteria.
- pKD3, pKD4 and pWRG717 vectors will be used as templates to amplify different resistance markers to generate deletion mutants in E. coli and other Gram-negative bacteria.

This list contains a general description of the genes of interest present in the different MGEs infecting Gram-positive and Gram-negative bacteria most commonly targeted in our studies, but may not be fully detailed.

Insert 1: S. aureus bacteriophage genes (e.g. phages 11, 80a, 85, among others) to assess functional role in phage biology.
Insert 2: S. aureus pathogenicity islands (SaPIs, e.g. SaPI1, SaPIbov1, SaPI2, among others) to assess functional role in the biology of the MGE.
Insert 3: E. coli bacteriophage and Phage-inducible chromosomal island genes to assess functional role in the biology of the MGEs.
Insert 4: B. subtilis bacteriophage genes (e.g. phages SPBeta, phi3T, phi105) to assess functional role in phage biology.
Insert 5: E. faecalis bacteriophage and Phage-inducible chromosomal island genes to assess functional role in the biology of the MGEs.
Insert 6: P. multocida bacteriophage and Phage-inducible chromosomal island genes to assess functional role in the biology of the MGEs.
Insert 7: S. enterica subsp. enterica serovar Typhimurium LT2 bacteriophage and Phage-inducible chromosomal island genes to assess functional role in the biology of the MGEs.

Origin & function

In some cases, the genes mutated are involved in increasing the pathogenesis of the bacteria. In this sense, the GMMs generated have the same or lower hazardous potential than that of the parental strain. Routinely, strains generated will not have more than two different antibiotic resistance markers and in any case the antibiotics will not be generally used for treatment of infections.

Evaluation of foreseeable effects

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste generated will be treated initially with Chemgen to be inactivated. Treatment of the GMM waste will be done mainly at the SECB autoclaving facility or alternatively using the autoclave in Flowers building, level 6:
- Liquid discard (which includes the agar plates) treated with heat inactivation (temp. 134.5 for 10 min.)
- Dry waste treated with heat inactivation (temp. 134.5 for 5 min.)
- Validation of treatment: Annual 12 point thermocouple test; all cycles verified using dummy loads; records of tests kept by Biochemistry lab services and for the unit on the laboratory (Flowers building, level 6.)
- Route of disposal: After autoclaving, transported in a closed container to the clinical waste compound at the back of the SAF building; removed from site by a specialist
Please enter comments on the GM safety committee on the risk assessment

Historical Date of Additional Info

Significant Change ID
The aim of this project is to create genetically engineered bacteria using synthetic biology technology to sense the gut environment and control the gut microbiome. This will include the construction of synthetic DNA constructs and expression (either as plasmids or by integration into the genome) in bacteria strains as appropriate. Further genome engineering (knock-outs, antibiotic resistance gene transfer) may also be made to these bacteria.

Recipient or parental organism

S. typhimurium (LT2, cloning strains, ATCC 14028s, SL1344) B. fragilis (638R, NCTC9343, and biobank isolates from healthy human donors) B. thetaiotaomicron (VPI-5482, and biobank isolates from healthy human donors)

Host/vector system

ColEI derived cloning and protein expression vectors (eg. pBR322, pUC, pGEM, pET, pGEX) for use in all hosts; pGRG36 derived tn7 transposon insertion vectors; RK2 derived expression plasmids EcoFlex cloning vectors P1vir bacteriophage pKD3, pKD4, pKD46 vectors for recombineering p2 bacteriophage for use in Salmonella hosts pNBU1, pNBU2, pKNOCK and similar for cloning, expression , shuttling and genetic insertion in Bacteroides species.

Origin & function

Insert 1: Reporter genes such as avGFP and DsRed derivatives, luciferase variants, beta-lactamase; Insert 2: Bacterial transcriptional repressors and activators, such as lacI, tetR, lambda-cl, lambda-cro.
Insert 3: DNA recombinases/ invertases such as lambda-recombinase, cre, flp, int7,int8, int9, int12.
Insert 4: antibiotic resistance genes and mutations for cloning and bacterial identification purposes to provide resistance to ampicillin, kanamycin, chloramphenicol, streptomycin, spectinomycin, tetracycline.
Insert 5: DNA promoter regions and two-component systems derived from human commensal (eg, E. coli Nissle 1917, MG1655) or pathogenic bacterial species (eg. Salmonella typhimurium, Enterheamorragiic E. coli). Note that no sequences encoding pathogenic protein products will accompany these promoter regions.
Insert 6: Intergenic DNA regions derived from human gut microbiome sequences corresponding to hypothetical small proteins.
Insert 7:Standard synthetic circuit components such as promoters and ribosome binding site variants to control gene expression levels and timing of expression for other insert components (eg. reporter genes, repressors/activators, recombinases/invertases, antibiotic resistance genes, and hypothetical proteins). Transcriptional terminators to insulate expression from adjoining DNA regions.
Insert 8: CRISPR Cas variants and guide RNAs for targetted deletion or insertion, activation and repression of gene
insert 9: synthetic peptides and antibody fragments/nanobodies designed to target specific proteins.

Evaluation of foreseeable effects

GMMs are not expected to be any more hazardous to humans or the environment than their non-modified variants. All modifications involve either non-functional edits or non-pathogenic processes (for example standard reporters or hypothetical genes derived from commensal bacteria found in healthy human guts).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Liquid waste (e.g., cultures and supernatants from cultures). Virkon will be added to a final concentration of 1% and incubated for at least 30 mins. For bacterial cultures and supernatants <5ml, these may instead be autoclaved prior to disposal.

Solid waste (e.g., agar plates, plastic universal tubes): will be autoclaved before incineration.

All waste management procedures are expected to give 100% kill.

### Project Additional Information

#### Purposes of the contained use

Mtb is one of about a dozen bacterial species for which some clinical isolates are now resistant to most or all antibiotics (abx) approved for treatment of the infections they cause. Mechanisms of antimicrobial resistance (AMR) in Mtb deserve study for their potential relevance to AMR in other pathogens; because tuberculosis (TB) is now the leading cause of death from infectious disease; and because drug-resistant TB may be the most prevalent of all drugresistant bacterial infections. Heritable AMR in Mtb emerges with interruption of treatment, and the long duration of TB treatment provides many opportunities for interruption and non-compliance. Prolonged treatment is necessary because of nonheritable resistance, also called phenotypic tolerance or persistence, defined as the transient tolerance of bacteria in an antibiotic-sensitive population to an antibiotic during exposure to an otherwise lethal concentration of that antibiotic. In contrast to “resisters”, whose AMR is genetically encoded, “persisters” are genetically sensitive bacteria whose phenotypic tolerance allows them to survive for prolonged periods during what would otherwise be rapidly curative treatment. The specific aim of this work is to identify genetic determinants that foster phenotypic tolerance in Mtb through the selection and analysis of high-persister (hip) mutants selected in vitro and in vivo; these strains produce a higher proportion of persister cells than a wild-type strain under the same conditions.

**Definition of tolerance in this work:**
Phenotypic tolerance manifests as “the presence of bacteria in an antibiotic-sensitive population that are not killed by that antibiotic but, when allowed to grow in its absence, give rise to populations that can be killed by the antibiotic in the same proportion as before” [C. Nathan, Fresh approaches to anti-infective therapies. Sci Transl Med 4, 140sr142 (2012)]. Of note, in E. coli, persisters increase the population surviving antibiotic exposure from which mutations arise that confer heritable antimicrobial resistance (AMR), and the heritably-resistant mutants are then selected during subsequent cycles of exposure to the antibiotic. The same is likely to be the case for Mtb.

The objective is to identify hip mutants in Mtb that form in vitro or in vivo during infection upon exposure to stresses imposed by a combination of host immunity and chemotherapy. The activities are divided into three parts, namely isolation of hip mutants in vitro, isolation of hip mutants in vivo and follow-up activities that pertain to mutants isolated using both methods.

Experimental procedures will include the use of routine microbiology techniques in Class I Microbiological Safety Cabinets (MSC), infection of cell lines with listed biohazard group 3 bacteria, molecular biology, mouse husbandry, mouse infections, harvesting tissues from mice, imaging of fixed cells using fluorescence microscopy, FACS analysis of fixed biological material, plasmid-based molecular cloning, and various biochemistry methodologies. All procedures are described in the Code of Practice document.

#### Recipient or parental organism

ACDP 3: Fully drug-sensitive laboratory strains such as M. tuberculosis H37Rv, Erdman or CDC1551 and M. bovis AF2122/97. Please note that the present work does not use M. tuberculosis clinical isolates.

Transposon libraries constructed by himar1 mutagenesis.

A strain of Mtb that bears a plasmid encoding a tetracycline-regulated (tet-on) version of beta-galactosidase. This plasmid encodes an antibiotic resistance cassette.

A strain of Mtb that will be used bears plasmids that encode a selection marker flanked by loxP sites and the Cre recombinase, respectively.

High persistence mutants selected during the research activities described here.

#### Host/vector system
1. Transposon libraries of Mycobacterium tuberculosis constructed by himar1 mutagenesis
2. A laboratory strain of Mycobacterium tuberculosis that bears a plasmid encoding a tetracycline-regulated (tet-on) version of a reporter such as beta-galactosidase. The plasmid is constructed using the Gateway cloning system technology.
3. A laboratory strain that bears plasmids that encode a selection marker flanked by loxP sites and the Cre recombinase. These plasmids are constructed using the Gateway cloning system technology.
4. High persistence (hip) mutants selected during the research activities. Importantly, these mutants won't be generated but rather selected from a culture of the laboratory strain of Mycobacterium tuberculosis that naturally contains mutations and is not a de facto virulent strain. None of the hip mutants selected will thus be more virulent than wild-type strains listed in 7.1.
5 and 6. Mutations will be further introduced in strains listed in 7.1 to confirm that they confer the hip phenotype. If a gene is essential for growth in vitro, knock-downs will be constructed by transforming Mtb with two plasmids: pNitETSacB-kan (https://www.addgene.org/107692), which allows for the replacement of the native gene by a selection marker by recombineering, and a second plasmid that allows for the conditional expression of the gene; this plasmid will be constructed using the Gateway cloning system technology. Alternatively, knock downs will be generated using the CRISPRi technology. Briefly, a dCas9 allele is under the control of a Tet-repressor-regulated promoter. Expression of Cas9 is induced in the presence of anhydrotetracycline; a cognate sgRNA (targeting the genomic region of interest) under the control of a tetR-regulated promoter; a tet repressor; a single-copy L5 integrating backbone; a pBR322-derived E. coli replication origin; a kanamycin selection marker. The current optimal backbone for M. tuberculosis is PLJR965. This backbone works as advertised in the Nature Microbiology manuscript "Programmable transcriptional repression in mycobacteria using an orthogonal CRISPR interference platform" [Rock JM et al. Nat Microbiol. 2017 Feb 6;2:16274]. If the gene is not essential, a knock out will be generated using the plasmid pNitET-SacB-kan described above.

Origin & function

Genes identified in the screens described above. Preliminary results in Msm hip mutants obtained in vitro using methodology 1b identified mutations in amino acid biosynthesis pathways, tRNAs and their modifiers, and transcriptional pathways. These are pathways that will be disrupted in M. tuberculosis. Importantly, these mutants won't be generated but rather selected from a culture of the laboratory strain of Mycobacterium tuberculosis that naturally contains mutations and is not a de facto virulent strain. None of the hip mutants selected will thus be more virulent than the parental strain.

Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

02/03/2022
We aim to define the intracellular signalling events that control differentiation, survival and proliferation of lymphocytes.

Recipient or parental organism

We will transfet E.Coli K12 and derivatives with Blusecript containing mouse cDNAs encoding components of lymphocyte signalling pathways. We will introduce these cDNAs into pBabe retroviral vector and transfect into rodent-specific packaging cells, for infection of mouse cells and tissues with these cDNAs in vitro. Although expression of the genes of interest in the retroviral vector may effect mouse lymphocyte development and differentiation in vitro, the retrovirus cannot infect human cells and so would have no effect on human tissues and will not be oncogenic. Nevertheless, as some of the genes of interest have been shown to be oncogenes in the mouse (eg. Smoothened), we will carry out the work under CLASS II, Containment level II conditions.

Host/vector system

E.Coli K12 type (strains JM101 and derivatives or XL1 and derivatives)

GP+E retroviral packaging line and derivatives (packaging for infection of rodent cells only: Morgenstern and Land, 1990, Nucl. Acids Res. 18, 3587-3596)
Bosc retroviral packaging line and derivatives (Packaging for infection of rodent cells only)
Primary mouse cells and tissue
Mouse cell lines

Vectors:
Blusescript and derivatives
Puc and derivatives
pBabe and derivatives
MIGR1 and derivatives

Origin & function
For E.Coli: Commercial (Strategene) or other labs
For mouse cell lines: other labs
For primary mouse tissues: mice from CBS, Imperial College
For retroviral packaging cell lines: other labs

The genetic material will be PCR products from mouse (geneomic or cDNAs, generated by ourselves or from other labs)
Vectors will be obtained commercially or from other labs.

The function of these genetic manipulations is to study T cell differentiation in vitro.

Evaluation of foreseeable effects
We hope the genes we introduce into mouse T cell cultures will interfer with or alter T cell differentiation in cell cultures, and thus enable us to study T cell differentiation.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All waste will be inactivated using Virkon 1% for at least 3 minutes (according to the manufacturer's recommendations). This will give 100% kill. The material will then be autoclaved, reaching 121 degrees C for 15 minutes. The autoclave will be monitored by autoclave printouts of the status of each run and 6 month checks by external contractors to make sure the correct temperature is reached. The waste will then be removed by a College approved contractor for incineration.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N
The Committee made the following statements:

1. "We are concerned about the potential oncogenic properties of the insert cloned in the vectors. Therefore we recommend that the production and handling of large quantities of DNA are carried out under Class II conditions to minimise exposure to high amounts of DNA with oncogenic potential. The Committee also requests that the packaging cell line used for generating the infectious pBabe does not generate viruses with residual infection for human cells. Could references be provided please".

2. "Please state the required contact time required for Virkon to be effective".

Project Additional Information
Purposes of the contained use

The aim project is to study the mechanism of host cell invasion by the protozoan parasite Toxoplasma gondii by analysing the interactions between three classes of invasion molecules that are expressed in T. gondii. These molecules include molecular motors called myosins, adhesins called microneme proteins and aspartyl proteases. Using stable transfection technique, we propose to disrupt the genes coding for these invasion factors. In parallel, we will express deletion mutant and GFP fusions of these proteins to study their biogenesis. The biochemical analysis of the motor proteins will necessitate the purification of these proteins from toxoplasma gondii.

Recipient or parental organism

Toxoplasma gondii tachyzoites from RH and Prugniaud strains as well as the attenuated strains ts-4 mutant derived from RH strain. Toxoplasma gondii is a mild pathogen infecting human and animals. In human, this parasite is pathogen only under two circumstances: infection by immunosuppressed patients and pregnant women. Toxoplasma gondii acute infection can be treated with antifolates drugs combined to antibiotics of the class of macrolides or atovaquone. The genetic modifications proposed in our project are not anticipated to increase the virulence but rather to impair the ability of recombinant parasites to invade host cells.

Host/vector system

The vectors to be employed in the proposed experiments are all derived from the commercially available bluestrip from Stratagene. Most of the constructs are designed to express modified proteins or to generate knockout by homologous recombination in Toxoplasma gondii. These vectors are all described in the literature and the corresponding publications are listed in the risk assessment protocol.

Origin & function

The genetic material originates from Toxoplasma gondii genes or homologues from other Apicomplexa parasites and E.coli. Genes originating from Toxoplasma gondii and apucomplexa:
- Adhesins proteins secreted by the micronemes at the time of invasion. MIC1 to MIC9
- Molecular motors including myosin light chain and myosin heavy chains and docking proteins: Myosin A to Myosin E, MLC MADP
- Aspartyl proteases. AP1 and AP2
- Functions: Components of the invasion machinery
- Gene originating for other organisms: Beta galactosidase (LacZ), tetracycline repressor (tetR), green fluorescent protein (GFP), chloramphenicol acetyl transferase (CAT)
- Functions: Selectable marker to disrupt genes by homologous recombination (CAT), reporter genes (LacZ) and Creation of chimeric fusion to follow the traffic of protein (GFP) and modulation of gene expression (tetR).

Evaluation of foreseeable effects

1. The genes coding for these proteins will be disrupted in Toxoplasma gondii by homolgous recombination or by conditional knockout using the inducible tetracycline based gene expression system.
   We anticipate an alteration of the ability of parasites to infect cells.
2. These genes will be expressed as mutants: site specific point mutations, deletions or GFP fusions of these genes will be used to generate transgenic parasites.
   No change in virulence is expected.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Toxoplasma gondii is a micor-organism.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No application for derogation.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Propagation of Toxoplasma gondii tachyzoites in tissue culture must take place in a containment level 2. All the proposed experiments will take place in a cell culture.
equipped laboratory located in containment level 3. The room and equipment fulfils all the safety requirements. The room will not be shared with and no containment level 3 activity will take place there. The manipulation of live parasites will be done in a safety cabinet. Wearing gloves and laboratory coats are requested. No material or equipment can leave to zone before decontamination or autoclaving. Both liquids and solids wastes will be autoclaved in the Containment 3 zone. Autoclaving: 30 mins at 121°C at 15p.s.i (1.1kg/sq cm. Monitoring: Autoclave performance is monitored continuously by means of the autoclave printout (including a multipoint thermocouple test) annually by an independent company. Work carried out in the Containment level 3 laboratory is autoclaved within the containment room prior to removal to the main autoclave for a second round of autoclaving.

The safety committee agreed that the project involving Toxoplasma gondii should be conducted in a containment level 2 and that the genetic modifications are not anticipated to change the category of the containment. They agreed that the project will be carried out in a fully equipped cell culture room located in the containment level 3 area since it was the only room available. This room will be exclusively used by the members of the group of D. Soldati. Cell culture will be restricted to Toxoplasma gondii and the host cells to propagate the parasites.

The Committee has suggested to use blunt needles for the rare cases the manipulation of seringes will be necessary. The chemical inactivation of solid wastes before autoclaving has been suggested but since Toxoplasma gondii is not an aerosol borned pathogen, this measure will not be necessary.

Please enter comments on the GM safety committee on the risk assessment

Project Ref 96/01.6

Date Ackn’d 13/02/2006

CU2 Project Title THE EFFECT OF GENE KNOCK-OUTS ON GENE EXPRESSION AND

Class 2

Culture Volume Class 2 < 1 Litre
**Project Additional Information**

**Purposes of the contained use**

In this project we wish to establish the role of metabolic and regulatory genes in the stationary phase survival of Mycobacterium bovis BCG. We propose to make gene knock-outs of metabolic and regulatory genes (for example transporter genes, two-component systems) and investigate the effect of these mutations on stationary phase survival and gene expression. We propose to use a single integrating vector to compliment the knock-out mutants. We plan to use macrophage infection studies to establish the effect of the knock-out mutations on virulence/infectivity.

**Recipient or parental organism**

*Mycobacterium bovis BCG* is an ACDP class 2 organism. It is widely used as a vaccination strain.

**Host/vector system**

The vectors that will be used in the project use kanamycin or hygromycin as selectable marker and are non-mobilisable. We will use reporter gene vectors containing XyIE or GFP as reporter genes, single integrating vectors and knockout vectors. All vectors contain an origin of replication for *E. coli* and mycobacteria, except for the knock-out vector, which only has an origin of replication for *E. coli*.

**Origin & function**

All vectors have been constructed and validated in our laboratories. To create the knock-out and complimenting vectors we have used genomic DNA from *M. bovis BCG* and *M. tuberculosis*. The genomic DNA of *M. bovis BCG* originated from our laboratories, while the *M. tuberculosis* genomic DNA was from a collaborating department within Imperial College.

**Evaluation of foreseeable effects**

*M. bovis BCG* is an attenuated vaccination strain, unlikely to survive outside the laboratory. We intend to knock-out genes that are involved in regulatory and metabolic functions. For the genes we propose to knock-out, homologues are described in other organisms and in these organisms the mutation caused the organism to become less virulent. In our laboratories we have made knock-out mutants of genes with metabolic functions in *M. smegmatis* (a non-pathogenic Mycobacterium species), and it was found that these mutants are less viable than wild-type strains. We expect that we will see a similar effect in *M. bovis BCG*.

Mycobacteria are environmental organisms, and gene transfer between mycobacteria and other organisms has been described. However our vectors are non-mobilisable and need antibiotic selection to be sustained in the organism, it is therefore unlikely that the genetic material will establish itself into another population outside the laboratory.
M. bovis BCG is a difficult strain to maintain in the laboratory, with very specific culture methods. Mycobacteria are also sensitive to UV light. If inadvertently genetically modified M. bovis BCG is introduced to the environment, it is unlikely that the organism will survive. In the unlikely event that the genetically modified M. bovis BCG causes infection, the use of kanamycin and hygromycin as selectable markers, will not affect the treatment since the organism will stay full sensitive to Isoniazid and Rifampicin.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid GM waste is autoclaved and this should give a 100% kill, as established by Collins, CH (1993), Laboratory Acquired Infections, 3rd edition, pp 146 et seq.. All liquid GM waste is disinfected with a 2% final concentration of Hycolin for at least 16 hours. This should give a 100% kill, as established by Collins, CH (1993), Laboratory Acquired Infections, 3rd edition, pp 146 et seq.. We will monitor this on an ongoing basis by plating out random samples to establish whether any viable cells are present.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The GM safety committee approved the project as Class 2, containment level 2. However the committee was concerned about the use of kanamycin as a selectable marker, as this may interfere with susceptibility of the GMO to aminoglycosides such as amikacin. We have submitted evidence, supported by experts in the field of mycobacteria, that anikacin and/or kanamycin are rarely used in the treatment of mycobacterial infection; that M. bovis BCG is fully sensitive to Rifampicin and Isoniazid; and the genetic exchange between mycobacteria is very difficult, therefore making the possibility of transferring resistance from M. bovis BCG to M. tuberculosis very remote. The GM safety committee was very satisfied with our response and granted approval of Class 2, containment level 2.

**Project Additional Information**

**Purposes of the contained use**

Study of the RNA polymerases and transcription factors involved in the replication of chrysanthemum chlorotic mottle viroid, potato spindle viroid, barley yellow dwarf virus and cereal yellow dwarf virus.

**Recipient or parental organism**

Chrysanthemum chlorotic mottle viroid
Potato spindle tuber viroid
Barley yellow dwarf virus
Cereal yellow dwarf

**Host/vector system**

Escherichia coli K12 derivatives, such as DH5 alpha/ pUC-derived vectors, such as pBluescript, and, for the virus studies, expression vectors, such as the pET and PQE series of vectors.

**Origin & function**

Chrysanthemum chlorotic mottle viroid (infected chrysanthemum plants in Spain, USA)

Potato spindle tuber viroid (infected potato plants in Germany, USA)

Both viroids will be used to study interactions with the cellular RNA polymerases which replicate them.

Barley yellow dwarf virus (Infected barley and other cereal plants in UK, USA)
Cereal yellow dwarf virus (infected barley and other cereal plants in UK, USA)

The RNA of both viruses will be used to study interactions with the cognate virus-encoded RNA polymerases which replicate them.

**Evaluation of foreseeable effects**

Sequences alterations in the viroid or virus RNA which interfere with the ability to bind the cognate RNA polymerase will be likely to reduce the infectivity of the viroid or virus RNA to plants or plant cells.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Application for derogation of some containment level 3 measures to containment level 2 for the work involving chrysanthemum chlorotic mottle viroid and potato spindle tuber viroid

Table 1a Measure 2 Laboratory: sealable for fumigation

There is no risk to human health as viroids do not infect humans. Any accidental spillages within rooms 418 and 426 can be adequately contained by the disinfectant measures described in the standard operating procedure (attached)

Table 1a Measure 5 Negative pressure relative to the pressure of the immediate surroundings

Viroid-infected plants will not be allowed to flower. Hence there is no possibility of viroid dispersal via pollen or seed. No other parts of the plants are airborne. Plant residues will not be allowed to dry out, so that there will be no possibility of viroid transmission in dust arising from dried infected plant residues. Immediately after use, all viroid-infected plant residues will be placed in sealed containers prior to disposal by autoclaving and incineration. Precautions are in place to prevent the generation of aerosols. For details please see the standard operating procedure (attached). There will be no susceptible plants in the vicinity of rooms 418 and 426.

Table 1a Measure 6 Extract and input air from the laboratory should be HEPA filtered

Viroid-infected plants will not be allowed to flower. Hence there is no possibility of viroid dispersal via pollen or seed. No other parts of the plants are airborne. Plant residues will not be allowed to dry out, so that there will be no possibility of viroid transmission in dust arising from dried infected plant residues. Immediately after use, all viroid-infected plant residues will be placed in sealed containers prior to disposal by autoclaving and incineration. Precautions are in place to prevent the generation of aerosols. For details please see the standard operating procedure (attached). The air intake into the Sir Alexander Fleming Building is filtered to exclude insects and dust.

Table 1a Measure 7 Microbiological cabinet/enclosure

Viroids are not infectious to humans and do not encode any proteins. Hence a microbiological safety cabinet will not be required. Furthermore precautions are in place to prevent the generation of aerosols (see attached standard operating procedure). There will be no plants in rooms 418 and 426 other than those which it is desired to infect as part of the research project.

Table 1a Measure 8 Autoclave required in the lab suite

There is no possible risk of contaminating the environment in transporting infectious viroid-containing material from rooms 418 and 426 to the autoclave. Liquid waste will be absorbed on a clay-based or wood (cellulose)-based absorbent and treated as for solid waste. Solid waste will be placed in sealed containers. The sealed containers will be placed in autoclave bags, the tops of which will be folded over and taped. The autoclave bags will be placed in autoclavable buckets on which lids will be placed. The buckets will be transported to the autoclave in contained trolleys. On reaching the autoclave, the buckets will be removed from the trolley, their lids removed and the tape removed from the autoclave bags. However the containers containing the infectious viroid material will remain sealed. The white buckets will then be placed in the autoclave. During the autoclave cycle, the specially designed sealed containers will melt allowing access of the steam to the viroid waste material. After autoclaving the waste will be placed in clinical waste sacks prior to incineration.

Table 1a Measure 14 Efficient control of disease vectors which could disseminate the GMM
Viroids are not transmitted by aphid vectors when the aphids feed on plants infected by only viroids. However potato spindle tuber viroid (PSTVd) has been reported to be cotransmitted with potato leafroll virus (PLRV) by aphids feeding on potato plants infected with both PSTVd and PLRV. Several precautions are in place to prevent plants becoming infected adventitiously by aphids which may be carrying PLRV, although it is extremely unlikely that there are aphids carrying PLRV in the vicinity of Imperial College because there are no potato-growing areas in the vicinity of the College. (a) No aphids will be used in the project and there are no other projects involving aphids being carried out in the Sir Alexander Fleming Building. The air exchange system in the level 6 glasshouses, where the healthy uninfected plants are grown, is protected by aphid-proof mesh. In the four years that the glasshouse have been in operation, no aphids have been detected. If any aphids were detected, they would be immediately destroyed by application of an aphicide. (b) Plants will be examined for symptoms of virus infection, prior to viroid inoculation. Any putatively virus-infected plants will be destroyed by autoclaving and incineration. (c) Aphids have never been found in rooms 418 and 426 and indeed are unlikely to enter the Sir Alexander Fleming Building because the air intake is filtered and there are no windows opening to the outside of the building. However as an additional precaution, sticky insecticidal tape will be placed in rooms 418 and 426.

Please enter comments of the GM safety committee on the risk assessment

Risk assessments are prepared by proposers according to ACGM/HSE/DOE note 7 and are submitted to the central safety office with a local GM Notification/assessment form. The proposals are then circulated to all members of the local GMSC who return their comments to the biological safety officer on the form provided. Comments are forwarded to the proposers for their response and possible amendment of the proposals or risk assessments. The final submissions are discussed at meetings of the local GMSC before final approval is given and the required containment level is agreed.

CU2 Project Title  
THE PRODUCTION OF RECOMBINANT OVINE AND BOVINE PRION PROTEIN (PRP) FOR THE GENERATION OF MONOCLONAL ANTIBODIES SPECIFIC FOR CONFORMATIONAL ISOMERS OF PRP

Class 2  
CultureVol 1-50 litres

Consent Granted not applicable

Project notified under transitional arrangements N
### Project Additional Information

#### Purposes of the contained use

The biological function of the prion protein PrPC is not known, it is thought that the disease isoform of this molecule, PrPSc may be the infectious agent for BSE in cattle and scrapie in sheep. We wish to produce recombinant truncated forms of ovine and bovine PrP. Once purified monomeric truncated PrP will be converted to the -form for use as a target for antibody isolation in order to produce -form PrP conformational specific antibodies. Such antibodies may also be specific for the disease isoform PrPSc.

#### Recipient or parental organism

The proposed E. coli hosts Novablue DE3 and TG1 are routinely used lab strains of E. coli that are inherently safe K12 derivatives. The PrP gene inserts, from bovine or ovine source, are truncated and do not possess the GPI anchor domain or the export signal domain. The truncated versions would therefore be significantly different from the disease and are likely to pose a reduced risk to human or animal health.

#### Host/vector system

The PTrcHis, pRSET, pET, pMal expression vector systems will be used in the K12 derived E. coli host strains Novablue DE3 and TG1.

#### Origin & function

The truncated PrP genes are from bovine or ovine origin. These would be produced in the E. coli host cells using the expression vectors PTrcHis, pRSET, pET, and pMal which produce target proteins fused to either a poly-His tag or maltose binding protein, these tags would then be used to affinity purify the PrP-fusion proteins.

#### Evaluation of foreseeable effects

Due to the truncated nature of the inserts in the constructs proposed here and that the expressed proteins are structurally distinct from the disease isoforms (they need prolonged incubation at low pH in vitro to produce the conformational change thought to be central to the propagation of PrPSc, i.e. from a predominantly α-helical structure to a predominantly β-structure) the hazards to human health are low and containment level 2 is appropriate.

#### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

#### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

#### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

N/A
Solid waste:
Disposable plastic ware will be used wherever possible, disposable solid waste (including E. coli plates) to be put in biohazard burn bins and sent for incineration (100% kill). Reusable contaminated solids (including E. coli growth flasks) to be soaked in 20,000 ppm available chlorine of sodium hypochlorite for at least 2 hours, except for contaminated metal equipment which will be soaked in 2m sodium hydroxide for at least 2 hours.

Lique waste:
All liquid waste (including E. coli cultures) will be treated with 20,000 ppm available chlorine of sodium hypochlorite for at least 2 hours. Spills would be cleaned up with paper towels which will be treated as solid waste, contaminated spill areas will be soaked in 20,000 ppm available chlorine of sodium hypochlorite for at least 2 hours, except for contaminated metal which will be soaked in 2M sodium hydroxide for at least 2 hours. Where soaking is not possible, contaminated areas will be wiped down with one of the above disinfectants (as appropriate) at least 3 times allowing drying between applications for at least 1 hour. All work using the listed constructs in E. coli will be carried out in the BSE suite (biology Dept., University fo Leicester) and the SOP for this lab followed.

Disinfectant to be used, exposure time and working concentration:
2M sodium hydroxide or 40% (v/v) Haychlor industrial bleach (Chloros hypochlorite bleach). A 40% (v/v) solution of Haychlor industrial bleach contains 20,000 to 64,000 ppm available chlorine (manufacturers data). Decontamination procedures obtained from "transmissible spongiform encephalopathy agents: safe working and the prevention of infection. Advisory Committee on Dangerous Pathogens, Spongiform Encephalopathy Advisory Committee. ISBN 0-11-322166-5.

N.B. The above waste treatment/decontamination procedures are to ensure that contaminating recombinant PrP is destroyed, these procedures will also ensure that viable E. coli are unlikely to remain after treatment. For example University's guidelines from "Genetically Modified Organisms" and "Hazardous Biological Agents" state that solutions containing 1,000 ppm available chlorine (e.g 1% Chloros) are suitable for routine disingection of bench tops and otehr surfaces. 2.5% Chloros or equivalent is suitable for pipette jars and spillages of blood etc. 10% Chloros or equivalent should be used for blood and other materials with a high organic content if the presence of infectious agents is suspected.

Agreed:
1. That a designation of Class 2 is appropriate
2. That the risk assessment is sound and that work should be carried out at Containment Level 2
3. That the proposer should forward the proposal to HSE for prior approval of the project.

The project aims to characterise the factors that control the generation of genetic variation in a group of related gram negative bacterial organisms that colonise the respiratory tracts of either humans (Neisseria meningitidis, Neisseria lactamica and Haemophilus influenzae) or animals (Actinobacillus pleuropneumoniae, specific for pigs). This project also aims to identify and to characterise the functional consequences of the generation of genetic variation in specific loci.

Recipient or parental organism

Host/vector system

Plasmids: pCR2.1-TOPO, pUC18, pGEM, pACYC, pET, pSU2718, pYHS25, and derivatives of each of these plasmids.

Origin & function
Native genes from each organism. These genes will be inactivated by cloning of the relevant gene, insertion of an antibiotic cassette into the cloned gene and recombination of the mutated gene back into the native organism. All cloning will be performed in E.coli GMM strains. Complementation will also be performed wherein a non-mutated version of the gene re-inserted into another position in the genome. The mutated genes will have functions in various aspects of DNA metabolism, in DNA uptake or will encode surface proteins or enzymes that modify surface structures. Mutations in these genes will reduce infectivity or will mimic naturally-occurring mutations (for example many meningococcal isolates have heightened mutation rates due to mutations in mismatch repair genes) and so construction of strains with these mutations does not constitute any risk to human or animal health.

Antibiotic cassettes. Antibiotic cassettes mediating resistance to kanamycin, tetracycline, erythromycin, chloramphenicol, or streptomycin/spectinomycin will be utilised. These cassettes will be employed in the construction of mutations in specific target genes (see previous paragraph). These cassettes have been derived from other bacteria or plasmids and have been widely utilised for research purposes. These antibiotics are not used for treatment of natural infections by the recipient organisms and so construction of mutants containing these cassettes does not constitute any risk to human or animal health.

Reporter genes. The lacZ reporter gene encodes a beta-galactosidase, an enzyme involved in the metabolism of lactose and of chromogenic substrates such as X-Gal. Fluorescent proteins emit light at particular wavelengths and will include green fluorescent protein or derivatives thereof. The lux genes also emit light. The phoA gene encodes alkaline phosphatase and is involved in the metabolism of phosphate. These genes have benign functions that will not increase the infectivity of GMMs. The reporter genes will be used for detecting production of genetic variants. All these reporter genes have been derived from bacterial sources and widely used for research purposes.

Evaluation of foreseeable effects

Most of the GMM's will not exhibit an increased level of virulence relative to the parental strain. The GMM's with elevated mutation rates may exhibit enhanced virulence in certain tests relative to parental strains but will not be more virulent than wild-type isolates, some of which are known to carry mutations that increase mutation rate. All procedures with these GMM's will be carried out at containment level 2 reducing the chances of spread beyond the laboratory to effectively zero.

The inserted genes (reporter genes/antibiotic cassettes) do not encode functions that will increase the virulence of these organisms whilst the antibiotic cassettes do not mediate resistance to antibiotics that are currently used to control these or related organisms. These genes will present on the chromosome in all but the E. coli GMM's and will not, therefore, be readily transferable to bacterial species or other genera. E. coli GMM's will be in strains/plasmid backgrounds with a limited ability to undergo conjuction such that there will be a limited risk to transfer to other strains of the species. All procedures with these GMMs will be carried out at containment level 2 reducing the chances of spread beyond the laboratory to effectively zero.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

None

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste (paper and plastics): Autoclaving for 30 minutes at 121 degrees centigrade. All material for autoclaving will be transported in appropriate sealed containers (bags or boxes). Autoclaved waste is sent to landfill. Degree of kill: 100%.

Liquid waste: Treatment with 0.5% Prespt or a 1:100 dilution of Trigene for 24 hours prior to disposal down the sink. Degree of kill: 100%.

Small spillages treated with 70% ethanol for 5 minutes and then disposed of as solid waste. Degree of kill: 100%.

Large spillages treated with 0.5% solution of Precept for 60 minutes and then disposed of down the sink. Degree of kill 100%.
The degree of kill will be monitored by plating aliquots of treated samples on appropriate media and incubating overnight under appropriate growth conditions for the relevant organism.

Historical Significant Changes
We have recently shown that shorter telomere length is a causal factor for coronary artery disease. The aim of this project is to produce cell lines with varying telomere lengths from a single genetic background in the absence of confounding factors such as varying stress due to different time periods that the cells are maintained in culture. To achieve this we will employ an established method of introducing an excisable telomerase reverse transcriptase (TERT) using the eRE/Lox system (Salmon P et al 2000, Mol Ther. 2(4):404-14; Stadler et al 2013, Nature Structural and Molecular Biology 20(6) 671-678). Once infected with the pLOX-TERT construct the telomeres will undergo elongation. At different time points TERT will then be excised by the addition of CRE, creating sub clones which will subsequently undergo telomere attrition in the absence of TERT. All sub clones will be grown in parallel, creating clones of varying telomere length at the final time point which have all been maintained in culture for the same period. Although addition of TERT can extend cellular lifespan by preventing senescence that results from telomere loss, other pathways are also involved in cellular senescence, such as the p16-Rb pathway. These can be triggered by cellular stresses that result from maintaining the cells within culture and act independently to telomere induced senescence. Therefore it may not be possible to maintain the cells for the experimental period using only TERT. If necessary we will first generate cell lines which express either CDK4 or a p16-insensitive CDK4 (CDK4 R24C). Expression of CDK4 has been shown to enable growth of the cells for extended periods in culture by preventing nontelomere mediated cell cycle arrest (Stadler et al 2011, Skeletal Muscle 1, 12: Stadler et al 2013, Nature Structural and Molecular Biology 20(6) 671-678). These lines will subsequently be infected with pLOX-TERT.
Human pluripotent stem cells

Host/vector system

DH5-alpha and Stbl3 will be used for maintenance of plasmids
HEK293 will be transfected with the relevant combination of vectors to produce replication deficient retroviral particles (pCMV-VSV-G, pUMVC and either pBabe-hygro-CDK4, pBabe-hygro-CDK4-R24C or pBabe-GW-GFP) or replication deficient lentiviral vectors (pMD2.G, pCMVdR8.74 and either pLOX- TERT-iresTK, pLOX-gfp-iresTK or pLOX-CW-CRE).

Resulting viral particles will be used to infect human cells.

Origin & function

The genes to be expressed are telomerase, CDK4, a CDK4 mutant and green fluorescent protein.
Telomerase is responsible for maintaining telomere length, overexpression will lead to telomere elongation.

Telomerase has been used to immortalise cell lines, and thus needs to be considered potentially oncogenic
CDK4 is cyclin dependant kinase 4 and is expressed during the G1-S phase transition in the cell cycle. In complex with cyclin D and CDK6, it is responsible for phosphorylating pRS. Hypophosphorylation of pRB will drive cells into S phase of the cell cycle. While COK4 is negatively regulated by p161NK4A, the mutated version of CDK4, CDK4 R24C escapes the negative regulation by p161NK4A. As overexpression of both CDK4 and CDK4 R24C lead to dysregulated cell cycle control, both are considered to be potentially oncogenic.

Green fluorescent protein is being used as a marker for transfection.

Evaluation of foreseeable effects

There are three different GMO's being produced during this process
1) Bacteria with the individual components
Bacteria will not contain more than one viral component and therefore are unable to produce viral particles. Strains used are standard K-12 derivative E.Coli, and the presence of the vectors is not expected to alter pathogenicity of the bacteria, nor alter their survivability in the environment.

2) Lentivirus/retrovirus
Individual components for the virus are transfected into HEK293 cells were they are packaged and released. The viral part of the work that involves HTERT and CDK4 is the most hazardous. Both HTERT and CDK4 can be used to immortalise cell because they enable cells to bypass normal growth arrest/cellular senescence regulation. This process has oncogenic potential. Furthermore, as lentiviral systems are capable of infecting non-dividing cells, skin contact or inhalation of aerosols with viral particles may harm human health. Work involving the virus particles will be in a microbiological safety cabinet. Gloves and laboratory coats will be worn and no sharps will be used.

The viral particles produced are non-replicative and self inactivating. The presence of the inserts will not alter this and therefore unlikely to alter survivability in the environment.

3) Infected mammalian cell lines
As the viral particles are non-replicative and self inactivating, once the target cells are infected, the virus will integrate and express the desired proteins, but will not cause any further viral production. Cell lines will have a growth advantage as they will have escaped normal cell cycle regulation, but this process is no different to the myriad of cancer cell lines available. These changes are not expected to alter the pathogenicity of the cell lines. Escaping cell cycle control may indicate a growth advantage. However, given the cell lines requirement to have specialised growth media, transduced cell lines are not expected to have altered survivability.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

02/03/2022
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid waste will be autoclaved at 126°C for 20 mins. Autoclaved waste is disposed of as clinical waste via the UHL hospital waste system.

Liquid waste is treated with 10,000ppm free chlorine sodium dichloroisocyanurate (eg presept) for >12 hours.

Small volume spillages will be cleaned up using 1% virkon. Large volume spillages will be cleaned up using 10,000ppm free chlorine sodium dichloroisocyanurate.

Source of validation data. Manufactures data for sodium dichloroisocyanurate and Virkon. Autoclave conditions used are to ensure 121°C for 15 minutes. All runs are recorded and filed. Autoclaves undergo annual service and calibration and statutory inspections. Further checks are made to ensure autoclaves are achieving the correct temperatures.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

In this study we hope to understand the molecular basis of aberrant gene expression observed in people with inflammatory airway diseases such as asthma. The work will involve expression and silencing of various genes in commercially available and primary mammalian cells.

Recipient or parental organism

- Top10
- Stbl3
- DH10B T1R
- Primeplus
- HEK293T
- Hela
- HMC-1
- LAD-2

Primary human cells: T-lymphocytes, innate lymphoid cells, peripheral blood mononuclear cells, airway smooth muscle cells, epithelial cells, mast cells, fibroblasts, fibrocytes

Bacterial expression: All plasmids contain antibiotic resistance for expression in E.coli.
Full length cDNAs obtained from the MGC clone collection are contained within the pCMV-SPORT6 vector and supplied in DH10B T1R bacterial cells. Genes amplified by PCR are placed into the pCR4-TOPO family of vectors for expression in TOP10 bacterial cells to facilitate subcloning into relevant vectors (pCDNA3.1 for mammalian cell expression; lentiviral expression constructs for primary cell work). Amplification of pCDNA3.1 and pCMV-SPORT6 constructs will proceed in TOP10 bacterial cells.
cells, all lentiviral-cDNA constructs will be expressed in Stbl3 bacterial cells.
shRNAs will be supplied in the pGIPZ vector and grown in E.coli Prime plus and Stbl3 bacterial cells.
miRNAs will be supplied in the relevant lentiviral construct (pMIRNA1 and pMIRZ2P) and amplified in Stbl3 cells.
Virus production: Virus particles for transduction of primary human cells will be produced in HEK 293T cells transfected with the expression plasmid containing the insert, the envelope plasmid (pMD2.G), the pRSV-REV plasmid and the required packaging constructs (for pGIPZ constructs psPAX2, all other constructs pMDLg/pRRE).
Gene overexpression and silencing in human primary cells: Tensin1 silencing will be achieved by using a proprietary lentiviral construct from Santa Cruz. All target genes for overexpression in primary human cells will be cloned into the pCDH and pCS2 lentiviral vectors. miRNAs will be expressed in the pMIRNA1 vector and shRNAs in pGIPZ. miRNA silencing will be achieved using pMIRZ2P constructs. These vectors will be used to make lentiviral particles as described above and then the lentiviral particles will be used to transduce human cells.

Mammalian cell transfection: Target genes will be transfected into the various mammalian cell lines using either pCDNA3.1 or pCMV-SPORT6.

### Target genes to be tested

- **Transcription factors:** These transcription factors have been demonstrated to either influence cell phenotype directly or to regulate genes involved in immune cell phenotypic determination and effector cell function. Myb, Maf, Ikaros1, GATA3, TBX21, RORα, RORc, FoxP3, PU1, TCF7, ID2 and IRF4 are involved in cell type specification. The glucocorticoid and Vitamin D3 receptors are nuclear hormone receptors with immunomodulatory functions.

  - **Cell surface receptors:** The target genes (CysLTR1, CysLTR2, KLRG1, IL17RB, IL1RL1, IL15RA, CRTH2) are listed as receptors involved in cell-cell communication, they mainly respond to cytokines and other inflammatory mediators to induce cell chemotaxis or the production of cytokines. The CysLTR1,2, and the CRTH2 receptors are G protein coupled receptors. The KLRG1 receptor is thought to be an inhibitory receptor, whilst the remaining cytokine receptors (IL15RA, IL1RL1, IL17RB) promote cell proliferation and gene transcription in the presence of their respective ligands.

  - **Tensin-1:** This protein is encoded by the TNS1 gene and localizes to focal adhesions, regions of the plasma membrane where the cell attaches to the extracellular matrix. This protein crosslinks actin filaments and contains a Src homology 2 (SH2) domain, which is often found in molecules involved in signal transduction. This protein is a substrate of calpain II and has not been identified as hazardous.

  - **TRP family:** The TRP channel family encodes a large (~30) number of cation channels that, when activated transport either Ca2+ or a mixture of monovalent ions across the cell membrane. Therefore, these channels regulate intracellular calcium concentrations, the most common signal transduction molecule in cells, thereby influencing a wide range of cellular processes. TRP channels are involved in cell differentiation, survival, migration and mediator release.

  - **CEACAM6:** The protein encoded by this gene is a cell adhesion molecule detected on leukocytes and epithelia. It mediates cell-cell adhesion to regulate multiple cellular activities including differentiation, apoptosis, metastasis and modulation of immune responses.

  - **shRNAs:** shRNAs will be employed to decrease amounts of the gene products of target genes, including those listed in this section.

  - **miRNAs:** MicroRNAs (miRNAs) are small RNA molecules that function to silence RNA and regulate gene expression, post-transcriptionally. They play critical roles in the establishment of cellular phenotype. In this project we will deliver both pre- and anti-miRNAs. Evidence on functions of specific miRNAs is sparse and all three listed in this proposal have been associated with cancer. miR-150 has been associated with haematopoietic malignancies, its target genes include myb and myc, therefore silencing miR-150 can lead to increased cell proliferation. miR-31 and miR-155 have both been reported to display highly varied and altered expression profiles across many cancers. miR-31 has many validated targets including, transcription factors, small GTPases and cytokines. miR-155 overexpression reduces mRNA and protein levels of the tumour suppressor gene, TP53INP1.

### Evaluation of foreseeable effects

**Risk from genes to be tested**

- cMaf, cMyb have been shown to have some oncogenic activity, none of the other transcription factors has been reported to be hazardous. There is no evidence that overexpression of any of the cell surface receptors is hazardous, however since they play a role in cell proliferation we will consider them as potentially hazardous. TRP channels are involved in cell differentiation, survival, migration and mediator release. Due to their varied roles and the association of some members of the family with cancer, we will treat all members as potentially hazardous. CEACAM6 has been reported to be overexpressed in several human cancers and has oncogenic properties this gene will be considered hazardous.

**Risk from the use of lentiviral delivery**

02/03/2022
The lentivirus vectors can transduce both dividing and non-dividing human cells and integrate into the genome. There is therefore potential for this to cause insertional mutagenesis. The main hazard to human health following accidental inoculation of viral particles is the potential to cause excessive cell proliferation resulting in tumour or lymphoma formation. However, the likelihood of exposure is low since all staff are specifically trained in cell culture and virus production technique and none of the procedures will include the use of sharps. Therefore the likelihood of exposure is extremely low. Additionally the lentivirus strategies adopted here use three or four plasmids which separates env and gag/pol on to separate plasmids thereby generating replication incompetent virus. Infection is therefore limited to a single round and the likelihood of the GMM causing harm to human health is low. Both second and third generation lentiviral plasmid systems will be used.

Risk to environment

In the event of accidental escape while it is possible for the bacteria to survive for a short time in the environment, the required growth conditions are unlikely to be met, thus it is unlikely that they will be able to persist in the environment. The presence of the inserts is not expected to alter this as none of the targets are being expressed. Mammalian cells require specified growth conditions that will not be met and they are unlikely to survive. Some of the inserts, while potentially oncogenic or may increase proliferation, are not expected to alter this. Due to the use of the split genome lentivirus system there is effectively no chance that genetic material could be transferred to wild type organisms in the environment. The virus is extremely unlikely to revert to wild type and therefore is limited to a single round of infection and could not persist in the environment to cause harm. The vectors used to construct the lentivirus need a specified packaging cell line in order to produce infective particles. Thus it is unlikely if there were co-release of the bacteria containing the lentiviral components that a infectious lentivirus would be produced.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

### Project Additional Information

02/03/2022
**Purposes of the contained use**

We are using silica analysis to identify genes involved in eye disorders, in particular uveal melanoma. This project will aim to understand the role of these genes within the disorders that they have been identified from. We shall use lentiviral systems to knock down and overexpress the genes in order to elucidate the function of the genes.

**Host/vector system**

NEB 10-beta and Stbl3 etc will be used for maintenance of all plasmids listed and for routine cloning in pLlV~Gateway

pENTRId-topo, pLV[EXP]-Hygro-EF1A and lentiCRISPRv2

HEK293 will be transfected with the relevant combination of vectors to produce replication deficient lentiviral particles.

Resulting lentivirus will be used to infect the listed human cells

Cell lines may be transfected with pLV[EXP]-Hygro-EF:1A and lentiCRISPRv2

**Hosts**

- E.coli strains: NEB 10-beta, DH5alpha, Top10, Stt?13, DH1 OB T1 R, PrimePlus

- Human cell lines: HEK293T, Hela

- Primary human cells: UM-T710A, UM-T1356A, UM-T1324A

**Vectors**

- To express in E.coli: pLV[EXP]-Hygro-EF1A, pET30, pETM6T1, pGEX, pRSF, pCDF, pBR322 vector, pBR328 vector, pLV-Gateway, pENTRId-TOPO, lentiCRISPRv2

- Transient cell line transfection: pLV[EXP]-Hygro-EF1A, lentiCRISPRv2

- Lentiviral packaging plasmids: pCMVdeltaR8.74

- Lentiviral Envelope plasmid: pMD2G

- Lentiviral vectors for gene expression: pCMVdeltaR8.74, pMD2G, pLV-Gateway, pLV[EXP]-Hygro-EF1A, lentiCRISPRv2

**Origin & function**

Target genes to be tested

**Health and Safety**
We aim to understand the role of genes within the eye disorders that they have been identified from. These genes may influence the processes of growth, proliferation and survival of the cells leading to deregulated expression or function. The exact function of the genes in the disorders is unknown. However, it will not be unreasonable to expect that as a worse case, some of these genes would be oncogenes but could also be tumour suppressor genes or transcription factors.

The first two genes we identified in uveal melanoma are KTN1 and DLK2. These are oncogenes however the exact function of the genes in uveal melanoma is unknown.

KTN1 is involved in cadherin, kinesin and RNA binding as well as in microtubule-based movement, cellular protein metabolic process and post-translational protein modification;

DLK2 is related to canonical and non-canonical notch signalling and the p38 MAPK signalling pathway. DLK2 expression may have a positive and negative effect on the proliferation rate of melanomas.

Evaluation of foreseeable effects

Risk from genes to be tested

Health and Safety

Executive

Contained Use Notification

There are more than 350 hereditary eye diseases; Genetic factors play a key function in many kinds of eye diseases including those diseases that are the leading cause of blindness among infants, children and adults.

We aim to understand the role of genes within the eye disorders that they have been identified from. These genes may influence the processes of growth, proliferation and survival of the cells leading to deregulated expression or function. The exact function of the genes in the disorders is unknown. However, it will not be unreasonable to expect that as a worse case, some of these genes would be oncogenes but could also be tumour suppressor genes or transcription factors.

KTN1 and DLK2 are oncogenes however their exact function in uveal melanoma is unknown.

KTN1 is involved in cadherin, kinesin and RNA binding as well as in microtubule-based movement, cellular protein metabolic process and post-translational protein modification.

DLK2 is related to canonical and non-canonical notch signalling and the p38 MAPK signalling pathway. DLK2 expression may have a positive and negative effect on the proliferation rate of melanomas.

In addition, one of the systems (pLV based vectors) utilises wild type WPRE. This contains a truncated version of protein X that has been demonstrated to be oncogenic under certain circumstances. The other lentivirus system contains a mutant version of WPRE that cannot express protein X.

Unless it has been demonstrated that the identified genes are not harmful to human health, genes identified through this study will be treated as if they could be harmful. All use of pLV based vectors will be treated as if they ‘could be harmful irrespective of the gene being investigated.

Risk from the use of lentiviral delivery

The lentivirus vectors can transduce both dividing and non-dividing human cells and integrate into the genome. There is therefore potential for this to cause insertional mutagenesis. The main hazard to human health following accidental inoculation of viral particles is the potential to cause excessive cell proliferation resulting in tumour or lymphoma formation. However, the likelihood of exposure is low since all staff are specifically trained in cell culture and virus production technique and none of the procedures will include the use of sharps. Therefore the likelihood of exposure is extremely low. 80th second and third generation lentiviral plasmid systems will be used in this study. These systems separate env and gag/pol onto different plasmids and will only produce replication incompetent virus. Infection will therefore be limited to a single round of infection. Thus the likelihood of the GMM causing harm to human health is low.
### Risk to Environment

In the event of accidental escape while it is possible for the bacteria to survive for a short time in the environment, the required growth conditions are unlikely to be met, thus it is unlikely that they will be able to persist in the environment. The presence of the inserts is not expected to alter this as none of the targets are being expressed. Mammalian cells require specified growth conditions that will not be met and they are unlikely to survive. Some of the inserts, while potentially oncogenic or may increase proliferation, are not expected to alter this. Due to the use of the split genome lentivirus system there is effectively no chance that genetic material could be transferred to wild type organisms in the environment. The virus is extremely unlikely to revert to wild type and therefore is limited to a single round of infection and could not persist in the environment to cause harm. The vectors used to construct the lentivirus need a specified packaging cell line in order to produce infective particles. Thus it is unlikely if there were co-release of the bacteria containing the lentiviral components that an infectious lentivirus would be produced.

### Purposes of the contained use

To clone and express genes that have been identified as having a possible involvement in haematological malignancies, in primary B cells and B cell lines of human origin. The aim in the first instance is to assess whether the genes of interest have an effect on cell growth and/or apoptosis. Primary B cells cannot easily be made to express cloned genes by any other transfection method.

### Recipient or parental organism

Primary normal human B cells and B cell lines of human origin.

### Host/vector system

Pseudolentiviral particle based on HIV is used to infect the primary B cells (Naldini et al., Science. 1996 Apr 12;272 (5259):263-7). The lentiviral transfer vector pRRLsin.PPT.hCMV.pre will contain the gene of interest under the CMV promoter and between the 5' and 3' LTRs of HIV for integration into the cellular genome. It is transfected into 293T cells together with 3 core packaging plasmids and hybrid viral particles are made with the core proteins and enzymes of a lentivirus and the envelope of vesicular stomatitis virus. All structural, regulatory and accessory genes of HIV are excluded from the lentiviral vector and from the packaging plasmids. Virus particles are made which are replication-defective. The procedure involves transient transfection ie a short time for production of particles. The particles are collected from the culture supernatant, concentrated by centrifugation and can be stored frozen before being used to infect the target cells.

### Origin & function

- **Bcl11A and B** - zinc finger genes, possible transcription factors. Human genes.
- **MLT** - a paracaspase and may be involved in apoptotic pathways. Human gene.
- **PRDM6** - SET domain, may be involved in chromatin remodelling. Human gene.

It is likely that we will use mutated versions of all these genes also. **GFOP** is only used as a test control gene. All the other genes are possible oncogenes.

### Evaluation of foreseeable effects

At the packaging stage the viral particles could infect human cells. Therefore, the production of the virus and infection of host cells with the virus is carried out in containment level 2. Cells infected by the lentiviral particles are not hazardous as the virus cannot replicate. However, they could be overexpressing the gene inserted. The inserted genes are of unknown function and could be oncogenes but it is unlikely they will function on their own without other cellular changes. There is a low possibility of infecting individual cells in vivo. The virus particles cannot replicate and infection would remain localised to the site of entry.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste:

Solid waste will be treated with hypochlorite (10,000ppm) before being autoclaved prior to disposal (100% kill). The sterile waste is then sent for incineration by authorised contractors.
Liquid waste:
Liquid waste will be treated with hypochlorite (concentration 10,000ppm available chlorine overnight and autoclaved before disposal. Any spillages will be cleaned with chlorine disinfectant and the waste paper autoclaved and incinerated.

Autoclave cycle - 121 degrees C for 15 minutes. The autoclaves are validated annually in the MRC Toxicology Unit.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

It has been agreed by the Genetic Modification Safety Committee that a designation of Class 2 is appropriate for this work and that the risk assessment is sound and should be carried out at Containment level 2.

### Project Additional Information

#### Purposes of the contained use

To clone and express genes encoding proteins involved in cellular processes such as apoptosis, the cell cycle, cell signalling and neuronal pathology. Genes will be expressed in cell lines of human and rodent origin.

#### Recipient or parental organism

Human cells including cell lines of human origin and primary cells. Amphotropic packaging cells (for example Phenix 293 cells) will be used to express the core packaging plasmids, therefore the virus produced could infect human cells. However, the packaged virus cannot replicate so infected target cells would not be hazardous, although they would be overexpressing the gene inserted. To minimize risk sharps will not be used and primary human cells will only be obtained from donors outside the building.

Rodent cells will also be used, both primary and cell lines. In this case ecotropic packaging cells will be used to ensure the viruses produced cannot infect human cells.

#### Host/vector system

Inserts will be cloned into the pRRLsin transfer vector. This HIV-derived vector lacks the structural, regulatory and accessory proteins required for making replication competent retrovirus. This vector will be co-transfected into packaging cells alongside the pMDLg/pRRE, pRSV-Rev and pMD2.VSVG vectors in order to create replication-defective lentiviral particles.

#### Origin & function

The genetic material to be expressed will include genes encoding proteins known to regulate cellular processes. This will include genes involved in apoptosis the cell cycle, cell signalling and neuronal pathology. Examples will include ALAS1, CREB, HIF, cJun, CEBP family, BCPN1, MLT, Bcl, m3-muscarinic receptor, PML, DAXX, calpastatin genes and Green fluorescent protein.

Genes will be expressed that are well characterised as well as potential oncogenes or tumour suppressors and also mutated forms of these genes (including the CEBP family, BCNP1, PRDM6, MLT, Bcl11, SNX25 and C2TA). However, it is unlikely these genes would function as potential oncogenes or tumour suppressors on their own in the absence of other additional cellular changes.

#### Evaluation of foreseeable effects

At the packaging stage the virus particles could infect human cells. The virus is, however, replication deficient. Transacting structural genes are excluded from the transfer vector, which only encodes the gene of interest. The essential regulatory genes gag and pol are encoded in a separate plasmid, as is rev gene. These constructs have been altered to contain non-overlapping sequences hence minimising the possibility of recombination. In addition non-essential genes have been eliminated, hence any replication-competent virus generated would lack essential factors for replication and virulence in vivo.
Some inserted genes would be of unknown function and could be oncogenes, however it is unlikely they could function on their own without other cellular changes occurring. It cannot, however, be ruled out that an insert in an environment as yet untested may have a deleterious effect on host cells. For this reason these inserts are considered as potentially harmful.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

</tr>
</tbody>
</table>

### Project Additional Information

**Purposes of the contained use**

Expression of the full length (residues 23-231) and a segment of the prion (residues 90-231) for structural and folding studies. Expression of mutant forms of the segment.
Recipient or parental organism

Syrian hamster.

Host/vector system

Escherichia coli K12 strain ST11 TIR variant 4 (expression vector carrying the Syrian hamster prion protein segment (residues 90-231). E. coli non-K12 non-B strain BLR (DE3) (BLR is a Rec- version of BL21 and is given an Access factor of 10 -6 - ACGM Compendium of Guidance Part 2A Annex II 12) and a pTrcHis vector.

Origin & function

The strains expressing the full-length prion protein, the segment of the prion protein and mutant forms of both forms of the prion protein were supplied from the Institute of Animal Health, Compton. The strains are only used to express the proteins at Warwick. The purified proteins are then used in structural studies and protein folding analysis.

Evaluation of foreseeable effects

It is not clear that the Syrian hamster prion can cross the species barrier into humans. The GMSC has therefore erred on the side of safety and assumed that it can. We presume in each case because the E. coli can express the prion there is a significant risk to human health if the GMO resides, even for a short time in the gut. This is especially the case as some prion expression is dependent on T7 bacteriophage RNA polymerase, which is itself under the control a lactose inducible promoter. Lactose is a common dietary sugar and so there is high probability the prion would be expressed by bacteria if in the gut. There are, therefore, serious potential health consequences of escape of these GMOs. We also assume that this prion is capable of infecting a wide range of animals and so there is also a very significant risk of Environmental damage if the GMO can escape. Thus the consequence of environmental hazard is severe. As all manipulation of the GMOs occurs under Containment level 3 conditions the likelihood of environmental hazard is negligible.

Evaluation of foreseeable effects

No relevant

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None sought

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All the work is carried out in a Containment Laboratory. The Containment Laboratory conforms to all the physical requirements of a Containment Level 4 laboratory (ACGM Compendium of Guidance Part 3A Table 1) but it is run as a Containment Level 3 facility as we do not require complete change of clothing and footwear before entry and exit (ACGM Compendium of Guidance Part 3A Table 1 Section 12). All effluent from hand washing sinks and showers is collected and chemically decontaminated before removal from the room. All GMMs in contaminated material and waste are inactivated by treatment with 20,000ppm chlorine bleach for twelve hours and autoclaving at 134 degrees C. Solid waste is inactivated by treatment with 20,000ppm chlorine bleach for twelve hours and incineration. The detailed protocol for decontamination is given in the letter to HSE dated 10 June 1997.

Is an emergency plan required according to regulation 20? Y

If yes, tick to confirm that it is attached to this form

Tick to confirm that you have attached a risk assessment to this form Y
The Brenner scheme for the GMOs bearing the prion gave the following values: BLR (DE3) is given an Access factor of $10^{-6}$; the Damage factor of the prion is $10^{-1}$. As maximal expression is sought, the Expression factor is $10^{-1}$. The overall value is thus $10^{-6}$ and following previous contact with the HSE, this has been ascribed a Containment Level of 3. The fact that the prion is potentially capable of infecting other species means there is a very significant risk of Environmental damage if the GMOs can escape. Thus the consequence of environmental hazard is severe. As all manipulation of the GMOs occurs under Containment level 3 conditions, the likelihood of environmental hazard is negligible.

All of this work has previously been categorised and approved by the GMSC and the HSE. The reason for this resubmission was that following the introduction of the new Genetically Modified Organisms (Contained Use) Regulations 2000, our submission of the continuing project under the Transitional Provisions was rejected as too late.

- **Non-GMM**: Project notified under transitional arrangements

**Historical Significant Changes**

- **Historical Date of Additional Info**: 20/03/2022
### Purposes of the contained use

The aim of this project is to generate virus with specific amino acid changes within certain genes to affect the presentation of B and T cell epitopes to the immune system. The long term aim is to determine which viral epitopes could be used to stimulate a protective response on vaccination.

### Recipient or parental organism

The parent virus used will be full-length molecular clones of HIV or SIV made available to researchers through the NIH AIDS Research and Reference Reagent Program. These generate infectious virus upon transfection into permissive cell lines. Unmodified immunodeficiency viruses are classified in hazard group 3 under the COSHH regulations. HIV-1 and 2 infect humans and there is no effective vaccine, chemotherapy suppresses virus replication but does not eliminate the infection. SIV infects non-human primates.

### Host/vector system

The parent virus is cloned into a non-mobilisable vector pDR8 (a derivative of pUC19) and will be propagated in XL-1 blue cells (E. coli K12). Virus will be generated by transfecting linearised plasmid DNA into human T-cell lines (CEM x 174, H9, C8166, HeLa T4) or human peripheral blood lymphocytes.

### Origin & function

The molecular clones encoding full length HIV and SIV were cloned directly from genomic proviral DNA. These clones produce infectious virus upon transfection into permissive cell lines.

### Evaluation of foreseeable effects

Glycoprotein spikes on the surface of immunodeficiency viruses are responsible for the attachment of the virus to the cell (gp120) and fusion of the virus to the cell membrane (gp41). Both glycoproteins are encoded by the env gene. We intend to modify part of this gene to give rise to specific amino acid substitutions, deletions or insertions. We are not mutating parts of the gene responsible for binding to primary or secondary cell receptors, or the genes responsible for proteins targeted by chemotherapy. HIV causes a lethal human infection and mutations are unlikely to increase its pathogenicity. RNA viruses such as the immunodeficiency viruses have a high level of genetic variability and the changes sought are similar to those which occur in nature.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None sought.

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Modification of plasmid DNA is carried out in a containment level 2 laboratory. All solid waste and soiled glassware is autoclaved at 121 degrees C for a minimum of 15 minutes. Paper waste and other porous materials are autoclaved at 134 degrees C for 10 minutes. The autoclave is validated by thermocouple testing once every three months. Liquid cultures are chemically decontaminated by treatment with 2500 ppm chlorine bleach for 12 hours before disposal.

The virus generated will be replication competent and all manipulations will take place within a class 1 safety cabinet within a containment level 3 laboratory which is run under negative pressure and is sealable for fumigation. Access to this laboratory is restricted to authorised personnel only. All waste from this lab is autoclaved before disposal in an autoclave situated within the laboratory suite. The autoclave is validated by thermocouple testing once every three months. All staff are specifically trained in the safety aspects of the work. Written training records are kept. All growth of virus involves standard laboratory protocols; there are no unusual procedures that require additional containment measures.
The committee discussed the extension of the HIV/SIV work to include site-direct modifications of the genomic molecular clones. 

*  The clones are contained in pUC-based, non-mobilisable vectors in disabled host strains.
*  The vectors lack promoter sequences, so no viral proteins are produced.
*  The molecular clones are of half genomes, so no E. coli contains a full complement of viral genes. A restriction site is used to retrieve each half and to religate the DNA in vitro before the transfection of human cells. The half-clones do not overlap - the restriction site is the only homologous sequence, so a full-length viral genome could not be reconstructed by homologous recombination even if the plasmids were present in the same E. coli (which they are not).

Notwithstanding, these GMMs and the DNA in question have always been handled in the category 3 lab using the same precautions as for the live virus. Following new guidelines from HSE, work involving wild-type molecular clones has been classified to containment level 2, and notified to HSE and the work in this department has already been approved by HSE at this level. HSE has indicated that any modified molecular clones should be classified to containment level 3.

The meeting discussed a risk assessment document circulated by NJD and LMcL (attached). The proposed modifications are deletions and point mutations. No foreign DNA will be inserted. The RNA polymerase involved in HIV replication is very error-prone. The viral RNA sequence is highly variable in nature, so the proposed modifications could also arise naturally. Given the large numbers of circulating virus particles, each of the proposed modifications is likely to exist in the wild already. The deletions are known to restrict the host range, and there is no reason to expect that the point mutations would increase the rate of infection, the persistence of virus in the environment or the response to treatment. The disease outcome cannot be worsened by the modifications, because unmodified virus already causes a lethal and incurable disease.

Environmental risks: the receiving environment contains no non-human hosts for HIV or SIV (negligible consequence of release), the likelihood of release from the category 3 lab is negligible, so the overall risk is effectively zero. The committee approved the proposal at containment level 3.

Project Additional Information

Purposes of the contained use

The aim of the project is to investigate the control of replication and transcription of pneumoviruses by identifying the role(s) of specific virus proteins in these processes. The ultimate aim of the work is to generate potential vaccines for the human and animal pneumoviruses.

Recipient or parental organism

The cDNA copies of the virus genomes cloned into plasmids cannot be expressed in bacteria or in normal tissue culture, or other, cells unless the bacteriophage T7 RNA polymerase is simultaneously expressed. Consequently, the recombinant viruses can only be generated under controlled laboratory conditions.

With the exception of PVM and APV the viruses are restricted to replication within the respiratory tract of a single host. In the case of PVM there is serological evidence of an antigenically related virus infecting humans, though there is no direct evidence that this is the same organism. There is no evidence that PVM (or its putative relative) causes significant disease in the human population. APVs restricted to birds and has been shown to infect a range of wild and domestic species. RSV is an ACDP group 2 organism. The situation with hMPV is less clear at the moment. It is proposed that the work with wild type hMPV, PVM and APV will be conducted at containment level 2.

It is proposed that specific mutations, expected to produce conditional lethal (primarily temperature sensitive) mutant viruses, will be carried out. Three other types of modification are intended. The first of these involves exchange of specific genes between pneumoviruses. The genes are involved in virus replication and most exchanges are expected to have a detrimental effect on viability. The second is deletion of specific genes, also expected to reduce viability. Both of these categories of experiment and the generation of site-specific mutations will be conducted at containment level 2. The third mutations will involve alteration of genes encoding proteins involved in virus attachment and cell-cell spread and/or cell-cell spread and some involved in eliciting host immune responses. In many cases it is expected that the proposed modifications will result in a reduction in viability of the recombinant virus compared to the parent. It is not anticipated that these mutations will affect the host ranges of the viruses but any modifications involving genes involved in attachment, spread or alteration of the immune system will be carried out at containment level 3. More detail is provided in the attached documents.
The cDNA copy of the virus genome will be cloned into one of several possible plasmid vectors. These will all contain the colE1 origin of replication and be non-mobilisable. The virus genome cannot be expressed in bacterial systems. The bacterial host will be an E. coli K12 strain which is RecA. Commonly used strains will be XL-1Blue and TG2.

Virus will be generated by introducing the plasmid DNA into cells constitutively expressing bacteriophage T7 RNA polymerase (either constitutively or as a result of prior infection with a recombinant poxvirus carrying the polymerase gene). The viruses will be propagated in a range of standard tissue culture cell lines including Hep-2, BHK and HeLa cells. The viruses can only be generated in cells simultaneously expressing the bacteriophage T7 RNA polymerase.

<tbody>
<tr>
<td>All of the recombinant viruses produced are very unlikely to have altered phenotypes which provide an advantage for survival in the natural environment or to enhance their ability to infect animals or humans. In almost all cases the predicted effect of the alteration(s) to the virus genome(s) will be either to have no effect or to reduce the efficiency of replication and also usually to reduce pathogenicity (with the exception of the PVM experiments identified below). No effect on host range is anticipated for any recombinant viruses.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Evaluation of foreseeable effects</th>
</tr>
</thead>
<tbody>
<tr>
<td>The initial stage of the work will be to rescue infectious viruses from each of the four pneumovirus cDNAs. These viruses will not contain any mutations but will be identifiable as recombinant viruses because of the novel, non-coding, sequence alterations which result from the cloning process. For purely practical reasons it may be expedient to generate recombinant viruses in which one or more genes from one strain of the same type of virus are inserted into another strain eg humans RS virus genes from one strains into the genome of a different human RS virus to improve the efficiency of the cloning process. These would appear as wild type viruses.</td>
</tr>
</tbody>
</table>

Subsequently, a range of mutants will be generated. The mutants fall into several classes:

1. Generation of site-specific mutants
   Selected mutations anticipated to induce a conditional lethal (usually temperature sensitive) phenotype, based on characterisation of mutants described in the literature will be selectively introduced into the virus genomes. These mutants will have significantly reduced capacity to replicate.

2. Insertion of genes from homologous viruses
   The genes of a non-pathogenic strain of PVM will each in turn be replaced with the genes of a temperature sensitive pathogenic isolate. The temperature sensitivity of the recombinants will be determined to locate the gene responsible for this phenotype. Any viruses so produced are unlikely to exhibit levels of pathogenicity greater than those found in wild type isolates. The genes of the pathogenic isolate will be replaced with the equivalent gene from the non-pathogenic isolate. This virus will be considerably less pathogenic than wild type isolates. These recombinants will only be grown in tissue culture and will not be used as animal experiments without prior approval of the ACGM at a future date.

3. Generation of deletion mutants of pneumoviruses
   All of the deletion mutants of RSV produced to date are able to replicate both in vitro and in vivo though they are significantly attenuated in their capacity to cause disease. We will investigate the ability of further deletion mutants to replicate to establish the requirements for other virus genes in virus replication for the pneumoviruses. It is anticipated that these viruses will be seriously impaired in their growth characteristics and will almost certainly be significantly attenuated.

4. Insertion of additional genes and non-coding sequences into recombinant pneumoviruses
   We will generate recombinant viruses carrying standard reporter genes such as that for the bacterial chloramphenicaol acetyl transferase, green fluorescent protein luciferase etc. to investigate the limits of the tolerance for carrying additional genes. We will also investigate the possibility of inserting marker genes, such as green...
fluorescent protein, into the coding regions of specific virus genes with the intention of generating molecular tags on on virus proteins. These recombinant viruses will either behave as wild type or be slightly restricted in ability to replicate efficiently.

We will introduce an extra attachment protein gene into the genome of a recombinant virus. This gene will be from a strain shown to be quite distinct from the genetic background of the parental virus. This will establish the level of plasticity of the pneumovirus genome in terms of its ability to support extra virus genes inserted at different locations. We will extend these analyses to generate recombinant viruses carrying additional fusion protein genes to investigate the potential capacity for viruses to carry additional epitopes.

NO RECOMBINANTS CARRYING IMMUNOMODULATORY GENES SUCH AS THOSE FOR CELLULAR CYTOKINES WILL BE PRODUCED IN THIS STUDY.

5. Alteration of the genetic organisation of pneumoviruses

The position of pneumovirus genes relative to the single 'promoter' element is thought to maintain controlled gene expression, and ultimately assembly, of progeny virions. We will disrupt the order of the pneumovirus genes and determine the effects of this. In particular, it will be of interest to investigate the consequence of over expression of the glycoprotein genes and under expression of the N and P protein genes. While it is expected that the permutation of the genome will not destroy infectivity it is likely to result in attenuation of infectivity in vivo.

6. Recombinant viruses carrying genes from other pneumoviruses.

We will construct recombinant pneumovirus genomes in which certain genes have been replaced by their counterparts from other pneumoviruses. Of particular interest will be substitution of the RS virus glycoprotein genes with those of PVM. We would also like to make chimeric viruses in which the genes encoding the major nucleoprotein (N), phosphoprotein (P) M2 and polymerase (L) genes of the pneumoviruses are replaced by their counterparts from other pneumoviruses. We have obtained evidence that these last four genes have different abilities to function in heterologous systems which suggest that recombinant viruses are likely to be impaired in their replication.

Following the analysis above, we would like to generate recombinant N, P, M2 and L genes with specific portions derived from different pneumoviruses to be inserted into recombinant viruses to define the functional domains of the various proteins.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None sought.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

For bacterial work all solid waste and glassware is autoclaved at 121 degrees C for a minimum of 15 minutes. The autoclave is validated by thermocouple test annually. Liquid cultures are chemically decontaminated by treatment with 2500 ppm chlorine bleach for a minimum of 2 hours prior to disposal.

Viruses generated and handled under containment level 2 conditions will be handled only in a class 2 microbiological cabinet fitted with two HEPA filters in a designated virus laboratory. The cabinets are tested for microbiological safety annually by an independent company. Solid waste and glassware will be autoclaved as described above. Liquid waste will be chemically decontaminated by treatment with 2500 ppm chlorine bleach for a minimum of 2 hours prior to disposal. Spillages will be immediately treated by flooding the area with detergent (1% Savlon). All pneumoviruses are exquisitely sensitive to detergents and are immediately inactivated. The detergent will be removed with tissue which will be treated as solid waste.

Viruses generated and handled under containment level 3 conditions will be handled only within a class 1 microbiological safety cabinet inside an approved category 3 facility. The containment facility will be run under negative pressure and is sealable for fumigation. Access to the laboratory will be restricted to authorised personnel only. All solid waste from the laboratory will be autoclaved at 134 degrees C for a minimum of 15 minutes, in an autoclave within the containment suite, prior to disposal. The autoclave will be validated by thermocouple test at no less than six monthly intervals. Liquid waste will be decontaminated by treatment with 2500 ppm chlorine bleach for a minimum of 2 hours prior to disposal or by autoclaving.
The committee discussed the extension of the RSV work to include a new human virus, hMPV. The committee has already approved projects to create viruses that recombine genes from human RSV and the related viruses, AVP and PVM.

The committee discussed a risk assessment for extending the project to include the new viruses.

The committee approved the proposal at the same containment levels as for the previous work.

Full minutes of safety committee edited for inclusion on public register.

Project Additional Information

Purposes of the contained use

1. The overall aim of our studies is to investigate the interaction of adenoviruses (Ads) with the host immune system. In particular, we are interested as to how Ads counteract and evade various immune mechanisms. We are concentrating on a set of virus proteins encoded in the early transcription unit E3. Several of these E3 proteins have been shown to function in immune evasion, other E3 functions are still elusive. To investigate the functions of adenovirus E3 proteins, we have used site-directed mutagenesis to introduce (previous work done in Germany) mutations or deletions into the E3 regions of Ad2, Ad3, Ad4, Ad19a to selectively inactivate E3 proteins or to study structure/function relationships. We plan to continue this work and will introduce further mutations or deletions. In some cases, we will also delete or inactivate parts of the E1 region (e.g., E1B 55K and E1B19K) to see the combined effect on apoptosis induction.

2. In addition, we intend to establish new Ad vectors for gene/cancer therapy. We have identified an Ad that efficiently infects professional antigen presenting cells (APCs). With the corresponding vector we should be able to transfer well-characterized tumour antigens (non-oncogenes) that can be recognized by cytotoxic T cells into these APCs. Thereby, we hope that we can stimulate an immune response against tumours carrying the corresponding tumour antigen. These vectors may be utilized in cancer therapy to stimulate an effective immune response to tumor antigens. Moreover, we will test the influence of E3 proteins on such immune responses. We will also test whether or not these new vectors can directly infect and possibly destroy certain tumour cells after replication or upon introduction of an apoptosis-inducing system.

Recipient or parental organism

1. Manipulation of the adenovirus genome is done in E. coli K-12 strains DH10B or DH5.

2. Ads are human viruses that are either endemic or widespread. They cause acute and persistent infections and stimulate lifelong immunity. Some serotypes have been explored as replication-competent or replication-deficient vectors for gene and cancer therapy in humans. Both types of vectors will be generated in our programme. The mutant viruses will contain deletions, specific mutations or may have incorporated a tumour antigen (see below).

3. E3 genes of the various Ads are cotransfected together with an antibiotic resistance gene (neomycin or hygromycin) into 293 cells and other eukaryotic cells to generate permanent cell lines expressing wild-type or mutated E3 proteins (Class 1 work).

Host/vector system

Mutant adenoviruses are constructed by recombination in E. coli K-12 strains. An antibiotic resistance gene is incorporated into the virus genome by in vitro transposition. Subsequently, the virus genome containing the antibiotic resistance gene is recombed with a plasmid containing the left and right end of the relevant Ad genome. The cloned backbone and used to transfect 293 cells to propagate the virus.

Origin & function
1. The constructed Ad mutants only contain specific point mutations or deletions, but no insert. Thus, we are generally not introducing any foreign material except in some cases where short pieces of DNA (restriction sites) or a tag, eg FLAG (artificial octapeptide) or HA (noneptide from flu hemagglutinin) may be inserted for convenient detection.

2. In the Ad vector constructs marker genes are derived from bacteria (B galactosidase), jelly fish (green fluorescent protein) and/or firefly (luciferase). To express these marker genes the expression cassette will contain additional elements (promoter, polyA region) from SV40, cytomegalovirus and/or human tissues (promoter, growth hormone poly A).

3. The tumor antigens inserted will be selected on the basis of their recognition by T cells. To achieve the proof of principle we will concentrate on well-characterized tumor antigens, such as MAGE 1-3 (Melanoma associated tumour antigens) of mouse, human or rat origin.

**Evaluation of foreseeable effects**

Ads are human viruses that are either endemic or widespread. They cause lifelong immunity and some serotypes are used for gene and cancer therapy in humans. Ads do not replicate in animals, except perhaps in cotton rats. We are introducing mutations that should arise in nature. As we are inactivating or deleting potential immune evasion genes, it is expected that these viruses are better recognized by the host immune system. As a consequence, these mutant viruses are presumably less virulent/partially defective in vivo. In summary, the mutant viruses do not pose a greater risk but rather a lower or equal risk to that of wild-type Ads.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None sought

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Modification of plasmid DNA is carried out in a containment level 2 laboratory. All solid waste and soiled glassware is autoclaved at 121 degrees C for a minimum of 15 minutes. Paper waste and other porous materials are autoclaved at 134 degrees C for 5 minutes. The autoclave is validated by thermocouple testing once every three months. Liquid cultures are chemically decontaminated by treatment with 2500 ppm chlorine bleach for 12 hours before disposal.

Virus work will be carried out in a containment level II laboratory within a class II microbiological safety cabinet. All infected waste is autoclaved at 121 degrees C for a minimum of 15 minutes. The autoclave is validated by thermocouple testing once every three months. Liquid waste is chemically decontaminated by treatment with 2500 ppm chlorine bleach for 12 hours before disposal. All growth of virus involves standard laboratory protocols; there are no unusual procedures that require additional containment measures.

Is an emergency plan required according to regulation 20?

If yes, tick to confirm that it is attached to this form  

N

Tick to confirm that you have attached a risk assessment to this form  

Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  

N
The project involves the generation of genetically modified adenovirus strains. This virus is a human-specific pathogen that is ubiquitous. None of the modifications were considered to increase the potential risk from the virus. In some cases mutations would mean the virus would be defective and could only propagate in specific tissue culture cells, i.e., 293 cells. Other engineered deletions and point mutations probably already occur in the natural populations and so can be expected not to increase the risk from the virus. Therefore, the constructs were considered to have either identical or reduced risk. In some cases insertions are to be made, i.e., GFP, β-galactosidase, FLAG, HA nonepeptide and tumour antigens (non-oncogenes). The inserts are very well characterised and the GMSC thought it extremely unlikely they could potentiate the pathogenicity of the virus. Therefore, containment at the same level as the unmodified virus (Containment level 2) was considered appropriate. As the virus cannot infect non-humans environmental impact was considered no greater than the unmodified virus.

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change

02/03/2022
Purposes of the contained use

The aim of the project is to investigate the interaction of vesiculoviruses with their host cells, at the level of individual virus proteins. The ultimate aim of the work is to extend our knowledge of the ways negative-strand RNA viruses subvert the host cell, and of the mechanisms of persistence of arboviruses in their insect hosts.

Recipient or parental organism

The cDNA copies of virus genomes cloned into plasmids cannot be expressed in bacteria, or in tissue culture cells unless the bacteriophage T7 RNA polymerase is simultaneously expressed. Consequently, recombinant viruses can only be created under controlled laboratory conditions. The parental organisms are the vesiculoviruses, CHPV and ISFV. The viruses cause usually sub-clinical infections in humans, and require an insect vector (not endemic to the UK) for efficient transmission. CHPV and ISFV are both handled at containment level 2. See attached document.

Host/vector system

The cDNA copy of the genome will cloned in a non-mobilisable plasmid vector which cannot be expressed in E.Coli; the host will be a recA-strain such as DH5alpha. Virus will be produced by introducing the plasmid, along with plasmids encoding the viral RNA polymerase complex, into mammalian cells which constitutively express T7 RNA polymerase. Progeny viruses will be propagated in standard cell culture lines including monkey (BS-C-1 and vero), human (Hep-2, 293, A549) and insect (Drosophila S2, C6/36) lines.

Origin & function

Parental strains will be molecular clones of the prototype strains of Chandipura (CHPV) and Isfahan (ISFV) viruses. Three types of recombinant viruses will be made: (1) mutations in the parental viruses; (2) addition of reporter genes; (3) exchange of whole or partial genes between viruses. None of these modifications are expected to increase the ability of the viruses to infect humans or animals, or to survive in the environment, above those of the parental viruses. Most of the alterations are designed, and are likely, to make the viruses less fit. As both parental viruses require an insect vector for efficient onward transmission from infected hosts, it is extremely unlikely that recombinants would lose this vector requirement.

(1) Mutations will be introduced into viral proteins in order to determine the resulting phenotype in terms of virus growth and interaction with host cell proteins. These mutations may be point mutations (some already known to be conditional lethal mutations), or deletions of partial or whole protein coding regions. In some cases short epitope tags (e.g. FLAG, hexaHis) will be added to a viral protein, to facilitate further analysis such as purification of protein interaction partners. All these changes are likely to reduce virus fitness if any effect is seen, and in the case of deletions, to result in defective viruses.

(2) Additional genes will be inserted into the virus which encode a standard laboratory reporter such as chloramphenicol acetyl transferase, luciferase, green fluorescent protein etc. These will enable rapid visualisation and titration of the GMM. These additions are expected to either have no effect on virus fitness, or to reduce it, depending on the site of insertion of the additional gene. The reporter gene products themselves have no known toxicity.

(3) Individual genes will be exchanged between CHPV and ISFV to allow determination of the molecular basis of host-range restriction seen in ISFV. Since parental CHPV already has a very broad host range, recombinants are likely to have a reduced host-range. To enable mapping of functional domains in CHPV proteins, parts of the gene thought to encode functionally relevant domains will be exchanged with the equivalent domain from ISFV. This approach allows the recombinant protein to retain its approximate conformation and can be more useful than a traditional deletion approach. There is no intention to introduce immunomodulatory genes into the viruses.

Evaluation of foreseeable effects

It is very unlikely that the alterations to CHPV or ISFV will make them more pathogenic to humans. Most of the alterations are designed, and are likely, to make the viruses less fit. As both parental viruses require an insect vector for efficient onward transmission from infected hosts, it is extremely unlikely that recombinants would lose this vector requirement. The vector does not occur in the UK (Phlebotomus spp.). There is no evidence for human-to-human or animal-to-animal transmission of these viruses in the absence of the vector.

In some constructs genes will be replaced (in whole or in part) by those from other vesiculoviruses. For genes encoding proteins involved in viral RNA synthesis (replication and transcription; N, P and L proteins) the likely outcome will be to reduce the replicative capacity of the recombinant virus and no hazards are foreseen. For those constructs in which the gene encoding the protein (G) involved in cell attachment/fusion is exchanged between vesiculoviruses, it is unlikely that this will increase the potential host range or pathogenicity of the recombinant viruses. CHPV infects a very broad range of cell types in culture, including human, other mammalian, avian and...
insect cells, suggesting that its receptor is very widely distributed. ISFV is more restricted in that its replication is greatly diminished in certain cell types; this is not simple host-range restriction, as ISFV grows in some human cell lines, but not in others. Replacement of CHPV genes with corresponding ISFV genes is therefore predicted to reduce the host range of the recombinant, if any effect is observed. Furthermore, ISFV and CHPV have essentially the same host ranges in whole organisms. The only animals which show severe consequences of infection are infant mice and hamsters, in which both CHPV and ISFV are lethal. It is very unlikely that recombinant viruses would have any broader host range than this.

The viral M protein is partly responsible for counter-acting the host immune response to infection. Alterations in, or exchange of, the M gene are therefore expected to produce recombinants with reduced ability to resist the immune response, and so which would be attenuated.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

For bacterial work, all solid waste and glassware is autoclaved at 121 C for at least 15 min. The autoclave is validated by thermocouple test annually. Liquid cultures are chemically decontaminated by treatment with 2500 ppm chlorine bleach for a minimum of 2 hours prior to disposal. Both these treatments give a 100 % kill for standard lab strains of E. coli.

For viruses generated and handled under containment level 2 conditions, all manipulations of the viruses will take place in a class 2 microbiological safety cabinet which contains two HEPA filters on the exhaust. The cabinet is in a designated virology laboratory, and is tested for microbiological safety annually by an independent company. The waste will be autoclaved or chemically treated as described above to ensure that no viable organisms are present prior to disposal. The manipulations will be carried out by trained staff and written records of all experiments will be maintained. Spillages will be immediately treated by flooding the area with detergent-based disinfectant (1% Hibicet). All vesiculoviruses are lipid-enveloped, and so highly sensitive to detergents. The detergent will be absorbed onto tissue which will then be autoclaved as for solid waste. Autoclaving, chlorine treatment and Hibicet treatment all lead to 100 % kill of vesiculoviruses.

Minutes of the Genetic Manipulation safety Committee held on 23rd November 2006 relevant to the notification:

GMSC 688
Recombinant vesiculoviruses expressing reporter genes.
Introduction of reporter gene (GFP, CAT, luciferase and/or SEAP) into the virus genome, either as a separate transcription unit, or as a fusion protein with one of the viral proteins, in order to monitor replication and spread of the virus by detecting the reporter protein. Reporter fusion proteins will be used to monitor distribution of virus proteins within infected cells.
Chandipura virus falls into hazard group 2. Unmodified viruses usually cause sub-clinical infection of humans, sometimes low-grade fever in the case of Chandipura virus. Human-to-human transmission has not been reported, and the insect vector does not occur in the UK. Inserted genes are likely to reduce replicative capacity of the viruses, and reporter proteins have no known toxicity.
Environmental Risks: Consequence: Low; Likelihood: negligible; Overall: effectively zero.
GMSC Decision: Containment Level 2.

GMSC 689
Chimeric recombinant vesiculoviruses.
One or more genes of Chandipura virus will be replaced with the corresponding gene(s) of the related Isfahan virus, or with a chimeric gene composed of parts of the two viruses. Purpose is to study function of the virus proteins in the replication cycle.
Chandipura and Isfahan viruses fall into hazard group 2. Unmodified viruses usually cause subclinical infection of humans, sometimes low-grade fever in the case of Chandipura virus. Human-to-human transmission has not been reported, and the insect vector does not occur in the UK. The modifications are likely to reduce replicative capacity of the viruses.

Date Project Ceased 02/03/2022
Purposes of the contained use

The broad aim of this project is to better understand the replication of hepatitis C virus. The relatively compact hepatitis C virus genome encodes all the proteins and contains the required genetic elements to replicate in a suitable cell line. We are particularly interested in the structure and function of RNA elements that are involved in the replication process. A better understanding of HCV replication may enable novel therapeutic methods to be developed to limit virus infectivity or spread in the infected host.

Recipient or parental organism

The parental organism is hepatitis C virus, an ACDP level 3 human pathogen. At the time of application this virus only undergoes a full replication cycle in the human hepatoma Huh7 cell line. Therefore virus can only be recovered from cDNA under controlled laboratory conditions and can only be cultivated in a specific cell culture system. The virus cDNA is contained in plasmids is under transcriptional control of a phage T7 promoter. In the absence of exogenously supplied T7 polymerase there can be no transcription and hence subsequent expression of HCV.

Host/vector system

The plasmid vector system is derived from pUC. It is therefore non-mobilisable. It is maintained in standard disabled laboratory strains of E. coli (DH5a, JM101 etc.). Virus production will follow in vitro T7-mediated transcription and transfection of Huh7 cells in culture. Progeny virus will be propagated in Huh7 cells. Huh7 cells are a permanent cell line defective in interferon production. They are the only cell culture system in which hepatitis C replication has been reproducibly demonstrated.

Origin & function

The parental genetic material is hepatitis C virus. Initially studies will be based on the genotype 2a JFH-1 infectious cDNA and virus recovered from this clone (Wakita et al., Nature Medicine 11, 791-796). Future studies will include additional genotypes as they become available in other laboratories. The JFH-1 system reproducibly produces infectious virus in Huh7 cells that can be passaged onto fresh cells. Mutations will be introduced into the cDNA into regions we suspect are involved in controlling virus replication. In particular we are interested in short stem-loop structures that are located in the core protein-encoding and NS5b polymerase-encoding regions. Mutations will be introduced to disrupt these structures and duplications of the structures will be introduced elsewhere in the genome. None of the changes are in regions of the virus implicated in influencing the primary tropism of the virus - they are not in the E1 or E2 envelope-coding regions. Mutations will include deletions, substitutions and short insertions.

A similar range of mutations will be introduced into a sub-genomic replicon system in which the structural proteins of HCV are removed and replaced with a reporter gene (luciferase) or an antibiotic coding gene (conferring G418 resistance). The sub-genomic replicon is transcribed in vitro using bacteriophage T7, the RNA transfected into Huh7 cells, and replication ‘monitored’ by an increase in luciferase activity, or the outgrowth over time of neomycin-resistant colonies in cell culture. The sub-genomic replicon cannot transfer from cell to cell and cannot encode infectious virus.
Some of the substitutions to be introduced will be of analogous regions of other genotypes of HCV. More divergent sequences are not included within the scope of this proposal i.e. the sequences are all derived from hepatitis C virus.

Studies from a number of laboratories have shown that disrupting this type of cis-acting replication elements (that are the targets of this project) is either neutral or deleterious to virus replication. There is no reason to suspect that the mutations to be introduced will enhance replication above that of the parental virus, or that the changes will increase or otherwise influence the tropism or pathogenicity of the recovered virus.

**Evaluation of foreseeable effects**

Hepatitis C virus is exclusively a human pathogen. Transmission is almost exclusively parenteral, with some limited evidence for sexual transmission. There is no evidence for aerosol or faecal-oral transmission of the virus. None of the changes proposed - if they yield viable virus at all - are expected (or designed) to alter the cell, tissue or host tropism of the virus, or influence the route by which the virus can be transmitted. The majority of the changes are expected to be deleterious to virus replication, and to reduce or abrogate virus fitness. There is no reason to expect that the planned changes will reduce the immune response to the virus, which clears infection in about one third of cases. Instead, a less fit virus may be more susceptible to immune clearance.

No vaccine is available to prevent HCV infection. Antivirals - currently ribavirin and interferon, with protease inhibitors shortly - are of limited benefit and lead to viral clearance in a proportion of cases.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity.  (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

For bacterial work, all solid waste and glassware is autoclaved at 121°C for at least 15 min. The autoclave is validated by thermocouple test annually. Liquid cultures are chemically decontaminated by treatment with 2500 ppm chlorine bleach for a minimum of 2 hours prior to disposal. Both these treatments give a 100 % kill for standard laboratory strains of E. coli.

Cell culture work not involving recovery or propagation of viable virus e.g. transfection and analysis of hepatitis C virus sub-genomic replicons, will be conducted in a level 2 tissue culture laboratory. All cells will be handled in a class 2 microbiological safety cabinet with HEPA-filtered exhaust. Waste is autoclaved or chemically inactivated prior to disposal. All staff handling replicon-transfected cells are trained.

Cell culture studies involving the attempted recovery and propagation of infectious hepatitis C virus will be conducted in a level 3 laboratory. Virus and infected cells will be handled in class 1 microbiological safety cabinets by personnel who have been specifically trained and approved to work in a level 3 facility. All biological waste is inactivated by treatment with a quaternary ammonium detergent and waste is autoclaved within the facility prior to disposal. Virus storage is in vapour phase, liquid nitrogen, within the level 3 facility.

Minutes of the Genetic Manipulation Safety Committee meeting held on January 19th 2007 relevant to the notification

GMSC 695 Professor David J. Evans
Cloning and mutagenesis of hepatitis C cDNA
This project aims to dissect the role of structured RNA elements in the replication of hepatitis C virus. The study will involve the manipulation (using standard molecular approaches in E. coli host/vector systems) – by deletion, modification and insertion – of stem-loop structures previously predicted by bioinformatic analysis. The virus cDNA cannot be replicated, or the proteins expressed in E. coli. Expression requires in vitro transcription by bacteriophage T7 polymerase, transfection into a permissive human hepatoma cell line (only one of which has reproducibly been shown to support replication) in which translation occurs. Translation involves cellular factors absent from bacterial cells. The disabled nature of the host, lack of mobilisation or conjugative features of the vector reduce the possibility of environmental risk to effectively zero.

Access 10-6 Expression 10-6 Damage 10-6 Total 10-18 GMSC Decision: Con. Level 1

Environmental Risks: Consequence: negligible; Likelihood: low; Overall: Effectively zero.

GMSC 696 Professor David J. Evans
Analysis of Hepatitis C virus replication using sub-genomic replicons. The aim of this project is to dissect the role of structured RNA elements in the replication of Hepatitis C virus. Functional analysis of the modified stem-loop structures will be undertaken using a hepatitis C virus sub-genomic replicon system. These consist of a virus cDNA from which the coding region for the core, E1 and E2 structural proteins have been deleted and replaced with an antibiotic (or enzymatic) selection marker. Following transfection of susceptible cells with RNA generated in vitro replication can therefore be monitored by an increase in antibiotic resistant colonies, or enzymatic activity. Due to the absence of the structural proteins the sub-genomic replicons is incapable of making virus particles and cannot be transmitted from cell to cell. Replication only occurs in the Huh7 human hepatoma cell line. Protein expression depends absolutely upon replication in one particular human hepatoma cell line. The sub-genomic replicons alone are incapable of being transmitted from cell to cell. Virus pseudotypes can be generated by co-infecting a replicon-containing cell with a suitable helper virus. However, replication would be restricted to a single passage. In the absence of exogenously added helper virus Huh7 cells are known not to contain any viruses capable of pseudotyping the sub-genomic replicons, and are not known to contain any adventitious agents. The requirement for Huh7 cells is due to the exquisite sensitivity of the replicon to the presence of interferon – Huh7 cells are defective in interferon production. Therefore, transfer to the environment is extremely unlikely, and if it did occur then the likelihood of the genome replicating would be very small. Finally, in the absence of any cell-to-cell transmission, damage would be restricted to a single recipient cell. Environmental Risks: Consequence: negligible; Likelihood: negligible; Overall: Effectively zero.

GMSC 697 Professor David J. Evans
Replication of hepatitis C virus – studies using replicating virus system.
The aim of this project is to analyse the role of conserved RNA structures in the replication of hepatitis C virus. Our in vitro and in silico studies have identified a number of stem-loop structures that we believe are implicated in fundamental aspects of virus replication. We propose to modify these structures by mutagenesis, deletion and substitution analysis and determine the effect upon the replication of the virus.

The following points were noted and discussed by the committee:
The project will involve mutagenesis of pre-existing stem-loop structures with the intention of disrupting the structure without altering the encoded protein. The majority of the changes will therefore involve synonymous substitution. It is also proposed to introduce a second copy of the stem-loop structure at an alternative position within the genome – either in a non-coding region, or at a proteolytically cleaved junction of the polyprotein. In these cases the insert will be a 'self' sequence, derived from the same or closely related genotype of HCV.

Changes are expected to have a deleterious effect upon virus replication. All the changes DJE has already constructed in HCV sub-genomic replicons are either detrimental, or have no detectable effect upon replication. None enhance the aspects of replication we are currently able to quantify (i.e. genome copy number per cell).

Furthermore, all the stem-loop structures of interest are located in the region encoding the non-structural proteins of HCV – specifically the NS5b RNA dependent RNA polymerase. There is no evidence that this protein specifically alters the host range of HCV. The virus only replicates efficiently in Huh7 liver cells in culture due to exquisite sensitivity to the presence of interferon – Huh7 cells cannot produce interferon.

Regarding susceptibility to antiviral drugs where treatable, HCV responds to interferon and ribavirin. There is no reason to expect the substitutions to be made to the polymerase will enhance resistance to either of these treatments.

Proposed categorisation: Hepatitis C virus only infects humans. Parenteral transmission to chimpanzees – but not other non-human primates – has been demonstrated, but the virus is cleared and the infected animals only present with transient symptoms (enhanced ALT levels indicative of liver damage). Virus clearance is by the acquired immune response.
Hepatitis C virus is an ACDP level 3 pathogen. GMSC Decision: Con. Level 3.
Environmental Risks: Consequence: severe; Likelihood: negligible; Overall: effectively zero.

Project Additional Information

The project will use molecular genetic approaches to study antibiotic biosynthetic pathways and to produce antibiotic analogues in Gram-negative opportunist bacterial pathogens belonging to the Burkholderia cepacia complex, and other Burkholderia species classified as ACDP as Hazard Group II biological agents (therefore excluding HG3 Burkholderia including B. mallei and B. pseudomallei).

Prof. Greg Challis at Warwick University and Prof. Esh Mahenthiralingam at Cardiff University have recently identified antibiotics as products of cryptic polyketide biosynthetic gene clusters in members of the Burkholderia cepacia complex. These antibiotics have novel anti-Gram-negative activity against multi-drug resistant strains like: Burkholderia dolosa, Burkholderia multivorans or Acinetobacteria baumannii. The activity against B. dolosa and A. baumannii is particularly significant. B. dolosa is a pathogen that is known to cause chronic infections in cystic fibrosis patients that are associated with accelerated loss of lung function and decreased survival. A. baumannii is resistant to most antibiotics and has emerged as one of the most troublesome pathogens for healthcare institutions globally. It has been implicated in a diverse range of infections, including of the respiratory track, blood stream, skin and soft tissue and kills tens of thousands of U.S. hospital patients each year.

The above findings suggest that such antibiotics may be promising leads for the development of novel drugs to tackle potentially life-threatening infections, e.g. B. dolosa in CF sufferers and A. baumannii infections in hospital patients. However, several aspects of the structures of these compounds present challenges for their development as leads for drug discovery. Additionally, the structural and stereochemical complexity of these metabolite hinder the development of concise and efficient synthetic routes, making the preparation of analogues for structure-activity relationship (SAR), metabolism and toxicity studies via conventional synthetic approaches impractical.

Professors Challis and Mahenthiralingam are developing an alternative approach to the production of novel antibiotic analogues for SAR, metabolism and toxicity studies via engineering of the Burkholderia antibiotic biosynthetic pathways. The intention is to delete genes proposed to be involved in the assembly of intermediates in antibiotic biosynthesis. Generated mutant strains will be fed with chemically-synthesised analogues of the intermediates to produce analogues of the antibiotics. Additionally, it is intended to inactivate genes which are proposed to be involved in late steps of antibiotic biosynthesis to generate analogues of the antibiotics directly.

A system for the construction of targeted unmarked gene deletions in the Burkholderia genus will be adapted from the method described by Flannagan et al. (Flannagan, R. S.et al.; Environmental Microbiology 2008, 10, 1652-1660). The authors reported the development of a system for the generation of targeted unmarked gene deletions in the B. cenocepacia strain K56 2. This method utilises the homing endonuclease I Scel which cleaves at a specific recognition site in DNA and initiates the repair system facilitating recombination of homologous DNA.

Regions flanking the gene(s) of interest have to be amplified and cloned into a suicide plasmid pGPI Scel. This plasmid encodes for a I-Scel recognition site and transmits trimethoprim (Tp) resistance. Triparental mating is carried out with K56-2 and the constructed plasmid, which is incorporated into the K56-2 genome via homologous recombination. The exconjugants are trimethoprim resistant. The plasmid cannot replicate in B. cenocepacia. If, therefore, the exconjugants are trimethoprim resistant, a recombination event must have occurred and the resistance gene is located in the genome, with the cloned flanking regions. A second triparental mating is carried out to introduce a second plasmid pDAI Scel into the K56-2 single cross over insertion strain. This plasmid contains the endonuclease gene I-Scel, expressed constitutively, and transmits tetracycline resistance. I-Scel causes a break at the I-Scel site and a recombination event occurs either restoring the parental DNA, or causing a gene deletion, depending on the site of the crossover. The exconjugants are sensitive to trimethoprim since the recombination event removes the Tp resistance gene, and they are resistant to tetracycline. The correct recombination is screened by PCR and positive clones are grown without antibiotic selection which results in loss of the pDAI-Scel plasmid.

Burkholderia DNA will also be incorporated into broad-host range plasmid vectors (with antibiotic selection markers such as tetracycline, chloramphenicol, kanamycin, trimethoprim) capable of replication in a wide range of Gram-negative bacteria like pUCP vectors, pSCOSBC1/PA1 vectors, pMLBAD, or other from the peer-reviewed...
published literature which all work for various Burkholderia species. After construct preparation in E. coli, these recombinant vectors will then be used for genetic complementation procedures such as the re-introduction of wild-type DNA into a corresponding Burkholderia mutant. Genetic complementation will also be used to examine expression of the cloned DNA. The broad host range vectors used for this procedure can only be introduced by electroporation and are not self-mobilizable between bacterial species.

Recipient or parental organism

- Bacteria belonging to the Burkholderia cepacia complex, e.g. Burkholderia ambifaria AMMD and other ACDP hazard group 2 Burkholderia species.

Host/vector system

Hosts:
- Escherichia coli SY327 strain; ACDP Group 1 microorganisms.
- Escherichia coli HB101 strain; ACDP Group 1 microorganisms.

Vector system:
- pGPI-SceI - suicide donor plasmid incapable of replication outside of E. coli hosts, but capable of transient transfer by conjugal mating procedures; carries I-SceI cut site and trimethoprim (Tp) resistance.
- pRK2013 - encodes genes required for DNA transfer during conjugal mating, carries kanamycin resistance.
- pDAI-SceI - expresses the I-SceI nuclease (yeast homing endonuclease) under the control of the constitutive P1 promoter, carries tetracycling resistance and can replicate in different Gram-negative bacteria.

Origin & function

DNA will derive from Burkholderia cepacia complex, e.g. Burkholderia ambifaria AMMD and other ACDP hazard group II Burkholderia species. In-frame deletions of genes proposed to be involved in antibiotic biosynthetic pathways will be carried out to determine their function. Prepared constructs that will contain fragments of Burkholderia genomic DNA in pGPI-SceI vector will be mobilized from E. coli back into Burkholderia species. Single colonies of generated transformants will be selected to identify correct mutants by genetic analysis. To determine if these disrupted genes play a role in the antibiotic biosynthesis, the wild-type gene will be cloned back into the mutant strain and restoration of the parental phenotype will then be examined.

Evaluation of foreseeable effects

Bacteria belonging to the Burkholderia cepacia complex, e.g. Burkholderia ambifaria AMMD and other ACDP hazard group II Burkholderia species are capable of causing opportunistic human infections. Possibility that a healthy laboratory worker will be infected is low and therapy is available to treat any potential infections. The likelihood of escape of bacteria from the laboratory or transfer to susceptible individuals is low given the level of containment and disinfection procedures employed during handling of these bacteria (including waste handling processes). Escherichia coli cloning strains to be used in the project have no associated hazard. The vector systems to be used carry no associated hazard. The recombinant Burkholderia strains will not present a pathogenicity hazard greater than the original host organism. The GMM is unlikely to disseminate from the research laboratory as it will be handled using ACDP containment level II procedures in a suitable CL2 laboratory. Other organisms will not be infected as no vectors capable of self-transfer to other organisms will be used.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste:
- Autoclaving 121 for 75mins (minimum hold time 15 minutes)
Liquid waste:
Autoclaving 121 for 25mins (minimum hold time 15 minutes)
Disinfectant to be used, exposure time and working concentration:
Metal items stand or soak in 1% aqueous solution Virkon (contact time should never exceed 10 minutes).
All contact must be followed by rinsing with water.
Hard surfaces outside of the MSC2
Spray or wipe with 1% aqueous solution Virkon using spray, mop or brush. Rinse/wipe with water if required after 10 minutes. Remove white deposit after Virkon solution has dried with paper towel.
Spillages
Small spills 0.2ml confined to a small area with no splashing can be cleaned with paper towel soaked in disinfectant as for surface disinfection.
Larger spills (up to 10ml) confined to a small area with no splashing can be contained with paper towel and covered with Virkon powder and left for 3 minutes or until all liquid is absorbed. Scrape up waste and place in biohazard bag and then wipe down area with 1% Virkon.
Major spillage Evacuate laboratory and follow Standard Operating Procedure for cat 2 laboratory
Surface disinfection in MSC2
Trigene (Distel) is used as 1% aqueous solution for cleaning of internal surfaces of the safety cabinet and equipment.

Project Ref 13/14.1

Date Ackn'd CU2 Project Title

Class CultureVolumeClass2 CultureVolumeClass3-4
A connected programme of work on the characterisation of virulence determinants from pathogenic bacteria of humans and animals on a range of ACDP category 2 pathogens in one laboratory and store room.

Work in the Division focuses on bacterial pathogenesis and genomics, with a particular emphasis on identifying and characterising virulence factors, resistance determinants and potential vaccine and drug targets from bacterial pathogens from ACDP category 2. Our work involves genetic manipulation of pathogenic and commensal strains that colonise or infect humans and other animals (including invertebrates) and the cloning, expression and characterisation of determinants from these strains in other strains or species (usually crippled laboratory strains of Escherichia coli or Bacillus subtilis).

The following is an overview of the GM research activities that form the connected programme of work:

Activity 1. Cloning of unexpressed DNA fragments from Category 2 bacteria into non-mobilisable vectors in laboratory strains of E. coli or B. subtilis. No attempt will be made to express the foreign DNA.

It is often necessary to clone genes or DNA fragments of interest from class 2 pathogens into class 1 disabled laboratory strains of bacteria such as E. coli and B. subtilis to enable subsequent analysis such as DNA sequencing or to enable further constructs to be engineered (Activities 2, 3, 4 and 5). This involves cloning of DNA fragments without any attempt to express them. Procedures within this class would not incur the expression of functional elements. We will exclude from this assessment deliberate cloning of intact soluble toxin genes.

Activity 2. Expression of bacterial genes in a disabled bacterial host.

It is often necessary to clone genes or DNA fragments of interest from class 2 pathogens into class 1 disabled laboratory strains of bacteria such as E. coli and B. subtilis for heterologous expression. This enables gene function to be analysed independently of the other source host phenotypes. Such expression strains may be used for challenges to host models (activity 6), in vitro enzyme assays or protein purification for structure/function studies.

Activity 3. Creation of mutants in hazard group 2 bacterial pathogens.

Allele replacement is a general approach for the creation of mutants in bacteria in which a wild-type gene is replaced by a mutant gene or is disrupted or removed entirely from the bacterial genome. This approach relies on the introduction of mutated non-replicating DNA (e.g. in a suicide plasmid, a low copy unstable plasmid or PCR.
The mutated DNA then integrates into the chromosome by homologous recombination, sometimes augmented with phage-derived recombinase functions (e.g., lambda red) or by group II introns that have been introduced to the cell on a plasmid. If complete ablation of gene function is required, the mutated DNA may contain a copy of the target gene disrupted by an antibiotic resistance gene to provide a selectable marker. However, with modern approach to mutagenesis, in the final GMO, the wild type allele is often replaced with a mutant allele without leaving any antibiotic resistance gene in the cell. In some cases, to monitor gene expression under different environmental conditions, allele replacement will be used to create a transcriptional or translational fusion to a marker gene/protein that is highly unlikely to have any biological effect (e.g., beta-galactosidase, luciferase, green-fluorescent protein). In a similar vein, random mutagenesis is sometimes performed used transposable elements that carry selectable markers or reporter genes to disrupt bacterial genes. Example plasmids that may be used for this activity include pPS856, pSIM5, pFLP2, pRedET, pDS and pLOF series integration plasmids.

Activity 4. Expression of bacterial genes in wild-type strains of bacteria.

The phenotypic effects seen when a gene is disrupted by allele replacement may result from polar effects on transcription downstream, or from other artefacts. In these circumstances it may be necessary to complement the mutation in trans to determine whether the original wild-type phenotype can be restored, and thus any phenotype in the mutant ascribed to the intended mutation rather than to some other cause (this approach is sometimes called “molecular Koch's postulates 2 (Falkow S (1988) "Molecular Koch's postulates applied to microbial pathogenicity." Rev Infect Dis 10(suppl 2):S274-S276). Similarly, to determine the localisation or secretion of a protein, it may be necessary to create and express a fusion to neutral marker or to a domain from another secreted protein. In both cases, this means controlled expression of the gene of interest on a vector that can replicate in the pathogen. The gene is usually cloned first in a crippled strain of E. coli (activity 1 above), and then transferred into the pathogen. This means expressing the gene of interest on a “shuttle vector” that carries origins of replication that work in both E. coli and the pathogen. Although usually the gene under study will have originated from the strain in which it is being expressed, on occasion it may be necessary to express genes from one strain in another strain of the same species. For example, when dissecting function, it may be fruitful to determine whether expression of a homologous but non-identical protein from another strain or species can complement a mutation or elicit a similar phenotype.

Activity 5. Expression of category 2 bacterial genes in yeast cells and in cultured animal and human cells.

Expression of bacterial proteins within eukaryotic cells is necessary for two purposes. Firstly, this approach is useful in identifying and characterising conserved eukaryotic targets of bacterial virulence factors, by identifying the impact of these proteins on cell survival and growth and by determining localisation of fusions to reporters such GFP. Secondly, the yeast two-hybrid system provides a convenient genetic screen for protein-protein interactions.

Activity 6. The use of cultured animal and human cells and invertebrate models of infection.

Well characterised and immortalised animal or human cell lines will be challenged with either wild-type or genetically modified strains of the pathogens described in this assessment. This approach is useful for assessing modes of action and virulence strategies of pathogens. For example we may wish to monitor the ability of a GFP labelled pathogen to invade cultured cells. Such co-culture experiments will all be performed in the class II laboratory and we have a dedicated tissue culture incubator for this. We also plan to use certain invertebrates as model infection hosts. Specifically; Acanthamoeba spp., insects such as Manduca sexta and Galleria mellonella and the nematode Caenorhabditis elegans. Both the amoeba and nematodes are maintained on solid agar plates or in small-scale liquid culture and require no special incubation conditions. Insect host models will be infected by direct injection of low doses of the pathogen using a hypodermic syringe. In these cases training in the procedure will be given before any worker is allowed to perform this. It should be noted that we have previously devised an operating procedure for this that minimises any risk of accidental needle-stick injury. The use of insect hosts in this manner has been previously approved by the UoW GMBSC.

Recipient or parental organism

The recipient bacteria will include crippled laboratory strains of E. coli and B. subtilis. In addition we will also perform various manipulations on the ACDP 2 pathogens themselves.

All the wild-type parent strains that we propose to handle and to potentially genetically modify fall within ACDP category 2. The pathogens can be classified into three overlapping groups according to potential routes of infection:
Respiratory pathogens, where the chief hazard is aerosolisation leading to inhalation. These include:
- Haemophilus influenzae and related species
- Streptococcus pneumoniae and related species
- Staphylococcus aureus and Staphylococcus epidermidis
- Mycobacterium bovis BCG
- Acinetobacter spp (principally A. baumannii)

Gastrointestinal pathogens, where the chief hazard is ingestion. These include:
- Escherichia coli, Salmonell enterica related Enterobacteriaceae (but excluding STEC and typhoidal serovars)
- Bacillus cereus and related species (excluding B. anthracis)
- Campylobacter jejuni
- Helicobacter pylori
- Clostridium difficile and Clostridium perfringens (excluding tetani or botulinum)
- Listeria monocytogenes

Pathogens of soft tissues (including opportunistic pathogens), where the chief hazard is needle-stick injury or infection of wounds or splashes on to mucosal surfaces. These include:
- Staphylococcus spp, including S. aureus and S. epidermidis
- Bacillus cereus and related species (excluding B. anthracis)
- Photorhabdus spp, and related species
- Acinetobacter spp (principally A baumannii)
- Pseudomonas aeruginosa and related species
- Veillonella spp

Host/vector system

Summary of proposed vectors and plasmids described in the six GMO related activities. The bacterial host strains will be ACDP category 1 or 2 as discussed above and the type of vector system will depend on the activity class as detailed above.

Activity 1. Commonly used non-mobilisable plasmids that can allow cloning without expression. Including; pUC-series (in non-lac promoter orientation), pBR322 and derivatives, Large insert vectors, Fosmids, Cosmids and BACs.

Activities 2 and 4. Non-mobilisable vectors that allow expression and reporter fusions (e.g. HIS-, FLAG-, MBP-, CBP-, GST-, GFP-, RFP-, YFP-, LacZ). Including; pUC, pGEX, pET, pBAD and the pCAL series plasmids and pTrcHis2-Topo, pACYC184 and pMTL derivatives.

Activity 4. Unstable or specific host replication dependent integration/suicide vectors Including ; pS856, pS1M5, pFLP2, pRedET, pDS and pLOF series integration plasmids.

Activity 5. Non-mobilisable Eukaryotic host expression plasmids that allow expression and reporter fusions. Including; E. coli -yeast shuttle vectors pYEp13, pYXplac22 and pSEY18 and the yeast two-hybrid vector pDEST22. Mammalian expression plasmids for transient expression (up to 48 hours) in non-replication-permissive cell lines including pRK5myc, pcDNA-DEST47/53 (which contain a conditional SV40-dependent origin of replication).

Origin & function

The origin and intended functions of the genetic material involved will depend upon the activity (1-6): this is set out in detail in the following section.
None of the bacteria we will use represent hazards to the environment. Although most of our work will make use of crippled laboratory strains and non-mobilisable vectors, we will need to use wild type-strains to study the effects of defined chromosomal mutations on virulence and other phenotypes. The 6 activities that we will employ involve standard molecular bacteriology techniques with a track record of substantial safety experience within the research community in the UK and elsewhere. It should be noted that where any cloning vectors or expression plasmids are used in microbial GM work, any specific antibiotic resistance genes employed will be made highlighted to Occupational Health and to researchers should medical attention be required. The lists of bacteria above mainly refer to specific species, although it should be noted we also include the qualifier "and related species" in several cases. We stress that this does NOT include and will not generate any organism that is classified as hazard group 3. Any work with "related species" that have not specifically been named in the above lists will be assessed through UoW procedures prior to work commencing.

Below we provide a detailed description of unexpressed DNA fragments from category 2 bacteria into non-mobilisable vectors in laboratory strains of E.coli or B. subtilis. No attempt will be made to express the foreign DNA.

This work involves commonly used well-characterised disabled laboratory strains from commercial or academic sources (e.g. DH5alpha, JM109, Top10, MG1655 for E. coli, 168, 1012 for B. subtilis, Lactobacillus lactis NZ9800). Cloning vectors would include commonly used non-mobilisable plasmids such as the pUC-series, pBR322 and derivatives, Fosmids, Cosmids and BACs. The bacterial host strains are generally considered incapable of survival in humans or the environment on account of absence of colonisation/virulence factors, auxotrophy etc.

This work involves cloning of DNA fragments without any attempt to express them. In rare cases, genes may be expressed from their own promoters. However, even if potential virulence factors were expressed, there is only a low risk they they will be targeted for secretion or cell-surface expression, particularly as we will exclude any deliberate cloning of intact soluble toxin genes.

We use a number of commonly used well-characterised non-mobilisable or mobilisation-defective vectors from commercial or academic sources. There is negligible risk they they will alter the existing traits of the disabled laboratory host to render it more virulent and a negligible risk they inserted sequences will be transferred to another organism.

ACTIVITY 2: Expression of category 2 bacterial genes in a disabled bacterial host.

It is often necessary to clone genes or DNA fragments of interest from class 2 pathogens into class 1 disabled laboratory strains of bacteria such as E. coli and B. subtilis for heterologous expression.

This work involves commonly used well-characterised disabled laboratory strains form commercial or academic sources (e.g. DH5alpha, JM109, Top10, MG1655 for E. coli, 168, 1012 for B. subtilis, Lactobacillus lactis NZ9800). These strains are generally considered incapable of survival in humans or the environment on account of absence of colonisation/virulence factors, auxotrophy etc.

In this work, we will use non-mobilisable vectors (e.g. pGEX4T3, the pET, pBAD and the pCAL vectors) that express a gene product, either from strong promoters (e.g. P_tac) or from the gene's native promoter in its native form or as part of a HIS-, FLAG-, MBP-tagged, calmodulin-binding peptide-tagged or similar fusion to an innocuous protein (e.g. GST), with a view to purifying and characterising the protein. Even though proteins associated with virulence will be expressed there is only a low risk associated with "damage" because the catalytic subunits of any toxins cannot exert any effect unless delivered in soluble active form to the appropriate compartment of the appropriate cells within the human body. This cannot happen in the context discussed here, as we will ensure that the necessary delivery mechanisms (e.g. a secretion system for getting out of the cell, a binding domain for attaching to cells and mediating entry) are absent from the cloning host for example, we will never express the binding and catalytic domains of a toxin in the same cell.

We use a number of commonly used well-characterised non-mobilisable or mobilisation-defective vectors from commercial or academic sources.

ACTIVITY 3: Creation of mutants in hazard group 2 bacterial pathogens.
This work involves wild-type strains of bacterial pathogens (and their derivatives) that have been assessed as requiring containment level 2 handling.

Example plasmids that may be used for this activity include pPS856, pSIM5, pFLP2, pRedET, pDS and pLOF series integration plasmids.

Antibiotic resistance genes encoded by plasmids and PCR products will be expressed. In most cases, antibiotic resistances will be expressed only transitory during the creation of the GMO, rather than in the final product. However, we will avoid the hazard of creating potential pathogens that are harder to treat than wild type parent strains by avoiding use of resistances to antibiotics that might be used to treat an infection. In particular, we will never manipulate or create pan-resistant strains. In the rare event of infection, the antibiotic resistances and sensitivities of the strain will be communicated to the relevant medical authorities. Any marker genes used will be well-characterised reporters (beta-galactosidase, luciferase, green-fluorescent protein) that have negligible effect on virulence. There is therefore a low risk associated with "expression" and "damage".

Gene deletion or disruption is a naturally occurring process, and so, if a loss of a gene increased the fitness of the pathogen, this would have already been selected for in nature. The disruption of putative virulence genes will thus produce a GMO which will be no more hazardous than the wild-type and which can therefore be handled at the containment level relevant to the wild-type (i.e. containment level 2).

A suicide or other low copy vectors can be propagated in disabled lab strains of E. coli, but will not replicate independently in the target species or strain. When introduced into the target strain a suicide plasmid can survive only by integrating into the chromosome by homologous recombination, while low copy unstable vectors can survive for very few generations after which they have to integrate or are lost. Such vectors will contain a copy of the target gene, disrupted by an antibiotic gene (this construct is created in a crippled laboratory strain of E. coli). Although these vectors are mobilisable, as the genes they carry are disrupted, there is negligible risk that they could cause harm if expressed in another organism. The potential that deletion of genes will enhance the GMM's fitness as a pathogen is considered low to negligible.

Mutagenesis is a naturally occurring process so any disruption or alteration of gene function as a result of deliberate mutagenesis will result in a less fit phenotype, which is likely to be outcompeted by the wild-type if it were to escape into the environment.

Transcriptional fusions will be made only to reporter genes with no conceivable environmental effect (genes for beta-galactosidase, luciferase, or green- or red-fluorescent protein). Any resistance determinants we will use are already abundant in naturally occurring isolates in the environment.

Activity 4. Expression of bacterial genes in wild-type strains of bacteria.

The gene is usually cloned first in a crippled strain of E. coli (activity 1 above), and then transferred into the pathogen. This means expressing the gene of interest on a "shuttle vector" that carries origins of replication that work in both E. coli and pathogen. Although usually the gene under study will have originated from the strain in which it is being expressed, on occasion it may be necessary to express genes from one strain in another strain of the same species.

This work involves wild-type strains of bacterial pathogens (and their derivatives) that have been assessed as requiring containment level 2 handling.

We will use non-mobilisable or mobilisation-defective expression vector including pBR322 derivatives such as pBAD, pTrHis2-Topo,pACYC184, pMTL derivatives. As the goal of this work is to restore wild-type expression genes, potential virulence genes will be expressed from their native or other weak promoters and will be carried on low-copy-number vectors or from a neutral site in the chromosome. The risk associated with "expression" and "damage" is thus identical to that associated with the wild-type parent.

Here we are simply restoring wild-type gene expression and so will produce a GMO that will be no more hazardous than the wild-type gene expression and so will produce a GMO that will be no more hazardous than the wild-type and that can therefore be handled at the containment level relevant to the wild-type (i.e. containment level 2).

Given that we are using non-mobilisable vectors, there is negligible risk that inserted sequences will be transferred to another organisms.
The non-mobilisable vector would not be able to leave the disabled host. Any release of DNA into the environment would be similar to that which occurs during the usual processes of decay. The environmental impact would therefore be effectively zero.

ACTIVITY 5. Expression of category 2 bacterial genes in yeast cells and in cultured animal and human cells.

This work involves expression of bacterial proteins within eukaryotic cells.

Yeast cells present no risks to the experimenter. Well-characterised lines of human and animal cells present negligible risks to the experimenter e.g. HeLa, A549, CACO2 (human colon carcinoma cells), NIH 3T3 (mouse fibroblasts). All of these are standard fully authenticated cell lines that have been safely used in labs for many years or will be purchased from approved tissue culture collections. All therefore count as "especially disabled hosts" according to the SACGM Compendium of Guidance. The use of immortalized cell lines has been approved by the UoW GMBSC committee.

We will study bacterial genes potentially involved in host cell subversion (but which are not oncogenic), fused to biologically irrelevant reporters (short tags, such as the myc tag, or inert proteins such as green fluorescent protein). The genes will have been PCR-amplified and cloned into vectors and propagated in disabled strains of E. coli before introduction into eukaryotic cells (see above for assessment of risks of expressing bacterial genes in E. coli). Bacterial genes may have been subjected to site-directed or truncation mutagenesis so that structure/function relations can be determined. For expression in yeast cells, we will use standard non-mobilisable E. coli-yeast shuttle vectors, e.g. the pYEp13, pYXplac22 and pSEY18 vectors and their derivatives or the yeast two-hybrid vector pDEST22. Constructs will be engineered to express foreign proteins (usually as reporter fusions) under an inducible yeast promoter. For expression in mammalian cells, we will use standard mammalian expression plasmids such as pRK5myc, pcDNA- DEST47/53. Although they contain a conditional SV40-dependent origin of replication, we shall be using them only for transient expression (up to 48 hours) in non-replication-permissive cell lines. They will rapidly be lost upon cell division. It is possible though exceedingly rare, i.e. it is very unlikely, for these vectors to be capable of chromosomal integration in mammalian cells, and they are no transmissible from one cell to another (i.e. "non-mobilisable"). The promoter is the human CMV constitutive promoter. Proteins will, at most, be expressed in nanogram quantities within the mammalian cells. The risk associated with expression and damage is thus effectively zero.

Transfected mammalian cells present no risk to human health, as they are incapable of survival outside of tissue culture media and are unable to colonize the worker. The transfected constructs are not transmissible and cannot replicate within normal human cells.

ACTIVITY 6. The use of cultured animal and human cells and invertebrate models of infection.

Well characterised and immortalised animal or human cell line will be challenged with either wild-type or genetically modified strains of the pathogens. We also plan to use certain invertebrates as model infection hosts. Specifically; Acanthamoeba spp., insects such as Manduca sexta and Galleria mellonella and the nematode Caenorhabditis elegans. Both the amoeba and nematodes are maintained on solid agar plates or in small-scale liquid culture and require no special incubation conditions. Insect host models will be infected by direct injection of low doses of the pathogen using a hypodermic syringe in a previously devised operating procedure that minimises any risk of accidental needle-stick injury. The use of insect hosts in this manner has been previously approved by the UoW GMBSC.

The amoeba will be handled as a class ll pathogen in itself and we already have approval by the Warwick GMBSC to handle this organism. The nematode C. elegans is commonly used for laboratory studies and is not considered hazardous and therefore presents no risk to the experimenter. The insect hosts are larval forms that have limited mobility and in any case will be contained in disposable plastic-ware (no adult forms will be used). They present no hazard to the experimenter. Well-characterised lines of human and animal cells present negligible risks to the experimenter e.g. HeLa, CACO2 (human colon carcinoma cells) and NIH3T3 (mouse fibroblasts). All of these are standard fully authenticated cell lines that have been safely used in labs for many years. All therefore count as "especially disabled hosts according to the SACGM Compendium of Guidance.

Any GM bacterial strain challenged against the tissue culture or invertebrate models will not be able to transfer genetic material to the eukaryotic host. Given that we
are using non-mobilisable vectors, there is negligible risk that inserted sequences will be transferred to another organism.

Infected tissue culture cells present no risk to human health (beyond that of the pathogen itself described in the other activities), as they are incapable of survival outside of tissue culture media and are unable to colonize the worker. Use of immortalized cell lines has been approved by UoW GMBSC. Invertebrate host models will all be contained and have been previously approved by UoW GMBSC.

The non-mobilisable vectors used in any of the GM class 2 pathogens would not be able to leave the eukaryotic hosts. Any release of DNA into the environment would be similar to that which occurs during the usual processes of decay.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid Waste:
Standard sterilisation of contaminated plastics and sharps when discarded into appropriate autoclavable jars, sharps bins or purpose-made autoclave bags before being transported. Items will be sterilised at 121°C for 15 minutes at 15 psi.

Liquid waste: Items will be sterilised at 121°C for 15 minutes at 15 psi.
Contaminated glassware washed in disinfectant prior to cleaning for re-use.

Disinfectant to be used, exposure time and working concentration: Activated chlorine solutions (such as chloros) at 1,000ppm v/v with 12 hour exposure time will be used as it is widely accepted to be lethal for these organisms when used freshly diluted and not inactivated by organic matter. Freshly prepared disinfectant which releases chlorine dioxide (such as Tristel) will be used at 1,000 ppm available in experiments that could produce spores. In addition to this treatment, all potential spore-containing waste will also be autoclaved.

Source of validation data: manufacturer's data and UoW studies

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The University GMBSC approved the risk assessment of the connected programme of work as Activity Class 2 noting the exclusion of any work with Hazard Group 3 micro-organisms and that the programme was subject to notification to the HSE.

Purposes of the contained use

Mycobacterium tuberculosis is one of the biggest causes of morbidity from a bacterial agent world-wide. We want to investigate the physiology, antibiotic susceptibility and pathogenicity of Mycobacteria. In particular we are interested in the role of nutrient uptake, metabolism and incorporation of nutrients into key biomolecules and signalling networks. The research will involve the use of M.tuberculosis, an ACDP HG3 species, and the related ACDP HG2 Mycobacterium species M.bovis BCG and M. marinum which will mainly be used to determine key differences in metabolism and uptake in non-pathogenic Mycobacterium strains compared with the pathogenic M. tuberculosis. M. tuberculosis is the only member of the Mycobacterium tuberculosis complex that can provide information regarding pathogenicity, virulence, the uptake of nutrients and metabolism with regard to susceptibility to new anti-microbials. Safer strains such as M. bovis BCG and M. marinum and are not such good models due to large differences at the genome level and differences in their pathogenicity to humans.

This project aims to identify new targets which can be developed for new anti-TB therapy and diagnostics. The following is an overview of the GM research activities that form the connected programme of work:
Only pure cultures of M. tuberculosis and other members of the Mtb complex - mainly M. bovis BCG and M. marinum will be used. The physiology and metabolic pathways of M. tuberculosis complex will be studied using a variety of techniques which will include the generation of deletion mutants, conditional gene deletion mutants, complementation of characterized mutants, overexpression of selected ORFs. All Mycobacterium strains will be obtained from ATCC and from the Cole Lab at the Global Health Institute, École Polytechnique Federal de Lausanne, Switzerland.

Recipient or parental organism

Host mycobacteria used are Mycobacterium tuberculosis (both the lab adapted strain H37Rv, and strains Ra, 18b, CDC1551). The work may at some stage include the use of clinical stains of M. tuberculosis but will not include multi-drug resistant strains. Other host mycobacteria will include M. bovis BCG (attenuated vaccine strain) and M. marinum M (can cause infection in fish – optimal growth temperature is 30°C).

Host/vector system

Vector systems that will be used are routinely used in mycobacteria research. These will include pMV261, pMV361, pVV16, p1NIL, p2NIL, phAE87, phAE159, pGEM15, pJG1100, pFRA, cosmid vectors. Mycobacterial phage vectors will also be used (to include phAE180, MycoMarT7).

Origin & function

The genes studied in this work will derive from mycobacterial species: M. tuberculosis, M. bovis BCG, M. marinum along with other pathogenic and non-pathogenic mycobacteria. The genes may be involved in nutrient uptake, metabolism, signaling, intracellular survival, in vitro growth and cell wall biosynthesis and assembly. The aim of this work is to establish the functions of genes involved in these essential processes in M. tuberculosis either through gene deletion, or by introduction of the gene into the host and observing/characterizing the phenotypes of these mutant strains.

Evaluation of foreseeable effects

• Exposure of humans to M. tuberculosis by inhalation or contact with contaminated aerosols could occur in the event of a breach of containment such as the spillage of viable culture. Active tuberculosis or a latent tuberculosis infection could result. It is unlikely that infection would result from any such exposure to M. bovis BCG or M. marinum. M. bovis BCG is the vaccine strain of M. tuberculosis and represents a very low risk to human health. M. marinum will infect fish but is only of risk to severely immunocompromised human individuals.

• All of the vectors are in common usage for TB research. None of the vectors are likely to transfer genetic material to any other environmental microorganisms. The genes which will be transferred or deleted in this investigation belong to specific targeted functional classes the expression or loss of expression of which is highly unlikely to influence the pathogenesis of the hosts. Expression of antibiotic resistance cassettes for selection use resistance to antibiotics (eg kanamycin, gentamicin or streptomycin), which are not used in the clinical treatment of TB.

• The selection strategy will specifically exclude the use of genes likely to be associated with pathogenesis functions such as in the secretion of antigens (eg RD1, ESAT-6, CFP10) or with the production of virulence factors, toxins or known allergens.

• For the reasons outlined above the risk to humans from exposure to the GMMs is highly unlikely to be greater than exposure to the original parental strains. None of the deletion mutants, overexpressing strains or other manipulated strains are likely to be any more or any less pathogenic than the parental strains. The GMM’s are expected to exhibit the same level of pathogenicity as the parental strains and will therefore be handled under the same level of containment (M. tuberculosis at CL3) and (M. bovis BCG & M. marinum at CL2) and with the same stringent handling and disposal procedures as the unaltered parental strains as described in the available associated SOPs and COPs (available on request).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All the project GMO’s are microorganisms.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No application for derogation from the containment levels specified for this programme.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
Disinfectant: Tristel is currently the most efficacious disinfectant against Mycobacterial species. Tristel is a disinfectant based on near instantaneous generation of chlorine dioxide by mixing 2 'safe' components and is the disinfectant recommended by numerous agencies for use in inactivating Mycobacterium tuberculosis and other Mycobacterial species including M.avium-intracellulare, M chelonae and M.terrae. and is compatible with a wide range of laboratory materials and surfaces - plastics, glass and stainless steel. Tristel comes in a variety of different forms for use for different applications of which Tristel One Day Concentrate (T1DC) is the version selected for lab use allowing for many different disinfection applications.

Sources of validation data: The manufacturer’s data and data from T1DC use in a number of mycobacteria labs (Ref: http://www.tristel.com/wp-content/uploads/2012/07/Tristel-for-Labs-Brochure-Jun-2007-Rev011.pdf). Because the disinfectant is versatile we will also validate our methods by in-house testing based on British Standard EN1276 (Ref Anon (1997) "BS EN1276 Quantitative suspension test for the evaluation of bactericidal activity of chemical disinfectants used in food industrial domestic and institutional areas - test method and requirements", British Standards Institution. Our results will be recorded as the validated methods for disposal of contaminated materials produced in the different procedures in these studies.

Autoclaving: Autoclaving will be carried out in the integral autoclave in the CL3 lab (M126b) using a standard autoclave cycle of 121oC for 20 minutes for simple and liquid loads or 134oC for 5 minutes for dry, complex, loads (disposable gowns, gloves and paper towels). This is the validated treatment to inactivate Mycobacterial strains. All runs are monitored by thermal cycle monitor. All autoclaving will be carried out according to the instructions in the CL3 Code of Safe Working practice for Containment Level 3 Laboratories, document COP_CL004_CL3_2014 (attached).

Autoclaving 121oC for 20 min will be used for waste disposal and culture plates from the CL2 facility according to the instructions in the Code of Safe Working Practice for Containment Level 2 Laboratories, document COP_CL001_CL2_2014 (attached).

Solid waste: All solid waste contaminated with Mtb will be inactivated by autoclaving in the integral CL3 autoclave in M126b. Following successful sterilisation as verified by the run log - the sterile waste is then placed in yellow biohazard bags and disposed of as clinical waste* for incineration. *NB the term 'clinical waste' here is generic for the 'waste stream' for materials to be disposed of by incineration and does not imply any human or animal material content. This will be carried out in accordance with Code of Practice for the CL3 lab. CL2 suite and sterile waste is then bagged as clinical waste* for incineration.

Liquid waste: Liquid waste is inactivated with T1DC – made up according to manufacturer’s guidelines (Ref: http://www.tristel.com/wp-content/uploads/2012/07/Tristel-for-Labs-Brochure-Jun-2007-Rev011.pdf) with a contact time of no less than 5 minutes) OR liquid waste will first be solidified by treatment with Vernagel before being sterilised by autoclaving as described above and the sterile waste then disposed of as clinical waste for incineration.

This will be carried out in accordance with Codes or Practice for the CL3 and CL2 labs.

Laboratory: The floor of the CL3 lab will be cleaned weekly with T1DC or Tristel Fuse, freshly prepared according to the manufacturer's guidelines. Door handles, keyboards and other contact areas are wiped regularly with Tristel Duo Foamer or Contec Prochlor (freshly prepared according to the manufacturer's guidelines). Tristel Products (Tristel Duo, Tristel Fuse and Tristel One day) have been validated by the manufacturer as effective disinfectants for Mycobacterium with exposure times of no less than 5 minutes for Tristel One day and Tristel Fuse, and no less than 30 seconds for Tristel Duo (http://www.tristel.com/wp-content/uploads/2012/07/Tristel-for-Labs-Brochure-Jun-2007-Rev011.pdf).

PPE - Good laboratory practices and rules will be adhered throughout. Hand washing facilities are in place and personnel are trained in hospital hand washing techniques. For the CL3 lab nitrile gloves will be worn at all times and double nitrile gloves when working in the Class I MSC. Back fastening disposable gowns must be worn at all times. All PPE waste will be autoclaved as described above. Safety glasses are to be worn if hazardous chemicals are to be handled. Heat insulated gloves will be worn when handling material from the -80oC freezer and autoclave. Further details of disinfection, autoclave treatments and PPE are provided in the attached Codes of Practice for the CL3 and CL2 labs - documents v. COP_CL004_CL3_2014 and vi.COP_CL001_CL2_2014 (attached).
The project risk assessments, CU2 form, SOPs, initial BSA assessment, were considered by the GMBSC on 25th September 2014. Following the HSE request (letter ref GM13, 28th Jan 2015) revised versions were considered by GMBSC on 25th February 2015. It was confirmed that the project details provided in the revised versions had not changed and the committee considered the project ready for CU2 HSE notification for the CL3 part of the project. The project was confirmed as High Risk Containment level 3 and was approved by the members.

GMBSC Comments: PI's responses to the committee’s comments are appended in blue italicised text.

a) That the Committee required amendments and clarifications to be made to the documentation for Project 136 on the “Connected program of work to understand the physiology pathogenicity and antibiotic susceptibility of the Mycobacterium tuberculosis complex”, noting that the Project required HSE notification and authorisation (via the Health and Safety Department) since the research covered both CL3 and CL2 work.
   1. GMBSC Comment transferred to section 17 (confidential).
   2. That the aims and objectives of the research should clarify how the research will mitigate risk, particularly because the over-expressing or adding of genes generate different risks. The documents have been amended to clarify that no known virulence factor, toxin, allergen will be over expressed in any CL2 or CL3 organisms.
   3. That the SOP for lone working should be revised to clarify exactly what persons can and cannot do in order to remove any ambiguity. Rebecca Allen has provided a copy of the relevant SOP to the Biological Safety Advisor and is included in the supporting documents with this notification form.
   4. That there should be sufficient emergency protocols drafted for handling emergency situations connected to the research. Emergency protocols are provided as part of the general and project-specific SOPs and COPs covering the safe use of the CL2 and CL3 containment facilities.
   5. That the risk assessment and SOPs should be revised and re-submitted to the Biosafety Advisor. Revised versions of these have been provided to the Biological Safety Advisor.
   6. That the preparation of samples could only be conducted under a separate Principal Investigator if there was a project amendment in place which incorporated that element of work. Point noted - any request for changes to the project as described in the RAs will be sent to the GMBSC using the Project Amendment Notification form.
   7. That the Designated Individual for HTA had confirmed that the project did not contain material of human origin. Point noted - any change to the project that might involve any material of human origin or use of human volunteers will be notified to the DI for HTA (Prof Davey).
   8. That all relevant SOPs and revised forms should be returned to the Biosafety Advisor who would help complete the notification to the HSE. All requested SOPs and revised documents have been sent to the Biological Safety Advisor.
   10. That work must not be carried out until both HSE and GMBSC authorisation had been granted. No project work has started pending HSE and GMBSC approval.

pBIO1878
Plasmid pAR1219 is a pBR322-based vector that expresses T7 RNA Polymerase under control of the IPTG-inducible lac UV5 promoter1 and is intended for use with the commercial TargeTron Gene Knockout System, Catalog Number TA0100 supplied by Sigma-Aldrich. Many TargeTron system plasmids use the T7 promoter for intron expression. By co-transforming plasmid pAR1219 with the TargeTron pACD4 plasmids, the T7 promoter can be used to express the intron and disrupt chromosomal genes in alternative hosts such as Salmonella typhimurium 2 and Shigella flexneri 2. Additionally, chromosomal gene disruptions in non-DE3 strains of E. coli can also be performed using pAR1219 with the pACD4 intron expression plasmids. Ampicillin, at 50 μg/ml, is used to select for pAR1219. To use pAR1219 in conjunction with the pACD4 plasmids, simply co-transform both plasmids and select in a liquid medium containing: 50 μg/ml ampicillin, 25 μg/ml chloramphenicol, and 1% glucose. Glucose is typically included to provide additional suppression of the lac UV5 promoter prior to IPTG-induction.

Origin & function

The aim of this project is to investigate the utilization and role of choline metabolism in the growth and swarming motility in Proteus mirabilis. The investigation will initially centre around the systematic knock-out of Proteus mirabilis genes involved in choline degradation and trimethylamine (TMA) production, followed by the individual complementation of the knocked out genes to confirm the function of each gene. The latter is essentially a 'self cloning' operation since the original Proteus genes will be cloned back into the Proteus KO mutants. The recipient microorganism is an ACDP human hazard group 2 pathogen although as indicated above realistically the risk to human health is only in immunocompromised individuals. The genes for targeted knock-out

The initial operations will produce transgenic Proteus mirabilis strains which are deficient in precisely targeted genes from the following list. In the process of the gene knock out process a functional kanamycin resistance cassette is transferred and used for selection.

Evaluation of foreseeable effects

The GMMs will not be any more infectious than the wild type / parental strain. No cases of laboratory-acquired infection from this species has been reported to date. Similarly, no person-to-person transmission has been reported. Infections usually affect surgical sites and the upper urinary tract causing infections such as urolithiasis (stone formation in kidney or bladder cystitis, and acute pyelonephritis). Opportunistic infections can occur in immunocompromised patients, particularly those with indwelling catheters (long-term catheterization) or under frequent antibiotic therapy. The modifications produce transgenic strains deficient in specific targeted genes and these would not be expected to be any more infectious than the starting strain and could be disabled. The knock out strains will have acquired kanamycin resistance from the gene knock-out plasmids. Kanamycin is not an antibiotic commonly used to treat urinary tract infections and there are several effective antibiotics currently used for treating UIs - sulfamethoxazole-trimethoprim; amoxicillin; nitrofurantoin; ampicillin; levofloxacin.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

No application for derogation

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid waste (agar plates, glassware, plasticware, dry waste): Solid waste collected in biohazard bags supported in metal autoclave containers and then autoclaved at 121°C for 20 min in a validated autoclave before disposal as clinical waste (incineration). Autoclaving under these conditions is adequate to achieve 100% kill of the GMMs described above.

Liquid waste (spent culture media, contaminated solutions and buffers): Inactivated using Presept tablets added freshly to liquid waste to provide 2,500ppm available chlorine (9 x 0.5g tablets (4.5g)/litre) exposed for a minimum of 30 minutes or overnight.

Work surfaces and microbiological safety cabinet surfaces: Wiped down with freshly made up Presept solution (1 tablet in 2 litres water, providing 140ppm available chlorine).

Disinfectant to be used, exposure time and working concentration: at least 30 min at 2500ppm available chlorine. Presept (sodium dichloroisocyanurate) or Clotabs (sodium triclosene), 1% (w/v), at least 30 minutes at room temperature

Source of validation data: (e.g. manufacturer’s data or own studies) risk assessment.

Validation of these data, these details were taken from Safety Data sheets and manufacturers instructions available on-line.

Solids and cultures on agar plates will be autoclaved at 121°C degree for 20min before disposal in ‘tiger’ waste bag as ‘non-infectious waste’ which does not require specialist treatment or disposal.
Project 23 risk assessment is an amendment to an existing non-GM project approved at CL2, to allow the use of gene deletions (gene knockouts), self-cloning and complementation procedures to investigate the role played by specific genes in the degradation of quaternary amines in the ACDP HG2 bacterium Proteus mirabilis.

The project was first considered at a GMBSC* meeting on 25th Sept 2014

Minute (e) That the Committee required further expert clarification whether the amendment to Project 23 on “Quaternary amine degradation” required notification to the HSE as a GM HG2 human pathogen, noting the project involved self-cloning”. (minute 06/14-15 e) of GMBSC meeting of 25th September 2014).

The committee agreed the bacterial host Proteus mirabilis is potentially harmful to human health (HG2) but members felt that the modifications proposed here would be most unlikely to increase the hazard class and the risk to human health. The committee agreed that the GMM was non-hazardous to the environment.

Subsequently Professor Croy contacted HSE and confirmed that notification using the HSE CU2 form was appropriate for this project.

The project GM RA and CU2 form was re-considered at a GMBSC* meeting on the 25th February 2015.

Members considered a need for appropriate validation of the disinfectant method, on the basis that a lower concentration that normal was proposed in the risk assessment for dealing with the disinfection of surfaces. A recommendation was also made to alter the waste disposal from yellow bags to tiger bags following autoclaving, as the waste should no longer require incineration following this process.

The Committee considered the project ready for CU2 HSE notification following review of the validation of the disinfection method (and making any required minor amendment to the risk assessment post this review) and inserting the minor amendment with regards to the waste procedure.

Committee Decision

The project involves genetic manipulation of a HG2 pathogen, is an activity class 2 project requiring CL2 containment facilities and is assigned a University medium hazard level and was approved by members, subject to the following conditions:

1. That the risk assessment is updated to reflect the following conditions:
   • Review of the validation of the disinfection method and revisions being made to the documentation as necessary.
   • Change to the choice of bag for disposal. Post autoclaving the waste material should be classified as offensive waste and placed in a tiger bag, rather than a yellow bag, as this indicates that the material inside is still highly infectious, which is incorrect.

2. The HSE are satisfied with the information provided in the CU2 form.

Professor Andrew Easton
Chair of the University Genetic Modification and Biosafety Committee
Date: 25/02/2015

*GMBSC = Warwick University genetic manipulation and biological safety committee.
Project Additional Information

Purposes of the contained use

Various activities in biological and biomedical research, including but not limited to: expression of known and putative oncogenes, growth factors and cytoskeletal proteins; regulation of gene expression by various methods including RNA interference and the introduction of degrons or repressible promoters; the use of CRISPR/Cas9 systems and single guide RNAs to tag and/or cause breaks in human and animal chromosomes; to induce immortalisation and pluripotency in vertebrate cells; and to administer viral vectors and cells transduced by such vectors to animal models.

Recipient or parental organism

Lentiviral and retroviral vectors based on a range of human and animal viruses, including HIV, EIAV, MMLV, MMTV and MSCV. The split vector systems and packaging
cell lines to be used will conform to designs of second generation or later, and will be demonstrably incapable of replication in humans or the environment. Vectors may have wider tropisms by the use of ecotropic and amphotropic envelope proteins, including VSV-G, and may include either wild-type or mutated forms of the Woodchuck Hepatitis Virus Post-transcriptional Response Element (WPRE).

Host/vector system

Viral vectors will be generated by transfecting all the plasmid components of a split-genome system into packaging cell lines, such as HEK293, or by introducing the backbone vector into commercially-available stable packaging cell lines expressing other components of the viral genome. Viral vectors produced will then be used to transduce a range of human and animal cells. This will include established cell lines from various lineages, mouse embryonic stem cells, and primary human and animal samples, other than those known or suspected to contain agents classified as Hazard Group 3.

Origin & function

As this is a connected programme of work, the genetic material to be introduced will be from a range of origins and have a variety of functions. This will include putative and known oncogenes and tumour-suppressor genes, cytoskeletal proteins, short hairpin RNA (shRNA) molecules intended to inhibit the expression of a range of genes including those or known or suspected to be involved in pathways of oncogenesis, and genes intended to induce immortalisation and the extension of the proliferative lifespan of cells. CRISPR/Cas9 systems may be expressed which are intended to cause double-stranded breaks in DNA, leading to mutation by non-homologous end-joining or insertion of specific mutations or tags with homology-directed repair constructs, but in some circumstances, Cas9 which is disabled for this function will be used to tag or label chromosomes for fluorescence microscopy. This connected programme does not include the use of viral vectors expressing toxin genes or major pathogenesis factors, which will be notified separately.

Evaluation of foreseeable effects

The use of second generation (or later) vector systems in which all accessory genes have been deleted, and where gag, pol, env and rev genes are provided in trans (either on additional accessory plasmids or integrated into the genome of packaging cell lines), means that the risk of production of replication-competent or infectious virus is effectively zero, and there is no documented evidence of replication-competent lentivirus being produced in third-generation vector systems.

However, transduction of a cell with such viral vectors will result in insertion of the viral genome into random sites within the genome of the host cell. While the use of self-inactivating (SIN) viral vector systems, in which promoter and enhancer elements have been removed from the long terminal repeats (LTRs), reduces the risk of transcriptional activation of genes proximal to the insertion site, this could be stimulated by constitutive promoter/enhancer sequences within the inserted genetic material. Insertion of the viral genome could also result in disruption of genes involved in cellular regulation (e.g. tumour-suppressor genes).

The use of WPRE sequences to increase the levels of expressed mRNA is becoming commonplace, especially in lentiviral vectors. Some versions of these elements also express a fragment of the Woodchuck Hepatitis Virus X protein, and there is limited (and controversial) evidence in the literature that this protein is implicated in the formation of hepatocellular carcinomas, albeit when administered systemically at high titres in animal models. It is most common for the intention of the activity to be to take the crude supernatant from a packaging cell line (where the viral titre is unlikely to be higher than 10E+7 particles/ml), and to use that supernatant to transduce a cell culture.

In those circumstances, and in the absence of significant (i.e. >100-fold) concentration of the viral titre and elimination of sharps, it can be argued that the risk of accidental systemic administration, such that the vector is delivered to the liver in sufficient quantity to induce hepatocellular carcinoma, is negligible. Such an activity can therefore be assigned to Class 1 (provided that there is nothing more hazardous in the vector), even in the presence of WPRE expressing protein X.

The inserted genes may also pose specific hazards:
- While oncogenesis is known to be a multi-factorial process, the expression of known or potential oncogenes could act in concert with the insertional effects to contribute to oncogenic pathways.
- The use of systems (shRNA, CRISPR, etc.) to deliberately disrupt tumour-suppressor genes pose a similar level of risk.
- Expression of cytokines and growth factors has the potential to cause inappropriate growth, differentiation or apoptosis of cells, all of which are associated with oncogenesis. Growth factors and cytokines may also be teratogenic, and have other effects on the immune response, so consideration will also be given during the local approval process for risk assessment as to whether expectant mothers and workers with other health issues should be excluded from such work.

All of these events could pose a risk to workers, but only in the event of self-inoculation. This risk will be controlled by eliminating sharps (except where they are required for administration of vectors to animals), and by other measures at Containment Level 2 (documented records of training, laboratories with access restricted to authorised
personnel, and the use of gloves).

All risk assessments for GM activities with retroviral and lentiviral vectors will continue to be subject to scrutiny and local approval by the University Genetic Modification and Biosafety Committee (GMBSC), and the GMBSC will determine if the activity falls within the scope of this Connected Programme. If so, no further notification will be made. The GMBSC will also ensure that the activities are undertaken in approved Containment Level 2 facilities.

The following activities will NOT be permitted within the connected programme of work, and will be the subject of a separate notification:

1. Preparation of high-titre retroviral or lentiviral stocks by methods that require the use of needles to harvest the virus (e.g. density gradient centrifugation)
2. The use of sharps, including hypodermic needles and glass pipettes, OTHER THAN for administration of viral particles to animals
3. Expression of a major pathogenesis factor or a toxin gene.
4. The use of retroviral or lentiviral vectors for which there is evidence for the presence of replication-competent virus.
5. Any other activity which the GMBSC decides constitutes one or more risks that might consign it to a higher Class.

Activities with lentivirus that will be considered as Class 1 genetic modification:

The risks to workers associated with the construction and amplification of the plasmids used to generate the viral vectors are considerably less than with the virus itself, as the passive uptake of circular DNA into human cells is very inefficient, chromosomal integration will not occur, and the plasmids will not be maintained episomally in a dividing cell population. For this reason, work with these plasmid vectors will be assigned as a Class 1 activity, unless the hazardous nature of the inserted gene(s) dictates otherwise.

Furthermore, since the risk to workers from inoculation relies solely on the presence of free viral vector particles, the risk is effectively eliminated by genomic integration step of the life-cycle of the Retroviridae. According to the SACGM Compendium of Guidance, the risks are negligible 'where the cells do not incorporate any helper function and where residual virus titres have been reduced by replacing the potentially infectious cell supernatant medium'. Consequently, cells used after that can therefore be re-assigned to Class 1 GMMs for subsequent use, storage and transport.

Where viral vectors are generated using packaging systems in which the envelope protein is documented as being incapable of infecting human cells (e.g. ecotropic envelope from Moloney murine leukaemia virus), the GMBSC may decide that the activity should be assigned to Class 1, and that notification is not required.

Some aspects of this connected programme will include the administration of lentiviral and retroviral vectors, and cells transduced with such vectors, to GM mice (which represent no increased hazard to human health or the environment compared to the wild-type parental strain).

The animal facility (BSU) has been purpose-built to house rodents and lagomorphs, and was designed in consultation with the Home Office and the HSE. It includes a containment suite capable of operating at CL3, but which is currently run at CL2. Control measures include:

- Rodent barriers to rooms containing mice to prevent escapees exiting the immediate area
- Computerised auditing of the facility rodent population, ensuring absences are quickly detected
- SOPs to monitor for, react to, and record escapes
- The facility and all rooms (including the containment suite) are subject to strict access control
- Staff are trained to handle animal in accordance with Home Office requirements.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None requested

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All liquid waste potentially containing lentiviral or retroviral particles will be collected in vacuum traps containing a minimum of 1% Virkon. This will then be disposed of via the sink after a minimum of one hour incubation. Plasticware containing virus packaging cells or transduced cells will be treated with a 1% virkon solution for one hour before disposal OR bagged and sent for autoclaving. All other solid waste will be collected in bags for autoclaving. Autoclaving will be performed for a minimum hold time of 15 minutes at 121°C in autoclaves that
are subject to insurance examination to a written scheme, and are serviced and validated at least annually. Material that has been autoclaved or disinfected is consigned as offensive waste, and sent to land-fill by licensed contractor.

Material that has been autoclaved or disinfected is consigned as offensive waste, and sent to land-fill by licensed contractor.

As this notification relates to a Connected Programme of Work, exemplar risk assessments have been attached.

The risk assessments for Projects 200 and 201 were discussed at the meeting of the GMBSC held on 24th September 2015, having been circulated in advance by email. The following comments were made, which have been incorporated into the attached revised version:
- It is unclear from the information provided whether the Cas9 and the CRISPR guide RNA are being carried on the same vector.
- There should be a greater consideration of the potential for lentiviral vectors to cause mutagenesis by insertion into the human genome, which is theoretically capable of contributing to an oncogenic pathway, although this will not require any higher level of containment than is necessary for work with vectors containing wild-type WPRE sequences.
- The risk to animals in the environment in the event of release of lentiviral vector in Section 6.5 was over-estimated. Taking into account the likelihood of release, the mode of transmission, the replication-defective nature of the viral vector, and the likely survival of the vector in the environment, the Containment Level required to protect human health is adequate to protect the environment.
- There needs to be clarification of how the Class 2 GM materials will be stored safely if they are outside a CL2 lab.
- The waste management and spillage procedures need a little more clarity. Waste that has been treated with Virkon should not be autoclaved subsequently.
- The scientific goals are too far-removed from that of notification 332/07.2 to allow notification of a significant change.

Risk assessments for Project 98 (Amendment) were discussed at the meeting of the GMBSC held on 15th October 2015, having been circulated in advance by email. The following comments were made, which have been incorporated into the attached revised version:
- L2.06 (CL1) is suitable for manipulation and construction of plasmids in E. coli only, due to the reduced likelihood of cellular entry of plasmid DNA, compared to lentiviral vectors.
- The zero sharps policy and necessary PPE and hygiene measures have been identified correctly.
- Waste treatment and spillage processes are appropriate.
- Controls for storage of Class 2 GM materials outside the CL2 lab have been identified.

Please enter comments on the GM safety committee on the risk assessment

Project Additional Information

Purposes of the contained use

The majority of work in the laboratory is focused on understanding how plants respond to virulent and avirulent challenges, both in local tissue (leaves) and systemically. We investigate induced defence responses, systemic induced immunity and suppression of plant defence. The majority of the work is done on Arabidopsis thaliana using chemical induced and T-DNA mutants as well as Arabidopsis over-expressing plant or phytopathogen genes either under strong ectopic, specific or conditional promoters. All procedures are standard molecular cloning and transformation. We use Nicotiana benthamiana for transient transformation studies and occasionally tomato, lettuce and banana, but only Arabidopsis is transgenic.

We use a range of pathogens, primarily Pseudomonas syringae pathovars or Xanthomonas campestris pathovars. Pseudomonas syringae pv. tomato DC3000 and pv. maculicola are most frequently used, with DC3000 being the strain we genetically modify, either by deleting effectors or adding effectors in under control of constitutive or inducible promoters. We also routinely use Botrytis cinerea as a necrotrophic pathogen to assess how plants with altered responses to biotrophs respond to this pathogen.

We use information from high temporal resolution microarrays, proteomics and metabolomics to inform on strategies to modify/re-engineer plant defence signaling pathways to prevent pathogen suppression of defence. There is a strong focus on modification of hormone signaling and modification of classical plant disease resistance proteins or pattern recognition receptors, often using bespoke promoters. Golden Gate cloning is used to transform in multiple genes, or biosynthetic pathway components.

A typical experiment would be to use genes identified from microarray studies and other prior knowledge to alter...
the Arabidopsis response to DC3000. We would then investigate how this perturbation occurs using yeast-2 hybrid
to identify interacting partners, over-expression or mutation of the gene of interest, in planta localization and cell
biology and examining the changes in the metabolome. The target is to generate broad spectrum resistance and
this will most likely require crossing lines with modified responses to DC3000 to enhance resistance.

Recipient or parental organism

Pseudomonas syringae is a host pathogen on tomato and a non-host pathogen on Arabidopsis. It is a poor
epiphyte and infection is primarily through wounds or stomata. No strains of P. syringae have been reported to
cause infection or represent any health risk to humans. Transformants would be capable of surviving within infected
plants but not in soil for sufficient time to allow re-infection and transfer to a new host plant. The strains of P.
syringae used are, however, not specifically disabled.
Xanthomonas campestris pathovars have very specific host ranges. There is no risk to humans or animals.

Host/vector system

In P. syringae, plasmid vectors pLAFR3, pVSP61 or pDSK600 in addition to ColE1 will be used. None of the
vectors is self-transmissible but the broad host range vectors are mobilisable via the helper plasmid pRK2013.
Plasmid vectors pDSK600, pVSP61 will be used in X. campestris.

Origin & function

One or more of 30 effector genes from Pseudomonas syringae pathovar DC3000. There will be no expression outside the plant apoplast following infection as these are
tightly controlled by the bacterial Type 3 Secretion System. Gene products are not harmful in isolation.
Effectors identified as differentially present/or polymorphic between virulent and susceptible Xanthomonas isolates. Harm from gene expression is highly unlikely as they
are only expressed in planta in the virulent isolate.

Evaluation of foreseeable effects

No strains of P. syringae have been reported to cause infection or represent any health risk to humans. The possibility that exchange of genes between strains would lead
to significant hazard to human health seems negligible.
The strains of P. syringae used in this work have a very narrow host range (Arabidopsis, Brassica, tomato). Modified P. syringae may in extremely rare cases be
significantly more virulent than the parental strain but coupled with their poor survival rate in the environment and extremely low load in a possible escape and highly
restricted host range, harm to other plants would be expected to be remote.
The likelihood of cloned genes having effects on other microbes in the environment, e.g. soil-inhabiting Pseudomonads becoming pathogenic is unlikely since regions of no
more than 5kb will be cloned and it is known that DC3000 requires type III secretion capabilities before inducing any response in plants.
The likelihood of mobilisation of the plasmid vectors to other Pseudomonas is also remote, and has not been demonstrated in vitro.
Should the transgenic P. syringae have altered pathogenicity this is, therefore, more likely to be manifested only in certain varieties of the plant host. The spread of disease
from heavily infected seed is dependent on the prevalence of rainfall and comparatively high temperatures. Thus in most years plant diseases caused by the bacteria do not
pose a major threat. If the GMM did have enhanced pathogenicity the consequence of release would be at most low and, more accurately, negligible.
Xanthomonas campestris pathovars have very specific host ranges. There is no risk to humans or animals. There is a remote possibility, if this GMM escaped AND came
into contact with on of its very limited hosts, it may infect. In the immediate environment brassica crops would be at risk. However virulence is very varietal specific AND the
GMM is unlikely to enhance this remote possibility.
The work involves examining the function of proteins that are only induced within the plant/host. There is a very specific induction system, so the chances that this GMM
would (i) enhance fitness and (ii) impact the environment is considered negligible. All work with these will never-the-less be undertaken in CL2 facilities.

Some aspects of this programme will include the administration of GM Pseudomonas syringae pathovars to GM strains of Arabidopsis thaliana (which themselves

02/03/2022
represent no increased hazard to human health or the environment compared to the wild-type parental strain). Work with these infected Arabidopsis plants will include transport of GMO material between Growth Facilities. This will be carried out following instructions in relevant SOPs. There is a low risk of seed escape. This risk will be mitigated by use of dedicated lab coats, cleaning all equipment, use of sticky foot mats and filtration of run-off liquid in the PBF (PhotoBiology Facility). The facility is surrounded by gravelled areas, which are regularly treated with herbicides for weed control. Infected plant material will be inactivated by autoclaving at 121°C for a minimum of 30 minutes, ensuring an effective 100% kill.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None requested

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Containment in laboratories, growth rooms and glasshouses will be based upon following detailed SOPs. Notably dedicated growth, culturing and inoculation areas will restrict possible pathogen infection.

All solid waste contaminated with GM material [eg. plastic pipettes, plates, small volumes of sealed liquid cultures, gloves, tips etc.] is placed in a rigid container lined with an autoclave bag. These materials are autoclaved on validated cycles ensuring a minimum temperature of 121°C for a minimum hold time of 15 minutes, ensuring an effective 100% kill.

Materials may be initially decontaminated using a validated disinfectant regime prior to autoclaving. Virkon and Jet-5 are effective against both Pseudomonas syringae and Xanthomonas campestris. We have validated the effectiveness of Jet-5 and Virkon in plating experiments carried out at Exeter University in 2008 and 2010. These disinfection methods also work for fungi (Magnaportha oryzae, Botrytis cineria, Alternaria alternata and Trichoderma hamatum). We set a minimum time of 20 minutes soaking in the disinfectant.

Autoclaves are subject to appropriate periodic servicing, validation and insurance inspection against a written scheme of examination. After autoclaving, all waste is placed in Tiger-striped bags, and removed from site by the University’s appointed waste contractor for disposal as offensive waste. All glassware used with plant pathogens is soaked in disinfectant prior to washing. Any spillages will be first taken up with tissue and the contaminated area then cleaned with validated disinfectant (Jet-5).

GM contaminated sharps, including syringes, needles and broken glassware are placed in a sharps bin, autoclaved, then disposed of by incineration.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

After extensive consultations between the Principal Investigator and the Technical Assurance Manager and the University Biosafety Adviser, the risk assessment was circulated to the Genetic Modification and Biosafety Committee (GMBSC) for their consideration.

There were no objections to the assignment of the contained use to CLASS 2, with many elements assigned to CLASS 1. Notably, while the GM strains of Arabidopsis thaliana will be infected with Pseudomonas syringae pathovars, these strains are not notifiable in their own right, posing no increased risk compared to the parental unmodified strain.

It is noted that the plant pathogens have been granted a licence by the Plant Health & Seed Inspectorate under the Plant Health Order.

Purposes of the contained use

1. To construct models of CF lung biofilm communities using artificial sputum and ex vivo pig lung tissue in order to explore the effects of inter-microbe interactions on infection, virulence, persistence and antimicrobial resistance profile.
2. To use these models to test the clinical potential of existing and novel therapeutics (antibiotics, antivirulence compounds and antibiofilm compounds).
3. To reconstruct anti-infection remedies from pre-modern medical texts and to explore the bactericidal, bacteriostatic and/or antivirulence effects of individual ingredients and whole recipes on a range of soft tissue pathogens in standard lab media, artificial wound models and the ex vivo lung model.
4. To reintroduce unmodified and mutated forms of the deleted genes to the GMMs in trans-complementation assays, followed by analysis in the above models.
### Recipient or parental organism

Parental organisms for the genetic modification are a range of ACDP Hazard Group 2 pathogens which are known or suspected to be involved in the establishment and progression of chronic bacterial infections. The species are transmissible by a number of routes including by aerosol, and come from commercial sources and clinical isolates, with a range of resistances to antibiotics.

GMMs will be applied to ex vivo lung models derived from porcine tissue fit for human consumption, and in in vitro wound models generated from either a) fetal bovine serum, peptone and collagen or b) coagulated blood (not of human origin).

**NB** While these species are listed in the associated risk assessment, amendment to include other HG2 organisms will be considered locally by GMBSC, and will not be considered a significant change provided there is no increase in overall risk.

### Host/vector system

A range of plasmid vectors will be used to deliver the genes of interest, and will include broad-host-range vectors, self-mobilisable vectors, shuttle vectors, suicide vectors, genome insertion vectors, cloning vectors and protession expression vectors with inducible promoters.

### Origin & function

Fluorescent/luminescent reporter constructs, antibiotic resistance markers and transposable elements originating from a variety of species. None known to be inherently harmful. Complementation will also be perfomed by providing unmodified and mutated forms of the deleted genes in trans.

### Evaluation of foreseeable effects

The host species, as Hazard Group 2 agents have the potential to cause disease in humans. In particular, immunocompromised people of any group are at increased risk of infection, most notably those with open wounds, cystic fibrosis, diabetes, or people who are taking broad-spectrum antibiotics or immunosuppressant drugs. *P. aeruginosa* produces toxins (cyanide, exotoxin A) and an allergen (LPS). *S. aureus* produces Toxic Shock Syndrome Toxin-1 and several enterotoxins. Many of the mutants used will be compromised in virulence or persistence, as they will have had virulence factors, biofilm polymers or quorum sensing components knocked out. Apart from the Tn library used for Tnseq, most mutants will be constructed using clean gene deletions or insertion of an antibiotic-resistance marker into the gene of interest. These are unlikely to be overcome, in the latter case because the marked strain will always be cultured in the presence of the selective agent. The genome insertion plasmids insert into the chromosome of a range of bacteria but the conditions for this to occur are very stringent and unlikely to be met outside of the laboratory or by accident, for example the Tn7 derived plasmids require an accessory plasmid to be co-conjugated in order for insertion to occur. The self-mobilisable vectors require a stringent set of conditions that are unlikely to occur outside of the laboratory. Vectors which are required for the expression of a protein will have a regulatory component (wherever possible) so that protein expression is linked to the presence of either IPTG or arabinose, or to species-specific quorum sensing signals, which are unlikely to be found outside the laboratory. The Gram-negative specific transposon mini-Tn5 requires unique conditions for transposition and subsequent mutation to occur. These conditions are likely only to be meet in laboratory environments and are unlikely to occur in the environment, and spread to environmental bacteria is considered highly unlikely.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None requested

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

SOLID WASTE:-

02/03/2022
Pipettes:
- Plastic pipettes must be discarded into the designated yellow discard. Boxes should be placed in an autoclave bin and removed when full for sterilisation by autoclaving.
- Disposable plastic material:
  - Universals, bijoux, tips and eppendorf tubes etc. must be discarded into a Disposafe jar. Full jars must be transferred into an autoclave tin lined with an autoclave bag and removed for autoclaving.
  - Petri dishes must be placed into an autoclave tin lined with an autoclave bag and removed for autoclaving.
- Contaminated non-disposable items eg flasks, beakers etc
  - Disinfect in 10,000 ppm sodium hypochlorite, dispose of this by the pump/drain system and place items into an autoclave tin without a bag.
- Handtowels and “clean” gloves
  - Handtowels and any gloves that are worn as a second pair underneath outer ones should be placed in the designated autoclave tins lined with an autoclave bag located under the handwash sinks.

The main autoclaves in SLS used for HG group 1 & 2 work are serviced twice a year. Validated loads include porous bagged waste, biobins and petri dishes. They are validated to a cycle of 121°C and 15 psi for 20 mins. Any new waste vessels introduced must be validated before use.

Work surfaces will be cleaned with 1% Chemgene (Medi-Mark Scientific) after each use. Chemgene has been certified by the manufacturer to disinfect Pseudomonas aeruginosa.

LIQUID WASTE:-
- Autoclave as above, or disinfect with sodium hypochlorite to 10,000 ppm chlorine and dispose of via drain.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

This risk assessment was circulated to GMBSC by email on 10th August 2016, and the following specific comments were made:-
- Consideration should be given to listing specific antibiotic resistant strains
- Has sufficient justification been made for the use of sharps?
- Very detailed assessment

Project Additional Information

Purposes of the contained use

We will induce the expression of exogenous proteins, or alter the expression of endogenous proteins, in the brain in a cell specific manner. These manipulations will be used to:
1) test the role of defined brain cells in specific behaviours and the role of specific proteins in the function of brain cells;
2) functionally dissect neural microcircuits; and
3) manipulate neural control of specific physiologically systems to determine how this affects other systems in the body.

Modifications may arise through:
1) altered excitability of cells;
2) Loss or gain of function; or
3) Cell specific lesions of brain nuclei.

This will be achieved in specific populations of cells in the brain by targeted genetic expression of various ion channels, receptors or toxins. The ion channels and receptors can then be activated in a specific manner (e.g. by light or by specific agonist injection) to achieve either the inhibition or activation of the cell populations. Expression of these proteins may be inducible by expression of other receptors, such as the tamoxifen receptor.

The introduction of these genes may be through transduction with viral vectors, or through breeding of transgenic lines.

Recipient or parental organism

Mice: including GM mice, which present no increased hazard compared to the parental wild-type strain
Rats: wild-type strain
Primary cell culture: including cells from GM rodents, for testing for viral expression in neurons and glia
HEK cells: for testing plasmids and viral constructs
Hela cells: including GM cells, to test the effects of proteins on specific functions
Host/vector system

Adeno-associated viral vectors (all serotypes including modified serotypes such as AAV-DJ)
E1- and E1/E3-deleted adenovirus 5
Lentiviral vector systems (based on HIV)
Plasmids pXcX and p2XcX
AAV plasmids from various sources

Origin & function

Cx26 -ion channel (rodent version; unlikely to result in any harmful effect)
Cre recombinase (bacteriophage enzyme; unlikely to result in any harmful effect)
Flp recombinase (bacteriophage enzyme; unlikely to result in any harmful effect)
Fluorescent proteins (jellyfish; unlikely to result in any harmful effect)
Opsins -ion channel (light-activated; unlikely to result in any harmful effect)
DREADD receptors - (modified receptor only activated by a synthetic molecule, clozapin-N-oxide; unlikely to result in any harmful effect)
Diphtheria toxin receptor (unlikely to result in any harmful effect)
shRNA (inactivating the rodent version of taste receptors; unlikely to result in any harmful effect)
Taste receptors (rodent version; unlikely to result in any harmful effect)
Cell specific promoters such as GFAP, TSH receptor promoter, EF1alpha (Unlikely to result in any harmful effect)
Allatostatin receptor (fruitfly receptor only activated by a non-mamalian ligand; unlikely to result in an harmful effects).
Diphtheria toxin subunit A (Causes apoptosis of transfected cells - may cause harm)
Tetanus toxin light chain (Causes loss of signalling in transfected cells - may cause harm)

Evaluation of foreseeable effects

The expression of toxin subunit genes in adeno-associated viral vectors results in apoptosis, lack of neurotransmitter release or loss of activity of brain cells, and could cause harm in the case of accidental inoculation of workers. However, this risk is minimised by the control measures in place, including the use of tissue-specific promoters of rodent origin, elimination of sharps wherever possible, the use of injection equipment which is distal to the operators' hands, the very low likelihood of the micro-injector pipettes penetrating human skin, and the high levels of operator training.

All viral vectors used in this programme are replication-incompetent, and incapable of forming a productive infection in humans or in the environment.

There is a low risk of third-generation lentiviral vectors inducing mutagenic events as a result of genomic integration.

GM mice will represent no increased risk to human health or the environment, compared to wild-type strains.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

This connected programme will include the administration of viral vectors, and cells transduced with such vectors, to rats and to GM mice (which represent no increased hazard to human health or the environment compared to the wild-type parental strain).

The animal facility (BSU) has been purpose-built to house rodents and lagomorphs, and was designed in consultation with the Home Office and the HSE. It includes a containment suite capable of operating at CL3, but which is currently run at CL2. Control measures include:-
• Animals are housed in sealed IVC systems, minimising risk of escape
• Rodent barriers to rooms containing mice to prevent escapees exiting the immediate area
• Computerised auditing of the facility rodent population, ensuring absences are quickly detected
• SOPs to monitor for, react to, and record escapes
• The facility and all rooms (including the containment suite) are subject to strict access control
• Staff are experienced and trained to handle animals in accordance with Home Office requirements.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
The risk assessment identifies that the injection of virus particles into rodents should be permitted to take place in the BSU outside an MSC. The positioning of, and access to the subject is not achievable in an MSC, volumes of virus involved are very small, and the risks of aerosol are negligible. The overall risk is very low.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid lab waste contaminated with GM material [eg. plastic pipettes, plates, small volumes of sealed liquid cultures, gloves, tips etc.] is placed in a rigid container lined with an autoclave bag. Clear bags are in use at CL1, and red bags at CL2. These materials are autoclaved on validated cycles ensuring a minimum temperature of 121°C for a minimum hold time of 20 minutes, ensuring an effective 100% kill.

At CL2, materials may be initially decontaminated using a validated disinfectant regime (e.g. 5% (v/v) Chemgene solution) prior to autoclaving. Autoclaves are subject to appropriate periodic servicing, validation and insurance inspection against a written scheme of examination.

After autoclaving, all waste is placed in Tiger-striped bags, and removed from site by the University’s appointed waste contractor for disposal as offensive waste. GM contaminated sharps, including syringes, needles and broken glassware are placed in a sharps bin, autoclaved, then disposed of by incineration. Waste in the above streams generated in the BSU is autoclaved within the Unit prior to disposal.

Almost all animals injected with toxins are transcardially perfused with paraformaldehyde post mortem, which inactivates any virus or products generated by the viral inserts, further reducing any risk. As the risk of contaminating GMMs is negligible post mortem, all animal cadavers (in sealed bins) and bedding materials are removed from site for incineration by the University's licensed waste contractor. Post mortem carcases and tissues that have been handled outside the BSU are returned to the BSU for disposal by the same route.

Liquid waste is either autoclaved on a cycle validated to provide an effective 100% kill, or treated with validated disinfectants, prior to disposal via the drains. Residual quantities of viral particle suspensions in tubes, etc, are treated as solid waste. No liquid waste is generated in BSU.

Please enter comments on the GM safety committee on the risk assessment

This risk assessment was circulated to GMBSC by email on 4th April 2017, and the following specific comments were made:-

1. Clarification requested of appropriate CL2 locations for virus administration in vivo and in cultured human cells.
2. Adenovirus 5 vectors and the HeLa and HEK-293 cell lines to be used should be assigned to HG1/Class 1 not 2 as in the risk assessment, provided they do not contain hazardous gene inserts which may assign them to a higher Class.
3. The Committee agrees with the recommendation to notify this as a connected programme of work.
4. Clarification requested on how separation will be achieved between subject preparation (involving the use of sharps) and the presence of viral vectors which would be harmful to the operator if self-administered.
5. The proposal currently includes shRNA knockdown of unspecified ion channels and receptors. This section should consider the possibility that this might have harmful effects at the individual cell level if an shRNA-expressing vector were to infect a person.
6. It is not accurate to state that ‘All viruses to be used can cause disease in other animals in their wild-type state’. This would actually be exceptional. Both HIV and adenovirus 5 are highly specific for humans, whilst AAV (as stated) doesn’t appear to cause disease in any system.
7. Concern was expressed that the proposal includes the creation and use of viral vectors which express diphtheria toxin A non-specifically that are capable of entering a wide range of human cell types (for lentivirus via the VSV-G pseudotyping, and naturally for AAV and Ad5).

The risk assessment has been amended to address these comments.

### Purposes of the contained use

Our laboratory studies the mechanism and function of proteins and complexes responsible for the coordination, detection and metabolism of the bacterial cell wall and cell division. These studies include aspects of bacterial metabolism that relate to potential targets for antibiotics in two main areas: bacterial cell wall biosynthesis and aminoacyl-tRNA biosynthesis.

For bacterial cell wall biosynthesis, this includes the proteins directly responsible for its construction and related metabolism, proteins responsible for coordination with bacterial cell division, and signaling proteins related to this area including antibiotic resistance determinants. As part of these studies we recapitulate in-vitro the biosynthetic pathway in order to produce and purify substrate level quantities of the peptidoglycan pathway intermediates.

For tRNA synthetases this includes alanyl, valyl, threonyl and seryl tRNA synthetases from selected bacterial pathogens that require editing mechanisms to prevent...
non-cognate amino acyl-tRNA synthesis. For all of the above areas we may need to create and study the phenotype of in-vivo gene deletions, additions and mutants, in order to more fully interpret in-vitro observations of isolated proteins or protein complexes. For all scientific areas, the translational rational is research that may lead to options for multi-targetting of future and current antimicrobial drugs eg beta-lactams that target multiple penicillin binding proteins.

Recipient or parental organism

Multiple strains of bacterial species classified on the ACDP Approved List at Hazard Group 2, but not those on Schedule 3, Part V of COSHH. All sourced from well-characterised culture collections, and have a range of antibiotic resistance profiles.

Host/vector system

- pET vectors with T7 promoters
- pBAD vectors with arabinose promoters
- pTac and pProEx vectors with tac promotor
- pTet vectors with inducible tetracycline promotors
- High copy number cloning vectors, pUC series, pBluescript
- All vectors are non-mobilisable.

Origin & function

Bacterial housekeeping genes including cell wall biosynthesis genes, Penicillin binding proteins, cell division genes and the wider peptidoglycan biosynthetic pathway that includes protein biosynthetic genes, e.g. tRNA synthetases required in cell wall biosynthesis

Constructs will be made to generate deletions of these genes in HG2 organisms, which will be tested for phenotype.

Genes will also be complemented on plasmids in trans, including related genes from other HG2 and certain HG3 species. None of these will be known or suspected to be toxins or pathogenic determinants. Knockdown will also be achieved using plasmid-based CRISPR/Cas9 technology.

While some of these activities may be defined as self-cloning, they cannot be exempt from the Regulations due to being in HG2 organisms.

Evaluation of foreseeable effects

The expression of these genes is unlikely in humans due to the promoter systems in place, and the likelihood of harm being caused is very low. The resulting GMMs themselves would not be predicted to be any more harmful to human health than the parental wild-type strains, as there are no genes to be expressed that constitute toxins or pathogenic determinants. The most likely effect of gene knockdown, if any, is to reduce viability or pathogenicity. The transfer of genetic material (including antibiotic resistance genes) into related species in the environment is unlikely due to use of non-mobilisable plasmids. None of the genetic modification is likely to confer a survival advantage in the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid lab waste contaminated with GM material [eg. plastic pipettes, plates, small volumes of sealed liquid cultures, gloves, tips etc.] is placed in a rigid container lined with a red autoclave bag. These materials are autoclaved on validated cycles ensuring a minimum temperature of 121C for a minimum hold time of 20 minutes, ensuring an effective 100% kill.
At CL2, materials may be initially decontaminated using a validated disinfectant regime (e.g. 5% (v/v) Chemgene solution) prior to autoclaving. Autoclaves are subject to appropriate periodic servicing, validation and insurance inspection against a written scheme of examination. After autoclaving, all waste is placed in Tiger-striped bags, and removed from site by the University’s appointed waste contractor for disposal as offensive waste. Liquid waste is either autoclaved on a cycle validated to provide an effective 100% kill, or treated with validated disinfectants (e.g. 5% (v/v) Chemgene solution, prior to disposal via the drains. Residual quantities of bacterial suspensions in tubes, etc, are treated as solid waste.

Project notified under transitional arrangements N

02/03/2022
### Purposes of the contained use

Adenoviruses and SV40 are amenable to precise genetic manipulation by reverse genetics. This approach is used both to establish the detailed molecular biology of the viruses, typically by targeted disruption of specific viral genome sequences, and to create recombinant viruses capable of expressing a heterologous gene with the purpose of delivering that gene into cells/organisms to achieve its expression - either for experimental studies to dissect virus or mammalian cell biology, or to elicit immune responses (recombinant vaccines), or to alter cell function (gene therapy).

### Recipient or parental organism

- Human adenovirus types 2 and 5 (HAdV-C2, C5)
- Simian virus 40 (SV40)
- E. coli K12 strains
- Human cell lines
- Simian cell lines
- Mouse cell lines
- Hamster cell lines
- Rat cell lines
- Inbred laboratory mouse strains

### Host/vector system

- pAdEasy-1; pShuttleCMV containing insert DNA; pAT153, pML2 or other similar non-mobilizable derivative plasmids containing insert DNA
- pSV4 - clone of SV40 genome in pBR322

### Origin & function

- Reporter genes: luciferase, beta galactosidase, eGFP, RFP and similar derivatives
- HCMV IE promoter/enhancer
- EBV EBNA1 and OriP providing episomal replication in mammalian cells
- Subgenomic or cDNA segments from other adenoviruses, pneumonia virus of mice (PVM)
- HIV-1 rre element and/or Rev gene
- SIVmac p55 Gag or gp120/gp160 Env sequences
- Subgenomic or cDNA segments from mammalian cells, including adenosine deaminase, factor VIII, factor IX, dystrophin plus others but excluding known oncogenes and cell cycle regulators (eg c-myc).

### Evaluation of foreseeable effects

Wild-type Adenovirus types 2 and 5 are classified as HG2, infectious to humans, and transmitted by aerosol. Risk to workers if activities not conducted in MSCs. Many
constructs will be generated which are deleted for combinations of E1a, E1b, E3 and E2/E4 regions, and are likely to be incapable of, or attenuated for replication or infection. The ability of SV40 to cause infection in humans is not well established, although it has an approved classification of HG2, and all constructs will be used at CL2. GM activities will not increase the pathogenicity of the viruses, with many decreasing this activity. In terms of risk to the environment, Adenovirus 2 and 5 are restricted to humans only, and SV40 is unlikely to infect any species that are found in the UK. Inbred laboratory mouse strains pose no greater risk to human health or the environment than the parental wild-type strains, and will only be treated with replication-defective E1-deleted Adenovirus (assigned to Class 1 contained use).

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

This programme will include the administration of viral vectors, and cells transduced with such vectors, to GM mice (which represent no increased hazard to human health or the environment compared to the wild-type parental strain). The animal facility (BSU) has been purpose-built to house rodents and lagomorphs, and was designed in consultation with the Home Office and the HSE. It includes a containment suite capable of operating at CL3, but which is currently run at CL2. Control measures include:-

- Animals are housed in sealed IVC systems, minimising risk of escape
- Rodent barriers to rooms containing mice to prevent escapees exiting the immediate area
- Computerised auditing of the facility rodent population, ensuring absences are quickly detected
- SOPs to monitor for, react to, and record escapes
- The facility and all rooms (including the containment suite) are subject to strict access control
- Staff are experienced and trained to handle animals in accordance with Home Office requirements.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None requested

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All solid lab waste contaminated with GM material [eg. plastic pipettes, plates, small volumes of sealed liquid cultures, gloves, tips etc.] is placed in a rigid container lined with an autoclave bag. Clear bags are in use at CL1, and red bags at CL2. These materials are autoclaved on validated cycles ensuring a minimum temperature of 121C for a minimum hold time of 20 minutes, ensuring an effective 100% kill.

At CL2, materials may be initially decontaminated using a validated disinfectant regime (e.g. 5% (v/v) Chemgene solution) prior to autoclaving. Autoclaves are subject to appropriate periodic servicing, validation and insurance inspection against a written scheme of examination. After autoclaving, all waste is placed in Tiger-striped bags, and removed from site by the University’s appointed waste contractor for disposal as offensive waste.

GM contaminated sharps, including syringes, needles and broken glassware are placed in a sharps bin, autoclaved, then disposed of by incineration. Waste in the above streams generated in the BSU is autoclaved within the Unit prior to disposal. As the risk of contaminating GMMs is negligible post mortem, all animal cadavers (in sealed bins) and bedding materials are removed from site for incineration by the University’s licensed waste contractor. Post mortem carcasses and tissues that have been removed from site for incineration by the University’s licensed waste contractor. No liquid waste is generated in BSU.

Y

**Tick if you are claiming exemption from disclosure for section of the risk assessment**

N
This risk assessment was discussed at the meeting of the Genetic Modification and Biosafety Committee held on 14th July 2016, having previously been circulated by email, and has since been amended in line with the following comments:-

1. Recommend that an active solution is sought to allow administration of these viruses to mice in BSU (and their subsequent holding) to be carried out under suitable containment, rather than CL1 as stated. NB: This has been addressed by clarification that only replication-defective viral vectors assigned to Class 1 will be administered to mice.

2. There is an over-reliance on chemical disinfection of waste materials at CL2, and there should be a greater acknowledgement of the autoclave waste stream for disposable materials. There needs to be a separate paragraph describing the waste procedures within BSU, both for GMMs and infected mice.

3. Spills should not be treated with 70% ethanol other than for small spills.

4. It is unclear from the GMO Public Register whether this activity falls within the scope of an existing notification made under transitional arrangements. NB This has now been clarified and it is not currently covered.

5. New staff/students will require training records to be kept.

**Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

Phage therapy is an alternative method to antibiotics for treatment/control of bacterial infections which has nowadays become more important due to the problem of antimicrobial resistance. *Staphylococcus aureus* is a traditional gram-positive extracellular pathogen, responsible for skin and respiratory infections and food poisoning, which has also been shown to be capable of invading host cells, including macrophage cells. The emergence of antibiotic-resistant strains of *S. aureus* such as methicillin-resistant *S. aureus* (MRSA), which consists a major problem for patients, in combination with the lack of an approved vaccine for *S. aureus*, has made the option of phage therapy very attractive. In this project, we aim to investigate the invasion of *Staphylococcus aureus* in macrophage cells and human skin fibroblasts and the potential of the control of infection using phage targeting *S. aureus*.

While the initial experiments will focus on *S. aureus* and phage K, other HG2 bacterial species and targeting phages may be used within this Connected Programme of Work, without further notification.

**Recipient or parental organism**

Parental organisms for the genetic modification are ACDP Hazard Group 2 pathogens (e.g. *Staphylococcus aureus*) which are known or suspected to be involved in the establishment and progression of bacterial infections. The species are transmissible by a number of routes and come from commercial sources and clinical isolates, with a range of resistances to antibiotics.

GMMs will subsequently be incubated with human cells, including but not limited to macrophages and dermal fibroblasts, to establish the ability of interfering bacteriophages (e.g. phage K) to inhibit the intracellular infection by the bacteria.

NB While the associated risk assessment focusses on initial experiments using *Staphylococcus aureus* and bacteriophage K, amendment to include other HG2 organisms will be considered locally by GMBSC, and will not be considered a significant change provided there is no increase in overall risk.

**Host/vector system**

Bacteria will be transformed with non-mobilisable plasmids

**Origin & function**

Genetic material to be introduced will be fluorescent reporter genes, such as red fluorescent protein from Acropora millepora.

**Evaluation of foreseeable effects**

*Staphylococcus aureus* is an ACDP Hazard Group 2 biological agent, with the ability to cause skin infections and, rarely, invasive infections including pneumonia and sepsis.

The bacterium is prevalent in 30% of the population, but disease is uncommon except in individuals with impaired immunity or skin injury. Infections are treatable with antibiotics.

The genetic modification proposed is unlikely to increase or decrease the level of harm, compared to the unmodified strain.

There is a further low risk posed by the presence of adventitious agents in the primary human cells.

There is a very low/negligible risk to the environment, but the measures to be adopted at Containment Level 2 will ensure that release is prevented.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None requested
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid lab waste contaminated with GM material [eg. plastic pipettes, plates, small volumes of sealed liquid cultures, gloves, tips etc.] is placed in a rigid container lined with an autoclave bag. Clear bags are in use at CL1, and red bags at CL2. These materials are autoclaved on validated cycles ensuring a minimum temperature of 121°C for a minimum hold time of 20 minutes, ensuring an effective 100% kill.

At CL2, materials may be initially decontaminated using a validated disinfectant regime (e.g. 5% (v/v) Chemgene solution) prior to autoclaving.

Autoclaves are subject to appropriate periodic servicing, validation and insurance inspection against a written scheme of examination.

After autoclaving, all waste is placed in Tiger-striped bags, and removed from site by the University’s appointed waste contractor for disposal as offensive waste.

Liquid waste is either autoclaved on a cycle validated to provide an effective 100% kill, or treated with validated disinfectants, prior to disposal via the drains. Residual quantities bacterial cultures in tubes, etc, are treated as solid waste.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

Please enter comments on the GM safety committee on the risk assessment

This risk assessment was discussed at the meeting of the Genetic Modification and Biosafety Committee held on 13th July 2017, having previously been circulated by email.

The Committee were broadly happy with the quality and content of the risk assessment, but there was recognition that the PI would need to identify an appropriate CL2 location for culturing of human cells, which does not generally happen in the location stated.

<td>25/05/2018</td>
<td>Fighting actinomycetoma, a neglected tropical human disease</td>
<td>Class 2</td>
<td>&lt; 1 Litre</td>
<td></td>
</tr>
</tbody>
</table>
Actinomycetoma is a neglected tropical disease, and can be caused by the pathogenic species Streptomyces somaliensis (HG2) and Streptomyces sudanensis (HG2). The aim of this project is to genetically modify these two species in order to study the pathogenicity mechanisms that enable them to cause disease. Putative genes involved in pathogenicity will also be cloned and expressed heterologously in alternative hosts. GMMs will be tested in a pathogenicity model using the larvae of the greater wax moth (Galleria mellonella).

Recipient or parental organism

While not classified specifically by ACDP, the recognised ability of Streptomyces somaliensis and S. sudanensis to cause actinomycetoma in humans would indicate a provisional assignment to Hazard Group 2.

These species are transmissible by a number of routes, including by aerosols. Lesions usually occur on the extremities, most often on the feet. They appear as localized swollen nodules that slowly enlarge. Multiple abscesses form, and draining sinuses open to the surface and discharge pus and granules.

Other species of Streptomyces and E. coli K12 to be used are confidently assigned to Hazard Group 1.

NB While the associated risk assessment focuses on two pathogenic species of Streptomyces, amendment to include other closely-related HG2 species will be considered locally by GMBSC, and will not be considered a significant change provided there is no increase in overall risk.

Host/vector system

Bacteria will be transformed with non-mobilisable plasmids.

Origin & function

Cas9 (from Streptococcus pyogenes) will be introduced to HG2 Streptomyces to knock out putative virulence factor genes.

Virulence factor genes from HG2 Streptomyces will be expressed in HG1 species of Streptomyces and E. coli K12 strains.

Other genes from HG2 Streptomyces not involved in virulence (e.g. biosynthesis of non-ribosomal peptides, polyketides, terpenes and other specialised metabolites) will also be expressed in HG1 species of Streptomyces and E. coli K12 strains.
While not classified specifically by ACDP, the recognised ability of Streptomyces somaliensis and S. sudanensis to cause actinomycetoma in humans would indicate a provisional assignment to Hazard Group 2.

Antibiotic treatment is effective for all of the organisms. Vaccines are not available. There is an increased risk of infection in the immunosuppressed.

The proposed use of CRISPR/Cas9 is intended to study the effects of knocking out the expression of virulence factors, so would be very unlikely to increase the level of harm, compared to the unmodified strain.

Expression of virulence factor genes from S. somaliensis and S. sudanensis in E. coli K12 and HG1 strains of Streptomyces has the potential to increase the severity of harm arising from those GMMs, but this may confidently be assigned as a Class 2 contained use.

There is a low risk to the environment, but the measures to be adopted at Containment Level 2 will ensure that release is prevented.

Evaluation of foreseeable effects

Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable: the administration of Class 2 GMMs to moth larvae will be in wild-type Galleria mellonella only.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None requested

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid lab waste contaminated with GM material [eg. plastic pipettes, plates, small volumes of sealed liquid cultures, gloves, tips etc.] is placed in a rigid container lined with an autoclave bag. Clear bags are in use at CL1, and red bags at CL2. These materials are autoclaved on validated cycles ensuring a minimum temperature of 121°C for a minimum hold time of 20 minutes, ensuring an effective 100% kill.

At CL2, materials may be initially decontaminated using a validated disinfectant regime (e.g. 5% (v/v) Chemgene solution) prior to autoclaving. Autoclaves are subject to appropriate periodic servicing, validation and insurance inspection against a written scheme of examination.

**Project Ref 13/19.1**

- Date Ackn'd: 15/08/2019
- CU2 Project Title: The development of in vitro systems to study Epstein-Barr virus (EBV) - epithelial cell interactions
- Class: Class 2
- CultureVol: < 1 Litre
- Consent Granted
- Project notified under transitional arrangements

**Historical Significant Changes**
- Withdrawn: N

**Project Additional Information**

**Purposes of the contained use**

We plan to interrogate the functional implications of tumour cell interactions with stromal-derived cells (fibroblasts) and immune cells to investigate how these interactions influence the growth, survival and phenotype of EBV infected cell lines in vitro.
Techniques to be used include:-
Infection of established nasopharyngeal and gastric cancer-derived epithelial cell lines with recombinant EBV isolates engineered to express suitable drug resistance genes (G418/Hygromycin B).
Growth and reconstitution of normal epithelial cells and EBV infected epithelial cell lines with normal fibroblasts and/or leukocytes in a 3D organotypic raft or organoid system to develop a model of the tumour and its microenvironment.
The impact of the modified stroma on tumour growth and viral gene expression will be assessed by standard immunohistochemical/immunofluorescence staining and in situ hybridisation (RNAscope).

Recipient or parental organism
HEK293 and B lymphocyte (BL) cells will be infected via a natural process with the GM strains of EBV. The cells pose minimal risk to human health or the environment. Cells will be induced into the lytic phase while in co-culture with a range of mammalian (including human) cell lines, which will subsequently become infected by the GM EBV. These cell lines are all confidently assigned to Hazard Group 1.

Host/vector system
Epstein-Barr virus (EBV) is a hazard group 2 agent which naturally infects a wide range of human cells, but to which approximately 90% of the population are sero-positive. The strains to be used have been genetically modified to include antibiotic-resistance genes to be used in selection techniques. The modification is unlikely to increase the pathogenicity of the EBV compared to unmodified wild-type strains.

Origin & function
The only genetic material involved are selectable marker genes expressing resistance to antibiotics such as neomycin (G-418) and hygromycin B. Other markers of similar function may be introduced during the lifetime of the project.

Evaluation of foreseeable effects
Infection of workers with GM EBV expressing antibiotic resistance markers is unlikely to be any more severe than a normal EBV infection, and the adoption of containment measures at CL2 will be adequate to control the risk from this potentially airborne infection. Antibiotics are not used in the treatment of EBV infection, and there is no vaccine available.

>90% of the population are known to have neutralising antibodies to EBV, although there is a risk of EBV to act as a cofactor in causation of cancers in certain populations and the immunosuppressed.

EBV infection is specific to humans, so the potential impact in the environment is likely to be negligible. Containment measures required for the protection of human health will control any risk to the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
None requested

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All solid lab waste contaminated with GM material [eg. plastic pipettes, plates, small volumes of sealed liquid cultures, gloves, tips etc.] is placed in a rigid container lined with an autoclave bag. Clear bags are in use at CL1, and red bags at CL2. Project Ref 13/20.1

Date Ackn’d 24/06/2020

CU2 Project Title Cell biology and pathogenicity of kinetoplastid parasites and mammalian cells

Date Project Ceased

Class 2

CultureVolClass2 < 1 Litre

CultureVolumeClass3-4

Non-GMM

Consent Granted
Trypanosomatids are microscopic vector-borne parasites that cause widespread human and animal diseases. They currently infect ~17 million people, kill 80,000 people annually and are a terrible agricultural and economic burden upon developing countries. There is an urgent need for new therapies because no vaccines are available and existing drugs are often ineffective and toxic.

Central to their ability to spread and cause disease is a protrusion of the surface called the flagellum. The flagellum is essential for parasite movement, sensing and avoiding the human immune system. Furthermore, defects in human flagella cause genetic diseases called 'ciliopathies'. Ciliopathies can affect multiple systems, causing blindness, deafness, chronic respiratory infections, kidney disease, heart disease, infertility, obesity and diabetes.

This project investigates kinetoplastid parasites and mammalian cells, with a special emphasis on understanding flagellum biology. This will give insights into a) fundamental biology, b) pathogenicity of parasites, and c) the molecular mechanisms of human genetic diseases (ciliopathies).

Recipient or parental organism

Leishmania species (including L. major and L. mexicana) - human HG2
Trypanosoma brucei complex (including subspecies T.b. gambiense and T.b. brucei) - human HG2
Trypanosoma congolense, T. evansi, T. equiperdum & T. brucei brucei - SAPO2

(NB An application for a SAPO2 licence has been submitted)

Host/vector system

Non-mobilisable plasmids containing antibiotic resistance selectable markers and fluorescent marker genes.

Origin & function

Fluorescent protein genes (including eGFP, eYFP etc) with a long history of safe use.
Kinetoplastid genes and gene fragments from HG2 and SAPO2 Leishmania and Trypanosoma spp, which are thought to have key roles in parasite motility and lifecycle.

Evaluation of foreseeable effects

None of the genetic modifications that will be made in this project are expected to increase virulence or pathogenicity of the organism. However, both GM and non-GM T.b. gambiense, L. mexicana and L. major are able to infect humans.
Similarly, it is the most likely outcome that the deletion or mutation of individual genes in Trypanosoma brucei, T. congolense, T. equiperdum, T. evansi would either disrupt
or not affect their virulence or pathogenicity in their normal animal hosts. It is likely that expressing the individual kDNA genes, gene fragments or gene fusions in human cells would present negligible risk.

Note that the use of third generation lentiviral vector systems expressing non-hazardous genes has been assigned as a Class 1 activity, and is not part of this notification.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None requested

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste-handling and spillage procedures will be subject to a standard operating procedure (currently in development) to which all staff will be trained. The procedures to be employed are as follows:

Solid waste that is potentially contaminated with HG1 or HG2 organisms (and Class 1 or 2 GMMs) will be sterilised by autoclaving at 121°C 15psi for a minimum hold time of 20 minutes.

All liquid waste contaminated with HG2 organisms (and Class 2 GMMs) will be sealed securely in autoclavable culture vessels prior to sterilising by autoclaving (121°C at 15psi for 20 minutes).

All waste to be autoclaved will be collected by a dedicated waste team and taken direct from the containment suite to the autoclave room within the same building to be autoclaved immediately, and will not be left unsupervised in an uncontrolled area at any time. All waste autoclaves have independent cycle monitoring recorded on data loggers to ensure that validated cycle conditions have been attained for every run.

All autoclaves used for handling waste are subject to annual validation and calibration by an accredited service provider, and are examined to a written scheme of examination by the University's insurers.

Liquid waste from HG1/Class 1 organisms will be sterilised by autoclaving (121°C at 15psi for 20 minutes) or treatment with 1% Chemgene (final) for 10 minutes.

NB: While autoclaving will always be used as the preferred method of inactivating SAPO parasites and their GM derivatives, the use of 5% Chemgene for one hour is available as a validated contingency (Wang et al, 2008, PMC2556999).

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
Due to the coronavirus restrictions, the meeting of the Genetic Modification & Biosafety Committee scheduled for 23rd April 2020 was held by email correspondence. The members made the following specific comments when reviewing the risk assessment for this activity, which have now been fully corrected in the attached version:-

1. Elimination of the species infectious to humans will be employed wherever possible, but the assertion that T. brucei brucei is not infectious to humans is contrary to its hazard group.
2. What system will you have in place to ensure that no SAPO or HG2 trypanosomes will be used in the CL1 laboratory you have identified?
3. There is insufficient detail on the lentiviral transduction aspect, to ensure that all the intended transgenes fall within the scope of [the relevant Class 1 GM risk assessment approved by this Committee]. The current description of what will be delivered is open-ended, and needs to be stated to be restricted as per the terms of Generic 008.
4. While it is stated that MSCs will be used when handling organisms posing a hazard to human health, the conditions of the SAPO licence will also require any animal pathogen to be handled in the MSC.
5. Some clarification is required on when CL2 materials will be treated with disinfectant, and when they will be autoclaved (which is the normal procedure at CL2). Is 10 minutes treatment with 1% Chemgene adequate to inactivate the materials?
6. While there is consideration of immunocompromised individuals as a vulnerable group (section 9.2), this should also be the case for expectant mothers. The front-line treatment for early-stage trypanosomiasis is not recommended in pregnancy. Referral of pregnant workers to Occ Health would be recommended.
7. The first aid and primary care protocol applies to Oxford. Please take steps to establish the correct reporting procedure at University Hospital Coventry in the event of a lab exposure.

02/03/2022
The diverse group of RNA viruses includes the pathogens responsible for devastating human diseases such as influenza, Zika, AIDS and Covid-19. These viruses result in substantial mortality as well as having severe economic impacts worldwide. Despite significant progress in the study of these viruses, many fundamental unanswered questions remain. Our laboratory uses a combination of biochemical and biophysical imaging techniques to study the replication processes, morphology and cellular interactions of RNA viruses, as well as develop novel experimental tools for viral diagnostics.

This will be achieved in four ways:

1. Propagation of influenza viruses in eukaryotic cell culture as our primary model system, which will be used for the development of viral diagnostic assays and for imaging experiments to investigate the morphology and cellular interactions of influenza viruses.

2. Propagation of infectious bronchitis virus (IBV), an avian coronavirus, in eukaryotic cell culture, and use as a safe proxy to image and study coronavirus replication.

3. Rescue of recombinant influenza virus strains using plasmid-based transfection systems. We aim to use reverse genetics to generate reassortant influenza viruses with additional reporter gene segments of innocuous and non-viral origin e.g. GFP, or containing tags for virus labelling or purification e.g. histidine, FLASH or SNAP tags, for use in downstream assays such as live cell imaging of fluorescent viruses.

4. Expression of viral polymerase and cofactor proteins from a range of RNA viruses for in vitro studies using transient expression of viral proteins in transfected eukaryotic, bacterial or insect cells. The aim of our work is to study viral replication using single-molecule techniques to measure the structural and functional properties of single replication complexes in real-time. Individual proteins, or subunits, will be expressed and biochemically purified for in vitro experiments.

### Recipient or parental organism

- Low hazard cells of mammalian, insect and avian origin.
- Laboratory-adapted strains of influenza virus, assigned to Hazard Group 2, including vaccine strains A/WSN/33 and A/PR/8/34.
- Seasonal circulating strains of influenza virus, other than those of pandemic potential.
- Avian infectious bronchitis virus (HG2 strains only).
- Respiratory syncitial virus (HG2 strains)
Non-mobilisable plasmids containing antibiotic resistance selectable markers.

**Origin & function**

Genes expressing proteins involved in the expression of viral proteins and viral RNA from influenza, infectious bronchitis virus and SARS-CoV-2. Expression cassettes may include fluorescent and epitope tag fusions.

Note that gene expression factors, etc. from other Hazard Group 2 viruses may be included at a later stage, without further notification, provided there is no increase in risk or requirement for additional control measures. These will be subject to local scrutiny and approval by the GMBSC.

**Evaluation of foreseeable effects**

None of the genetic modifications that will be made in this project are expected to increase virulence, host range or pathogenicity of any viruses or other GMMs.

It is unlikely that expressing individual virus transcription factor and polymerase genes, gene fragments or gene fusions in mammalian cells would result in a GMO of increased risk.

To minimize the risk of human infection and disease, all reassortant viruses will be generated on the background of viruses with low pathogenic potential in humans i.e. the lab-adapted PR8 or WSN strains, found to be non-infectious in humans. Both ‘acceptor’ viruses are classified as Hazard Group 2 organisms, with a long history (> 70 years) of safe use in the laboratory. Furthermore, PR8 forms the backbone of the currently used inactivated influenza virus vaccines. Any insertions into the viral genome are expected to lead to a loss of function, and therefore even further decreased virulence.

The proteins, without the context of a virus particle, pose no toxic or pharmacological hazard, therefore the risk to human health is negligible.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

None requested

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Solid waste that is potentially contaminated with HG1 or HG2 organisms (and Class 1 or 2 GMMs) will be sterilised by autoclaving at 121°C 15psi for a minimum hold time of 20 minutes.

Liquid waste contaminated with HG2 organisms (and Class 2 GMMs) will be inactivated by treatment with validated disinfectant for the appropriate contact time prior to disposal via the drains. Alternatively, it may be sealed securely in autoclavable culture vessels prior to sterilising by autoclaving (121°C at 15psi for 20 minutes).

All waste autoclaves have independent cycle monitoring recorded on data loggers to ensure that validated cycle conditions have been attained for every run.

All autoclaves used for handling waste are subject to annual validation and calibration by an accredited service provider, and are examined to a written scheme of examination by the University's insurers.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N
Due to the coronavirus restrictions, the meeting of the Genetic Modification & Biosafety Committee scheduled for 29th October 2020 was conducted by video conference. The members made the following specific comments when reviewing the risk assessment for this activity, which have now been fully corrected in the attached version:

1. You state that you will be expressing (and constructing) the viral genome segments in E. coli, but these are not included in Sections 4 or 6, and need to be added.
2. Polymerase genes from other viruses, fluorescent markers and epitope tags are referred to in Section 3, but not mentioned in 6.4.
3. In Section 6.3, you state that expression from the non-mobilisable plasmid vectors is not likely or intended in humans. This would not appear to be correct, other than for the insect expression.
4. In Section 5.2, members asked for more detail on your direct experience working with respiratory pathogens at Containment Level 2.
5. There is no mention of the increased risk of influenza complications in pregnancy. This ties in with the need for the involvement of occupational health and the provision/offer of seasonal flu vaccine, which the Committee believe should be in place. This will also minimise the potential for generation of novel reassortant viruses, although that risk is admitted quite low.
6. There was concern that the waste team might be at risk from live flu virus in the waste, and that additional controls might be appropriate when disposing of the waste (e.g. ensuring that the bags are folded over before placing the lid on the autoclave tin). It would also be appropriate to offer flu vaccine to the waste team.
7. There is no mention of what infectious bronchitis virus will be used for, but this is infectious in avian species. More detail is needed before the environmental risk can be defined.
8. More detail is required on how ultracentrifugation of infectious material will be conducted safely.

</table>
Our laboratory, with industry partners Bicycle Therapeutics, are looking to develop the next generation of therapeutic anti-toxins. To do this we need to express and purify the target bacterial toxin. This will enable us to screen for toxin inhibitors produced by our partners which we will initially validate by simple (in eppendorf tube) haemolysis assays.

The initial family of ~20 toxins to be considered will be the 'cholesterol dependant' toxins which include pneumolysin, listeriolysin, etc. Pneumolysin is a pore-forming toxin of 53 kDa composed of 471 amino acids. We will express full length wild type toxin and truncated non-toxic versions including domain4 only variants which are demonstrably non-toxic. The study will also investigate anti-toxins to alpha-hemolysin from Staphylococcus aureus which, while not a cholesterol-dependent cytolysin due to its receptor interaction, has a similar structure and mode of action to the CDCs.

### Recipient or parental organism
Multiply-disabled K12 and B lab-derived strains of Escherichia coli

### Host/vector system
- pET vectors with T7 promoters
- pBAD vectors with arabinose promoters
- pTac and pProEx vectors with tac promotor
- High copy number cloning vectors, pUC series, pBluescript
- All vectors are non-mobilisable.

### Origin & function
- Genes from encoding cholesterol-dependent toxins, including the following:-
  - Pneumolysin from Streptococcus pneumoniae
  - Alpha-hemolysin from Staphylococcus aureus

NB: While the initial investigations will focus on these two toxins, it is likely that the work will move on to other members of the CDC family produced by related (HG2) bacterial species. These are unlikely to pose any increased risk or require any additional control measures to be implemented, so will be subject to local approval of the risk assessments by the GMBSC, and will not be subject to a significant change notification.
### Evaluation of foreseeable effects

The genes to be expressed in E. coli constitute secreted toxins which have the potential to display cytotoxic effects in isolation by virtue of pore formation in mammalian cells including macrophages. The resulting risk to human health is low, but cannot be considered nil or negligible, so Class 2 would be appropriate.

The transfer of genetic material (including antibiotic resistance genes) into related species in the environment is unlikely due to use of non-mobilisable plasmids. None of the genetic modification is likely to confer a survival advantage to the E. coli in the environment.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All solid lab waste contaminated with GM material [eg. plastic pipettes, plates, small volumes of sealed liquid cultures, gloves, tips etc.] is placed in a rigid container lined with a red autoclave bag. These materials are autoclaved on validated cycles ensuring a minimum temperature of 121°C for a minimum hold time of 20 minutes, ensuring an effective 100% kill.

At CL2, materials may be initially decontaminated using a validated disinfectant regime (e.g. 5% (v/v) Chemgene solution) prior to autoclaving. Autoclaves are subject to appropriate periodic servicing, validation and insurance inspection against a written scheme of examination.

After autoclaving, all waste is placed in Tiger-striped bags, and removed from site by the University’s appointed waste contractor for disposal as offensive waste.

Liquid waste is either autoclaved on a cycle validated to provide an effective 100% kill, or treated with validated disinfectants (e.g. 5% (v/v) Chemgene solution, prior to disposal via the drains. Residual quantities of bacterial suspensions in tubes, etc, are treated as solid waste.

### Is an emergency plan required according to regulation 20?

N

If yes, tick to confirm that it is attached to this form

N

Y

Tick if you are claiming exemption from disclosure for section of the risk assessment

N
This risk assessment was discussed at a virtual meeting of the University GMBSC held via Teams on 14th January 2021, having been circulated in advance, and the following specific comments were made:

1. There is some detail lacking in Section 6 relating to the components of the genetic modification, which makes it difficult to assess the level of potential risk.
2. There is a little lack of clarity in Section 4 regarding the exact locations to be used for the activities with E. coli expressing toxin genes and with purified toxins.
3. In terms of waste disposal, what is the likelihood that the toxins will survive treatment with the disinfectants named?
4. Chemgene would normally be regarded as effective at 5%, rather than 1% as you have stated.
5. The description of the range of which toxins you intend to study is not detailed enough. Please provide a list of which specific toxins you will be using

The risk assessment has been amended to address these comments.

**Project Additional Information**

**Purposes of the contained use**

CMV- 2b-GFP and CMV-GFP
A mutant of cucumber mosaic virus (CMV) that lacks the 2b protein gene and expressing free green fluorescent protein (GFP) and the wild type CMV expressing free GFP obtained in the laboratory of Prof P Palukaitis (SCRI) will be used as a model system to determine whether 2b-less CMV isolates/mutants make better cross-protecting strains and test the hypothesis that cross-protection occurs via virus induced RNA silencing.

Virus movement in the plant will be assayed by detection of GFP under UV light.

Presence of the 2b protein will be determined by Western blotting.

Two well established markers for the silenced state in plants are 25nt oligonucleotides (SiRNA) and increased levels of host RdRP (RNA dependent RNA polymerase) determination of whether levels of these markers are increased will be determined by Northern blotting

TRV-GFP
A tobacco rattle virus (TRV) modified to remove the non-structural 2b and 2c genes and replaced with GFP driven by a second coat protein gene subgenomic promoter derived from a different tobravirus isolate provided by Dr S Macfarlane (SCRI) will be used as a control for CMV-GFP experiments. Virus movement in the plant will be assayed by detection of GFP under UV light.

Two well established markers for the silenced state in plants are 25nt ologonucleotides (SiRNA) and increased levels of host RdRp (RNA dependent RNA polymerase) determination of whether levels of these markers are increased will be determined by Northern blotting.

**Recipient or parental organism**

CMV is one of the most important and widespread viruses of field grown horticultural crops in the world. CMV has a particularly wide host range including Cucumis sativus, Lycopersicon esculentum and Spinacia oleracea. In total it infects over 1,000 species including many weed species. CMV can be transmitted mechanically, and in few cases via seed, but the major mode of infection in vegetable crops is by aphids in a non-persistent manner.

Tobacco rattle virus belongs to one of only two genera of viruses that are transmitted by nematodes, the tobraviruses. Tobraviruses are transmitted only by nematodes belonging to the genera Trichodorus and Paratrichodorus. It can also be transmitted via seed, grafting and by mechanical inoculation. TRV has a wide natural host range including Stellaria media, Voila arvensis. Beta vulgaris. Spinacia oleracea, Capsicum annum Solanum tuberosum Narcissus pseudonarcissus. Tulipa sp. and Hyacinthus sp.
### Host/vector system

**CMV-2b-GFP and CMV-GFP**

To ensure that virus stocks are genetically uniform and satellite-free, 2b-less CMV and the parental wild type CMV will be reconstituted from cDNA clones by in-vitro transcription and the resultant RNA inoculated onto tobacco to bulk up the virus for subsequent experiments.

**TRV-GFP**

Clones of RNA2 of TRV were modified to remove the non-structural 2b and 2c genes and replaced with GFP driven by a second coat protein gene subgenomic promoter, derived from a different tobravirus isolate (pea early-browning virus).

### Origin & function

The CMV-2b-GFP and CMV-GFP will be obtained from the laboratory of Prof P Pulukaitis (SCRI) and the TRV-GFP from Dr S Macfarlane (SCRI). GFP will be used as a reporter gene for virus movement within the plant.

### Evaluation of foreseeable effects

The 2b protein gene in virus interferes with virus induced gene silencing in plants protecting the virus against host defences. It is hypothesised that the properties of the 2b protein may play a role in the induction of cross protection. If the virus lacks a functional 2b protein and is therefore unable to prevent gene silencing it should be less pathogenic. The CMV-2b mutant is less able than the wild type virus to spread systemically and accumulates to lower levels than the wild type in inoculated and uninoculated tissues (Soards A. J. et al 2002, Mol. Plant-Microbe Interact Vol 15, No. 7 pp 647-653). There is therefore no predicted hazard arising from the deleted gene. The inserted gene GFP is well characterized and there is no evidence for it being a hazard.

**TRV-GFP**

The deletion of the non-structural 2b and 2c genes should not alter pathogenicity as infection can occur in the complete absence of RNA 2. The non-structural genes on RNA 2 have been shown to be necessary for transmission of tobraviruses by vector nematodes; thus constructs in which these genes have been deleted should be effectively contained in the plants under test. (Macfarlane and Popvich 2000 Virology 267 29-35).

The inserted gene, GFP is well characterized and there is no evidence for it being a hazard.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Plant pots will be placed on trays or saucers in order to catch run-off water and this water will be allowed to evaporate naturally. All plant material, soil pots and labels will be autoclaved at 121 degrees C before final disposal in the skip. An autoclave is situated in the glasshouse. All trays, saucers, glass, flooring and benching will be thoroughly disinfected with Jet 5 disinfectant (8mls/L)

Plant material used in the laboratory will be autoclaved at 121 degrees C along with bags, tips and any other items used during laboratory procedures. This will then be placed in the skip. An autoclave is present in the same building as the laboratory. Benches in the laboratory are impervious and will be swabbed down with 70% ethanol before and after use.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]
The risk-assessment has been discussed and approved by the Genetic Modification and Biological Safety Committee at HRI, Wellesbourne.

### Project Additional Information

- **Historical Significant Changes**
- **Historical Date of Additional Info**
- **Significant Change ID**
- **Date of Significant Change**
Purposes of the contained use

a. Oomycete effector genes (from Hyaloperonospora arabidopsidis and Phytophthora infestans) will be fused to the secretory signal of the Pseudomonas syringae pv Tomato DC300 effector AvrRPS4 and transformed into Pseudomonas syringae pv Tomatoe Dc3000 isolate.

B. Arabidopsis plants will be inoculated with the modified DC300 isolate and tested to determine if the introduced effector triggers a defence response from the plant via recognition by a plant resistance gene (effector triggered immunity) or if the effector increases isolate virulence due to suppression of the plant's basal defence response (effector triggered susceptibility). The following plants may also be inoculated: Potato, Tobacco and Brassica oleracea.

Recipient or parental organism

Pseudomonas syringae pv Tomato is a gram negative, aerobic, rod-shaped bacterium, which is able to survive in soil, in debris form diseased plants and on seeds. Infection is spread by rain splash allowing entry into leaves via natural openings, such as stomata, where it multiplies in the intercellular space resulting in lesions on infected leaves.

Successful infection is dependant upon the translocation of effector molecules into the plant cell to promote disease and suppress/avoid PAMP (pathogen associated molecular patterns) triggered immunity and effector triggered immunity (Ponciano et al 2003, Jones and Dangl 2006)

Pseudomonas syringae pv Tomato is able to cause disease on Solanum Lycopersicum (tomatoe), Capsicum annuum (pepper) and Solanum melongena (aubergine) (Bradbury 1986). In addition, some strains, which include DC3000 are virulent on Arabidopsis thaliana, Brassica oleracea (cabbage, cauliflower, broccoli) and B. campestris (turnip) (Whalen et al 1991). DC3000 is also able to infect Nicotiana benthamiana (tobacco) if the effector hopQ1-1 is removed (Kvitko et al 2009). The isolate DC3000 was isolated in Ontario, Canada by Diane Cuppels and is widely used for moecular studies as it is a naturally occuring pathogen of the model plant Arabidopsis thaliana. In addition, the genomes of both DC3000 and Arabidopsis have been sequenced. Consequently, the technology we wish to use has been developed using this Pseudomonas isolate (Sohn et al 2007).

References:
- Bradbury JF. (1986) Guide to the Plant Pathogenic Bacteria. CAB International Mycological Institute, Kew, UK

Host/vector system

The host strain Pseudomonas syringae pv Tomato DC3000 will be used, which was isolated in Ontario Canada in 1986.

Oomycete effector genes will be cloned into the pEDV6 vector and transformed into DC3000. The pEDV6 vector was developed in Jonathon Jones's lab at the Sainsbury laboratory and contains the N-terminal secretory signal from the DC3000 effector AvrRPS4 and is expressed using the native AvrRPS4 promoter. This allows delivery of the oomycete gene into plants cells via the bacterium's type three secretion delivery mechanism. This vector carries gentimicin to allow antibiotic selection of transformed cells. The pEDV6 vector is a replication compromised plasmid that is unstable and lose in the absence of persistent antibiotic selection.

Origin & function

DC3000 transformants will be grown in liquid culture in volumes of no greater than 30 ml. Cultures will then be adjusted to an aproprite O.D (1 - 2.5) before infiltration of leaves using a 1ml syringe (without needle) or spray inoculation using a hand held atomiser. Infected plants will be analysed after 0-7 days. All plants and soil will be autoclaved at the end of the experiment (see section 12).
All activities will be performed and effectively contained within purpose built laboratories and growth rooms at Warwick HRI, The University of Warwick, Wellesbourne. Pseudomonas syringae bacteria are non-sporulating and can be readily contained using good microbiological practice.

The oomycete effectors may increase, decrease or have no effect on DC3000 virulence when it comes into contact with its host plants. The modified DC3000 isolates may be able to suppress/avoid the host's basal resistance response. Conversely, the introduced effector may act as an avirulence factor and trigger an R gene mediated resistance response in a normally susceptible accession.

Whether the modified DC3000 strains could infect a new host plant has never been tested but this is unlikely to happen, as a single effector, evolved to function in a specific plant-microbe interaction, is unlikely to happen, as a single effector, evolved to function in a specific plant-microbe interaction, is unlikely to overcome the reasons why the plant is a non-host to DC3000 in the first instance. For example, where DC3000 is unable to overcome the plant's passive defence mechanisms, such as a waxy cuticle, rigid cell walls and preformed antimicrobials or effector triggered immunity.

During escape this organism could potentially transfer the oomycete effector gene to other bacteria and possibly cause the undesirable spread of resistance to gentamicin. The likelihood of these hazards occurring is extremely low due to the use of the replication-compromised plasmid that is unstable and lost in the absence of antibiotic selection.

Evaluation of foreseeable effects

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y
Risk assessment approved by the Genetic Modification Safety Committee at Warwick HRI on 15/06/2009

Please enter comments on the GM safety committee on the risk assessment

Tick if you are claiming exemption from disclosure for section of the risk assessment

Animal Units  
Large Scale Activities  
Human Clinical Applications
Replication deficient lentiviral constructs encoding shRNAs will be used in the study of microtubule-associated proteins.

The production of cells deficient in microtubule-associated proteins or expressing mutant forms in order to study function. Also the production of microtubule-associated proteins with epitope tags or fluorescent proteins for live cell imaging and biochemical experiments.

Cell lines with a history of safe usage within the scientific community. Any primary cells used are isolated from sources held in a controlled environment and should therefore be free of pathogens. Any E.coli variants, cultured cells and replication-deficient lentivirus particles produced cannot survive outside the laboratory. Neither the generated virus particles nor the transduced cells are pathogenic to animals or plants.

Well characterised E.coli K12 derivates, such as TOP10. Lentiviral particles are designed for use in gene therapies and thus have the potential to infect human cells in vivo, however as none of the HIV-1 structural genes are actually present in the packaged viral genome, they are not able to propagate in vivo.

Lentiviral constructs encoding shRNAs targeted against murine microtubule-associated proteins will be transferred, using lentivirus, to cell lines. shRNAs will be used to bring about RNA interference, silencing the targeted genes and enabling studies on the function of microtubule-associated proteins. Other constructs expressing microtubule-associated proteins with epitope tags or fluorescent proteins.
will also be produced in order to allow live cell imaging and biochemical experiments.

**Evaluation of foreseeable effects**

inserts display no potential for a pathogenic phenotype. The likelihood of an environmental hazard is negligible as none of the particles produced can survive outside the laboratory. Neither the generated virus particles nor the transduced cells are pathogenic to animals or plants.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

not applicable

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All solid waste (tissues, gloves, plasticware) is autoclaved at 121 degrees Centigrade for 15 minutes (as measured in load) to give effectively 100% kill. Waste media is inactivated by addition of Virkon tablets to a final concentration of not less than 1% and left overnight. Manufacturer’s validation states 100% kill when left in contact with 1% Virkon for a minimum of 10 minutes.

Pipettes are decontaminated by complete submersion in 1% Virkon overnight, followed by autoclaving at 121 degrees Centigrade for 15 minutes (as measured in load) to give effectively 100% kill; Virkon manufacturer’s validation states 100% kill when left in contact with 1% Virkon for a minimum of 10 minutes.

If the use of glassware is unavoidable, this is decontaminated by complete submersion in 1% Virkon overnight. Manufacturer’s validation states 100% kill when left in contact with 1% Virkon for a minimum of 10 minutes.

### Project Additional Information

**Purposes of the contained use**

1. To ascertain the extent and significance of inactivation of the tumour suppressor gene p15 in childhood leukaemia.
2. To investigate the relationship between p15 and other known molecular abnormalities in childhood leukaemia.

**Recipient or parental organism**

GMMs generated from this activity have no foreseeable effects to human health or safety. The hosts are all disabled or non-colonising in humans and plasmid and cosmid vectors are non-mobilisable.

**Host/vector system**

</tbody>
</table>

**Origin & function**

| p15 is a known tumour suppressor involved in cell cycle regulation and its loss in human tumours is thought to contribute to the malignant phenotype. Overexpression of |
this gene leads to suppression of cell division and cell death. This activity involves the use of vectors containing several known oncogenes eg c-ABL (J Mol Appl Genet 1983;2(1):57-68) and chimeric gene products that have potential to induce increased cellular proliferation and have been shown to be leukaemogenic in in-vivo systems. Eg MLL/AF9 (EMBO J 1999 Jul 1;18(13):3564-74)

Evaluation of foreseeable effects

The host and vector systems used to generate the constructs present minimum risk to human health and safety and could be handled adequately as a class 1 activity under level 1 containment. However, as this project involves the generation of naked oncogenic DNA it will be subject to the appropriate containment and control measures for a class 2 activity and level 2 containment.

Although there is no direct evidence that contact with naked oncogenic DNA can lead to tumours in humans it is intended to incorporate measures which will limit accidental inoculation or transmission of these DNAs to the laboratory workers.

All experiments will be carried out in ADCP level 2 laboratories with emphasis on the following points in accordance with our local rules and recommendations given in ACGM Compendium of Guidance Part 2A - Annex III and Part 3A - Annex 1.

1. Gloves will be worn at all times and changed when working elsewhere.
2. Steps are in place to limit aerosol production and aerosol contamination (filter tips)
3. Limited use of sharps and glassware to avoid accidental inoculation.
4. Staff are aware of the hazards of handling oncogenic DNA.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste from GMMs will be handled according to our local rules. Bacterial cultures will be inactivated by chemical treatment with fresh Chloros for a minimum of 24 hours. All plastic disposables and gloves will be autoclaved and incinerated.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The risk assessment for this activity has taken into account the oncogenic potential of the DNA sequence to be inserted in the GMO. The activity has therefore been designated as Class 2. Suitable precautions to limit the risk of accidental inoculation of named oncogenic DNA are already practiced in the laboratories designated for Level 2 containment. All other working practices described are in accordance with our local rules.
Primary immunodeficiencies (PID) are congenital disorders that affect the function of the immune system. In recent years, a number of genes causing PID have been cloned, which has made gene replacement therapy for these diseases a realistic alternative for bone marrow transplantation. With increased knowledge of haematopoietic stem cell (HSC) biology and improved retroviral transduction protocols, it is now feasible to use onco-retroviral vectors for efficient corrective gene transfer into HSCs of affected individuals. Since transduced self-renewing HSCs are capable of reconstituting a complete immune system, this approach potentially provides a life-long cure of the disease.
HSCs isolated from cord blood, bone marrow or mobilised peripheral blood will be transduced ex vivo in a closed system with clinical grade retroviral supernatant.

**Host/vector system**

**Vector:** Moloney Murine Leukemia Virus (MoMuLV) based retroviral vectors, containing retroviral 5’ and 3’ LTRs, packaging signal and part of the gag gene, expressing full-length human cDNAs encoding wild type PID causing genes.

**Host:** Human CD34+ haematopoietic cells isolated from cord blood, bone marrow or mobilised peripheral blood.

**Origin & function**

MoMuLV based replication deficient retroviral particles pseudotyped with the envelope of Gibbon Ape Leukemia Virus (GALV), will be used to transduce human CD34+ cells. The GALV envelope has been shown to mediate efficient transduction of HSCs. Replication deficient retroviral particles were generated in packaging cell lines, which provided retroviral gag/pol and env helper functions in trans. The MoMuLV-based retroviral vector was introduced into the packaging cell independently and replication competent retrovirus (RCR) can only be generated after three independent recombination events, which is very unlikely to occur. The production of clinical grade retroviral supernatant, with all the required safety testing, was performed by a licensed commercial organisation.

In the vector, the retroviral genome is replaced by the cDNA encoding the appropriate corrective gene, whereas only 5’ and 3’ viral LTRs, the packaging signal and part of the gag coding sequence (for optimal protein expression) are still present.

Clinical grade retroviral supernatant is provided by a commercial organisation licensed to undertake such a process and has been tested extensively for the presence of RCR. The transduced CD34+ cells will be returned to the patient and the patient will be monitored over time for RCR.

**Evaluation of foreseeable effects**

The patient will be monitored extensively for the possible production of PCR, though as discussed, this possibility has been minimised by the use of packaging cell lines providing the gag, pol and env functions in trans. Expression of the inserted gene will be monitored by PCR, protein and functional assays. The inserted gene is not judged to be an oncogene or growth factor which could cause potentially harmful effects. The gene is unlikely to act alongside existing characteristics of the cell as to endow the cell with altered pathogenic properties.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

The work with CD34+ haematopoietic cells constitutes no higher risk than work with fresh blood or blood-related products. Patients will be screened for presence of pathogens prior to donation of cells.

To reduce the risk, all the work is performed in a Class II safety cabinet and cells will be grown in a closed system.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All processes will take place in a closed system inside a class II tissue culture cabinet.

The class II tissue culture cabinets will be swabbed with 70% IMS before and after use, and any spillages will be dealt with immediately using 1% Virkon followed by 70% IMS. In the event of a larger spill, paper towels will be used prior to disinfection.

All solid waste, such as discarded bags, pipettes, tips, towels, etc will be disposed of in autoclave bags. These will be removed when full and autoclaved prior to incineration.

The use of sharps (eg needles, Pasteur pipettes) will be avoided, however when use is unavoidable they will be safely disposed of using sharps bins.
These processes should give 100% kill.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The genetic modification safety committee was satisfied with the risk assessment and had no further comments.

Project Ref 133/01.6

Date Ackn’d 24/04/2012

CU2 Project Title INVESTIGATION OF PROTEINS THAT INERACT WITH THE TUMOUR SUPPRESSOR GENE P15

Class CultureVolClass2 CultureVolumeClass3-4

Class 2 < 1 Litre

Non-GMM Consent Granted Not Applicable

Tick if notifying a connected programme of work N

Project notified under transitional arrangements N
c-Jun Activation domain Binding protein (JAB1) and Geminal centre kinase Like Kinase (GLK) have been shown to interact with the tumour suppressor gene p15 in the yeast two-hybrid system. These nature and significance of these novel interactions will be tested in the mammalian system using both in-vitro and in-vivo techniques. 

In-vitro expression: Full length cDNA and partial constructs of GST-JAP1 and GST-GLK chimeric proteins will be expressed in bacteria and tested for interaction with endogenous p15 protein extracted from established human cell lines. Both proteins will also be transcribed and translated in-vitro using the rabbit reticulocyte system and tested for interaction with in-vitro translated p15. 

In-vivo expression: Full length cDNA and partial constructs of JAP-1 and GLK and p15 will be cloned into mammalian expression vectors and transiently expressed singly or in combination in established human cell lines.

Recipient or parental organism

Bacteria: JM109, SURE, DH5a
All bacterial hosts used in this study are K-12 derivatives and non pathogenic in humans. They are able to survive for short periods in the gut and lung of mammals but are non-colonising. They are able to survive for a similar time in the environment. The plasmid vectors used in this study express antibiotic resistance genes eg ampicillin or neomycin. The vectors are non mobilisable and are defective in one or more functions required to transfer to other hosts. Although transfer of antibiotic resistance to other bacterial hosts is possible, the likelihood is low.

Cell Lines: Hela, MM6, Jurkat, CEM
All human cell lines are established and characterised. Conditions for growth include maintenance at a constant temperature (37 degrees C) in low CO2. They are unable to survive outside these conditions. Both parental and modified cell lines present negligible risk to human health or the environment.

Host/vector system

Vectors  pGex-6p-2, pGEMT, pcDNA3.1, pEGFP-N1, pDsRed1-N1, pGADT7
Hosts  Disabled K-12 derived E.coli vectors: Sure, JM109, DH5a

Origin & function

All cDNAs are human in origin.
p15 full length and partial c-DNA sequences promotor region and exon 1 antisense cDNA. p15 is a known tumour suppressor involved in cell cycle regulation and its loss in human tumours is thought to contribute to the malignant phenotype. Although functional loss of p15 is associated with many human malignancies, there is no evidence to suggest that loss of p15 expression alone is a transforming event. Overexpression in mammalian cells can lead to cell cycle arrest or retardation of proliferation. JAB-1 full length and partial c-DNA sequences. JAB-1 is expressed in a wide range of normal cells and is involved in several signalling pathways involving gene transcription, (JNK), cell cycle control (p27) and integrin signalling. JAB1 is also known to regulate protein levels of the cell cycle regulator p27 by promoting its degradation. Overexpression may lead to cellular proliferation, apoptosis or differentiation.

GLK full length and partial c-DNA sequences. GLK is involved in cellular stress pathways (JNK). It is also expressed in a wide range of tissues. Overexpression may lead to growth retardation or apoptosis.

Evaluation of foreseeable effects

The non-mobilisable GMMs used for this study contain full length and partial cDNA sequences designed for maximum expression in mammalian cells and as GST fusion proteins in bacteria. They are propagated in bacterial hosts, which are disabled or non-colonising in humans. Should the bacteria or GMMs be accidentally released into
the environment their chance of survival is negligible and the potential to cause harm is effectively zero.

HUMAN HEALTH

Inserts into the pGEX vector are designed to be expressed as a fusion protein with glutathione-s-transferase (GST). The expressed proteins are unlikely to change the properties of the parental recipient. Inherent risks and outcomes are the same as the unmodified recipient. i.e. the risk to human health is negligible. Expression of single and multiple proteins from these genes in mammalian cell lines may alter their growth properties. The most likely outcomes are growth arrest and/or cell death. However, overexpression of JAB1 protein may lead to cellular proliferation in some instances. Over expression of either GLK or JAB1 may inhibit the regulatory nature of p15 allowing greater cell proliferation. Expression of antisense p15 is likely to have a similar effect. Accidental insertion of naked cDNA into humans may lead to limited protein expression, however normal immunological response would rapidly eliminate foreign DNA or protein. Modified cell lines present no additional risks or hazards compared with the parental lines.

CONTROL MEASURES

Accidental inoculation of CDNA sequences or gM cell lines into laboratory workers by stick injury or entry via cuts and abrasions may constitute a hazard and therefore use of needles and scalpels will be limited, cuts and abrasions will be covered and gloves will be worn at all times. All cell work is carried out in Class 2 Safety hoods and use of filter tips limits aerosol formation.

All experiments will be carried out in ADCP level 2 laboratories with emphasis on the following points in accordance with our local rules and recommendations given in ACGM Compendium of Guidance Part 2A-Annex III and Part 3A-Annex 1.

1. Gloves will be worn at all times and changed when working elsewhere.
2. Steps are in place to limit aerosol production and aerosol contamination (filter tips)
3. Limited use of sharps and glassware to avoid accidental inoculation.
4. Staff are aware of the hazards of handling potentially damaging cDNA.

GM human cell lines. Accidental inoculation of sequences into laboratory workers by stick injury or entry via cuts and abrasions may constitute a hazard and therefore use of needles and scalpels will be limited, cuts and abrasions will be covered and gloves will be worn at all times. **CU2 Project Title:** MECHANISMS OF MURINE HAEMATOPOIETIC CELL TRANSFORMATION AND APOPTOSIS

**Class:** Class 2

**CultureVol:** < 1 Litre

**Non-GMM Consent Granted:** Not Applicable

**Project notified under transitional arrangements:** N

---

### Project Additional Information

**Purposes of the contained use**

Apoptosis regulatory genes and oncogenes will be introduced into established mouse and human cell lines in order to study the effects of these genes on apoptosis and their transforming capacity. Disabled retroviral vectors will be used to transduce the cells with members of the Bcl-2-gene family and with the oncogenes, MLL-AF4, MLL-ENL, MLL-AF9, TEL-AML, and TEL-JAK2.
Recipient or parental organism

E. coli K-12 multiple auxotroph XL1-Blue bacteria will be used. These bacteria are unlikely to survive in the human gut, lung or elsewhere in environment and are non-pathogenic to humans. NIH-3T3, BafF/3 and s49.1 mouse cell lines and primary cells, 293T human cell line. The mouse and human cell lines used are all long-term established cell lines and present no apparent hazard to workers or the environment. Work with primary mouse cells constitutes no higher risk than work with fresh tissue. Animals will be screened for the presence of pathogens prior to the donation of cells. All cells will be grown in a closed system. Despite the possibility that some of the genetic alterations planned may confer growth advantages to the cells, the derivative cell lines would not survive outside the culture conditions (ie. in the environment) used for their propagation. In the extremely unlikely event, that the cells are accidentally introduced into humans the cells would be very unlikely to survive because host allo- and zeno-immune responses would lead to their total destruction.

Host/vector system

pcDNA3.1 and pBluescript plasmid vectors
The plasmid vectors used in this work will not cause expression of inserted genes in XL1-Blue cells and they are non-mobilisable or mobilisation-defective. It is envisaged that neither the original XL1-Blue cells nor their genetically modified derivatives will be harmful to humans, since the risks of the bacteria infecting and persisting in humans and/or transferring genetic information to other micro-organisms is very low.

pMSCV and pRwevTRE retroviral vectors. Both these vectors are disabled retroviral vectors since they do not contain the gag (structural), pol (reverse transcriptase/integrase) and env (coat glycoproteins) genes necessary for particle formation, infection and replication. Replication-incompetent retroviral particles will be made by transfecting the retroviral vectors into the ecotropic Phoenix-eco (ATCC) packaging cell line. This cell line has the gag, pol and env genes stably integrated in its genome. For both the gag-pol and the env constructs non-moloney promoters were used to minimize recombination potential and different promoters for gag-pol and env were used to minimise their inter-recombination potential. After transfection with disabled retroviral vectors, the Phoenix-eco cells produce ecotropic viral particles containing envelope proteins derived from the Moloney Murine Leukaemia virus, which are only capable of infecting murine cells. The Phoenix-eco cell line has been established as being helper-virus free). Recombination would also be limited since retroviral vectors would only be transiently transfected into packaging cell lines and the cells would be disposed of after virus harvest (48 hours after transfection), thus long-term culture of packaging cell lines containing retroviral vectors would be avoided. In the extremely unlikely event of a replication competent virus being made, this would only be ecotropic and thus would not infect humans.

Origin & function

The DNA sequences that will be used in the project belong to the Bcl-2 family of apoptosis regulatory molecules or are known and presumed oncogenes.

Gene sequences: Oncogenes MLL-AF4, MLL-ENL, MLL-AF9, TEL-AML, TEL-JAK2
Apoptosis regulatory molecules Bcl-2, BclXL, BclX, Bid, Bim, Bak, Bax, Bad

Evaluation of foreseeable effects

It is expected that the gene sequences will be active in mammalian cells and will affect their growth and differentiation characteristics. Measures to avoid accidental inoculation and transmission of these sequences to the laboratory workers will be adhered to. For these sequences to be dangerous to humans or other organisms in the environment, they would have to integrate into the genome of the organism in question. Although there is a small risk of this once the DNA sequences are introduced into bacterial and mammalian cells, the use of non-mobilisable and mobilisation defective vectors, disabled retroviral vectors and disabled bacteria will minimise this risk.

Although there is no direct evidence that contact with naked oncogenic DNA can lead to tumours in humans it is intended to incorporate measures which will limit accidental inoculation or transmission of these DNAs to the laboratory workers.

All experiments will be carried out in ADCP level 2 laboratories with emphasis on the following points in accordance with our local rules and recommendations given in AcGM Compendium of Guidance Part 2A - Annex III and Part 3A - Annex 1.

1. Gloves will be worn at all times and changed when working elsewhere.
2. Steps are in place to limit aerosol production and aerosol contamination (filter tips)
3. Limited use of sharps and glassware to avoid accidental inoculation
4. Staff are aware of the hazards of handling oncogenic DNA

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The work with the genetically modified primary cells and established cell lines constitutes no higher risk than work with the parental cells.

Work with these cells is performed in a Class II safety cabinet and cells will be grown in a closed system.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Please enter comments on the GM safety committee on the risk assessment

The risk assessment for this activity has taken into account the oncogenic potential of the naked DNA sequences to be inserted in the GMMs and GMOs. Activity has therefore been designated as Class 2. Suitable precautions to limit the risk of accidental inoculation of naked oncogenic DNA are already practiced in the laboratories designated for Level 2 containment. All other working practices described are in accordance with our local rules.

Under these conditions, the risk to the environment or human health from the GMMs is negligible.

<th>Laboratory Activities</th>
<th>Glass Houses</th>
<th>Growth Rooms</th>
</tr>
</thead>
</table>

02/03/2022
We are conducting a number of projects looking at inflammatory and immunological responses of human dendritic cell, neutrophils, endothelial cells in vitro to the organism Neisseria meningitidis. We will use genetically modified strains lacking a number of known virulence factors (lipopolysaccharide and capsule) to explore the relevance of their presence or absence on these responses.

Recipient or parental organism

Neisseria meningitidis serogroup B will be the recipient organism for this work. This is a gram negative organism which only infects humans. It is carried by up to 25% of the population, and can cause meningitis and/or meningococcal sepsis, particularly in children between 0-5 years, and young adults between 15-19 years old. Meningococcal disease (where there is both meningitis and sepsis) has a case fatality rate of approximately 10%. There is currently no vaccine for this serogroup.

Host/vector system

The strains are already transfected with linearised DNA containing an antibiotic resistance cassette, which results in the disruption of the gene of interest (lpxA and siaD).
These are stable transfectants and do not harbour transmissible plasmids. The kanamycin cassettes released from puc17 and the gene of interest is cloned in proprietary cloning vector pcr2.1. The gene is then excised by restriction digest and the antibiotic resistance cassette inserted. These are subcloned in E.coli, extracted and then linearised by restriction digest.

**Origin & function**

The bacterial strains to be used were generated by insertional inactivation of enzymes involved in the lipopolysaccharide biosynthesis and capsulation. In general all the mutant strains involve loss of virulence compared to the wild type parent strain. For example, one strain, ipxA (1) lacks any LPS, the major virulence factor in N.meningitidis. Other strains to be used include ipxA gene under control of an isopropyl-β-D-thiogalactopyranoside (IPTG)-inducible promoter allowing for controlled biosynthesis of LOS by the bacteria (2). In the presence of IPTG, this strain will have similar virulence potential to the wild strain but in the absence of external source of IPTG, bacteria harbouring sequence cannot produce LPS.

Another mutant strain, salD-, lacks the enzyme required for capsule biosynthesis (3). Almost all infection with N.meningitidis are due to capsulated strains therefore this mutant is of no greater virulence than wild type and potentially less.

The mutated strains will not be modified further in any way. These were kindly provided by Dr. Peter van der Ley from the National Vaccine Institute, RIVM, Bilthoven Netherlands. The description of the mutants are available in full in the following references:

They are only intended for in vitro stimulation work and will not be modified in any other way.

**Evaluation of foreseeable effects**

The genetically modified strains should have no more and probably less virulence potential than their wild type derived strains. For the purpose of the projects, they will be handled in the same fashion as the wild type organism.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

- Culture volumes will not exceed 40mls but in the main are only 5mls.
- Bacteria will be inactivated for use by 20 minute exposure to 2% paraformaldehyde, or heat inactivation at 560°C for 30 minutes. This is accepted practice in laboratories used to dealing with this organism. Testing for killing is not normally performed if equipment is functional; ie thermocouple thermometer in water bath is accurate and reagents are freshly prepared.
- Tissue culture incubated with live bacteria will be inactivated in either 2% formaldehyde or 4% paraformaldehyde. Liquid waste will be disposed of in 5% Hycolin (phenolic surface disinfectant), contained in pot within Class 1 cabinet. This is disposed of by laboratory staff at the end of each working day.
- Dry waste and agar plates are autoclaved.
- Sharps are incinerated.
- Small spills can be inactivated with squeeze bottle of 5% Hycolin allowed to soak for 30 minutes and mopped up with absorbent paper and autoclaved.
- All these waste management procedures are monitored and quality controlled in the Microbiology laboratory which has CPA accreditation.
All laboratory workers should have the necessary training and supervision on any work involving Genetically Modified Neisseria Meningitides and all safety precautions and measures should be placed in the laboratories carrying out this type of work. Furthermore, where possible, culture volumes should be kept to a minimum and all waste disposals should be treated with the appropriate detergent and disposed into designated clinical waste for incineration.

### Additional Information

- **Historical Significant Changes**
- **Historical Date of Additional Info**
In this research project we aim to identify genes that promote cell lethality in the most aggressive forms of neuroblastomas using shRNAmir library.

Neuroblastomas is a paediatric tumour that derives from primitive sympathetic neural precursors. Amplification of MYCN oncogene is very frequent in a neuroblastoma and is often associated with advanced disease stages with poor prognosis and resistance to therapy. Interestingly, overexpression of MYCN protein in non MYCN-amplified cells can sensitize cells to drug treatment and induce cell death. This could suggest that survival and growth of MYCN-amplified tumour cells relies on expression of genes triggered by MYCN overexpression. When certain gene becomes essential for cell survival in response to MYCN overexpression, this gene can be called "synthetically lethal" partner of MYCN. The mechanism of synthetic lethality is very attractive for the development of drugs that could selectively kill tumour cells, since targeting the synthetic lethal partner of MYCN will cause growth inhibition of MYCN-amplified aggressive tumour cells leaving normal cells relatively intact.

The shRNAmir library consists of over 70,000 pGIPZ individual lentiviral vectors. Each vector contains a unique hairpin sequence designed to target and reduce the expression of most/all genes within the human neuroblastoma cell lines with the shRNAmir library. We will follow the change in relative abundance of individual shRNA over time by microarray hybridization to detect genes essential for cell proliferation since shRNAs important to cell survival will disappear from the population. We will pick the candidate genes by comparing the lethality profile of MYCN-amplified and non MYCN-amplified neuroblastoma cell lines and will validate the candidates after screening using available human neuroblastoma cells. The group of genes common for MYCN-dependent synthetic lethality in several neuroblastoma cell lines will be selected as the potential clinical targets that can selectively kill MYCN-amplified neuroblastoma cells.

Recipient or parental organism

Recipient/Parental organisms:
• Bacterial E.coli strains - HB101, XL1-blue, Top10F, DH5alpha.

Associated risks and likeliness of occurrence:
The bacterial strains used are attenuated non-colonising strains so are incapable of causing human infection and are therefore harmless to humans.
The viral vector to be used will be pseudotyped with the envelope protein VSV-G from Vesticular Stomatis Virus so, if introduced into the body by injection, ingestion or through a wound, the virus could enter human cells and integrate into cellular DNA. Although the virus is replication incompetent (does not carry gag, pol or env genes) so it cannot make a new progeny virus and establish a productive infection, its insertion into cellular DNA could result in a potentially oncogenic mutation. The recipient cells are harmless to humans.
The viral vectors are replication incompetent so therefore can not self-replicate and transfer to another host so are harmless to the environment. The cell that will eventually receive and integrate the DNA cannot survive in the environment as they are only viable under culture conditions and therefore are harmless to the environment. The bacterial strains used are attenuated non-colonising strains that cannot survive outside culture conditions and are therefore harmless to the environment. The viral vectors are replication incompetent so therefore can not self-replicate and transfer to another host so are harmless to the environment. The cell that will eventually receive and integrate the DNA cannot survive in the environment as they are only viable under culture conditions and are therefore harmless to the environment.

Host/vector system

Lentiviral vectors:
Commercial pGIPZ vectors fro Open Biosystems.
**Lentiviral Gag/pol expression vectors p8.9, pPAX2 and derivatives (HIV-1). Viral envelope expression vector pMDG and derivatives (VSV-G).**

**Associated Risks and likelihood of occurrence:**
The viral vector used is a lentiviral vector that contains the CMV (PolI) promoter to drive expression of the hairpin cassette. The lentiviral vector does not contain the appropriate accessory elements to form a viral particle itself and therefore poses no harm to health and the environment. Packaging and envelope proteins are contained on two additional plasmids to the lentiviral expression vector and these plasmids must be introduced into the cell and expressed alongside the lentiviral vector for viable lentiviral particles to be produced.

Woodchuck hepatitis B virus post-transcriptional regulatory element (WPRE) sequence is also incorporated into the pGIPZ vector in order to enhance the stability and translation of the transcripts. This negates the need for rev in the lentiviral vector packaging systems and improves biosafety by eliminating lentiviral genes from the system. However, the WPRE has potential promoter activity and the potential to express part of the X protein from woodchuck hepatitis virus (WHV) which may be oncogenic. There is no direct experimental evidence of oncogenic activities of the truncated fragment of X protein. Moreover, there is low probability that it would be expressed from the X promoter that is present in the WPRE since many studies have suggested that the X promoter is not functional in the absence of a second enhancer, which is not present in the WPRE. There is possibility of expression directed from other promoter/enhancer at chromosomal integration sites as well as the possibility that truncated X protein fragment has oncogenic properties. However, the likelihood of this is very low.

**Origin & function**

The inserted RNAi hairpins are sequences that have been derived de novo and are not from an organism. The sequences contain a 22bp sense and antisense sequence that is homologous to the gene of interest to which the hairpin is designed. These sequences are separated by a small loop sequence and flanked by mir-30 sequences. When transcribed in the cell, the RNA will form a hairpin structure which will initiate a normal cellular in vivo downstream cascade of processing events in response to foreign cellular single-stranded RNA intruder molecules. This process results in the post-transcriptional down regulation of the gene to which the hairpin sequence is designed and targeted by destroying the corresponding mRNA molecules prior to translation. The utilization of this normal endogenous pathway to down-regulate genes of interest is known as RNA interference.

**Evaluation of foreseeable effects**

**Risks and likelihood of risks:**
- The bacterial strains to be used are non colonising and incapable of surviving in the environment or causing human infection. They pose no risk to users or the environment.
- None of the DNA viral vector plasmids are harmful to health or to the environment and do not supply a survival advantage to any microorganisms. The packaging viral components are from the HIV-1 virus. HIV-2 is harmful to humans, however, the packaging vector does not contain full length HIV-2 molecule. Many components of HIV-1 that are critical for HIV-2 infection have been removed from the packaging vector. Only those essential for viral packaging remain.
- The most dangerous GMM is the lentiviral preparations of pGIPZ particles and the most dangerous step is the collecton, concentration and use of this lentivirus, however this risk is minimal. Lentiviral vectors can infect human cells and therefore if introduced into the body by injection, ingestion or through a wound, the virus could potentially enter cells and integrate its genome into cellular DNA. If the inserted sequence were to be expressed in humans after accidental transfer the hairpin could lead to the down-regulation to the gene to which it targets via RNA interference. This could be a gene essential for growth regulation such as a tumour suppressor gene therefore resulting in a potentially oncogenic mutaion. Additionally, physical insertion of the virus into the genome of the host cell could potentially disrupt a tumour suppressor or oncogene, however the likelihood of this is very low. Theoretically the virus can also infect other mammalian cells and knockdown the gene of interest. However this is extremely unlikely as the hairpin is targeted to human genes and many hairpins are not homologous with the genes from other species. The overall risk is very low.
- Woodchuck hepatitis B virus post-transcriptional regulatory element (WPRE) in the pGIPZ vector has potential promoter activity and the potential to express part of the X protein from woodchuck hepatitis virus (WHV) which may be oncogenic. However, there is no direct experimental evidence of oncogenic activities of the truncated fragment of X protein and the likelihood that the expression of this protein would be directed from the promoter/enhancer at chromosomal integration sites in mammalian cells is very low. Any infection would not be severe as the virus is replication incompetent and therefore self-inactivating (does not carry gag, pol or env genes) so it cannot make new progeny virus and establish a productive infection. Also, it would only be a small number of cells and would not impact on the pathogenic outcome of an exogenous viral infection. Additionally, the viral particles are labile and do not survive on environmental surfaces outside the laboratory making infection unlikely.
- The cell lines used cannot survive outside the laboratory incubators and as such pose no threat to health or environment.
Precautions in place to minimize risks:
The Institute of Child Health is secured by restricted access at all entrances and additionally to all laboratory areas. Additionally, Molecular Haematology and Cancer Biology Unit has level 2 facility. All work involving viruses will be performed in class 2 cabinets in containment level 2 laboratories specified particularly for retroviral and lentiviral GMM work. All DNA plasmids containing viral proteins will be grown separately to avoid opportunity for recombination. To prevent contamination of workers by virus, when handling any GMM or GMM-derived DNA virus, no glass or other sharps will be used in the rooms where the viruses are prepared and used and workers will be protected by a lab coat and nitril gloves. Skin lesions will be covered with a bandage in addition to the protective wear described above. Specific guidelines will be in place to ensure all viral preparations are handled, labelled, stored, transported and cleaned up correctly. A separated clearly labelled compartment in the freezer to store viral supernatant will be used to prevent access to the stored materials for departmental staff and students, who are not involved in the project. All those involved in the project will be made aware of the guidelines and the associated risks as well as anyone else who may use the laboratory. Persons involved on project from other Institutes will work under the supervision of a competent trained worker from this project. No-one visiting the laboratory that is not involved in this work will work on this project. All persons entering the facility will be made aware of the safety precautions upon entering the facility. All equipment used in the level 2 laboratory will be available in other general purpose laboratories for general use so it should not be necessary for others who are not involved in retroviral or lentiviral work to enter the laboratory.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

1% Virkon (w/v) will be used to treat liquid waste (18 hours) and also used to decontaminate any spills and for disinfection of any reusable bottles or other equipment and laboratory materials used. Liquid waste is subsequently poured down the sink after treatment with Virkon. Work surfaces will be wiped down with 1% Virkon and 70% IMS after use. Virkon is certified by the PHLS to provide 100% vircidal and GMO kill under these conditions by denaturing and inactivating viral and cellular proteins. Virkon will be used with their lifespan to ensure required kill is achieved. Solid waste will be disposed of into biological waste bags, sealed and autoclaved 132º for 15 mins by trained staff then bagged in yellow biohazard bags and removed by UCL waste services. Autoclave runs are regularly validated by waste management staff.

### Project Additional Information

**Purposes of the contained use**

The aim of this project is to generate induced pluripotent stem (iPS) cells from mouse and human fibroblasts by employing lentiviral vectors coding for 4 reprogramming genes Sox2, Oct4, Klf4 and c-Myc. iPS cell technology has the potential to transform regenerative medicine especially in the areas of stem cell transplantation and patient-specific gene therapy. Briefly, mouse and human fibroblasts will be infected with 4 different lentiviral constructs and reprogrammed to become embryonic stem (ES) cell like cells which are known as iPS cells. Once generated, these cells can be expanded at will maintaining their undifferentiated pluripotent state and can be subjected to differentiation pathways eventually leading to the formation of terminally differentiated somatic cells. As for example, these iPS cells can be induced to become different kinds of blood cells. The efficiency of reprogramming is pretty low (0.01-0.05%) and to obtain sufficient number of iPS cell generation. Upon successful execution, the iPS cells generated from this project will help us to study various genetic defects either from murine disease models or from human patient samples and would be crucial in our therapeutic approaches.

**Recipient or parental organism**

E.coli disabled strains (e.g. DH5alpha), Mammalian cell lines (established, commercially available) and mammalian primary cells. Neither of these are pathogenic to humans, nor capable of survival in the environment.
Host/vector system

Prokaryotic plasmids, eukaryotic expression vectors, replication-deficient self-inactivating (SIN) lentiviral vectors,
The lentiviral vectors used are multi-attenuated meaning it is devoid of all potentially pathogenic HIV-1 encoded functions (1.2). In addition it is replication-defective which means that the vector cannot multiply on its own unless supplied by certain proteins in trans. It is self-inactivating which means that the viral promoter in the U3 region of the 5' LTR has been disabled by genetic manipulation. Only a very unlikely event of multiple recombinations during the process of generation of the viral vector can expose the person to a wild type HIV-1. The probability of such an event is extremely low.

Origin & function

Mus musculus, Homo sapiens sapiens

Production of transcription factors that will reprogram the somatic cells to become iPS cells

The vector sequences (sox2, oct4, klf4 and c-myc) code for oncogenic products which if accidentally transferred to a human host might cause tumour formation depending on the size of the inoculums but is most likely expected to be nullified by immuno-competent individual.

Sequences cannot cause harm if transferred to species in the environment; the donor organism is not pathogenic

Evaluation of foreseeable effects

The donor organism does not have apathological or harmful characteristics

Only a very unlikely event of multiple recombinations during the process of generation of the viral vector can expose the person to a wild type HIV-1. The probability of such an event is extremely low. The most hazardous GMM are the lentivirus vectors and the most hazardous step is the harvesting of the viral supernatant before infecting the target cells.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All GMMs are inactivated for disposal using standard biosafety level 2 procedures. Briefly, liquid and solid wastes are treated with PRESEPT effervescent disinfecting tablets (2.5g). All plastic ware used in tissue culture are autolaved. Work surfaces are decontaminated on completion of work or at the end of the day and after any spill or splash of viable material with disinfectants that are effective against the agents of concern. Proline and IMS are used which have been shown to be 100% effective in tissue-culture related decontamination.

**Project Additional Information**
Purposes of the contained use

To undertake gene therapy on autologous HSC from patients with Wiskott Aldrich Syndrome. The study is summarised below.

Phase 1/2 clinical trial of haematopoietic stem cell gene therapy for the Wiskott-Aldrich Syndrome
This is an open labelled, non-randomised, single centre, phase I/II, cohort study involving a single infusion of autologous CD34+ cells transduced with the w1.6_hWASP_WPRE (VSVg) lentiviral vector in up to 5 patients with WAS.

Primary Objectives
To safely administer a lentiviral gene therapy vector encoding the human WAS cDNA to stem cells from WAS patients.
To provide sustained engraftment of WASP-expressing transduced cells, reconstitution of humoral and cell mediated immunity, and correction of microthrombocytopenia

Secondary Objectives
To improve the overall health of the patient, including reduction in frequency of infections, resolution of autoimmunity, and improvement in eczema, reduction in bruising and bleeding episodes.
To evaluate the longitudinal clinical effect in terms of augmented immunity.

Recipient or parental organism

The lentiviral vector (LV) vector used in the proposed clinical trial is a 3rd generation replication-defective hybrid viral particle made by core proteins derived from Human Immunodeficiency virus type 1 (HIV-1) and the envelope of the unrelated Vescicular Stomatitis Virus (VSV). The transfer vector encodes the 12 exons of the human WAS cDNA under control of a 1.6 kb endogenous promoter sequence and leads to the integration of a 5.6 kb sequence.

Replication deficient lentiviral vector is used to transduce hematopoietic cells ex vivo. The GMP grade lentiviral vector will not be directly administered to patient.

Host/vector system

Lentiviral vector (w1.6_hWASP_WPRE (VSVg). There is no recommended International Nonproprietary Name (INN). The vector is pseudotyped with the VSV.G envelope.

The lentiviral vector is a 3rd generation replication-defective, self inactivating, hybrid viral particle made by core proteins derived from HIV-1 and the envelope glycoprotein of the unrelated Vescicular Stomatitis Virus (VSV). The transfer vector encodes the 12 exons of the human WAS cDNA under control of its native promoter. This lentiviral vector leads to the integration of a 5.9 kb proviral sequence into the cellular genome.

The system is based on 4 non-overlapping expression constructs in order to maximize the segregation of cis and transacting functions. The system is engineered in such a way that minimal homology regions are present between packaging and transfer vectors, thus minimizing the likelihood of homologous recombinational events and the generation of replication competent lentiviruses (RCLs).

In addition, the packaging construct is deleted of all HIV accessory proteins (vpu, vpr, nef, vif) and Tat. The conditional packaging system segregates gag/pol and rev genes in two separate plasmids. The Rev responsive element (RRE) maintained in the gag/pol plasmid makes the gag/pol gene expression rev dependant. As the transcripts of gag and pol genes contain cis acting repressor sequences, they are expressed only in the presence of Rev, expressed in trans on separate plasmid, which promotes their nuclear export and expression by binding to RRE.

The transfer vector codes for the therapeutic human WASP gene and for the sequences necessary for expression, incapsidation, reverse transcription and integration of the viral genome. RRE sequences permit the nuclear export and expression of the viral RNA. In order to minimize the risk of RCL generation, the 3' LTR of the transfer vector has been deleted in the U3 region. The introduction of this 400 bp deletion abolishes the production of full-length vector RNA in transduced cells by exploiting the reverse transcriptase mechanism which generates both U3 regions from the 3' of the viral genome, thus transferring the deletion to the 5' LTR of the proviral DNA. The lentiviral particle is therefore conceived with a self-inactivating mechanism that enables the production of infective particle only in the presence of accessory plasmids.

Origin & function

The human WAS protein (WASp) is expressed exclusively in haematopoietic cells where it functions as a regulator of actin cytoskeleton reorganisation by linking various
types of signals to Arp2/3-mediated actin polymerization. Two main molecular activators of WASP are Cdc42 and PIP2. In T cells, WASP is an essential component of the signal transduction cascade initiated by T cell receptor engagement contributing to the establishment of immunological synapse and T cell activation.

Risk of transfer to environmental species is negligible, and would not be expected to cause harm

**Evaluation of foreseeable effects**

The potential for harm is negligible. Work will be at level 2 containment.

All personnel involved in the ex vivo transduction of HSC at ICH/GOSH are trained in GMP cell processing procedures and there competency is assessed every 6 months. Sharps will not be used for the direct manipulation of vector.

A policy is in place for accidental needlestick injuries and can then be assessed via our hospital website (section 2.2.3 http: www.ich.ucl.ac.uk/clinical_information/clinical_guidelines/cpg_guideline 00121. A copy of the document is appended

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

NA

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Autoclave facilities are in an adjoining building. However, all waste will be double bagged and transported by the lab worker in accordance with a written operating procedure to the autoclave facility and this will be recorded in the batch manufacturing record. Sharps will be disposed of in appropriate puncture-proof containers.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

For routine cleaning all surfaces are wiped down with 70% ethanol after use. Liquid GMM waste is first disinfected using Sanichlor (effervescent chlorine tablets) to give a final concentration of 2500ppm chlorine overnight before being disposed of down the sink. This is a standard procedure and viability is below detectable levels. Any solid GMM waste is placed in autoclave bags, labelled with the department's name and autoclaved at the ICH. All sharps are placed in puncture-proof containers and disposed of through the central collection service for contaminated waste. All spillages are cleaned using 1% sodium hypochlorite or 70% ethanol.

External reviewer Prof F F, Rayne Institute, Kings College London has advised that the procedures outlined for this study should be undertaken under level 2 containment conditions.

The cell handling and transduction procedures have been approved by the NHRA

The site has been awarded a manufacturing licence for this project.

**Project Containment**
Kidney and urinary tract malformations are the commonest cause of end-stage renal failure in children, whilst progressive destruction of normal kidney tissues by cysts or interstitial fibrosis account for most cases in older patients. Very few of these conditions are monogenic but we have an increasing understanding of the processes involved in maldevelopment, cyst formation and fibrosis, which highlight potential targets for therapies. An example is the multifunctional lectin, galectin-3; this molecule is expressed in normal collecting ducts in the developing kidney and exogenous therapy reduces growth of collecting duct-derived cysts in vitro.

Lentiviruses are excellent tools for gene delivery, due to their relatively large packaging capacity and ability to infect a wide range of cell types when coated with different envelopes. Gene therapy requires a functional version of a gene to be delivered and then expressed over long periods. The aim of this project is to develop lentiviral vectors to modulate galectin-3 in the kidney.

Recipient or parental organism
E. coli disabled strains (e.g. DH5alpha)
Mammalian cell lines (established, commercially available such as human embryonic kidney 293 cells, renal proximal tubular epithelial cells, inner medullary collecting duct cells and Madin-Darby kidney cells) Mammalian primary cells (primarily kidney-derived, such as glomerular, proximal and collecting duct cells, and human fetal renal progenitor cells)
Whole kidneys in organ culture

Mice strains

The bacteria and recipient cells used in this project are not hazardous to human health because they are incapable of causing human infection. Nevertheless, we will still maintain the highest standards to prevent accidental spillage or splashing of workers, and ensure that the equipment is cleaned and disposed of correctly. The infected mice are no greater than normal animals because the virus is not shed; hence standard animal handling precautions will be used. These currently include a gown, protective clothing, gloves and masks (to reduce mouse allergen exposure of the workers). Injection involves use of a needle which would be hazardous in a mobile, mature mouse. However, we use newborn mice which are easily immobilised by hypothermia, and the injection procedure is then carefully controlled by two workers - one places the needle into the vein and holds it in position whilst the other does the injection. These procedures will be done in quiet rooms with limited access, that meet containment level 2 standards, using disposable materials that will be removed at the end of the procedure. The area will then be cleaned and signed off as ready for future work by our personnel.

Recombinant (inactivated non-replicating) lentiviral vectors. Replication deficient lentivirus particles are generated in cell lines following co-transfection of three different plasmids. These supply the self-inactivating transfer vector containing galectin-3 and viral long terminal repeat (LTR) (but lacking any expression of HIV genes; packaging and structural proteins, gag/pol; and envelope (env), vesicular stomatitis virus g (VSV-g). The vector itself is self-inactivating due to a deletion in the promoter enhancer region of the 3LTR. The only expression from the vectors is of the transgene cDNA, controlled by an internal promoter such as SFFV. Galectin-3 mRNA has been cloned into a VSV-G pseudotyped HIV-1-based vector by GeneArt, a commercial biotechnology company. This strategy is similar to the production of Mertk as described in Tschemutter M et al. Gene Ther. 2005 12:694-701.

There is a finite (albeit very small) risk that lentiviral vectors could infect human cells, but we will be using multi-attenuated lentiviruses that are replication incompetent because they lack the gag, pol or env genes. Hence, they are unable to spread even if workers are accidentally exposed by injection, ingestion or through a wound; risk of entry through these routes will be limited by wearing appropriate labwear and gloves, and completely covering open wounds. Although replication incompetent, lentivirus could theoretically insert into cellular DNA and this might result in a potentially oncogenic mutation. The infection with high titre lentiviral vectors encoding growth promoting molecules and selection in vivo for cells with altered growth potential. No adverse affects have ever been described through he accidental exposure to retroviral vectors. The major risks in this project are when the lentivirus is being prepared and then injected but this will be done into immobilised mice by experienced staff, in quiet CL2 standard rooms, wearing a laboratory coat and latex or nitrile gloves.

Origin & function

Gene Sequences: cDNAs encoding human and wild-type and modified galectin-3

Origins and functions of the genetic material involved: Galectin-3 is a lectin that modulates cell adhesion, differentiation and proliferation. It is normally expressed during mammalian development in the kidney, and reactivated in diverse diseases. We predict that increased galectin-3 will reduce the severity of cyst formation and fibrosis in vivo.

Will the sequences cause harm if expressed in humans? Galectin-3 is involved in multiple cellular processes including cancer but the lectin does not have any direct oncological effects by itself, indeed treatment with recombinant galectin-3 protein has been shown to reduce cancer metastases in mice models and the severity of several other renal diseases. Therefore, any accidental increased expression of galectin-3 is unlikely to have any detrimental effects on humans.

Will the sequences cause harm if transferred to the environment? Galectin-3 is a naturally occurring lectin and therefore highly unlikely to cause environmental harm. The potential routes of transmission or escape to the environment of the virus that may occur are known (air or liquids) and full protective measures will be taken to minimise or prevent the access of the virus to other organisms and the environment.

Evaluation of foreseeable effects

The biggest potential harm would be accidental transfer and overexpression of galectin-3 in humans by needlestick injury when the virus is being injected. These risks will
be reduced by carefully controlling the mice, procedure and environment for the injection. We use new born mice which are easily immobilised by hypothermia, and the injection procedure is then done by two workers - one places the needle into the vein and holds it in position whilst the other does the injection. Dr ***, will teach us how to do this procedure and he has already done this over a thousand times without mishap. Even with accidental human injection, the risks are minimal because we are using multi-attenuated lentiviruses which are unable to spread in humans even if they do infect cells.

In addition, we have in place in association with UCL Biological Services various specific control measures for the lentivirus experiments to minimise exposure and have completed a separate risk assessment for all personnel involved in the animal work. The general work will be performed in a containment level 1 environment but preparation work with virus handling will be in level 2 safety cabinets and injection will be in a quiet room that meets CL2 requirements; personnel involved with the virus work will wear gloves, glasses and a mask.

In the case of a laboratory accident, such as defective/leaking plasticware or dropped samples leading to viral spillage, all the necessary procedures will be applied to eliminate any potential hazardous effects of the virus in the environment. These include: wash with virkon, detergents, and disinfectants. Both wild-type and optimised lentiviruses are sensitive to UV, temperature and other physical agents so their chances of survival are low. All of the liquid waste will be treated with virkon and autoclaved; solid waste will be autoclaved and disposed as biohazard materials.

In the case of a needlestick injury, we will contact occupational health immediately or attend an Accident and Emergency Department immediately to assess injury and treatment required for the penetrating wound. Risks from viral inoculation are minimal as described above.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

1. 5% Virkon or equivalent PHLS certified treatment will be used to treat liquid waste (18 hours) and also any spills and for disinfection of equipment and laboratory materials. Work surfaces will be wiped down with this and 70% ethanol after use. Sharps will be placed in sharps bins that will be autoclaved.

2. 199%

3. Virkon is certified by the PHLS to provide 100% viridical kill under these conditions. Additionally, we will ensure that only in-date products are used to maintain optimal efficiency. Autoclave runs are regularly validated by waste management staff.

4. Solid waste will be double-baged in biological waste bags and sharps in sharps bin. Both are autoclaved at 132°C for 15 minutes, then collected for disposal (usually incineration) by the contractors employed by ICH to handle potentially infectious clinical waste.

The shRNAmir laboratory is available from Open Biosystems through UCL, and consists of over 70,000 individual E. coli glycerol stocks containing the pGIPZ lentiviral vector. Each stock contains a unique hairpin sequence within the pGIPZ vector designed to target and reduce expression of most/all genes within the human genome via RNAi interference. We will also use other selected shRNA sequences that we will clone into either pGIPZ or another lentiviral vector, pLL3.7, ourselves in case hairpins from the Open Biosystems stocks are ineffective, or if knockdown in non-human cell lines is required.
This project will involve maintenance, storage and use of this shRNAmir library for use in various projects. Specifically, this project will involve lentiviral production from either pGIPZ or pLL3.7 plasmids and the subsequent use of this lentivirus in cell based screening functional assays. Additionally, clones will be pooled at the bacterial, DNA and viral level to make various intermediate pools of clones to be used to transduce cells in screens and subsequently undertake functional assays.

The bacterial strains used are attenuated non-colonising strains so are incapable of causing human infection and are therefore harmless to humans. The viral vector to be used will be pseudotyped with the envelope protein VSV-G from Vesticular Stomatitis Virus so, if introduced into the body by injection, ingestion or through a wound, the virus could enter human cells and integrate into cellular DNA. Although the virus is replication incompetent (does not carry gag, pol or env genes) so it cannot make new progeny virus and establish a productive infection, its insertion into cellular DNA could result in a potentially oncogenic mutation. The recipient cells are harmless to humans.

The recipient cells are harmless to humans.

The bacterial strains used are attenuated non-colonising strains that cannot survive outside culture conditions and are therefore harmless to the environment. The viral vectors are replication incompetent so therefore cannot self-replicate and transfer to another host so are harmless to the environment. The cell that will eventually receive and integrate the DNA cannot survive in the environment as they are only viable under culture conditions and therefore are harmless to the environment.

**Host/vector system**

<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>The viral vector used is a lentiviral vector that contains the CMV (Pol II) promoter to drive expression of the hairpin cassette. The lentiviral vector does not contain the appropriate accessory elements to form a viral particle itself and therefore poses no harm to health and the environment. Packaging and envelope proteins are contained on two additional plasmids to the lentiviral expression vector and these plasmids must be introduced into the cell and expressed alongside the lentiviral vector for viable lentiviral particles to be produced.</td>
<td></td>
</tr>
</tbody>
</table>

**Origin & function**

| The RNAi hairpins are sequences that have been derived de novo and which are not derived from known sequences with both a sense, antisense and loop sequence to form a RNA hairpin when transcribed which will initiate a downstream cascade of events leading to knockdown of the target gene to which the hairpin was designed. |
|---|---|
| The accessory proteins are from the HIV-1 virus. |
The hairpin sequence will be transcribed and the RNA will then form a hairpin structure. The hairpin structure will induce a normal cellular in vivo downstream sequence of processing events in response to foreign cellular single-stranded RNA intruder molecules that will result in the post-transcriptional down regulation of the gene to which the hairpin sequence is targeted.

If the inserted sequence were to be expressed in humans after accidental transfer the hairpin could lead to the down-regulation of the gene to which it targets via RNAi interference. This could be a gene essential for growth regulation such as a tumour suppressor gene therefore resulting in a potentially oncogenic mutation. This, however, would not be severe as the virus is replication incompetent and therefore self-inactivating as none of the structural genes are actually present in the packaged viral genome, such that no new virus can be produced and no other cells can be infected. Physical insertion of the virus into the genome of the host cell could potentially disrupt a tumour suppressor or oncogene, however the likelihood is very low.

VSV-G pseudotyped lentivirus can only infect mammalian cells. Potentially the hairpin could be expressed in another mammalian species and lead to the down-regulation of a growth regulatory gene such as a tumour suppressor gene resulting in a potentially oncogenic mutation. This, however is extremely unlikely as the hairpin is targeted to human genes and many hairpins are not homologous with the genes from other species. If the hairpin were to target and lead to the reduction of a gene via RNA interference it would not be severe as the virus is replication incompetent and therefore self-inactivating as none of the structural genes are actually present in the packaged viral genome so no new virus can be produced and no other cells can be infected.

The envelope protein is VSV-G from the Vesticular Stomatitis Virus so, if introduced into the body by injection, ingestion or through a wound, the virus could potentially enter cells and integrate into cellular DNA. Although the virus is replication incompetent (does not carry gag, pol or env genes) so it cannot make new progeny virus and establish a productive infection, its physical insertion into cellular DNA could result in a potentially oncogenic mutation. This would be a very unlikely event and if so only a very small number of cells and would not impact on the pathogenic outcome of an exogenous viral infection. The packaging viral components are from the HIV-1 virus. The full length HIV-1 virus is harmful to humans, however the packaging vector used does not contain the full length HIV 1 molecule. Many components of HIV-1, that are critical for HIV-1 infection but not required for viral packaging, have been removed so the virus is attenuated.

The de novo hairpin donor sequences could potentially be expressed in cells and lead to the knockdown of certain genes leading to the increase of oncogenic potential of the virus. This would, however, only be a very small number of cells and as the virus is replication incompetent and cannot make new viral progeny, it would not impact on the pathogenic outcome of an exogenous viral infection.

This would, however, only be a very small number of cells and as the virus is replication incompetent and cannot make new viral progeny, it would not impact on the pathogenic outcome of an exogenous viral infection.

The most dangerous GMM, is the lentiviral preparations of pGIPZ particles. The most dangerous step is the collection, concentration and use of the lentivirus.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

2.5% Trigene advance or Virkon (v/v) will be used to treat liquid waste (18 hours) and also used to decontaminate any spills and for disinfection of any reusable bottles or other equipment and laboratory materials used. Liquid waste is subsequently poured down the sink after treatment with Virkon. Work surfaces will be wiped down with 5% Trigene advance and 70% ethanol after use. Virkon and Trigene advance are certified to provide 100% vircidal and GMO kill under these conditions by denaturating and inactivating viral and cellular proteins. Trigene advance and Virkon will be used with its lifespan to ensure required kill is achieved. Solid waste will be double bagged in biological waste bags, sealed and autoclaved 132°C for 15 mins by trained staff then bagged in yellow biohazard bags and removed by UCL waste services. Autoclave runs are regularly validated by waste management staff.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Date Ackn'd 24/04/2012

Date Project Ceased

CU2 Project Title Immortalization of human cells

Class CultureVolClass2 CultureVolumeClass3-4

Class 2 < 1 Litre

Non-GMM Consent Granted
Purposes of the contained use

The aim of this project is to immortalize human cells (e.g. skeletal muscle derived myoblasts and stem cells, blood-derived stem cells and fibroblasts). Cells will be prepared from normal individuals and from patients with neuromuscular diseases (e.g. Duchenne muscular dystrophy). Myogenic cells have a limited life span in culture, which prevents their expansion to sufficient numbers for experimentation and seriously limits any potential use in cell replacement or ex vivo gene therapy. An immortalization protocol for normal human cells (e.g. myoblasts) would allow one to isolate cellular models from various neuromuscular diseases, thus opening the possibility to develop and test novel therapeutic strategies. We intend to use a method developed by M and colleagues (names removed. Aging cell. 2007 Aug; 6(4):515-23. Epub 2007 Jun 8: names removed Biochem Biophys Res Commun. 2009 Oct 16;388(2):333-8. Epub 2009 Aug 6). Cells will be infected with lentiviruses coding for hTERT and cdk-4, selected by antibiotic resistance, expanded in culture and stored in liquid nitrogen. Immortalized cells will be stored and distributed under the auspices of the MRC Centre for Neuromuscular Diseases Biobank.

Recipient or parental organism

HIV.PGK.Puro.CMV.hTERT
HIV.PGK.Neo.CMV.cdk4
Human myoblasts, fibroblasts and stem cells.

The lentiviral vectors used are multi-attenuated, meaning they are devoid of all potentially pathogenic encoded functions. In addition the are replicon-defective which means that the vector cannot multiply on its own unless supplied by certain proteins in trans. It is self-inactivating which means that the viral promoter in U3 region of the 5' LTR has been disabled by genetic manipulation. Only a very unlikely event of multiple recombinations during the process of generation of the viral vector can expose the person to a wild type HIV-1. The probability of such an event is extremely low.

The intended recipient organisms are not capable of independent survival in the environment and will not infect or transfer to other hosts.

Host/vector system

HIV-derived lentiviruses, prepared in 293 Cells:
HIV.PGK.CMV.hTERT
HIV.PGK.Neo.CMV.cdk4

The lentiviral vectors used are multi-attenuated, meaning they are devoid of all potentially pathogenic encoded functions. In addition they are replication-defective which means that the vector cannot multiply on its own unless supplied by certain proteins in trans. It is self-inactivating which means that the viral promoter in the U3 region of the 5' LTR has been disabled by genetic manipulation. Only a very unlikely event of multiple recombinations during the process of generation of the viral vector can expose the person to a wild type HIV-1. The probability of such an event is extremely low.
WPRE is not present in either lentivirus.

**Origin & function**

Mus musculus, Homo sapiens sapiens

Lentiviruses - can infect human cells.
Puro and Neo - antibiotic resistance genes.

H-TERT - catalytic subunit of telomerase, that lengthens telomeres in DNA strands. Expression of telomerase bipasses telomere-dependent senescence so that cells that would otherwise become postmitotic and undergo apoptosis exceed the Hayflick limit and become potentially immortal.

Cdk4 is the catalytic subunit of the protein kinase complex that is important for cell cycle G1 phase progression; its expression prevents p16INK4a-associated premature growth arrest.

Cdk4 therefore extends life span and immortalization is induced by hTERT.

There would be a risk of cell immortalization if cdk-4 and h-TERT were introduced into human cells.

The risk of transfer to species in the environment is negligible, but would be a risk of cell immortalization if cdk-4 and h-TERT were introduced into human cells.

The lentiviruses are HIV-derived, but are replication-deficient, therefore represent a low risk.

The donor organism has no pathological or harmful characteristics

**Evaluation of foreseeable effects**

The lentiviruses are HIV-derived, but are replication-deficient, therefore represent a low risk.

The donor organism has no pathological or harmful characteristics.

Only a very unlikely event of multiple recombinations during the process of generation of the viral vector can expose the person to a wild type virus. The probability of such an event is extremely low. The most hazardous GMM are the lentivector viruses and the most hazardous step is dealing with concentrated viral stocks before infecting the target cells.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All GMMs are inactivated for disposal using standard biosafety level 2 procedures. Briefly, liquid waste is treated with 1% Virkon. Work surfaces are decontaminated on completion of work, or at the end of the day, or after any spill or splash of viable material, with 1% Virkon. Virkon has been shown to achieve 100% GMO kill when used as directed. After decontamination, liquid waste is disposed of via the sink. Solid waste is double-bagged in biological waste bags, sealed, transported to the autoclave,
autoclaved and then removed by waste services

A representative group of the UCL Institute of Child Health GMSC has reviewed this project, and the forms being amended according to their recommendations, agrees this work should be classified as an activity class 2 (AC2) notification.

Project Ref 14/01.1

CONSTRUCTION AND PRE-CLINICAL TESTING OF MODIFIED FORMS OF HERPES SIMPLEX VIRUS FOR VACCINATION PURPOSES (PROJECT TRANSFERRED TO GM 785)

Class 2

Non-GMM not applicable

Project notified under transitional arrangements
**Purposes of the contained use**

Construction and pre-clinical testing of modified forms of herpes simplex virus for vaccination purposes.

**Recipient or parental organism**

Herpes simplex virus strains with attenuating mutations but in which replication competence is retained. Attenuating mutations remove HSV genes, which usually inhibit immune responses and also render the virus non-pathogenic. These genes are VHS and/or ICP47 and may additionally include further mutations in ICP34.5, UL43, U35 and/or vmw65. The modified HSV strains also have genes encoding non-HSV antigens inserted (from infectious disease causing agents or which are selectively expressed in tumour cells) and may additionally have inserted genes encoding immune modulatory molecules such as cytokines and chemokines.

The work aims to include immune responses to the delivered antigens and to untoward effects are anticipated. The mutations to the virus have previously been shown to render the virus non-pathogenic and the genes to be delivered are not anticipated to be harmful according to previous work published in the literature.

**Host/vector system**

Herpes simplex virus 1 or 2.

**Origin & function**

Inserted genetic material is of either human or rodent origin and has been cloned by PCR or obtained from collaborators in plasmid form. Genes to be inserted include tumour antigens such as MART-1, MAGE-1, tyrosinase, gp100, Her2neu, Muc-1, PS1, CEA for the development of antitumour vaccines. Antigens from a variety of infectious agents for vaccine development purposes will also be used as will human or rodent forms of various immunomodulatory molecules eg GM-CSF, IL12, CD40L, B7.1, RANTES. The immunomodulatory genes are aimed at the enhancement of the immune response to delivered antigens.

**Evaluation of foreseeable effects**

None of the genes to be inserted are anticipated to result in harmful effects.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

All waste generated during the activity that has been in contact with the GMM will be treated with a Virkon solution. This broad spectrum disinfectant is effective against herpes simplex virus at a 0.5% (w/v) concentration giving terminal disinfection after 10 minutes of contact.

After treatment with the above disinfectant, the waste will then be placed into clinical waste bags and burnt offsite.

**Is an emergency plan required according to regulation 20?**

N

**If yes, tick to confirm that it is attached to this form**

N
The GMSC opinion is that the viruses to be used are probably Class 2, although as the risks are low, Class 1 could be considered appropriate.

Non-GMM Consent Granted: not applicable

Project notified under transitional arrangements: N

Historical Significant Changes

Project Additional Information
Purposes of the contained use

Retrovirus vectors based on an oncovirus, murine leukaemia virus (MLV), or lentiviruses, such as human immunodeficiency virus and equine infectious anemia virus, are promising tools for gene therapy. We aim to develop more efficient and safer vector systems. Better understanding of retrovirus biology, namely how retroviruses interact with host cells and how retrovirus genes function, will lead to such improved vector systems as well as insights into prevention of virus infection, treatment for retrovirus diseases.

Recipient or parental organism

Cells:
Mammalian cell lines: human TE671, HT1080, Hela, Raji, 293, 293T, mink Mv-1-Lu, dog D17, Cf-2-Th, cat CCC, CRFK, mink Mv-1-Lu, mouse NIH3T3, balb/c3T3, MDTF, rat NRK, HSN, pig PK15, PAE, ST-IOWA cells.
Avian cells include quail QT6 and chicken CEF cells.
In addition, primary human, pig, mouse and rat cells may be used, but not of the origin of any worker at Room 302B.

Viruses:
Mammalian type C viruses
which infect human cells in vitro, but not known to infect humans;
porcine endogenous retrovirus, cat endogenous retrovirus RD114, gibbon ape leukemia virus, amphotropic/xenotropic/ polytropic murine leukemia viruses, feline leukemia viruses, baboon endogenous retrovirus Murine type C virus which does not infect human cells: ecotropic murine leukemia virus.

Host/vector system

1. Mammalian cell cultures/Mammalian type C viruses
2. Mammalian cell cultures/Retrovirus vectors based on MLV, HIV and EIAV
3. Culture cells/Cloning plasmids, (lambda) derived disabled phage vectors, eukaryotic expression plasmids, retroviral cDNA expression vectors.
4. Animal retroviruses which are not human pathogen/Cloning plasmids

Origin & function

1. MLV, HIV, EIAV-based vectors with markers: lacZ, green fluorescence proteins (gfp), and neomycin, puromycin, phleomycin resistance genes
2. MLV vectors containing SV40 T-Ag, polyoma virus T-Ag, the catalytic component of human telomerase and marker genes.
3. Cellular genes, unlikely to be oncogenic. Protein tags include green fluorescent proteins, His/myc/flag tags, bacterial lacZ.
4. Genes from animal retroviruses which are not human pathogen: Retrovirus-like sequences endogenous to mammalian cells, including humans. Protein tags including green fluorescent proteins, His/myc/flag tags, bacterial lacZ.

Evaluation of foreseeable effects

The major risk associated with culture cells producing whole, infectious viruses is the possibility of infection of laboratory workers. Pseudotyping is unlikely to cause risk additional to that of RCV, which were classified as non-pathogenic Group 1, by GMAC committee at our former institute, Institute of Cancer Research in 1995. It is proposed to carry out this work at the containment level 2 handling culture cells in Class II safety cabinet with air-circulation through double filters. Although there is no reason why recombinant, replication-competent viruses should be more pathogenic than biological isolates, this possibility cannot be totally excluded. All work with these engineered viruses will therefore be carried out at level 2 containment in Class II safety cabinet with air-circulation through double filters.

The major risk associated with retrovirus vector production and subsequent transduction is occurrence of replication competent, recombinant viruses (RCR). Although a minimum of 3 recombination events are necessary to produce RCE in these systems, this possibility cannot be totally excluded. While RCR derived from HIV and EIAV vectors may cause harm for humans and environment (HIV is ACDP Hazard Group 3 and EIAV is MAFF regulated). It is therefore proposed to carry out this work at the containment level 2 handling culture cells in Class II safety cabinet with air-circulation through double filters and vector preparations and transduced cells will be rigorously tested for the absence of replication competent virus.
Viral T-Ag and the catalytic component of human telomerase are capable of expanding the life span of and/or immortalising certain mammalian somatic cells. Transduction of cells with both viral T-Ag and the telomerase component is likely to immortalise human primary cells in an efficient manner (P.Jat, personal commun.), but the effect in non-human cells is less clearly predicted. As this combination per se results in cell immortalisation, but not cell transformation, accidental transduction of small number of lab workers' cells is unlikely to cause neoplasia, although this possibility cannot be totally excluded. Widely used marker genes are unlikely to be toxic/oncogenic/allergic when expressed in eukaryotic cells.

Retrovirus vectors may undesirably activate cellular genes by insertion mutagenesis. Retroviral cDNA library may contain cDNA for growth factors/oncogenes/allergens. Accidental injection into workers may result in undesirable expression of the above genes.

No gene of the source viruses or protein tags has been shown to be oncogenic or allergic. Replication competent viruses will be produced by transfection of full-length virus genomes or multiple plasmids containing a full set of viral genes. There is no additional risk of such recombinant viruses compared with biological virus isolates. Most of these replication competent viruses have been handled in either Cat 1 or 2 laboratories in our former institute, Institute of Cancer Research. It is highly unlikely that a hybrid or tagged infectious viruses are more harmful than their parent viruses.

## Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

### SOLID WASTE DISPOSAL

Laboratory workers are responsible for the follow procedures:

a) the waste is collected in an autoclavable bag which is supported in a flip top white bin.

b) when 2/3rds full the bag is inserted into a 2nd bag and both bags are tied with a blue elastomere band.

c) a piece of autoclave tape is stuck to the outside of the bag.

d) the bag is placed in blue wheely bin.

It is the responsibility of laboratory workers that waste is completely contained before insertion in the blue bin. If bags split or tear a further 2 bags must be used to ensure safe transfer to autoclave.

Wash up staff are responsible for the following steps in the disposal process:

a) the waste is transported in the blue wheely bins to the autoclave room. Waste bags must be transported in a bin - under no circumstances can they be carried by hand to the autoclave room.

b) wearing gloves, the bags are transferred to the autoclave and inserted in the stainless steel bins.

c) remove gloves, discard in yellow waste bag.

d) close the autoclave door and run cycle 3 which is the validated discard cycle.

e) at end of cycle check cycle has operated successfully by checking the display for "finish" light on and no fault lights showing.

f) open autoclave and, wearing insulated gloves, remove waste bags and check autoclave tape has changed (black stripes).

g) transfer waste bags to yellow bags, seal the bags and leave in area for collection by cleaning staff.

h) empty liquid waste from autoclave bins by discarding down the sink with hot water tap running.

### LIQUID WASTE DISPOSAL

Liquid waste is disinfected with DS607 at a final concentration of 5%. Leave overnight before discarding down sink.
These risk assessments were considered at a meeting of the GMSC held on 5 April 2001. The committee, having taken advice from its Advisers, approved the risk assessments as declared by the research group subject to the three amendments indicated and attached to the risk assessments for experiments numbered 603, 604, 606, 607, 609 and 610. The committee noted that the work would be conducted in a containment level 2 laboratory.

**Project Additional Information**

**Purposes of the contained use**

Cloning cellular factors essential for retrovirus replication will improve the design of retroviral vectors for gene therapy and will help developing anti-retroviral drugs. The interaction between virus and cellular factors may be blocked by small synthetic compounds hence reducing virus spread in humans and animals. On the other hand, cellular factors may be targeted by replication-incompetent viral vectors to improve efficiency of therapeutic gene delivery in gene therapy applications.

**Recipient or parental organism**

For this type of research only replication incompetent retroviral vectors are used. Vectors are based on human immunodeficiency virus type-1 (HIV-1) and Moloney murine leukaemia virus (MoMLV). All viral coding regions have been deleted and are provided in trans by packaging cells. Retroviral vectors are made by 3 separate components: core-enzyme proteins, envelope, vector genome. The core enzyme and envelope plasmids are provided in trans and cannot be packaged in the viral particle. Thus, the viral particle will contain the vector genome only and will be unable to replicate. The use of split core-enzyme and envelope plasmids will reduce the chances of recombination to almost zero. To further reduce the risk of recombinant virus spreading, cells will be screened periodically by polymerase chain reaction (PCR) and reverse transcriptase (RT) assay for the presence of recombinant virus.

Vectors will contain marker genes like GFP or LacZ that cause no harm but may induce some degree of immune response in animals or humans. Viral vectors will be used to infect a variety of cell lines and primary cells from different species including: human, african green monkey, mouse and rat. All infections will be carried out in contained hoods. The presence of pathogens in primary cell donors will be screened beforehand by the appropriate hospital facility. Cell lines are periodically screened for mycoplasma contamination.

**Host/vector system**

**TISSUE CULTURE**

Hosts: mammalian cell lines include TE671, HT1080, AmpliGPE, PA317, TECelB, HeLa, 293, 293T, COS7, NIH373, musdunni, Simian lung fibroblasts, simian kidney epithelial cells (MAFF licence pending for these simian cell lines). Primary cells may include: peripheral blood monocytes, macrophages, lymphocytes, myoblasts, skin fibroblasts.

Vectors: Retroviral vectors: pHR', pHR'cPPT, pCMVd8.2, pCMVd8.9, pMD.G, pLNPOZ and derivatives, pMFG and derivatives. All vectors have been thoroughly tested for the lack of recombination. PMFG has been approved for clinical trials while pHR', pCMVd8.2 and 8.9 are used in pre-clinical studies.

**MOLECULAR BIOLOGY**

Vectors: cloning plasmids: Bluescript, pGEM derivatives, pUC series, Bacteria expression plasmids: pGEX series

Retroviral vectors: pHR', pHR'cPPT, pCMVd8.2, pCMVd8.9, pMD.G, pLNPOZ and derivatives, pMFG and derivatives. All vectors have been thoroughly tested for the lack of recombination, PMFG has been approved for clinical trials while pHR', pCMVd8.2 and 8.9 are used in pre-clinical studies.

**Origin & function**

All viral vectors were cloned by other research groups. TelCeB packaging cell lines were made at the Chester Beatty Laboratories in London by Drs Takeuchi, Cosset and Collins. Cell lines are bought from the American or European tissue culture collections. Primary cells are provided by healthy or diseased human volunteers at appropriate hospitals. Bacterial cloning and expression vectors are bought from specialised companies. Competent bacteria are made in house.
Replication incompetent MoMLV and HIV-1 will be used to infect cells in vitro and prepare intracellular viral reverse transcription complexes. These complexes will be used for electron microscopy analyses. Viral complexes will be labelled and used to study nuclear import in mammalian cells. Cellular factors involved in uncoating and nuclear import of viral complexes will be purified by chromatographic methods and their specific activity tested in tissue culture cells and primary cells. Factors will then be cloned by peptide sequencing and RT-PCR to isolate relevant cDNAs.

Evaluation of foreseeable effects

There is a very low risk of infection by recombinant vectors for humans or animals by accidental contact. In this case, however, the virus will not be able to spread in the infected organism. Moreover, viral vectors used in this study carry marker genes like GFP or LacZ that do not cause harm to humans or animals. To avoid any such risk, all infection procedures will be carried out in Class II MSC hoods with air circulation through double filters. All workers must wear appropriate protecting clothes and gloves and must be trained beforehand on the procedures for handling recombinant virus, dispose of potentially infectious material and waste disposal. In case of accidental contact with recombinant virus, workers are instructed to remove contaminated clothing into an autoclavable bag. Any wound must be let bleeding within reasonable limits, washed with alcide and dressed appropriately. Accidents must be reported immediately to local supervisor or safety officer who will contact the Occupational Health Service if appropriate. All surfaces in working hoods are treated with the appropriate disinfectant to inactivate any vector. Tissue culture media from infected cells will be disposed after appropriate disinfection and infected cells will be autoclaved. Primary cells and cell lines used are not from the persons working in the laboratory and are known to be free of pathogens. These cells will not survive outside of the laboratory without feeding and incubation, nor colonise immunocompetent workers after accidental injection.

Access to the working area is restricted by a code lock. All solid waste is collected in autoclave bags and transferred to a different floor in appropriate sealed bins for autoclaving at 131 degC. Four Class II MSC with air circulation through double filters and 9 CO2 incubators operate in the working area. Biological solid waste from molecular biology work is collected in yellow plastic bags for incineration.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

none

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Tissue culture liquids containing recombinant virus are treated with Basol for at least two hours before disposal. Treatment with Basol for 1 hour is sufficient to sterilize cultures. All plasticware, including tips and pipettes, is soaked in Basol and subsequently autoclaved. Surfaces are treated with Alcide at the beginning and at the end of the work. Bacterial cultures are treated with Basol overnight and disposed. Glassware is washed and sterilised by autoclaving. All solid waste from Level 2 labs must be autoclaved before leaving the Windeyer Institute. The following procedure is applied:

a) the waste is collected in an autoclavable bag which is supported in a flip top white bin.
b) when 2/3rds full the bag is inserted into a 2nd bag and both bags are tied with a blue elastomere band.
c) a piece of autoclave tape is stuck to the outside of the bag
d) the bag is placed in a blue wheely bin.
e) the waste is transported in the blue wheely bins to the autoclave room. Waste bags must be transported in a bin - under no circumstances can they be carried by hand to the autoclave room
f) wearing gloves, the bags are transferred to the autoclave and inserted in the stainless steel bins
g) gloves are removed and discarded in yellow waste bag
h) close the autoclave door and run cycle 3 which is the validated discard cycle
i) at end of cycle check cycle has operated successfully by checking the display for “finish” light on and no fault lights showing.
j) open autoclave and, wearing insulated gloves, remove waste bags and check autoclave tape has changed (black stripes).
k) transfer waste bags to yellow bags, seal the bags and leave in area for collection by cleaning staff
l) empty liquid waste from autoclave bins by discarding down the sink with hot water tap running
IF THE AUTOCLAVE CYCLE FAILS OR THE AUTOCLAVE DOES NOT FUNCTION AS NORMAL, WASTE IS NOT REMOVED AUTOCLAVE FAILURE MUST BE IMMEDIATELY REPORTED.

**Project Additional Information**

**Purposes of the contained use**

Cloning and functional analysis HIV envelope pseudotypes: Molecularly cloned full-length HIV envelopes will be used. HIV envelopes will be amplified from patient material and cloned into mammalian expression vectors. Cotransfection into mammalian cell lines with a full-length HIV backbone defective in the envelope gene results in the production of virus pseudotypes carrying HIV envelopes from patient samples.

The HIV envelope pseudotypes will be used to identify the coreceptors and cell types that are infected by the HIV envelopes derived from patient material.

An adenovirus vector that contains CD4 in the early E1 region of the adenovirus genome will be used to transfact CD4 into primary cells that do not normally express CD4. This will allow for infection of CD4 negative primary cell types by the above HIV envelope pseudotypes.

Cloning and functional analysis of HIV genes and HIV segments: Plasmids containing complete recombinant or chimeric infectious HIV DNA clones of HIV prepared in the containment level 2 laboratory will be transferred into mammalian cell lines to produce infectious virus stocks in the containment level 3 laboratory. Properties of the recombinant HIVs to be tested will include cell tropism, effects on host cells, and neutralisation.

An adenovirus vector that contains CD4 in the early E1 region of the adenovirus genome will be used to transfact CD4 into primary cells that do not normally express CD4. This will allow for infection of CD4 negative primary cell types by the above HIV chimeras.

**Host/vector system**

HIV envelope pseudotypes and HIV genes:

Vectors: Cloning plasmids (pcDNA3.1, pGEM-Teasy, pGEM13, pBABE, other commercially available ACDP level 1 plasmids).

Host: Disabled bacteria (TopF10', HB101, SCS110, XL1blue), Culture cells (T-cells, fibroblasts, epithelial cells, testicular cells, peripheral blood lymphocytes, and Macrophages).
Expression of CD4 in cells using an Adenovirus vector:
Vector: Recombinant Adenovirus vector that carried the human CD4 gene in the early E1 region of the Adenovirus genome.
Host: primary cell cultures (Leydig cells, astrocytes).

Origin & function

Cloning and functional analysis of HIV pseudotypes: HIV envelope genes amplified from patient material are cloned into mammalian expression vectors. Cotransfection into mammalian cell lines with a full length HIV clone defective in the envelope gene results in the production of virus pseudotypes carrying HIV envelopes from the patient samples.

Cloning and functional analysis of HIV genes: Plasmids containing complete recombinant or chimeric infectious HIV DNA clones of HIV prepared in the level 2 laboratory will be transferred into mammalian cell lines to produce infectious virus stocks in the containing level 3. Various properties of the recombinant HIVs will be tested including cell tropism, and neutralisation. The HIV segments and HIV genes used are cloned by PCR from patient material.

Expression of CD4 in cells using an Adenovirus vector: An adenovirus recombinant vector will be used that carries the human CD4 gene in the early E1 region of the genome. Following infection of cells, CD4 is expressed but late viral genes are not since they are controlled by products encoded by the missing E1 region. The vector however can be produced as virus by infecting HEK293 cells which contain the E1 region (but not other Adenovirus DNA) stably integrated into their chromosomes. We will use the recombinant virus to express CD4 on primary cell cultures before testing infection by HIV. This strategy will reveal primary cells that express functional HIV coreceptors that require CD4 to confer HIV infection.

Evaluation of foreseeable effects

HIV carries the risk of AIDS. The main risk of HIV infection in the laboratory is via cuts or abrasions with contaminated sharp instruments. Aerosols are not likely to be a risk since work will be carried out in class 1 or T-fronted class II microbiological safety cabinets. Work using recombinant HIV carrying mutated or chimeric viral genes are unlikely to be of any higher risk than a typical clinical isolate from an AIDS patient. All work with infectious HIV particles whether using clinical isolates or recombinant strains is therefore carried out in our level three laboratory (as defined in the ACDP level 3 containment) under our local rules. These include a ban on sharp instruments, the use of T-front class II safety cabinets to prevent aerosols in a laboratory with restricted access.

PCR amplification of HIV genes is done under level 2 conditions from HIV cultures that have been treated, in the containment 3 laboratory, with detergents to lyse cells and virus particles in the first nucleic acid purification step. Cloning of amplified HIV genes into disabled bacterial vectors is also done under level 2 conditions. Manipulation of and subcloning into full-length infectious DNA clones of HIV is carried out at level 2. Introduction of infectious HIV DNA into cells by transfection and subsequent production of infectious virus is carried out at containment level 3. Naked viral DNA is manipulated under containment level 2 conditions but the production of infectious virion is carried out in containment level 3 conditions.

The recipient cell cultures are cell lines and primary cells which are not from the persons who work in the same laboratory and are known to be free from human pathogens of ACDP 2-4 groups. These cells will not survive outside of the laboratory, without feeding, nor colonise in immunocompetent workers after accidental injection. There is a small likelihood that the HIV pseudotypes will include some that contain infectious replication competent genomes that result from recombination between the 2 plasmids encoding defective HIVs. These recombinant viruses are no more of a risk than a typical clinical isolate from an AIDS patient. All work after transfection of HIV clones into cell lines is therefore done in containment level 3 and in a class 2 safety cabinet to protect the worker. All pseudotypes are treated as potentially live HIV.

The Adenovirus vector will be propagated in HEK-293 cells which contain the E1 genes that are missing in the recombinant Adenovirus. It is conceivable that the recombinant Adenovirus will recombine with the E1 regions integrated in HEK-293 chromosomes. This would produce a replication competent virus. As far as we are aware, such recombination does not occur. If it did, such a virus would not be any more dangerous than normal Adenovirus. The main danger is exposure to an aerosol containing the recombinant Adenovirus. Such exposure may confer CD4 expression on cells of the respiratory system making them susceptible to HIV infection. The likelihood of significant numbers of cells becoming CD4+ and then being exposed to an HIV aerosol of sufficient concentration to infect them is nil under our level 3 conditions and safety precautions. The recombinant virus will be used in the level 3 containment laboratory in a T-fronted class II microbiological safety cabinet to prevent...
exposure to aerosols. Cells exposed to the vector are then infected with HIV 48 hours later allowing time for CD4 to be expressed. At this time, levels of residual adenovirus will be negligible. The precautions taken will therefore eliminate the envisaged danger.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

**Containment 3:** All disposable plastic-ware is soaked in Basol detergent overnight before autoclaving. A tray of Basol is kept inside all Safety cabinets during work for the temporary disposal and treatment of micro-pipette tips and small plastic waste. Beside each cabinet there is a tube of Basol for the disinfection of serological pipette tips. Tissue culture flasks and culture tubes are rinsed and filled with Basol and put in a waste bin after use. All pipette tips, disposable plastic-ware, and tissue culture flasks, are treated with Basol after use where they stay until the next day or at least 12 hrs when they are processed in a double-ended autoclave.

All waste is processed through a double-ended autoclave. Waste is loaded on the containment 3 laboratory side and is unloaded on the lobby side of the containment three after the autoclave cycle is finished. The autoclave maintains a temperature of 134 degrees C for 20 minutes that is sufficient to kill all life within the autoclave. A report is printed by the autoclave that confirms the maintenance of temperature during the sterilisation cycle. These reports are kept for a minimum of two months after printing. All waste is labelled with marker autoclave tape before being sterilised in the autoclave. This tape turns black when the appropriate sterilisation temperature has been reached.

Soaking in Basol detergent and subsequent autoclaving is sufficient to kill 100% of all life that is exposed to this treatment.

The efficacy of the Basol has been tested with a blue-spot B-Galactosidase assay for HIV infection. A 2% solution of Basol was added to cell-free HIV supernatant. One hour later, the Basol/HIV solution was plated onto HIV permissive cell lines. After two hours, the inoculum was removed and the cells were washed twice with fresh growth medium. The cells were stained to detect HIV infection three days later. No infection could be detected.

Both solid and liquid wastes are produced in the containment level three laboratory and are treated as containment level three waste and are autoclaved.

**Is an emergency plan required according to regulation 20?** No

**If yes, tick to confirm that it is attached to this form.** No

**Tick to confirm that you have attached a risk assessment to this form.** Yes

**Tick if you are claiming exemption from disclosure for section of the risk assessment.** No

### Please enter comments on the GM safety committee on the risk assessment

The work proposed in this notification was approved by the Genetic Modification Safety Committee at a meeting on 5 April. The Committee agreed with the proposed containment levels and were satisfied that adequate arrangements were in place for safety management.

### Project Containment

02/03/2022
A disabled molecular clone of HXB2 and appropriate complementary domain(s) from patient-derived viruses will be co-transfected into Sup-T1 cells, resulting in the generation of full-length, viable HIV-1 in culture. Using a modified recombinant virus assay (RVA), patient-derived HIV-1 Gag and/or Pol domains will be introduced by intracellular homologous recombination into a constant HIV-1 genetic background (HXB2), and cultured in immortalised human T-cells (Sup-T1 cells - ATCC ref: CRL-1942). The relative fitness of resultant recombinant viruses will be investigated using pairwise competition experiments, also performed in Sup-T1 cells.

Prior to transfection, neither component is thought to present significant risk either to humans or to the environment. The only potential risk would come from complementation of the disabled molecular clone of HIV-1 (HXB2) with endogenous human retroviruses which could in theory generate viable human retroviruses. In view of the specialisation of the Lentivirus genus of Retroviridae, this would seem to be a remote possibility. We intend to use containment level II for the propagation of vector in E. coli.
The risks posed by the experimentally-derived recombinant viruses are equivalent to those of HIV-1 isolates rescued from patient material and which are already present in HIV-infected patients. The requirement for containment of these pathogens, whether experimentally-derived or rescued by conventional culture, is ACDP hazard group III.

References:

Recipient or parental organism
As described above, the recipient for the GMO will be Sup-T1 cells obtained from the AIDS Reagent Project, NIBSC, Patters Bar, Herts, UK (Catalogue Ref. ARP024, ATCC ref: CRL-1942): These have been derived from a patient with non-Hodgkin's Lymphoma not known to bear any know human pathogenic agent.

Host/vector system
A molecular clone of HIV-1 (HXB2) lacking its entire 5’ region will be generated and used as the vector in this work. The 3’ sequences of HXB2 from the integrase domain to the 3’ long terminal repeat will be PCR-amplified and cloned into a commercially-available vector (pUC18, Roche Molecular Biochemicals). Prior to use, this vector will be propagated in E. coli to microgram quantities and linearised using an appropriate restriction enzyme.

Origin & function
Three HIV-1 domains will be rescued from clinical samples - gag, protease, and reverse transcriptase. Either singly and/or in combination, these domains will be amplified by nested RT-PCR directly from nucleic acid extracted from clinical materials. Using unique restriction sites introduced into the termini of the nested RT-PCR products, these sequences will be digested and ligated to previously PCR-amplified flanking HXB2 sequences. This will generate a fragment which comprises a contiguous 5’ coding region. The 3’ end of this resultant fragment will overlap the 5’ end of the 3’ HIV-1 coding region in the vector by approximately 500 bp, facilitating homologous recombination between the two fragments in Sup-T1 cells. This will lead to the generation of a panel of recombinant viruses in which specified sequences from patient-derived viral nucleic acids are expressed in a constant genetic background, enabling phenotypic comparison between gag, protease, and/or reverse transcriptase domains.

Evaluation of foreseeable effects
Linearised vector and recombinant 5’ coding regions will be co-transfected into a human T cell line, whereupon the two fragments will undergo homologous recombination such that contiguous full-length viral nucleic acid is generated. Intracellular expression of this nucleic acid will result in the generation of infectious virus, enabling culture of recombinant viruses.

Prior to transfection, neither component is thought to present significant risk either to humans or to the environment. We consider that the only potential risk would come from complementation of the disabled molecular clone of HIV-1 (HXB2) with endogenous human retroviruses which could in theory generate viable human retroviruses. However, in view of the complex genomic organisation found within primate lentiviruses, any such recombination is extremely unlikely to result in genomes able to express viable viruses. Therefore we intend to use containment level II for the propagation of the vector in E. coli.

The risks posed by the experimentally-derived recombinant viruses are equivalent to those of HIV-1 isolates rescued from patient material by widely used co-culturing techniques, and are present in vivo in HIV-infected patients. The requirement for containment of cultured HIV-1, whether experimentally-derived or rescued by conventional culture, is ACDP hazard group III.

Therefore we intend to use our containment level III laboratory for the handling of these viruses.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

none requested

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Standard category III containment procedures for the disposal of waste will be adhered to:

Liquid waste, including disposable items used in its manipulation (eg. pipettes) will be sterilised in Virkon solution for a minimum of 16 hours. Both solid waste (eg. gloves and equipment wrappings) and Virkon-treated liquid waste will be autoclaved to destruction (131 degrees C, 2 atmospheres, 30 minutes). Subsequent disposal of autoclaved waste is via the established double-bag system, before finally being incinerated.

Virologically dangerous materials such as cultures will be treated as per liquid waste, and both chemically sterilised and autoclaved before disposal.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The work proposed in this notification has been considered by a representative panel of scrutineers acting for the UCL Genetic Modification Safety Committee. They recommended that approval could be given for this project at the classification proposed by the research group of activity class 3 subject to confirmation at the next full meeting. The laboratory premises where the proposed work is to be undertaken were last inspected on 24th May 2001 and were found to be acceptable for this level of work (containment level 3).

Date Ackn’d 02/03/2022
GENERATING LENTIVIRAL VECTORS ENCODING FOR ONCOGENIC VIRAL PROTEINS

Date Project Ceased
12/09/2018

Purposes of the contained use
To study the effects of potential cancer causing genes (oncogenes) on cell growth, we need to infect primary cells with these oncogenes. To do this efficiently, we use HIV-1 viruses to carry the oncogene of interest into the primary human cells. These HIV viruses are made incompetent, meaning they can only infect the cells of interest and no new HIV viruses are then produced that are able to infect new cells. The HIV viruses can therefore not replicate.

Recipient or parental organism
The gene delivery system involves 3 plasmids that are transfected into virus producing cells, the 293T cell line. The lentiviral system is secured by gene removal such that no new particles can be produced from infected cells. This system functions as the 293t cells express:
- The viral envelope protein (VSV-G envelope) from a plasmid called p-VSVG.
- The modified HIV-1 genome with the transgene (modified HIV-1 called pHR with deleted envelope and accessory genes like tat, nef and vpr)
- The HIV -1 accessory genes, including the reverse transcriptase and the other viral genes involved in replication (from pCMV8.9 plasmid)
The vector can stably integrate into DNA for sustained long-term expression of the transgene. The vector has the ability to infect primary human cells, with subsequent expression of the foreign gene and GFP in these cells. All progeny cells will also express the foreign genes, but no new HIV-1 virions can be produced from the infected cells (replication defective). Because the HIV-1 envelope, that usually binds CD4 and chemokine receptors, has been replaced by the vesicular stomatitis virus envelope (VSV-G), this vector can infect many different cell types in vitro and possibly in vivo. VSG envelope allows entry of virus into cells by way of binding non-specifically to membrane phospholipid of target cells, rather than relying on specific receptor binding.

Host/vector system
We are testing the functional role of different proteins encoded by Kaposi's sarcoma-associated herpesvirus (KSHV) and by human T-cell leukaemia virus-1 (HTLV-1). These include a viral cyclin homologue (v-cyclin), a latent membrane protein (K15), a latent nuclear antigen (LANA), anti-apoptotic proteins called K7 and a FLIP (FLICE inhibitor protein) homologue (vFLIP) and a membrane protein (K8.1), all encoded by KSHV. The viral cyclin, LANA and K15 are potential oncogenic proteins. We are also testing the mechanisms of transformation by the oncogenic Tax protein encoded by HTLV-1.

Origin & function
To transduce (infect) primary human cells with these different viral genes, we will clone them into a lentiviral vector. The lentiviral vector is based on HIV-1 pseudotyped
with a vesicular stomatitis viral (VSV) envelope, allowing infection into a broad range of cell types. The HIV-1 vector can infect cells but not replicate ("one shot" or "self-inactivating"). In addition, this lentiviral system incorporates a green fluorescent protein (GFP) from a bicistronic transcript allowing the identification of infected cells by immunofluorescence. The transduced cells will include primary human haematopoietic cells, endothelial cells and human stem cells.

Evaluation of foreseeable effects

1. The transduced cells can only survive in tissue culture at 37C.
2. The modified lentivirus cannot survive outside cells (dependent on cells for DNA integration), and is replicative incompetent: thus the lentivirus cannot propagate to infect new cells and pose a negligible risk to the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

none

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Virkon (a peroxygen compound) used at a concentration of 1% is known to have a wide range of microbial activity and is bacteriocidal against many human viruses, including HIV. All tissue culture material and disposable plasticware will be soaked for a minimum of 18-24hours in a freshly prepared 1% Virkon solution. The fluid is then disposed of down a laboratory sink with excess water. Solid waste is then double bagged in biohazard bags and autoclaved at 134C for 20 minutes at 3.2 bar pressure. Validation of this method will be by independant thermocouples placed in the centre of the load. Verification that the correct conditions have been reached will be obtained by checking the chart recorder printout. The autoclave undergoes a planned preventative maintenance inspection every 3 months. All inactivated waste is then treated as "clinical waste" and removed from site by a UCL contractor.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

In view of the disabled nature of the HIV, the GM Safety Committee accepted the containment level proposed by the investigator subject to the vigorous application of the risk control measures identified as required by the assessment. The room in which the work will be undertaken was last inspected in June 2001 and was found to be in good order. It is due a revisit in January 2002.

### Project Additional Information

**Purposes of the contained use**

To investigate the regulation of K+ channels in native tissue by cell signalling pathways.

**Recipient or parental organism**

Existing cDNAs (see Leaney et al PNAS 97:5651 for exact details and source of starting materials) encoding heterotrimeric G-proteins (Galpha i) will be subcloned into an adenoviral shuttle vector ("transfer vector" in pAdEasy system from Qiagen http://www.qbiogene.com/products/adenovirus/). Recombinant adenovirus will be generated according to manufacturer's instructions in HEK293 cells. The virus is replication deficient in any other host. After generation of the virus it will be used to transfect primary neuronal, cardiac and smooth muscle cell lines. If we are not successful with the pAdEasy system we will use an analogous system from Clontech (Adeno-X adenoviral system, http://www.clontech.com/products/families/adeno/index.shtml).

**Host/vector system**

adenoviral shuttle vector ("transfer vector" in pAdEasy system from QBiogene http://www.qbiogene.com/products/adenovirus/). THESE ARE NOT MEMBERS OF THE SMALL G-PROTEIN FAMILY. A second class of reporter consisting of a small domain of a protein that monitor changes in intracellular lipid concentration by changes in fluorescence may also be used depending on results (PLCd-PH-CFP and C1d-YFP see Botelho et al, 2000 J Cell Biol).

Origin & function

Summary:- Transfection of primary cell lines using recombinant adenoviral expression vectors according to manufacturer's protocols.

Existing cDNAs (see Leaney et al PNAS 97:5651 for exact details and source of starting materials) encoding heterotrimeric G-proteins (Galpha i) will be subcloned into an adenoviral shuttle vector ("transfer vector" in pAdEasy system from QBiogene http://www.qbiogene.com/products/adenovirus/). THESE ARE NOT MEMBERS OF THE SMALL G-PROTEIN FAMILY. A second class of reporter consisting of a small domain of a protein that monitor changes in intracellular lipid concentration by changes in fluorescence may also be used depending on results (PLCd-PH-CFP and C1d-YFP see Botelho et al, 2000 J Cell Biol). Recombinant adenovirus will be generated according to manufacturer's instructions in HEK293 cells. The virus is replication deficient in any other host. After generation of the virus it will be used to transfect primary neuronal, cardiac and smooth muscle cell lines. If we are not successful with the pAdEasy system we will use an analogous system from Clontech (Adeno-X adenoviral system, http://www.clontech.com/products/families/adeno/index.shtml)

Evaluation of foreseeable effects

The virus is replication deficient in any other host other than HEK 293.

There is a risk of self-limiting human infection with the adenovirus when infecting the host cells.

The transferred genes are not likely to be harmful to human health.

The personnel will be asked to report the development of any unusual symptoms especially those of an upper respiratory tract infection.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

n/a

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None applied for.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

To generate the shuttle vector standard molecular cloning techniques will be used. All bacterial strains are attenuated and no risk to human health. Waste is disposed of in designated bins, double-bagged and autoclaved prior to disposal.

The virus will be generated in Class II cell culture facilities in a designated and purpose-built laboratory with designated hoods and incubators. Waste will be disposed of in designated bins, double-bagged and autoclaved prior to disposal. Recombinant virus may be stored prior to use.

Primary cell lines will be isolated or obtained from companies and will be manipulated in Glass II facilities. Infection with the virus will take place in the designated facility above. On completion of the experiment the transfected cell lines will be destroyed.

All reagents will be disposed of on completion of the project (100% kill).
A panel representing the UCL GMSC has given interim approval for this project at Class 2 following the supply of further information, including more detail on the experimental procedures. The project will be discussed at the next meeting of the full GMSC due on 4 July 2002.

**Project Additional Information**

### Purposes of the contained use

HIV-1 envelope expression is boosted by the use of a bacteiophage T7 RNA polymerase recombinant Vaccinia virus VR-2153. The harvested HIV-1 envelopes are then titrated with serum from the envelope donor (autologous serus) or a different donor (heterologous serum) to quantitate the levels of envelope specific antibody present.

### Recipient or parental organism

| VR 2153 Vaccinia virus vector contains Bacteriophage T7 RNA polymerase inserted into the Vaccinia endogenous Thymidine Kinase gene (purchased from American Tissue Culture Collection ACTCC). |

### Host/vector system

| Host: Mammalian culture cells without ACDP 2-4 pathogens (293T, Vero). |
| Vector: VR 2153 Vaccinia virus vector with Bacteriophage T7 RNA polymerase inserted into the Vaccinia endogenous Thymidine Kinase gene. |

### Origin & function

HIV-1 envelope sequences are obtained from patient material. The HIV sequences cloned in this project are envelopes only. Core sequences required for HIV replication will not be amplified or otherwise manipulated. The risk assessment for obtaining HIV-1 envelope sequences from patient material has been submitted and has HSE approval (Cloning and functional analysis of HIV envelopes (GM 14/01.5)).

VR 2153 Vaccinia virus vector with Bacteriophage T7 RNA polymerase inserted into the Vaccinia endogenous Thymidine Kinase gene (purchased from ATCC).

### Evaluation of foreseeable effects

Vaccinia is a poxvirus of the genus Orthopoxviridae. It infects humans and other animals such as cows, horses, rabbits and guinea pigs and is classified as being an ACDP level 2 pathogen. It is infectious through ingestion and contact with open skin and eyes. Infection causes rash and pustules at the site of contact only and recovery is full in the immunocompetent. Vaccinia stably accepts large foreign sequences into its genome so it is a very popular tool in immunology and vaccine research and is a well-established and studied vector.

Vaccinia virus will infect animals other than humans; including rabbits, cows, buffalo and guinea pigs. The containment measures are aimed at protecting both the workers and the surrounding environment.

Vaccinia virus produced from a Vaccinia vector with the T7 polymerase gene insert is not likely to be any more or less infectious than a wild type Vaccinia virus (ATCC) American Tissue Culture Collection product information sheet for VR-2153). Thus, the T7 Vaccinia virus VR-2153 is classified as a USA Biosafety level 2 virus that is equivalent to the United Kingdom AQCDP containment level 2 (http://www.cdc.gov/ohs/biosfty/bmbi4s3.htm).

There is the possibility of recombination between the HIV envelope containing plasmids and the Vaccinia vector genome, however this is unlikely. The resulting pseudo-virus would likely be an HIV enveloped Vaccinia core of reduced fitness when compared to wild type Vqaccinia virus. Once sufficient levels of HIV-1 envelope protein are produced the cultures are lysed with Nonidet P-40 detergent that will inactivate any virion present in culture, whether it is wild type or artificial.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
Waste Disposal

Solid Waste - Paper gowns and towels, disposable gloves, filter papers and plasticware must be discarded into an approved autoclavable bag, supported within a labelled biohazardous waste bin. Before the bag is too full, it must be closed with an elastomeric seal before being placed within the autoclave to await a sterilising run. If the autoclave is in use, full bags may be temporarily stored in the bin beside the autoclave. The autoclave discard cycle holds at 134 degrees C for 15 minutes. This is sufficient to kill 100% of life in the autoclave after a cycle has run.

Plastic Ware - Disposable culture dishes, tubes and flasks used for infectious material must not be discarded until after an aliquot of 50% Kleencare DS607 has been added to them (in a MSC). They must then be dealt with as described in 8.1.

Graduated Pipettes - Plastic graduated pipettes must be totally immersed in 1% Kleencare DS607 for at least 2 hours in the grey cylindrical drums. After disinfection the pipettes can be removed from the Kleencare DS607 and allowed to drain. They are discarded into an autoclavable bag and disposed of as for solid waste.

Plastic Straws/pipette tips - Plastic straws and plastic pipette tips must be totally immersed in 1% Kleencare DS607 in a plastic bath within the MSC for at least 1/2 hour before draining and disposal into an autoclavable bag (solid waste). If Gilson tips are used in conjunction with Eppendorf multidosers, the tips must be separated before disposal.

Autoclaving waste - The bags of solid waste are autoclaved in the stainless steel containers in the Priorclave Double Ended Autoclave. On completion of the cycle, the bags are removed in the Prep Room 401E and placed in medibins. When full these bins are sealed and removed from the prep room to await collection for incineration.

Autoclave failure - Should the double ended autoclave be unavailable, bags of solid waste may be autoclaved in the Priorclave EV150 autoclave which is sited in the Prep laboratory, the bags must be sprayed with alcide then placed directly into the autoclave. When the discard cycle is complete, the waste is treated as in 8.7 above.

Liquid Waste - Large volumes of liquid which are, or might be, infectious must be treated with Kleencare DS607 at a final concentration of 5% for at least 12 hours before being discarded.

Solvent waste - Chlorinated and non-chlorinated solvents must be discarded into the appropriately labelled 2.5L plastic containers which are kept in the flammable storage cabinet.

When full, or at least 6-monthly, after having their outer surfaces thoroughly washed with Alcide, they are removed from the lab and disposal is arranged according to Windeyer Institute procedures.

Blood - An equal volume of 50% Kleencare DS607 must be added to all waste blood before autoclaving.

Please enter comments on the GM safety committee on the risk assessment
A panel representing the UCL GMSC has given interim agreement that this project should be classified at Class 2, prior to consideration by the full Committee at its next meeting.

Although a separate project at a lower classification, it is related to project number GM 14/01.5 and will be carried out in the same laboratories under the precautions described in the risk assessment accompanying this notification. These procedures will adopt the same level of stringency as required for other notified work being undertaken simultaneously in the same laboratories.

### Project Additional Information
### Purposes of the contained use

To generate human continuous cell lines

### Recipient or parental organism

Human cell cultures transduced with one or two viruses

### Host/vector system

- PA317 - pZIPneoSV(X)1 retroviral vector
- TELFLY A and RD cells - pBABEno/hygro, pZIPneoSV(X)1, pLHCX retroviral vectors
- Primary human cell cultures transduced with one or two of these retroviral vectors

### Origin & function

The aim of the project is to use amphotropic viruses to deliver immortalising genes into primary cultures of human cells.

### Evaluation of foreseeable effects

The transduced genes either singly or in combination can immortalise human cells. Therefore the viruses containing these genes could immortalise the operator's cells if they were exposed by inoculation. Safety procedures are in place that make the possibility of self infection remote. In addition, because the viruses are defective and helper free, they should not be able to spread themselves beyond the site of inoculation.

The cultures of human cells transduced with the viruses should not produce infectious virus, because the viruses are defective and helper free. In addition, such cells should be rejected by the immune system following inoculation.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

The transduction and selection of the human cell cultures will be carried out in a level 3 containment facility. To test whether the transduced cells are still expressing retrovirus, control cells will be exposed to the culture medium. Once the transduced cells have been proven to be negative for virus production, they will be transferred to a level 2 containment facility for routine culture and subcloning.

### For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None requested

### Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

- All liquid waste will be treated with chloros for a minimum of 24 hours at a concentration of at least 10% (10,000ppm). This is a validated procedure for 100% inactivation (Parmjit Jat, personal communication). The inactivated liquid waste will be disposed of in dedicated drains leading directly to sewer waste.
- All solid waste will be soaked in chloros for at least 24 hours >10% chloros (10,000ppm), followed by autoclaving for 15 minutes at 120°C, followed by incineration. This is a validated procedure for 100% inactivation (Parmjit Jat, personal communication).
- All waste inactivation procedures will be carried out within the level 3 containment facility.

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID

Date of Significant Change
Project Additional Information

Purposes of the contained use

To generate high titre pseudotyped lentiviral vector systems containing genes that can be used for the immortalisation of freshly isolated primary human cells. This system will be used for cells that have failed to be immortalised using simple retroviral systems due to low proliferation rates or absence of amphotropic receptors.

Recipient or parental organism

E. coli JS4 - rec A - derived from E. coli MC1061. This is disabled E. coli.

293T kidney cells - produced from human embryonic 293 kidney cells by transformation with SV40T (Studies on in vitro transformation by DNA and DNA fragments of human adenoviruses and simian virus 40, Graham, FL; Abrahams, PJ; Mulder, C; Heijneker, HL; Warnaar, SO; De Vries, FA; Fiers, W; Van Der Eb, AJ. Cold Spring Harb Symp Quant Biol. 1975; 39 pt 1: 637-50) These cells have a history of safe use for the production of lentiviruses.

Cultures of primary human cells and of established human cell lines. The primary human cells will be from colonic epithelial cells and from mammary neoplastic tissue.

Host/vector system

293T will be transduced with the 3 plasmids pVSV-G, p8.91 and pHR into which is inserted hTERT, tsA58-U19 SV40T, U-19 SV40T, bcl-2 to produce the lentivirus.

Primary human cells and cell lines will be transduced with the VSV-G pseudotyped minimal lentiviral vector containing hTERT, tsA58-U19 SV40T, U-19 SV40T, bcl-2.

Origin & function

Minimal HIV1-based lentiviral vectors transducing genes corresponding to a temperature sensitive SV40T-antigen (tsA58-U19), wild type SV40T-antigen (U19), a catalytic protein component of human telomerase (hTERT) and bcl2, a gene that produces anti-apoptotic proteins, will be used to generate immortal cell lines from human primary cell types including colonic epithelial cells and neoplastic mammary epithelial cells.

The immortalising genes are derived from the Papovavirus SV40 and the catalytic subunit of the human telomerase gene.

SV40 large T antigen is an immortalising gene that has the potential to extend the lifespan of human cells. It can inactivate the p53 and RB pathways.

The catalytic subunit of telomerase activity can be used to reconstitute telomerase activity in human somatic cells that are null for telomerase and thus maintain their telomeres. Maintenance of telomeres is a critical step in the immortalisation of primary human somatic cells.

Bcl-2 is a gene sequence that can produce proteins that inhibit the apoptosis pathway. Death of epithelial cells may occur through loss of anchorage to the basement membrane triggering the apoptosis pathway. Therefore introduction of bcl2 has the potential to prolong survival of the cells.

Evaluation of foreseeable effects

The E. coli cells are non-colonising and disabled (recA-) and the inserted sequences are driven by eukaryotic specific promoters (eg CMV). Therefore there is no risk from this part of the work.

The 293T cells will produce a lentivirus containing the inserted genes. The production of a lentivirus increases the risk compared to a simple retrovirus as these can enter non-dividing cells. Also pseudotyping the lentivirus with VSV-G increases the risk as this enables the virus to bind to multiple cells types. However, the virus is replication defective and like all retroviruses these lentiviral particles have a limited survival capacity (half-life of 2-4 hours). The main risk to the worker as for HIV1 is from needlestick
injury and by operating in a sharps-free environment and using a class II hood in a level 3 environment the risk to the worker is very low.

Primary cells once tested for absence of replication competent virus have no risk other than that of being human cells, so possibly contaminated with viral and microbial particles. However, donor tissues will be from cosmetic surgery or cancer surgery in which the likelihood of such contamination, for example, HIV-1 and hepatitis B is less than 0.5%.

The main hazard is from the inserts which are either potentially immortalising oncogenes, telomere stabilising genes or anti-apoptotic genes and therefore each gene either singly or in combination can immortalise, but not transform, human cells and therefore, in principle create a pre-neoplastic clone in vivo in a worker exposed to them. However, the tsA58 is temperature sensitive and has little activity at the non-permissive temperature, which corresponds with near physiological temperatures (38 degrees C). bcl-2 and telomerase are naturally occurring proteins and any risk from them comes from their possible expression at higher than normal levels.

Also, the virus prepared with the inserts is replication defective and therefore cannot be self-propagating, further reducing the risk from these insets, but in any event naturally occurring lentiviruses are not transmitted via aerosols.

The main risk comes from needlestick injury or via an open wound or from an aerosol of these high titre viruses. To minimise these risks the work is carried out in a class II laminar flow cabinet in a level 3 room and working in a sharps-free environment. Any wounds will be covered and gloves and laboratory coats will be worn at all times. Aerosol is minimised by not using a vacuum for aspiration of medium.

Therefore although the consequence of the hazard of transfer of the sequence to the workers could be severe, resulting in the generation of a pre-neoplastic clone(s) in the worker, with the application of the described control measures the risk of the foreseeable effects is extremely low.

The transfection of plasmids to 293T cells and transduction of virus to human primary cells and cell lines will be carried out in a class II hood in a level 3 containment facility. The recipient human cells will be tested to determine whether they are producing lentivirus by taking culture medium from the transduced cells and placing on control cells, EJ and testing for gene transfer. Once they have been shown to be negative for virus production, they will then be transferred to a level 2 containment facility for routine culture and subcloning.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

Project Additional Information

Purposes of the contained use

To study the replication and immunobiology of Hepatitis B virus in vitro by:

1. Transfecting plasmids containing HBV-DNA into hepatoma cell lines with transient viral expression.
2. Culturing cell lines that have HBV integrated into their genome and produce full infectious virus in culture.

Recipient or parental organism

Recipient organism: The plasmid containing HBV-DNA will be transfected into 2 human hepatoma cell lines - HepG2 and HUH-7. These cells pose no risk to workers.

Parental organism: A cell line which has the HBV genome integrated into their genomic DNA - HepG2215 cells. These cells produce full infectious Hepatitis B virions in culture. The foreseeable risk in handling these cells is the inoculation of the worker with the cells or the culture supernatant and thereby infecting the worker with HBV.

The most hazardous risk to workers would be of infection by the virus therefore -

1. All workers will be vaccinated against HBV and have proven protective antibody titres prior to commencing the work.
2. All work will be carried out in our containment level 3 (CL3) facility.
3. As the major risk of infection is through needle stick injury there is a NO SHARPS policy in the CL3 laboratory.

If control measure failed the most severe risk would be inoculation of the worker with the virus.

Host/vector system

Hosts: Bacterial - E. coli: Disabled host
Vector: PUC 19 plasmid: non-mobilisable, BOM (-)/NIC (-), MOB (-), TRA (-) and with ampicillin resistance.
There is no foreseeable effects with this host/vector system.

Origin & function

The gene sequence to be inserted into the plasmid is the full HBV-DNA extracted from human patients infected with HBV.

This sequence will be inserted into the PUC19 plasmid vector and transformed into E. coli (DH5-alpha). This DNA will then be extracted and transfected into the HepG2 and HUH-7 cell lines. These cells will be cultured and experiments to monitor viral replication will be carried out.

Evaluation of foreseeable effects

The foreseeable effect of this project, if control measures failed is the infection of the person handling the cell line with HBV.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All waste generate in the containment level 3 facility will be autoclaved in the double-ended autoclave.

1. Solid waste:
This includes laboratory plastics, laboratory overalls, gloves, paper wastes etc will be collected in double autoclave bags within a sealed container and when 3/4 full loaded into the ‘dirty’end of the autoclave which is within the CL3 laboratory. Once the cycle is complete the worker the waste is collected from the 'clean' end of the autoclave situated outside of the CL3 facility. The receipt from the autoclave is checked to ensure the run has passed (100% kill) and the waste is collected into yellow bags for incineration.

2. Liquid Waste
The liquid waste is decontaminated with Virkon powder - using 1g of powder per 100 ml of culture medium. This has been tested and proven to be 100% effective against Hepatitis B virus.

Preliminary assessment by a panel of expert advisers on behalf of the full GMSC agrees that this is an activity class 3 project.

The aim of this project is to use lentiviruses as an expression system for investigating mechanisms of molecular regulation of a family of ion channels expressed in neuronal cells. A commercially available lentivirus expression kit from Invitrogen will be used. We will make recombinant lentiviruses encoding membrane proteins which we are interested in: e.g., heteromeric G proteins of the Gi/o family (THESE G PROTEINS ARE NOT MEMBERS OF THE SMALL G PROTEIN FAMILY) and fluorescent reporter proteins such as PLCdelta-PH-CFP and PSD95-GFP. The cDNA inserts themselves are very unlikely to have any harmful effects and they are currently used in our research into mechanisms of cellular signalling. The cDNAs encoding these proteins will be subcloned into a viral expression construct (pLenti6, Invitrogen). This will be transfected into HEK293FT cells (producer cells) to generate recombinant virus. The recombinant virus will then be used to infect cultured rat or mouse central neurons in vitro. The neurones will then be used in electrophysiological studies where the effects of the heterologous membrane proteins on the neuronal ion channels will be assessed. These experiments will allow the investigation of specific single proteins (e.g., Gi/o proteins) on the activity of ion channels in their native neuronal environment.

The commercially available kit from Invitrogen is a third generation system based on HIV-1 (see Dull et al., 1998: J. Virol. 72, 8463-71) which allows the construction of a recombinant replication-incompetent, HIV-1-based lentivirus. There are a number of biosafety features which have been introduced to minimise risks. These are as follows: (1) All HIV sequences required for encapsidation and reverse transcription are absent. (2) There is a deletion in the 3' UTR resulting in self-inactivation of virus genome. (3) None of the HIV-1 structural genes contain LTRs and are thus never expressed in the target cell. (4) It contains the minimal number of HIV-1 genes required to generate an efficient vector (only three of the nine are used: gag, pol, and rev). (5) The removal genes are those which are pathogenic therefore no recombinant vector can acquire the pathogenetic features of the parental virus. (6) The tat gene, which is important for replication, has been removed. (7) The packaging genes are contained on 4 separate plasmids and thus the system relies on 4 separate plasmids for the production of transducing particles. (8) These plasmids contain no regions of homology thus preventing any recombination which could occur. (9) The virus is replication incompetent and as a replication-deficient vector it poses significantly reduced risks. Thus these viruses may infect cells and integrate DNA into the target cell but they are incapable of further replication.

Host/vector system
Vectors: HIV-based lentivirus expression vector (pLenti6) into which the gene of interest will be cloned. This vector also contains the elements needed for packaging of the expression construct. Kit also contains viral packaging mix of vectors; this is an optimised mixture of three packaging plasmids which supply the structural and replication proteins required for production of lentivirus.
Hosts: HEK293FT cells will be used to produce the virus. Recombinant proteins will then be expressed in primary neuronal cells.

Origin & function

Recombinant lentivirus will be used to transduce primary central neurones in vitro which have been isolated and cultured from rat or mouse. The intention of this project is to study the effects of the signalling proteins (described in Section 6) on ion channel activity in these neurones by using electrophysiological techniques.

Evaluation of foreseeable effects

Recombinant virus is produced in the HEK293FT producer cells. In these cells the virus can replicate. The potential risk which may arise from this is direct exposure of the viral supernatant produced to the operator. This could arise through the use of sharps and a direct needlestick injury, or if viral supernatant is accidentally splashed onto exposed areas of skin which are cut or scratched. This will be prevented by total avoidance of use of glass and sharps (including needles and forceps) since only sterile, disposable plasticware will be used. The plastic pipettes and pipette tips used are blunt and are also aerosol-resistant and contain a filter thus reducing any aerosol formation. Furthermore labcoats and gloves (and overshoes) are worn at all times. In addition, there is virtually no risk to the environment because retroviruses exhibit poor survival in the general environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All surfaces are swabbed before and after use with 10% Virkon and 70% IMS. Sharps (rarely used) and Pipetman pipettes are placed in specified sharps bins. Waste media, pipette tips and plasticware are doused in Virkon prior to autoclaving in sealed and double-bagged plastic autoclave bags. These procedures will ensure an anticipated 100% kill of virus.

The proposal has been reviewed by a representative panel of the Genetic Modification Safety Committee, which agreed with the proposer’s classification of Class 2. The notification will be submitted to the next meeting of the full Committee on 10 April 2003. The laboratories were last inspected in December 2002 and conditions were found to be satisfactory.

Project Containment

Laboratory Activities | Glass Houses | Growth Rooms
INVOLVEMENT OF RHO GTPASES IN THE REGULATION OF DENDRITIC SPINE MORPHOLOGY AND THE ESTABLISHMENT OF NEURONAL MORPHOLOGY

Primary hippocampal neurons will be transduced by adenoviral or sindbisviral vectors in order to overexpress small GTPases (dominant negative or constitutive versions) or their interacting proteins. Adenoviral vectors are the system of choice for long-lasting experiments due to their low cytotoxicity, while sindbisviral vectors efficiently transduce large number of selectively neurons and are inevitable for batch experiments to ensure only neuronal effects.

Recipient or parental organism

We will work with replication deficient variants of Adenovirus (serotype 5) or a replication deficient, neuron specific variant of the sindbisvirus. In adenovirus this is achieved by a E1 deletion which renders the virus incapable of autonomously reproducing itself, while in the case of sindbisvirus the replication incompetence is achieved by employing a helper virus containing the structural proteins, which cannot be packaged.

Adenovirus will be generated by homologous recombination in 293 cells or be Cre/lox recombination in 293 cells expressing stably Cre recombinase. Sindbisvirus will be generated by cotransfecting in vitro translated RNAs of the helper virus and the transgene containing constructs into BHK (baby hamster kidney) cells.

The replication deficient viral vectors will be used to transduce either neurons or for testing purposes Hela, MDCK and PC12 cells.
Host/Vector System

Host: HEK293 or BHK cells for virus production.
Primary rat and mouse neurons in vitro.
PC12 cells, MDCK, 3T fibroblasts and Hela cells for testing the virus.

Vector: PJM17, pAdlox, PXCHJL1, pAdlox; pAdloxIRESGFP for adenoviral construction
Sinrep5; nsp2S; DH(26S); DH26St for sindbisviral construction.

Origin & Function

Inserts:
- Small GTPases of the Rho family and their interactors (mouse):
- Indicator proteins (GFP, dsRed, β-Galactosidase);
- Cytoskeletal proteins (tubulin and actin from mouse);

Members of the Rho family of small Ras-like GTPases - including RhoA, -B and -C, Rac1 and -2, and Cdc42 - exhibit guanine nucleotide-binding activity and function as molecular switches, cycling between an inactive GDP-bound state and an active GTP-bound state. The Rho family GTPases participate in regulation of the actin cytoskeleton and cell adhesion through specific targets. Identification and characterization of these targets have begun to clarify how the Rho family GTPases act to reulate cytoskeletal structure and cell-cell and cell-substratum contacts in mammalian cells. The Rho family GTPases are also involved in regulation of smooth muscle contraction, cell morphology, cell motility, neurite retraction, and cytokinesis (Kaibuchi et al., 1999).

We want to interfere with the normal polarity establishment of hippocampal neurons using small GTPase mutants and their interactors and image the effect onto hippocampal neurons using fluorescently tagged cytoskeletal proteins.

Since Rho family GTPases are also involved in Ras-mediated cell transformation (Qui et al., 1995) special precautions as described in the next paragraph will be taken when used the active versions of Rho GTPases.

There are no harmful effects caused by the overexpression of cytoskeletal proteins or marker proteins such as GFP or beta Galctosidase.

Evaluation of foreseeable effects

In addition to the described replication incompetence of additional system is build in the used adenovirus system is that DNA of only limited size can be packaged into viral particles. If the virus DNA containing the transgene becomes too large or too small the packaging of it will be prevented. Thus unwanted (even though extremely rare) recombination events will be selected out. Moreover virus is purified by two rounds of plaque isolation. All plaques are tested for the containing of the correct transgene. This safety procedure again will select against the rare event of recombination events may be leading to wildtype viruses. A direct proof of the presence of wt virus in our stocks is the plaque assay on non-host cells, which are transducible by the virus. There should not be a plaque forming activity. Most commonly Hela cells are used for this purpose.

The pSinRep5 alone cannot infect cells and cannot drive the synthesis of Sindbis virions. Together with the Sindbis-helper infectious recombinant viruses can be made, but these are limited to a single round of infection. It is possible that recombination of pSinRep5 and Sindbis-helper may occur in cells transfected with both RNAs. However, this recombination is only likely to occur with very low frequency and will give rise to Sindbis virions.

We will check our stocks for the rare event of recombination by using a plaque assay on BHK cells. The virus should not have plaque forming activity on BHK cells.

Thus the risk of accidental exposure is very low since secondary rounds of infection are avoided. Primary transduction of accidentally exposed tissue could only be harmful using active form of Rho GTPases with potential cell transforming effects.

Thus the risk of accidental exposure will be limited:
- Any spillage will be immediately removed by treatment with 3% Virkon.
- Gloves and coats will be worn all the time and can be autoclaved in the accident of spillage.

02/03/2022
Working in a safety hood will prevent air-mediated exposure.

To avoid any possible transfer of this virus all experiments involving adenoviral and sindbisviral vectors will be conducted in a laboratory suite reserved for virus work. The cultures will be handled within microbiological safety cabinets and appropriate precautions will be adopted throughout. Laboratory workers handling these cultures will have extensive experience in tissue culture and microbiological experiments and will be fully aware of the principals of occupational safety and handling.

By autoclaving cultures and plastic ware, which were in contact with transduced cells and transduced cells the virions will be completely inactivated. Liquid waste will be treated with 3% Virkon for at least 60 mins.

In the viral suite (G17), media containing virus will be removed from cell cultures and disinfected with 3% Virkon for 60 mins.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Before wasting any virion containing media or plastik ware, a 100% killing of viral particles will be sured:

Aerosols may be produced during the handling of supernatants from transduced cultures. Aerosol production will be minimised through the use of microbiological practice and transduced cultures will only be handled within a microbiological safety cabinet.

Contaminated tips, straws, etc. will be placed in the sandwich box filled with 3% Virkon for at least 60 minutes before draining and disposal into an autoclave bag. Bottles of media used for infection should be isolated from all other and immersed in 3% Virkon before being placed into standard glassware containers.

Liquid waste will be treated with 3% Virkon for at least 60 minutes before disposal.

Incubators.

Incubators reserved for transduced cultures (room G17) will be used. Transduced cell culture flasks should be placed in a closed plastic sandwich box with small holes pierced in side in order to kinimise the chance of accidental spillage in the incubator but still allow access of CO2.

Spillage

Spills will be treated with 3% Virkon. If there is a spillage on the laboratory coat, it will be placed into a biohazard bag and autoclaved.

Avoidance of airborne transmission

since adenovirus could be transmitted by air-borne routes, procedures will be adopted to avoid the formation of aerosols. Aerosol production will be minimised through the use of microbiological practice and transduced cultures will only be handled within a microbiological safety cabinet (to BS 5726). Room G17 does not contain windows and is not readily accessible to insects, etc. Windows in adjacent laboratories will be kept closed. The laboratory environment will be monitored for insects and any that are found will be killed.

As indicated above the recombinant virions produced in this sytem do not have the capacity to replicate in host cells or host organisms.

Treatment of Adenovirus and Sinbisvirus before disposal.

By autoclaving cultures and plastic ware which were in contact with transduced cells and transduced cells the virions will be completely inactivated. Liquid waste will be treated with 3% Virkon for at least 60 mins.
Processing of materials for use in locations outside of the viral suite.
In the viral suite (G17), media containing virus will be removed from cell cultures and disinfected with 3% Virkon for 60 min. Cells will then be washed extensively (the wash again disinfected) in order to remove viral particles from the cultures. We will test how often we have to wash to get rid of any viral particles by taking the wash medium to transduce untransduced cell cultures (293 cells, since they are most sensitive by amplification of the virus). Since we assured that the virus does not contain any wt particles (see above) and thus does not contain any infectious particles, there will be no viral particles left with the capacity to infect any other cells, since the virus taken up already lost the competence for further infection. Thus there is no harm connected to work with cultures previously transduced with adenoviral vectors, if the cultures were extensively washed and these cultures can be handled safely. Containers holding the inactivated virus products will be wiped out (3% Virkon) before removal. For subsequent analysis of live cells, culture dishes containing washed cell-cultures will be placed in a tray and analyzed without opening the dish. The dishes will be returned to the viral suite after the experiment and there disinfected with Virkon 3% and autoclaved.

Project Ref 14/03.4

Date Ackn'd CU2 Project Title

22/05/2003 INVESTIGATING THE ROLE OF SMALL GTPASES IN CELL MORPHOLOGY

Class CultureVolClass2 CultureVolumeClass3-4

Class 2 < 1 litre
Project Additional Information

Purposes of the contained use

Tissue culture cell lines will be transduced by replication-deficient retrovirus vectors in order to overexpress small GTPases (dominant negative or constitutive versions) or their interacting proteins.

Recipient or parental organism

We will work with replication deficient retroviruses. These viruses are made by transfecting HEK293T cells with: 1) a plasmid expressing the gag and pol genes from murine leukemia virus (MLV) (which encode for viral structural and polymerase proteins, respectively); 2) a gene encoding a viral envelope protein, which will determine the host range of the virus produced; 3) an expression plasmid containing the gene of interest and a packaging signal, allowing it to be incorporated into the virus particles.

Host/vector system

Host: HEK293T cells for virus production.
Immortalized mammalian cell lines in vitro.

Vector: pBabe-puro, pRetroSUPER, pGagPol, pVSV-G

Origin & function

Inserts:
Small GTPases of the Ras superfamily, their upstream regulators, and their downstream effectors (mouse, human)
Small oligos for the production of siRNA in vivo
Indicator proteins (GFP, dsRed, lacZ)
Cytoskeletal proteins (tubulin, actin) (mouse, human)

Intended functions: we would like to interfere with the activity of the Ras superfamily of small GTPases, their regulators, and their effectors, to investigate the involvement of these signalling pathways in cellular behaviours.

Evaluation of foreseeable effects

Primary transduction of accidentally exposed tissue could be harmful using forms of members of the Ras superfamily of GTPases with potential cell transforming effects.
Thus the risk of accidental exposure will be limited:
Any spillage will be immediately removed by treatment with 3% Virkon.

Gloves and coats will be worn all the time and can be autoclaved in the accident of spillage.
Working in a safety hood will prevent air-mediated exposure.

To avoid any possible transfer of this virus all experiments involving retroviral vectors will be conducted in a laboratory suite reserved for virus work. The cultures will be handled within microbiological safety cabinets and appropriate precautions will be adopted throughout. Laboratory workers handling these cultures will have extensive experience tissue culture and microbiological experiments and will be fully aware of the principals of occupational safety and handling.

By autoclaving cultures and plastic ware, which were in contact with transduced cells and transduced cells the virions will be completely inactivated. Liquid waste will be treated with 3% Virkon for at least 60 min.
In the viral suite (G17), media containing virus will be removed from cell cultures and disinfected with 3% Virkon for 60 min.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The local rules for working in the containment level II laboratories will be followed in all locations. These practices include the rules for work in a microbiological safety cabinet.

Gloves and laboratory coats must be worn at all times. All cuts or abrasions will be covered with waterproof dressings.
No sharps of any type (glass Pasteur pipettes, needles, razors) will be present in the vicinity of work when handling viral stocks.
Waste will be bagged for autoclaving, and the bags sealed before removing from the designated rooms.
Eye protection must be worn.
Aerosols may be produced during the handling of supernatants from transduced cultures. Aerosol production will be minimised through the use of microbiological practice and transduced cultures will only be handled within a microbiological safety cabinet (to BS 5726).
Contaminated tips, straws, etc. will be placed in the sandwich box filled with 3% Virkon for at least 60 minutes before draining and disposal into an autoclave bag. Bottles of media used for infection should be isolated from all others and immersed in 3% Virkon before being placed into standard glassware containers.
Liquid waste will be treated with 3% Virkon for at least 60 minutes before disposal.

INCUBATORS
Incubators reserved for transduced cultures (room G17) will be used. Transduced cell culture flasks should be placed in a cloased plastic sandwich box with small holes pierced in side in order to minimise the chance of accidental spillage in the incubator but still allow access of CO2.

SPILLAGE
spills will be treated with 3% Virkon. If there is a spillage on the laboratory coat, it will be placed into a biohazard bag and autoclaved.

AVOIDANCE OF AIRBOURNE TRANSMISSION
Procedures will be adopted to avoid the formation of aerosols. Aerosol production will be minimised through the use of microbiological practice and transduced cultures will only be handled within a microbiological safety cabinet (to BS 5726). Room G17 does not contain windows and is not readily accessible to insects, etc. Windows in adjacent laboratories will be kept closed. The laboratory environment will be monitored for insects and any that are found will be killed.
As indicated above the recombinant virions produced in this system do not have the capacity to replicate in host cells or host organisms.

TREATMENT OF VIRUS BEFORE DISPOSAL
By autoclaving cultures and plastic ware which were in contact with transduced cells and transduced cells the virions will be completely inactivated. Liquid waste will be treated with 3% Virkon for at least 60 mins.

PROCESSING OF MATERIALS FOR USE IN LOCATIONS OUTSIDE OF THE VIRAL SUITE
In the viral suite (G17), media containing virus will be removed from cell cultures and disinfected with 3% Virkon for 60 min. Cells will then be washed extensively (the wash again disinfected) in order to remove viral particles from the cultures. Since the virus used for transduction does not contain a viral genome, and is thus replication deficient, there will be no viral particles produced by the transduced cells. Thus there is no harm connected to work with cultures previously transduced and these vectors, and these cultures can be handled safely. Containers holding the inactivated virus products will be wiped out (3% Virkon) before removal. For subsequent analysis of live cells, culture dishes containing washed cell-cultures will be placed in a tray and analysed without opening the dish. The dishes will be returned to the viral suite after the experiment, disinfected with Virkon 3%, and autoclaved.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment
A representative group from the GMSC has reviewed the risk assessment and agreed that the work should be ascribed to activity Class 2. The proposed location is a containment level 2 laboratory set aside for this kind of work. The notification will be reviewed at the next meeting of the full committee.

Project Ref 14/03.5

Date Ackn’d CU2 Project Title Class CultureVolClass2 CultureVolumeClass3-4

02/03/2022
The aim of this project is to investigate the functions of the latent genes expressed by KSHV. This work will involve the cloning and expression of latent viral genes and cellular factors involved in viral transformation and pathogenesis. The viral genes and cellular factors described below will be transfected and expressed in bacterial and mammalian cells by virtue of promoters from expression vector plasmids. In some cases the stable expression of KSHV viral genes in mammalian cell lines will be mediated via lentivirus transduction. Gene modifications will be single mutations, partial deletions and fusion to tags (eg antigen tags, GST fusions). KSHV is an oncogenic virus and we will therefore be working with potential oncogenes. However, this work will focus on the function of individual genes and it is unlikely that any one KSHV latent gene has the capacity to act as an oncogene on its own.

Recipient or parental organism
Human 293T, Jurkat T, NIH 3T3, BJAB, 70Z/3, DG75, Ramos, RPMI, KM3, DEL

Host/vector system
1. Culture cells/Cloning plasmids, eukaryotic expression plasmids
2. Mammalian cell cultures/Lentivirus vectors based on HIV.

Origin & function
1. Cellular genes, unlikely to be oncogenic. Protein tags include His/Myc/FLAG/GST/Xpress will be used to study protein interactions.
2. KSHV latent genes, which may have oncogenic activity. Protein tags include His/Myc/FLAG/GST/Xpress
3. HIV-based vectors with markers: GFP, and neomycin resistance genes.

Evaluation of foreseeable effects
We aim to use lentivirus to transduce cell lines with individual KSHV genes. The risks from accidental infection by lentiviruses are insertional mutagenesis/over expression of cellular genes by random integration. The main risk is to the laboratory personal directly handling the lentivirus. The risk attached to using the replicative defective HIV vectors is minimised because these viruses are extremely susceptible to dessication and will only survive a few hours at room temperature. In addition, the replicative defective nature of the HIV vectors ensures that even in the case of a breach of containment and accidental injection, no virus can spread from individual to individual.
Similar work using lentivirus technology is currently carried out in a category 2 tissue culture laboratory (Rm424) in which the use of sharps and glassware is prohibited to reduce the theoretical risk attached to accidental injection of lentivirus.

The risks inherent to the viral genes to be used are the potential expression of an oncogene or tumour progression factor. Although KSHV is able to transform mammalian cells, it is unlikely that any one gene has the capacity to act as an oncogene on its own. Expressed proteins are not toxic and will not survive more than a few hours at room temperature. They cannot be diffused by aerosol. However, we do identify an increased risk when using these KSHV genes in lentivirus vectors, and extra care will be exercised when handling and expressing these genes and their products. It is possible that in the event of a breach of containment, accidental injection into workers may result in the undesirable expression of the KSHV genes. However, the replication defective vectors will not be transmitted to other cells and all plasmids containing viral genes will be grown separately to avoid any chance of recombination. The cell factors which we intend to express are unlikely to be toxic/oncogenic/allergic as they are expressed in normal cells.

In view of the associated risks of this work, it is proposed to carry out these experiments at the containment level 2 handling culture cells in Class II safety cabinets with air-circulation through double filters.

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

| Not applicable |

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

<table>
<thead>
<tr>
<th>Described the waste management measures which you will apply to the activity (including type &amp; form, treatment, ultimate form &amp; fate)</th>
</tr>
</thead>
</table>

**Solid waste:**
Uncontaminated waste (eg tissue/wrappings) is disposed of directly into yellow bags. All tissue culture containers exposed to virus must be treated with Kleencare DS607. After disinfection, excess liquid is drained off and the container placed directly into yellow bags. Tips are ejected directly into freshly made up DS607 within the safety cabinet. After draining, tips are placed directly into yellow bags. Pipettes are placed into autoclave bag-lined holders, which are emptied regularly. The double-bagged pipettes are boxed and placed into a yellow bag. It is the responsibility of the laboratory workers to ensure that waste is completely contained before removal by cleaning staff. If bags split or tear, a further two bags must be used.

**Liquid waste:**
All liquid should be removed from tissue culture containers prior to disposal. Liquid waste is disinfected in fresh DS607 at a final concentration of 5%. It is left to soak overnight and then disposed of down the sink.

### Project Additional Information

**Purposes of the contained use**

To study the effects of potential cancer causing genes (oncogenes) on cell growth, we need to infect primary cells with these oncogenes. To do this efficiently, we use HIV-1 viruses to carry the oncogene of interest into primary human cells. These HIV viruses are made incompetent, meaning they can only infect the cells of interest and no new HIV viruses are then produced that are able to infect new cells. The HIV viruses can therefore not replicate.
All retroviral vectors are based on Moloney Murine Leukaemia Virus. Vectors lack pol and env sequences and only encode a short sequence of ATG negative gag. Third generation LinX (derivative of 293T) packaging cell lines will be used to produce replication-incompetent virus. The gag, pol and env genes are integrated into the genome or expressed from a BPV based episomal vector that contains no regions of homology to the MMLV based vectors. Three separate recombination events would be required to produce replication-competent virus. The LinXE packaging cell line produces ecotropic virus which is incapable of infecting human cells. The cell line has been tested exhaustively for production of replication competent virus; none was detected. The combined choice of the packaging cell lines and the replication defective nature of the vector used will prevent the production of helper/replication competent virus by the transduced cells, reducing the risk to the environment.

The lentiviral system involves three plasmids that are transfected into virus producing cells, the 293T cell line. The system is secured by gene removal such that no new particles can be produced from infected cells. This system functions as the 293T cells express:

a. the viral envelope protein (VSV-G envelope) from a plasmid called pVSVG
b. The modified HIV-1 genome with the transgene (modified HIV-1 called pHIV with deleted envelope and accessory genes like tat, nef and vpr)
c. the HIV-1 accessory genes, including the reverse transcriptase and the other viral genes involved in replication (from pCMV8.9 plasmid).

This vector can stably integrate into DNA for sustained long-term expression of transgene. The vector has the ability to infect primary human cells, with subsequent expression of the foreign gene and GFP in the cells. All progeny cells will also express the foreign genes, but no new HIV-1 virions can be produced from the infected cells (replicative defective). Because the HIV-1 envelope, that usually binds CD4 and chemokine receptors, has been replaced by the vesicular stomatitis virus envelope (VSVG), this vector can infect many different cell types in vitro and possibly in vivo. VSV envelope allows entry of virus into cells by way of binding non-specifically to the membrane phospholipids of target cells, rather than relying on specific receptor binding.

### Host/vector system

**HOSTS:** E. coli strain DH10B, murine Escells, murine embryonic fibroblasts, rat neural precursors, human primary cells.

**VECTORS:** pMARXII, pMARXIV, pWZL, pBabe, attenuated HIV-1 (lentiviral) vector.

### Origin & function

All retroviral vectors are based on Moloney Murine Leukaemia Virus. Vectors lack pol and env sequences and only encode a short sequence of ATG negative gag. Third generation LinX (derivative of 293T) packaging cell lines will be used to produce replication-incompetent virus. The gag, pol and env genes are integrated into the genome or expressed from a BPV based episomal vector that contains no regions of homology to the MMLV based vectors.

Three separate recombination events would be required to produce replication-competent virus. The LinXE packaging cell line produces ecotropic virus which is incapable of infecting human cells. The cell line has been tested exhaustively for production of replication competent virus; none was detected. The combined choice of the packaging cell lines and the replication defective nature of the vector used will prevent the production of helper/replication competent virus by the transduced cells, reducing the risk to the environment.

The lentiviral system involves three plasmids that are transfected into virus producing cells, the 293T cell line. The system is secured by gene removal such that no new particles can be produced from infected cells. This system functions as the 293T cells express:

d. the viral envelope protein (VSV-G envelope) from a plasmid called pVSVG
e. the modified HIV-1 genome with the transgene (modified HIV-1 called pHIV with deleted envelope and accessory genes like tat, nef and vpr)
f. the HIV-1 accessory genes, including the reverse transcriptase and the other viral genes involved in replication (from pCMV8.9 plasmid)

### Evaluation of foreseeable effects

1. The transduced cells can only survive in tissue culture at 37 degrees C.
2. The modified lentivirus cannot survive outside cells (dependent on cells for DNA integration), and is replicative incompetent; thus the lentivirus cannot propagate to infect new cells and pose a negligible risk to the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Virkon (a perioxygen compound) used at a concentration of 1% is known to have a wide range of microbial activity and is bacteriocidal against many human viruses, including HIV. All tissue culture material and disposable plastic ware will be soaked for a minimum of 18-24 hours in a freshly prepared 1% Virkon solution. The fluid is then disposed of down a laboratory sink with excess water. Solid waste is then double bagged in biohazard bags and autoclaved at 134 degrees C for 20 mins at 3.2 bar pressure.

The autoclave undergoes a planned preventative maintenance inspection every 3 months together with an annual thermometric testing by the installation company. Chart recorder print-outs are available for checking that the correct temperature and holding time have been achieved.

All inactivated waste is then treated as "clinical waste" and removed from site by a UCL contractor for incineration.

### Project Additional Information

**Purposes of the contained use**

HEK293 cells will be used for amplification of the adenovirus, then primary porcine pulmonary endothelial and smooth muscle cells will be infected to express recombinant proteins.

**Recipient or parental organism**

HEK293 cells, of human origin, require handling at containment level 2. Porcine cells are not a hazard to humans and will not survive in the environment. Disabled adenoviral vectors are described below.

**Host/vector system**

Disabled adenoviral vectors due to removal of E1 and E3 elements in genome. Unable to replicate except in an engineered cell line (HEK293). Source: Dr Anne Ridley, Ludwig Institute for Cancer Research, UCL.

Adenoviral vectors have a limited host range, primarily human but they will infect some other animal species, although they are not pathogenic.

**Origin & function**

Disabled adenoviral vectors due to removal of E1 and E3 elements in genome. Unable to replicate except in an engineered cell line (HEK293). Source: Dr Anne Ridley, Ludwig Institute for Cancer Research, UCL.

Adenoviral vectors have a limited host range, primarily human but they will infect some other animal species, although they are not pathogenic.
Insert DNAs:
- constitutively active (V12) RhoA, Rac1 and Cdc42 (source organism: human). Function: Mutant is unable to hydrolyse GTP. Alters actin organization, intercellular junctions and growth regulation.
- B-gal (source organism: E. coli). Function: Hydrolyses lactose to yield galactose and glucose.
- GFP (Source organism: Aequoria victoris). Function: fluoresces green.

Source Laboratory: Dr Anne Ridley, Ludwig Institute for Cancer Research, UCL.

Evaluation of foreseeable effects

The adenoviruses are replication-defective due to removal of E1 and E3 elements in genome and will not multiply if they infect an animal. Although non-replicative, there is a risk that genes encoded by the adenovirus could be potentially harmful to humans. This would be limiting and non-infectious. Dominant negative and constitutively active forms of Rho GTPases: RhoA, Rac1 and Cdc42 have potential growth altering properties. Other inserts, B-gal and GFP can be toxic when expressed at high levels in cultured mammalian cells.

Risk to the environment following accidental release of any of the GMMs is very low. However, the risk of dissemination in the environment will be eliminated by handling in containment level 2 laboratory where all the waste is decontaminated prior to exit from the laboratory.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None applied for

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The risk of dissemination in the environment will be eliminated by handling in containment level 2 laboratory where all the waste is decontaminated prior to exit from the laboratory.

Liquid waste: 5,000 ppm hypochlorite (PreSept tablets) for 6-12h, then disposed of down laboratory sinks. This has been shown to kill 100% of infectious organisms and cells.
(Pasteur pipettes, pipette tips, tissue culture dishes): 5,000 ppm hypochlorite for 6-12h, followed by autoclaving at 135 degrees C for 20 minutes, then incinerated.

Solid Waste: 5,000 ppm hypochlorite (PreSept tablets) for 6-12h, then autoclaved at 135 degrees C for 20 mins, then incinerated. This is accepted to kill 100% of infectious organisms and cells.

Project Additional Information

Purposes of the contained use

Aims: To identify the molecular basis for the virulence of respiratory pathogens, especially Streptococcus pneumoniae, and their interaction with the host, and to investigate potential new therapies of vaccine candidates.
Methods: Candidate Streptococcus pneumoniae virulence genes will be inactivated by targeted deletion or disruption in the pathogenic bacteria, and the phenotypes of the resulting mutant strains characterised. In order to do this candidate virulence genes will have to be amplified from S. pneumoniae DNA and ligated into shuttle or suicide vectors propagated in laboratory strains of E. coli to construct gene deletion/disruption, complementation, and inducible expression plasmids. In addition S. pneumoniae genes will be expressed in E. coli for purification of the corresponding protein for vaccine experiments and biochemical analysis. Most culture volumes will be small scale (10 to 20 mls), although the occasional large scale protein purification will require culture volumes of up to 2000 mls. As the project is constantly evolving which candidate virulence genes cannot be specified, but will include cell membrane transporters, regulators, cell wall and stress response proteins. In addition, experiments may be performed using other wild-type and genetically modified Gram positive bacteria, including Streptococcus species (S. pyogenes, S. agalactiae and viridans Streptococci) and Staphylococcus species (S. aureus and S. epidermis). The GMM strains of these species will be acquired from other laboratories and not constructed within Dr Brown’s laboratory.

The majority of the work uses capsular serotype 3 (0100993) or 2 (D39) S. pneumoniae strains, and as those are wild type S. pneumoniae clinical isolates capable of causing disease in humans (otitis media, pneumonia, septicaemia and meningitis) they pose the most hazard inherent to the project. However, the genetic modifications to S. pneumoniae will usually either decrease or have no effect on the virulence of the recipient strain. S. pyogenes, S. agalactiae and S. aureus strains will also be clinical isolates capable of causing disease in humans (mainly soft tissue infections and septicaemia). Viridans Streptococci and S. epidermis are only of low pathogenicity in the normal host.

Recipient or parental organism

| Escherichia coli (K12 laboratory strains) |
| Streptococcus pneumoniae (pathogenic and laboratory strains) |
| Streptococcus pyogenes (pathogenic and laboratory strains) |
| Streptococcus agalactiae (pathogenic and laboratory strains) |
| Viridans Streptococci (pathogenic and laboratory strains) |
| Staphylococcus epidermis (pathogenic and laboratory strains) |

Host/vector system

| pEVP3, pID701, pACH74, pUCMUT, pJPC9111, pJPC9112, pLSIGFP, pLS70GFP, pLS70GFPcat, pNE1, puc18/19, pBluescript, Acceptor vectors, TOPO vectors, pACYC184, pQE expression vectors, pET15b, pEMCat, pEMSpc, plus the Magellan2 transposon. |

Origin & function

| Streptococcus pneumoniae genome (to allow construction of vectors for targeted gene disruptions, inducible expression or complementation), antibiotic resistance genes (to allow selection of mutant strains), green fluorescent protein gene and its derivatives, other markers for gene expression (eg lacZ). |

Evaluation of foreseeable effects

| Bacterial species: |
| E. coli - no hazard as laboratory non-pathogenic strain (K12 derivatives, ACDP category 1) |
| Viridans Streptococci and S. epidermis: Both these species are only pathogens in immunocompromised hosts or those with cardiac structural defects. They are present in all humans in very large numbers in the oropharynx (viridans Streptococci) or on the skin (S. epidermis). The only risk of infection is after inadvertent parenteral inoculation of a researcher, and even then this would only have a low risk of causing a significant infection (eg septicaemia) in the absence of severe immunodeficiency. |
| S. pneumonia, S. pyogenes, S. aureus, S. agalactiae - ACDP category 2 organisms. The project will use clinical isolates which could potentially cause invasive disease in humans. Infection will require either accidental parenteral inoculation (all species), transfer to broken epithelial barriers (S. aureus and S. pyogenes) or inhalation of an aerosol (all species). Transfer to damaged epithelial layers of S. pyogenes or S. aureus could cause mild and self-limiting soft tissue infections (eg minor cellulitis or abscesses) but very rarely could cause a more serious illness (erysipelas, necrotising fasciitis, or septicaemia). Inhalation of an aerosol initially could result in asymptomatic nasopharyngeal carriage (all species) followed by invasive disease including pharyngitis (S. pyogenes), pneumonia (S. pneumoniae and S. aureus), |
meningitis (S. pneumoniae) or septicaemia (S. pneumoniae). As nasopharyngeal colonisation by these pathogens is present in many of the population at any one time only a minority of whom develop invasive disease, the rate-limiting step for invasive infection occurs after nasopharyngeal colonisation and limits the potential danger of accidental exposure to an aerosol of these pathogens. Parenteral inoculation is potentially hazardous as it could result in direct introduction of the pathogenic species into the blood. However this can only occur if bacteria are being inoculated using needles which effectively is only during work with animals. Of importance is that any accidental parenteral inoculation is readily identifiable by the recipient. S. agalactiae is not usually a pathogen in adults except after labour and is only likely to cause infection after accidental parenteral inoculation.

S. pneumonia, S. pyogenes, S. aureus, S. agalactiae are all obligate human pathogens and therefore will not be able to spread within the environment. Nosopharyngeal colonisation of a researcher could lead to spread of the bacteria (wild type or GMM strains) to other close contacts. However person-to-person spread of all these pathogens is a continuous process involving a high proportion of the population at any particular time, and the significance of one researcher spreading one of the clinical isolates of the pathogens used for this research would therefore be limited. Most GMM strains will have gene deletions are likely to be less virulent or have a survival disadvantage compared to wild type strains due to disruption of virulence genes and insertion of heterologous DNA. On occasions regulator genes maybe inserted into replicating plasmids under the control of an inducible promoter and transformed into S. pneumoniae, and therefore create a strain which can overexpress a virulence regulator. However the level of expression would be dependent on a specific environmental signal (eg raffinose) which is unlikely to be present at a high concentration within the nasopharynx, and expression would therefore not occur if the strain were to colonise a researcher.

Vectors:
Potentially could spread antibiotic resistance to environmental organisms and hence from there to pathogens, but this is an unlikely train of events in the absence of positive selection. In general genes conferring resistance to antibiotics not routinely used in clinical practice are used as selectable markers (eg kanamycin and chloramphenicol), hence the clinical effect of inadvertent spread of antibiotic resistance to pathogenic species is reduced.

Inserted sequences:
No potential harm likely, as fully functioning virulence determinants usually require interaction with other proteins and only one S. pneumoniae gene will be expressed or carried in E. coli at one time.

GMM:
S. pneumoniae GMM strains will have either a similar or lower pathogenic potential as described for the wild type strains above.

Propagation of plasmids containing S. pneumoniae DNA or expression of S. pneumoniae proteins in E. coli will be very likely to result in increased virulence as (a) only non-pathogenic laboratory strains of E. coli will be used and the expression of a single S. pneumoniae virulence trait will not alter this (b) pneumoniae proteins tend to be detrimental to E. coli replication (c) most S. pneumoniae virulence proteins require co-operation with several other S. pneumoniae structures to achieve virulence.

Potential cross-contamination between GMM bacterial pathogens and one of the other Streptococci or Staphylococci species under investigation is unlikely to occur as usually experiments involving different pathogens will occur at different times and most of the vectors used will not replicate within Gram positive organisms. In addition in general transfer of genetic modifications requires positive selection and specific environmental signals to encourage bacterial uptake of heterologous DNA (eg Competence Stimulating Peptide of S. pneumoniae). Finally, as discussed above most bacterial virulence proteins require co-operation with several other structures to achieve virulence and will be unlikely to substantially affect the virulence of a different bacterial species in isolation.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
This project was approved as a class 2 activity by the UCL GM Safety Committee at its meeting on 3 July. The laboratory in which it will be carried out is constructed and managed to containment level 2 standards.

Project Ref 14/04.1

GENETIC MODIFICATION OF HAEMATOPOIETIC AND VASCULAR CELLS WITH REPLICATION INCOMPETENT VIRAL VECTORS CARRYING THERAPEUTIC GENES.

Class 2

Consent Granted not applicable
We aim to modify haematopoietic and vascular cell progenitors with antioxidant or anti-inflammatory genes and study the effects of these genes on the functional properties of the recipient cells. In future we will examine the therapeutic potential of the genetically modified cells in models of cardiovascular disease. We also aim to modify progenitor and mature vascular cells with genes that alter the activity of the enzyme telomerase in order to elucidate its function in vascular cell physiology.

Recipient or parental organism

The recipient organisms used in this study are human haematopoietic/vascular progenitor cells, or mature endothelial cells and vascular smooth muscle cells isolated from human, rabbit and pig vessels. These are eukaryotic cells which do not survive outside cell culture conditions unless introduced into animals or humans, regardless as to whether they are genetically modified or not. In the case of human cells the work carries an inherent potential risk due to the possible presence of human pathogens (however, cells are derived from donors certified to be free of common pathogens such as HepB and HIV). We have no reason to believe that genetic modification of these cells will trigger additional risks.

Host/vector system

We will use the following retroviral vectors: 1) MFG-IRES-EGFP a vector based on MoMLV, supplied by Queen Mary University of London, containing and IRES sequence and the marker gene EGFP; 2) pBABE-puro, supplied by Harvard Med School, USA, expressing the puromycin resistant gene; 3) pMKO.1-puro which is based on pQCXIN (Clontech), pSUPER.retro.puro which is based on a self-inactivating pMSCV-puro, purchased from OligoEngine, USA. We will also use lentiviral vectors based on HIV-1, AAV based on serotype 2, adenoviral vectors based on serotype 5 and baculovirus, all of which are obtained from University of Kuopio, Finland). All viral vectors are replication incompetent. In the case of retroviral vectors sequences encoding structural genes and envelope proteins essential in replication and virus assembly are mutated or removed totally or partially from the viral backbones. Self-inactivating lentiviral vectors will have deletions in the U3 region. In adenoviral vectors, genes involved in transcriptional regulation, virus replication and virus assembly (ie E1 alone or together with E2A, E2B and E4) are deleted partially or totally. In AAV vector backbones, viral genes are mostly replaced by non-viral DNA and by sequences of oncoretroviral vectors such as the LTR promoter, but not with genes essential for replication and virus assembly. In all cases missing gene functions are provided in trans by packaging cells. Baculoviral vectors are considered safe and nearly all the viral genome is included. The following packaging cells are used to produce viral particles: pHi-NX, PT67 and 293. Transgene expression is driven by commonly used eukaryotic promoters such as CMV, SV40E, U6, PGK and H1-RNA. An IRES sequence is used to obtain a bicistronic mRNA.

Origin & function

All the genes of interest used in this study are based on human sequences and do not alter the characteristics of the vectors carrying them. They correspond to

1) The extracellular superoxide dismutase gene, supplied by Queen Mary University in London. When expressed this gene localize to the extra cellular surface of the cell where it catalyses the conversion of superoxide into hydrogen peroxide. Expression of this gene effects the extracellular redox environment of the cell.

2) A chimeric TNF-alpha receptor antagonist comprising two monomeric forms of the human p75 soluble TNF receptor extracellular domain linked by a 15 amino acid bridge. (Croxford et al. J Immunol 164:2776, 2000). When expressed this gene produces a secreted molecule which binds to TNF-a and neutralises its activity. Expression of this gene will modulate cellular responses where TNF-a is involved, in particular inflammatory processes.

3) A catalytically inactive human telomerase mutant (DN-hTERT) supplied by Harvard Med. School, USA (Hahn et al. Nat. Med. 5:1164, 1999). When expressed this gene will produce a catalytically inactive form of telomerase. Expression of this gene will result in an overall inhibition of intracellular telomerase activity which may interfere with the maintenance of telomere integrity and cellular replicative capacity.

4) A human telomerase catalytic subunit small interfering RNA (hTERT siRNA) comprising hTERT sequences from nt 3114-3134, followed by 9 bp to form a loop and the corresponding anti-sense hTERT nucleotides, followed by 5 uridines, (Masutomi et al. Cell 144:241 2003). When expressed this sequence will activate the destruction of endogenous telomerase mRNA. This will have the same effect as the described for DN-hTERT above.
Evaluation of foreseeable effects

ENVIRONMENTAL EFFECTS: except for adenoviruses which can remain viable for a limited period of time outside laboratory conditions, all other viruses and infected eukaryotic cells do not survive if accidentally released into the environment.

EFFECTS ON HUMAN HEALTH: In case of accidental infection with any of the viruses used in this study there is a theoretical possibility of reversion of the disabling mutations by recombination between the viral vector sequences and endogenous viral sequences already carried by the host. However, the presence of pre-existing viral sequences in the accidentally infected cells is rare. In addition some of the viruses used in this study are self-inactivating, further increasing their safety.

In the case of vectors able to integrate in the host genome (oncoretrovirus, lentivirus and AAV-derived vectors) there is a very low possibility of insertional mutagenesis into the host genome.

In the case of adenoviruses, these are known to cause adverse immunological reactions, but very high exposure is required for this to occur.

The inserted genes used in this study are not oncogenic or known to be harmful by themselves in any other way. However, if a large quantity of viral particles containing anti-oxidant or anti-inflammatory genes used in this study were to gain access to the blood stream or the lung airways accidentally, there is a theoretical possibility that they might temporarily lower the body's natural defences. Rare cases of tuberculosis have been reported in association with anti-TNF-alpha therapy. Where inhibition of telomerase is concerned this is unlikely to have an effect on quiescent cells; it may however confer a growth disadvantage of replicating cells (e.g. blood cells) but the effect may not be manifested before many cell divisions occur, in which case the cells will naturally be replaced by healthy ones.

In case of accidental exposure to the genetically modified cells, these cells are unlikely to survive for a significant period as the host immune system will eventually eliminate them.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Cell cultures, liquid waste or any other material coming into contact with viruses will be treated with 10% Virkon (a strong oxidising agent) for more than 12 hours and/or autoclaved. This treatment gives 100% kill. After viral inactivation liquid waste is disposed in designated sinks and solid waste is incinerated.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

Although this project was considered by the GM Safety Committee to be on the borderline between classes 1 and 2, nevertheless the Committee felt that there was sufficient potential for severe consequences (though low in likelihood) for this project to be classified as an activity class 2 project.

02/03/2022

Page 665 of 1532
### Project Additional Information

**Purposes of the contained use**

A commercially available disabled lentiviral vector (Virapower Lentiviral system (Invitrogen) to be used to transfer genes to human or mouse cells in vitro to determine the effect of their expression on human cells.

**Recipient or parental organism**

The genes will be transferred to human prostate cancer cell lines including DU145 and PC3, normal human prostate epithelial cells including NP1542, mouse fibroblast cell line NIH3T3, dog and human kidney cell lines MDCK and 293T, monkey cell line Cos1 and other related mammalian cells. The vector DNA will be grown up in E. coli.
The genes to be transferred include plexins, semaphorins, Met, Rac, Rho, Rnd, PDZRhoGEF and other related genes.

Host/vector system

A commercially available disabled lentiviral vector (ViraPower Lentiviral system (Invitrogen)) will be used as vector.

Origin & function

The vector system will be obtained from Invitrogen, the cells lines are already available in the lab, previously obtained from the originators. cDNA of the genes to be transferred have been synthesised in the lab or obtained from other labs. The genes will be transferred in order to determine the effect of their expression on human cells.

Evaluation of foreseeable effects

Since the vector to be used is a disabled virus it will be unable to replicate in any host. The virions however could possibly infect human cells in vivo if inadvertently injected. The recipient cells will not survive in the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All work to be carried out in a designated laminar flow cabinet. All waste to be disinfected and autoclaved. Sharps will not be used in work involving the virions and gloves and lab coats will be worn.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste will be disinfected with Virkon and then autoclaved.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

A representative panel from the GMSC accept sthat this project should be classified as 2, rather than 1. Oncogenesis may depend on more events than merely the (accidental) insertion of one gene but it is possible that, in a "worst case" scenario, this might happen.

### Project Additional Information

**Purposes of the contained use**

The use of replication deficient lentiviral-based vectors to express cDNAs encoding synaptophysin, synaptotagmin, synaptobrevin, potassium channel Kir2.1, and any of their dominant-negative, and green-fluorescent-protein fusion protein forms, and siRNA against sodium channel subunits, in a number of established rodent and human cell lines, in cultured cells isolated from rodent tissue and in brains of rodents. The aim is delineate the molecular mechanisms of regulating synapse strength and plasticity, and viral vectors are required for efficient delivery of synapse proteins to mark synaptic terminals and/or to perturb their function.

**Recipient or parental organism**

The primary recipient organisms will be cultured cells, including human 293 cells and rodent neurons. In some experiments, we will carry out injections into rat or mouse brain.

**Host/vector system**

The vectors will be based on the latest generation of lentiviral vector design (see Lois et al. 2202 Science 295:868-72), which includes refinements that rended accidental generation of a replication competent virus to be virtually impossible. The viruses, however, contain some HIV sequences and are pseudotyped with VSVg envelope such that human cells can be infected even if they are not dividing. Therefore, production and handling of viruses will require implementation of special safety measures at the containment level "2".

**Origin & function**

The use of replication deficient lentiviral-based vectors to express cDNAs encoding synaptophysin, synaptotagmin, synaptobrevin, potassium channel Kir2.1, and any of their dominant-negative, and green-fluorescent-protein fusion protein forms, and siRNA against sodium channel subunits, in a number of established rodent and human cell lines, in cultured cells isolated from rodent tissue and in brains of rodents. The aim is delineate the molecular mechanisms of regulating synapse strength and plasticity, and viral vectors are required for efficient delivery of synapse proteins to mark synaptic terminals and/or to perturb their function.
The inserted sequences encode brain specific proteins that are expressed in synapses. Our primary purpose of the use of the viral vectors will be to permit visualisation of synapses modification of synaptic efficacy at individual synapses.

**Evaluation of foreseeable effects**

The likelihood of viral vectors causing harm to health and environment is minimal. This is due to the fact that the viruses are defective for replication, and non-oncogenic and the overall non-invasive properties of gene sequences to be inserted.

The inserted sequences encode brain specific proteins and they are not oncogenic. Potential harm, which is expected to be minimal, cannot manifest unless the sequences

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

This derigation applies only to the work in the animal unit, involving the transport and injection of virus particles into rodent brains. Procedures used in the laboratory will be applied to the work in the animal facility. Note that injections require only small amounts of virus particles (less than 1 nl) at a time, and the virus has been modified in such a way that it is virtually impossible to accidentally generate a replicon competent virus. The virus is replication deficient due to (i) separation of packaging genes into two plasmids, each lacking both LTRs and the viral packaging signal (ii) deletion of env, vpr, vpu, vif, and nef viral genes from the packaging vector, (iii) the presence of self-inactivating LTR (TATA box deletion) in the vector expressing the packaged viral genome, and thereby resulting in no expression viral gene products, (iv) the expression of envelope VSVg on a separate vector. A full explanation is provided in the Risk Assessment.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Following virus usage, any material that come into contact with the viruses will be thoroughly decontaminated by soaking in 3% Virkon for at least 60 min, followed by draining and disposal to biohazard waste. Bottles of media used for infection will be isolated from all others and immersed in 3% Virkon before being placed into standard glassware containers. Liquid waste will be treated with 3% Virkon for at least 60 minutes before disposal. Spills will be immediately treated with 3% Virkon. If there is a spillage on the laboratory coat, it will be placed into a plastic bag and autoclaved. Aerosol production will be minimised through the use of microbiological practice, plugged-tips, plugged-pipettes, and infected cultures will only be handled within a microbiological safety cabinet (to BS 5726) in the viral suite (G17). G17 does not contain windows and are not readily accessible to insects, etc. The laboratory environment will be monitored for insects and any that are found will be killed. As indicated above the recombinant virions produced in this system are replication deficient.

Project Additional Information

Purposes of the contained use

This connected programme of work aims to investigate how the human herpesvirus, Kaposi's sarcoma associated herpesvirus (KSHV) is able to infect, persist in a latent state, reactivate into a lytic cycle of virus production and in some cases immortalise certain cell types. This connected programme will use a number of standard molecular biology/virology methods to produce recombinant KSHV and monitor KSHV infection, over-express different viral and host genes and ablate through RNAi different virus and host genes. These methods will be used to determine the phenotypic outcomes of KSHV and host interaction. We will use the BAC36 Recombinant KSHV bacterial artificial chromosome to transfect human cells and rescue infectious KHSV virus that has an integrated GFP/puromycin selectable marker expression cassette within the viral genome. This infectious virus will be used to infect eukaryotic cells (including human), both cell lines and primary cells using GFP expression as a marker for virus infection. Further, the BAC36 Recombinant KSHV plasmid will be used to delete additional KSHV
genes by homologous recombination of a Kanamycin resistance, gene disruption cassette with the BAC36 in E.coli DH10B in the presence of the helper plasmid pGETrec. Kanamycin resistant BAC DNA will be isolated from the E.coli and used to transfect human cells to produce gene deletion KHSV mutant viruses for further characterisation. This system will be used to monitor the infection of human cells by KSHV and identify the function of KSHV genes in the appropriate cellular context.

We will use standard eukaryotic gene expression vectors and recombinant retroviral vectors to deliver into eukaryotic cells (including human), both cell lines and primary cells, host and/or KSHV genes. The expression cassettes will direct either the controlled or constitutive expression of said genes to investigate the effect of these genes on host and virus interaction. Similarly, we will use recombinant retroviral vectors to deliver into eukaryotic cells (including human), both cell lines and primary cells, an RNA polymerase III promoter expression cassette that directs the production of shRNA that is converted in the cell to RNAi. These RNAi’s will target either host and/or KSHV genes to ablate their expression at the mRNA level. We will use these methods to investigate the result of the loss of these genes on host and virus interaction.

### Host/vector system

Host cell lines and primary cells including: 293T, HeLa, NIH3T3, B-cell lines from all stages of B-cell including BJAB, Ramos, Raji Tom-1, DEL RPMI-8226, BCP-1, BCBL, HBL-6, BC3, T-cell lines including C8166, CEM, SupT1, monocyctic cell lines including THP1, dendritic cell line MUTZ3, endothelial cells DMVEC, BMVEC. All cell lines and primary cells will NOT be from the workers. The bacterial hosts for expression vectors will be disabled E.coli: XL-1 Blue, TopF10, JM109, SURE. The cloning plasmids will be pGEM derivatives, pUC series, pBLSRIPT series, pcDNA3.1, pCMV/Zeo, and pEGFP-1. The retroviral vectors for either gene expression or shRNA production are retroviral vectors that use the tripatite packaging plasmid pCMVR89.1 (packaging plasmid), pMDG (envelope VSV-G plasmid) and as a transfected cell lines under puromycin selection. The foreseeable effects of transduction of the eukaryotic cells with expression vectors, or the infection of these cells with either recombinant KHSV or recombinant retroviruses would be the production of all cell line with altered properties able to establish a tumour in the laboratory workers.

### Origin & function

The pMHGP36 Bac containing the GFP gene was recombined into the KHSV genome between ORF18 and ORF19 and the resulting BAC propagated in E.coli DH10B. This is supplied to us as a gift from Professor SJ Gao (see J.Virol 2002, 76, 6185-6196 for details). The intended function of the KHSV BAC is to produce infectious KHSV particles containing a genome with an inserted GFP and puromycin expression cassette. These KHSV particles will be used to infect human and animal cells. In addition the defined gene knockouts of KHSV allowing the investigation of KHSV the gene functions. The retrovirus vector systems are standard laboratory reagents within the Division of Infection & Immunity. The vector systems originated from infectious retroviruses of
Evaluation of foreseeable effects

The bacterial strains used for all plasmid propagations within this programme of work are disabled in key bacterial functions (i.e. recombination defective) and are unable to survive in the environment or pass genetic onto host bacterial flora following a breach of containment. The cloning vector/BAC is maintained within the bacteria essentially as an extra bacterial chromosome. Due to its size it is highly unlikely to transmit from the host bacteria to environmental bacteria following a breach of containment. In addition, the GMO (bacteria containing the KSHV BAC) is not a risk to the environment as the bacterial strains used for plasmid propagation are disabled in key bacterial functions (i.e., recombination defective) and are unable to survive in the environment. The bacteria are unable to express the viral genes encoding the complete virus particle and are unable to replicate and package the viral genome contained within the BAC. Therefore there is no risk of KSHV particles being produced from bacterial culture. Similarly, the plasmids used for the production of retroviral vectors split the retroviral genome into three separate plasmids such that virus production is only initiated when all three plasmids are present in a eukaryotic cell. Therefore there is no risk of retroviral particles being produced from bacterial culture. OVERALL THE RISKS OF ADVERSE EVENTS FROM THE HANDLING OF BACTERIA, PLASMIDS (INCLUDING THOSE EXPRESSING KNOWN OR POTENTIAL ONCOGENES) AND THE KSHV BAC ARE LOW.

The risks associated with BAC36. Recombinant KSHV plasmids are through the risk from accidental transfer of the vector to the worker. The main risk is therefore to the laboratory personal directly handling the BAC. If this was to transfer into a permissive host cell there is a small chance of the vector establishing a KSHV infection. This is a very low risk as herpesviruses require viral proteins to initiate the infectious cycle and these would not be present with the BAC DNA as the bacteria are unable to express the viral genes. The BAC36 Recombinant KSHV will only efficiently produce replication competent extracellular KSHV when transfected into human cell lines and induced by the addition of TPA or sodium butyrate. Therefore the control of virus particle production can be contained both physically in a category 2 tissue culture laboratory and by prevention of virus production by the absence of the inducing agent. Recombinant or wild type KSHV are therefore unlikely to be transmitted to, or on from the laboratory workers during routine laboratory experiments or following disposal of laboratory waste.

Wild type KSHV is categorised as a Hazard Group 2 virus similar to Epstein Barr virus. Like Epstein Barr virus, KSHV is none hazardous in a healthy individual but can cause tumours in an immunodeficient setting. BAC36 Recombinant KSHV or any further virus gene deletion mutants will not pose a greater risk to the individual than wild type virus following a breach of containment. KSHV as a Hazard Group 2 pathogen can be handled routinely in a Category 2 tissue culture laboratory and therefore the BAC36 Recombinant KSHV and virus deletion derivatives will also be safe to handle under the same containment. OVERALL THE RISKS OF ADVERSE EVENTS FROM HANDLING VIRUS DERIVED FROM THE KSHV BAC ARE LOW.

For the retroviral gene expression and gene ablation vectors production of infectious viral particles only occurs following transfection of the three plasmid system into eukaryotic cells. Therefore the control of virus particle production can be contained both physically in a category 2 tissue culture laboratory and by prevention of virus production by the absence of all three plasmid vectors. Retroviral vectors are therefore unlikely to be transmitted onto the laboratory workers during routine laboratory experiments involving the retroviral vector plasmids or following disposal of laboratory waste. The main risk is accidental exposure of laboratory workers to recombinant retroviruses. As these retroviral vectors are self-inactivating the risk of onwards transmission to another person is almost zero. The main risk is therefore alteration of the cellular function of the exposed person through insertional inactivation/activation of tumour suppressor genes/oncogenes respectively, or the alteration of cellular function by gene overexpression or ablation from the transferred genetic material within the vector. THESE ARE EXTREMELY UNLIKELY EVENTS THAT HAVE ONLY OCCURRED IN A CLINICAL SETTING FOLLOWING PROLONGED INFECTION WITH HIGH TITRE RETROVIRAL VECTORS AND SELECTION IN VIVO FOR CELLS WITH ALTERED GROWTH POTENTIAL. THEREFORE THE OVERALL RISKS ARE LOW.

Together the risks identified within this integrated programme of work can be minimised to acceptable LOW levels by working to existing laboratory standards and practices in designated Category 2 level containment. This is supported by the accompanying risk assessment.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Not applicable.

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Laboratory workers are responsible for the following procedures:
Method of GMM inactivation: In accordance with Departmental COP Bacterial culture supernatants are treated with Hycolin (1:80 concentration) for at least 16 hours before disposal to the drains. Bacterial plates are double bagged in clear autoclave bags and placed in designated (green) bins for autoclaving.

Method of GMM inactivation: In accordance with Departmental COP cell culture supernatants are treated with Hycolin (1:80 concentration) for at least 16 hours before disposal to the drains. Tissue culture plastics are double bagged in clear autoclave bags and placed in designated (green) bins for autoclaving.

Wash up staff are responsible for the transport of designated green bins to the autoclave room, autoclaving the double bagged contents and transfer of autoclaved waste into yellow bags for collection and disposal by incineration.

Project Ref  14/05.3

02/03/2022  Page 673 of 15326
Our interest is in Schwann cells, the myelinating cells of the peripheral nervous system. These cells are an ideal system in which to study mechanisms controlling cell proliferation, survival and differentiation. Their ability to regenerate after nerve injury may give key insights into increasing the repair process after injury to the central nervous system. By using adenoviral mediated gene transfer, we hope to study the intracellular pathways and transcription factors that control the development and differentiation of this exquisitely specialised cell type.

All adenoviruses used for this work are deleted for the E1 and E3 regions of the adenoviral genome and are therefore replication deficient; these are therefore classified as Category 1. The host cells, Schwann cells, are primary cells which are non-immortalised and non-transformed. The transcription factors such as Pax-3 or molecules that alter intracellular signalling such as the receptor Notch may have effects upon the differentiation and proliferation of the host Schwann cells in vitro.

The preparation of adenoviruses would be performed using the AdEasy adenoviral kit (from Qbiogene Inc), which is a widely used reagent. Adenoviruses used are E1/E3 deleted and are therefore replication deficient. E1 function is complemented in 293 cells for the amplification and production of viral stocks. Adenoviruses would then be used for infection into primary mouse or rat Schwann cells.

The cDNA's encoding the transcription factors and proteins involved in cell signalling would be either of rodent or human origin. Initially for example we would look at the function of Pax-3, a DNA binding transcription factor that regulates gene expression during normal development in cells. The Pax-3 coding sequence that we would express is from the mouse. For the analysis of signalling pathways involved in Schwann cell development and differentiation, we would use either activated or dominant negative forms of the intracellular signalling molecules, for example the p38 MAP kinase pathway, that have been obtained in collaboration with other scientific research groups. These would be used to either switch on or inhibit certain signalling pathways in Schwann cells, and we would then measure the effect of this upon the phenotype of our cells using a number of different analyses.
Expression of molecules such as Pax-3 and Notch may well change the proliferative and differentiation state of the recipient Schwann cells. However, even if there were a complete breakdown of containment, because the adenoviral vectors are replication deficient, the risk to both human health and the environment is low.

N

The Committee noted that the applicant classified this project at level 2 on the basis of one report that deregulation of Pax3 can transform mouse cells in culture. The Committee noted further that there is no evidence that it will transform Schwann cells for other cells in culture.

Nevertheless, the Committee agreed with the proposer's assessment that, as a precaution, the work ought to be carried out at containment level 2 and accordingly approved this project as a class 2 activity.

Project Additional Information

Purposes of the contained use

Tissue culture cell lines will be transduced by replication-deficient retrovirus vectors in order to overexpress or knock-down cadherin and its binding proteins.

Recipient or parental organism

We will work with replication deficient retroviruses. These viruses are made by transfecting HEK293T cells with: 1) a plasmid expressing the gag and pol genes from murine leukemia virus (MLV) which encode for viral structural and polymerase proteins, respectively, 2) a gene encoding a viral envelope protein (VSV-G) which will determine the host range of the virus produced, 3) an expression plasmid (either pBabe-puro or pRetroSUPER) containing the gene of interest and a packaging signal, allowing it to be incorporated into the virus particles.

Host/vector system

HOSTS: HEK293T for virus production, immortalized mammalian cell lines in vitro.
VECTORS: pRetroSUPER, LZRS-MS-neo, pBabe-puro.

Origin & function

Inserts:
cadherin and its binding proteins
small oligos for the production of siRNA in vivo
indicator proteins (GFP, dsRed, LacZ)

Intended functions:
We would like to interfere with the expression of the cadherin and its binding proteins to investigate the involvement of these molecules in cellular behaviours.

Evaluation of foreseeable effects

Primary transduction, with the recombinant replication defective retroviruses, of accidentally exposed tissue, could be harmful using cell-cell adhesion protein cadherins and their binding proteins with potential cell transforming effects. Thus, the risk of accidental exposure will be limited: Any spillage will be immediately removed by treatment with 3% Virkon.

Gloves and laboratory coats will be worn at all times and can be autoclaved in the case of accidental spillage. Working in a safety hood will prevent air-mediated exposure.

To avoid any possible transfer of this virus all experiments involving retroviral vectors will be conducted in a laboratory suite reserved for virus work. The cultures will be handled within microbiological safety cabinets and appropriate precautions will be adopted throughout. Laboratory workers handling these cultures will have extensive experience tissue culture and microbiological experiments and will be fully aware of the principles of occupational safety and handling.

By autoclaving cultures and plastic ware that were in contact with transduced cells and transduced cells the virions will be completely inactivated. Liquid waste will be treated with 3% Virkon for at least 60 min.

In the viral suite (G17), media containing virus will be removed from cell cultures and disinfected with 3% Virkon for 60 min.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The local rules for working in the containment level II laboratories will be followed in all locations. These practices include the rules for work in a microbiological safety cabinet.

Gloves and laboratory coats will be worn at all times. All cuts or abrasions will be covered with waterproof dressings.

No sharps of any type (glass Pasteur pipettes, needles, razors) will be present in the vicinity of work when handling viral stocks.

Waste will be bagged for autoclaving, and the bags sealed before removing from the designated rooms.

Eye protection will be worn.

Aerosols may be produced during the handling of supernatants from transduced cultures. Aerosol production will be minimised through the use of good microbiological practice and transduced cultures will only be handled within a microbiological safety cabinet (to BS5726).

Contaminated tips, straws, etc. will be placed in a sandwich box filled with 3% Virkon for at least 60 minutes before draining and disposal into an autoclave bag. Bottles of media used for infection should be isolated from all other and immersed in 3% Virkon before being placed into standard glassware containers.

Liquid waste will be treated with 3% Virkon for at least 60 minutes before disposal.

Incubators.

Incubators reserved for transduced cultures (room G17) will be used. Transduced cell culture flasks should be placed in a closed plastic sandwich box with small holes pierced in side in order to minimise the chance of accidental spillage in the incubator but still allow access of CO2.

Spillage

Spills will be treated with 3% Virkon. If there is a spillage on the laboratory coat, it will be placed into a biohazard bag and autoclaved.
Avoidance of airborne transmission.
Procedures will be adopted to avoid the formation of aerosols. Aerosol production will be minimised through the use of microbiological practice and transduced cultures will only be handled within a microbiological safety cabinet (to BS5726). Room G17 does not contain windows and is not readily accessible to insects, etc. Windows in adjacent laboratories will be kept closed. The laboratory environment will be monitored for insects and any that are found will be killed.
As indicated above the recombinant virions produced in this system do not have the capacity to replicate in host cells or host organisms.

Treatment of virus before disposal
By autoclaving cultures and plastic ware which were in contact with transduced cells and transduced cells the virions will be completely inactivated. Liquid waste will be treated with 3% Virkon for at least 60 min.

Processing of materials for use in location outside of the viral suite.
In the viral suite (G17), media containing virus will be removed from cell cultures and disinfected with 3% Virkon for 60 min.
Cells will then be washed extensively (the wash again disinfected) in order to remove viral particles from the cultures. Since the virus used for transduction does not contain a viral genome, and is thus replication deficient, there will be no viral particles produced by the transduced cells. Thus there is no harm connected to work with cultures previously transduced with these vectors, and these cultures can be handled safely. Containers holding the inactivated virus products will be wiped out (3% Virkon) before removal. For subsequent analysis of live cells, culture dishes containing washed cell-cultures will be placed in tray and analysed without opening the dish. The dishes will be returned to the viral suite after the experiment, disinfected with Virkon 3%, and autoclaved.

02/03/2022
The objective of this research is to determine the role of HIV-1 infection on human brain and placental cells as models of HIV-1 neuropathogenesis in adults and HIV-1 transmission in utero in children, respectively. Little is known about the direct impact of HIV-1 infection of human neurones and other brain cells and what role this infection may have in the development of HIV-1 associated dementia. In this study we aim to describe this type of infection in terms of neurone subtype infected and the impact this infection has on global gene expression by gene chips. HIV-1 transmission in utero occurs in 14% of newborns with HIV mothers. We know very little about why paediatric neuroAIDS is more aggressive than its adult counterpart. Viral entry into the placenta and brain across the endothelial barrier has not been previously compared. This study will define the protective properties of the placenta and brain barrier to viral infection for the first time and how these are overcome to result in utero transmission of the virus by using cell biology approaches and changes in global gene expression will be assessed by gene chips upon HIV-1 infection.

Human cell lines and primary cells will be transfected with marker sequences that indicate the replication of HIV-1. These cells will be prepared and cultured in containment level 2 laboratory. After a maintenance period, cultures will be transferred to the CL3 laboratory and inoculated with HIV-1 isolates. The cells will then be fixed and assayed for HIV replication.

Recipient or parental organism

Human cells comprising T cell lines, primary human brain and placental endothelial cells are to be grown in culture within a category 2 tissue culture environment. Working with these cells poses some hazard due to the clinical origin of tissue (e.g. hepatitis B, herpesviruses, Mycobacteria (tuberculosis)) to researchers by accidental exposure. However these cells, themselves, do not pose any infectious hazard to researchers, or the environment as the cultures cannot survive in ambient conditions for longer than 30 minutes.

T cell lines transfected with HIV-1 LTR indicator constructs are to be used for measuring viral load in cell supernatants. These modified cells do not contain the full length viral genome and are therefore not infectious. The main hazard to health in this project originates from infection of these human cultures with viruses. HIV lab and primary
Isolates viral stocks are grown in a containment level 3 laboratory environment.

**Host/vector system**

1. Human T and monocyte cell lines/HIV-1 isolates (for viral stocks)
2. Human Indicator T cells/HIV-1 isolates (to quantify viral stocks)
3. Primary human brain cells/HIV-1 isolates (for infection studies)
4. Primary placental endothelial cells/HIV-1 isolates (for infection studies)

**Origin & function**

Indicator T cell lines (MAGI-CCR5 and CVG37), transfected previously with HIV-1 LTR driven indicator marker of β-galactosidase in MAGI cells and green protein GFP in CVG37, are used to quantify viral stocks for infection studies. Other T cells, brain and endothelial cells will be infected with full length HIV-1 isolates that have not been genetically modified and are derived from donated clinical specimens where consent has been given for their use for biomedical research.

**Evaluation of foreseeable effects**

The growth of HIV-1 stocks in human T cell lines by co-cultivation and their concentration by ultracentrifugation pose the greatest risk to the health of researchers by accidental exposure. HIV-1, a blood borne human pathogen is the causative agent of AIDS and as such will be handled and disposed of within a validated containment level 3 environment. Infection of brain cells by HIV-1 results in a persistent infection with limited viral protection. All cell supernatants and lysates are still potentially infectious.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Not applicable.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

In the containment level 2 laboratory, cell culture supernatants and excess clinical brain tissue are treated with Hcolin(1:80 concentration) for at least 16 hours before disposal. This approach achieves 100% kill of human cells and their endogenous pathogens. Tissue culture plastics are double bagged and autoclaved. The waste is later incinerated.

In the containment level 3 laboratory, disposal of hazardous and infectious material is tightly regulated, any products resulting from working with HIV-1 infected Human cell lines and Human brain cell cultures: All equipment, surfaces and floors are routinely disinfected with 5% Trigene II; Materials used in research (laboratory clothing, plastic ware) are decontaminated with up to 5% Trigene II for 16 hours prior to being discarded and autoclaved; any products from HIV-1 viral stocks or human cell cultures will be inactivated with 5% Trigene II for 16 hours to ensure 100% kill. Set procedures for waste disposal are in place within the category 3 environment: (1) solid waste (paper towels, laboratory protective clothing, plasticware) are discarded and autoclaved at 134°C for 20 mins and later incinerated; (2) Liquid waste which are, or might be infectious must be treated with 5% Trigene II for at least 12 hours before being discarded; (3) Blood waste is inactivated with 5% Trigene II for a minimum of 12 hours before being autoclaved. 5% Trigene II is a quaternary ammonium compound based detergent sanitiser that has a combined cleaning and disinfection action that is effective in inactivating all known microorganisms (inc. viruses) and ensures, with the combination of autoclaving, 100% kill of viruses in any solid, liquid or blood product that has been deemed potentially bio-hazardous during the course of experimental research in a category 3 environment.

**Is an emergency plan required according to regulation 20?**

N

**If yes, tick to confirm that it is attached to this form**

N
The UCL GM Safety Committee have approved this project as a class 3 activity involving GMMs. Although the genetically modified cells are not, in themselves, hazard group 3 materials, the experimental procedures that follow their establishment in culture must be carried out under containment level 3 management conditions.

Purposes of the contained use

The aim of this project is to investigate the mechanisms controlling the assembly and cell-to-cell transmission of enveloped viruses, in particular the human immunodeficiency virus (HIV) and the human cytomegalo virus (HCMV). Recent studies have indicated that in many cells these viruses assemble on compartments of the endocytic pathway and that a key cellular machinery, the ESCRT machinery, is essential for HIV budding. Moreover, transfer of viruses from cell-to-cell appears to occur through specialised cell surface domains with similarity to immunological synapses. The aim of these experiments is to use dominant negative forms of proteins that normally control sorting in the endocytic and exocytic pathways, and small interfering RNAs (siRNA), to investigate how the components of these viruses are brought together on late endosomal membranes to allow virus assembly and transmission to occur. Because macrophages will be a main target for analysis, lentiviral vectors will be used rather than non-lenti retrovirus vectors.

Recipient or parental organism

HEK293T for virus production, immortalised mammalian cell lines (e.g. HeLa, Cos, Chinese hamster ovary (CHO), SupT1, Jurkat, CEM, CEMx174), primary macrophages isolated from screened blood obtained from the Blood Transfusion Service, fibroblasts from knock out mice (MEF).

Host/vector system

The vectors will be based on the latest generation of lentiviral vector design (see Lois et al. 2002 Science 295-868-72), which includes refinements that render accidental generation of a replication competent virus to be virtually impossible. The viruses, however, contain some HIV sequences and are pseudotyped with VSVg envelope such that human cells can be infected even if they are not dividing. Therefore, production and handling of viruses will require implementation of special safety measures at the containment level 2.

Origin & function

The inserted sequences encode cellular proteins that are implicated in the assembly and transmission of HIV and HCMV - two major human viral pathogens. Our primary reason for using lentiviral vectors is that they allow transfection and expression of these proteins in non-dividing cells - macrophages - to permit visualisation of assembly and viral transmission.

Evaluation of foreseeable effects

The likelihood of viral vectors causing harm to health and environment is minimal. This is due to the fact that the viruses are defective for replication, and non-oncogenic and the overall non-invasive properties of gene sequences to be inserted.

The inserted sequences encode cellular proteins that are not oncogenic.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All experiments will be conducted in mammalian cell lines kept in ACDP containment level 2 facilities in the MRC-LMCB.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Following virus usage, any materials that come into contact with the viruses will be thoroughly decontaminated by soaking in Trigene (5%) for at least 60 min, followed by draining and disposal to biohazard waste. Bottles of media used for infection will be isolated from all others and immersed in Trigene (5%) before being placed into standard glassware containers. Liquid waste will be treated with Trigene (5%) for at least 60 minutes before disposal. Spills will be treated immediately with Trigene (5%). If there is a spillage on a laboratory coat, it will be placed into a plastic bag and autoclaved. Aerosol production will be minimised through the use of microbiological practice, plugged-tips, plugged-pipettes, and infected cultures will only be handled within a microbiological safety cabinet (to BS 5726) in the viral suite (G17). G17 does not contain windows and are not readily accessible to insects, etc. The laboratory equipment will be monitored for insects and any that are found will be killed. As indicated...
above the recombinant virions produced in this system are replication deficient.

This project has been considered by a representative panel of advisors on behalf of the UCL GM safety committee who agreed with the classification and risk assessment for notification to the HSE. The proposal will additionally be considered in full at the next scheduled GMSC meeting in accordance with the procedures of the committee.

**Project Ref** 14/06.5

- **Date Ackn'd**: 13/11/2006
- **CU2 Project Title**: Cloning and characterisation of cellular factors involved in the early steps of retroviruses replication.
- **Class**: Class 3
- **CultureVolClass2**: 1-50 Litres
- **Consent Granted**: Yes
- **Project notified under transitional arrangements**: N

**Historical Significant Changes**: 14/06.5 replaces 14/01.4 and the sig. Change to it 14/06.2.
Cloning of cellular factors important for retrovirus replication will foster progress in the development of specifically targeted anti-viral compounds. Mapping the molecular interactions between cellular factors and viral proteins and understanding such interactions at a structural level will increase our chances to find small molecules inhibitors by rational design. Knowledge about the molecular processes involved in retroviruses’ replication will improve the design of both viral and non-viral gene therapy vectors and may reveal unexpected biological phenomena. Ultimately the function of any cloned cellular factor as well as its possible inhibitors will have to be tested with both replication incompetent and replication competent retroviruses, in particular HIV-1 and SIV. HIV-1 is pathogenic in humans and causes AIDS, thus it must be used only in an appropriately contained environment. SIV represent a valid target of research because of its use in primate animal models of AIDS.

1. Recombinant viral vectors. Murine leukaemia virus (MLV), HIV-1 and SIVmac-based retroviral vectors will be used. Theses vectors are made by three separate Componenets: core-enzyme proteins, envelope (wild type or VSV-G) and vector genome. The core enzymes and envelope plasmids are provided in trans and cannot be packaged in the viral particles. Thus viral vectors will be unable to replicate. The use of three plasmids system will reduce the chances of recombination to almost zero. Viral vectors will express marker proteins, specific cDNAs or shRNAs. Viral vectors are infectious and their tropism is increased by pseudotyping with VSV-G envelope. Infection with such vectors may induce an immune response against viral proteins and other proteins expressed by the vectors themselves. Retroviral vectors may activate cellular genes by insertion mutagenesis. Accidental injection into workers may result in unwanted expression of genes carried by the retroviral vector. Expressed proteins are not toxic or dangerous to animals or plants and will survive for more than a few hours at room temperature. They cannot be diffused by aerosol and cannot infect plants. Even in case of total breach of containment, viruses would need to be injected or eaten or drunk to infect humans or animals. The inability of such recombinant viruses to replicate means that even in case of total breach of containment and accidental infection, no virus spread from individual to individual (or animal to animal) is possible.

2. HIV-1 and SIV molecular clones. Replication competent HIV-1 and SIV will be made by transfection of 293T cells with plasmids encoding for such viruses. These viruses are infectious and can replicate in humans (HIV-1) or non-human primates (SIV) and cause AIDS. Tropism is limited to CD4+ cells. Virus produced by transfection 293T cells may be high-titre. SIVmac and HIV cannot infect plants or micro-organisms in the environment. HIV-1 and SIVmac are enveloped viruses, which can survive for a short time in the environment (a few hours). The tropism of these viruses is limited to humans (HIV) or non-human primates (SIVmac). No other mammals can be productively infected.

3. HIV-1 and SIVmac deleted viruses. Mutant viruses, which have a deleted envelope gene or both the envelope and the nef genes, will be used to map viral determinants of the interaction with specific cellular factors. The env-viruses will be pseudotyped in trans with VSV-G envelope, which will broaden their tropism. These viruses are not replication competent because they lack envelope, which is provided in trans. To produce virus, 293T cells will be co-transfected with the mutant virus plasmid and the VSV-G plasmid. There is no significant homology between HIV-1 and SIVmac env genes and VSV-G, thus recombination is very unlikely. These viruses may recombine with wild type HIV-1 or SIV and reconstitute the envelope gene, thus becoming fully infectious. The risk to the environment is similar to that of recombinant viral vectors (see point 1) but viruses pseudotyped with VSV-G have broadened tropism and could infect other mammals in case of total breach of containment. However, viruses will be able to complete one replication cycle only and will not be able to spread within an individual or pass to other animals.

4. Plasmids and recombinant bacteria. Full length molecular clones of HIV-1 and SIV will be grown in competent and disabled E.coli. There is the remote possibility that full-length HIV-1 and SIV plasmid DNA at very high concentration may cause infection and AIDS if infected through the skin or inhaled. Disabled E.coli do not represent a risk to the environment. Plasmid DNA may survive for quite a long time outside the laboratory but it is very unlikely that it will ever generate infectious virus. Even if they do generate infectious virus, the same assessment as for points 2 and 3 applies.

Host/vector system

Vectors: Retroviral vectors: pHR', pHR'cPPT, pCSGW and derivatives, pCMVd8.2, pCMVd8.9,pMD.G, pLNPOZ and derivatives, pMFG and derivatives, pSRVdNBDM and
pSRvdNPurodH. PSIV3+ (SIVmac gag-pol expression vector) and SIVeGFP. All vectors have been thoroughly tested for the lack of recombination. PMFG has been approved for clinical trials while pHR', pCMVd8.2 and 8.9 are used in pre-clinical studies. Cloning plasmids: Blusscript, pGEM derivatives, pUC series, bacteria expression plasmids: pGEX series, pQE60, pET, pQE32 Mammalian expression vector pCMV Tag and derivatives pGEMU6-LINKER.

Recombinant HIV/MLV chimeric vectors (replication incompetent) pME411-delta env, pBRU3-delta env-mMA12, pBRU3-delta env mMA12-luc, pBRU3or-delta env-mMA12CA-luc2. Virus made from these vectors can replicate due to deletion of the envelope sequence and are suitable for single round infection assays only.

Full length HIV-1 molecular clones like NL4.3, SF162, HIIIIB, YU-2, and derivatives, SIVmac full length molecular clones pBRmac239 and pBRmac 239 RT-SHIV and derivatives.

Hosts: disabled E. coli: XL-1 blue, HB101, DH5 alpha, SURE, JM109, BL21, KS1000, DE3.

Hosts: mammalian cell lines include TE671, HT1080, HeLa CD4, 293, 293T, U87, Jurkat, NP-2, SupT1, NIH3T3, mus dunni, Simian lung fibroblasts, simian kidney epithelial cells (OMK), rabbit epithelial cells (SIRC). Primary cells may include: peripheral blood monocytes, macrophages, lymphocytes.

Origin & function

All viral vectors have been cloned by other research groups. Cells are bought from the European or American Tissue Culture Collection. Disabled E. coli are bought from specialised companies. Competent bacteria are prepared in-house. Additional HIV-1 or SIV plasmid DNA may be bought/obtained from the UK AIDS Repository Reagent Programme (NIBSC) or the US AIDS Repository Reagent Programme (NIH). Primary cells will be obtained from anonymous health volunteers through the Blood Bank. Plasmids will be used to generate virus by transfection of 293T cells or other suitable cells. SIVmac and MLV vectors will be used to infect cells in culture and prepare intracellular reverse transcription complexes and to test the effects of specific cellular genes on virus infection and early replication. Viral vectors will also be used to express cDNAs of interest in cultured cells or to knock down expression of specific genes using RNAi. HIV-1 and SIVmac will be used to infect cells in tissue culture to test the effects of specific celluar genes on virus replication and early stages and to test the effects of small molecules inhibitors. HIV-1 and SIVmac deleted viruses and pseudotyped with VSV-G will be used to map viral determinants for interaction with cellular factors in different mammalian cell lines, including mouse, rat and rabbit, which are not normally permissive to these retroviruses. Mapping will be performed by systematically mutating virus genes in the context of an otherwise wild type virus (except for the deletion in envelope).

Evaluation of foreseeable effects

HIV carries the risk of AIDS. The main risk of HIV infection in the laboratory is via cuts or abrasions with contaminated sharp instruments. Aerosols are not likely to be a risk since work will be carried out in class 1 or T-fronted class II microbiological safety cabinets. Work using recombinant HIVs carrying mutated or chimeric viral genes is unlikely to be of any higher risk than a typical clinical isolate from an AIDS patient. All work with infectious HIV particles whether using clinical isolates or recombinant strains is therefore carried out in our level three laboratory under local rules. These include a ban on sharp instruments, the use of T-front class II safety cabinets to prevent aerosols in a laboratory with restricted access. Introduction of infectious HIV DNA into cells by transfection and subsequent production of infectious virus is carried out in level 3 safety laboratory. HIV-1 and SIV plasmid DNA will be grown in disabled E. coli in a level 2 safety cabinet. Sharps and needles will not be allowed while handling HIV-1 or SIV plasmid DNA. Such DNA will be dried in a fume hood to prevent aerosol inhalation and kept diluted in small aliquots. Small DNA stocks will be produced (max 100 micrograms) of replication competent HIV-1 and SIV.

The recipient cell structures are cell lines and primary cells which are not from the persons who work in the same laboratory and known to be free from human pathogens of ACDP 2-4 groups. These cells will not survive outside of the laboratory, without feeding, nor colonise in immuneincompetent workers after accidental injection. There is a small likely-hood that the HIV pseudotypes will reconstitute the envelope gene by recombination with another HIV-1 virus containing the envelope gene. This may happen if the same cells are accidentally infected by two different viruses. However, these recombinant viruses are no more of a risk than a typical clinical isolate from an AIDS patient. Cells used to generate pseudotypes virus will be clearly labelled and kept separated from other infected cells, for example in a dedicated incubator. All work after transfection of HIV clones into cell lines is therefore done in level 3 and all pseudotypes are treated as potentially live HIV.
Accidental infection with retroviral vectors (replication incompetent) may cause an immune response against viral proteins or against other proteins expressed by the vector. It may also cause insertional mutagenesis. Production and handling of these vectors is carried out in a level 2 safety laboratory using class II laminar flow cabinets.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Bacterial cultures are treated with 5% Trigene (final concentration) for 12 hours and disposed. Glassware is washed in 5% Trigene for 12 hours and sterilised by autoclaving. All plasticware is collected in dedicated autoclavable double bags and sterilised by autoclaving. All solid waste is sterilised by autoclaving before leaving the Windeyer Building. The following procedure is applied:

a) The waste is collected in double autoclavable bag, which is supported in a flip top blue bin.
b) When 2/3 rds full the bag is inserted into a 2nd bag and both bags are tied with a blue elastomere band.

Level III safety laboratory

SOLID WASTE

Paper gowns and towels, disposable gloves, filter papers and plasticware must be discarded into an approved autoclavable bag, supported within a labelled "biohazardous waste" bin. Before the bag is too full, it must be closed with an elastomere seal before being placed within the autoclave to await a sterilising run. Double bagging is mandatory to prevent leaks. If the autoclave is in use, full bags may be temporarily stored in the bin beside the autoclave. The autoclave discard cycle holds at 134 C for 15 minutes.

PLASTICWARE

Disposable culture dishes, tubes and flasks used for infectious material must be treated by immersion in 5% Trigene for 12 hours and then autoclaved. Degree of kill: sterilisation.

GRADUATED PIPETTES

Plastic graduated pipettes must be totally immersed in 5% Trigene for 12 hours in the grey cylindrical drums. After disinfection the pipettes can be removed and allowed to drain. They are discarded into an autoclavable bag and disposed of as before. Double bagging is mandatory to prevent leaks. Degree of kill: sterilisation.

PLASTIC STRAWS/PIPETTE TIPS

Plastic straws and plastic pipette tips must be totally immersed in 5% Trigene in a plastic bath within the MSC for 12 hours before draining and disposal into an autoclavable bag. If Gibson tips are used in conjunction with Eppendorf multidosers, the tips must be separated before disposal. Bags are autoclaved as before. Degree of kill: sterilisation.

AUTOCLAVING WASTE

The bags of solid waste are autoclaved in the stainless steel containers in the Priorclave Double Ended Autoclave. On completion of the cycle, the bags are removed in the Prep Room 401E and placed in medibins. When full these bins are sealed and removed from the prep room to await collection for incineration.

Autoclave failure: Should the double ended autoclave be unavailable, bags of solid waste may be autoclaved in the Priorclave EV 150 autoclave sited in the Prep
laboratory, the bags must be sprayed with alcide then placed directly into the autoclave. When the discard cycle is complete, the waste is treated as above.

LIQUID WASTE

Large volumes of liquid, including bacterial cultures, must be treated with Trigene at a final concentration of 5% for at least 12 hours before being discarded in the drain. Degree of kill: sterilisation.

SOLVENT WASTE

Chlorinated and non-chlorinated solvents must be discarded into the appropriately labelled 2.5L plastic containers, which are kept in the flammable storage cabinet. When full, or at least 6-monthly, after having their outer surfaces thoroughly washed with 5% Trigene, they are removed from the lab and disposal is arranged according to Windeyer Institute procedures.

BLOOD

A final volume of 5% Trigene must be added to all waste blood and samples treated for 12 hours before autoclaving.

Queries (below) raised by the GMSC concerning the internal GM notification numbers 934 and 935 were resolved satisfactorily and the committee recommended the approval of this work as a class 3 activity.

"Experiment 934 and 935 should be rolled together into one single overall experiment. If full length HIV DNA is being made and out into mammalian cells this should be carried out at containment level 3".

"Section 1.08 states 2% Trigene for 24 hours, whereas the appendix states 5% Trigene for 12 hours. Which is to be used and has this been validated? If both are validated and both are to be used, this should be stated".

"Sections 2.1: The statement "aerosols are not harmful because naked DNA uptake by the respiratory tract is not documented" is incorrect. The commonly used technique of intra-nasal immunization with naked DNA is very well documented. For a recent example see Hinto et al. J. Imminol. 174, 7423."

02/03/2022
**Project Ref** 14/07.1

**CU2 Project Title**
Genetic engineering of T-cells for cancer immunotherapy.

**Class**
Class 2

**Culture Volume**
< 1 Litre

**Project Additional Information**

**Purposes of the contained use**
Various novel proteins will be introduced into T-cells with retroviral vectors. These proteins will re-direct T-cells to cancer antigens, direct T-cells to home to appropriate sites of disease, augment and modulate their function. This project involves standard molecular cloning techniques and the generation of replication incompetent retroviral vector by three-plasmid transient transfection. Retroviral vectors will be generated to transduce T-cells or cell lines. These vectors are generated by triple transfection. Replication incompetent. As an additional precaution, these vectors will be handled in level 2 containment.

**Recipient or parental organism**
1. **Bacteria:** Laboratory strain of E. coil transformed with recombinant plasmids providing antibiotic resistance geno to the bacteria.
2. **Retroviral Vectors:** Gagpol and Vector sequence (LTR5, packaging sequence) derived from Moloney Murine Leukemia Virus. The env is derived from RD1 14 — an endogenous Feline retrovirus.
3. **T-cells:** Normal human T-cells from peripheral blood of healthy donors transduced with above retroviral vectors.
1. Bacteria
E. coli will be used to facilitate molecular cloning and to grow up sufficient plasmids for transfection of 293T cells. The competent bacteria used are commercially available NEB 5-alpha Competent E. coli (High Efficiency), New England Biolabs, Catalogue #C2987H. Their genotype is: fhuA2A(argF-lacZ)U 169 phoA glnV44 8O A(lacZ)M15 gyrA96 recA1 relA1 thi-1 hsdR17. Further details can be found in the New England Biolabs catalogue or website.

2. Retroviral Vectors:
The replication deficient oncoretroviral vector is generated by a standard three plasmid transfection process. Plasmid 1 is RDF (generated by Prof. Mary Collins, here at LJCL). This is an expression vector for the RDI14 envelope; Plasmid 2. Peq-PAM-env an expression plasmid for MoMLV gagpol (envelope coding sequence has been deleted). — it was a gift of its creator: Dr Elio Vanin currently working in Children’s Memorial, Chicago. Plasmid 3 is the vector itself which was made in the Mulligan lab. It contains both MoMLV LTRs and the packaging signal. The remaining portion of gagpol (that is not part of the packaging signal) and the env have been deleted. Transgenes are cloned into where the env would have been.

3. Genetically modified T-cells
We will clone many genes and other elements into this retroviral vectors to engineer T-cells. Many will be novel fusions of antibody fragments and signalling molecules. An exhaustive list is not possible as the research will be quite fluid, but a categories of sequences are: chimeric antigen receptors (fusions of antibodies with T-cell signalling molecules), native T-cell receptors (cloned from antigen-specific T-cells), intracellular signalling proteins, homing signalling proteins, suicide genes, cytokines, fluorescent and bioluminescent proteins.

Host/vector system

Origin & function

An exhaustive list is not possible. Genetic material used will be cloned mostly from human cDNA. Some constructs may be made from murine, chicken and bovine DNA. Most of the genetic material will be fusion proteins or modified proteins involved in T-cell biology (e.g. signalling, homing and target killing). Some more exotic proteins (e.g. for jellyfish and insects) will be used for fluorescence and bioluminescent tagging of T-cells.

Chimeric Antigen Receptor Fusions of antibody variable region single chains (scFv) with spacers (usually derived from hinge and CH2CH3 regions of IgGI or CD8) and signalling endodomains from e.g. CD28, CD3-Zeta or 0X404

Native TCR receptors: T-cell receptor alpha and beta chains cloned from antigen-specific T-cells.

Intracellular signalling e.g. calcineurin, Calcineurin mutants, NFAT mutants, LAT (Linker of activated Tcells), Ick, src.

Homing Signals e.g. FLTI

Luciferases e.g. luciferase from Phrixotrix Hirtis, Click Beetle, Firefly and Gaussia.

Suicide Genes: inducible Caspase 9 (iCasp9)

Cytokines e.g. IL-2, IL-15, IL-21

Flourescent proteins e.g. enhanced Green Fluorescent Protein, dsRed, enhanced Blue Fluorescent Protein

Tagging proteins e.g. truncated CD34, truncated Nerve-growth factor receptor, CD20 fragments

miRNA pre-miRNA loops to target various transcripts

expression elements to e.g. NEAT response elements, Chromatin insulators, Scaffold attachment sequences, RNA processing elements.

Evaluation of foreseeable effects

1. Bacteria
Plasmids are engineered such that vector coding genes should not be expressed by E.coli - only antibiotic resistance genes. Even if retroviral proteins were expressed by E. coli they would not be functional in a prokaryote. These are standard molecular biology techniques. The only hazard anticipated is the environmental release of non-pathogenic strain of antibiotic resistant E. coli.

2. Retroviral Vectors:
Triple transfection is very safe since a three plasmid recombination events would need to occur to generate a replication competent vector. Further, the volumes of virus made will be small (maximum batch of 100mL). Retroviral vector is labile. Competent retroviral vector could only infect a researcher by inoculation or exposure to broken skin. Even if a competent retroviral vector were to infect a human host, it would be rapidly cleared by the host immune system. Accidental release of replication incompetent retroviral vector would have no environmental consequence. Accidental release of replication competent vector would result in environmental exposure of a very labile virus that could only infect human hosts by inoculation and even...
that case would likely be rapidly cleared by the host immune system.

3. Genetically modified T-cells

These gene-modified T-cells will not be able to survive out of tissue culture. The only hazard they pose is if they were accidentally injected into a researcher. To minimize even this hazard, researchers will not work with genetically modified T-cells derived from their own blood. Hence, in the very unlikely event of inoculation with these T-cells, an allogeneic immune response will rapidly clear them.

**Project Ref** 14/08.1
The aim is to produce live intact lentivirus based viral vectors. These vectors will be transiently expressed in producer cells (cultured 293T cells) and the viral particles produced from the cells will be concentrated. The concentrated stock of viral particles will be used to infect salamander cells and mammalian cells in culture. The intended sequences are widely used bio markers such as Green and Red fluorescent proteins. In addition to this, newt-specific genes (eg. Prod 1) which is not known to cause any pathogenesis will be expressed in newt and mouse cells. The transfected cells will be used to study cell migration and interaction with other cells.

Recipient or parental organism

The intended recipient organisms are newt cells and mouse cells. Neither should be able to release any infectious agent and no adverse consequences are anticipated. The potential risk is accidental exposure and transfer of inserted genetic material. The intended vector sequences are non-oncogenic in humans and lentiviral vectors so far are not known to cause oncogenesis in humans. Newts represent a negligible hazard in terms of displacing or competing with other species. We do not use poisonous species so there is a negligible hazard in terms of adverse effects on other animals or plants. In terms of the vector employed there is a negligible hazard of transfer of genetic material from the newts to other organisms. If the GM newts were consumed by another animal there is a negligible probability of the products of gene expression causing harm. The possibility that phenotypic or genotypic instability could cause a hazard is negligible. None of the gene products being expressed in the newts could cause a viral disease, and shedding of vector sequences or particles is also of negligible probability given the nature of the constructs.

Host/vector system

Host - HEK293T, XL1 Blue, Newt cells, Mouse cells
Vector system — Trans Lentiviral ORF system consist of the following vectors: pTLA1 -PAK, pTLA-ENZ, pTLAI -ENV, pTLA-REV, pTLAI -TOFF, pLEX-JRED/TURBOGFP, pLEX-MCS
pTLA1-,PAK, pTLA1-FNZ, pTLA-ENV, pTLA-REV and pTLA1-TOFF are he vector and helper constructs contain no significant areas of homology, minimising their chance for recombination. None of the HIV-i genes (gag, pol, rev) will be expressed in transduced cells, instead they are expressed from packaging plasmids lacking packaging signal. The lentiviral vector Long tTerminal Repeats (LTR) do not contain highly active transcriptional enhancers; this feature reduces the possibility of oncogenic genotoxicity resulting from insertional mutagenesis.

pLEX-JREDITURBOGFP vector sequences are marker genes derived from jelly fish and widely used in the laboratory as a biological marker. pLEX-MCS is the vector intended for introducing the newt-specWc gene, Prod-i. The newt-specific sequences are derived from the genome of salamnders which include structural and non-structural gene sequences. These proteins are not known to cause pathogenicity but all are anticipated to play physiological roles.

**Origin & function**

The recipient organism for the vectors a E. coli XL-i -Blue, which is a commercially available E. coli strain derived from E. coli K12 strain and used for routinely in molecular biology studies. This strain has an established safety record in the laboratory with no adverse effects on human health, animal or plant health or the environment. Furthermore, F. coli XL-i-Blue is incapable of survival outside the laboratory.

The inserted sequences are marker genes derived from jelly fish and widely used in the laboratory as a biological marker. The newt-specific sequences are derived from the genome of salamnders which include structural and non-structural gene sequences. These proteins are not known to cause pathogenicity but all are anticipated to play physiological roles. Transient expression of viral construct with packaging plasmids in human 293T cells will produce live viral particles which can infect both dividing and non-dividing cells in a broad host range.

The intended recipient organisms are newt cells and mouse cells. Neither should be able to release any infectious agent and no adverse consequences are anticipated.

**Evaluation of foreseeable effects**

The containment facility is a dedicated animal facility approved by the Home office. The entry to the room is with steel doors and digital lock. Only authorised personnel have access to this facility. GM animals will be held in lidded plastic tanks (20cm x 2 x 1 4 high). Groups of 4 tanks will be enclosed in a custom made Perspex lidded box, which provides a second layer of containment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

All disposable plastic ware which come into contact with the liquid during handling within the biological safety cabinet will be disinfected by immersion overnight in peroxygen disinfectant. All other solid waste materials generated in the facility will be collected in autoclavable bags and will be kept in a closed container. These waste materials will be autoclaved within the facility before disposal as clinical waste. The autoclaves are programmed appropriately (124 degrees for 35 minutes) for the degree of kill. Trained personnel are available to perform this work. The incubators have built in decontamination facility for periodical disinfection. All the work surface will be wipe cleaned with peroxygen cleaner after work.

The safety and efficacy of the measures taken will be periodically examined by the Principal Investigator and Departmental Safety Officer. The disinfected materials will be disposed off as clinical waste in sealed bags approved by the university. Facility for daily collection of waste materials is available.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

### Project Additional Information

**Purposes of the contained use**

The aim of this project is to understand the link between single cell mechanical properties and movement, and the mechanics and morphogenesis of multicellular aggregates (such as cysts or cell sheets). To do this, we aim to generate cell lines stably expressing wild type versions of the cytoskeletal and regulatory proteins for observation of protein organisation (or reorganisation) during mechanical perturbation. Mutant versions of the proteins that are involved in resisting mechanical forces will be made, cloned, and stably expressed in cells. The aggregate and cellular mechanical properties will then be reexamined. A similar approach will be taken to determine...
which proteins play a role in simple morphogenetic movements such as invagination and single cell movement. If more acute treatment is needed, purified protein microinjection will be used for rapid perturbation of cell function. Recombinant viruses will be used to create cell lines stably expressing the inserts under the control of the retroviral vector.

Recipient or parental organism

We will utilise commercially available recombinant virus systems such as MMLV retroviruses and lentiviruses for infection of human cell lines. Though commercially available recombinant retro- and lenti-viruses have disabled replication, the risk of accidental recombination with a wild type virus still exists, particularly since a number of cancer cell lines also carry viral loads. The risk in this case is the emergence of a replication competent virus carrying an oncogene under the control of a strong promoter as load. Even in the case where replication deficiency is maintained, recombinant viruses pose a risk through the genes they are carrying. In our experimental work, we wish to express constitutively active mutants of oncogenes. The consequences of upregulation of these oncogenes at the level of a whole organism are difficult to predict and therefore, we believe that these GMQs should be treated as Class 2 risk. Finally, as with all genetic mutations, it is possible that accidental insertion of exogenous DNA sequences within actively transcribed host sequences could have unpredictable and harmful consequences (insertional mutagenesis).

Host/vector system

Hosts; Human and mammalian cell lines.
Retroviruses;
BD clontech retroviral system based on MMLV retroviruses that are replication incompetent. Vectors to be used are pLNCX, pLNCX2, pLXSN, pLXIN, pLPCX, pRetroQ-Dsred,-GFP-C1, GFP-N1, pRevTRE, pRevTetOff, pRevTetOff-IN, pRevTRE-Luc.
Lentiviruses;
Though as of now, we are not using lentiviruses, we do plan to in the future and would be using commercially available kits such as the Virapower expression system commercialised by Invitrogen.

Origin & function

The genes liable to be cloned into viral expression kits can be roughly divided into two categories; coskeletal proteins and regulatory genes (including oncogenes). At present, all of the cDNA in our possession is in purified plasmids. The following genes are being considered at present but any gene playing a role in tissue morphogenesis, cell mechanics, or cell locomotion may be cloned in the future; beta actin, M10277, human tubulin, NM006009, human vimentin, NM003380, human septin 6, SC036240, human anillin, BC070066, human thymosin beta 4, M17733, human myosin regulatory light chain, BC046702, xenopus myosin heavy chain, AF055895, xenopus alpha-actinin, NM001102, human fimbrin, NM005032, human coronin, NM014325, human tropomyosin, BC057705, xenopus PH domain of Phospholipase C delta, U091 17, human Ezrin wild type, T567A, T567D, NM003379, human Moesin, M69066, human keratin 8, BC063513, human keratin 18, BC072017, human daamil, BC038428, human kiaaO861, BC064632, human rho A, NM001664, human rac1, BC107748, human rac2, BC001485, human cdc 42, BC018266, human E-cadherin, U04708, xenopus C-cadherin, U04707, xenopus mdial, BC070412, mouse arp3, AF006083, human net, BC053553, human p115rhogef, human rhoGDI-alpha, NM004309, human p50rhoGAP, NM004308, human cofilin 1, BC012265, human profilin 1, BC002475, human nedd5, AF038404, human tandem dimer red fluorescent protein monomeric red fluorescent protein 1 adducin, BC01393, human annexin 2, NM1002858, human VASP, BC015289, human alpha spectrin, J05243, human integrin beta 1, BC020057, human cor-tactin, BC008799, human gelsolin, BC026033, human myr2, NM023092, rat myr3, NM173101, rat shroom, BC104914, human nhel, AF146439, human protein 41, BC039079, human ankyrin B, BC007930, human Fascin, AF281049, human Rhotein, BC017727, human occiudin, U49185, mouse capZ, BC000144, human tropomodulih, 8C047163, xenopus Proteins not yet cloned but of use in the project:
desmosomal proteins (desmoplakin)
tight junction proteins (alpha-catenin, beta catenin)

**Evaluation of foreseeable effects**

The effects of infection of a human being by a large dose of recombinant viruses are generally unforeseeable. Depending on the nature of the gene, they may range from benign to dangerous. This is especially true since the vectors used are under the control of very strong promoters such as CMV and therefore the quantity of protein expressed may be dangerous for cells rather than the gene itself. When the gene expressed is an oncogene, its overexpression in cells within an organism is unpredictable.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

not applicable

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

All containment measures will be applied.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Risk to the environment with retro- and lenti-viral vectors arise from accidental spillage of solutions containing virus and from improper decontamination of waste products. Spillages will be dealt with immediately, the area will be wiped dry and disinfected as detailed below. The waste material from cleanup will be autoclaved and disposed of in biohazardous waste. Under normal circumstances, risk to the environment should be minimal. Waste products will be in the form of cell culture supernatants, which contain viruses. To disinfect them, we will use commercially available decontamination products such as Virkon S. According to the manufacturer, Virkon S is a powerful disinfectant that has been proven effective against all types of pathogens at dilutions of 1 or 2%. Guidelines from Stoner et al, Journal of Oncological and Pharmacological practices, 2003, 9, 29 recommend using a 2% solution of virkon for disinfection of surfaces potentially contaminated with retroviruses. For cleaning, it needs to be sprayed upon the surface and left to act for two minutes before wiping clean and it kills over 99.99995% of organisms. Waste liquids will then be autoclaved. Final waste is biodegradable and can be released in sewage water.

We will test the infectivity of Virkon containing supernatants and autoclaved waste products by adding them in tissue culture medium of living cells. If the waste liquid still contains virus, we should be able to detect this as the proteins we will express will be tagged with fluorescent reporter constructs such as GFP or mRFP.

**Is an emergency plan required according to regulation 20?**

N

If yes, tick to confirm that it is attached to this form

N

Tick to confirm that you have attached a risk assessment to this form

Y

Tick if you are claiming exemption from disclosure for section of the risk assessment

N

**Please enter comments on the GM safety committee on the risk assessment**

Following minor clarification of the original risk assessment, the UCL GM Safety Committee agreed that this work should be classified as an activity class 2 project at its meeting on 14th November 2007.

**Project Containment**

02/03/2022
The aim of the project is to identify and characterise mammalian genes that impact on viral infection. We will screen cDNA libraries as well as selecting genes that impact on viral infection. These genes will be expressed, or their expression reduced with RNAi, using non replication competent retroviral vectors, or herpes viruses such as HSV-1 and CMV. Once factors have been identified, their mechanism of action will be characterised by measuring various aspects of viral replication such as DNA synthesis or early protein synthesis. Mutants of the antiviral proteins will be made to inform which parts of the protein are important for their activity. We will also examine the ability of retroviral proteins to influence human gene expression using microarray techniques. This project therefore aims to understand host virus interactions focusing on host virus proteins that effect permissivity to infection and viral proteins that influence gene expression in the host.
the ability of retroviral proteins to influence human gene expression using microarray techniques. This project therefore aims to understand host virus interactions focussing on host virus proteins that effect permissivity to infection and viral proteins that influence gene expression in the host.

Host/vector system

Vectors:
All the vectors (plasmids) will be transformed into E. coli (see above) for cloning and propagation of mammalian and virus sequences. Group 1 vectors (cloning vectors) will only be present in E.coli. Mammalian and virus sequences will also be transferred to expression vectors(2.) and transferred into human cell lines for expression. We will also transfer the sequences to virus expression vectors(3.) to allow long term expression in human cells and infection of otherwise difficult to transfect cell types. Virus expression vectors are packed inside VSV-G pseudotyped virus vectors, made from gag-pol and VSV-G expression vectors transferred into human cells (4.) Details of this retroviral vector system is outlined below. We will also inactivate HIV genes in HIV molecular clones (full-length HIV genomic DNA contained within a bacterial plasmid in E.coli) and other genes in other mammalian retroviruses. (5.)

1. Cloning vectors: pCR-TOPO, pGEM-T, pGEMU61, pCR2.1, p9B-18 and other similar HIV molecular clones,
2. Expression vectors: pcDNA3, pCR3.1, pires family, pTRE2 family expression vectors
4. Gag-pol expression vectors (called packaging constructs) and envelope expression vectors: CMVintron (murine leukaemia virus gag-pol expression vector), p8.9 (HIV-1 env expression vector).
5. HIV molecular clones eg. P9B-18, MLV, FIV and SIV molecular clones.

DETAILS ON RETROVIRAL VECTORS
Retroviral vectors are made by transfecting 3 plasmids, an expression plasmid into which the sequences of interest is cloned, together with a retroviral packing construct, a gag-pol expression vector and an envelope expressing vector (which are not packaged into progeny viruses). All vectors are disabled by separating the packaging sequence, coding sequence and the viral coding sequences from each other on independent plasmids. Retroviral vectors are produced by transfection of all 3 plasmids. These viral particles do not contain genome that encodes virus proteins and so this system cannot produce replication competent virus. VSV-G-enveloped retroviruses are only potentially harmful to human health if introduced into the body by injection, ingestion or through a wound. The potential harm arises from the possibility the virus would enter cells and integrate itself into cellular DNA. Although the virus is not replication competent (does not carry gag, pol or env genes) and so it cannot make new progeny virus and estabilish a productive infection, its insertion into cellular DNA could labile and do not survive on environmental surfaces outside the lab.

MAMMALIAN CELL LINES
Canine MDCK, DK, D17, C2F, feline, AH927, CRFK, Mya 1, human HeLa, TE671, HT1080, 293T, HEL, HFFF, BJ1, Jurkat, CEM, supT1, C8166, U937, THP-1 KG-1, A549, mouse MDTF, NIH3T3, avain QT36; marsupial SC300, bat Tb11u; non human primate FRhK4, LLCMK2, CV1, VERO, Pindak, SMLF; bovine MDBK, IMR31, porcine PK15, SKL, CPK, STIOWA, mink mv-1-lu, rabbit SIRC, eREP, rat HSN, RAT2, 9L, NRK.

Primary human cells derived from peripheral blood including lymphocytes and macrophages.

Origin & function
Mammalian DNA: The aim of the project is to identify and characterize mammalian genes that impact on viral infection. We will screen cDNA libraries as well as selecting genes based on their reported ability to influence permissivity to viral infection. These genes will be expressed, or their expression reduced with RNAi, using replication incompetent retroviral vectors. The modified cells will then be tested to permissivity to retroviruses, tested again using replication incompetent vectors, or herpes viruses, such as HSV-1 and CMV. One factors have been identified their mechanism of action will be characterised by measuring various aspects of viral replication such as protein important for their activity. This project therefore aims to understand how viral permissivity, and species-specificity of viral replication, is controlled by host proteins.

cDNA or cDNA derived clones will be cloned into MLV or HIV based retroviral vectors. Virus genes, identified as having antiviral or interferon modulating properties, will be cloned into mammalian expression vectors. These will be expressed in mammalian cell lines using retroviral vectors. Mammalian cell lines will also be modifieled by transient and stable expression of small interfering RNA. We will also express Bovine diarrhoea virus protein Npro, paramyxovirus SV5 V protein, KSHV vFLIP and EBV
LMP1 in mammalian cell lines and test them for permissivity to viral infection. We will also use expression vectors to express cellular proteins with roles in the immune response such as tripartite motif proteins 1-70, cyclophilins A-H, NFkappaB and interferon regulatory 1-8. Note that all proteins expressed are done so with non-replicating retroviral vectors and not with live virus. Also no live virus related to African swine fever or bovine diarrhoal virus will be used at any point either for expression or testing of permissivity.

VIRUS DNA:
We will also examine the effect of virus proteins on host cell transcription. We will clone individual HIV(Tat, Vpr and Rev), KSHV (LANA, RTA, vIRF, ORF57), EBV (EBNA2, EBNA3, ZTA) or other herpesvirus proteins into cloning vectors and then into expression vectors and retroviral expression vectors. These proteins will be selected based on their ability to regulate human gene expression, as reported in the literature. The expression vectors will also be modified to express HIV proteins from the HIV LTR (promoter element) We will not be introducing virus proteins into viral vectors that can cause the production of replication competent virus. We will tag these proteins with an epitope (HA or FLAG) tag to allow the proteins to be detected. We will also inactivate HIV genes within HIV molecular clones such as p9B-18 by mutating them or deleting them. Once we have identified human genes regulate by virus proteins, we will express these proteins in human T-cells and macrophages from a retroviral vector and knock down their expression levels using siRNAs encoded in retroviral vectors. We will not be introducing full-length HIV or SIV into mammalian cells to produce HIV or SIV virus in these experiments.

None of the vectors are harmful to the environment and do not supply a survival advantage to any microorganisms. The cloning and expression vectors are also not a hazard to human health.

The bacterial strains to be used are non colonising and incapable of surviving in the environment or causing human infection. They pose no risk to users or the environment.

Plasmids encoding full length HIV-1 could theoretically generate infectious HIV if accidently injected directly into the body. These vectors will not be introduced into human cells in tissue culture in these experiments.

Retroviral vectors can infect human cells and therefore, if introduced into the body by injection, ingestion or through a wound, the virus could enter cells and integrate its genome into cellular DNA. Although the virus is not replication competent (the genome does not encode viral gag, pol or env genes) it cannot make new progeny virus and establish a productive infection, its insertion into cellular DNA could result in a potentially oncogenic mutation. The insertion of human genes regulated by HIV into a retroviral vector, or the insertion of siRNAs that knockdown these genes, could theoretically increase the oncogenic potential of the virus. If retroviral vectors encoding genes that affect interferon signalling were injected into a person some cells may become infected and therefore more outcome of an exogenous viral infection. None of the inserted sequences are likely to have oncogenic potential and so retroviral vectors encoding such sequences are extremely unlikely to have pathogenic consequences if accidentally injected. cDNA libraries in retroviral vectors will likely contain oncogenic sequences but the relative infectious titres of these vectors within the population are too low to measure, making the vector preparation very safe.

HSV-1 and CMV GFP viruses are infectious in humans but are of low pathogenicity. The vast majority of individuals have been exposed to environmental infection and will mount an effective immune reaction against it. The insertion of GFP sequences and/or deletion of ICPO in HSV-1 in no way increases pathogenicity or toxicity or hazard to human health or the environment. Exposure of workers to CMV or HSV-1 will be limited, as all work involving infectious virus will be performed in category 2 containment facility in class 2 microbiological safety cabinets. To prevent contamination of workers by virus, no glass or other sharps will be used and workers will be protected by a lab coat, latex or nitrile gloves and eye protection. Skin lesions will be covered with a bandage in addition to the protective wear described above. Pregnant workers will be prevented from working CMV. The risk of harm is therefore extremely low. Both HSV-1 and CMV infection are treatable with drugs (acyclovir and gancyclovir respectively). The modified viruses pose no more threat to the environmental than the wild type virus. None of the virus or vector infected cells cannot survive in the environment.

It is important to note that there are no circumstances where cells will be infected by more than one replication competent virus. There is therefore no chance for any kind of recombination between viruses. No live virus related to African swine fever or bovine diarrhoal virus will be used at any point for expression or testing of permissivity. There are no sharps in the rooms where the viruses are prepared and used. Sharps will also not be used in conjunction with HIV DNA-encoding plasmids. All work with virus will take place inside a microbiological safety cabinet within a category 2 containment lab. Wokers will also be protected by a lab coat. Safety glasses and latex or nitrile gloves when handling any GMM or GMM-derived DNA or virus.
The cell lines used cannot survive outside the lab incubators and as such pose no threat to health or the environment.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

**Guidance:**
For micro-organisms and cells in culture nothing need be added here. In addition to the advice in Note 7, it should be noted that some projects may require GMM vectors to be administered to animals (or plants). Appropriate containment measures must be adopted for handling such GMMs during this process even though the intention may not be to create a GM animal (or plant). The best place for these is probably in the risk assessment that is separate from this document.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

5% TriGene (v/v) will be used to treat liquid waste (16 hours) and also any spills and for disinfection of any reusable bottles or other equipment. Solid waste will be double bagged and autoclaved. Work surfaces will be wiped down with 70% ethanol after use. These procedures result in 100% kill of all GMO. Autoclave runs are regularly validated by waste management staff. TriGene is certified by the PHLS to kill viruses. All TriGene will be used within its 3-year life. Solid waste is autoclaved inside two elastic band-sealed clear plastic autoclave bags by trained staff and then these bags transferred to a yellow biohazard waste bag for incineration. Liquid waste is poured down the drain after treatment with TriGene for at least 16 hours. This leads to denaturation and inactivation of viral and cellular proteins.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

Tick to confirm that you have attached a risk assessment to this form [N]

Tick if you are claiming exemption from disclosure for section of the risk assessment [N]

Please enter comments on the GM safety committee on the risk assessment

The GM safety scrutinisers, acting on behalf of the GM Safety Committee agreed that this project was correctly classified at class 2.

[20/02/2022]
The aim of this project is to investigate the mechanisms controlling the assembly and cell-to-cell transmission of enveloped viruses, in particular the human immunodeficiency virus type 1 (HIV) and the related simian virus (SIVmac). Recent studies have indicated that these viruses assemble on plasma membrane domains that are in some cell types sequestered within the cell, and that cellular proteins including the ESCRT machinery and various adaptor complexes are essential for this process. Moreover transfer of viruses from cell-to-cell appears to occur through specialised cell surface domains with similarity to immunological synapses. The aim of these experiments is to use morphological techniques including electron microscopy and fluorescence microscopy, coupled with molecular biology to investigate how HIV components are bought together within infected cells to allow virus assembly and transmission to occur. These experiments will require the use of replication competent infectious HIV and SIV and will therefore need to be conducted under containment level 3 conditions.

HEK293T for virus production, immortalized mammalian cell lines (eg HEK293, HeLa, SupT1, Jurkat, CEM, CEMx174), primary macrophages and T lymphocytes (isolated from screened blood obtained from the Blood Transfusion Service) will be used to produce viruses or for experimental infections.

Viruses to be used will be X4, R5 and dual tropic HIV and SIVmac239. These will be generated by viral infection and transfection of molecular clones. Infectious virus particles will be stored and handled using protocols and techniques established for the safe handling of HIV.

HIV particles could possibly infect research workers and lead to AIDS. SIVmac239 is not infectious to humans. Mutations introduced into molecular clones to alter the amino acid sequence of specific viral proteins are likely to attenuate infectivity/risk.

To allow reproducible virus production and modification of viral proteins to investigate the role of packaging motifs (eg Gag Late domain motifs) molecular clones will be...
used. We will use molecular clones of HIV-R3A, Ad8, and HxB2 as well as SIV molecular clones from SIVmac239. In some cases viruses will be pseudotyped using cloned envelope proteins from R5 tropic or X4 tropic viruses, or the vesicular stomatitis virus (VSV) G protein.

Viruses will be produced in HEK293T cells by transfecting single or multiple plasmids (for Pseudotyped virus) using lipid based transfection, reagents such as Fugene or Lipofectamine. Virus containing media will be collected 24 and 48 hrs post transfection, clarified of cell debris by low speed centrifugation and stored at -80°C in small volume (~1ml aliquots). All virus preparations will be limited in volume to <60ml.

Mammalian expression vectors, eg pcDNA3, pSV2-neo, pBabe vectors, pUC18/19, SP62, pMD, phage λ EMBL4 (Stratagene).

Origin & function

The genetic material to be used originates from HIV, SIV and VSV viruses originally isolated from infected individuals or animals, molecularly cloned and inserted into mammalian cell expression vectors for production of recombinant, infectious virus particles. Only the VSV G protein will be used and no infectious VSV will be produced.

The use of molecular clones allows us to modify the viruses so that the role of specific viral sequences can be analysed in experimental tissue culture systems. No animal experiments will be undertaken and no virus will be removed from the laboratory unless it has been fixed/inactivated with aldehyde fixatives (as used for light and electron microscopy analysis).

Evaluation of foreseeable effects

The likelihood of the viruses infecting lab personnel is remote. In all cases full bio-containment category three precautions will be taken, including the use of appropriate personal protective clothing (double gloving, etc) no use of glass pipettes or needles, handling of virus only within biological safety cabinets. The personnel involved in the work have previously worked with HIV and SIV under category three conditions as well as with other viruses including Herpes simplex.

In the unlikely event of a research worker becoming exposed to infectious virus particles, he/she will seek immediate medical assistance, and the administration of anti-virals as appropriate, from University College Hospital.

Due to the restricted host range of the constructs, their lack of ability to survive outside laboratory conditions, restrictions on access to the facility and the risk control and disinfection/disposal measures described in this assessment, we conclude that the program of work presents no risk to the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All experiments will be conducted in mammalian cell lines kept in ACDP containment level 3 facilities in the UCL Cancer Centre, Huntley Street. There will be no use of animals.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Solid Waste: Following virus usage, any materials that have, or may potentially have come into contact with the viruses will be thoroughly decontaminated by soaking in Trigene Advance* (5%) for at least 12 hours, followed by draining and disposal into the autoclave waste stream. The autoclave is a double-ended design situated within the containment facility. The autoclave is validated (12 point thermocouple test) by a competent engineer on an annual basis.

Liquid waste:

Liquid waste will be treated with Trigene Advance (5%) for at least 12 hours before disposal down the laboratory sink.
The genetic modification safety committee has approved this project as a Class 3 activity. It notes that the work is closely similar in risk to notified work currently being undertaken in a different part of this GM Centre.

**Project Additional Information**

**Purposes of the contained use**

**AIM** - The purpose of this project is to produce stable immortalized cell lines derived from human prostate cells, using a construct that will result in minimal genetic changes in the cell lines. This project is an updated version of a similar project aiming to produce immortalized cell lines from prostate cells started in 1997, which produced prostate cell lines, but with extensive genetic changes (Daly-Burns et al., 2006).

We want the prostate cell lines as models for studying the genetic polymorphisms that control susceptibility to prostate cancer. Recently single nucleotide polymorphisms (SNPs) have been identified that are associated with altered susceptibility to prostate cancer (e.g., Gudmundsson et al., 2007). The genotypes of the cell lines we develop will be determined and the cell lines used to provide model systems with which to study the mechanisms underlying altered susceptibility, partly for understanding and partly in the hope that there may be ways of altering susceptibility. One of the potential susceptibility genes that our collaborators have identified is TCF2 (Gudmundsson et al., 2007) and our later studies will involve up and down regulation of selected genes such as TCF2 in the cell lines produced.

**CELL LINES** - The immortalizing vectors extend lifespan allowing transformation to occur either by random spontaneous genetic events (as during crisis following transfection with SV40 T antigen), or with an additional transforming (ie oneogenic) construct containing a gene such as Ras. The sequential use of hTERT and the SV40 large T construct permits both extended lifespan and transformation. The immortalized cell lines we derived using the earlier system rate non-tumorigenic (Daly-Burns et al., 2006), in contrast to about 75% of standard continuous cell lines derived from human carriers. However, immortalization was associated with additional genetic changes and an unstable karyotype. Our collaborators (Professors Jar and O'Hare) have found that a triple SV40 large T mutant (non-DNA binding non-bub1 binding thermolamide U19d189-97tsA58) produces karyotypically stable cells when used in conjunction with reconstitution of telomerase activity (Gjeorup et al., 2007; Hein et al., 2008). We will use the newly developed technology in this study.

In case there is confusion over the use of the terminology "cell lines", it refers in this proposal to the derivatives of the primary cultures. A culture is primary only until the first time it is passaged, at which point it becomes a cell line. Once a cell line has indefinite growth potential it is described as a continuous cell line. We will infect primary cultures or, if greater numbers of cells arc required, cell lines at the first or second passage, with immortalizing vectors to produce continuous cell lines.

**Immortalization**

It is the processes used to grow the vectors and immortalize the primary cultures cell lines using infectious virus that require level 2 containment. The packaging cell system TE-FLY-A is used to package the T and hTERT viruses. Phoenix eco/ampho cells are used for introducing new genes into the immortalised cells.

We are also using this GM proposal to cover a second approach that will allow a lower level of containment. Our collaborator Professor Jat is developing a new system to engineer human cell lines expressing mouse ecotropic receptor. Ecotropic viruses can only infect marine cells and consequently work using them can be carried out at level I, whereas work with amphotropic viruses requires level 2. Human cell lines that express the ecotropic receptor are infectable by ecotropic viruses that normally only infect murine cells.

**Classification**

There has been over a decade of safe usage of these methods. The retroviral vectors have a history of safe use of over 12 years. The construction of the mobilization defective helper free amphotropic retrovirus by Professor Jat at UCL (Institute of Neurology) and their use for the immortalization of primary human cells has HSE Approval at level 2 (NDD reference number NDD/2006/A.016).

GV, Mayordomo .1f, Catalona WJ, Kiemeney LA, Barkardottir RB, Gulcher JR, Thorsteinsdottir U, Kong A, Stefansson K.

Recipient or parental organism

Primary human somatic cells and cell lines. The cells are non-mobilizable. The primary cells could be infected with unknown adventitious agents. Infection by such agents is extremely rare and would only take place as a result of poor laboratory practice, ie injury with needles or other sharp instruments. Immortalized cells will be banked under liquid nitrogen and used in culture dictated by the demands of the project. Under good laboratory practice immortalized cells do not constitute any hazard health. The cells can only survive in tissue culture or following implantation into immunosuppressed animals. There is a theoretical risk that as a result of poor practice cells could become implanted in the person using them. However, the cells would have to overcome the immune response and in practice this occurrence has been extremely rare. Anyone who: immunity is compromised for any known reason will not work with transformed cells.

Phoenix ampho cells are a non-mobilizable derivative of HEK293 used for production of high titre amphotropic stocks of virus. They are obtained from ATCC and are free of adventitious agents. History of safe usage.

TEFLYA and RD cells are derivatives of TE671 cells, third generation human packaging cell lines used for the production of stable, high titre defective helper-free amphotropic retroviruses that have a murine or feline envelope. Non-mobilizable. History of safe usage.

PA371 is a second generation mouse amphotropic producer cell lines used to derive the high titre producer of the U19tsA58 T antigen that we used earlier to immortalize prostate cells (Daly-Burns et al, 2006). Non-mobilizable defective.

Host/vector system

pZiPneoSSV(X)1 is derived from a T-antigen construct (U 19tsA58) cloned into a Moloney marine leukaemia virus derivative. The construct is generated in PA317 cells which produce a large T antigen in the form of an amphotropic retrovirus (clone8). Mobilization defective.

TE-FLY-A and RD cells produce pBABEneo/hygro/zeo, pLNCX2, pLi-ICX, pLPCX, pWZLpuro/BlastF. Mobilization defective.

Phoenix ampho cells will be used to generate pBABEneo/hygro/puro, pLNCX2, pL1-ICX, pLPCX, pWZLpuro/BlastF, pTMP, pRetroSuper. Mobilization defective.

Origin & function

Two cell systems will be used to package the LT and hTERT containing viruses for immortalization (TE-FLY-A) and fc introducing new genes (associated with susceptibility to prostate cancer) into the immortalized cells (Phoenix ampho). Bot systems are designed to minimise the risk of inadvertent production of replication competent viruses from endogenous sources.

Both are third generation split function packaging systems, based on human cell lines and capable of generating only replication-defective particles. In each case a separate promoter-driven gag-pol and env plasmid has been separately transduced into the recipient line, and in both cases the plasmids lack both the psi packaging site and have the 3'LTR replaced with SV40polyA sequence. Under these circumstances at least two cross-over events would be required to generate a replication competent virus.
In the case of TE-FLY-A the human cell line used is the rhabdomyosarcoma TE571(TE) transduced with the CEB gag-pol expression vector (FLY) and the AF murine amphotropic (A) envelope vector both driven by an LTR sequence. When transduced with hTERT or LT and an appropriate selectable marker TE-FLY AL will stably produce packaged constructs at a titre of <1E7. For generation of high titre packaging it is generally necessary to clone the transduced lines (hence terminology like clone13 for the hTERT virus) It has been extensively tested by its originators (the Weiss laboratory) and shown to be free of helper virus activity to a level of <1 in 10E7 particles. The Phoenix eco/ampho systems are based on the highly transfectable 293T human cell line and are essentially identical except as the name implies in one case the tropism is governed by an ecotropic env sequence, and in the other by an amphotropic equivalent. The Phoenix systems produce a high level of transient expression from the 293T cells when further transduced with the gene of interest and are therefore not generally subject to further cloning, thus enhancing their safety by reducing risk of cross contamination from a putative helper virus containing line that might be present in the lab. As mentioned above the gag-pol and env sequences were introduced into the packing line separately to minimise possibilities of recombination, which in this system is further reduced by the use of different promoters, CMV for the env and RSV for the gag-pol. Stringent tests by the lab of origin (the Weiss lab) have shown no evidence of the generation of replication competent virus using these systems. In the unlikely event of reactivation of virus, infection could only occur through high-titre safe laboratory practices (needlestick injury).

Evaluation of foreseeable effects

Human cells could contain unknown adventitious organisms, but infection of laboratory workers by human cells growing in tissue culture is very rare. The vector could cause harm if it infects a laboratory worker and is integrated in DNA in a position that modifies the expression of a cancer-related gene. However, the standard safety and disposal measures make the environmental risk very low. The vector is unlikely to be integrated unless in the absence of deliberate transfection. The inserts are immortalizing genes and therefore have the capacity to extend the lifespan of human cells. Integrated proviruses could be reactivated with helper viruses. The environmental risk is very low due to the short life of the virus and the fact that it needs multiple genetic changes to be reactivated. Infection could only occur through unacceptable practices (needlestick injury).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All work will be strictly confined to 3.17 of Charles Bell House to minimise the possibility of contamination of other laboratory work space. Researchers not involved in this project do not use this laboratory. Cell lines, virus stocks and producer cells will be stored frozen at -20C and used only as needed throughout the project.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

None requested

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be treated with Virkon 4% (w/v) for a minimum period of 24 hours. Treated waste will be disposed of via dedicated drains within the lab. All solid waste will be immersed in 4% (w/v) for minimum of 24 hours followed by autoclaving for 15 minutes at 120 degrees and finally incinerated.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y
The GM safety committee agreed that the application of containment level 2 precautions would be appropriate to manage the risk of this project. The committee therefore approved this project as a class 2 GM activity.

Project Ref 14/09.1

- **Date Ackn'd**: 01/04/2009
- **CU2 Project Title**: Nuclear Organisation of Immunoglobulin Genes During the Development of Maturation and Activation of B and T Lymphocytes
- **Class**: Class 2
- **CultureVolClass2**: 1-50 Litres
- **Consent Granted**: Not Applicable
- **Non-GMM**: No
- **Project notified under transitional arrangements**: No

**Project Additional Information**

- **Purposes of the contained use**: To understand how nuclear organisation of immunoglobulin genes affects V(D)J recombination and expression
Recipient or parental organism

The following bacteria strains will be used: XL1 BLUE, TOP10F, JM101 and JM105, and other commercially available E.coli strains. Bacteria strains to be used are not pathogenic to humans and incapable of surviving in the environment.

The following viral vectors will be used: modified replication-defective Moloney murine leukaemia virus (MoMLV) vectors under EF1 alpha promoter and blastocytin? puromycin selection, and pMD.G and pMD.OGP vectors or equivalent encoding for modified replication-defective vesicular stomatitis virus G glycoprotein (VSV-G) pseudotyped MoMLV under cytomegalovirus (CMV) or EF1 alpha promoter.

Modified MoMLV viral vectors are not capable of replication but can enter rodent cells, which can lead to virus integration into cellular DNA, potentially disrupting tumour suppressor gene or activating an oncogene, and lead to cancer. Modified MoMLV viral vectors are deficient for replication but can enter insect and mammalian cells including human cells, which can lead to the same effects as described above in rodent cells.

The following cell lines and cells will be used: Adenovirus-transformed and simian virus 40 T large antigen-expressing 293T cell line and derivatives (such as Plat-E cell line that produces modified replication-defective MoMLV under EF1 alpha promoter and blastocytin/puromycin selection), recombination activating gene (RAG) 1 or RAG2-deficient Abelson virus transformed mouse B cell lines, Abelson virus transformed mouse B cell lines previously transduced with retroviral vectors to express RAG1 or RAG2 or truncated or mutated derivative, RAG1 or RAG2-deficient mouse primary lymphoid cells, and primary lymphoid cells derived from mice genetically modified to express truncated or mutated versions of RAG1 or RAG2. Cell lines and cells to be used are not pathogenic to humans and can not survive in the environment.

Host/vector system

The following vectors will be used:
- pBR322 derivatives commercially available, BACS
- Retroviral pMIG, and derivatives that contain RAG1 or RAG2 encoding sequence or truncated or point-mutated derivative, and GFP reporter gene under murine cell virus (MSCV) LTR promoter and IRES.
- Retroviral pRetro, and derivatives that contain RAG1 or RAG2 encoding sequence or truncated or point-mutated derivative, and puromycin selective gene under MoMLV LTR promoter and IRES.
- Commercially available retroviral pCFB-EGSH and pFB-ERV, and derivatives. pCFB-EGSH contains modified EcRE sequence, minimal heat shock promoter (mHSP), MoMLV LTR and CMV promoter, and hygromycin selective gene under herpes simplex virus thymidine kinase (HSV_TK) promoter. RAG sequences from pMIG or pRetro vector derivatives will be inserted into pCFB-EGSH plasmid under modified EcRE sequence, mHSP, MoMLV LTR and CMV promoters. pCFB-ERV contains modified Ecdysone receptors VgEcR and RXR genes and neomycin selective gene under MoMLV LTR and CMV promoters and IRES. pFB-ERV derivative will be obtained by replacing neomycin gene with puromycin selective gene from pRetro vector.

The vectors have low potential for harm to human health or environment, although accidental injection of large amounts of purified plasmids containing RAG expressing sequences could theoretically lead to RAGs-induced recombination of cellular DNA in cells where both RAG1 and RAG2 would be present either physiologically or subsequently to accidental transfer.

Origin & function

The origins of the genetic material involved are: mouse (for RAG sequences), bacteria (for selective genes), or insect (for modified Ecdysone system genes). The donor organisms are not pathogenic.

RAG proteins will induce recombination of Immunoglobulin (Ig) and T-cell receptor (TCR) genes in B and T lymphoid cells, respectively. Expression of RAG1 inserted sequences will induce DNA recombination in RAG1-deficient cells expressing RAG2, and inversely, expression of RAG2 inserted sequences will induce DNA recombination in RAG2-deficient cells expressing RAG1.

Accidental transfer of RAG1 or RAG2 expressing sequences to human or species in the environment could induce recombination of Ig and TCR genes or other endogenous DNA sequences in cells where both RAG1 and RAG2 would be present either physiologically or subsequently to accidental transfer, and could affect immune system or generate lymphoid translocations that could lead to cancer.

Evaluation of foreseeable effects

The most hazardous GMM's are the retroviral vectors when collected, centrifuged and filtered from supernatant or transfected 293T cells or derivatives, transferred to host cells and removed for disposal.
Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

TriGene will be used to treat liquid waste and any spill. TriGene is certified by the manufacturer to kill all bacteria and viruses to be used, is validated worldwide for its efficiency, and will be used by trained staff within its life-span limitations.

Liquid waste will be poured down the drain only after appropriate treatment with TriGene.

Work surfaces will be wiped down with 70% ethanol after use.

Solid waste will be autoclaved inside two elastic band sealed clear plastic autoclave doubled bags by trained staff before these bags are transferred to a yellow bag for incineration. Autoclave runs are regularly validated by waste management staff and achieve a 100% degree of kill.

Is an emergency plan required according to regulation 20? N

Tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

The UCL GM Safety Committee considered that, although the risk of this project is now very high, nevertheless it is appropriate to use containment level 2 conditions to manage the risk. Accordingly it approved the project as a class 2 GM activity.

Project Ref 14/09.2

Date Ackn'd 02/03/2022  CU2 Project Title

Class CultureVolClass2 CultureVolumeClass3-4
The shRNAmir library consist of over 70,000 individual E.coli glycerol stocks containing the pGIPZ lentiviral vector. Each stock contains a unique hairpin sequence within the human genome via RNAi interference.

This project will involve library maintenance and storage of this shRNAmir library as well as distribution of clones as bacterial stocks, DNA plasmids and/or lentivirus to members within University College London for use in various projects.

Specifically this will involve lentiviral production from the pGIPZ plasmid and subsequent use of this lentivirus in cell based screening functional assays. Additionally, large numbers of clones will be pooled at the bacterial, DNA and viral level to make various intermediate pools of clones to be used to transduce cells in screens and subsequently undertake functional assays. Pooled bacteria/DNA/virus will be distributed to people within the Institute and wider UCL for screening in various other projects.

Recipient or parental organism

- Cell lines: canine- MDCCK, DK, D17, C2F; feline- AH927, CRFK, Mya1; Human-HeLa, Te671, HT1080.293T, HEL, HFFF, BJ1, Jurkat, CEM, supT1, C8166, A549, LECs, tMScs; Mouse- MDTF, NIH323; Avian- QT36; Marsupial- SC300; Bat Tb11u; non-human primate- FRhK4, LLCMK2, CV1, VERO, Pindak, SMLFR; bovine- MDBK, IMR31; Porcine- PK15, SKL, CPK, STIowa; Mink- mV-1-1u; Rabbit- SIRC, eREP, ratHSN, RAT2, 9L, NRK.

- Primary Human cells: Derived from various human tissues including peripheral blood derived lymphocytes and macrophages.

Associated risks and likeliness of occurrence:

- The recipient cells (cell lines and primary cells) that will eventually receive and integrate the DNA are harmless to humans. They are also unable to survive outside conditions and are therefore harmless to the environment.

- The bacterial strains used are attenuated non-colonising strains that are harmless to humans and cannot survive outside culture conditions and are therefore harmless to
Host/vector system

Lentiviral vectors

- Lentiviral expression vectors: Commercial TZV vector from Tranzyme and derivatives (including pGIPZ).

Details on Lentiviral systems and vectors:
Lentiviral vectors are made by transfecting 3 plasmids into a packaging cell line such as HEK293T cells. The 3 plasmids used are contained within or will be transformed into E.coli (see above) for propagation. The plasmids are 1) a packaging plasmid expressing the required accessory proteins for viable viral particle production 2) an envelope plasmid, expressing the envelope protein for the viral particle and 3) the lentiviral vector carrying the cassette with the inserted sequence of interest. Once all 3 vectors are in the cell, each component from the 3 vectors will be expressed. The co-expression of the components from the various vectors will allow the formation of viral particles which will be released from the cells. By seperating the components onto 3 independent plasmids the viral packaging elements are not packaged into the virus themselves making the vector disabled and incapable of self-replication. This system therefore is incapable of producing replication competent virus making it very safe. In this particular project, the shRNA hairpin expression vectors (pGIPZ) are packaged into VSV-G pseudotyped viral vectors made from gag-pol and VSV-G expression vectors transfected into human cells. The lentiviral vector contains the CMV Pol II) promoter to drive expression of the hairpin cassette.

Associated Risks and likelihood of occurrence:
VSV-G enveloped lentiviruses can infect human cells and therefore are potentially harmful to human health if introduced into the body by injection, ingestion or through a wound. The potential harm arises from the possibility the virus would enter and integrate itself into cellular DNA. The physical insertion into cellular DNA could result in a potentially oncogenic mutation. This, however, is unlikely and has only occurred in a clinical setting following prolonged infection with high titre lentiviral vectors encoding growth promoting molecules and selection in vivo for cells with altered growth potential. Some of the hairpin cassettes are potentially oncogenic as some hairpins will target genes with essential cellular function e.g. Tumour suppressors leading to undesirable effects such as cancer. However, the likelihood of infections is very low and no adverse effects have ever been described through accidental exposure to retroviral vectors. VSV-G pseudotyped virus can also infect other mammalian cells but not cells of other origin, however, the virus vectors are of no risk to the environment as viral particles are labile and do not survive on environmental surfaces outside the laboratory.

Origin & function

The inserted RNAi hairpins are sequences that have been derived de novo and are not form an organism. The sequences contain a 22bp sense and antisense sequence that is homologous to the gene of interest to which the hairpin is designed. These sequences are separated by a small loop sequence and flanked by mir-30 sequences. When transcribed in the cell, the RNA will form a hairpin structure which will initiate a normal cellular in vivo downstream cascade of processing events in response to foreign cellular single-stranded RNA intruder molecules. This process results in the post-transcriptional down regulation of the gene to which the hairpin sequence is designed and targeted by destroying the corresponding mRNA molecules prior to translation. The utilization of this is normal endogenous pathway to down-regulate genes of interest is known as RNA interference.

Evaluation of foreseeable effects

Risks and likelihood of risks:
- The bacterial strains to be used are non colonising and incapable of surviving in the environment or causing human infection. They pose no risk to users or the environment.
- None of the DNA viral vector plasmids are harmful to health or to the environment and do not supply a survival advantage to any microorganism. The packaging viral components are from the HIV-1 virus, HIV-1 is harmful to humans, however, the packaging vector does not contain the full length HIV-1 molecule. Many components of HIV-1 that are critical for HIV-1 infection have been removed from the packaging vector. Only those essential for viral packaging remain.
- The most dangerous GMM is the lentiviral preparations of pGIPZ particles and the most dangerous step is the collection, concentration and use of this lentivirus, however this risk is minimal. Lentiviral vectors can infect human cells and therefore if introduced into the body by injection, ingestion or through a wound, the virus could potentially...
enter cells and integrate its genome into cellular DNA. If the inserted sequence were to be expressed into humans after accidental transfer the hairpin could lead to the
down-regulation to the gene to which it targets via RNAi interference. This could be a gene essential for growth regulation such as a tumour suppressor gene therefore
resulting in a potentially oncogenic mutation. Additionally, physical insertion of the virus into the genome of the host cell could potentially disrupt a tumour suppressor or
oncogene, however likelihood of this is very low. Theoretically the virus can also infect other mammalian cells and knockdown the gene of interest. However this is
extremely unlikely as the hairpin is targeted to human genes and many hairpins are not homologous with the genes from other species. The overall risk is very low. Any
infection would be severe as the virus is replication incompetent and therefore self inactivating (does not carry gag,pol or env genes) so it cannot make new progeny virus
and establish a productive infection. Also, it would only be a small number of cells and would not impact on the othogenic outcome of an exogenous viral infection.
Additionally, the viral particles are labile and do not survive on environmental surfaces outside the laboratory making infection unlikely.
. The cell lines used cannot survive outside the laboratory incubators and as such pose no threat to health or the environment.

Precautions in place to minimise risks
The entire of the Cancer Institute is a containment level 2 facility which is secured by restricted access at all entrances and additionally to all laboratory areas. All work
involving viruses will be performed in class 2 cabinets and in containment level 2 laboratories specified particularly for retroviral GMM work. All DNA plasmids containing
viral proteins will be grown separately to avoid opportunity for recombination. To prevent contamination of workers by virus, when handling any GMM or GMM-derived DNA
or virus, no glass or other sharps will be used in the rooms where the viruses are prepared and used and workers will be protected by a lab coat and nitrile gloves. Skin
lesions will be covered with a bandage in addition to the protective wear described above. Specific guidelines will be in place to ensure all viral preparations are handled,
labelled, stored, transported and cleaned up correctly. All those involved in the project will be made aware of the guidelines and the associated risks as well as anyone else
who may use the laboratory. Persons involved on project from other Institutes will work under the supervision of a competent trained worker from this project. No-one
visiting the laboratory that is not involved in this work will work on this project. All persons entering the facility will be made aware of the safety precautions upon entering the
facility. All equipment used in the retroviral laboratory will be available in other general purpose laboratories for general use so it should not be necessary for others who are
not involved in retroviral work to enter the laboratory.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

2-5% Trigene advance or Virkon (v/v) will be used to treat liquid waste (18 hours) and also used to decontaminate any spills and for disinfection of any reusable bottles or
other equipment and laboratory materials used. Liquid waste is subsequently poured down the sink after treatment with Virkon. Work surfaces will be wiped down with 5%
Trigene advance and 70% ethanol after use. Virkon and Trigene advance are certified by the PHLS to provide 100% viricidal and GMO kill under these conditions by
denaturating and inactivating viral and cellular proteins. Trigene advance and Virkon will be used with their lifespan to ensure required kill is achieved. Solid waste will be
double-bagged in biological waste bags, sealed and autoclaved 132°C for 15 mins by trained staff then bagged in yellow biohazard bags and removed by UCL waste
services. Autoclave runs are regularly validated by waste management staff.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N
The panel of advisers and the full GM Safety Committee approved this project as a Cass 2 GM activity.

### Project Ref 14/09.3

- **Date Ackn'd:** 09/11/2009
- **CU2 Project Title:** Gene therapy to the foetus in utero
- **Class:** Class 2
- **CultureVol:** < 1 Litre
- **Consent Granted:** Non-GMM

### Project Additional Information

**Purposes of the contained use**

The aim of the project is to devise safe and effective methods of delivering gene therapy to the fetus or placenta or uterine arteries, with the long term aim of reducing disability and death due to conditions that affect the placenta such as placental insufficiency and fetal growth restriction, and genetic conditions that affect the fetus such as cystic fibrosis, and renal failure.
Recipient or parental organism

The vectors to be used will be adenovirus, retrovirus, lentivirus and adeno-associated virus which contain reporter genes (lacZ beta-galactosidase, Green Fluorescent Protein, luciferase) or therapeutic genes (human factor IX, X or VII, beta-globin, Cystic Fibrosis Transmembrane Regulator).

Only adenovirus vectors will contain Vascular Endothelial Growth Factor, Placental Growth Factor and Insulin Growth Factors.

The vectors will be produced by a number of different sources including Ark Therapeutics Inc, Kuopio, Finland, Department of Haematology (UCL, Dr A N) and Department of Paediatric Immunology (Institute of Child Health, Prof B G).

Host/vector system

Adenovirus: replicative functions are removed such as E1A and placed into packaging cells 293, or removal of E1A and E3, or removal of all early genes (gutless vectors). Supernatant is checked for the presence of wild-type virus.

Lentivirus (second generation) and retrovirus: separated packaging functions transfected into producer cells, theses are gag, pol and env genes. Virus genomes with cDNA will be packaged in vitro.

Origin & function

In this project we will study the use of viral vectors in normal and growth restricted animal fetuses (sheep, rabbit, guinea pig, rat and mouse), their placentae, at various stages of gestation in order to provide basis for gene therapy of fetal animals. Vectors will be delivered to a variety of fetal sites and to the placenta and uterine artery by ultrasound-guided percutaneous needle insertion in the anaesthetised pregnant ewe as well as via chronically implanted fetal catheters in the anaesthetised pregnant ewe, or by injection at laparotomy in anaesthetized animals. Vectors may also be delivered under direct vision by laparotomy and hysterotomy. Some vectors will carry marker genes for beta-galactosidase, Green Fluorescent Protein (GFP) or human factor IX. The former two act as histological markers and allow detection of transgene expression in different tissues while the latter can be detected in blood and will be used to determine the magnitude and timing of gene expression. The remaining vectors will carry therapeutic genes such as for Cystic Fibrosis Transmembrane Regulator, clotting factors VII, IX, and X, beta-globin, Vascular Endothelial Growth Factor, Placental growth Factor and Insulin Growth Factor. Vectors will only be injected into animals held at the Royal Veterinary College, Camden or in the Biological Services Unit, UCL, where post mortem examination will also be carried out. Both the surgery and post mortem examination will be done in level 2 facilities. Animals will be examined at various time points after vector injection. Tissues will be analysed at other laboratory locations including Institute for Womens Health, Rayne Institute and Department of Haematology, UCL. Tissues will be tested using histology, immunohistochemistry, PCR, RT-PCR and ELISA for vector spread, transgene expression and pathology.

Evaluation of foreseeable effects

The transgenes used in these vectors are expected to result in temporary changes in vascular reactivity and blood vessel formation (Vascular Endothelial Growth Factor, Placental Growth Factor and Insulin Growth Factor only present in adenovirus vectors), increase in human clotting factors (VII, IX, and X), or human beta-globin, expression of reporter genes (beta-galactosidase, Green Fluorescent Protein), increased expression of the CFTR gene. None of these effects are likely to be harmful to animals or humans.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

All GM animal material generated by the project will be either stored (fixed in 4% formaldehyde for 24 hours, or snap frozen) or disposed of via incineration arranged by the Biological Services Unit, RVC, Camden.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

n/a

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Waste such as contaminated needles, tubes and syringes will be treated with 10% chloros solution or incinerated as required. All surgical instruments are cleaned in 10% chloros before autoclaving. Animal post mortems will be performed in a designated post mortem room with category 2 facilities at the royal Veterinary College, Camden or the Biological Services Unit, UCL. All gowns and drapes used during surgery are first sterilized by autoclaving before being washed and then resterilized for use in further...
This project, originally a class 1 activity, was extended to include the administration of integrating viral vectors by injection to animals. This change in activity requires reclassification to a class 2 GM activity as advised in Part 2 of the SACGM Compendium of Guidance.

**Historical Significant Changes**

**Historical Date of Additional Info**
**Project Additional Information**

**Purposes of the contained use**

The aim of this project is to use shRNA, cDNA, RNAi and small molecule libraries, using viral and non-viral vectors, for functional screening of cell-based phenotypes. Cellular processes such as signal transduction, protein trafficking and cytoskeleton organization will be investigated under conditions of cDNA overexpression, small molecule treatment or shRNA/RNAi-mediated knockdown of specific genes. The libraries are envisaged to encompass the complete human genome.

**Recipient or parental organism**

HEK293T for virus production, immortalized mammalian cell lines (e.g. HeLa, Cos, Chinese hamster ovary (CHO)), murine embryonic fibroblasts (MEF), primary rat neurons, primary rat Schwann cells, HUVECs, primary human monocytes and macrophages. Yeast cells.

**Host/vector system**

Non-viral: The cDNA expression vectors are standard expression plasmids (e.g. pEAK12, pCMV) with a CMV, EF1A or beta-chicken actin promoter. A puromycin cassette driven by PGK promoter is also included.

Viral: The viral vectors for shRNA are commercially available from vendors (e.g. SigmaAldrich, Open Biosystems) and will be based on the latest generation of lentiviral vector design that renders generation of a replication competent virus to be virtually impossible. The viruses, however, contain some HIV sequences and are pseudotyped with VSV-G envelope such that cells can be infected even if they are not dividing.

**Origin & function**

The inserted shRNA, cDNA & RNAi sequences encompass the entire human genome. The primary reason for using lentiviral vectors is to allow transfection and expression in non-dividing cells, e.g. neurons and macrophages, to permit functional screening of cellular morphologies in these cells. cDAN expression vectors are to be used to transfect mammalian cell-lines.

**Evaluation of foreseeable effects**

Infection with Lentivirus

The materials and the techniques to be used in this specific work program are well established and routinely used by researchers throughout Europe, North America and Australasia. In all experiments we will use replication defective viruses, derived from molecular clones in which key viral genes have been deleted or replication defective viruses, derived from molecular clones in which key viral genes have been deleted or inactivated, thus rendering the virus particles competent for only a single round of infection and replication.

All work with lentivirus will be performed under containment level 2 conditions and open cultures of virus will always be handled inside a microbiological safety cabinet. Provided the local rules established for labs G17 (LMCB SOP 005) and G17 (LMCB SOP 011) are followed, the risk of infection is negligible. These local rules document arrangements for training and induction, waste disposal, sharps policy, emergency procedures etc.

VSV G pseudo-types

Although VSV G pseudo-types can permit infection of a wide range of cell types and species, there is no evidence that these viruses represent a significant risk when handled under biosafety level 2 conditions. These reagents have been used extensively in research and, to our knowledge, there is no documented evidence of infections of laboratory workers through pseudotyped viruses.
Virus mutations and recombination

Although mutation/recombination could potentially render lentiviral vectors replication-competent, such an event is highly unlikely and, to our knowledge, has not been reported previously in a laboratory setting.

Non viral vectors

There is now potential for harm to human health or the environment using these vectors.

Exposure to infected primary cells

All primary cells for these experiments will be obtained from laboratory animals and serologically tested donors (e.g. HUVECS) and will present no significant risk to human health.

Risk to the environment

Due to the restricted host range of the constructs, their lack of ability to survive outside laboratory conditions, restrictions on access to the facility and the risk control and disinfection/disposal measures described in this assessment, we conclude that the program of work presents no risk to the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste will be treated with Trigene Advance* (100% trigene solution added to liquid to make a final concentration of at least 5%) for at least 12 hours before disposal in the laboratory sink.

Solid waste: The LMCB policy is that any solid material containing, or potentially contaminated with, viable biological material must be autoclaved prior to disposal into the clinical waste stream (removed from site by licensed waste carrier and incinerated). Following virus usage, any materials that have, or may potentially have come into contact with virus will be thoroughly decontaminated by soaking in Trigene Advance* (5%) for at least 12 hours prior to draining and placing into an autoclave bag.

Autoclave bags must be doubled (one bag inside the other).

At the end of each session, autoclave bags must be partially** sealed with autoclave tape and left in the blue crate (located in ante-room in G.17 and under lab sink in 1.33) for collection by the autoclave room staff.

Autoclaving is performed in room G.12 (MRC building). The autoclave is validated (12-point thermocouple test) by a competent engineer on a six monthly basis.

*Trigene Advance labs study titled “Virucidal efficacy of a disinfectant for use on inanimate environmental surfaces”, March 2007. This study concluded that TriGene advance (at 1:100) demonstrated complete inactivation of HIV type 1 at 30 min exposure time at RT.

**The autoclaves used pulsed vacuum/stem injection to ensure contact between steam and material. If the bags are completely sealed this process will be compromised.

Is an emergency plan required according to regulation 20? [N]

If yes, tick to confirm that it is attached to this form [N]

**Project Ref** 14/10.1

**CU2 Project Title**

Maintenance, Distribution and Manipulation of Open Biosystems Human retroviral shRNAmir library, and of retroviral and lentiviral vector systems for gene expression and gene knockdown in mammalian systems

**Date Ackn’d** 09/02/2010

**Date Project Ceased**

**Class** Class 2

**CultureVol** 1-50 Litres

**Class CultureVol** Class 2 Culture Volume

**Consent Granted**

**Non-GMM Consent Granted**

**Project notified under transitional arrangements**

**Tick if notifying a connected programme of work**

**Historical Significant Changes**

**Historical Date of Additional Info**

**Significant Change ID**

**Date of Significant Change**

**Project Additional Information**
Purposes of the contained use

The Open Biosystems shRNAmir library consists of over 70,000 individual E. coli glycerol stocks containing the pSM2 retroviral or the pGIPZ lentiviral vector. Each stock contains a unique hairpin sequence within the pSM2 or pGIPZ vector designed to target and reduce the expression of most/all genes within the human genome via RNA interference (RNAi). Retroviral vectors used for gene overexpression originated from Clonetech. Genes of interest are introduced with standard molecular cloning techniques. Adenoviral vector for expression of recombinant Cre Recombinase is replication deficient due to deletions in the E1 and E3 regions and will be used in mouse embryonic fibroblasts (MEFs) originating from a conditional knock out animal models.

The Project will involve retroviral and lentiviral knockdown and overexpression vector maintenance, storage and use of Open Biosystems shRNA library and adenoviral, retroviral and lentiviral mammalian expression plasmids, as well as distribution of clones as bacterial stocks, DNA plasmids and/or retrovirus/lentivirus to members within University College London for use in various projects. Adenovirus Cre will be used for conditional gene targeting. Cre recombinase is a Type I topoisomerase from bacteriophage P1 that catalyzes the site-specific recombination of DNA between loxP sites. Recombinant adenoviruses will be replication deficient due to deletions in the E1 and E3 regions.

Specifically, this project will involve retroviral/lentiviral production form the pSM2 and pGIPZ plasmid and subsequent use of retrovirus/lentiviral stocks in cell based screening functional assays. Further, adenovirus will be used for conditional gene targeting in cell culture systems.

Recipient or parental organism

Cell lines: HMEC, 293T, 293, canine-MDCK, MCF-7, MCF-10A, DU145, PC3, HELA, Jurkat, BT20, DU4475, HBL100, HCC1007, HCC1008, HCC1143, HCC1187, HCC1395, HCC1419, HCC1428, HCC1500, HCC1569, HCC1599, HCC1739, HCC1806, HCC1937, HCC1954, HCC202, HCC2157, HCC2185, HCC2218, HCC3153, HCC38, HCC70, HCC712, MCF10F, MCF12A, MDAMB134VI, MDAMB157, MDAMB175VI, MDAMB231, MDAMB330, MDAMB361, MDAMB415, MDAMB435, MDAMB435S, MDAMB436, MDAMB453, MDAMB468, SKBR3, SUM102PT, SUM1315MO2, SUM149PT, SUM159PT, SUM185PE, SUM190PT, SUM225CWN, SUM229PE, SUM44PE, SUM52PE, T4, T47D, UACC812, UACC893, ZR751, ZR7530, ZR75B, SF9, OvCA 420, OvCA 429, OvCA432, OvCA433, DOV-13, OvCar 5, SkOV3, OvCar3, OvCa 3, C1, C11, C2, C22, C3, T1, T11, T2, T22, T3

Primary human and mouse cells: derived from various human and mouse tissues including peripheral blood-derived lymphocytes.

Bacterial E.coli strains: HB101, XL1-blue, Top10, PrimePlus, JM109, BL21, DH5alpha, SURE, KS10000, The bacterial strains used are attenuated non-colonising strains so that they are incapable of causing human infection and are therefore harmless to humans.

The viral vectors (lentiviral, retroviral, as well as adenoviral) used will be pseudotyped with replication incompetent envelope protein, so if introduced into the body by injection, ingestion or through a wound, the virus could enter human cells and integrate into cellular DNA. Although the virus is replication incompetent so that it cannot make a new progeny virus and establish a productive infection, its insertion into cellular DNA could result in a potentially oncogenic mutation.

The cancer cell lines are minimal risk to harm human.

The bacterial strains used are attenuated, non-colonizing strains that cannot survive outside culture conditions and are therefore harmless to the environment.

The viral vectors are replication incompetent and therefore cannot self-replicate and transfer to another host and are harmless to the environment.

The cells that will receive and integrate the DNA cannot survive in the environment as they are only viable under culture conditions, and are therefore harmless to the environment.

Host/vector system

Lentiviral vectors: Commercial TZV vector from Tranzyme and derivatives (including pGIPZ).
Retroviral vectors: Commercial retroviral hairpin p2M (pSHAG-MAGIC2) vector from Open Biosystems. Retroviral overexpression vectors, i.e. pLXSN, originate from Clonetech. pBabe.

Adenoviral Vector: Commercial human Adenovirus Type5 (dE1/E3).

The viral vectors used are retroviral, lentiviral and adenoviral vectors. The lentiviral and retroviral vectors contain the CMV (Pol II) promoter to drive expression or the hairpin cassette or gene sequence. The lentiviral and retroviral vector do not contain the appropriate accessory elements to form viral particle itself and therefore pose no harm to health and the environment. Packaging and envelope proteins are contained on two additional plasmids to the viral expression vector and these plasmids must be introduced into the cell and expressed alongside the viral vector for viable viral particles to be produced. There are no differences in risk assessment or technique compared to viral downregulation of genes. The Vectors used for each specific task are specifically designed, meaning that the viral knockdown vectors contain elements, i.e. mir-30 sequence flanking the hairpin containing the shRNA, that enhance gene knockdown efficiency. Otherwise the backbone of viral vectors is very similar.

Concerning the usage of adenovirus, there is no integration with the host system, and therefore no viral replication can take place.

Origin & function

The RNAi hairpins are sequences that have been derived de novo and are not from an organism. They have been designed as small sequences with both a sense, anti-sense and loop sequence to form a RNA hairpin when transcribed which will initiate a downstream cascade of events leading to knockdown of the target gene to which the hairpin was designed. The accessory proteins are from the HIV-1 virus. Sequences from retroviral over-expression plasmids originate from human and mouse genes. The Cre recombinase sequence originates from P1 bacteriophage.

The hairpin sequence will be transcribed and the RNA will then form a hairpin stucture. The hairpin structure will induce a normal cellular in vivo downstream sequence of processing events in response to foreign cellular single stranded RNA intruder molecules that will result in the post-transcriptional down-regulation of the gene to which the hairpin sequence is targeted.

DNA gene sequences in overexpression vectors will express a defined gene sequence. The quantity of gene transcript will depend on the chosen promoter system, which defines the strength of the promoter and subsequently the amount of gene expression.

If the inserted sequence were to be expressed in humans after accidental transfer of the hairpin, this could lead to the down-regulation of the gene to which it targets via RNA interference. This could be a gene essential for growth regulation such as a tumour suppressor gene, therefore, resulting in a potentially oncogenic mutation. Also, over-expression of genes in humans after accidental transfer may result in over-expression of a gene essential for growth regulation, such as an oncogene. This, however, would not be severe as the virus is replication incompetent and therefore self-inactivating as none of the structural genes are actually present in the packaged viral genome, so no new virus can be produced and no other cells can be infected. Physical insertion of the virus into the genome of the host cell could potentially disrupt a tumour suppressor or oncogene, however the likelihood of this is very low.

Retrovirus and VSV-G pseudotyped lentivirus can only infect mammalian cells. Potentially the hairpin could be expressed in another mammalian species and lead to the down-regulation of a growth regulatory gene such as a tumour suppressor gene resulting in a potentially oncogenic mutation. This, however, Is extremely unlikely as the hairpin is targeted to human genes and many hairpins are not homologous with the genes from other species. If the hairpin were to target and lead to the reduction of a gene via RNA interference it would not be severe as the virus is replication incompetent and therefore self-inactivating as none of the structural genes are actually present in the packaged viral genome, so no new virus can be produced and no other cells can be infected. Over-expressed gene sequences could be expressed in another mammalian species and lead to over-expression of growth regulatory genes such as an oncogene resulting in a potential oncogenic mutation. There are no differences in risk assessment or technique compared to viral downregulation of genes. The Vectors used for each specific task are specifically designed, meaning that the viral knockdown vectors contain elements, i.e. mir-30 sequence flanking the hairpin containing the shRNA, that enhance gene knockdown efficiency. Otherwise the backbone of viral vectors is very similar.

If virus is introduced into the body by injection, ingestion or through a wound, the virus could potentially enter cells and integrate into cellular DNA. Although the virus is replication incompetent (does not cary gag, pol, or env genes) so it cannot make new progeny virus and establish a productive infection, its physical insertion into cellular DNA could result in a potentially oncogenic mutation. This would be a very unlikely event and if so only a very small number of cells would be affected and it would not impact on the pathogenic outcome of an exogenous viral infection. The packaging viral components are from the HIV-1 virus. The full length HIV-1 virus is harmful to the host system, and therefore no viral replication can take place.
humans, however the packaging vector used does not contain the full length HIV-1 molecule. Many components of HIV-1 that are critical for HIV-1 infection but not required for viral packaging, have been removed, so the virus is attenuated. There are no differences in risk assessment or technique compared to viral downregulation of genes. The Vectors used for each specific task are specifically designed, meaning that the viral knockdown vectors contain elements, i.e. mir-30 sequence flanking the hairpin containing the shRNA, that enhance gene knockdown efficiency. Otherwise the backbone of viral vectors is very similar. Recombinant adenoviruses are replication deficient due to deletions in the E1 and E3 regions and considered of ordinary potential harm. In the unlikely event of recombination, wild type, replication competent adenoviruses provoke cold symptoms and strong immune responses in healthy individuals and generally do not cause serious illness.

The de novo hairpin donor sequences or the de novo gene sequences could potentially be expressed in cells and lead to the knockdown or expression of certain genes leading to the increase of oncogenic potential of the virus. This would only be a very small number of cells and as the virus is replication incompetent and cannot make new viral progeny, it would not impact on the pathogenic outcome of an exogenous viral infection. There are no differences in risk assessment or technique compared to viral downregulation of genes. The Vectors used for each specific task are specifically designed, meaning that the viral knockdown vectors contain elements, i.e. mir-30 sequence flanking the hairpin containing the shRNA, that enhance gene knockdown efficiency. Project Ref 14/10.4

Date Ackn'd 13/08/2010

CU2 Project Title Determining the mechanism of protein export by the human malaria parasite, Plasmodium falciparum.

Date Project Ceased

Class 3

CultureVolClass2 < 1 Litre

CultureVolumeClass3-4 < 1 Litre

Non-GMM Consent Granted Yes

Project notified under transitional arrangements

Historical Significant Changes

Historical Date of Additional Info

Significant Change ID
**Project Additional Information**

**Purposes of the contained use**

The malaria parasite lives inside human and red blood cells. It exports proteins into the red blood cell cytoplasm.

**Aim 1:** To find out what determines whether a protein is exported, we will generate parasites that are transfected with GFP (green fluorescent protein) tagged exported proteins. We will introduce mutations into these proteins to see what regions of the protein are required for protein export.

**Aim 2:** Several components of the protein export apparatus have been identified. We will generate malaria parasites that are transfected with these components and then use these parasites for biochemical analysis with the aim of determining what proteins interact with these known components of the export machinery.

**Recipient or parental organism**

GMM/1: lines 1.13, 1.19, 1.20

*Plasmodium falciparum*

*Plasmodium falciparum* causes human malaria. Malaria can be treated effectively with drugs. Parasites used are not resistant to widely used anti-malarial drugs. If untreated, malaria can be fatal.

Recipient organisms are not capable of independent survival in the environment.

**Host/vector system**

GMM/1: lines 1.12, 1.24

Custom made expression vectors will be used (sequences can be provided). These are circular vectors derived from E. coli plasmids but with the following additions that allow them to be propagated in E. coli and plasmodium.

1. A drug selection marker, either human dihydrofolate reductase or Blasticidin deaminase, that will allow selection of transfected parasites using either WR99210 or blasticidin, respectively. Neither of these drugs is used for treatment of malaria and both are widely used in transfection of malaria parasites. Both selection markers will be expressed from a plasmodium promoter, pcDT

2. A plasmodium promoter that allows expression of the proteins in section 1.10 (calmodulin promoter)

3. An AttP site that allows transposase (Bxb1) mediated integration at a specific site into the plasmodium genome, or terminal repeats that allow random insertion of the plasmid into the lasmodium genome using the Piggybac transposase.

4. GFP or strep tag will be fused to the gene to be expressed.

To facilitate plasmid integration into the parasite genome a second plasmid that expresses the transposase Bxb1 or piggybac will also be used. These transposases will be expressed from a plasmodium promoter and the plasmids will not be selected for using a drug selection.

Plasmids also contain an E. coli origin and Ampicillin selection marker to allow propagation of the DNA in E. coli.

**Origin & function**

GMM/1: 1.11, 1.14 - 1.16 - 1.18
DNA is derived from plasmodium falciparum, which causes human malaria

Inserted gene products are expected to have the following activities:

**PFl1755c, pfemp3**: small fragments of these genes, fused to GFP will be used. These fragments will be sufficient to direct the export of GFP into the red cell cytoplasm. They are not expected to have any other biological activity.

**PF11_0175 and Exp2**: proteins are thought to be involved in unfolding of proteins prior to export.

The proteins themselves will not cause harm if expressed in humans after accidental transfer and neither will selectable markers used to select transfected parasites. Parasites will be resistant to drugs WR99210 and Blasticidin but neither drug is used to treat malaria. Parasites will remain sensitive to drugs commonly used to treat malaria such as Artemisinin.

Sequences will not cause harm if transferred to species in the environment

Sequences derived from plasmodium are not implicated in pathological or harmful characteristics of the organism.

### Evaluation of foreseeable effects

**GMM/1: lines 1.17, 1.16, 1.32**

DNA is derived from plasmodium falciparum, which causes human malaria.

Sequences derived from plasmodium are not implicated in pathological or harmful characteristics of the organism.

Potential harm includes infection with malaria or unknown pathogens contained in human blood.

Blood will be obtained from NHS Blood and Transplant (National Blood Service) - product - (NC15-Research Red Cells)

This product is screened, by the NHS, for Syphilis, HIV, Hep B and Hep C. No other blood products will be used.

The most dangerous part of this procedure will involve handling and propagating malaria cultures

### Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

The laboratory to be used is not sealable to permit fumigation because the malaria parasite cannot survive outside of carefully controlled growth conditions, and so any spillage outside of primary containment (the microbiological safety cabinet) would result in rapid die-off of the infectious agent.

Additionally, the malaria parasite is not transmissible by the airborne route.

No work with other HG3 agents will take place in the laboratory at the same time as work with *P. falciparum* takes place

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

**GMM/1: line 1.29 or GMM/2: lines 2.13 (as applicable)**
1. Liquid waste: 10% bleach overnight (liquid waste will be aspirated into a vacuum trap containing sufficient bleach such that even if the trap is full it will contain at least 10% bleach at all times). This is a standard method that results in 100% killing of the malaria parasite.

2. Plasticware: disposed in clearly labelled biohazard bins, double bagged in appropriately labelled bags, and autoclaved. This is a standard method that results in 100% killing of the malaria parasite.

3. Glass microscope slides will be fixed in 100% methanol and autoclaved. This is a standard method that results in 100% killing of the malaria parasite.

This project was reviewed by the University Biological Safety Advisor and one of the UCL GM advisors on behalf of the Committee. Subject to some minor amendments and clarifications, they were content with the risk assessment.

Project Ref 14/10.5

Date Ackn'd 24/08/2010

Date Project Ceased

CU2 Project Title Analysis of glial cell function in nerve repair and cancer

Class 2

CultureVolClass2 < 1 Litre

Consent Granted

02/03/2022
**Project Additional Information**

**Purposes of the contained use**

The aim of this project is to use shRNA and cDNA adenoviral and lentiviral expression vectors to either remove gene function or constitutively express proteins in order to determine the role of specific proteins in glial cell function in relation to nerve repair and cancer. Viral vectors are required to ensure high efficiency of expression. Glial cells interact with other cell types such as neuronal cells and fibroblasts, therefore viral infection of these cells may also be required to determine glial cell function. Many of the genes to be suppressed or expressed will have been identified as a result of genome-wide screens using the facility at the LMCB run by R K.

**Recipient or parental organism**

The hosts will be bacteria used for cloning all E. coli based TopF10, DH5alpha, STBL3). HEK293T for virus production, Rat and mouse Schwann cells and relevant human tumour cell lines (e.g. MPNSTs), immortalized mammalian cell lines (e.g. HeLa, Hek293, Cos, Chinese hamster ovary), fibroblasts from mice (MEFs) and rats (REFs), rodent neuronal cells.

**Host/vector system**

Replication-deficient lentiviral -based vectors for shRNA (available from Open Biosystems or Sigma Aldrich); replicaion-deficient lentiviral-based expression vectors for cDNA expression (FUW or RRL backbone vectors). Replication-deficient adenoviruses for cDNA expression (AdEasy and related vectors (Stratagene and Qbiogene Inc)).

**Origin & function**

Small hairpin RNAs for gene knockdown and cDNA covering a large selection of genes , and indicator proteins (GFP, dsRed, lacZ) or drug selection markers (neo/puro). At the current time it is not possible to be specific about the genes involved as many will be identified in a screen. We will be doing genome-wide lentivirus siRNA screens in collaboration with R K. We would then do a secondary screens and follow-up experiments for the genes which are positive. It is most likely these genes will code for receptors, kinases or phosphatases . Initial experiments will be expressing ligands and receptors of the ephrin signalling pathways and are highly unlikely to be transforming. In any case, all work with infectious virus will be performed in the virus suite which is category 2.

Small hairpin RNAs for gene knockdown cDNA covering a large selection of genes, and indicator proteins (GFP, dsRed, lacZ) or drug selection markers (neo/puro).

All the above are derived from human, mouse or rat genome projects.

shRNA are intended to prevent expression of targeted proteins in recipient cells. cDNA will lead to expression of translated protein in target cells.

**Evaluation of foreseeable effects**

Recipient organisms:
Recipient organism will be E. coli bacteria (Top10, DH5alpha & STBL3) and established & screened cell lines of human & rodent origin. Exposure to these organisms could occur due to ingestion, injection or inhalation of material whilst handling due to poor laboratory practice. The likelihood of exposure is low as workers will handle material in accordance with good laboratory practice (as specified in the LMCB Code of Practice for Laboratory Workers and in the SoPs for lab G.17 (virus lab). None of these organisms are likely to have any harmful effects on human health or the environment.

Viral vectors:

The disabled viral vectors contain some HIV sequences and may be pseudotyped with VSVg envelope such that human cells can be infected even if they are not dividing. Upon infection the virus could conceivably cause harmful effects by disruption to host gene sequences or by constitutive expression of the cDNA due to insertion of viral genome.

Infection with wild-type adenovirus can lead to infection of the upper-respiratory tract resulting on cold/flu like symptoms. Reversion of the replication deficient adenoviral vector to a replication-competent strain is highly unlikely. Moreover, we test for RSV in new virus by testing the supernatant of infected cells for virus. To date we have not been able to detect virus.

Exposure to vectors could occur due to ingestion, injection or inhalation (particularly sub-cutaneous injection in the case of lentivirus and inhalation of adenoviruses) of material whilst handling. Key risks relate to work with adenoviral and lentiviral vectors and are a) spillage during infection b) sub-cutaneous infections during manipulations of plates whilst performing tissue culture and c) generation of aerosols due to spillage or failure of equipment whilst performing tissue culture.

All virus production and cell infections will be performed in the Virus laboratory (G.17), in accordance with the SOP for work in the Virus Laboratory, using class II safety cabinets.

The risk to the environment from the viral vectors is, due to their replication-deficient nature, negligible.

Gene sequences:

Due to their intended effect of shRNAs of supressing targeted proteins it is possible that harmful effects could occur. cDNAs lead to expression of translated protein products which could also have positive harmful effects. It is not possible to predict the severity of the effects but due to the minimal effects of expressing single genes severe effects are unlikely. Exposure to these sequences could occur due to ingestion, injection or inhalation of material whilst handling due to poor laboratory practice. The likelihood of exposure is low as workers will handle material in accordance with good laboratory practice (as specified in the LMCB Code of Practice for Laboratory Workers and in the SoPs for lab G.17 (virus lab).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All material containing, or potentially containing adenoviral or lentiviral vectors will be immersed in 5% Trigene solution overnight prior to autoclaving in room G12 (MRC building). Liquid waste will be mixed with Trigene Advance to a 5% solution and left for 12 hours (min) before disposal down a laboratory sink within a Category 2 laboratory (G.17). Green fluorescent reporter constructs for lentivirus and adenoviruses can be assayed for infectivity with & without Trigene treatment. We anticipate that infectivity will be undetectable after Trigene treatment.

Trigene Advance: ATS labs study titled "Virucidal efficacy of a disinfectant for use on inanimate environment surfaces" March 2007. This study concluded that TriGene...
Advance at (1:50) demonstrated complete inactivation of HIV type 1 at 30 min exposure time at RT. Likewise the Abbott Analytical study of Sept 1996 showed that Trigene Advance (at 1:50) completely inactivated adenoviruses following 15 minutes exposure at RT. Consequently, we are confident that Trigene Advance would be equally effective against lentivirus and adenoviruses.

All other GMMs including transfected cells that have been fixed with 4% paraformaldehyde or lysed with Triton x100, will be autoclaved prior to disposal without prior chemical disinfection.

The autoclaves are regularly serviced and a 12-point thermocouple validation is performed every 6-months.

Is an emergency plan required according to regulation 20?  N

Non-GMM Consent Granted

Project notified under transitional arrangements N
We are conducting studies on the impact of Human Immunodeficiency Virus (HIV) and its treatment among people who are co-infected with the hepatitis B virus (HBV). For this purpose we are collecting blood samples from two cohorts of patients in Ghana and Malawi. In these regions antiretroviral therapy has recently become available to treat HIV infection. The first-line combination includes three drugs active against HIV, typically stavudine, lamivudine (LMV) and nevirapine. Of these drugs, LMV also has activity against HBV. Thus patients who are HIV/HBV co-infected receive three drugs for HIV but only one for HBV. There are two problems associated with the use of LMV as the sole agent against HBV:

1) Control of HBV replication is usually suboptimal, leading to the development of HBV drug resistant variants carrying mutations in the polymerase (pol) gene targeted by LMV. Ongoing HBV replication leads to progressive liver damage and a risk of liver cancer. Thus, as survival increases in these communities due to control of HIV, a potential is emerging for significant HBV-related liver disease to become apparent.

2) As the HBV surface (S) and pol genes are expressed in alternative reading frames from the same region of the viral genome (Figure 1), selective pressure exerted by LMV on pol can cause mutations in both pol and S. Mutations in the HBV surface antigen (HBsAg) can affect key antigenic determinants, creating the potential for immune and vaccine escape. In addition mutations in HBsAg can lead to loss of recognition in diagnostic assays.

We have preliminary data that show high rates of emerging HBV LMV resistance in the two African cohorts and have also identified virus variants that carry highly mutated HBsAg, including some diagnostic escape mutants. We now wish to extend these studies by constructing a system for HBV that will allow us to characterize the viral phenotype, including drug resistance, viral fitness, and HBsAg expression and immune recognition in vitro. We have extensive experience with similar systems applied to the study of HIV phenotypes, where we use both replicative and non-replicate recombinant vectors containing virus gene segments of interest inserted as “cassettes”. The vector may also be modified by site directed mutagenesis (SDM) to study mutations of interest. We plan to follow a similar approach with HBV.

It has long been established that certain circular DNA viruses replicate through a rolling circle mechanism. By mimicking this mechanism, a construct that contains a full length viral genome plus a partial repeat (“full-length plus”) can direct the production of virus particles upon transfection into cell lines in vitro. HBV clones have been traditionally produced in this way. We will amplify the whole HBV genome from one or a few interesting samples and clone it into standard cloning vectors (pUC or pCR based vectors). Full-length plus HBV clones will be generated by adding a partial repeat to the cloned full genome. Individual gene segments will be sub-cloned into generic expression vectors (pCMV or pSV40 expression vectors). In some cases, gene segments derived from certain patient viruses will be exchanged with those of the reference clone to study their effect on phenotype in the context of a common backbone. In addition, mutants of interest will be introduced by SDM. We will then transfect the viral construct in vitro into cell lines with the purpose of studying replication capacity, drug susceptibility and immune recognition of the various viruses.

To facilitate the interpretation of the proposed experiments, we summarise below the main characteristics of the HBV replication cycle (Figure 2). One key feature is that the virus replicates through an RNA intermediate form by reverse transcription, and in this respect it is similar to HIV.

Figure 1. Schematic representation of the structure of the HBV genome with the four opening reading frames (ORFs) P, S, C, and X. The ORFs encode seven different
proteins through use of varying in-frame start codons. ORG P encoded for the polymerase protein; ORF S encodes the three surface proteins; ORF C encodes both the e and core protein; ORF X encodes the X protein. The genome also contains genetic elements which regulate levels of transcription, determine the site of polyadenylation, and mark a specific transcript for encapsidation into the nucleocapsid. The four ORFs transcription are controlled by four promoter elements (preS1, preS2, core, and X).

HBV regions contain a partially double stranded 3.2 kb genome termed the relaxed circle DNA (rcDNA). The negative sense strand is complete while the positive sense strand is only partial. Upon infection of cells, the genome is transported into the nucleus where it is converted into a fully double stranded, covalently closed circular DNA (cccDNA). This persists as an episome in the nucleus, a sort of minichromosome that serves as a template for the transcription of viral RNAs by the cellular RNA polymerase II. Several transcripts are produced, which are classed as genomic and sub-genomic RNAs. Subgenomic transcripts serve as mRNA for the X and surface proteins. The larger genomic transcripts are longer than one genome in length and serve to produce e, core and polymerase proteins. A particular genomic transcript, lacking the ATG start codon for the e protein, is designated as pregenomic RNA (pgRNA). The pgRNA, in addition to serving as mRNA for the core antigen and the viral polymerase, is selectively packaged into immature viral capsids in the cytoplasm, and reverse transcribed by the viral polymerase to produce the rcDNA genome for progeny virions.

UNABLE TO INCLUDE DIAGRAM (Figure 2)
Figure 2. Schematic representation of the HBV life cycle. The virus particle attaches to the hepatocyte through cellular receptor (1). After translocation to the cytoplasm (2), the nucleocapsid releases the viral genome to the nucleus (3) where it is converted into a covalently-closed circular DNA (cccDNA) to serve as template for viral RNA transcription (4). The viral mRNAs are translated into viral proteins in the cytoplasm (5), and the pgRNA (6) is encapsidated together with the viral polymerase into a capsid made of core protein (7). Upon maturation of the virus particle, DNA is synthesized by the viral polymerase using pgRNA as template (8-9). The newly synthesized nucleocapsid can either initiate a new round of cccDNA synthesis in the nucleus (10), or acquire the viral envelope in the ER/Golgi apparatus with release of mature virions by exocytosis (11).
This mode of virus production does not result in cell death

Recipient or parental organism
E. coli strains K12 (for example DH5 alpha, HB101, TOP10 and Mach1)
Cell lines - Epithelial cell lines such a HepG2, HepaRG cells, HepG2.2.15, HeLa; T-cell lines such as Jurkat; Embryonic cell lines such as HEK293.
E. coli K12 (DH5 alpha, HB101, TOP10 and Mach1) used for DNA cloning poses little risk as it is not considered to be pathogenic to humans or animals. It requires biosafety level 1.
A number of cell lines will be required for the proposed experiments.
The human cell line HepaRG poses little risk and requires biosafety level 1. This is a hepatoma cell line which is differentiated before use. The differentiated cells have very similar properties to primary hepatocytes.
The human cell line HepG2 are also poses little risk and requires biosafety level 1. HepG2 cell are adherent, epithelial-like cells derived from the liver tissue of a fifteen year old male with differentiated hepatocellular carcinoma. HepG2 are not tumorigenic even in immunocompromised mice.
HepG2.2.15 cells are HepG2 cells stably transfected with full-length plus HBV genome; they express all viral RNAs and proteins, produce viral genomes, and secrete virus-like particles. HepG2.2.15 cells are a biosafety category 3 cell line that will be handled in containment level 3 laboratory. The cells will be stored in the -80°C freezer in the containment level 3 laboratory in ladled boxes.
The human cell lines HeLa, Jurkat, and HEK293 require as biosafety level 2. The gene that maintains continuous viral growth in vitro may be expressed if accidently transferred into humans and has potential to cause cancers.
E. coli K12 strains have limited survival in the environment. Bacteria that have been transformed by viral constructs do not produce any harmful by-products other than the
viral genome being studied. The inserted plasmids are only maintained with the use of antibiotic selection and are not likely to be maintained within the bacteria in the environment.

Human cell lines HepaRG, HepG2 and HepG2.2.15 cells, HeLa, Jurkat, Hek293 require specialised sterile tissue culture conditions to be maintained and have limited survival in the environment as the serum and nutrient requirements are not likely to be met outside laboratory tissue culture.

**Host/vector system**

Cloning vectors: pUC and pCR vectors.  
Mammalian expression vectors: pCMV and pSV vectors.

The cloning vectors used for this study will be pUC or pCR vectors. They contain a T7 promoter/priming site as well as f1 and co/E1 origin of replication. They also contain genes that confer resistance to the antibiotics Kanamycin and Ampicillin. They are not known to cause harm to humans. If cloning vectors escaped into environment, their antibiotic resistance gene may potentially be taken up by bacteria making them less susceptible to the antibiotics.

The expression vectors used will be pCMV and pSV vectors. They contain promoters/replication origin sites from cytomegalovirus and SV40 respectively, which are needed to maintain plasmids in mammalian cells and transcribe the inserted genes. They also contain genes that confer resistance to Kanamycin and Ampicillin to allow selection in E. coli and to Gentamicin or Puromycin for selection in mammalian cells. They are potentially able to replicate in mammalian cells and cause the cells to become resistant to the specific antibiotics. They may potentially cause drug resistance if they are taken up by and maintained in bacteria.

Two full-length and full-length plus constructs will be produced for each sample in cloning vectors (pUC or pCR) (Figure 3).

The first two products, pF1 and pF2, corresponding to the full-length 3.2kb HBV DNA genome, are produced with two sets of PCR primers targeting different sites of the HBV genome. The third construct, pHB-1, contains full-length HBV DNA plus a partially repeated sequence (“full-length plus”). Only this full-length plus plasmid is capable in vitro of producing all the viral proteins and RNAs required for assembly of HBV virions.

Individual viral genes (i.e. surface antigen, e antigen, core antigen, x protein, polymerase) will be subcloned into expression vectors. The proteins will be expressed in cell lines.

Some of the products will be modified by SDM.

HBV production does not cause major pathogenic effects on the cells. If samples are not handled appropriately, virus proteins may potentially cause immune reactions.

All plasmid production and purification will occur in the containment level 2 molecular laboratory. All bacterial cultures will be grown in plastic flasks and laboratory health and safety procedures will be followed. Plasmids will be stored in clearly labelled boxes at -20°C.

**Origin & function**

**Hepatitis B Virus**

The cloned full-length plus HBV genome will be capable of expressing the proteins and the nucleic acid required for the assembly of HBV particles. The individual gene clones will be able to produce individual proteins, such as HBsAg, e antigen, core antigen, polymerase, x protein. Samples may harbour mutations in certain regions of the genome, either occurring in vivo in the clinical sample under study or introduced SDM. Some of the mutations are expected to modify the susceptibility of HBV to antiviral drugs or immune responses, while others are expected to modify the levels of HBsAg expression and recognition. Some mutations are expected to affect virus fitness i.e. the virus ability to replicate and infect. The mutations that will be studied are those found to occur naturally in infected individuals. In SDM experiments involving the pol gene, it is anticipated that mutations will also indirectly be introduced to the S gene due to overlapping structure of the ORFs.
The likelihood of adverse events after accidental exposure is estimated to be low.

Accidental transfer may occur through percutaneous exposure (e.g., sharp injuries) or membrane exposure (e.g., splash to the eyes) of infectious material. HBV virus particles are quite stable and remain viable for 7 or more days on environmental surfaces at room temperature. The full-length plus HBV sequences and HBV particles are potentially harmful to humans. The outcomes may include acute infection resulting in hepatitis; in a subset of individuals a chronic carrier state may be established. Over several years, a subset of chronically infected individuals will develop complications such as liver cirrhosis and hepatocellular carcinoma.

A number of factors attenuate the risk of adverse outcomes.

Production of infectious HBV by the in vitro system described in this proposal has proved difficult. To date only non-productive infections have been achieved. However, transfection of full-length plus genomes has been shown to produce virions capable of infecting transgenic mice. Thus the possibility of human infection should be taken into account. Clinical samples from HBV infected patients represent a further and more significant potential source of infection.

In the healthcare setting we are very familiar with the management of occupational exposure to HBV and clear protocols are in place. These include minimising the risk of accidental exposure through good laboratory practice (e.g., no sharps, use of personal protective equipment, prompt disinfection of spillages), pre-exposure HBV vaccination, and post-exposure HBV prophylaxis. All people performing the laboratory work have been vaccinated against HBV as per national regulations. Should an exposure occur the laboratory worker has received instructions on how to manage exposed sites by careful washing and first aid kits are available in the laboratory for this purpose. The laboratory worker will then contact the responsible virology consultant immediately (or deputy) for deciding upon post-exposure prophylaxis. This may include further HBV vaccine dose, HBV Immunoglobulin or antiviral therapy as deemed appropriate by the consultant, who will take into account the circumstances of the exposure, the source of the exposure, and the vaccination history of the recipient to guide the decision. Should infection occur despite these pre- and post-exposure interventions, acute hepatitis may result which may require clinical management but very rarely will result in a risk of mortality. Pre-exposure vaccination and post-exposure prophylaxis, even in the unlikely scenario that they are not sufficient to prevent infection, will attenuate the risk of severe acute hepatitis. In immune competent adults, acute hepatitis B rarely (<1-5%) results in a chronic HBV infection, and the risk is further reduced by the use of pre-exposure vaccination and post-exposure prophylaxis.

Thus, the overall risk of exposure to infectious material is considered to be low and the clinical risk associated to an exposure is considered to be minimal.

As a further potential hazard, individual proteins may cause immune reactions and trigger antibody production.

The full-length plus sequences and virus particles are unlikely to cause harm to species in the environment as HBV has a narrow host range which is limited to humans and chimpanzees; in these species it may cause acute and chronic hepatitis. Humans are the main natural host for HBV. As noted above, HBV virus particles are quite stable in the environment and remain viable for 7 or more days on environmental surfaces at room temperature. The individual proteins have the capacity to cause immune reactions if accidently transferred to species in the environment.

These risks will be addressed by HBV vaccination of laboratory workers as per national guidelines, good laboratory practice (e.g., no sharps; use of personal protective equipment including laboratory coats, eye protection and gloved, and prompt disinfection of spillages with either 5% Trigene or 70% ethanol and proper disposal of waste). These procedures are covered in the laboratory Health & safety manual and Standard Operating Procedure (SOP). HBV particles produced in vitro as part of this study will be maintained in the containment level 3 laboratory. It should be noted that the HBV constructs have no or limited ability to establish productive infections (see above).

Evaluation of foreseeable effects

The HBV sequences to be used in this study will be derived from plasma and serum of HBV infected patients. The donor organism is pathogenic if not handled appropriately and may cause infection as described above.

The risk of infection and related adverse clinical events is considered to be low.

The HBV sequences that we aim to amplify and express are the cause of HBV infection and mediate disease pathogenesis.
The full-length plus HBV clone is capable of producing virions when expressed in HepG2 cells; therefore the most hazardous step is transfection of the construct into the cell line and transduction with HBV viral supernatants.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All waste in the Department of Virology is disposed of by autoclaving (Standard autoclave cycle is 135 degrees C, 3150 mBar, 10 minutes) Liquid waste is collected in glass waste bottles and autoclaved. Solid waste is placed in double autoclave bags, autoclaved and then disposed of through approved routes. Details of these procedures can be obtained in the department Safety Manual. Spillages should be absorbed onto paper towels which will be autoclaved and the surface should be decontaminated and cleaned with 70% ethanol.

Waste from the CL3 laboratory (GF478) is additionally treated with the following measures. Virus, infected cells, pipette tips, flasks and all other plastics used will be inactivated in 10% Trigene overnight in disposable jars. Liquid waste, in 105% trigene, is solidified with vernagel prior to removal from the CL3 laboratory. Sealed containers and disinfected bags are placed inside metal tins which will be closed and disinfected prior to transport to the autoclave. The autoclaving conditions are checked with 12 thermocouples. The expected degree of kill is 100%

1. Liquid waste including viruses, infected cells, pipette tips, flasks and all other plastics used will be inactivated by Trigene 5% followed by autoclaving.

Bacterial culture liquid waste and contaminated plastics will be autoclaved. Bacterial cultures will be grown in disposable plastic flasks that will be autoclaved after use.

2. The degree of kill for these procedures is 100%

3. The autoclaving conditions follow those applied to the NHS diagnostic guidelines according to the requirements of Clinical Pathologic Accreditation. Standard autoclave cycle is 135 degrees C, 3150 mBar, 10 minutes. The autoclaving conditions are checked with 12 thermocouples.

4. Sealed and disinfected bags placed inside metal tins which will be closed and disinfected prior to transport to the autoclave.

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

Please enter comments on the GM safety committee on the risk assessment

In consultation with virology experts at the Royal Free, the GMSC approved this work as an Activity Class 3 project.

Project Containment

02/03/2022
Project Additional Information

One of the barriers to studying neurological diseases is the inaccessibility of diseased tissue for study. One way to circumvent this is to take fibroblasts from patients, and reprogram them to take on an induced pluripotent stem (iPS) cell state, where they behave like embryonic stem cells, and can be directed to differentiate into cells of interest.

We are aiming to use this technique to study inherited neurologic diseases including Parkinson's disease, Alzheimer's disease and frontotemporal dementia amongst others, and we have collections of fibroblast cell lines derived by us from skin biopsies taken from individuals with these diseases.

The next step would be to carry out reprogramming to iPS cells, as described in Takahashi and Yamanak, Cell 2006;131:861-872) which requires the use of retrovirus bearing four transcription factors (Oct4, Sox2, c-Myc and Klf4) to transduce the target fibroblasts. This drives expression of these four genes at a level similar to that seen
in embryonic stem cells, leading to development of an iPS cell phenotype in a small proportion (<1%) of target cells.
This is an essential step before these IPS cells are used to generate cells of interest (neurons and glia) for disease modelling purposes. GMM approval is required for us to carry out the iPS cell generation step of this work.

Recipient or parental organism
The recipient organisms will be replication-deficient amphotrophic retroviruses, platinum A viral packaging cells and human primary fibroblasts cells. The viral particles that will be produced are replication deficient but capable of infecting individual mammalian cells. The viral particles contain genes that will be expressed in the transduced cells including the proto-oncogene c-Myc.

Host/vector system
The vector used will be the PMXs-GW retroviral vector from Cell Biolabs which is based on the Moloney murine leukemia virus (MMLV). The vector backbone contains the psi packaging signal, transcription and processing elements. Replication machinery (e.g. gag, pol and env genes) have been removed. Each of the four genes used in this study have been cloned in to this backbone with the Gateway cloning system (Invitrogen). The pMXs vector backbone with inserted gene is itself not harmful to health or the environment, however the resultant viral particles (formed following transfection of the vectors into Platinum A packaging cells) have the potential to be harmful as described herein.

Origin & function
The genetic material is cloned cDNA from human and mouse tissues. These cDNAs will encode the human and mouse transcription factors c-Myc, Sox2, Klf4 and Oct4. When target cells (patient fibroblasts) are transduced with the combination of four genes (Oct4, Sox2, c-Myc and Klf4), the expectation is that each of these genes will be transcribed at a relatively high level (much higher than endogenous activity in fibroblasts, comparable instead to the level seen in embryonic stem cells) to drive reprogramming to an induced pluripotent stem (iPS) cell state (Takahashi and Yamanaka Cell 2006;131: 861-872). As c-Myc is a protooncogene, prolonged expression has oncogenic potential. Therefore, retroviral particles containing c-Myc sequence could be harmful if accidentally transferred to humans. However, the infected cells (patient fibroblasts) would not themselves be hazardous, because the viral particles are replication-incompetent.

Evaluation of foreseeable effects
The most hazardous step in this procedure is the generation of replication-incompetent retrovirus containing c-Myc, a protooncogene, with the capability of infecting human cells. If accidentally transferred to a worker's tissue through, for example, a needlestick injury, there is oncogenic potential. There is a theoretical risk of recombination of the replication-incompetent vectors with replication-competent retroviruses in the patient samples. This risk is minimal, as the patient cohort recruited into this study is highly unlikely to harbour HIV or HTLV infection due to their age and immune status. Any known HIV or HTLV positive patients would be excluded from recruitment into this study. Further to this, the derived fibroblast cells are CD1 negative, making infection and/or propagation of active HIV or HTLV possible but of low efficiency.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)
N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)
All plasticware, media and disposable waste will be treated with 10% trigene for a minimum of eight hours and then autoclaved prior to disposal as clinical waste. Laboratory surfaces will be treated with 10% trigene and 70% ethanol and cell culture hoods will be UV radiated after use. Trigene has a 100% kill rate against both viral particles and also the recipient cells (from manufacturers instructions). The activity of trigene can be monitored by changes in the colour of cell culture medium associated with a change in pH. Disinfected and autoclaved solid waste will be removed in clinical waste bags for incineration.
The UCL GSMC approved this project without any amendment at its meeting on 17th February 2021.

Project Additional Information

Purposes of the contained use

The Open Biosystems library contains over 70000 individual E. Coli glycerol stocks containin the pGIPZ lentiviral vector or pSM2 retroviral vector. Each stock contains a unique hairpin sequence within the vector designed to target and reduce the expression of the majority of genes within the human genomes via RNA interference (RNAi).

The project will involve lentiviral or retroviral knockdown vector maintenance, storage and use of Open Biosystems shRNA library, including lentiviral mammalian expression plasmids, as well as distribution of clones as bacterial stocks DNA plasmids and or lentivirus to members within University College London for use in various projects.

Specifically, these constructs will be used to identify the key functional regulators of normal and tumour-derived neural stem cell lines.

Recipient or parental organism

Cell lines: a panel of mouse and human cell lines derived from mouse or human foetal nervous system and/or adult tissues or tumour biopsies.

Primary cell cultures: derived from mouse or human foetal nervous system and/or adult brain tissues or tumour biopsies.

Established cell lines: 293T (for viral preparations)

Bacterial E.coli strains: HB101, XL1-blue, TOP10, Prime Plus, JM109, BL21, DH5alpha, SURE, KS1000, DE3

Host/vector system

Lentiviral vectors: commercial TZV vector from Tranzyme and derivatives (including pGIPZ).

Retroviral vectors: commercial retroviral hairpin pSM (pSHAG-MAGIC-2) vector from Open Biosystems.

The viral vectors are lentiviral vectors. The vectors contain the CMV (Pol II) promoter to drive expression of the hairpin cassette or gene sequence. The lentiviral vector does not contain the appropriate accessory elements to form a functioning viral particle. Therefore it poses no threat to health or the environment. Packaging and envelope proteins are contained on two additional separate plasmids which are required in combination to produce viral particles. This separation of genetic elements essential for full viral functioning provides an addition safety measure. There shRNA cassettes are designed to target specific genes and will result in their knockdown.

Origin & function

The RNAi hairpins are sequences that have been derived de novo and are not from an organism. They have been designed as short sequences with both a sense and antisense and loop sequence. This results in formation of a RNA hairpin following transcription which in turn will trigger the appropriate RNA interference response (RNAi). The accessory protein derive from the HIV-1 virus.

Evaluation of foreseeable effects

The hairpin sequence will be transcribed following delivery into the host cells. This hairpin structure will trigger a normal cellular response pathway that results in the target sequence being suppressed in its translation or stability - this is known as the RNA interference pathway. The lentivirus and retrovirus can only infect mammalian cells. The target sequence of the shRNA is designed specifically for human sequences. There is a small risk that 'off target' sequences might be hit, including other mammalian species.

As the sequences are designed to target human genes there is the possibility that if the vector was delivered by accidental transfer to human cells it would result in gene...
If the resulting downregulated gene was a gene such as tumour suppressor this might result in aberrant regulation of cell proliferation pathways. However, the virus is replication incompetent and therefore would not spread beyond the initial cell targeted. Genetically normal human cells which received this vector would undergo a process of programmed cell death. Physical insertion of the vector into the host genome might also disrupt critical gene functioning. However, the likelihood of this is extremely low, and similarly cells would trigger an endogenous cell death pathway. Thus, the ability of the virus to be accidentally transferred to human cells is extremely low, there is no possibility for the virus to spread and even if inserted the cells would be removed rapidly as part of their normal cellular response. If virus is introduced into the body by injection, ingestion or through a wound the virus could potentially enter cells and integrate into the genome. Although the virus is replication incompetent (does not carry the packaging protein) its physical insertion into cellular DNA could result in an oncogenic mutation. This would be a very unlikely event and if so only a very small number of cells would be affected. It would not impact on the pathogenic outcome of an exogenous viral infection. The packaging viral components are from HIV-1 virus. The full length HIV-1 virus is harmful to humans, however the packaging vector used does not contain full length HIV-1 molecule. Many components of HIV-1 that are critical for HIV-1 infection but not required for viral packaging have been removed. So the virus is attenuated and replication incompetent and will not make new viral progeny.

The most dangerous GMM is the lentiviral and retroviral preparations of viral particles. The most dangerous step is the collection, concentration and use of retrovirus/lentivirus.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

- All work will be carried out in level 2 containment facilities within Paul O’Gorman Building. Stably modified human cancer cell lines will ne maintained using level 2 containment facilities.
- All staff involved in the project will be made aware of the associated risks described here and will be required to have appropriate safety training prior to beginning work on the project.
- Workers will be required to wear lab coats as well as latex or nitrile gloves whilst working on all procedures. Any open wounds will be covered with a bandage also.
- All solid waste and any spills will be treated with Virkon and/or trigene advance, both of which are certified to kill 100% of virus, bacteria and cells.
- After treatment, all solid waste will be double-bagged, autoclaved, placed in yellow biohazard safety bags and further treated by UCL waste services.
- All viral supernatant will be stored in double containment and transferred within the laboratory within doubly sealed containers.

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

- 2-5% Trigene advance or Virkon (v/v) will be used to treat liquid waste (18 hrs) and also used to decontaminate any spills and for disinfection of any reusable bottles or other equipment and laboratory materials used. Liquid waste is subsequently poured down the sink after treatment with Virkon. Work surfaces will be wiped down with 5% Trigene advance and 70% ethanol after use. Virkon and Trigene advance are certified by the PHLS to provide 100% viridal and GMO kill under these conditions be denaturing and inactivating viral and cellular proteins (Degree of kills: 100%). Trigene advance and Virkon will be used with its lifespan to ensure required kill is achieved. Solid waste will be double-bagged in biological waste bags, sealed and autoclaved 132C for 15 min by trained staff then bagged in yellow biohazard bags and removed by UCL waste services. Autoclave runs are regularly validated by waste management staff.

**Is an emergency plan required according to regulation 20?**

- No

**If yes, tick to confirm that it is attached to this form**

- No
The project was approved by the GMSC, subject to minor changes, as an Activity Class 2 project.

Project Additional Information
Purposes of the contained use

Our understanding and application of gene transfer vectors has advanced tremendously in recent years however further optimisations are still required to ensure that this technology can be of maximum benefit to future therapy clinical protocols. In addition, these vectors are also showing great promise for generation of somatic transgenic mice. For development and improvement of gene transfer vectors, the efficacy of these complex entities is poorly modelled by in vitro systems. In contrast, in vivo mouse models provide an excellent platform.

Gene transfer technology has improved dramatically over the past decade and there have now been several clinical trials for gene therapy where therapeutic benefit has been reported. Therefore there is substantial impetus to translate basic gene therapy research into clinical application and preclinical models are an indispensable and valuable step towards achieving this goal.

A variety of disease-specific transgenes will be packaged into various different gene therapy delivery agents (vectors), which will then be tested for their efficacy in either normal outbred mice or the appropriate transgenic mouse model. The diseases studied include defects in the blood clotting cascade (e.g. haemophilia a and B, Factor VII deficiency), metabolic disorders (e.g. Gaucher's disease, Ornithine Transcarbamolyse deficiency) and lung disorders (e.g. Cystic Fibrosis). The gene therapy vectors will include adenoviral, adeno-associated viral (AAV) and lentiviral constructs.

In addition, we have discovered that gene transfer can be used to deliver luciferase under the control of signalling pathway-specific promoters. Therefore, the equivalent of luciferase-reporter mice can be generated easily and quickly without having to purchase and breed entire colonies. This technology is likely to significantly reduce the number of mice used to study disease pathways and we aim to explore the full potential of this technology (“photonic somatotransgenic biosensing”) across numerous disciplines, by using various disease model systems.

This project involves the construction of various viral backbones and so we will be using many combinations of promoter, transgene and viral backbone (e.g. retro/lentivirus, AAV, adenovirus). For example, we may wish to construct an adenoviral backbone containing the human factor X gene controlled by the liver-specific LP1 promoter. Alternatively, we may wish to construct a lentiviral backbone containing the human Protein C gene controlled by the ubiquitous CMV promoter. To keep this application as broad as possible it is not possible to provide exhaustive lists of all constructs. However, as all constructs being dealt with here are non-toxic DNA sequences they all carry the same risks and have the same health and safety considerations.

The production of the viral backbones will be carried out in Lab 103, Chenies Mews and is covered by another GM form (HC66/09; Development of gene delivery vectors for gene therapy). The preparation of all viruses will be stored in Lab 103, Chenies Mews and then taken to the animal unit (Malet Place, Central facility) when required. They will then be administered to mice by various routes of injection and/or instillation. It is the use of these viruses within the Malet Place animal facility that is covered by this application.

Recipient or parental organism

Recombinant adenoviruses:

All adenoviral vectors to be used are E1-deleted first generation adenoviral vectors based on the pJM17 system described by M and co-workers (1) All stocks are routinely tested for the presence of replication-competent adenovirus (RCA) and will be negative. All stocks will also be purified on cesium chloride gradients. E1-deleted adenoviruses cannot replicate unless the mutation is complemented in trans. The recombinant adenovirus will pose less of a threat once in the cell than most expression vectors as they will definitely not replicate or integrate into the host genome.

Recombinant adeno-associated viruses (AAV):

All AAV vectors used here are replication-defective through deletion of the rep and cap genes and insertion of the recombinant gene expression cassette within the AAV inverted terminal repeats (ITRs). The AAV vectors are generated by co-transfection of the AAV vector (carrying the expression cassette) and a helper plasmid carrying the helper functions necessary for AAV packaging in trans. The cells are then infected with a plasmid containing the adenoviral serotype 5 genomic sequence to provide helper
function for AAV replication. Upon a cytopathic effect in the cells, AAV particles are harvested and purified by HPLC.

Recombinant retroviruses (including lenti- and spuma-viruses):

Replication deficient retroviral particles are generated in cell-lines following co-transfection of three different plasmids. These supply the self-inactivating transfer vector containing the insert gene and viral Long Terminal Repeats (LTR) (but lacking any expression of HIV genes); packaging and structural proteins, gag/pol; and envelope (env) in the multi-deleted packaging plasmid pCMVdeltaR8.74 and in the pMD.G2 plasmid (in the case of VSV-G). The env gene is taken from another virus (eg vesicular stomatitis virus G (VSV-G), baculovirus gp-64, filovirus glycoprotein or mouse leukaemia amphotrophic/ecotrophic envelopes) which result in lentiviral particles able to transduce a variety of cell types. The transfer vector also contains a poly-purine tract (cPPT) and the woodchuck hepatitis virus post-transcriptional regulatory element (WPRE) for increased efficiency of production. The vector produced is self-inactivating due to a deletion in the promoter/enhancer region of the 3' LTR, that gets copied onto the 5' LTR during transduction of the cell and prevents prouction of viral RNA. The only expression from the vectors is of the transgene cDNA, controlled by an internal promoter.

Recombinant baculoviruses:

Baculoviruses are a family of insect viruses that have recently been developed for use in gene therapy applications. They are produced with a co-transfection protocol in insect cells. As a result of their origin, baculoviruses have the ability to enter mammalian cells but do not have the molecular mechanism for replication i.e. they transduce but do not infect mammalian cells. Additionally, they do not cause any disease or pathogenesis in healthy humans. Their native gp64 envelope gives them a limited mammalian cell tropism but this can be expanded through pseudotyping with the VSVG envelope. The baculovirus used is part of the BacMam Technology range of products commercially available from Invitrogen™

Non-viral DNA constructs:

Mouse, rat, non-human primate and human cells, including ES cells.

The recipient organisms (viral vectors) are not harmful to humans. They are all attenuated versions of the wild-type viruses and so cannot replicate (details can be found in 1.13). If the virus became inserted into cellular DNA, it could result in a potentially oncogenic mutation but the risk for this happening using the amounts and volumes here are very remote.

All viral vectors of all type are replication incompetent so therefore cannot self-replicate and transfer to another host. They are therefore harmless to the environment.

The mice that will eventually receive the recipient organisms would not have any survival advantage in the environment. They could conceivably escape from the holding facility (although this is extremely unlikely) but even then they would not be able to transmit the viral construct to another organism and could also not transmit the DNA in the germ line to an offspring.

Host/vector system

Prokaryotic plasmids, eukaryotic expression vectors, replication-deficient self-inactivating (SIN) lentiviral vectors which are based on third generation lentiviral vectors (ie pCCLSIN) or second generation vectors (ie pHRSIN) with engineered safety features which are resembling third generation vectors in terms of safety. In addition, we are using Moloney murine leukemia virus (MoMuLV) derived vectors in (MSCV, Sfada/W, SRS11) lacking international non-proprietary names (INN), again representing a similar level of safety, when using inserts which are deemed harmless.

Origin & function
All inserted sequences are from either human, mouse, macaque, firefly or bacteria.

All gene products are either enzymes (e.g. Factor VIII, GBA), reporter genes (e.g. GFP), transmembrane proteins (e.g. CFTR) or siRNA hairpin sequences.

None of the sequences fall in to any harmful category such as concogenes and proto-oncogenes, growth factors and GF receptors, any other sequences coding for significant biological activity that might be harmful were these to be expressed in people accidentally exposed to the vector.

In the unlikely event that any of these inserted sequences were to be expressed in humans after accidental transfer, the cDNA sequences or the RNAi hairpins could lead to expression of functional proteins or to the down-regulation of the gene to which the RNAi hairpin it targets via RNAi interference respectively.

Expression of the inserted cDNAs is deemed to hold little risk due to the non-harmful nature of the sequences used and the number of cells that would be affected by accidental exposure. Accidental targeting of RNAi in humans is not deemed to be harmful either due to a combination of the function of the targets, no expected harmful action of other molecules when presence of lower amounts of the target, and the expected relatively low amount of cells involved.

In addition, for both types of sequence, the effect of accidental expression would not be severe due to the fact that all viruses used are replication deficient (see 1.13) and so no new virus particles can be produced so no other cells can be infected. It is possible that physical insertion of the virus into the genome of the host cell could potentially disrupt a tumour suppressor or oncogene, however, the likelihood of this is extremely low.

The risk to the species in the environment is even lower since they would only be exposed to much small amounts of the sequences.

**Evaluation of foreseeable effects**

The mammalian donor organisms are not harmful however some of the donated sequences are from viruses (e.g. the envelope proteins VSV-G from Vesticular Stomatitis virus and gp64 from baculovirus) some of which are infectious to humans.

The sequences used from viral donor organisms are either promoters/enhancers or envelope proteins so none of these are involved in the harmful characteristics of the original donor organism. Even if these viral sequences were introduced into the body by ingestion, through a wound or after spillage onto skin the viral sequences would not enter human cells and would therefore not be expressed. The sequences used from mammalian or bacterial donor organisms are the transgenes or RNAi hairpin sequences, none of which are pathogenic.

The most hazardous GMM is lentivirus. The most hazardous step is injecting the lentiviral constructs into mice due to the use of sharps.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

N/A

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

Work surfaces and equipment are decontaminated on completion of work or at the end of the day by spraying with Trigene or 2% Virkon (as per manufacturer's instructions, has been shown to kill 99.9995% of organisms in under 10 minutes). Spills and splashes are mopped up with Wypall and then the area thoroughly sprayed with Trigene or 2% Virkon.

Solid waste, such as tips, eppendorfs or syringes containing lentiviral constructs, will be soaked in 2% Virkon overnight before disposal in a clinical waste sharps bin. Liquid waste will be treated in the same way before disposal down the drain (very small volumes of lentivector are treated in this way, <1 ml). Surgical equipment (e.g. scissors, forceps etc), whilst not in direct contact with any GMM, will also be sprayed with Trigene or 2% Virkon. Once disinfected, the instruments are then cleaned in hot water.
using a fine bristled brush.

The UCL GMSC approved the project as Activity Class 2 with regard to the procedures involving injection of lentivirus into animals with the remainder of the project being Activity Class 1.

CU2 Project Title Bacterial affects on connexion in chronic wounds

Class 2
CultureVolClass2 CultureVolumeClass3-4
Consent Granted

Tick if notifying a connected programme of work N

Historical Significant Changes

Page 742 of 1532
Chronic wounds are typified by slow, poor healing. All open wounds are colonized with bacteria and it is increasingly being recognized that bacteria can inhibit wound healing without eliciting clinical signs of infection. Biofilms, organized communities of bacteria encased within an extracellular polysaccharide matrix, are receiving increasing interest within wounds, as they are thought to be integral to the resistance bacteria within chronic wounds have to antibiotics and host immunity. Furthermore the biofilm acts as a reservoir, releasing planktonic bacteria into the wound. Research has shown that biofilms of Staphylococcus aureus and epidermidis, two bacteria frequently found in infected wounds, retard re-epithelialization within wounds. Thus due to the inability of the host immune response and current clinical methods to effectively destroy biofilms, local infections can become invasive. The escalating emergence of antibiotic resistant bacterial strains also presents a worrying problem for the healing of chronic wounds and patient morbidity.

Connexin dynamics are increasingly being recognized as being important in the wound healing process. Connexins are hexameric transmembrane proteins that form channels within the plasma membrane, called connexions. These connect with a connexion in an adjacent cell to allow gap junction intercellular communication (GJIC), whereby ions and small molecules can pass freely between the cytoplasms of interacting cells. It is becoming increasingly evident that GJIC is integral in many coordinated cellular activities, and wound healing is no exception. Gap junctions are involved in coordinating keratinocyte proliferation and migration during re-epithelialization, and they are implicated in the immune response in the regulation of leukocyte recruitment and activation. In normal healing wounds, gap junction dynamics are altered within the epidermis in response to wounding, and only return to normal following complete reconnexion which is normally switched off at the epidermal wound edge, showing persistent elevated levels of expression. It is thought that Cx43 expression is required to be turned off in order for keratinocytes to migrate, thus high levels are associated with a lack of re-epithelialization. Preliminary studies within this lab have also shown that bacterial wall components increase Cx43 expression between fibroblasts, which need to migrate into the wound bed in order to rebuild the extracellular matrix. Thus the relationship between bacteria and connexions within wound healing is intriguing, and further understanding may improve our ability to treat chronic wounds.

Through this project we aim to investigate the effects if different bacterial components and biofilms on connexion dynamics and communication, and what affect they have on the healing process. We intend to research the mechanisms behind bacteria induced retarded wound healing and whether this can be reversed or prevented by manipulating connexion dynamics. We will transform specific bacterial strains to contain plasmids encoding fluorescent proteins. These GMOs will make identification of bacterial location and species quick and easy. It will also make it possible to observe the spread of bacteria in situ, within cell culture or an inoculated wound, without necessitating swabbing and sub culturing the bacteria.

Recipient or parental organism

- Staphylococcus aureus ATCC 29213
- Pseudomonas aeroginosa ATCC 27853
- Bacteriodes fragilis ATCC 43935/6
- Escherichia coli ATCC 25922
- Klebsiella pneumonia ATCC 13883

Staphylococcus aureus, Pseudomonas aeruginosa, Klebsiella pneumonia, Escherichia coli and Bacteriodes fragilis is an obligate anaerobe and is unable to survive in the environment. Escherichia coli can survive in the environment for a few hours to days. Staphylococcus aureus is part of the normal skin flora and is able to survive on a new host. It is also able to survive in the environment for a few days to weeks. Klebsiella pneumonia and Pseudomonas aeruginosa are part of the normal human skin flora but both can also survive in the environment.
The vectors will be plasmids containing antibiotic resistance, an origin of replication and promoter for the host organism. They will actively express functional fluorescent protein in the bacteria. The antibiotic resistant proteins will also be expressed.

No plasmids conveying resistance to an antibiotic currently used to treat individuals infected with these bacteria will be used.

**Origin & function**

The genetic material encodes fluorescent proteins, modified from Aequorea victoria, which is a non-pathogenic organism. The translated protein from the inserted genes will fluoresce when excited by the correct wavelength of light. There will also be an antibiotic resistance gene that conveys antibiotic resistance to any of the bacteria taking up the plasmid. The sequences can cause harm if expressed in humans as the vectors don't contain a mammalian origin of replication. The sequence won't cause harm if transferred to other species in the environment as the species will just fluoresce.

**Evaluation of foreseeable effects**

All GMOs will be essentially the same as the Hazard Group 2 parental agent from which they are derived but will fluoresce and gain antibiotic resistance to one type of antibiotic. The most potentially hazardous GMOs will be the modified Pseudomonas aeruginosa and Klebsiella pneumoniae as they are capable of surviving in the environment. However, these organisms are found naturally in our environment and part of our skin flora, and all precautions will be taken to prevent their release.

The most potentially hazardous step in this procedure is probably transportation of the bacteria between location, but this should be minimal as they will be transported in double sealed containers to prevent any seepage, should, in the unlikely circumstances, a leak occur.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Contaminated liquids will be decontaminated in 1% Virkon and autoclaved. Solid waste will be autoclaved. Bacteria within animal wounds will be killed by fixing with 4% formaldehyde. The expected degree of kill is 100%

Is an emergency plan required according to regulation 20?  N

If yes, tick to confirm that it is attached to this form  N

Tick to confirm that you have attached a risk assessment to this form  Y

Tick if you are claiming exemption from disclosure for section of the risk assessment  N

The Biological Safety Adviser approved this on behalf of the GMSC, subject to clarification concerning the information that will be given to staff working on the project - although the agents are classified as Hazard Group 2 and do not cause severe disease in healthy humans, they can cause severe disease in those whose immune system is compromised in some way. It was confirmed that it will be made clear to those involved in any aspect of the project, or sharing facilities where the HG2 agents are handled, that the bacteria can cause disease and that immune-compromised individuals are at greater risk.
## Project Additional Information

**Purposes of the contained use**

The main project covered under this application aims to use lentiviral vectors for targeted delivery of lung therapies for both inflammation and cancer.

Our initial approach would be to use lentiviral vectors to transduce bone marrow derived cells (such as macrophages and mesenchymal stem cells) with targeted gene therapies for lung injury and cancer. Genes encoding anti-cancer or anti-inflammatory proteins (for example Keratinocyte growth factor (KGF) and TNF-related apoptosis inducing ligand (TRAIL)) would be used to transduce human bone marrow derived cells to produce modified cells that would be delivered as anti-cancer and anti-fibrotic therapies. Alongside the therapeutic gene controls for tracking and imaging cell behaviour and location (such as fluorescent reporter proteins and luciferase) would also be inserted into the lentiviral vector. Expression of these genes is controlled by the administration of antibiotics (doxycycline).
Recipient or parental organism

GMM/1: Lines 1.13, 1.19, 1.20
Lentivirus: 3rd and 4th generation vector and generation FIV vector with virulence genes deleted, on split plasmids

Cells: standard laboratory cell lines (e.g. 293T, HeLa, A549 and other immortalised cancer cell lines), mouse macrophages cell line IC-21, primary human lung cells and both human and murine bone marrow-derived cells.

The viral vectors themselves are not pathogenic to humans as all virulence genes have been deleted from the original parent viral sequences. However, these vectors have the potential to integrate into human DNA and there is a low risk that infection could damage the health of the laboratory worker directly handling the viruses.

The use of self-inactivating (SIN) vectors to make viral particles has been shown to significantly reduce the risk of insertional mutagenesis. In addition lentiviral vectors have been shown to insert preferentially into coding regions of DNA, rather than the more risky promoter or control regions. Overall, when taking into account these factors the risk to humans are very low and there are no known cases to date where a replication competent virus has been produced.

The vector particles are produced with the Vesicular Stomatitis Virus envelope protein, VSV-G, conferring a broad host specificity. While this may increase the susceptibility of different cells to the virus, it does not increase the risk of insertional mutagenesis.

A WPRE element is included in these vectors to aid translation of the inserted gene. This encodes a putatively oncogenic protein (protein X) which has been mutated in all vectors and is not functional.

These vectors are replication deficient and undergo a single infection of target cells so there is no risk of spread to other recipients. The vectors will only be used as gene delivery systems and transduced cells will not produce viral particles.

Host/vector system

GMM71: lines 1.12, 1.24

Vectors are standard microbiology plasmids and all cloning is performed using commercial disabled bacterial strains which are not harmful to health or the environment. The promoters used for gene expression in lentiviral vectors are not expressed in bacteria.

Origin & function

GMM/1: lines 1.11 - 1.16, 1.17 -1.18
Sequences come from the bacteria DH5α, DH10B and other common disabled E. coli K12 derivatives. All bacterial strains used are disabled.

The inserted sequences may be amplified originally from mouse or human genomic DNA or cDNA before cloning into bacteria.

Keratinocyte growth factor (KGF) is an epithelial mitogen found in many organs, which plays a role in epithelial repair in response to injury. For this project we aim to target KGF expression to the lung parenchyma where it can exert effects on type 2 alveolar epithelial cells. Its expected effects include increased proliferation and reduced apoptosis, increased fluid and electrolyte transport and increased surfactant production.

TRAIL is a transmembrane protein that is bound to circulating immune cells within the body. It has a role in immune surveillance against cancer and virally infected cells by inducing apoptosis or target cells. Whilst inducing apoptosis in cancer cells it has no known effect on healthy cells. We aim to deliver TRAIL to the site of cancer and induce
cancer cell apoptosis.

Luciferase is a naturally occurring oxidative enzyme that catalyses the conversion of luciferin to oxyluciferin and light. It is not known to cause transformation of the target cells and will be used to monitor cell activity and location.

A WPRE element is included in the vector plasmid to aid translation to the inserted gene or sequence. This encodes a putatively oncogenic protein (protein X) which has been mutated in all vectors and is not functional.

**Evaluation of foreseeable effects**

GMM/1: lines 1.17, 1.18, 1.32

The viral vectors themselves are not pathogenic to humans as all virulence genes have been deleted from the original parent viral sequences. However, these vector share the potential to integrate into human DNA and there is a low risk that infection could damage the health of the laboratory worker directly handling the viruses. The use of self-inactivating (SIN) vectors to make viral particles has been shown to significantly reduce the risk of insertional mutagenesis. In addition lentiviral vectors have been shown to insert preferentially into coding regions of DNA, rather than the more risky promoter or control regions. Overall, when taking into account these factors the risk to humans are very low and there are no known cases to date where a replication competent virus has been produced.

The vector particles are produced with the Vesicular Stomatitis Virus envelope protein, VSV-G, conferring a broad host specificity. While this may increase the susceptibility of different cells to the virus, it does not increase the risk of insertional mutagenesis.

A WPRE element is included in these vectors to aid translation of the inserted gene. This encodes a putatively oncogenic protein (protein X) which has been mutated in all vectors and is not functional.

The most hazardous step and the only risk that we identify at the moment is direct delivery of the viral particles into mice.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

Not applicable

For only GMMs - application for any derogation from full containment for the Class of activity.  (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

GMM/1: line 1.29 or GMM/2: lines 2.13 (as applicable)

For routine cleaning, all surfaces will be wiped down with 70% alcohol after use which is known to be effective against enveloped viruses. Liquid GMM waste will first be disinfected using 2% Virkon before being disposed of down the sink. This is a standard procedure and viability is below detectable levels. Solid GMM waste will be placed in autoclave bag and autoclaved at 121° for 15 minutes.

It is not possible to estimate a "degree of kill" lentivirus. However, autoclaving is sufficient for a 100% inactivation of enveloped viruses.

For administration of lentivirus to mice pipette tips and needles will be disposed of in dedicated sharps bins (without dissociation from the attached syringe). The sharps bins will be placed in autoclave bags and autoclaved as described above. Mice will be housed in individually ventilated cages.

In the event of spills, 70% ethanol will be used for surface disinfection. This agent is effective and is widely used for inactivating enveloped viruses. Absorbent tissues will be used to mop the affected area and will be disposed of by autoclaving as described above.
This was originally assessed as activity class 1 but after discussion at the UCL GMSC was revised as activity class 2.

### Project Additional Information

#### Purposes of the contained use

Throughout life, cells follow instructions encoded in our DNA that tell them what type of cell to be, for example brain cells or muscle cells. Cells also follow these instructions in adults when tissues are repaired or when new cells are needed to fight infection. The instructions tell cells when to divide and when to stop and disruptions in how the instructions are read can lead to cancer and other diseases.

We have discovered a new class of RNA molecule that is produced from parts of our DNA that contains these instructions. The molecules appear to be part of the mechanism used to read the instructions because they interact with proteins that control which instructions are read. Evidence suggests that the molecules are also turned off in cancers, which would prevent the instructions from being followed correctly.

We would like to find out more about the new class of molecule and how they work. This will provide information about how cells follow instructions about what type of cell to be and how this goes wrong in cancer. This information might also be useful to generate specific cell types for treating disease and injuries. Generation of GMOs is required for this work in order to test for the function of the RNAs and to produce the proteins that are involved in this process and to test for the activity of such proteins in the cell.

#### Recipient or parental organism

Standard E. coli strains XL1-blue, TOP10, HB101, DH5alpha, SURE, JM109, BL21. Also DH10Bac™, that contains a baculovirus shuttle vector (bacmid bMON14272) and a helper plasmid (pMON7124). All of these strains are disabled and unable to survive in the environment outside the lab. No hazard to human health or the environment.

Virus genome expression vectors: LNCX, CNCG, pSIREN-RetroQ, pMY-family (derived from murine leukaemia virus), pHRSINcSGW/cSRW/cSPW (derived form lentiviruses). See information below.

Insect baculovirus (cannot replicate in mammalian cells). Encoded by bacmid bMON14272.

Human cancer cell lines, eg. HeLa, 293T, HT29, Jurkat, CEM, SupT1, C8166, U937, THP-1, KG-1, Human ES cell lines, eg. H1 and H9. Mouse cancer cell lines eg. NIH3T3. Wild-type mouse ES cell lines, eg E14, JMB, and lines containing various mutations or reporter constructs. Primary human cells derived from peripheral blood including lymphocytes and macrophages. Insect cell lines, eg. SF9. These cells can only survive under carefully controlled laboratory conditions.

#### Host/vector system

Vectors:
All the vectors (plasmids) will be transformed into E. coli (see above) for cloning and propagation of mammalian and virus sequences. Group 1 vectors (cloning vectors) will only be present in E. coli. Mammalian and virus sequences will also be transferred to baculovirus expression vectors (2) or mammalian expression vectors (3) and transfected into cell lines for expression. We will also transfer the sequences to virus expression vectors (4) to allow long term expression in human cells and infection of otherwise difficult to transfect cell types. Virus expression vectors are packed inside VSV-G pseudotyped viruses, made from gag-pol and VSV-G expression vectors transfected into human cells (5) Details of this retroviral vector system is outlined below.

1. Cloning and bacterial expression vectors: pCR-TOPO, pGEM-T, pENTR, pCR-Blunt, pCR2.1. Theses have bacterial promoters driving expression of antibiotic resistance and contains a promoter driving lacZ, into which the transgene is inserted. pGEX bacterial expression vectors - these contain bacterial promoters driving expression of the inserted nucleic acid sequence.

2. Baculovirus (insect) expression vectors: pFastBac and similar baculovirus vectors containing bacterial promoters driving expression of antibiotic resistance and a baculovirus polyhedron promoter driving expression of the inserted sequence, which is only active in the presence of insect baculovirus in insect cells.
3. Mammalian expression vectors: pcDNA3, pCR3.1, pIRES family, pTRE2 family, pYY1Luc, pSICheck-2 mammalian expression vectors. These contain CMV or actin or similar promoters used to drive the expression of transgenes in human cells. In pIRES vectors, the promoter also drives expression of genes encoding antibiotic resistance. In pYY1Luc, the promoter drives expression of luciferase.

4. Virus genome expression vectors: LNCX, CNCG, p SIREN-RetroQ, pMY-family (derived from murine leukaemia virus), pHR'SINcSGW/cSRW/cSPW (derived from lentiviruses). These contain internal promoters used to drive the expression of inserted transgenes in mammalian cells.

Details on retroviral vectors: Retroviral vectors are made by transfecting 3 plasmids; an expression plasmid into which the sequence of interest is cloned, together with a gag-pol expression vector and an envelope expression vector (which are not packaged into progeny viruses). All vectors are disabled by separating the packaging sequence, the envelope coding sequence and the viral coding sequences from each other on independent plasmids. Furthermore, deletion of the U3 of the long-terminal repeat (LTR) ensures that the HIV-derived pHR'SINcSGW vectors are self-inactivating and cannot replicate.

Retroviral vectors are produced by transfection of all 3 plasmids. These viral particles do not contain genome that encodes virus proteins and so this system cannot produce replication competent virus. VSV-G enveloped retroviruses are only potentially harmful to human health if introduced into the body by injection, ingestion or through a wound. The potential harm arises from the possibility the virus would enter cells and integrate itself into cellular DNA. Althouhg the virus is not replication competent (does not carry gag, pol or env genes) and so it cannot make new progeny virus and establish a productive infection, it's insertion into cellular DNA could result in a potentially oncogenic mutation. The virus vectors are of no risk to the environment. Viral particles are labile and do not survive on environmental surfaces outside the lab.

Origin & function

1. Nucelic acid sequences encoding mammalian proteins that act to modify gene transcription and chromatin structure in recipient mammalian cells. Mutant forms of these proteins will be made to identify the parts of the protein important for activity. Sequences encoding epitope tags may be added to facilitate protein identification.

2. Mammalian and viral sequences coding for RNAs that don’t code for proteins (non-coding RNAs). These RNAs may have regulatory functions in mammalian cells.

3. Mammalian and viral regulatory element DNA sequences that don’t code for proteins such as promoters, enhancers, polycomb response elements. These act to recruit mammalian transcription factors and chromatin regulatory proteins and may produce non-coding RNAs.

4 Artificially-designed and natural short hairpin RNAs for knocking down the expression of endogenous transcription factors and chromatin regulators.

None of these sequences are predicted to cause significant harm but it is possible that some proteins encoded in the vectors could be oncogenic, or that they could modulate the expression of oncogenes or tumour suppressor genes. They will have no effect on bacteria or viral vectors and will not cause harm if transferred to species in the environment.

Evaluation of foreseeable effects

None of the vectors are harmful to the environment and do not supply a survival advantage to any microorganisms. The cloning and expression vectors are also not a hazard to human health.

The bacterial strains to be used are non-colonising and incapable of surviving in the environment or causing human infection. They pose no risk to users or the environment.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

10% Trigene (Distel) (v/v) will be used to treat liquid waste (16 hours) and also any spills and for disinfection of any reusable bottles or other equipment. Liquid waste is poured down the drain after treatment with TriGene (Distel) for at least 16 hours. This leads to denaturation and inactivation of viral and cellular proteins and results in 100% kill of all GMO. TriGene (Distel) is certified by the PHLS to kill viruses. All TriGene (Distel) will be used within its 3-year life.

Solid waste is double bagged and secured with a cable tie. The waste is autoclaved by trained staff and then these bags transferred to a yellow tiger-stripe biohazard waste bag for off-site removal by UCL waste services.

Work surfaces will be wiped down with 70% ethanol after use. These procedures result in 100% kill of all GMO.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The project was approved by the UCL GM Safety Committee following minor changes requested by the advisers

Project Ref 14/12.12

Date Ackn'd 11/01/2013

CU2 Project Title Epigenetic regulation in the brain and paediatric brain tumours. Role of the histone variant H3.3 and its chaperone DAXX

Date Project 02/03/2022

Class CultureVolClass2 CultureVolumeClass3-4

Class 2 ≤ 1 Litre

Non-GMM Consent Granted
Epigenetic regulation is emerging as a fundamental mechanism by which cells adapt their transcriptional response to developmental and environmental signals. Disruption of this process is believed to contribute to central nervous system pathogenesis, highlighted by the recent realization that most genes associated with mental retardation regulate chromatin structure. In addition to histone modifications and chromatin remodelling, chromatin structure variation is also generated by the deposition of variant histone proteins, with the help of dedicated chaperones. I recently showed that the chaperone DAXX mediates loading of the histone variant H3.3 at promoters and enhancers of selected genes and contributes to the modulation of their transcription. Moreover I showed that DAXX function is regulated by phosphorylation at a specific serine residue.

My experiments aimed at characterising the chromatin binding of DAXX and H3.3 deposition and their transcriptional regulation. I also aim to describe the role of DAXX and H3.3 in key developmental and functional processes of the brain. Overall this research addresses an exciting and yet unexplored area of epigenetics in the central nervous system and will highlight new factors involved in neuropathologies.

Brain tumours are currently the leading cause of cancer-related mortality and morbidity in children. Despite extensive research, complete understanding of the cause and the pathobiology of childhood brain tumours is still lacking. Interestingly the histone variant of H3.3 and its chaperones DAXX and ATRX have recently been found to be mutated in a variety of cancers and particularly in paediatric glioblastoma pathogenesis.

The involvement of DAXX phosphorylation in malignant models has never been studied before. Therefore I propose to study DAXX expression and phosphorylation in paediatric glioblastoma. I aim to define the role of DAXX phosphorylation in the deposition of H3.3 and highlight the pathways regulating DAXX phosphorylation and thus H3.3 loading. Overall this research has the potential to improve our knowledge in the regulation of a pathway newly identified as a driver of paediatric brain tumours and will potentially highlight new therapeutic targets.

Use of genetically, modified organisms will be essential for the completion of this research. Several constructs will be used to express mutant form of DAXX, histone H3.3 and other histone chaperones to understand their role in the central nervous system and in brain tumorigenesis. Specifically, this project will involve lentiviral production from either pGIPZ or TRIP-PGK-ATGm-MCS-WHV plasmids and subsequent use of this lentivirus to infect murine and human cells.

DH5 alpha bacteria, lentivirus, mouse cortical neurons, mouse neural progenitors, Human 293T cells, human glioblastoma cell lines. DH5 alpha bacterial strain cannot survive or attach to human intestinal epithelium.

Lentiviral particles. The envelope protein is VSV-G from the Vesticular Stomatitis Virus so, if introduced into the body by injection, ingestion or through a wound, the virus
could potentially enter cells and integrate into cellular DNA. Although the virus is replication incompetent (does not carry gag, pol or VSV-G genes) so it cannot make new progeny virus and establish a productive infection, its physical insertion into cellular DNA could result in a potentially oncogenic mutation. This would be a very unlikely event and if so only a very small number of cells would be infected. Moreover six of the nine genes encoding HIV-1 virulence factors have been deleted from the derived vector system. The resulting multiply-attenuated design of HIV vectors ensures that the parental virus cannot be reconstituted. The recipient organisms for expression of exogenous proteins will be murine or human cells. These cells cannot survive in the environment nor transfer the inserted sequence.

Host/vector system

TRIP-PGK-ATGm-MCS-WHV (from Trono Lab), PGIPZ (from OpenBiosystem) or any second/third generation lentiviral expression vector. pMD.G (From Trono Lab) or any second/third generation packaging system. Viral envelope (VSV-G) expression vector. pCMVdeltaR8.91 (From Trono Lab) or any second/third generation packaging system. Gag and Pol expression vector. pcDNA3, pCMS-GFP, TOPO or any other commercially available backbone vectors commonly used for mammalian protein expression.

Origin & function

Mouse, human jellyfish, drosophila, Bacteriophage P1, HIV-1
DAXX and ATRX are both histone chaperones specific for H3.3.
H3.3 is a histone H3 variant that is expressed throughout the cell cycle.
Calcineurin is a calcium dependent phosphatase implied in cell signalling
PML is a signalling protein
HIPK1/2 are protein kinases
GFP is commonly used in cell biology to label cells.
Cre recombinase is tyrosine recombinase enzyme derived from the P1 Bacteriophage. It catalyses the site specific recombination event between two DNA recognition sites (loxP sites).
shRNA (small hairpin RNA) are small RNA molecules which form a hairpin structure. The hairpin structure will induce a normal cellular in vivo downstream sequence of processing events in response to foreign cellular single-stranded RNA intruder molecules that will result in the post-transcriptional down regulation of the gene to which the hairpin sequence is targeted.

DAXX, ATRX, H3.3, HIPK1/2 and PML have been showed to be differently modulated in human tumours therefore there are potentially harmful effects in the event of accidental transfer to human. Potential harm is oncogenic events. Therefore particular precaution will be used when producing lentiviral particles for expression or downregulation of these factors. The viral vector system used contains numerous safeguards. 1) The sequence encoding the various components are distributed over three independent plasmids to maximize the number of recombination events that would be required to recreate a replication competent virus. Thus far, no replication competent recombinants have been detected among a total of 1.4 x10^10 transducing units. 2) Six of the nine genes encoding HIV-1 virulence factors have been deleted from the derived vector system. The resulting multiply-attenuated design of HIV vectors ensures that the parental virus cannot be reconstituted.

VSV-G pseudotyped lentivirus can only infect mammalian cells. Potentially the lentiviruses could infect other mammalian species and lead to the expression or the down-regulation of the factors. This however, is extremely unlikely as the lentivirus has a very poor survival rate outside the growth conditions. Moreover, the virus is replication incompetent and therefore self-inactivating as none of the structural genes are actually present in the packaged viral genome so no new virus can be produced and no other cells can be infected with new particles.

Evaluation of foreseeable effects

DAXX, ATRX, H3.3, HIPK1/2 and PML have been showed to be differently modulated in human tumours therefore there are potentially harmful effects in the event of accidental transfer to human. However none of these factors have been showed to induced tumour formation when overexpressed or downregulated alone.

The most dangerous GMM, is the lentiviral preparations. The most dangerous steps are the collection, concentration and use of the lentivirus.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

No animal or plant will be used
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

| 1% Virkon (v/v) will be used to treat liquid waste (18 hours) and also used to decontaminate any spills and for disinfection of any reusable bottles or other equipment and laboratory materials used. Liquid waste is subsequently poured down the sink after treatment with Virkon. Work surfaces will be wiped down with 5% Trigene advance and 7-% ethanol after use. Virkon and Trigene advance are certified to kill 100% virus and bacteria under these conditions by denaturating and inactivating viral and cellular proteins. Trigene and Virkon will be used with its lifespan to ensure required kill is achieved. Solid waste will be doublebagged in biological waste bags, sealed and autoclaved 132°C for 15 mins by trained staff then bagged in yellow biohazard bags, and stored in a secured, sealed bin for removal by UCL waste services. Autoclave runs are regularly validated by waste management staff. |

Project Ref 14/12.2

Date Ackn'd 20/02/2012

CU2 Project Title Gene therapy for the treatment of Adenosine Deaminase Severe Combined

Class 2

CultureVolClass2 < 1 Litre

CultureVolumeClass3-4
Primary Objectives
To evaluate the safety, feasibility and tolerability of the introduction of autologous cells, transduced with lentiviral vectors encoding relevant transgene, to patients with either HIV-infection, ADA SCID, X-CGD and Netherton Syndrome.

Secondary objectives
A. Gene therapy for ADA SCVID and X-CGD
1. Transduction of CD34+ haematopoietic cells from patients be ex vivo lentivirus-mediated gene transfer
2. Infusion of transduced autologous CD34+ cells into myelosuppressed recipients
3. Evaluation of safety
4. Evaluation of engraftment kinetics and stability
5. Evaluation of biochemical and functional reconstitution in progeny of engrafted cells
6. Longitudinal evaluation of clinical effect in terms of augmented immunity against infections.

B. Gene Therapy for Netherton Syndrome
1. Generation of SPINK5 gene modified keratinocyte stem cells (KSC) from patients with NS
2. Generation of skin sheets for autografting using gene corrected KSC
3. Grafting of gene corrected skin sheets onto patients with Netherton Syndrome
4. Longitudinal evaluation of safety and efficacy clinical effect

C. Gene Therapy for HIV infection
1. Extent of engraftment and survival of gene-containing cells over time, assessed by PCR and flow cytometry
2. Change in plasma HIV viral load;
3. Change in CD4+ T lymphocyte counts;
4. Potential development of CXCR4 or mixed R5/X4 trophic HIV virus

Recipient or parental organism
● The lentiviral (LV) vectors are 3rd generation replication-defective hybrid viral particle made by core proteins derived from Human Immunodeficiency virus type 1 (HIV-1)
and the envelope of the unrelated Vesicular Stomatitis Virus (VSV)

- The transfer vector encodes the human gp91phox/ADA/SPINK 5/C46 gene cDNA under the control of non viral tissue specific promoters.

Replication deficient lentiviral vector is used to transduce autologous haematopoietic or skin cells ex vivo. The GMP grade lentiviral vector will not be directly administered to patients.

The lentiviral vector is not expected to survive in the environment and cause harm. The risk of recombination events between vector and wildtype HIV have not been detected to date. The risk remains theoretical (Cornetta et al. 2011, Molecular Therapy, Vol 19, no. 3, 557-566)

**Host/vector system**

The vector particles are pseudotyped with VSV-g and are produced by transient transfection of four separate plasmids into 293T cells using the calcium phosphate precipitation technique:
- A transfer plasmid encoding the transgenes.
- Three separate accessory plasmids encoding respectively HIV gag pol, VSV-G and HIV Rev which will respectively produce the structural proteins, nucleic-acid polymerases/integrase, reverse transcriptase, surface glycoprotein, and regulatory elements required for packaging a recombinant lentiviral particle.

The system is based on 4 non-overlapping expression constructs in order to maximize the segregation of cis and trans acting functions. The system is engineered in such a way that minimal homology regions are present between packaging and transfer vectors, thus minimizing the likelihood of homologous recombinational events and the generation of replication competent lentiviruses (RCLs).

In addition, the packaging construct is deleted of all HIV accessory proteins (vpu, vpr, nef, vif) and Tat. The conditional packaging system segregates gag/pol and rev genes in two separate plasmids. The Rev responsive element (RRE) maintained in the gag/pol plasmid makes the gag/pol gene expression rev dependent. As the transcripts of gag and pol genes contain cis acting repressor sequences, they are expressed only in the presence of Rev, expressed in trans on a separate plasmid, which promotes their nuclear export and expression by binding to RRE.

The transfer vector encodes the relevant therapeutic transgenes and sequences necessary for expression, incapsidation, reverse transcription and integration of the viral genome. RRE sequences permit the nuclear export and expression of the viral RNA. In order to minimize the risk of RCL generation, the 3’ LTR of the transfer vector has been deleted in the U3 region. The introduction of this 400 bp deletion abolishes the production of full-length vector RNA in transduced cells by exploiting the reverse transcriptase mechanism which generates both U3 regions from the 3’ of the viral genome, thus transferring the deletion to the 5’ LTR of the proviral DNA. The lentiviral particle is therefore conceived with a self-inactivating mechanism that enables the production of infective particle only in the first run of infection.

**Origin & function**

1. **X-CGD gene therapy**
   The gp91phox (phox standing for phagocyte oxidase) protein is large subunit of the NADH oxidase system expressed in phagocytic cells e.g. in neutrophils, monocytes, macrophages and eosinophils. NADPH oxidase is a multicomponent system that includes a membrane bound by flavocytochrome b558 comprised of the large subunit, gp91phox, and a small subunit, p22phox. Phagocytosis of microorganisms leads to translocation of four cytosolic factors (p47, p67, p40phox and Rac2) to the cell membrane to form the activated NADPH oxidase complex, which then binds NADPH and generates the respiratory burst. Defects in the genes that encode any of the NADPH oxidase components may abolish the electron transport from cytoplasmic NADPH to FAD, haeme and onto intraphagosomal molecular oxygen.

2. **ADA SCID gene therapy**
   The ADA transgene encodes the enzyme Adenosine deaminase, expressed in all tissues. During DNA breakdown, ADA catalyses the deamination of deoxyadenosine (dAdo) and adenosine to deoxyinosine and inosine respectively. The lack of the ADA enzyme in ADA patients, results in the accumulation of dAdo in both intracellular and extracellular compartments. Intracellularly, dAdo is then converted by deoxycytidine kinase (dCydK) to deoxyadenosinetriphosphate (dATP) which accumulates within the cell. The buildup of these two metabolites has profound effects on lymphocyte development and function and is the most likely cause of the immunological defects. dATP inhibits enzyme ribonucleotide reductase which is necessary for DNA replication and repair and also induces apoptosis in immature thymocytes. dAdo inactivates the enzyme S-adenosylhomocysteinehydrolase (SAHH): SAHH accumulation inhibits transmethylation reactions and the lack of SAHH activity as a consequence of ADA.
deficiency may also contribute to the immunodeficiency. It has also been speculated that the effects of adenosine acting through G protein receptors on the surface of thymocytes may play a role in the pathogenesis of the disease. Although ADA is expressed ubiquitously, the most profound effects are manifest in the immune system. Introduction of the ADA gene is expected to restore lymphocyte development and function in ADA patients.

3. Gene Therapy for Netherton syndrome

The SPINK5 gene encoded a protein named as LEKTI. It is a serine protease inhibitor expressed in the uppermost compartments of the epidermis, and plays a critical role in the regulation of two serine proteases, kallikrein 5 and 7 which hydrolyze the extracellular corneodesmosomes in the skin. In Netherton Syndrome patients, the control of kallikreins by LEKTI is abolished due to mutations in SPINK5 and as a consequence, a hyper-activated kallikreins can cause premature degradation of corneodesmosomes and result in a defective skin barrier.

4. Gene Therapy for HIV

The C46 component codes for production of a membrane-anchored C-peptide derived from the HIV-1 envelope glycoprotein gp41. The peptide is expressed on the surface of the transduced cell and acts as a fusion inhibitor thereby blocking the entry of HIV into the cell. The sh5gene encodes a short hairpin RNA against the HIV co-receptor CCR5 (sh5RNAi). CCR5 is the major co-receptor for HIV. Studies on a naturally occurring □32 mutant of CCR5 (present in approximately 1% of Caucasians) have shown that these individuals are naturally resistant to HIV infection.

Risk of transfer to environmental species for all of the above is negligible, and would not be expected to cause harm.

**Evaluation of foreseeable effects**

The potential for harm is negligible. Work will be at level 2 containment. All personnel involved in the ex vivo transduction of HSC at ICH/GOSH are trained in GMP cell processing procedures and their competency is assessed every 6 months. Sharps will not be used for the direct manipulation of vector. In the case of needlestick injury, the Cellular Therapies needle stick policy (GTLHS007) and guidelines on UVL website (http://www.ich.ucl.ac.uk/clinical_information/clinical_guidelines/cpg_guideline_00121) are followed.

**Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)**

N/A

**For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)**

Autoclave facilities are in an adjoining building. However, all waste will be double bagged and placed in a sealed plastic container. The container is disinfected before being transported using a dedicated trolley by trained staff to the autoclave via service lifts and corridors where possible. This procedure is documented in SOP for the Management of spillage and waste disposal (CT.PR.SOP.012). Sharps will be disposed of in appropriate puncture-proof containers using the above procedure.

**Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)**

For routine cleaning, all surfaces are wiped down with 70% ethanol after use. Liquid GMM waste is first disinfected using Sanichlor (effervescent chlorine tablets) to give a final concentration of 2500ppm chlorine overnight before being disposed of down the sink. This is a standard procedure and viability is below detectable levels. Any solid GMM waste is placed in autoclave bags, labelled with the department’s name and autoclaved at the ICH as above. All sharps are placed in puncture-proof containers and disposed of through the central collection service for contaminated waste. All spillages are cleaned using 1% sodium hypochlorite or 70% ethanol.

- **Date of Significant Change**

**Project Additional Information**

**Purposes of the contained use**

The overall aim of the project is to identify and characterise the molecules and processes controlling the self-renewal, lineage commitment and differentiation of haematopoietic stem and progenitor cells. We wish to assess the molecular and cellular consequences of manipulating the expression of normal and selectively modified regulatory factors including microRNAs in a range of murine and human in vitro systems and murine in vivo systems. Some of these factors are already well-characterized and known to play an important role in haematopoiesis while others are candidate regulators identified primarily by their differential expression in different haematopoietic...
stages. Our aim is to deliver regulatory genes such as transcription factors, growth factors, cytokine receptors and signalling molecules to human and murine blood cells and monitor the effects on the survival, growth and differentiation of the recipient cells. The genes may be either wild-type or in the form of the point mutants or chimeric factors generated by chromosomal translocations associated with human leukaemias, or selectively altered variants of any/all of these genes designed to modify and dissect their function.

Recipient or parental organism

Mouse and human ES cells, Human iPS cells, primary human and mouse haematopoietic cells, primary human leukaemia cells, human and mouse cell lines. Primary cells will be a range of haematopoietic cell types including FAC-sorted normal and leukaemic stem/progenitor cells and more committed populations from screened human cord blood, bone marrow, peripheral blood and murine bone marrow, peripheral blood, foetal liver and the aorta-gonad-mesonephros (AGM) region of early embryos.

Human lines: EML, FDCP mix, LHX2, M210B4, Si/Si, BaF3, NIH 3T3, 32D 416B, s17, MEL, BHK-MKL, WEHI3

Bacterial host strains (E.coli): NM522, HB101, XL-1 BLUE, XL-2 BLUE, TOP10 F", JM109, SURE, ABLE, DH5alpha, DH10alpha, DE3.

Both bacteria and cell lines transduced with these GMM are very unlikely to propagate outside the laboratory environment. K12 and B derivatives of Escherichia coli will be used as bacterial cloning hosts. These are disabled strains that cannot colonise the human gut and have a history of safe use. Standard plasmids produced in disabled E. coli present no added risk to human health.

The infected human and murine recipient cells would be unlikely to be pathogenic due to rapid complement-mediated lysis of these cells when recognised by the immune system as of non-self origin. These cells contain only the expression vector, are no longer capable of producing packageable viral genome, so these mice would not carry infective viral particles. Expression of the inserted gene(s) is likely to affect cell growth and differentiation within the target cell but would no cause the animal to be hazardous to the environment.

Host/vector system

All vectors are either third-generation (self-inactivating), replication-defective lentiviral vectors based on human immunodeficiency virus type 1 (HIV-1) virus, or based upon the Moloney Murine Leukaemia Virus (retroviral system)

The lentiviral vectors carry a deletion in the 3'LTR that does not affect generation of the viral geome in producer cells but results in "self-inactivation" of the lentivirus after transduction of the target cell. Once integrated into the transduced target cell, the lentiviral genome is no longer capable of producing packageable viral genome. A constitutive Rous sarcoma virus (RSV) promoter has been placed upstream of the 5'LTR in the expression vector to offset the requirement for Tat in the efficient production of viral RNA. Only 3 HIV-1 genes are used in the system (gag, pol and rev). Expression of the gag and pol genes has been rendered Rev-dependent by virtue of the HIV-1 rev-response-element (RRE) in the gag/pol mRNA transcript. The Rev protein itself is expressed from a separate plasmid. Addition of the RRE prevents gag and pol expression in the absence of Rev. The VSV-G gene from Vesicular Stomatitis Virus is used in place of the HIV-1 envelope protein. Genes encoding components required for packaging are on separate plasmids, which do not contain regions of homology to each other to prevent undesirable recombination events which could contribute to the generation of replication-competent virus. None of these 'packaging plasmids' that allow expression in trans of proteins required to produce viral progeny (i.e. gag, pol, rev, env) in the 293T producer cell line contain LTRs or the psi packaging sequence. Thus none of the HIV-1 structural genes are actually present in the packaged viral genome and, thus, are never expressed in the transduced target cell. The lentiviral vectors are replication incompetent and only carry the gene, microRNA or shRNA of interest.

The viral vectors :

MSCV and derivatives (Hawley et al 1996)

pLentilox 3.7 and derivatives (Rubinson et al Nat Gen 2003)

pGIPZ, pTRIPZ (Open Biosystems)

pLenti6/V5 (Invitrogen)

Non-viral vectors include standard mammalian expression vectors for transient transfection studies. These will be used for transgene overexpression and utilise RPOLII promoters.
**Origin & function**

**Human and Mouse. HIV1. VSV as above.**

**Origins of genetic material:** Vector backbones and fluorescent reporters - commercial sources, inserted genes and microRNA - mouse and human genomic DNA, short hairpins - artificially synthesized.

**Classes of Inserted genetic material:**

Wild-type transcription factors: including but not necessarily restricted to GATA family members, hex, Pax 5. Theses factors exert their function within the nucleus and are expected to alter the balance between self-renewal and lineage differentiation in stem and progenitor cells and in some cases alter the lineage output of committed cells e.g. to elicit erythroid cells from a granulocyte-monocyte progenitor. Forced expression of these molecules is likely to influence the self-renewal and differentiation of haematopoietic cells, based on what is known about their normal function. The factors are not known to be transforming or oncogenic, although point mutations in GATA-1 have recently been reported in Down’s syndrome related acute megakaryoblastic leukaemia and Pax5 expression is deregulated in human medullablastomas.

Other regulatory molecules such as components of the notch pathway, cytokine receptors and growth factors. Although acting primarily outside the nucleus, modulation of the expression of these factors is expected to result in a transcriptional response within the nucleus and to alter the balance between self-renewal and lineage differentiation in stem and progenitor cells and perhaps also to alter the lineage output of apparently committed cells. An example of the type of genes we wish to study is given below.

**Notch pathway:** Human chromosome 9 contains a gene highly homologous to the Drosophila gene ‘Notch’. Transcripts of the human, gene, for which the name TAN1 was proposed for translocation-associated Notch homolog), and its murine counterpart were demonstrated in many normal human fetal and adult mouse tissues but were most abundant in lymphoid tissues. Cytogenetic studies have shown that chromosome 7 band q34-q35, which contains the gene for the beta T-cell receptor, is a common site for translocation in T-cell neoplasms. In t(7;9)(q34;q34.3) translocations from 3 cases of acute T-cell lymphoblastic leukemia, breakpoints occur within 100bp of an intron n TAN1, resulting in truncation of TAN1 play a role in the pathogenesis of some T-cell neoplasms. At least 1 Notch homolog is expressed in human bone marrow CD34+ cells, a population enriched for hematopoietic precursors. Members of the Notch family, including TAN1, may be involved in mediating cell-fate decisions during hematopoiesis.

Other candidate regulatory molecules form differential expression analysis including microRNAs, expected to function in a similar manner to the genes described above. The aim of the study will be to study their function in haematopoietic progenitors and so this study will be to study their function in haematopoietic progenitors and so this may, by definition, be currently unknown. However, the genes of most interest to this study will be those found to have some impact on controlling haematopoietic cell self-renewal, growth and differentiation and are likely to include transcription factors, cytokines and growth factors and their receptors, signalling molecules, cyclins, apoptotic and anti-apoptotic factors, enzymes such as kinases, phosphatases, proteases, acetylases.

**Known products of chromosomal translocations, their normal counterparts, or other naturally occurring mutated versions with deletions, insertions and/or point mutations.** These genes will include, but not necessarily be limited to: ETV6-AML1 (ets variant gene 6-Acute Myelocytic leukaemia 1), PML-RARA (Promyelocytic Leukaemia-Retinoic Acid Receptor alpha), PLZF-RARA (Promyelocytic Leukaemia Zinc Finger-Retinoic Acid Receptor alpha), bcr-abl. These are suspected oncogenes by virtue of their expression as a result of specific translocations associated with different forms of human leukaemia. In particular, experimental expression of bcr-abl appears able to induce leukaemia in mouse models. The bcr-abl p190 oncogene is associated with B-cell acute lymphoblastic leukaemia (B-ALL) in humans. Chimeric mice generated with mutant ES cells carrying a bcr-abl fusion created by homologous recombination systematically develop B-ALL, with the phenotype of the tumours being very close to the phenotype of the leukaemias seen in patients with p190 leukaemias. Similarly, use of tetracycline-responsive expression system has allowed controlled expression of bcr-abl p210 in transgenic mice. Lethal acute B cell leukaemia developed in all mice within 3 months, and complete remission was obtained by suppression of p210 expression. The induction of B-ALL rather than chronic myelogenous leukaemia (CML) - with which p210 is most commonly associated in humans - is probably due to the promoter used, which directed expression to B cells rather than the stem cell compartment.

Selective modifications of any/all of the above: activity of many factors can be rendered inducible by fusion to the ligand-binding domain of estradiol receptor. We have
successfully used this approach with transcription factors GATA-1 and GATA-2 and will continue to use this system where appropriate. In other cases, the transcriptional activation/repression properties of a factor may be modified by fusion to more potent positive and negative trans-activators such as VP16 or engrailed domains. Other modifications will be designed to determine the sequence requirements for oncogenic and other functional features. Mutation of potential sites of post-translational modification such as phosphorylation and acetylation and mutation/deletion of sites of protein-protein interaction will be performed. Altering these sites is likely to alter the regulation of the factor's activity within the cell. Deletion of certain domains to allow further dissection of function will also be performed. Most of the modified versions of the proteins under study would be expected to display essentially the same biological activity in an experimentally inducible manner or to display a subset of the activities of their wild-type counterparts. However, the possibility of inadvertently generating novel biological activities cannot be excluded.

All the technologies described are now standard in biomedical reasearch. The GMM and lent/retroviral vectors cannot survive outside the laboratory culture. In principle however there is a very low risk that a lentivirus may infect an experimenter and thereby pose a risk to human health. The exact effects of such putative viral transfers are unpredictable and would be dependent on the cells infected and the site(s) in the genome where any virus integrated. Nevertheless, these integrations may be oncogenic.

The modified viruses should not pose a risk to the environment. The viruses are unstable, inactivated by detergent, UV light and ethanol, and would not survive outside the laboratroy environment. There is no intention to modify the tissue tropism or host specificity of the viral vectors and it is unlikely that any of the gene inserts proposed would affect these. Similarly no alterations in the interaction of the genetically manipulated retroviral vectors with host defences are anticipated. All of the proposed recombinant viruses are replication defective.

**Evaluation of foreseeable effects**

VSV pseudotyped lentiviruses are highly unstable outside the cell and cannot be passively transferred. VSV is a zoonotic arbovirus, which causes lameness in farm animals. Infection in humans is rare and usually by insect bite. It is often asymptomatic and immunity against VSV has not been extensively studied in humans. In most series the majority of people are seronegative, suggesting that the innate immune system may clear infections, and there is no vaccine. Aerosols are an unlikely source of infection (Schlereth et al J Gen Virol 2003). Gene transfer could possibly occur through accidental exposure to viral particles, via a cut or similar break in the skin. Therefore sharps will not be used in preparations containing viral particles or transfected packaging cells. If an accidental exposure were to occur, such viral particles would conceivably have hazardous effects if they infected a stem cell; reducing the risk to human health. It is standard practice in our group to 'double glove' for lentiviral work. As has been stated already, all vectors are replication defective and so productive or replicative infections are not possible. It should be reiterated that these lentiviruses are extremely unstable even in tissue culture conditions.

The modified viruses should not pose a risk to the environment. The viruses are unstable, inactivated by detergent, UV light and ethanol, and would not survive outside the laboratroy environment. There is no intention to modify the tissue tropism or host specificity of the viral vectors and it is unlikely that any of the gene inserts proposed would affect these. Similarly no alterations in the interaction of the genetically manipulated retroviral vectors with host defences are anticipated. All of the proposed recombinant viruses are replication-defective.

The most dangerous GMM: pantropically packaged lentivirus/retrovirus. The most dangerous step is the harvesting and concentration of packaged virions.
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All work will be carried out in CL2 containment facilities in the POGB. All staff will be trained prior to starting work and will be aware of the safety hazards. Lab coats and gloves are mandatory. Care will be taken to minimize the production of aerosol.

Solid material will be autoclaved, pipette tips and other small items of plastic-ware will be treated for 18 hrs with 2-5% Virkon (v/v). Treated liquids can either be disposed of in the sink or autoclaved in an autoclavable pastic container. All waste is placed in an autoclave bag and then double bagged. Waste is kept within the lab until it is taken to the autoclave in an enclosed trolley. The waste is then loaded directly into the autoclave for immediate treatment (hold time of 132°C for 15 min) by trained staff then bagged in Biohazard bags for removal by UCL waste services.

The efficacy of this approach has been shown to be 100% elsewhere:

All autoclaves are maintained by the Institute. They have pre-set parameters (132°C for 15min) which if un-met, lead to a 'cycle-fail' warning.

02/03/2022
Induced pluripotent stem (iPS) cells are a powerful tool for research and provide a new source of cells and tissue for therapies where immune rejection is a common problem. We have previously shown that human embryonic stem cells and iPS cells can be used to generate functional retinal pigment epithelium (RPE). In this project we aim to take cells from informed patients at Moorfields Eye Hospital and generate iPS cells using the vectors described below. We will then differentiate these cells into RPE and retinal cells in order to study the impact of retinal degenerative diseases. We will also use a direct reprogramming approach with the aim of transforming somatic cells directly into RPE cells by transforming somatic cells with candidate genes thought to be involved in RPE cell development. We will also use animal models of retinal degenerative diseases to produce iPS-derived cells for disease study.

**Recipient or parental organism**

Virus: The lentiviral vector systems pSIN, FUW, LL and Fu-tet-o, the retroviral vector systems pMIG, pCL, pCAG system and the episomal vector system pCEP (pEP).

Cells: 293 cell lines, competent bacterial cells, patient and animal derived cells (fibroblast, epithelial and blood cells).

**Host/vector system**

All viral vector constructs will be transformed into competent E. coli cells. There is no potential for harm to health and/or harm to the environment.

Commerically available packaging vectors, such as pMD G, pMD2.G, pVSV-G, psPAX2, pCMV-dR8.2 dvpr, will be used.

All viral vector constructs for somatic programming using iPS technology are available complete from a plasmid repository (Addgene) and already contain the insertion genes (embryonic transcription factors) of interest.
To construct viral vectors for direct RPE reprogramming, intermediate constructs will be made using general lab strain of E. coli. There is no potential for harm to health and/or harm to the environment.

Viral transfer vectors containing inserted genes for direct cell reprogramming (somatic cell to RPE) will be constructed using safe vectors pSIN, FUW, LL and Fu-tet-o and pMIG, pC L, pCAG.

Cells: 293 cell lines, competent bacterial cells, patient and animal derived cells (fibroblasts, epithelial and blood cells).

We will also use commercially available mRNA for direct transfection into the mammalian cell lines.

Origin & function

Functions:
Klf4, Oct4, c-myc, Sox2, Nanog and Lin28 are embryonic transcription factors associated with pluripotency.
Transfection of somatic cells with a combination of these genes (Klf4, Oct4, c-myc and Sox2 or Lin28, Nanog, Oct4 and Sox2) result in the induction of pluripotency.

Direct reprogramming Origin: Genes involved in RPE development, including Otx2, Mitf, Pax6, Rax, Lhx2, Six3, BMPs, Activin, SHH, Wnts, MMPs.

Functions:
Otx2, Mitf, Pax6, Rax, Lhx2 Six3/9 and Hes1 are transcription factors involved in gene regulation during development BMPs and Activin are part of the TGF-b family of proteins, which are important signalling molecules during RPE cell development. SHH and Wnt regulate the patterning of the central nervous system during development. MMPs are thought to play a role in cell proliferation and differentiation

Evaluation of foreseeable effects

The use of replication defective and retroviral vectors to modify mammalian cells is well established and safe. The induction of pluripotency in mammalian cells involves the introduction of potentially oncogenic sequences such as c-Myc and Klf4. The introduction of oncogenic genes is a potential hazard to human health, however working with appropriate containment procedures renders the risk low.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

The viruses, and cells cannot survive in natural conditions. They will be destroyed and disposed of by standard methods listed below.

E.coli and mammalian cells will be inactivated by treatment with 1% virkon for at least 30 minutes. Liquid waste will be dispensed into a container containing 1% virkon. All plastic ware exposed to virus will be treated with 1% virkon solution for 30 minutes. All waste material will be subjected to UV exposure in the tissue culture hood prior to removal for disposal. All waste will be double-bagged in autoclave sterilisation bags and autoclaved prior to final disposal (by incineration). We expect that 100% of viral particles/cells will be de-activated using the disposal procedure.

Historical Significant Changes

Significant Change ID
The aim of this project is to examine the effects on axonal regeneration of altering candidate gene expression in the rodent nervous system using third generation non-replicating, non-integrating viral vectors. Briefly, viral vectors will be generated in a tissue culture system and delivered into the brain using intracranial injection. The brain and spinal cord tissues will be subsequently collected and the tissues will be examined for the neurotoxic, neurotrophic and regeneration-promoting effects.

Recipient or parental organism

Replication-deficient self-inactivating (SIN) lentiviral vectors with a mutated integrase element so that the vector does not integrate into the host genome (non-integrating lentiviral vectors). The recipient organisms (viral vectors) are not harmful to humans. They are attenuated versions of the wild-type viruses and so cannot replicate or integrate. If the virus became inserted into cellular DNA, it could result in a potential oncogenic mutation, but the risk for this to happen using the amounts and volumes here are very remote. The viral vectors are replication incompetent so therefore cannot self-replicate and transfer to another host. They are therefore harmless to the environment.

The rodents that will eventually receive the recipient organisms would not have any survival advantage in the environment. They could conceivably escape from the holding facility (although this is extremely unlikely) but even then they would not be able to transmit the viral construct to another organism and could also not transmit the DNA in the germ line to an offspring.

Host/vector system

Replication-deficient self-inactivating (SIN) lentiviral vectors with a mutated integrase element so that the vector does not integrate into the host genome (non-integrating). The SIN system relates to the engineered long terminal repeats mutation, which prevents viral genomic RNA transcription from the reverse transcription product residing in the cell after infection. Non-integration, on the other hand results from the mutation in the viral integrase gene, which prevents the integration of the viral genome into the host DNA. In this project, we intend to use the viral integrase mutation D64V. Using this mutation in a population of dividing cells, the expression of transgenes has been shown to become completely extinct within two weeks (Apolonia et al. (2007). Molecular Therapy: the journal of American society gene therapy. 15.11 (1957-54)). Theoretically, a very low level of integration could occur due to endogenous and random DNA recombination. However, we assess that the chance of integration is reduced by the order of $10^3-10^4$ compared to an equivalent integrating vector.

The stability of the D64V mutation is considered equivalent to that of any neutral sequence change resulting from mistakes in DNA polymerisation - it does not alter any survival properties in the self-inactivating system. Ultimately, where the vector persists the risk it poses is definitely not higher than the conventionally used integrating vectors. However, the probability of persistence is very much lower. The lentiviral vectors used are multi-attenuated meaning it is devoid of all potentially pathogenic HIV-1 encoded functions (1.2). In addition it is replication-defective which means that the vector cannot multiply on its own unless supplied by certain proteins in trans. It is self-inactivating which means that the viral promoter in the U3 region of the 5' LTR has been disabled by genetic manipulation. Only a very unlikely event of multiple recombinations during the process of generation of the viral vector can expose the person to a wild type HIV-1. The probability of such an event is extremely low.

Origin & function

The inserted sequence comes from Mus musculus, homo sapiens, rattus norvegicus. Inflammatory cytokines will produce perineuronal inflammation. Genes interfering with intracellular signalling (dominant-negative MEK, dominant negative EGFR) will modify the responses of neurons to axonal injury. The inflammatory cytokines could induce a
localised immune reaction. As the vector does not integrate in the genome of the host cells its persistence after the transfer is limited. Further, the reaction is expected to be neutralised by an immune-competent individual. These cytokines are used clinically in humans. DN-MEK and DN-EGFR would be expected to have no harmful effects since they are non-oncogenic and not secreted. The sequence will not cause harm if transferred to species in the environment.

The donor organism is not pathogenic.

Evaluation of foreseeable effects

The donor organism is not harmful, however some of the donated sequences are from viruses e.g. the envelope proteins VSV-G from the Vesicular Stomatitis virus, which may be infectious to humans.

The sequences used from the viral donor organisms are either promoter or envelope proteins so none of these are involved in the harmful characteristics of the original donor organism. Even if sequences were introduced into the body by ingestion, through a wound or after spillage onto skin, the viral sequences would enter the human cells and would therefore not be expressed. The sequences used from mammalian donor organisms are transgenes sequences, non of which are pathogenic.

The most hazardous step is injecting the lentiviral constructs into the mice due to sharps.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All GMMs are inactivated for disposal using standard biosafety level 2 procedures. Briefly, liquid and solid wastes are treated with PRESEPT effervescent disinfecting tablets (2.5g). All plastic-ware used in tissue culture are autoclaved. Work surfaces are decontaminated on completion of work or at the end of the day and after any spill or splash of viable material with disinfectants that are effective against the agents of concern. Prolin and IMS are used which have been shown to be 100% effective in tissue-culture related decontamination.

Work surfaces are decontaminated on completion of work or at the end of the day by spraying with Prolin and IMS and after any spill or splash of viable material with disinfectants that are effective against the agents of concern. This procedure has been shown to effectively eliminate all possible contamination. All cultures, stocks, and other regulated wastes are decontaminated before disposal by an approved decontamination method such as autoclaving. Injected animals will be killed by perfusion with fixative that will remove any risk from the injected tissues.

### Project Additional Information

**Purposes of the contained use**

The ultimate aim of this connected programme of work is to develop novel antimicrobial strategies to combat infections caused by selected Gram positive and negative bacteria. This will be achieved by disrupting genes on the chromosome and determining their role in growth, survival, stress resistance and interactions with host tissues and cells. Complementation of the mutation will follow mutagenesis in an effort to restore wildtype phenotype. Additionally reporter constructs will be made in order to determine the transcriptional and translational effects of mutant genes, environmental stimuli and growth phase on expression of genes involved in virulence and pathogenesis. This will enable us to generate attenuated mutants which will give us clues to genes that are required for...
virulence and fitness in these bacteria.

Recipient or parental organism

1) The firmicutes; (the majority of which are classed as 'group 2 by the ACDP. None are above group 2), Clostridium spp. including C. difficile & C. septicum, Staphylococcal spp. (including S. aureus & S. epidermidis), Streptococci spp. (including S. mutans, S. sanguinis, S. gordonii, S. mitis, S. sobrinus, S. intermedius, S. thermophilus, S. pneumonia & S. pyogenes and other oral streptococci), Enterococcal spp. (including E. faecalis, E. casseliflavus & E. faecium), Bacillus spp. (including B. subtilis & the taiotaomicron), Listeria spp. (including ivanovii, monocytogenes and innocua).
2) Campylobacter jejuni
3) Helicobacter pylori
5) Porphyromonas gingivalis
6) Prevotella intermedia
7) Eschericia coli
8) Pseudomonas aeruginosa
9) Viellonella parvula, V. dispar
10) Propionibacterium aenes
11) Actinomycyes naeslundii
12) Lactobacillus casei
13) Fusobacterium nucleatum
14) Neisseria subflava
15) Pichia pastoris
16) Corynebacterium spp.

The majority of these are classified as human commensal or opportunistic pathogens. However the majority of organisms are not likely to cause disease in healthy humans; e.g. C. difficile primarily causes disease only after treatment with antibiotics therefore the risk of infection to humans with these organisms is low. However, complementation of mutants in potential virulence genes may involve insertion of the wild-type gene into a mutant strain under control of a non-native promoter. Such strains could have increased virulence. Some of the organisms listed above are human pathogens and exposure could result in disease with differing severities of harm (e.g. S. pneumoniae can cause pneumonia, otitis media and meningitis).

The intended recipient organisms are wild type and many are clinical isolates and will therefore be capable of independent survival.

Host/vector system

The vectors have been separated into groups based on the organisms, or groups of organisms in which they will be used (see above)

1) Firmicutes
2) Transposons
   Tn916, (Broad host range conjugative transposon TcR Used for, transposon mutagenesis in a variety of Gram positive bacteria. Recombinant versions used to insert DNA into Gram positive chromosomes).
   Tn917, (Nonconjugative-transposon EmR. Used for transposon mutagenesis in a variety of Gram positive
Self transmissible plasmids

- pMTL9301, Bom + Tra+ (ColE1 origin of replication, ApR & CmR. Suicide vector in B. subtilis. Carries a c. difficile promoter for expression in Gram positives [Minton et al., 1990; Roberts et al., 2003]). pMTL007, (delivery vehicle for re-targeted group II intron from E. coli to Clostridium spp) [Heap et al., 2007].
- pMTL960 (Bom+, Tra+) E. coli-C. difficile shuttle vector [Emerson et al., 2009].
- pG01, (Bom+, Tra+) Used as a mobilisation vector in various Gram positive bacteria.
- pRPF185 (Bom+, Tra+) pMTL960 derivative with fdx transcriptional terminator added after tetR [Fagan and Fairweather, 2011].

Mobilisable defective plasmids

- pAULA, (Bom+, Tra-)
- pG(+)Host9, (Bom+, Tra-)
- pTEX5501 Bom+ Tra-

Non mobilisable plasmids

- pKOR1. (Bom+, Tra-)
- pMAD, (Bom-, Tra-)
- pLTV1, (Bom-, Tra-) contains Tn917
- pD701, (Bom-, Tra-) suicide vector for S. pneumonia derived from pEVP3 CmR
- pACH74, pVA891 derivative containing polylinker from pALTER; EryR CmR. Gram-positive suicide vector.
- pAM120, (pUC18 containing Tn916).
- pGEM-T-Easy (Promega): ColE1 origin of replication; ApR; suicidal in Gram Positive bacteria; classified as non-mobiliseable (Bom-, Mob- and Tra-minus) by the ACGM.
- pVA838: contains Gram positive and Gram negative replicons, Em-, Mob- and Tra-.
- pFW5: contains Gram negative origin only, suicidal in streptococci, SpR: Bom-, Mob- and Tra-
- pNE1:gfp: contains Gram positive and negative replicons, SpR: Bom-, Mob- and Tra-
- pDL278: contains Gram positive and Gram negative replicons. SpR, Bom-, Mob- and Tra-
- pCR-TOPO: for DNA cloning in E.coli (pBR322 origin, ampicillin resistance, not mobilisable). Suicide vector in these organisms.

PTEX5500 Bom- Tra- shuttle-E.coli/ Enterococcus spp

2) Non-mobilisable Plasmids

- pRRC: (ColE1 origin of replication, CmR, carries C. jejuni 16S-23S rRNA spacer region, suicidal in Campylobacter sp. [Karlyshev and Wren, 2005]; derived from pGEM which is classified as non-mobilisable (Bom-, Mob-, and Tra-minus) by the ACGM).
- pDENNIS: (ColE1 origin of replication, CmR, carries sequences of C. jejuni pseudogene (nucs 205297-207475), suicidal in Campylobacter sp.; derived from pGEM which is classified as non-mobilisable (Bom- Mob- and Tra-minus) by the ACGM).
- pC46: (ColE1 origin of replication, lacking lacZ alpha and AmpR gene, CmR. carries C. jejuni Cj0046 gene sequences amplified from strain NCTC 11168 and fdxA (iron-induced ferredoxin) promoter sequence, suicidal in Campylobacter sp. (van Vliet et al unpublished); derived from pGEM which is
3) Non-mobiliseable Plasmids

plR203C04: (ColE1 origin of replication, CmR, carries H. pylori intergenic region, suicidal in Helicobacter (Langford 2006); derived from pBluescript which is classified as non-mobiliseable (Bom-, Mob-, and Tra-minus) by the ACGM)

plR203K04: (identical to plR203C04 except KmR).

4) Non-mobiliseable Plasmids

pUC18, used as a suicide vector in the Pasteurellaceae. Bom- Mob- Tra- ColE1 replicon ApR.

pGEM-T-Easy (Promega): (ColE1 origin of replication), ApR, suicidal, classified as non-mobiliseable (Bom-, Mob- and Tra-minus) by the ACGM).

5) Non-mobiliseable Plasmids

pUC18, used as a suicide vector. Bom- Mob- Tra- ColE1 replicon ApR.

pGEM-T-Easy (Promega): (ColE1 origin of replication), ApR, suicidal, classified as non-mobiliseable (Bom-, Mob- and Tra-minus) by the ACGM).

6) Non-mobiliseable Plasmids

pUC18, used as a suicide vector. Bom- Mob- Tra- ColE1 replicon ApR.

pGEM-T-Easy (Promega): (ColE1 origin of replication), ApR, suicidal, classified as non-mobiliseable (Bom-, Mob- and Tra-minus) by the ACGM).

7) Non-mobiliseable Plasmids

pET-22b vector for E.coli periplasmic expression (pBR322 origin, ampicillin resistance, not mobilisable)

8) Non-mobiliseable Plasmids

pUC18, used as a suicide vector. Bom- Mob- Tra- ColE1 replicon ApR.

pGEM-T-Easy (Promega): (ColE1 origin of replication), ApR, suicidal, classified as non-mobiliseable (Bom-, Mob- and Tra-minus) by the ACGM).

9) Non-mobiliseable Plasmids

pUC18, used as a suicide vector. Bom- Mob- Tra- ColE1 replicon ApR.

pGEM-T-Easy (Promega): (ColE1 origin of replication), ApR, suicidal, classified as non-mobiliseable (Bom-, Mob- and Tra-minus) by the ACGM).

10) Non-mobiliseable Plasmids

pUC18, used as a suicide vector. Bom- Mob- Tra- ColE1 replicon ApR.

pGEM-T-Easy (Promega): (ColE1 origin of replication), ApR, suicidal, classified as non-mobiliseable (Bom-, Mob- and Tra-minus) by the ACGM).

11) Non-mobiliseable Plasmids

pGEM-T-Easy (Promega): (ColE1 origin of replication), ApR, suicidal, classified as non-mobiliseable (Bom-, Mob- and Tra-minus) by the ACGM).

12) Non-mobiliseable Plasmids
pUC18, used as a suicide vector. Bom- Mob- Tra- ColE1 replicon ApR.

13) Non-mobiliseable Plasmids

14) Non-mobiliseable Plasmids

15) Non-mobiliseable Plasmids

pPICZA vector: for protein expression in Pichia pastoris (pUC origin. resistance is to zeocin, not mobilisable)

16) Non-mobiliseable Plasmids

As regards health the VECTORS will not have the potential to cause harm (non-mobilisable)

Mobilisable defective have the possibility to transfer if they are complemented in trans by a mobilisable vector. This would require a total breach of containment;

Transposons, self transmissable and mobilisable vectors have the possibility to transfer to organisms in the environment following a total breach of containment

Antibiotic resistance genes will be present on these vectors which may be able to transfer to heterologous species. There will also be promoters cloned into mobilisable vectors (eg) also there will be genes with promoters cloned for complementation studies into integrative conjugative vectors.

The majority of the DNA will come from E. coli (vectors), however gene sequences from the organisms below may be used as substrates for homologous recombination. None of the organisms listed will be above group 2 (classified by the ACDP).

1) The firmicutes; (the majority of which are classed as group 2 by the ACDP. We do not propose to use any organisms which are above group 2). Clostridium spp. (including C. difficile & C. septicum),
2) Campylobacter jejuni
3) Helicobacter pylori
4) The Pasteurellaceae; Actinobacillus actinomycescomilans, Haemophilus innuenzae, Haemophilus ducreyi, Haemophilus somnus, Actinobacillus pleuro pneumoniae, Mannheimia haemolytica, Mannheimia succiniciproducens
5) Porphyromonas gingivalis
6) Prevotella intermedia
7) Escherichia coli
8) Pseudomonas aeruginosa
9) Veillonella parvula, V. dispar
10) Propionibacterium acnes
11) Actinomyces naeslundii
12) Lactobacillus casei
13) Fusobacterium nucleatum ss. polymorphum,
14) Neisseria subflava
15) Pichia pastoris
16) Corynebacterium spp.

The majority of the inserted DNA will encode resistance to an antibiotic and will be used to inactivate
genes in the recipient organisms. Fragments of genes from the donor organisms may be cloned to
facilitate homologous recombination during allelic replacement. It is possible that these fragments may be
expressed. The biological activity of these fragments is likely to be limited but will depend on the gene
being investigated and could include e.g. adhesins, response regulators, transcriptional and translational
repressors and virulence factors. Following knock-out generation complementation studies will be
undertaken which will require the cloning and expression of genes from the parental organism. These will
be recloned into the parental organism potentially with a different promoter and therefore the expression of
the cloned genes may be different to the natural expression.

It is possible that if the gene sequences are expressed accidentally in humans harm would occur
however it is likely that the severity would be low and again will depend on the particular gene under
investigation.

There is always the potential of any given DNA sequence to transfer, by horizontal gene transfer
processes, to other microorganisms in the environment. However by adopting good laboratory practice
and by following the codes of practice for the Division of Microbial Diseases, the chances of a breach of
contamination are effectively zero.

Whilst the majority of the initial cloning will be carried out in E. coli (using disabled lab strains) the majority
of the final experiments/mutations will be carried out in wild-type organisms. The majority of these are
classified as human commensal or opportunistic pathogens. However the majority of organisms are not likely to cause disease in healthy humans; e.g. C. difficile primarily causes disease only after treatment with antibiotics therefore the risk of infection to humans is low. Some of the organisms listed above are human pathogens and exposure could result in disease with differing severities of harm (e.g. S. pneumoniae can cause pneumonia, otitis media and meningitis).

It is envisaged that some of the genes being investigated will be virulence factors, therefore fragments of
these may be cloned to facilitate homologous recombination with the recipient organisms. In the
complementation studies full length genes will be cloned into the parental organisms and expressed.

Evaluation of foreseeable effects

Whilst the majority of the initial cloning will be carried out in E. coli (using disabled lab strains) the majority

organisms and expressed.

Cloning in E. coli should not have pathogenic or ecological disruptive effects. It is not foreseen that DNA insertion onto the chromosomes for the purposes of gene inactivation in the selected bacteria will result in GMMs that are more hazardous than the parental strains. Therefore the most hazardous GMMs are likely to be those that are complemented with the inserted gene under the control of a strong promoter resulting in increased expression. However, we would avoid using strong promoters because we wish to restore the natural phenotype for functional studies.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

N/A

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

N/A

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

GMM/1 line: 1.29 or GMM/1: line 2.13 (as applicable)

All GMMs will be killed before leaving the laboratories. Liquid and solid waste containing GMMs will be autoclaved on a "kill cycle" at 121°C for 30mins before disposal for incineration. Contaminated glassware will be similarly autoclaved before entering washing-up. Contaminated sharps will be autoclaved in their sharps bins on a kill cycle prior to disposal for incineration. These sharps bins have been tested in-house and stand up to the autoclavage process. Killed liquid waste will be disposed of down the sink. All benches and surfaces will be swabbed down with a 0.1% hypochlorite at the end of each laboratory session.

Degree of kill; 100%

The autoclaves contain internal temperature probes in order to monitor the cycles. In addition, TST strips and autoclave tape are used in every kill cycle.

Killed liquid waste will be disposed of down the sink. All autoclaved solid waste will be bagged into orange bags for incineration and collect from the locked yellow bins by the Eastman's contractors. These bags are labelled with an identifiable cable tie provided by the Safety Officer at the Eastman Dental Institute and are therefore traceable back to the division of Microbial Diseases. Yellow sharps bin. once autoclaved will be deposited in the designated, locked sharps bin container for collection, these are labelled with date, department and researcher. No live GMM will leave the department in the form of waste.

**Project Additional Information**

**Purposes of the contained use**

Human embryonic stem cells (hESCs) are of great interest in the field of regenerative medicine as they are pluripotent and have unlimited proliferative capacity in vitro. Pluripotency describes the potential of the cell to differentiate into any cell type of the body. This would allow us to generate any desired cell type in the lab and replace diseased or absent cells in patients. In our case, we are interested in generating retinal pigment epithelial cells (RPE) in the lab to treat patients with age related macular degeneration. However, the main disadvantage of using hESCs is the possibility of immune rejection given that hESCs are derived from blastocysts.
A landmark technique discovered in 2007 by Takahashi and Yamanaka allowed the generation of hESC-like cells (coined induced pluripotent stem cells or iPS cells) from adult somatic cells without the use of embryonic material. This technique is known as induced pluripotency and allows us to generate pluripotent iPS cells from patient's cells. If RPE cells are differentiated from patient derived iPS cells, they would be genetically identical to the patient and therefore, overcome any potential immune rejection problems. The ability to generate patient specific iPS cells thus has immense potential for cellular therapies.

The original induced pluripotency technique involves the overexpression of key pluripotency genes/factors: Oct4, Sox2, Klf4 and cMyc. This ectopic expression is achieved by retroviral infection of somatic cells with the 4 factors which then integrate into host genome. As the 4 factors are under control of the MMLV (monkey moloney leukemia virus) promoter, once the somatic cell becomes reprogrammed to a pluripotent state, the transgenes will switch off. While this original method of iPS cell generation is useful for in vitro disease modelling and drug discovery, its application to the clinical therapies is limited due to the possibility of insertional mutagenesis and the re-activation of oncogenes, such as cMyc. The objective of this project is to investigate different methods for generating iPS cells and identify the method that would be most translatable to the clinic.

The other methods investigated will include various non genome integrating techniques (episomal plasmid, mRNA and miRNA mimic transfection). Since we do not understand the mechanisms behind reprogramming, we do not know if the method chosen will have an effect on the quality of iPS cells produced. Our aim is to compare the different iPS cell lines generated from the different integration-free methods (episomal plasmid, mRNA and miRNA mimic transfection) with iPS cells generated using the retrovirus gold standard. Comparisons will include the expression of pluripotency markers, genome wide expression and methylation patterns. This comparison will allow us to determine which method is most suitable for the clinical application of iPS cells. Our future studies will include the development of the chosen method to generate GMP (good manufacturing practice) grade iPS cells.

As the mRNA and miRNA mimics methods do not involve use of vectors or generation of viruses and are synthetic oligos/RNA, they will no be discussed in this GMM form as they pose NO harm to humans, the environment and other species as mRNA and miRNA are rapidly degraded when not stored at -80°C in RNA nuclease free conditions.

### Recipient or parental organism

**Mammalian cells**

(Recipient organisms)

- IMR90 human lung foetal fibroblast cell ine (ATCC, USA)
- Patient fibroblast cell lines
  (Support cells)
- Newborn human foetal fibroblasts, Nuffs (Amsbio)

**Bacterial E. coli strains**

- DH5alpha (New England Biolabs)

**Retroviral packaging cell line**

- Platinum A (based on the 293 T cell line encoding gag, pol and env under control of the EF1α promoter from Cell biolabs Inc.)

The likelihood that bacteria transformed with retroviral/episomal vectors and GMM cells will propagate outside the laboratory is extremely low. Its is also highly unlikely that GMM cell lines could persist in the environment and be transferred to other organisms. Both transformed bacteria and GMM cells will not survive outside of the controlled tissue culture environment as these cells are highly dependent on specific in vitro culture conditions (they require low carbon dioxide levels, 37°C, specific growth factors to survive) and thus would not survive outside of the in vitro environment. When handling live recipient organisms, sharps (glass pipettes and needles) will not be used to avoid accidents, hence there is minimal risk associated with working with recipient cells. The minor risk occurs if the recipient cells were directly transferred in vivo to in an immune-compromised individual either by needle stick injury or via the mucosal membranes. However, by following standard safe laboratory practice including local rules for avoiding sharps and using personal protective equipment, their risk associated with working with recipient cells is minimal.
We will follow standard safe laboratory practice for the treatment of waste (vectors and cells) to ensure that the recipient cells is minimal.
We will follow standard safe laboratory practice for the treatment of waste (vectors and cells) to ensure that the recipient organisms are not pathogenic to humans:
- we will treat bacterial cells used to grow vector plasmids and other tissue culture waste (viral supernatant) with Virkon 2-5(v/v)% at least overnight (approximately 18 hours). Virkon powder will be used to decontaminate any spills as the powder absorbs the spill and prevents further spreading of the liquid spill. Liquid waste will subsequently be disposed of down the sink with copious amounts of water. Work surfaces will be wiped down with Trigene Advance (Trigene advance fully meets the criteria of the European Biocidal products directive (ref 98/8/EC) and is bactericidal, fungicidal and virucidal), followed by 70% IMS after use.
- Solid waste will be double bagged in biohazard bags and removed by UCL waste services who autoclave the bags at 132°C with a holding time of 20 mins prior to being incinerated. UCL waste services will validate all the autoclave cycles to ensure no risk to the environment.

Host/vector system

pMXs-hOct4 (Addgene, USA)
pMXs-hSox2 (Addgene, USA)
pMXs-hKlf4 (Addgene, USA)
pMXs-GFP (Cell Biolabs Inc., USA)
pCXLE-hSK (Addgene, USA)
pCXLE-hUL (Addgene, USA)
pCXLE-hOct3/4-shp53 (Addgene, USA)
pCXLE EGFP (Addgene, USA)
pEP4 EO2S ET2K (Addgene, USA)
pEP4 EO2S CK2M EZ2L (Addgene, USA)

The pMXs retroviral vectors used contain an MMLV promoter to drive the expression of the 4 factors and GFP. None of these vectors contain the essential virion replication and packaging elements that are required to form the viral particle itself and so, poses no harm to health and the environment. The packaging and envelope proteins are produced by the packaging cell line, Platinum A(Plat A) cells which expresses the gag, pol and env genes. These packaging and envelope genes are maintained stably in Plat A cells only if placed in medium containing blasticidin and puromycin antibiotics. Therefore, for viable retroviral particles to be produced, the retroviral vector must be transfected using a liposomal reagent into Plat A cells that have been under antibiotic selection. Therefore the viral vectors on their own pose no risk.

The episomal plasmid vectors are not used to make virus and nor does it contain the essential virion replication and packaging elements that are required to form a viral particle itself and so, poses no harm to health and the environment. Furthermore, these episomal plasmids do not contain any sequences that enable integration into the host genome and are maintained in the cytosol of target cells and therefore pose no harm even if directly transferred to humans.

Origin & function

Oct4, Sox2, Klf4, and cMyc sequences were amplified from Homo sapiens sequences and then cloned into the pMXs retroviral vector described by Kitamura et al. (2003).

Oct 4, Sox2, Klf4, L-myc, Lin28, shp53, SVT40 large antigen and Nanog sequences were amplified from Homo sapiens sequences and then cloned into the pCEP4 and pCXLE episomal vectors described by Yu et al, (2009) Okita et al. (2011) respectively.

Overall, the 4 factor (Oct4, Sox2, Klf4 and cMyc) sequences from the pMXs retroviral vectors will be transcribed and the translated transcription factors will act co-operatively to activate the pluripotency network of genes while repressing differentiation pathways. We expect this overexpression to reprogram the target somatic cells and transform them into iPS cells. As the viral vectors are under control of the MMLV promoter, we expect the transgenic sequences to be silenced once the cells are reprogrammed to a pluripotent state. Integration of the MMLV-GFP sequence will have little or no biological consequence aside from labelling cells GFP. The individual known functions and expected activity of each of the 4 factors is described below:

Oct 4 is a key transcription factor in pluripotency and is highly expressed during embryonic development and in embryonic stem cells. It acts co-operatively with Sox2 and Nanog to promote pluripotency and suppress differentiation. Overexpression of Oct 4 in somatic cells is expected to activate the pluripotency network.
Sox2 is a transcription factor that is involved in the regulation of embryonic development and in the determination of cell fate. It acts co-operatively with Oct 4 and Nanog to promote pluripotency and suppress differentiation. Overexpression of Sox2 in somatic cells is expected to activate the pluripotency network.

**Evaluation of foreseeable effects**

Klf4 is a transcription factor that is known to bind putative regulatory elements of Oct 4, Sox2, Nanog and other pluripotency associated genes. Its exact function is not known but is thought to be a key player regulating the pluripotency network. The overexpression of Klf4 in somatic cells is hypothesised to upregulate Nanog while repressing p53.

C-Myc is a transcription factor that plays roles in cell cycle progression, apoptosis and cellular transformation. Mutations, overexpression, rearrangement and translocation of the cMyc gene is associated with various tumours, leukemias and lymphomas. The overexpression of cMYc in somatic cells is thought to cause rapid proliferation of the cells which is expected to promote reprogramming to a pluripotent state.

The genes encoded by the episomal plasmids (pCXLE-hSK, pCXLE-hUL, pCXLE-hOct3/4-shp53, PCXLE EGFP, pEP4 EO2S ET2K and pEP4 EO2S CK2M EN2L) will be transcribed and the translated transcription factors will have similar roles to the ones described above. In summary, these genes will act co-operatively to activate the pluripotency network of genes while repressing differentiation pathways. We expect their expression to reprogram the target somatic cells and transform them into iPS cells. These genes will be expressed by the episomal plasmids alone and will not involve any viral packaging. The episomal plasmids all contain EBNA-1 and OriP sequences for limited maintenance in the host cell without integration into the host genome.

The retroviral vectors used lack viral structural genes and require packaging cells to generate retrovirus, therefore all the retroviruses generated are non-replicating.

The MMLV based GFP is not expected to cause any harm as the sequence only contains a GFP cassette. GFP is a widely used marker of transgene expression following transduction and its expression has not been associated with any adverse effects.

The 4 factor pMXs based retroviruses used in this project are standard practice in iPS cell research and no reports of safety issue have arisen where proper precautions have been taken. If there were an accidental transfer to human iPS cells from target cells is only 0.02% under favourable culture conditions (Takahashi et al., 2007). Furthermore, pMXs retroviruses can only infect actively dividing cells, so is unlikely to be able to infect human cells readily. Furthermore, the recipient organism is not pathogenic.

There is a theoretical possibility of insertional mutagenesis following retroviral transduction of human tissues and uncontrolled cell proliferation if cMyc were to integrate into the genome of human tissues. However, these risks have never been realised in any of the human and non-human primate studies to date using retroviral vectors. The infectivity of retroviral vectors are low as they are labile and do not survive prolonged culture at 37°C. The viruses are not transmissible through unbroken skin or by aerosol. The main risk is by needlestick injury or through the mucous membranes. This would be minimised by safe laboratory practice and restricted access to laboratories where the retroviral procedures are being carried out.

The episomal plasmids (pCXLE-hSK, pCXLE-hUL, pCXLE-hOct3/4-shp53, PCXLE EGFP, pEP4 EO2S ET2K and pEP4 EO2S CK2M EN2L) pose NO harm to humans as they are used as naked DNA plasmids. They will NOT be transfected into viral packaging cells to generate virus. Even if directly transmitted into a human by accidental transfer, the plasmid DNA would be immediately degraded by DNA nucleases on the skin and by other host defences.

It is theoretically possible that the sequences can cause harm to other species in the environment.

## Purposes of the contained use

There are estimated 400 million people worldwide chronically infected with the hepatitis B virus (HBV), leading to deaths resulting from liver diseases as cirrhosis and hepatocellular carcinoma. There is currently no cure for infection and antiviral therapy have limited effect. Successful control of chronic HBV infection depends on mounting a robust T cell response towards infected hepatocytes. A possible therapy to treat chronically infected HBV patients is by redirecting healthy T cells against immunodominant epitopes of HBV antigens. The levels of antigens expressed on the surface of hepatocytes are therefore in focus. Another objective is to investigate immune regulatory surface markers as secondary objective to investigate if redirected HBV specific T cells receive down regulating signals from HBV infected hepatocytes.

We want to investigate if hepatocytes transfected with naturally occurring HBV genotypes have different levels in antigen presentation of immunodominant epitopes. As our research project is about redirecting T cells and antibodies against these HBV epitopes, it is necessary to see if there is a variation in presentation or any cross-specificity of the peptide specific antibodies between HBV genotypes. This will have implications in future therapies and necessity to tailor antiviral therapy according to which HBV genotype the patient is infected with.

## Host/vector system

Naked linearized HBV DNA will be transfected into cells using a liposome reagent (Lipofectamine 2000, Invitrogen). No harm to health or environment according to the product MSDS.

Plasmid DNA production was done at a biosafety level 2 Laboratory in our collaborator's group in Bordeaux, France. Enzyme digested plasmid DNA is separated with standard electrophoresis methods and linearized HBV is purified from the plasmid backbone. Only the HBV encoding DNA strand is used for transient transfection of Huh7A2 cells. The linearized plasmid backbone containing T7 promoter and ampicillin resistance gene will be trapped in solid agar and disposed as biological waste.

Origin & function

The hepatitis B genome is derived from a patient isolate, described in the article
Genome of hepatitis B virus restriction enzyme cleavage and structure of DNA extracted from Dane particles
PMID: 1060140

The hepatitis B genotype c core sequence is derived from patient isolate, described in the article:
The complete nucleotide sequences of the cloned hepatitis B virus DNA; subtype adr and adw.
PMID: 6300776

Whole HBV genome will be expressing the proteins for the hepatitis B virus and the nucleic acid sequence required for viral assembly.

The hepatitis B virus is non-cytolytic, and will secrete virus particles, HBeAg and HBsAg.

Very little chance of accidental transfer in humans, as the viral DNA is linearized before transfection, making the genomic material unstable and prone to degradation. If infectious HBV viral particles accidentally transfers (sharps injuries), there is a possibility of infection in unvaccinated persons, resulting in an acute liver infection. In a subset of individuals a chronic carrier state may be established. A chronic HBV liver disease may result in cirrhosis and possible hepatocellular carcinoma. Individual proteins may cause immune reactions and trigger antibody production. The HBV genomic DNA will not express properly unless transferred into human liver hepatocytes, as they require human hepatic transcription factors.

HBV infection can cause acute fulminant hepatitis in adults. Estimated 5% of infected adults develop chronic infection with increased risk of developing cirrhosis and HCC. Whole HBV genome is transfected into target cells. The core antigen and the envelope antigen are thought to be the target of immunological response causing hepatic flares and low-level inflammation of the liver.

The HLA-A*0201 gene is derived from human patient isolate

Evaluation of foreseeable effects

HBV infection can cause acute fulminant hepatitis in adults. Estimated 5% of infected adults develop chronic infection with increased risk of developing cirrhosis and HCC. Whole HBV genome is transfected into target cells. The core antigen and the envelope antigen are thought to be the target of immunological response causing hepatic flares and low-level inflammation of the liver.

Potential harm if HBV transfected cells are supernatant from cell culture comes in contact with unvaccinated person with cuts or open sores. The most hazardous GMM are the stable transduced cell lines that constitutively produce HBV at relatively low viral titre: HepG2 117, HepG2 H1.3 and HepG2 2.2.15. Most hazardous step in the procedure is when cells are stimulated to produce viral protein, the cells will go from very low viral titre to producing relatively high viral titres (105-106 genome copies per ml).

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

No GM animals will be used in this project application
For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

Liquid waste is inactivated by 5% (v/v) Distel/Trigene for a minimum period of 12 hours and then discarded to drain. Solid waste is autoclaved. Plasticware is decontaminated by soaking in 5% 9v/v) Distel/Trigene for a minimum of 12 hours and then autoclaved. The degree of kill for these procedures is 100%

The autoclaving is conducted inside the CL3 facility. The autoclaving conditions are 134°C for 30 mins. This is monitored by 12 thermocouples. The records are automatically generated by the autoclave, signed off by the user and retained.

Following autoclave treatment, solid waste bags are placed inside clinical waste containers and sent for incineration.

Date Project 02/03/2022

CU2 Project Title Reconstitution of dimethylarginine dimethylaminohydrolase 1 (DDAH-1) in a rodent model of liver disease

Class Non-GMM
CultureVolClass2 ≤ 1 Litre
Consent Granted

Page 782 of 15326
The aim of the study is to demonstrate an attenuation or exaggeration of portal hypertension and liver injury in a rodent model of liver disease with modulation of DDAH-1 (work will be conducted using project license PPL 70/6615, Complications of Liver Disease, PI Dr N D), following transduction of DDAH-1 in diseased liver. The DDAH-1 expressing, or anti-DDAH1 shRNA/miRNA expressing, or control, lentivirus particles will be diluted in DMEM media and injected into anaesthetised (isofluorane) mice. This mode of virus administration for liver transduction has been validated by several investigators[7]. Portal pressure will subsequently be measured 2-6 weeks later.

The lentiviral vectors to be used are: pSIN_Thy1.1_SFFV_DDAH!, pSIN_THY1.1_SFFV_GFP, pSIN_Thy1.1_PGK_GFP, pSIN_Thy1.1_RFP, pGIPZ_shRNA_antiDDAH1.

These vectors are designed to manipulate DDAH1 levels, or be scrambled control vectors expressing GFP or RFP proteins. Lentiviral vectors cannot replicate in humans or animals because complementary packaging and helper proteins are absent and, although insertional mutagenesis is a theoretical possibility, this is not reported for any human or non-human primate studies. Our lentiviral vectors will be used for gene transfer to liver in rodent models. No additional risk is anticipated with any of these procedures; transmission to the germ-line is highly unlikely, while in most cases vectors will have tissue-specific promoters, which further minimizes risk.

The DDAH1 insert is from human cDNA. Other sequences are validated anti-DDAH1 shRNA or anti-miRNA inserts, green or red fluorescent proteins, or scrambled/non-coding control insets. The inserts do not code for oncogenes or other known harmful proteins. The lentivector backbones, and GFP/RFP/scrambled controls are not species-specific.

The transcribed DDAH-1 protein acts to hydrolase ADMA tp :-citrulline. There is no evidence of harm following overexpression of DDAH-1.
Lentiviral vectors are constructed from a three-plasmid system of a transfer vector containing only modified long-terminal repeats (LTRs), the transgene and a suitable promoter. The other plasmids are a gag-pol packaging plasmid and a VSV-G envelope plasmid. This three-plasmid system renders the virus replication deficient since the structural genes are not actually present in the packaged viral genome so no new virus can be produced and no other cells can be infected. Additionally, the 3’ sequence of the U3 element in the transfer plasmid has been modified so that only 18bp remains, this eliminates promoter activity and means that proviruses resulting from this vector cannot transcribe their full genome and are therefore said to be self-inactivating.

The envelope protein is VSV-G from the Vesicular Stomatitis Virus so, if introduced into the body by injection, ingestion or through a wound, the virus could potentially enter cells and integrate into cellular DNA. Although the virus is replication incompetent (does not carry gag. Pol or env genes) so it cannot make new progeny virus and establish a productive infection, its physical insertion into cellular DNA could result in a potential mutation. This would be a very unlikely event and even if it were to occur it would affect only a very small number of cells, and is therefore extremely unlikely to affect the individual. The packaging viral components are from the HIV-1 virus. The full length HIV-1 virus is harmful to humans, however the packaging vector used does not contain the full length HIV-1 molecule. Many components of HIV-1, that are critical for HIV-1 infection but not required for viral packaging, have been removed so the virus is attenuated. This packaging system is routinely utilised in the preparation of lentiviral vectors, with no reported adverse events.

The lentiviral vectors are replication defective and generated by 4 plasmid transfection to minimise potential for recombination and therefore will not cause harm if transferred to other species in the environment.

Evaluation of foreseeable effects

The most hazardous GMM is the lentivirus expressing DDAH1. The most hazardous step is the injection of viral particles into rodents. As previously noted, there is no evidence of toxicity or pathogenicity from DDAH1 overexpression. Good laboratory practice will mitigate the risk of exposure to lentiviral particles. All trained personnel will have specific training in the handling of sharps, and use of gloves/masks, associated with biological vectors, with a dedicated training log. A microbiological safety cabinet will be used for handling low-volume viral culture media. Until they are required for in vivo use, the particles will be stored with restricted access in triple-packed containers.

Containment and control measures for GMOs that are not microorganisms (e.g. GM animals & plants)

Since the work will take place in an operating theatre in the BSU, then only trained personnel will have exposure to the vector. Outside of this environment, lentiviral particles will be stored in an area with restricted access, contained in a second sealed, triple-packed box, labelled with description of contents and emergency contact details. The inserts do not pose any health risk upon inadvertent exposure. The antibiotic selection inserts pose a theoretical risk of spreading antibiotic resistance to wild type bacteria. This is extremely unlikely to occur due to good laboratory practice measures that are routinely undertaken. Also, the virus is replication deficient, since the structural genes are not actually present in the packaged viral genome so no new virus can be produced and no other cells can be infected. Additionally, the 3’ sequence of the U3 element in the transfer plasmid has been modified so that only 18bp remains, this eliminates promoter activity and means that proviruses resulting from this vector cannot transcribe their full genome and therefore said to be self-inactivating. Without these processes, the risk to the environment is very low.

Additionally, the following measures are in place at the BSU to prevent rodents escaping to the environment:

* For all rodents the cage represents the primary means of confinement. Rodents are only housed in cageing that is free from damage. The cage type has an outer fitting lid with a spring lock mechanism to ensure tight closure. Placement of the lid securely back onto the box base is most important and staff and user’s are trained to ensure they do this properly. BSU policy is to recapture any escaped rodents.
* All cages are labelled with the number and sex of the rodents.
* Rodents are counted at a minimum frequency of once per week, and discrepancies investigated.
* All of the rodent rooms are fitted with rodent barriers across the doorway, providing a further tier of security to the room.
* Additional passages and doorways off sub corridors or within inner lobbies further protect many of the rodent rooms.
* Storage in animal rooms and in corridors is minimal, allowing few places to hide.
* The main CBU corridors have three sets of double doors in addition to the two main entry/exit points.
* A lobby with two self-return doors protects the main point of entry/exit.
* Vigilance and no attention to detail by BSU staff and user's.
We expect to see less than 1 rodent a year in the BSU main corridors and less than 1% of those making it that far to escape the BSU into the local area. Put another way, 1 rodent in 100 years, could possibly escape beyond the confines of the BSU.

For only GMMs - application for any derogation from full containment for the Class of activity. (Measures & Justification)

Described the waste management measures which you will apply to the activity (including type & form, treatment, ultimate form & fate)

All contaminated waste (including disposable plastics & lab glassware) will be treated with 2% Virkon overnight, and subsequently autoclaved at 134degC for 10 min when the level of GMM inactivation is below detectable level, and then placed in clinical waste bags for disposal and subsequent incineration. Animal carcasses will be disposed of by incineration. The expected degree of kill is 100% - there has been no documented survival of GMMs following incineration.

Bacterial culture medium will be disinfected with 10% Trigene. Other liquid waste will be disinfected overnight with chlorine releasing tablets (Presept) or 2% freshly-made Virkon prior to disposal via a designated laboratory sink.

Solids, such as pipette tips, will be discarded into plastic containers with lids prior to autoclaving, as before.

Surfaces will be routinely cleaned using 70% IMS.

Spillages will be dealt with according to departmental policy, which is available to workers in paper and electronic forms (S:\Hepatology\Safety\spillage\management). Regarding work with E. coli, comply with the safety guidelines as outlined in GM COP in Appendix 1 on S:\CentreForHepatology\Safety\Rik Assessments, Codes of Practice and Standard Operating Procedures\GM Code of Practice.

Disinfection of benches: 70% IMS or Milton solution; Disinfection of centrifuges: 70% IMS only.

Spillages: application of Presept granules for at least 5 min, prior to wiping with a damp cloth and disposal into an autoclave waste bag.

Is an emergency plan required according to regulation 20? N

If yes, tick to confirm that it is attached to this form N

Tick to confirm that you have attached a risk assessment to this form Y

Tick if you are claiming exemption from disclosure for section of the risk assessment N

Please enter comments on the GM safety committee on the risk assessment

The UCL GMSC approved this as an Activity Class 2 project (July 2012)

Project Containment
The shRNAmir library consists of individual E. coli glycerol stocks containing the pGIPZ lentiviral vector. Each stock contains a unique hairpin sequence within the pGIPZ vector designed to target and reduce the expression of genes within the human genome via RNAi interference. We are particularly, but not exclusively, interested in targetting protein tyrosine phosphatase (PTP) genes.

This project will involve virus library maintenance, viral storage, lentiviral production from pGIPZ plasmids and use of this lentivirus in cell based screening functional assays. Additionally, clones will be pooled at the bacterial, DNA and viral level to make various intermediate pools of clones to be used to transduce cells in screens and subsequently undertake functional assays.

Our specific scientific goals are to reduce the expression of PTP genes, or components of PTP signalling pathways, in neuroblastoma cell lines, in order to identify those PTPs that act as oncogenes in these cancer cells. We will also introduce a limited range of cDNAs into cells using viral delivery, to test further the function of the critical PTP pathways. This will ultimately lead to further development of chemical or RNA/DNA-based inhibitors of PTP pathways that could be used therapeutically to tackle this cancer.
**Recipient or parental organism**

GMM/1: lines 1.13, 1.19, 1.20

(1.13) Cell lines: Human 293T, NIH3T3; human neuroblastoma cell lines including SKNAS, SKNDZ, SKNSH, SHSY5Y, LAN5, LAN1, KELLY, SMS-KCN, SMS-KCNR, IMR32; human glioma cell lines including T98G, KNS242, Res186, Res259, SF188, UW479; simian Cos7.

Primary murine cells: Derived from various mouse adult or embryo tissues and including neurons and adrenal cells.
